.

UNIVERSAL HERBAL;

OR,

BOTANICAL, MEDICAL, AND AGRICULTURAL

DICTIONARY.

CONTAINING AN ACCOUNT OF

All the known Plants in the World,

ARRANGED ACCORDING TO THE LINNEAN SYSTEM.

SPECIFYING THE

USES TO WHICH THEY ARE OR MAY BE APPLIED, WHETHER AS FOOD, AS MEDICINE, OR IN THE ARTS AND MANUFACTURES.

WITH THE BEST

METHODS OF PROPAGATION,

AND THE

MOST RECENT AGRICULTURAL IMPROVEMENTS.

Collected from indisputable Authorities.

ADAPTED TO THE USE OF

THE FARMER-THE GARDENER-THE HUSBANDMAN-THE BOTANIST-THE FLORIST -AND COUNTRY HOUSEKEEPERS IN GENERAL.

BY THOMAS GREEN.

VOL. I.

LIVERPOOL; PRINTED AT THE CAXTON PRESS BY HENRY FISHER, Printer in Ordinary to His Majesty. Sold at 87, Eartholemew Close, London.

PREFACE.

The obvious design of this work is to present the Botanist, Farmer, Gardener, and Country Housekeeper, with a compendium of Botanical, Agricultural, and Medical knowledge, collected from the accumulated labours of the most eminent authors, and hitherto only to be obtained in separate and very voluminous publications.

From the Introduction, which immediately follows this Preface, the Botanist will at once perceive that the Linnean Arrangement is exclusively adopted, not merely because it is most universal, but because, (to adopt the language of the present acute and learned president of the Linnean Society," "Without wasting any words on those speculative and fanciful changes, which the most ignorant may easily make in an artificial system; and without entering into controversy with the very few competent writers who have proposed any alterations, the discriminating characters of the Linnean System are founded in nature and fact, and depend upon parts essential to every species of plant, when in perfection : and as the application of them to practice is, above all other systems, easy and intelligible; nothing more useful can be done, than to perfect, upon our own principles, any parts of this system, which experience may shew to have been originally defective. Speculative alterations in an artificial system, are calless, and scarcely answer any more useful purpose than changing the order of letters in an alphabet. The philosophy of botanical arrangement, or the study of the natural administo of plants, is quite another matter."

The general exemplifications of the Introduction-to which the Essay on the Physiology of Plants, in the second Volume, forms an important supplement-are followed by an Analysis illustrating the Linnean System of classification, and by Rules for Investigation, intended to "explain and apply to practice those beautiful principles of method, arrangement, and discrimination, which render Botany not merely an amusement, a motive for taking air and exercise, or an assistance to many other arts and sciences; but a school for the mental powers, an alluring incitement for the young mind to try its growing strength, and a confirmation of the most enlightened understanding in some of its sublimest and most important truths." The explanatory Plates which exhibit the various kinds of Leaves, Trunks, Roots, Armature of Plants, and more especially those which present the Parts of Fructification, the Classes and Orders of the Sexual System, with the Dictionary of Botanical Terms, will gradually introduce the young student into the midst of this delightful science: and lest he should there find himself bewildered, the Introduction closes with succinct Instructions how he is to ascertain to what Class, Order, Genus, or Section, any known or strange plant he may meet with belongs; an assistance to which will be found in the Index to the Classes and Orders at the close of the second Volume. To avoid also any perplexity which might arise from the Specific Character not being here printed in a different letter from the general description of each plant, and to account for any apparent repetitions, the reader will only have to bear in mind, that the specific character is always contained in the first sentence, under the name of each plant; what follows being superadded description, or directions for their culture. The notes of interrogation imply that the parts of the plants to which they are subjoined require further investigation, not having yet been perfectly described.

The foreign names of many plants, and, as far as could be ascertained, the *labilatts*, or exact places of growth, where those which occur wild in our own country may be found, have been minutely recorded, as they always should be by every lover of Botany; the former for the accommodation of those who may take the UNIVERSALIBERRALabroad; and the latter, to facilitate the researches of those who botanize at home: to both of whom it is strongly recommended to interleave their copies in the binding; that their own observations, additions, or corrections, may be noted in their proper order, either for their individual use, or, if they will have the goodness to communicate them to the Publisher, for the improvement of future Editions. Such persons also as have preferred the plain plates, may find an elegant amusement in occasionally colouring them at their lesinger from nature.

PREFACE.

The methods of propagation and culture, when peculiar, will be found under each species: but wherever the same treatment applies to a whole genus, the Farmer, Gardener, and Florist, will find the most explicit directions either immediately following the Essential Character, or subjoined to the description of the first species, to which all the rest are in the latter case invariably referred. Under every species of Grain, and of all plants used for the sustenance of man or beast, as well as under the articles Grass, Land, Moss, Mould, Meadow, Manure, Mowing, Pasture, Blight, Mildew, Vermin, Watering, Warping of Land, Weather, Weeds, Weeding, Wells, Hedges, Fences, &c. the intelligent Farmer may ascertain the opinions, practice, and experience, of the first authorities in every thing that relates to agricultural improvement.

The very copious Catalogue of Trees and Shrubs, given at the end of the second Volume, will at once enable the Gardener and Planter to select such as by their size, qualities, or places of growth, may best suit either general or particular purposes, and will save the intolerable labour and loss of time, that must have been incurred had they been left to examine the whole work in order to make that selection; which, when thus readily made, refers them for further details to the various species under their respective genera. The articles Dwarf Trees, Espaliers, Green-house. Hot-beds, Melonary, Stove, Pine-Stove, Ice-honse, Nursery, Orchard, Grafting, Inoculation, Lopping, Planting, Pruning, Gravel and Grass Walks, Avenues, Wilderness Woods and Groves, Yard-manure, &c. with the Plates containing plans of the Conservatory, Hot-house, Stove-Pinery, and those for ornamental laying out of grounds, &c. will be found of essential use to the Planter, Nurseryman, and Gardener: the latter of whom will find the account of every plant with which he can have the most immediate or remote concern, accompanied with copious directions. calculated to advance his useful labours. He may also, under the head of Diseases of Plants, avail himself of all the knowledge and experience of Willdenow, as to the treatment of unhealthy plants, concerning which so much uncertainty has long prevailed. The articles entitled Planting, Timber, and Woods, are peculiarly adapted for those whose attention is principally directed to the propagation of useful trees, especially the Oak, Ash, Beech, Larch, Walnut, Chestnut, &c.: they will there find such general information as could not have been conveniently introduced into the particular description of each kind of Timber-tree, to which, under the names just enumerated, they are further referred for the most important details relative to their several qualities, and to the best means for their propagation. The Florist also, under the various species of flowers, will arrive at the most approved methods of bringing them to perfection, minutely laid down, principally upon the undoubted authority of the late celebrated Philip Miller to, whom this Work, as well as the Science of Botany, is largely indebted.

Interesting notices relative to the Arts, Manufactures, and Commerce, are intervoven, wherever articles of Trade, as Tanner's Bark, &c. have been described; or wherever there appeared any possibility of applying the plant under examination to commercial our economical purposes. It the last place, (but not on that account of the least conscquence,) those Country Housekeepers who take delight in Botany, Agriculture, or Gardening, beside sharing the advantages already specified under those particulars, will find throughout this Work, very numerous excellent Recipes, which the copious Indices of Diseases, accompanying each Volume, will readily refer them to, for the cure, or at least the mitigation, of most disorders to which they are exposed. To render this part of the work still more complete, the plates of a certain number of copies have been coloured from nature, which, with the Directions for Gathering and Preserving the various medicinal Herbs given at the end of the Introduction, will always enable them to collect, and keep ready for use, an ample stock of those simple, but efficacious, remedies.

London, 1st August, 1820.

INTRODUCTION.

NATURAL History properly signifies that study by which we learn to distinguish from each other, all bodies, whether animal, vegetable, or mineral, which surround us; to discover as much as possible their nature and properties, and especially their dependence on each other in the general scale of beings. In a more extensive sense, it may be said to teach the secondary properties of natural bodies, or the various uses to which they have been or may be converted, in the service of man : for an acquaintance with their properties is our only sure guide to a knowledge of their artificial uses. But as this definition would include many arts and sciences, each of which would be sufficient to occupy any common mind, such as agriculture, medicine, chemistry, and many others, it is sufficient for a philosophical naturalist to be acquainted with the general principles upon which such arts and sciences arc founded.

Botany, (from Borgen an herb, from Borge of Bognes, I feed, because vegetables are the natural food of most animals,) is the science of plants; or that part of natural history which relates to vegetables. It may be divided into three branches : 1st. The physiology of plants, or a knowledge of the structure and functions of their different parts; 2dly. The systematical arrangement and denomination of their several kinds; and, 3dly. Their economical or medical properties, all of which should be kept in view by an intelligent botanist. In the utmost extent of the word, Botany signifies a knowledge of plants, and of the uses to which they may be applied, in medicine, chemistry, or the arts in general: but it is commonly restricted to a bare knowledge of the plants themselves, and of the distinguishing marks whereby each species may be known from every other. This knowledge is indispensably necessary. Many animals are endowed with an instinctive faculty of distinguishing salutary from noxious food. Mankind have no such instinct. They must have recourse to experience, and to observation. But these are not sufficient guides in every case. A general caution, not to eat any thing but what we know to be salutary, will not answer in every instance. A ship's company, in want of provisions, may be thrown upon an uninhabited coast, or a desert island. Entirely ignorant of the nature of the plants they meet with, disease, or a scarcity of animals, may compel them to have recourse to vegetable food. The consequences may be dreadful-they must first eat before they can form any certain conclusion; and many lives have already been lost in these hazardous experiments. If the whole science of botany were as complete as some of its parts, very little skill in it would be sufficient to guard with certainty from committing such fatal mistakes. There are certain classes and orders which are called natural, because every genus and species comprehended under them, is not only distinguished by the same characteristic marks, but likewise possesses the same qualities, though not in an equal degree. For instance; shew a botanist the flower of a plant, the calix of which is a double-valved glume or husk, with three stamina, two pistilla, and one naked seed; hc can pronounce with absolute cer- and borne fruit these thirty years, but the fruit never ripened,

tainty, that the plant from which the flower was taken, bears seed of a farinaceous quality, and that it may be safely used as food. In like manner, shew him a flower with twelve or more stamina, all inserted into the internal side of the calix, though it belong to a plant growing in Japan, he can pronounce without hesitation, that its fruit may be eaten with safety. On the other hand, shew him a plant whose flower has five stamina, one pistil, one petal, and whose fruit is of the berry kind; he will tell you it is poisonous. Facts of this kind render botany a most interesting science. With respect to medical uses, it is found by experience, that plants, which are distinguished by the same characters in the flower and fruit, have the same qualities, though not always in an equal degree; so that upon inspecting the flower and the fruit, a botanist can determine the effects that will result from its use as a medicine. To determine therefore the medical virtues of all the plants belonging to a particular class, the physician has nothing to do but to ascertain, by a set of clear and unquestionable experiments, the virtues of any one of them; and this amazingly shortens the labour of investigation. As the number of species are known to be upwards of 20,000; by ascertaining the virtues of one genus, at a medium, you determine the number of 12 species. But by ascertaining the virtues of one genus belonging to a natural order, the virtues of perhaps 3 or 400 species are ascertained. A natural arrangement of the classes, orders, genera, and species, free in every instance from heterogeneous combinations, and disturbing no real affinities, is the ne plus ultra of classification. It is the point of perfection to which every naturalist should labour to approach, though what no one can expect actually to attain. To have formed the idea, is, however, no small advance towards it; and in itself implies a very important acquisition of knowledge.

This elegant science, which so manifestly displays the unbounded goodness and wisdom of God, was cultivated in some degree among the ancients, but chiefly with relation to medicine. As, however, they adopted no regular method of distribution and arrangement, the knowledge they gained was soon and easily lost. It would be as tedious as useless here to detail the various systems of those botanists who preceded the great Linneus, as it is well known that the system which bears his name is greatly superior to all that have been hitherto devised. It is called the Sexual System, because founded upon the important discovery, that in plants, as well as in animals, there is an indisputable distinction of the sexes; the following authenticated proof of which will probably be acceptable to the intelligent reader. In Vol. xlvii, of the Philosophical Transactions, No. 25, there is a letter from Mr. Mylius of Berlin, concerning a remarkable experiment made upon the palm-tree. He says, "The sex of plants is very well confirmed, by an experiment that has been made here upon the palma major foliis flabelli formibus, or, the greater fan-shaped-leaf palm. There is a great tree of this kind in the garden of the Royal Academy. It has flowered

and when planted, did not vegetate (or produce young plants.) experiments to proceed from the branches towards the roots, The palm-tree, as you know, is a planta diacia, that is, one of those in which the male and female parts of generation, are upon distinct plants, some being males and others females. We having therefore no male plants, the flowers of our female were never impregnated with the farina of the male. There is a male plant of this kind in a garden at Leipsic, twenty German miles from Berlin. We procured from thence, in April 1749, a branch of male flowers, and suspended it over our females, and the experiment succeeded so well, that our palm-tree produced more than an hundred ripe fruit, from which we already have eleven young palm-trees. This experiment was repeated last year, and our palm-tree bore above two thousand ripe fruit."

A plant, like an animal, is a very compound organized living being, in which various operations, both chemical and mechanical, are continually carrying on, from its first produc-tion to its final dissolution. It springs from a seed fertilized by the pollen of its parent plant. It takes in foreign substances by its inhaling and absorbent vessels. It extracts from, and assimilates to its own substance, those parts of them that are nutritious, and throws off the rest. It secretes a variety of fluids by the means of glands, and other unknown organs. It gives that motion to the sap, upon which the continuance of its life depends.

Of the theory of vegetation, or growth, propagation, and nutriment of vegetables, our knowledge is very slight and superficial. On making a transverse section of a tree, i. e. cutting it through horizontally, it appears to consist of three parts:

I. The BARK, which is also subdivided into two parts, 1. The cuticle, or external covering, which consists of numerons layers of circular fibres or threads, which are easily separated from each other. 2. The true bark, which appears upon removing the former, and is a collection of cellular or spongy substances, containing two kinds of organs; the vessels peculiar to the plants, and the longitudinal fibres or perpendicular threads.

II. On removing the bark, the WOOD appears. It has been discovered to contain the vasa propria, or proper vessels, and longitudinal fibres, besides large vessels with spiral or curved coats, running from one end of the tree to the other, and are denominated vasa aëria or air-vessels, which are chiefly situated in the wood, leaves, and petals, but are not found in the bark of trees, nor in herbaceous plants. They are called air-vessels, because they contain no liquor, and because large quantities of air are generally found wherever they are placed; and hence they are supposed to be the organs of respiration or breathing in vegetables; but in what manner this function is performed, is not clearly understood.

III. In the centre of the tree is the PITH, which is of a similar structure in all vegetables; and is very plentiful in young plants, but as they ripen dries up, and appears in smaller quantities, and in aged trees altogether disappears. Between the wood and the pith lies a green-coloured substance, called the corona or crown, which is said to contain all the parts of young plants in embryo.

These are the solid parts of plants, which likewise contain fluids or juices of two kinds : 1. The succus communis, or common sap, is of the same nature in all vegetables, and differs little from common water, except that it sooner becomes putrid on exposure to the air. It is supposed to ascend from the root, and to abound in proportion to the inclosed in a pericarp or seed-vessel. The receptacle or base humidity of the soil. 2. The succus proprius, or peculiar on which the fructification is situated, is commonly considered sap, which varies according to the different plants in which it as one of its parts; and in many plants there is a nectary or exists, giving to each its sensible qualities. It appears from honey-cup connected with it,

and never in a contrary direction .- Capillary attraction is thought to be the cause of the motion of these juices, the continuance of this power being supposed to depend on the evaporation from the leaves :, and of late years a vital power assisting the flow of the juices has been ascribed to plants, because their return from the branches to the roots cannot be otherwise explained.

Every plant is also composed of several external parts, differing from each other in their outward appearance, and which cannot fail to strike the most careless spectator. Many of these parts are themselves compounded, and obviously capable of being separated into subordinate divisions. The first grand division adopted by most botanists, is into the root, the body of the plant, and the fructification, or flower and fruit. The last, or something equivalent to it, is essential to all plants; the first is visible in almost all, and the second is not wanting in many.

The ROOT is stated by Linneus to consist of the radicle, and the descending caudex. The radicle is that fibrous part which draws nourishment from the earth, and in many in-stances constitutes the whole of the root. The descending caudex is properly part of the stock or body of the plant, which extends itself below the surface of the ground, as the ascending caudex rises above it. That the ascending and descending caudex have precisely the same nature is evident, from the well-known fact, that if a young tree be inverted, what was before the root will produce leaves, while the former stem throws out radicles. Roots are divided, according to the term of their duration, into annual, biennial, and percnnial. The annual and biennial produce flowers and fruit only once, and then soon die: the former passing through all the stages of vegetable life in one season ; the latter throwing out roots and leaves the first year, but not completing the fructification till the next. The perennial root has within itself a principle of continued life, and gives being to new flowers and seeds year after year, to an indefinite length of time. Of the roots that are called perennial, some are truly, others imperfectly such. In the true perennial root, the descending caudex and the radicle preserve the same individual organization, and increase in size as long as the plant continues to flourish. The imperfect perennial, are the bulbous and the tuberous, which perish after producing the bulbs, the tubers or tubercles, which are to be the parents of future plants.

The BODY of the plant springs from the root, and is terminated by the fructification. It is called by Linneus the herb, and according to him consists of the trunk, the leaves, the fulcra, props or supports, and the hybernacula, or bnds.

The FRUCTIFICATION is a temporary part of the vegetable, designed to perpetuate the species, by producing a perfect seed, in which is contained the rudiment of a plant similar to that by which it was generated. Its essential parts are the stamen and the pistil; the former corresponding with the male, and the latter with the female, in the animal kingdom. The stamen consists of the filament and the anther; the pistil, of the germ or seed-bud, the style, and the stigma. They are generally protected by two coverings, the outward called the calix, and the inward the corolla; but in many kinds of plants, either the one or the other, and in some both of them, are wanting. The pistil, in the last stage of its growth, is the parent of the seed or seeds, which are either naked, or

Upon these parts Linneus has founded his celebrated system of botany, called the Sexual System. To elucidate this, take a Martagon lily, for instance, Class Hexandria, Order Monogunia; which, though deficient in the calix or outer green part, usually consisting of five divisions or small leaves, which embraces and supports the flower, as in the rose, is still the best example; the largeness of its size allowing all the parts of the flower to be distinctly seen. Before it opens, at the top of the stem we find a long greenish bud, which grows whiter the nearer it is to opening; and when quite opened, assumes the form of a cup or basin, divided into several parts. These parts, taken separately, are called petals; but as a whole, the eorolla ; and not the flower, which is composed of various parts, whereof the corolla only is not the principal. The corolla of the lily not consisting of one entire cup or piece, but of six divisions or petals, is termed a hexapetalous, or six-petaled corolla. Exactly from the middle of the bottom of the corolla, or cup of the flower, there rises a sort of little column or pillar, pointing directly upwards. This is called the pistil or pointal, and is divided into three parts : 1. The swollen base with three blunted angles or corners at the bottom of the corolla, called the germen, periearp or seed-vessel, or bud. 2. A thread or small stem rising out of this, called the style, or shaft of the column, which, 3. is crowned with a sort of capital or head with three notches, called the stigma. Between the pistil and the corolla of the lily are six other bodies, entirely distinct from each other, and called the stamina; one part of which is long and thin, and rising from the side of the seed-bud at the bottom of the corolla, is called the *filament*; the other part, placed at the top of the filament, is thicker, and called the anther. Each anther is a box, which opens when it is ripe, throwing out a fine yellow dust with a strong smell, called the pollen, farina, or fertilizing dust, which falls upon and impregnates the germen or seed-bud, as in the instance of the palm-trees before cited, and without which no young plants can be produced. The parts here described are found in the flowers of most other plants, but in different proportion, situation, and number. By the resemblance of these parts, and their different combinations, the families of the vegetable kingdom are determined : and these analogies or resemblances are connected with others, in those parts of the plant which often seem destitute of all relation to them. Thus, this number of six stamina, sometimes only three, of six petals or divisions of the corolla, and the triangular or three-cornered form of the germen or seed-bud, distinguish the lily tribe; the roots whereof are in general bulbous, i. e. round, and many-coated. like an onion; while that of the above specimen, is individually distinguished by being a squamous bulb, or scaly ball.

A description of the different parts of a plant, must necessarily be obtained before it can be known. It is necessary, therefore, to pursue resemblances and differences through a number of gradations, and to found upon them primary and subordimate divisions; either ascending from particulars to generals, or descending from generals to particulars. Linneus has employed four principal divisions, *Classes, Orders, Genera, and Species*; occasionally introducing an intermediate one between the order and the genus, and another between the genus and the species. To illustrate this, no comparison can be more in point than that which considers the vegetables upon the face of the globe as analogous to, the inhabitants, thus:—

VEGÉTABLES resemble the INHABITANTS in general, Classes resemble Nations—Orders resemble Tribes, Genera resemble Families—Species resemble Individuals, Varieties, the same Individuals, in different circumstances. A Class, is an assemblage of orders, having one or more characters in common, but retaining their specific distinctions; and as it stands at the top of the series, it seizes the most general and most widely-diffused resemblances, and comprehends the greatest number of particular differences.

An Order is a collection of genera connected together by one or more common characters; but, like the classes, still preserving their specific distinctions.

A Genus is an assemblage of species, which, as well as the classes and orders, have some one or more characters in common to connect them, and at the same time retain their specific distinctions.

A Species consists of individuals, resembling each other in the form, position, proportion, and general appearance, of their several parts, produced from similar individuals, and having a power to produce other individuals of the same kind : or, as it is concisely defined by Jussieu, it is a perennial succession of similar individuals, deriving their origin from a successive generation. These individuals are not indeed like each other in every minute respect; such a perfect conformity does not exist in any two individuals, either of animate or inanimate organized nature. But the difference between those of the same species, though sufficiently discernible by the eye, cannot casily be expressed in words. With a stronglymarked resemblance in all their parts, there is a perpetual variation in their outline, and other particulars; so that no two individuals, lying one upon the other, will entirely correspond. They are formed after the same model, not cast in the same mould. In the general, an accurate description of all the parts belonging to any individual, will discriminate the whole species. There are, however, some sensible qualities, of importance enough to be distinguished by proper names, which are, in many cases, too uncertain to enter into any specific character. Of these, size, colour, smoothness or hairiness of surface, and luxuriance of one part at the expence of another, are the chief; and they are owing either to difference of soil, climate, particular exposure, and other accidents: or to artificial cultivation, which is the most abundant source of perpetual varieties.

In the Linnean system, the fructification has been justly considered of the first consequence. The characters of the classes, orders, and genera, are accordingly taken entirely from it.

In the greater number of planis, the parts of fructification may be readily discerned by the naked eye, or with the assistance of a common lens; but there are also not a few in which they have not been satisfactorily discovered, or are too miuate to be described with sufficient accuracy for the purposes of systematic arrangement. In most of linose whose parts of fructification have been clearly ascertained and distinetly described, the stamina and pistilla are inclosed within the same envelope, or at least are absolutely contiguous; but in some, they are contained in separate flowers, or placed at a distance from each other. In both cases there is much varietly with respect to their number, position, and other circumstances.

On these distinctions the distribution into classes and orders is founded. The characters of the classes are taken almost exclusively from the *stamina*; those of the orders either from the *stamina* or the *pisilla*, but most generally from the latter.

The essential characters or marks of the genera are taken from some particulars in the flower before unnoticed; but generic descriptions are designed to contain an account of all the most obvious appearances in every part of the flower.

The species are mostly characterised from peculiarities in the stem or leaves; sometimes from parts of the flower; and in some instances, though very rarely, from the roots,

1				XXIV.	Cryptogamia, or conceased and cannot be described, called con- cealed marriages;	Ferns, mosses, mushrooms, mould, algæ.			

The Number of the GENERA and SPECIES of PLANTS of the *Phanogamous Kinds, in the following TABLE, are taken from C. H. Persoon's Edition of Linneus, published at Paris in 1805 and 1807. In his Classification of Plants, he has differed in some respects from Linneus ; especially in his retrenchment of the Classes Polyadelphia and Polygamia, (the plants of which, he has distributed in what he conceives to be their more proper places in the remaining twenty-one Classes) and his cutting off the order Monogamia, from the Linnean class Syngenesia. The number of Genera and Species of +Cryptogamous plants, is taken from Turton's Edition of Linneus, Vol. VI. printed at Swansea in 1803.

	SYNOPSIS OF THE PRECEDING TABLE. Grand Total,	2431	23,782
	Total of Genera		
	Total of Genera	eta.	Species.

13" These Orders are named from the Pistillum, or female part of a plant, which is usually reckourd from the base of the Style, if there be any; if that be wanting, it is fixed from the Stiguate—Mongquia therefore means one wite, female, or style; Digmin, two; Triggnin, three; Tetraguia, four; Pentegnin for; Pentegnin ary.

Phanogamous, from φαινω to appear, and γαμος marriage :- Plants in which the parts of fructification are visible and distinct.

+ Cryptogamous,-from xoveru to hide, and yourse a marriage :- Plants in which the parts of fractificationarc either totally concealed or imperfectly visible. * Dr. Edward Smith, President of the Linnean Society, has removed the plants of the Monogamia order of this class into their proper place in the class Pentandria, because the flowers of its different genera are not composite, or compounded. C

1.

RULES FOR INVESTIGATION.

WHEN a plant offers itself to our investigation, the first thing to be determined is, the class to which it belongs. This is to be done by observing the number of stamina, and referring to the preceding tables of the Classes. Should there be a difficulty in ascertaining the number of stamina, on account of the number appearing different in different flowers, though belonging to the same plant, it is advisable to examine one or more of the flowers which are yet unopened ; for the antheræ are in that state more distinct, and we may be certain that none of them have been lost. Having fixed upon the class, we must again refer to the preceding tables, where we shall find of how many orders the class consists; and after observing the circumstances by which the orders in each class are determined, in the Linnean Table at the end of the work, they must be compared with the plant before us. If the order we refer it to has any subdivisions. we shall soon perceive under which of the subdivisions the genus should be found : and as this dictionary presents the student with the characteristics of the orders and their respective subdivisions, and also with the genera belonging to each order or subdivision alphabetically arranged, after having discovered the class by the assistance of the preceding analysis, he will easily ascertain the order in this table under the class to which it belongs, and will there find himself at once referred to the genera and species in the body of the work.

After comparing the flowers, with the characters of the different genera contained in the order, or in the particular subdivision of the order, it will soon be seen with which of them it best corresponds; and if any one agree pretty exactly with our specimen in all the leading characters, we are then certain of the genus. Doubtful matters will sometimes arise; but these are for the most part made clear, by observations subjoined to the generic descriptions. In consulting these generic descriptions, the learner is advised to pay particular attention to the structure of the *pistil*, and especially to that of its gennen, when it begins to ripen into a seed-nesel ; because these parts being most essential to the continuation of the species, are less liable to variation, than those which are less important.

If none of the generic characters at the beginning of the class agree with the flower, we must then look at the end or subdivision of the order to which it was referred, and see what plants are there mentioned. If we have not found the plant before, it must be some one of these; looking therefore for these, and comparing the generic descriptions with the specimen in hand, we shall not only discover the genus, but the circumstance which produced our perplexity.

The young student is also recommended to practise the investigation of genera only, for a considerable time, before he attempts to ascertain a new species; and when by this means has attained a pretty accurate knowledge of classes and orders; also of the parts composing a flower, and its subsequent state of fructification, with the terms employed in describing them; he may next proceed to determine the species. Whenever the species are numerous, they are subdivided. Consider with which of these subdivisions it agrees; and having determined that, compare it with the several specific characters, as it will probably agree with some one of these. If you are still in doubt, guided by the references to figures which commonly follow the specific character, turn to such figures as you possess; and to make the point still more certain, compare your plant with the descriptions which follow the references to figures; for these will remove many an existing doubt, and obviate many a possible mistake. If the plant in question be any remarkable variety, you will probably find it introduced after the additional descriptions above alluded to.

Make it an invariable rule, not to pass over a single term, the precise meaning of which you do not thoroughly understand: always consult the Botanical Dictionary, at the end of this Introduction, which will soon remove the necessity of consulting it at all.

Lastly, When gathering plants for examination, collect a considerable number of the flowers, and, if possible, some just opening, others fully expanded, and others with the seed-vessels almost ripe; take care also to gather one specimen of the plant at least, as perfect and entire as possible.

It is deemed necessary to subjoin various examples for investigation; the student will however do well, after examining, to try his strength by examining any unknown flowers he may pick up in his walks.

EXAMPLES.

COMMON PRIVET .- Ligustrum Vulgare.

This shrub is found in hedges and shrubberies in many parts of England. It generally blossoms in June, and its blossoms are white. Having obtained a branch of it in blossom, we proceed to investigate it; and looking into several blossoms. find two stamina in each, by which we know it belongs to the Diandria class. This class contains three orders, which depend upon the number of pistilla ; looking again at the flowers, we discover one pistil in each ; so that the plant evidently belongs to the order Monogynia .- This order is subdivided into several parts; and observing the marks of these subdivisions, we find that in our specimen the blossom is formed of one regular corolla, fixed beneath the germen; which corresponds with the first subdivision, and that contains only one English genus, so that there can be no doubt but the plant is a ligustrum. We shall also find that the blossom is cloven into four parts, and that it is succeeded by a berry containing four seeds. Referring to the genus ligustrum, and comparing it with the generic description, we have the satisfaction to perceive a perfect coincidence. Having ascertained the genus, we proceed to discover the species, and as there are only two species of that genus, we know the shrub in question, from its lanceolate leaves, must be the common privet, or ligustrum vulgare of Linneus.

REED .- Arundo.

The Reed is plentiful upon the banks of rivers and borders of pools, and in wet ditches; it is a sort of large grass, five or six feet high, and flowers in June. Having gathered a specimen of this, we proceed to examine it systematically. At first sight we observe that the flowers grow in panicles, and that each flower contains three stamina. We therefore refer it to the third or Triandria class, which is divided into three orders, depending upon the number of pistilla. Each of the flowers contains two pistilla, and therefore belongs to the order Digynia. This order is subdivided into several parts. The first subdivision contains the plants with flowers scattered, or irregularly disposed, one only in each calix. Our plant agrees with the first circumstance, but not with the last, for we find five flowers in each calix. Another subdivision contains only two flowers in a calix ; we therefore pass that over, and come to the third, with scattered flowers, and several in each calix. Before we proceed further, we just look at the remaining subdivision, but finding those flowers in the form of a spike, or a long and slender receptacle, we immediately recur to the third subdivision. This subdivision contains several genera, and we compare the characters of each with the plant in hand : the want of an awn, and the woolliness at the base of the blossoms, determines us to call it Arundo. Turning therefore to the genus arundo, we compare it accurately with the generic description, and find it correspond with it. But as the parts constituting the flowers of grasses are frequently very minute, we make use of the botanical microscope and dissecting instrument,* to display them more clearly to the eye. Having discovered it to be an arundo or reed, we next proceed to ascertain the species. There are four only natives of Great Britain : and each calix containing five florets upon a flexible panicle, which is observed to be waved about with every wind, decides that it is common reed, or arundo phragmites of Linneus.

PLANTAIN.-Plantago.

The Plantain flowers in June and July, and is very common in mowing grass, and upon the road side. It is frequently stuck in the cages of linnets and canary birds, who are fond of the seeds. Examining a specimen of this, we find each flower to contain four stamina, nearly of the same length, it therefore belongs to the fourth or Tetrandria class. This class contains four orders, depending upon the number of pistilla. Each of our flowers contains only one pistil, and therefore belongs to the first order, which admits of twelve subdivisions. Our specimen presents blossoms of one petal, fixed beneath the germen; this induces us to seek it in the fourth subdivision; and finding, by cutting across the seed-yessel, that it is divided into two cells, twe conclude that it is a plantago. We now compare it with the generic description, and as that agrees, try next to determine the species. There are thirtyfive species of plantain; these are subdivided into plantains with naked scapes, and those furnished with a stem. Our plant has a naked scape, and therefore belongs to the first subdivision. It agrees with the plantago lanceolata in every particular ; and hence we call it the ribwort plantain, or plantago lanceolata of Linneus.

BIRCH.-Betula.

This tree is very generally known. The flowers are disposed in catikins, which appear in A pril and May. Some of these catkins contain only stamina with their scales, and others on the same tree only pisialli. In the former, each floret contains four stamina, and in the latter two pistilla. These agree with the twenty-first or Monecia class, and with the order Tetrandria, which contains twelve genera. Attention to the other parts of the character, and a comparison with the generic description, will determine it to be of the betala genus, which having fifteen species, the shape of the leaves will prove the specimen to be the common birch-tree, or betula alba of Linneus.

HONEYSUCKLE.-Lonicera.

This plant is common in our hedge-rows, and is very universally known; but let us suppose a person, who never saw it before, struck with the beauty and fragrance of its blossoms, carrying a piece of it home for examination. Finding five stamina in each flower, and the antheræ, not united, he refers it to the fifth or Pentandria class. The orders in that class being determined by the number of pistilla, he knows it belongs to the order Monogynia, for he finds only one pistil in each flower. This order is subdivided into eleven parts. The absence of the four naked seeds, and the ROUGH LEAVES. immediately determine him to reject the third subdivision. The blossom being fixed beneath the germen, does not correspond with his flower; hence he rejects the fourth and fifth subdivisions, and passes on to the sixth, where he finds flowers of one petal superior. This flower consists of one petal, and this petal is fixed superior to, or above, the germen. This subdivision containing many genera, he observes in his plant the seed-vessel is a berry with two cells; this circumstance, added to the equality of the blossom, and the knob at the ton of the pistil, induces him to think it a lonicera, which, upon comparing the flower with the generic description, he finds to be correct. Under this genus he finds twenty species; he compares it with the specific character of each, and thereby determines it to be the woodbine honeysuckle, or lonicera periclymanum of Linneus.

SNOWDROP.-Galanthus.

The Snowdrop, though not frequent in a wild state, is to be found in almost every garden, and is among the first of our spring flowers. When we examine it attentively, the first thing that strikes us, is the want of a cup; but instead of that, we find upon the fruitstalk a sheathing substance, which covers the blossom in its infant state. The six stamina direct us to the sixth or Hexandria class, and the single pistil fixes it upon the first order of that class. This order is subdivided into, 1. Flowers with a cup and blossom. 2. Flowers with calix, corolla, or spathe. 3. Flowers with a sheath or husk. A Flowers madel. 5. Flowers with a sheath or husk. A Flowers madel. 5. Flowers within a tpetals. The want of a cup, and the presence of the sheath, teach us to expect it in the third subdivision, which contains several genera. In the allium the blossom is fixed *beneath* the germen, but in our bant it is *above* it. In the Narcissus there is a bell-shaped

^{*} The botanical microscope, and dissecting instruments, may be purchased for about two guineas. The microscope is of a form suited to the pocket, and is also made to stand steady while in use.

[#] To judge whether a capsule consists of one or more cells, the best method

is to cut it through horizontally with a sharp knife, then carefully to pick out the seeds, leaving the dividing membranes entire. If it be very minute, cut off a thin slice horizontally, place it on the stage of the microscope, view it through the magnifier, and at the same time dissect it with the instrument.

nectary, and six petals; but our plant has six petals only, and no such bell-shaped nectary. The circumstance of three inner petals, shorter and notched at the end, is sufficiently observable in our specimen, and clearly distinguish it from the lencojum; it agrees only with the galanthus. The generic character answers the description; and the three inner and shorter petals may be considered as a nectary. As there is but one species, it must therefore be the galanthus nivalis of Linneus, or common snowdrop.

PEAR .- Pyrus.

Finding about twenty stamina in cach flower, we know it must belong either to the twelfth or thirteenth classes. In the twelfth, or Icosandria class, the number of stamina alone will not sufficiently distinguish it from the classes Dodecandria and Polyandria: but as the calix is formed of a single concave leaf, the petals fixed to the sides of the calix, and the stamina do not stand upon the receptacle, we conclude that it belongs to that class. Each flower having five pistilla, we look for the genus under the order Pentagynia. This order contains six genera. The calix being cloven into five parts, and the blossoms being composed of five petals, are circumstances common to three. But the fruit of one is a berry containing five seeds, and the fruit of another is a pomum or apple, with five cells and many seeds. Hence it appears, that our plant is undoubtedly the pyrus; and turning to the generic description, we are confirmed in this opinion. We next compare it with the twenty-four species, and are soon able to determine whether we have got the pyrus communis or the pyrus malus; i. e. the pear or the apple.

CROWFOOT.-Ranunculus.

The beautiful shining vellow blossoms of crowfoot, and the frequency of it in pastures, in the months of June and July, will probably attract our notice, especially as cattle leave it untouched, even when the pasture is bare. We therefore collect some of it, and finding a great number of stamina in each blossom, refer it to the thirteenth or Polyandria class, the stamina of which stand upon the receptacle, and not upon the cup or blossom. As this must be the class, we next examine the pistilla, aud finding them more than can readily be counted, turn to the order Polygynia. This order includes twenty-one genera. Upon an accurate examination we observe a little pore or nectary within the claw of each petal; and governed also by a number of leaves forming the cup, and of petals composing the blossom, we turn to the generic description of the ranunculus. Quite satisfied about the genus, we observe the species are numerous, and arranged according as the leaves are divided, or not divided. In our specimen the leaves are divided. We then compare it with each of the species; and from its open or expanded calix, its cylindrical fruit-stalks, its leaves with three divisions, many clefts, &c. find it to be the upright crowfoot, or ranunculus acris of Linneus.

WALL-FLOWER,-Cheiranthus.

This plant is very generally known. It grows wild upon long to the two first, because in the former all the stamina old walls, and is frequently cultivated in gardens. Carefully are united, and in the latter the stigma is publescent; nor which are shorter than the other four. It therefore mostly one-celled, without the marks of the two first subdiblescents correstly remove the cality on the former of the seed-vessel; and of plants with the legume one-celled and many-seeded. Our after examing the specimen, you necessarily refer it to plant having a two-celled legume, without the marks of the marks of the set o

the first subdivision of the second order; for the seed-vessel is a long pod, and the leaves of the cup stand upright, and close to the blossom. It is possible you may have to dissect several flowers, before you can ascertain the genus; for this class, like the preceding, is composed of a natural assemblage of plants, whose flowers bear a strong resemblance to each other; and the differences, when this is the case, are not very obvious. At length, however, the small glandular substance on each side the base of the germen, determines you to refer it to cheiranthus. Upon a comparison with the generic description, you'nd it corresponds; and the shape of the leaves, &c. puts it beyond all doubl, that it is the wall July flower, or cheiranthus cheir of Linnens.

DANDELION .- Leontodon.

Or, Pissabed. This plant is in blossom during great part of the spring and summer; it grows in pastures, road sides, and the uncultivated parts of gardens. At the first view we perceive its structure to be very different from any we have ever examined before; we hardly know what to call stamina, or what pistilla. The fact is this, it is a true COMPOUND FLOWER, or a flower formed of a number of little flowers (or florets) sitting upon one common receptacle, and inclosed by one common calix. Separating one of the florets, and examining it carefully, we find five stamina, with the antheræ united, and the pistil passing through the cylinder formed by the union of the antheræ. We therefore refer it to the nineteenth, or Syngenesia class: finding that all the florets are furnished with stamina and pistilla, we perceive that it belongs to the first order. From the shape of the blossoms of the florets, which are all long and narrow, we know that we must look in the first subdivision of that order. Perceiving that the receptacle is an important circumstance in the character of compound flowers, we pull off all the florets in one of the flowers, and expose the receptacle to view. We find it naked, that is, not beset with chaffy or bristly substauces. We find too a sort of down adhering to the seeds : and observe the scales of the calix laid one over another, like the tiles on a roof; the outer scales loose, flexible, and turned back. These characters corresponding pretty well with the leontodon, we fix upon that as the genus: we look forward to the generic description, where we are informed, that in the leontodon taraxacum, the down of the seed is supported on a long pedicle, which we had already remarked in the flower before us. We next read the characters of the different species; and, from the deep notches in the leaves, judge our plant to be the leontodon taraxacum of Linneus, or common dandehon.

MILK-VETCH .- Astragalus.

This genus is very common every where in Great Britäm. Examining a specimen of it when in flower, we immediately collect from the papilionaceous, or butterfly-shaped blossoms, that it must belong to the Decandria order of the Diadelphia class of plants. In referring to the Linnean classification of the plants in this order, we find that there are not fewer than six grand subdivisions. Our plant cannot belong to the two first, because in the former all the stamina are united, and in the latter the stigma is pubsecent; nor with the three last, which consist of plants with the legume mostly one-celled, without the marks of the two first subdivisions; of plants with the lowent separating into joints; and of plants with the legume, without the marks of the the third subdivision. In this there are only three genera, viz, phaca, biserbula, and astragalus. The plant in question not having a half-two-celled inflated legume, it cannot be the phaca; it must therefore be either the biserbula or astragalus. The gibbous shape of the legume, leaves no doubt of its being an astragalus; but as the species of this genus are extremely numerous, in order to determine the species, we must pay very particular attention to the minute circumstances by which they are distinguished. The species of astragalus are divided into not fewer than seven subdivisions. The specimen before us cannot belong to the six first subdivisions, because the first consists of astragali, with leafy erect stems and axillary flowers; the second of leafy erect stems, with spikes cylindrical, axillary, sessile, or nearly so; the third of leafy erect stems, with spikes and racemes peduncled; the fourth of leafy diffuse stems; the fifth of leaflets placed in whorls; and the sixth of a naked scape, without a leafy stem. Our plant must therefore be a species of astragalus, in the seventh subdivision, containing shrubby plants with the petioles permanent, and becoming spinous. As the species of astragali in this subdivision are numerous, we must be very careful in examining all the specific characteristics. The leaflets being in ten pairs, determine it to be either the astragalus longifolius, or astragalus pugniformis. It cannot be the latter, which has oblong mucronate glabrous leaflets; therefore there is not the least doubt that the plant in question is the astragalus longifolius, from the lanceolate mucronate glabrous leaflets, the flowers being in oblong heads, and the calix having filiform villous teeth.

STARWORT.-Aster.

Upon the first sight of this plant, we refer it to the class Syngenesia, because of its composite flowers. As this class is subdivided into five orders, we soon perceive, by a careful inspection of the florets, that it cannot belong to the first order, which consists of plants having florets all hermaphrodite and fertile. Neither can it belong to the third order, which consists of plants with the florets of the centre hermaphrodite, and those of the ray neuter and barren; neither can it be one of the fourth order, which consists of plants having the florets of the centre hermaphrodite and barren, and those of the margin, female and fertile; nor can it belong to the last order, which consists of plants with the fiorets separated by a proper perianth, containing one or more florets, and placed within a common calix. The florets of the disk, in the specimen before us, being hermaphroditc, and those of the margin female, and all fertile, leave not the least shadow of doubt of its being in the order Polygamia Superflua. This order has three grand subdivisions. In the first, all the florets are tubular, which is not the case with the plant in question; in the second, the florets are semi-floscular, and somewhat two-lipped, circumstances not in our specimen. The radiate florets of our specimen, is the striking characteristic of the third subdivision, and is decisive of its being in this subdivision. Its naked receptacle is a proof that it cannot be the boltonia, siegesbeckia, anthemis, achillea, tctragonotheca, ximenesia, georgina, relhania, pascalia, buphthalmum, rhanterium, amellus, tridax, rosenia, verbesina, schlechtendalia, galinosogea, zinnia, balbisia, nor starkea. Its simple down, in union with its naked receptacle, confines it to the doronicum arnica, inula, erigeron, solidago, cineria, denecio, tussilago, aster, and boebera. Its imbricate calix, with the lower scales spreading, and the florets of the margin more than ten, class. As the orders of this class depend upon the number

two first subdivisions, it must necessarily be one of those in [very numerous, and arc divided into seven grand subdivisions. It cannot belong to the first, which consists of species more or less shrubby; nor to the second, consisting of herbaccous plants, with the stem one or two flowered; nor to the third, containing herbaceous species, with linear or lanceolate leaves very entire ; nor to the fourth, consisting of herbaceous plants, with heart-shaped, ovate, and serrate leaves; nor to the fifth, containing herbaceous plants, with ovate very entire leaves; nor to the sixth, which contains herbaceous plants, with lanceolate leaves, the lower ones more or less serrate. Our plant being herbaceous, with pinnate leaves, must belong to the last subdivision, in which there are only two species, the aster aurantius, and aster pinnatus. The pinnate leaves, with the midriff winged, leave no doubt of its being the aster pinnatus; and the additional circumstances of the leaflets being linear-wedge-form, serrate at top, put the matter beyond all controversy.

TRUMPET-FLOWER. - Bignonia.

The stamina of this plant being two longer and two shorter, is sufficient to determine it to be in the Didynamia class; and the seeds being inclosed in a capsule, shew it to be of the angiospermia order. The plants of this order are numerous, and subdivided into seven parts, all of which, except the last, depend upon the form of the calix. The plant in question is not in the first subdivision, which consists of plants with undivided calixes; nor in the second, consisting of bifid calixes; nor in the third, containing plants with threecleft calixes; nor in the fourth, which contains plants with four-eleft calixes; nor in the sixth, containing plants with many-clefted calixes; nor in the seventh, containing plants with more than one petal. Our plant having a five-clefted calix, there can be no doubt of its belonging to the fifth subdivision. The genera in this subdivision are numerous, which are generally distinguished from each other by the capsule and corolla. Our specimen has a two-celled capsule, and a campanulate corolla; the union of which particulars, restrict it to the following genera: capraria, digitalcs, bignonia, incarvillea, ruellia, sesamum, and gloxinia. The imbricate-winged seeds and the filaments, with the rudiment of a fifth, shew it can be no other than the bignonia. The species of this genus are very numerous, and are subdivided into seven parts; all of which depend upon the shape or number of the leaves. The plant in question consequently cannot be in the first subdivision, which contains plants with simple leaves; nor in the second, consisting of plants with two leaves on each petiole; nor in the third, having plants with three leaves, on a common stalk ; nor in the fourth, with leaves in finger-like divisions ; nor in the fifth, with pinnate leaves; nor in the seventh, with doubly pinnate leaves. The decompound leaves of our specimen, shew it to be in the sixth subdivision. In this there are only three species. The decompositely pinnate leaves, with knotty petioles and axillary corymbs, shew it to be no other than the bignonia alba. The additional circumstance of its having white flowers on a many-flower-forked axillary peduncle, puts the question beyond all dispute.

SEDGE-GRASS .- Carex.

Upon a minute investigation of the apetalous flowers of this plant, we discover that some are male and others female, growing from the same root; but we are not able to find any hermaphrodites; consequently it must belong to the Monoccia restrict it entirely to the aster. The species of this genus are or position of the stamina, our plant must be in the order n

1.

Triandria, from the circumstance of its having three stamina. The want of a corolla, the imbricate ament, the calix being a one-valved scale, the three stigmata, and the coated seed, are sufficient in warranting us to call it a carex. The species of this genus are very numerous, (upwards of 200) and are parted into five grand subdivisions. The plant in question is not in the first subdivision, which consists of species with simple solitary spikes; nor in the second, with compound androgynous spikes; nor in the last, with male and female spikes distinct, and the males several. The male and female flowers growing on distinct spikes, and nearly of equal number, each shew that our specimen must be either in the third or fourth grand subdivision. As the species of carex, in these two subdivisions, are distinguished from each other by the female flowers being sessile in one, and peduncled in the other, we are assured that our plant, from its sessile, female, apetalous flowers, must belong to the third subdivision. Its short sheaths nearly equalling the peduncles, its female roundish spikes, beaked fruit curved downwards, and nearlysmooth stem, leave no doubt of its being the carex flava, or yellow sedge-grass.

summe

It will be very proper for the learner thus to examine several more genera of this class, as the coltsfoot, the burdock, the thistle, the tansy, the daisy, and the groundsel; for by doing this, he will soon overcome the difficulties which present themselves; and it will be satisfactory to compare the plant with the figures in the plates of English plants in this work.

The compiler cannot conclude with more appropriate words than those of the justly admired author, who has supplied him with several of the above rules and exemplifications .----" After having passed in this familiar though cursory manner, through the different parts of the system, I must suppose that the Reader no longer stands in need of my assistance; and that he will soon find himself equal to the investigation of every useful plant which may come before him. But this is not all : he will find that the study of Nature is ever attended with pleasing reflections; that the study of botany in particular, independently of its immediate use, is as healthful as it is innocent ; that it beguiles the tediousness of the road ; that it furnishes amusement at every footstep of the solitary walk ; and, above all, that it must fill our hearts with gratitude, while we discover the bounty, wisdom, and power of the great CREATOR."

INTRODUCTION.

PLATE II.

SIMPLE LEAVES continued.

Fig.

- 39. Folium crispum, a curled leaf.
- 40. ----- obtusum, a leaf which terminates obtusely.
- 41. acutum, a leaf which terminates in an acute angle.
- acuminatum, a leaf whose apex is subulate or awl-shaped. (Vide fig. 8.)—an acuminate leaf.
- 43. —— obtusum acumine, a sharp-pointed leaf, which does not begin to taper till very near the apex—obtuse with a point.
- emarginatum acutê, a leaf, the apex of which is deficient in its margin, and ends sharply.
- 45. <u>cuneiforme emarginatum</u>, a leaf that is shaped like a wedge, and has a rounded notch or deficiency at the apex.
- 46. ---- retusum, a leaf which ends in an obtuse sinus.
- *pilosum*, a leaf, from the surface of which proceed long distinct hairs.
- tomentosum, a leaf whose surface is covered with a beautiful white down. Vide tomentum.
- 49. hispidum, a leaf whose surface is covered with hard bristles.
- ciliatum, a leaf, the margin of which is fringed like an eye-lash, (cilium.)
- 51. _____ rugosum, (ruga, a wrinkle) a wrinkled leaf.
- 52. ----- venosum, a leaf whose surface abounds with veins or branched vessels.
- 53. ——— nervosum, a leaf whose surface abounds with nerves, ribs, or simple unbranched prolongations of the pedicle.
- 54. papillosum, a leaf, from the surface of which arise little bladders or blisters, (papilla, a nipple.)
- 55. ____ linguiforme, a tongue-shaped leaf.
- 56. acinaciforme, a leaf shaped like a Persian scimitar, (acinaces.)

- 59. triquetrum, a three-sided leaf, as in unthericum ossifragum.
- 60. —— canaliculativm, (canaliculus, a little pipe, or channel) a channelle leaf; a leaf that has one longitudinal groove, running from the base to the apex on the upper surface, the lower being convex.
- sulcatum, a furrowed or fluted leaf; a leaf that has several deep grooves or furrows,

and in the same direction as the channelled leaf.

- 62. Folium teres, a cylindrical or pillar-shaped leaf.
- 69. panduraforme, a leaf shaped like a violin, or Spanish guitar, as in rumex pulcher, (pandura, a musical instrument with three strings.)
- 64. ---- lyratum, a lyre-shaped leaf.

COMPOUND LEAVES.

- 1. ----- binatum, a fingered leaf with two leaflets.
- ternatum foliolis sessilibus, a fingered leaf with three leaflets that are sessile. See fig. 12 and 14 in Plate VI.
- ternatum foliolis petiolatis, a fingered leaf having three stalked leaflets; the reverse of the preceding term.
- digitatum, in general a fingered leaf; in the figure before us in particular, a leaf of that description with five sessile leaflets.
- pedatum, a leaf somewhat resembling a bird's foot; exemplified in passion flower, and black hellebore.
- 6. *pinnatum, cum impari,* a pinnate or winged leaf with an odd leaflet at the apex.
- *abruptè pinnatum*, a pinnate leaf, which at the apex has neither an odd leaflet nor tendril.
- *pinnatum, alternatim,* a pinnate leaf having the leaflets placed alternately along the mid-rib.
- pinnatum foliolis oppositis, a pinnate leaf with opposite leaflets.
- interruptè pinnatum, a pinnate leaf with unequal leaflets—interruptedly winged.
- pinnatum cirrosum, a pinnate leaf terminated by a tendril.
- *pinnatum conjugatum, a pinnate leaf with only two pair of leaflets.
- pinnatum decursive, a leaf decursively pinnate, that is, in which the leaflets run down or extend themselves into the stalk.
- 14. <u>pinnatum articulat</u>è, a pinnate leaf, in which the common footstalk connecting the leaflets is *articulate* or jointed.

* The reader must be careful to distinguish betwixt folium binatum and folium conjugatum; the first being the lowest modification of the digitate or fingered leaf, the second the lowest of the pinnate or winged one.

÷.

Published by Nutrall, Fisher & C'Liverpool, March 1, 1816.

EXPLANATION OF THE PLATES.

PLATE HI.

Fig.

E

COMPOUND LEAVES continued.

- 16. Folium biternatum, a re-compounded leaf that is doubly-ternate, that is, has the common footstalk divided into three parts, each of which has three leaflets.
- 17. ----- triternatum, a leaf that is triply-ternate, that is, has the common footstalk divided into three parts, each of which is doublyternate.
- 18. ----- bipinnatum, a doubly-pinnate leaf.
- 19. ---- tripinnatum sine impari, a triply-pinnate leaf, each pinna of which terminates abruptly.
- 20. ---- tripinnatum cum impari, a triply-pinnate leaf, with an odd leaflet at the apex of each pinna or wing.

DETERMINATION OR DISPOSITION OF LEAVES.

- 1. _____ inflexum, a leaf bent inwards, or towards the stalk.
- 2. _____ erectum, an erect leaf, or that is nearly perpendicular.
- ----- patens, a leaf bent outwards, or declining from the stalk at an acute angle ; a spreading leaf.
- 4. ----- horizontale, an horizontal leaf, which is placed at right angles with the stalk.
- ---- reclinatum, a leaf that is bent downwards.

- 6. Folium revolutum, a leaf whose summits are rolled inwards.
- 7. _____ seminale, a seed-leaf.
- 8. ____ caulinum, a stem-leaf.
- 9. _____ rameum, a branch-leaf. 10. _____ florule, a leaf that is stationed near the flower.
- 11. ----- decurrens, a decurrent or running leaf; a leaf which extends itself downwards along the stalk beyond its proper basis.
- 12. ____ petiolatum, a leaf supported on a petiolus or footstalk.
- 13. ----- peltatum, a target-shaped leaf.
- 14. _____ sessile, a leaf that is seated immediately on the stem or branch, without any manifest footstalk ; opposed to petiolatum.
- 15. _____ amplexicaule, a leaf which transeversely embraces the stem by its base.
- 16. ---- perfoliatum, a perforated leaf. This leaf differs from the preceding chiefly in the perforation, which is likewise transverse, taking place at a greater distance from the margin.
- connatum, a leaf formed by the union of two 17 ---leaves at the base.
- 18. ----- vaginans, a leaf the base of which longitudinally surrounds the stem like a sheath. By the circumstance of its longitudinal perforation, this species of leaf may be easily distinguished from those described at No. 15. and 16.

2.

Fig.

13

INTRODUCTION.

PLATE IV.

DETERMINATION OF LEAVES continued.

- 19. Folium articulatum, a jointed leaf, a species of compound leaf, in which the leaflets are produced each from the summit of that immediately under it, as in Cactus opunta. This singular appearance Berkenhout very properly compares to the links of a chain.
- 20. Folia stellata, leaves surrounding the stem in the form of a radiant star; synonymous to verlicillata.
- 21. quaterna, leaves growing by fours; a modification of the two former terms.
- 22. opposita, leaves growing in pairs.
- alterna, leaves ranged singly in succession on both sides of the stalk; the reverse of the preceding term.
- imbricata, leaves laid over one another like tiles, (imbrex, a gutter tile) as in the genus saxifraga.
- 25. accross, chaffy leaves; leaves that are slender and of equal breadth throughout, somewhat hard, evergreen, pointed like pins, and surrounded at the base by chaffy scales. The term is exemplified in fir, pine, yew, and juniper.
- *fasciculata*, leaves which proceed in bundles (*fasciculi*) from the same point, as in the larch tree, and some pines.

27. Frons, a composition of a leaf and branch. The trunk of the palms and ferns is so termed by Linneus. This term serves as a connecting link betwixt leaves and trunks. The two following terms belong to the division containing simple leaves.

15

Fig.

 Folium spathulatum, a leaf shaped like a spatula, as in cistus incanus, and philomis purpurea.
 —— parabolicum, a leaf which in figure, somewhat resembles the geometrical curve termed

a parabola.

TRUNKS.

- 1. Culmus squamosus, a scaly culm, straw, or haulm; a species of that trunk or stem which is peculiar to the grasses.
- 2. Caulis repens & scandens, a creeping and climbing stem, exemplified in *bignonia* and ivy.
- Scapus, a species of trunk which elevates the fructification, but not the leaves; a naked flowerstalk, exemplified in auricula, and many of the liliaceous plants.
- 4. Culmus articulatus, a culm or straw that has knots or joints at certain intervals.
- Caulis volubilis, a twining stem, exemplified in convolvulus, black bryony, and hop.
- dichotomus; (bzza, in two parts, and τµio, to cut) a forked stem; a compound stem, the divisions of which are always by pairs; as in ccrustum dichomum, and valeriana locusta.
- *—— brachiatus, (brachium, the arm) a simple stem,* whose branches grow by pairs, resem-bling arms; as in mercurialis annua.
- Stipes, the trunk of a fingus. The term is likewise used for the *basis* or stalk of that peculiar species of trunk called a *frons*. See Plate VII. fg. 27.

Determination of Leaves continued.

PLATE IN.

PLATE V.

PLATE V.

SUPPORTS AND ARMATURE OF PLANTS.

Fig.

- Fig. 1. Stipula, a stipule; a scale or scales at the insertion of the footstalks of the leaves and flowers. Cirrus, a clasper or tendril.
- Aculeus simplex, that species of vegetable armature called prickles, (aculei) in which the weapons in question proceed singly from the stem or branch.
- triplex, prickles which grow by threes; a three-pronged prickle.
- 4. Spina simplex, a simple or single thorn.
- 5. ---- triplex, a triple thorn.
- 6. Stimuli, stings, as in the nettle, acalypha and tragia.
- 7. Bractea, floral leaves; leaves which differ in colour and shape from the other leaves of the plant. In some species of sage, laven-

der, and crown-imperial, they assume the appearance of a tuft of hair at the end of the flower-stem, and hence have obtained the name of coma.

- 8. Glandulæ concavæ concave glandulær appearances, seated on the footstalk of the leaves.
- pedicellata, glands placed on short footstalks, and which likewise have their seat on the petiolus.
- 10. Pili, hairs; a species of pubescence.
- 11. A thorny leaf and branch.
- 12. The prickly capsule of the beech.
- 13. Pedunculus, a flower-stalk.
- 14. The thorny fruit of the horse-chesnut.
- 15. The prickly fruit of the chesnut.

PLATE VI.

ROOTS.

Fig.

Fig.

- 1. Radix fusiformis, a spindle-shaped root, as in carrot. 2. _____ subrotunda, a roundish root, as in turnip.
- 3. --- fibrosa, a fibrous or stringy root, as in senecio vulgaris.
- 4. --- granulata, a granulated root-a root consisting of a number of little knobs resembling grain, which are fastened to one another by small fibres or strings, as in saxifraga granulata.
- 5. ---- pramorsa, a root which ends abruptly, having the appearance as if bitten off. The term is exemplified in plantain, and scabiosa succisa.
- 6. --- tuberosa, pendula, a tuberous and pendulous root; as in spiræa filipendula, or dropwort.

- 7. Radix fascicularis, a species of tuberous root, in which the knobby parts grow in bundles. This is sometimes termed a grumous root, and
- is exemplified in ranunculus and peony. 8. Bulbus squamosus, a scaly bulb, as in the white lily.
- 9. _____ solidus, a solid bulb, as in tulip. 10. ______ a transverse section of a solid bulb.
- 11. ----- tunicatus, a coated bulb, as in onion.
- 12. ------ a transverse section of a coated bulb.
- 13. The roots, or pattes, as they are termed, of anemone.
- 14. Radix testiculata, a twin-root, as in orchis.
- 15. The root of bird's nest, a species of ophrys, which is evidently a modification of the fascicular or bundled root.

PLATE VII.

ROOTS continued.

Fig.

Fig.

1

- 16. Radix dentata, a root whose knobs resemble teeth; a species of the granulated root, and exemplified in primula.
- 17. palmata, a hand-shaped root, as in the genus orchis.
- repeas, a creeping root; a root which extends in a horizontal direction, and sends forth radicles at certain intervals, as in the couch-grass.
- 19. Bulbs produced in the angle formed by the leaf and branch, as in *ranunculus ficaria*, or pilewort.
- 20. Roots sent forth from the midrib of the leaf, as in cuckoo-flower, (cardamine.)
- 21. Roots produced from the joints of the stalk, as in potentilla reptans.

PARTS OF FRUCTIFICATION.

« CALIX.

- 1, Perianthium, the flower-cup properly so called.
- 2. Amentum, a catkin.
- 3. Spatha, a sheath ; as in narcissus.
- 4. Calix auctus, an increased calix ; a perianth, which
- has a row of leaves distinct from the flower-cup
- 5. surrounding the base, as in *dianthus*.
- 6. Involucrum universale, the universal calix or cover of an umbelliferous flower, which is placed under the large or general umbel.
- partiale, the partial calix or cover of an umbelliferous flower, which is placed under the smaller or partial umbel.
 - 8. Calyptra, the calix of the mosses.
 - 9. Volva, the calix of the fungi, or mushroom tribe.
- 10. Gluma, the husky calix of the grasses.
 - \mathbf{F}

PLATE VIII.

PARTS OF FRUCTIFICATION continued.

Fig.

COROLLA.

(COMPOUND FLOWERS.)

- Fig. 1. Corolla monopetala, a corolla or flower of one petal. 2. ---- hexapetala, a corolla or flower of six petals.
- 3. ____ polypetala serie duplici, a corolla or flower of many petals, in a double series or row.
- 4. ---- ringens, a gaping or grinning flower; a, the upper lip, termed galea or helmet; b, the under lip.
- 5. -- papilionacea, a butterfly-shaped flower.
- 6. Exhibits the several parts of a papilionaceous flower : a, representing the vexillum, or banner;
 - bb the alæ, or wings;
 - c, the carina, or keel;
 - d, the stamina.
- 7. Corolla personata, a masqued flower, or which re-
- sembles the snout of an animal ;- a, the upper 8
 - lip; b, the under lip.

- 9. Corolla composita flosculis ligulatis, a compound flower with flat, tongue, or strap-shaped florets; the semi-floscular flower of Tournefort.
- 10. Flosculus ligulatus, a flat or tongue-shaped hermaphrodite floret ; the semi-floret of Tournefort.
- 11. Corolla composita radiata, a compound radiated flower, having semi-florets in the radius or circumference, and florets in the disk or centre.
- 12. The ligulated floret of a radiated flower, which wants both the sexual organs.
- 13. Corolla composita flosculis tubulosis, a compound flower with tubular or hollow florets ; the floscular flower of Tournefort.
- 14. Flosculus tubulosus, a tubular or hollow floret; the floret properly so called.

PLATE VIII.

Compound Flowers.

PARTS OF FRUCTIFICATION.

COROLLA continued.

14. Corolla campanulata, a bell-shaped flower.

15. 16. Different modifications of the same.

Fig.

17. Corolla infundibuliformis, a funnel-shaped flower.

18. ----- hypocrateriformis, a salver-shaped flower :

- a, the lumb, (*limbus*) or upper spreading part of the petal;
- b, the tube, (*tubus*) or lower hollow part.
- crucifornis, a cross-shaped flower.
 The petal of a cross-shaped flower, the upper spreading part of which, as of the petals of all polypetalous flowers, is termed (amina, the plate or border; the lower tapering part, unguis, or the claw.
- 21. Corolla rotata, the back or under side of a wheelshaped flower.
- 22. The front or upper surface of a flower of the same description.

γ NECTARIUM.

Fig. 1. The flower of aconite or monk's-hood.

- The horned nectaries of the same, being two fistular nodding bodies, resembling stamina, with an oblique mouth and recurved tail, seated on long awl-shaped footstalks, and completely hid by the upper helmet-shaped petal.
- 3. A bell-shaped nectary, exemplified in narcissus triandrus.
- 4. The glandular nectary of willow (salix.)
- 5. Nigella, fennel flower, or devil-in-a-bush.
- 6. The eight-lipped nectaries of the same.
- 7. Tropacolum, or Indian cress, the nectary of which terminates the calix, and resembles a cock's spur.

INTRODUCTION.

PLATE X.

PARTS OF FRÜCTIFICATION continued.

SEXUAL.ORGANS.

Fig.

- 1. The germen or seed-bud of poppy, crowned with its flat, radiated, and target-shaped stigma.
- 2. Exhibits the different parts of a pistillum, viz. stigma, style, and germen.
- 3. Another illustration of the same.
- 4. Pistillum of nis.
- A pistillum with a three-cornered stigma, germen, and no style.
- 6. Pistillum of Oenothera, or tree-primrose :
 - a, the quadrifid stigma.
 - b, the style.
 - c, the germen.
- 7. Oenothera:
 - a, the pistillum.
 - b, the stamina.
 - c, the petals.
 - d, the upper spreading part of the calix.
 - e, the tube, or long cylindrical lower part.
 - f, the germen.
- 8. The parts of a stamen or male organ of fecundation, in which,
 - a represents the anther,
 - b the filament,
 - č the pollen or fertilizing dust.

NECTARIUM resumed.

- 8. Represent the singular nectaries of parnassia.
- 10. Passion-flower with its nectary, termed by Linneus a triple crown.
- 11. The nectary of crown imperial, being a *fovea* or pit in the base of each petal.
- 12. The five horned nectaries of columbine, as connected with the flower.
- 13. One of the horned nectaries of columbine detached from the flower.
- 14. The fringed or bearded nectarium in iris.

MODES OF FLOWERING.

- 1. VERTICILLUS, a whirl or whorl.
- 2. FASCICULUS, a bundle or bunch.
- 3. SPICA, a mode of close inflorescence resembling a spike or ear of wheat, rye, or barley.
- 4. RACEMUS, a cluster; as of currants, grapes, &c.
- PANICULA, a panicle; a mode of loose inflorescence resembling that of oats, and some other grasses.

•

Modes of Flowering.

Modes of Flowering continued.

PLATE XI.

MODES OF FLOWERING continued.

Fig.

- 6. THYRSUS, a panicle contracted into an oval form.
- 7. (CYMA, a cyme; a mode of inflorescence which differs from an umbel, in having the partial
- 8.7 footstalks placed without any regular order.
- 9. CORYMBUS, a mode of flowering, which, like the preceding, resembles an umbel in its general appearance, but may easily be distinguished by the unequal length of the footstalks, which do not, as in the umbel, proceed from the same centre, but are produced from different parts on both sides of the stalk.
- 10. CAPITULUM, a little head.

Fig.

PARTS OF FRUCTIFICATION resumed.

PERICARPIUM, OR SEED-VESSEL.

- 1. A Capsule, with an undivided cavity or single cell.
- 2. _____ with two cells. 3. _____ with three cells.
- 4. _____ with four cells.
- 5. ----- with six cells.

- 6. A capsule with many cells.
- 7. That species of pod termed legumen, in which the seeds are fastened along one suture only.
- 8. Folliculus, a species of dry seed-vessel, which opens longitudinally on one side from bottom to top, and has the seeds loose within it.
- 9. Represents that pulpy kind of pericarpium termed pomum, with its inclosed capsule, having five cells, in which are contained the seeds.
- 10. Drupa, a pulpy seed-vessel of the cherry kind, containing a nut or stone.
- 11. The section of a drupa, exhibiting the pulpy part and the stone.
- 12. A nut, or seed covered with a shell.
- 13. Strobilus, a cone.
- 14. Bacca, a pulpy pericarp without valves, inclosing naked seeds.
- 15. The transverse section of a bacca, to exhibit the disposition of the seeds within the pulp.
- (That species of pod ternied siliqua, in which the 16.
- seeds are fastened to both sutures or joinings 17.
 - of the valves alternately.

THE ORDERS OR SECONDARY DIVISIONS OF THE SEXUAL SYSTEM.

Fig.

- 1. The Order monogynia, containing hermaphrodite flowers with one pistillum or female organ.
- 2. Digunia, hermaphrodite flowers with two pistilla; -a, the pistilla detached from the flower.
- 3. Trigunia, hermaphrodite flowers with three pistilla ;--a, the pistilla separated.
- 4. Tetragynia, hermaphrodite flowers with four pistilla; -a, the pistilla separated.
- 5. Pentagynia, hermaphrodite flowers with five pistilla; -a, the pistilla separated.
- 6. Hexagynia, hermaphrodite flowers with six pistilla;a, the pistilla separated from the flower.
- 7. Heptagynia, hermaphrodite flowers with seven pistilla; -a, the pistilla detached from the flower.
- 8. Decagynia, hermaphrodite flowers with ten pistilla ;a, the pistilla separated.
- 9. Dodecagynia, hermaphrodite flowers with twelve female organs.
- 10. Polygynia, hermaphrodite flowers containing an indefinite number of pistilla, or female organs.

- 11. Gymnospermia, the name of the first order in the class didynamia, in which a represents a longitudinal section of the flower, to display the four naked seeds in the bottom of the calix.
- 12. Angiospermia, the name of the second order in the class didynamia, containing such hermaphrodite flowers with four stamina, two longer than the others, as have their seeds contained in a vessel ;--a, the pericarp, or vessel.
- 13. Siliculosa, the first order in the class tetradynamia. containing such flowers possessed of the classical character, as have their seeds contained in a short round pod ;-a, the silicula, or pod divided to shew the seeds.
- 14. Siliquosa, the second order in the class tetradunamia. containing such plants possessed of the classical character, as have their seeds contained in a siliqua or long slender pod, to each suture of which they are alternately attached ;-a, the siliqua.
- 15. Polygamia Æqualis, the first order in the class syngenesia;-a, a floret separated from the aggregate.
- 16. - superflua, the second order in the class syngenesia :- a represents a female floret in the circumference or ray; b, an hermaphrodite floret in the centre or disk.
- 17. -- frustranea, the third order in the class syngenesia.
- 18. - necessaria, the fourth order in the class syngenesia.
- 19. -- segregata, the fifth order in the class syngenesia.

a, a floret with its proper flower-cup detached from the aggregate.

- 20. Monogamia, the sixth order in the class syngenesia; a, representing a section of the flower, to exhibit the union of the stamina by the anthera.
- 21. (Triacia, the third order in the class polygamia, in
- which hermaphrodite flowers are intermingled with 22
- male or female flowers, or both, on one, two, or 23.
- three plants.
- 24. Filices, ferns, the first order, 25. Musci, mosses, the second order,
- 26 Alga, sea-weed, the third order,
- 27 Fungi, mushrooms, the fourth order, -
- in the class
- Cryptogamia.

Que due autoria francese	Channel. Remain stemp hearings tolly turned unside down
Quadrangularis, Iour-cornered.	Resuprational like not work
Quadrituentarias, jour-toomed.	Retrofractive broken back
Quadrilohum, four-lobed	Retrorsim serratum inversely serrated.
Quadriloculare, four-celled.	Retrorsum sinuatum, crookedly bent back.
Quadripartitum, with four divisions.	Retusum, bluntly notched at the end, and sometimes merely
Quadrivalve, four-valved.	blunt,
	5

5

32 -

Revolutus, rolled back.

Rhombeus, diamond-shaped.

Rhombidcous, rhomboidal; nearly diamond-shaped, but broader one way than the other.

Rigid, (rigidus) stiff, not easily bent.

Rimosus, full of cracks.

Ring, (annulus.)

Ringens, gaping.

- Rising upwards, differs from ascending, in first inclining downwards, and then rising upwards.
- Rod-shaped, (virgatus) having many slender and nearly straight parallel branches or shoots.
- Rolled back, (revolutus) with respect to the leaf in general, means rolled downwards like the leaves of sweetwilliam.
- Root. See Radix.
- Root-leaves, (radicalia) the leaves which proceed immediately from the root, without the intervention of a stcm.
- Rostellum, the scaly part of the corculum, or embryo of the seed, which shoots downward into the soil, and becomes the root.
- Rostratum, having a bill.

Rostrum, a bill or beak.

Rotula, wheel-shaped (blossom.)

Rough, asper.

Round. See Globular.

Round, (orbicularis) round and flat.

- Ruffle, or Ring; the part of the curtain of an agaric, which adheres to the stem after the outer part of it has vanished. Rugasum, wrinkled.
- Rumer, (flagellum) a barren twig or shoot, lying upon the ground, as in the garden strawberry, and stone bramble: they are sometimes called wires.

Runcinatum, notched.

Rundle. See Umbella.

Rundlet. See Umbellula.

Running, along the stem. Sce Decurrent.

s.

Saggittarum, arrow-shaped.

- Salver-shaped, (hypocrateriformis) the shape of a blossom of one petal, the lower part of which is tubular, the upper flat and expanded; as in the blossom of the periwinkle.
- Sapor, taste; which is too uncertain to be of any utility in discriminating plants.

Sarmentosus, having runners.

- Saucer, (scutellum) like a china saucer; a circular and concave fructification of some of the lichens.
- Scaber, rough like a file.

Scabridæ, plants with rough leaves.

Scabrities, roughness.

Scaly, (squamosus) like the skin of a fish.

Scandens, climbing.

Scape, See Scapens.

Scapus, stalk; such as supports the flower, but not the leaves of a plant, and rises immediately from the root.

Scariosus, skinny.

Scarred, (cicatrasatus) marked with scars, where the leaves have fallen off.

Scolloped, (crenatus) as the leaves of bird's-eye and gill.

Scored, (striatus) marked with superficial parallel lines, as the cup of a pink.

Scrobiforme, like fine saw-dust.

Scrotiforme, purse-shaped.

- Sourfy, (squarrosus) applied to a cnp in compound flowers, the scales of which are bent ontwards at the end, so as to give the whole a rongh ragged appearance.
 - 3.

Scutellum, a saucer.

- Scymetar-shaped leaf, (acinaciforme) a long fleshy leaf, thick and straight at one edge, thin and arched at the other.
- Scyphifer, glass-shaped, as the fructification of some of the lichens.
- Sea-green. See Glaucous.
- Scam, or suture, the line formed by the union of the valves of a seed-vessel.
- Secundus, pointing one way.
- Securiformis, axe-shaped.
- Seed, see Semen ; a decidnous part of a vegetable, containing the rudiments of a new plant.
- Seed-bud. See Germen.
- Seed-coat, (axillus) the proper coat of a seed which falls off spontaneously.
- Seed-cover, (calyculus) the real cover of the seed.
- Seed-lobes, (cotyledones) the perishable parts of a seed, designed to afford nourishment to the young plant when it first begins to expand.
- Seed vessel. Sec Pericarpium.
- Segment, (lacinium) the small parts of a leaf, cup, or petal, included between the incisions.
- Semen, seed; the essence of the fruit of every vegetable, containing the rudiments of a new vegetable, and fertilized by the sprinkling of the male dust.
- Semi-cylindrical, (semi-teres :) if the trunk of a tree was sawn lengthwise through the middle, each part would be semicylindrical.
- Seminal leaves, those which rise immediately from a seed, or rather from the seed-lobes.
- Scmi-orbiculatum, shaped like half a globe.
- Semi-sagitta, shaped like half the head of an arrow.
- Semi-teres. See Semi-cylindrical.
- Semper-virens, evergreen.
- Senis, (foliis) growing in sixes.
- Separate. See Monœeia.
- Sericeus, silky.
- Serpentine, (repandus) the edge of some leaves is formed like a serpentine line, without any angles or corners.
- Serrated, (serratus) like the teeth of a common saw.
- Serrulated, (serrulatum) very minutely serrated.
- Sessilis, sitting.
- Setaceous, bristle-shaped.
- Seta, bristles.
- Setosus, bristly, or set with bristles.
- Scrangulare, six-sided or cornered.
- Sex-fidus, six-clefted.
- Sex-loculare, six-celled.
- Shaft. See Style
- Sheath. See Spatha.
- Sheathed, fruit-stalk. See Spadix.
- Sheath-scale, a membrane found at the top of the sheaths, which surround the stem of the grasses, just where the sheath ends, and the proper leaf begins.
- Sheathing, (vaginans) leaves; when the base of a leaf infolds the stem, as in most of the grasses.
- Shedding. See Caducous.
- Shell. See Legumen.
- Shoot, (surculus) the branch of a moss.
- Short, (abbreviatus :) a cup is said to be short, when it is shorter than the tube of the blossom.
- Shrirelling, (marcescens) fading and withcred, but not falling off.
- Shrubby, (fruticosus) somewhat woody and perennial, as the stems of the rose.
- Silicula, a broad and short pod or pouch.

IN'	TRO	DD	UC'	TI	ON.

protruded from the wood of the plant, and therefore of a stronger and harder nature than prickles, which are only detached portions of the bark. Strictus, stiff and straight,

Strigæ, strong spear-shaped bristles or thorns.

Strigosum, furnished with strigæ.

Strings, fibres. See Filamentum.

Strobiliformis spica, a cone-shaped spike.

Strobilus, a cone; a species of seed-vessel, composed of woody scales, which are placed against one another, and split only at top, being fixed below to an axis, which occupies the centre of the cone.

Style, or shaft. See Stylus.

Stylus, the style; the slender part of the pistillum, or female organ, resembling a pillar, and corresponding to the vagina in animals, which stands upon the seed-bud, and elevates the stirma.

Subdivisus, subdivided.

Submersus, under water.

Subovate, subovatum.

Subovatum, nearly egg-shaped.

Subramosus, a little branched.

Subrotundus, nearly globular.

Subulatus, awl-shaped.

Succulentum, succulent, juicy.

Succus, sap ; the juices of plants.

- Suckers, (stolones) shoots which rise from the root, spread along the ground, and then take root themselves, as in the sweet-violet.
- Suffructicosus, somewhat woody, nearly shrubby, as sage and lavender.

Sulcatus, furrowed.

Summit, (stigma) the upper part of the Pistillum, which see. Superficies, the surface.

Superflua, superfluous.

Superior (superus) cup or blossom, when the cup or blossom is situated above the germen, it is said to be superior; as in the honevsuckle.

Superus, superior, above.

Supinus, the upper surface.

Supra-decompositus, more than doubly compound.

Supra-foliaceous, placed above the leaf.

Surculus, a shoot; the branch of a moss.

Sutura, a seam.

- Sword-shaped, (ensiforme) as the leaves of the iris, or fleurde-lis.
- Spragenesia, from evo, together; and yearse; generation; the name of the injectent totas in the Sexual System of Linneus; it consists of plants in which the anthere or mole organs of generation are united into a cylinder, the filaments by which they are supported remaining separate and distinct.

т.

Tail, (cauda) a sort of slender-pointed appendage to some seeds.

Taper leaf, (acuminatum) gradually tapering to a point.

- Target, (pelta) a kind of fructification on the leaves of some of the lichens, which is circular, and a little convex.
- Target-shaped, (peltatum) applied to a leaf having its leafstalk fixed, not at the edges, but nearly in its centre.

Target-shaped summit, one that is circular and flat.

Tendril. See Cirrus.

Tenuis, thin, slender.

Teres, columnar.

Tcretusculus, roundish.

Tergeminum, (leaf) doubly twin fork.

Terminalis, terminating.

Terminating, (terminalis) opposed to lateral; standing at the end of the stem or branches, as the fruit-stalks of borrage.

Ternatis, leaves growing three together from the same point. Ternis, by threes; three in a place.

Tessclatum, chequered.

- Tetradynamia, from τισσποις, four; and δυπαμις, power: four powers; the name of the fifteenth class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, having six stamina, four of which are longer than the rest.
- Tetragginia, from resources, four; and yow, a woman; the name of an order or secondary division in the fourth, fifth, sith, eighth, and thirteenth classes, of the Linnean system; it consists of plants, which, to the classic character, whatever it be, add the circumstance of having four styles or female organs, as its name imports.

Tetragonous, four-cornered

Tetrandria, from ressarce, four; and dang, a husband: the name of the fourth class in Linneus's Sexual System, consisting of plants whose flowers are hermaphrodite, and have four stamina or male organs of equal length.

Tetrapetala, four-petalled.

Tetraphyllous, four-leaved.

Tetrasperma, four-seeded.

Thalamus. See Receptaculum.

Thorn. See Spina.

- Thread. See Filamentum.
- Thread-shaped, (filiformis) of the same thickness from top to bottom, like a piece of packthread; like the leaves of fennel, the style of crocus, or of honeysuckle.
- Three edged, (trigonus) or three-cornered; a stem having three corners or angles, and the sides not flat.
- Three-fibred, (trinervatus) having three veins or nerves, running from the base to the end of a leaf, without branching off.
- Three-lobed, (trilobatum.)
- Thronging, (confluentia) assembled in close parcels, with intervening naked places.
- Thyrsus, a cluster; according to Linneus, is a panicle contracted into an oval or egg-shaped form.
- Tiled, (inbricatus) one leaf or scale partly covering another, like the tiles of a house; as the cup of dandelion or burdock.

Tip. See Anthera.

Tomentosus, cottony,

- Tomentum, short wool; a species of hoary or downy pubescence, which covers the surface of many plants.
- Tongue-shaped, (lingulatum) applied to express a thick fleshy leaf, somewhat in the shape of a tongue.
- Toothed, (dentatus) when the edges of a leaf are set with little teeth, as in primrose.
- Tooth-servated, (dentato-servatum) when the edge of a leaf is set with servated teeth.

Top-shaped, (turbinatus) nearly conical.

Torosus, protuberating.

Torulosus, a little swelling out.

Tortilis, twisting.

Trailing stems, (procumbens) lying along upon the ground, and not sending out roots, as common speedwell.

Transversum, crosswise.

Trapeziformc, the shape of a flat leaf, having four unequal sides.

Trebly-compound. See Triply compound.

- Triangular lcaf, stem, or stalk, having three sides, and three augles or corners.
- Triandria, from $\tau_{\xi^{\text{tright}}}$, three; and $\&\sigma_{\theta_{\xi}}$, a husband: the name of the third class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, with three stamina or male organs.

GENERAL RULES

FOR THE

GATHERING AND PRESERVING HERBS.

ROOTS, BARKS, SEEDS, AND FLOWERS;

Together with the Methods of Making such Preparations from them, as may best retain their Virtues, or be most useful to be kept in Families. -----

THE intention of the author is, to inform those who live in | If opium may be dangerous in an unexperienced hand, the the country, and are desirous of being useful to their families and friends, or charitable to the poor in relieving their disorders, of the virtues of those plants which grow wild about them; that they may be able to supply the necessary assistance, in places where apothecaries are not at hand, without putting themselves to the expense of costly medicines, when the common herbs, that may be had for gathering, will answer the same purpose. However, as there are cases wherein more help may be obtained from foreign drugs, than from any thing produced at home, an account of those roots, barks, seeds, gums, and other vegetable productions, kept by the druggists and apothecaries, is added, together with their virtues, and those of the several trecs and plants from which they are obtained.

The plants are alphabetically arranged, according to their English names, that they may be the more readily found. With regard to the virtues of plants, too many have been attributed to most of them, but here their real virtues only, as ascertained by the experience of the best judges, are introduced, and placed in the most conspicuous light.

Nature has, in this country, as well as in all others, provided, in the herbs of its own growth, the remedies for the several diseases to which it is most subject; and although the addition of what is brought from abroad, should not be supposed superfluous, there is no occasion that it should cause the other to be neglected. This neglect has been the consequence of the too great respect shewn to them; which, with the present universal use of chemical preparations, has almost driven the whole of Galenical medicine out of our minds.

To restore this more safe, more gentle, and often more efficacious part of medicine to its natural credit, has been one great intent in writing this treatise; and it is the more necessary for the service of those, who are intended most to be directed in this matter, since this is much less dangerous than the other; for in most instances it is hard to say that this is dangerous at all.

The apothecaries are apt, in their unfeeling mockery, to say, that they are obliged to the good persons who give medicines to their sick neighbours, for a great deal of their business; for out of little disorders they make great ones. This may be the case where their shops supply the means; for chemical medicines, and some of the drugs brought from abroad, are not to be trusted with those who have not great experience; but there will be no danger of this kind, when the fields afford the supply. This is the medicine of nature, and as it is more efficacious in most cases, it is more safe in all. the fruits; in others, the seeds; in some, the roots; and of

person who will give in its place a syrup of the wild lettuce, (a plant not known in common practice at this time, but recommended from experience in this treatise) will find that it will ease pain, and that it will cause sleep, in the manner of that foreign drug, but will never find any ill consequences from it: and the same might be said in many other instances.

As the descriptions in this work very readily distinguish what are the real plants that should be used, the great care will remain, in what manner to gather and preserve, and in what manner to give them; it will be useful to add directions upon those heads. As to the former, it should be perfectly understood, because a great deal depends upon it; the latter cannot easily be mistaken.

Having displaced the drugs brought from abroad in a great measure from charitable practice, every person who has the spirit of true benevolence, should keep a kind of druggist's shop, which should be supplied from the neighbouring fields, and from their own gardens. There is no reason the drugs should not be as well preserved, and as carefully laid up, as if the product of a different climate, though the use of the fresh plants will in general be best when they can be had,

As there are some which will not retain their virtues in a dried state, and can be met with only during a small part of the year; it will be proper to add the best methods of preserving these in some way, according to the apothecaries' manner; with the method of making the preparations from them for ready service, which will be sufficient to lead to the perfect use of the medicines of our own growth; and it will be found upon experience, that those who sufficiently know how to make a proper use of these, need seldom have recourse to any others.

***** Concerning the Methods of Collecting and Preserving Plants, and Parts of them, for Use.

THE virtues of different plants residing principally in certain parts of them, and those differing according to the nature of the herb, these several parts are to be selected, and the rest left; and these are in some to be used fresh, and just gathered; in others, either necessity, or the natural preference, make it proper to dry and preserve them.

In some only the leaves are to be used ; in others, the whole plant cut from the root ; in others, the flowers only; in others, some trees, the barks; some, the woods; and only the excrescences of others: while some vegetables are to be used entire, whether fresh gathered, or dried and preserved. Of all these, instances will be given in great number in the following sheets, and the matter will be specified under each article, as the part of the plant to be used will always be maned; and it will be added whether it he best fresh, or best or necessarily dried or otherwise preserved; but it will be proper in this place to enter into the full examination of this matter, to save unnecessary repetitions under the several particular articles.

The whole of most plants, native of our country, dies off in winter, except the root; and in many that perishes also, leaving the species to be renewed from the fallen seeds. When the whole plant dies, the root is seldom of any virtue; but when the root remains many years, and sends up new shoots in the spring, it commonly has great virtue. This may be a general rule : for there is very little to be expected in the roots of annual plants; their seeds, for the most part, contain their greatest virtues.

In others, the root lives through the winter, and there arise from it large leaves in the spring, before the stalk appears. These are to be distinguished from those which afterwards grow on the stalk, for they are more jnicy, and for many purposes much better. In the same manner, some plants, from their seeds dropped in autumn, produce a root and leaves which stand all the winter, and the stalk does not rise till the succeeding spring. These are of the nature of those leaves, which rise from the root of other plants before the stalks in spring; and are in the same manner to be distinguished from those which root of other plants before the stalks in under whet the stalks at the starks; they have the full nourishment from the root, whereas the others are starved by the growth of the stalk and its branches, and the preparations made by nature for the flowers and seeds; which are the plant.

For this reason, when the leaves of any plant are said to be the part fittest for use, they are not to be taken from the stalk, but these large ones growing from the root are to be chosen; and these where there is no stalk, if that can be; for then only they are fallest of juice, and have their complete virtue; the stalk running away with the nourishment from them. This is so much done in some plants, that although the leaves growing from the root were very vigorous before the stalk grew up, they die and wither as it rises.

When the juice of the leaves of any plant is required, these are the leaves from which it is to be pressed : when they are ordered in decoction, notice is always taken in this work, whether they be best fresh or dried; if fresh, they should be just gathered for the occasion; they should be cut up close from the root, and only shook clean, not washed; for in many, that carries off a part of the virtue : they are to be cut into the pot. If they are to be dried, the same caution is to be used; and they are best dried, by spreading them upon the floor of the room, with the windows open, often turning them. When thoroughly dried, they should be put up in a drawer, pressing them close down, and covered with paper. When the entire plant is to be used except the root, care is to be taken, that it be gathered at a proper season. Noture in the whole growth of plants, tends to the production of their flowers and seeds, but when they are ripe, the rest begins to decay, having done its duty; so that the time when the entire plant is in its most full perfection, is when it is in the bud; when the heads are formed for flowering, but not a single flower has yet disclosed itself: this is the cxact time.

When herbs are to be used fresh, it is best not to take them entire, but only to cut off the tops; three or four inches long,

if for infusion, and if for other purposes, less: if they are to be beaten up with sugar, they should be only an inch, or less; just as far as they are fresh and tender. The tops of the plant thus gathered, are always preferable to the whole plant for immediate use.

When the entire herb is to be dried, the season for gathering is to be as just described, when the flowers are budding; and the time of the day must be when the morning dew is dried away. This is a very material circumstance, for if they be eut we with the dew, herbs will not dry well, and if they be eut at noon-day, when the sun has made the leaves flag, they will not have their full power.

Care must also be taken to cut them in a dry day; for the wet of rain will do as much harm as that of dew.

When the herbs are thus gathered, they are to be looked over, the decayed leaves to picked off, and the dead ends of the stalks cut away: they are then to be tied up in small bunches, (the smaller the better), and hung upon lines drawn across a room, where the windows and doors are to be kapt open in good weather; the bunches are to be half a foot asunder, and they are to hang ill perfectly dry. They are then to be taken softly down, without shaking off the buds of the dowers, and haid evenly in a drawer, pressing them dowr, and covering them with paper. They are thus ready for infusions and decoctions, and are better for distillation than when fresh.

The flowers of plants are principally used fresh, though several particular kinds retain their virtue very well dried; they are on these different occasions to be treated differently.

Lavender flowers, and those of steelas, keep very verl; they are therefore to be preserved dry; the lavender flowers are to be stripped off the stalks, husk and all together, and spread upon the floor of a room to dry. The steechas flowers are to be preserved in the whole head; this is to be cut off from the top of the stalk, and dried in the same manner; when dry, they are to be kept as the herbs.

When rosemary flowers are dried, they are generally taken with some of the leaves about them, and thus is very right, for the leaves retain more virtue than the flowers. Some dry borage, bugloss, and cowslips, but they retain very little virtue in that condition. Rose-basis are to be dried, and to this purpose, their white heads are to be cut off; and the fullblown flowers may be preserved in the same manner. The red rose is always meant, when we speak of the dried flowers.

For the rest of the flowers used in medicine, they are best fresh; but as they remain only a small part of the year in that state, the method is to preserve them in the form of syraps and conserves. Such as the syrap of cloves and poppies, the conserves of cowslips, and the like. Of these, a short general account shall be subjoined, that nothing may be wanting to make this work as useful for families as the nature of it will admit.

Among the fruits of plants, several are to be used fresh, as the hip for conserve, and the quitce, mulberry, and black currant; from the juices of which syraps are made. As to those which are to be dried, as the juinper berries; the bay berries, and the like, they are only to be gathered when just ripening, not when quite mellow, and spread upon a table or floor, often turning them till they are dry. But of these we use very few of our own growth; most of the fruits used in medicine are brought from abroad, and must be purchased of the druggist or apothecary.

With respect to the seeds and plants, it is otherwise : many of them are of our own growth, and nothing is so casy as to preserve them. These are all to be used dry; but nature has in a manner dried them to our hands: for they are not to be gathered till perfectly injet, and them they need very little farther care. They are only to be spread for three or four days upon a clean floor, where the air has free passage, but where the sun does not come; and they are then ready to be put up.

The seeds used in medicine, may be referred to three general kinds. They either grow in naked heads or umbels, in fennel, parsley, and the like; or in pods, as in mustard and resesse; or in large fleshy fruits, as an melon and cucumber. In each case they must be left mpon the plant till perfectly ripe; then they are only to be shock from the heads we what upon the floor, when they are thoroughly ripe, will discuss the each other manog the we matter, separated upon a table, in a dry place, where they nust be often turned aroutbed as they grow dry, that in the end they may be perfectly and lean.

Among the roots, a great many are to be used fresh, but a greater number are best dried. The black and white briony, the arum, and some others, lose all their virtues in drying; and many-that retain some, yet lose the greater part of it; there are others which are excellent both fresh and dried, as the marshmallow and some more.

As to the few which lose their virtue entirely in drying, it will be best to keep some of them always in the garden, that they may be taken up as they are wanted. The others are to be managed according to their several natures, and they do a great deal lowards furnishing the draugsit's shop, which should be filled with medicines, the produce of our own country.

The best season for gathering roots for drying, is in the carly part of the spring; what matter does for plants when they are just going to flower, she does for roots when the leaves are just going to bud; the juices are rich, fresh, and full, and the virne is strongest in them at this season, therefoe they are to be then taken up.

In the end of February and the beginning of March, the ground should be searched for the first budding of leaves, and the roots taken up. They are to be wiped clean, not washed; and, according to their several natures, prepared for drving.

Some are full of a mucilaginous juice, as marshmallow, and above all other roots, the squill, and in some degree many others of that kind; these must be cut into thin sitese crosswise, and they will dry best if laid upon a lain-cloth stretched across a frame. They must be frequently turned, and be very thoroughly dry before they are put up, else they will become modely; but, rightly prepared, they keep very well.

Other roots have juices that evaporate more easily. These have the virtue either throughout the whole substance, or only in the outer part, and they are to be prepared accordingly. When roots are of one uniform substance, they generally have the virtue equal, or nearly so, in all parts. These should be split open lengthwise, first cutting off the head, and the little end; or if considerably thick, they may be quartered; when this is done, they are to be strang upon a line, by drawing a needle, threaded with a small twine, through their thickest part, and they are then to be hung up to dry in the manner of the herbs; the line being stretched across a room, the doors and windows of which are to be kept open in good weather.

When roots consist of a sort of thick rind, or fleshy substance within the rind, and a hard sticky part in the middle,

this fleshy substance under it possesses all the virtues; the hard inner substance having none: in this case, the root is to be split longwise as before, and the hard woody part is to be taken out and thrown away: the rest is to be strung as before described, and dried in the same manner.

When roots consist of fibres, these arc generally connected to a head, if it be ever so small, and the best method is to split this in two, and then string up the separate parts for drying.

It is needless to enumerate the examples of the several kinds of roots here; they follow in their places: but if charitable people would, on first looking over this book to see what are most useful, order their gardeness to take out of his ground, and to seek in the fields the several roots there mentioned, and see them dried and preserved according to these directions, they would be possessed of a set of drugs of a new kind indeed; but they would save the price of many brought from other countries, and might be used with less dauger.

The barks of trees make but a small part of the English drugs, and most of them are best fresh; but such as will preserve and retain their virtues dried, are very easily prepared that way; noulling more is required than to cut them into moderate pieces, and string them up in the same manare asthe roots. When theyare dry, they are to be put up as the others, and they will keep ever so long; but in all this time they are for the most part losing their virtues.

It may be prindent to preserve drugs brought from abroad a great while because of their price; but as these cost only the trouble of gathering and preserving them, I would advise that the whole shop be renewed every year; what is left of the old parcel of every kind, being thrown away as the fresh one is collected in its season.

The place for keeping these should be a dry room, neither damp nor hot; and they should now and then be looked at, to see that they are in order; that they do not grow monldy, or smell musty through damp, or become lighter, and lose their virtue by too much heat.

It may be proper just to mention, that the woods which we use are best kept in the block, and shaved off as they are wanted; for being kept in shavings, they lose their virtue; and in the same manner as to the foreign woods, it is best to keep a block of sassafras, and of lignum vitæ in the house, and cut them as they are wanted.

As to the excrescences, such as galls of the oak, and the burr upon the wild briar, they are naturally so dry, that they only require to be exposed a few days to the air upon a table, and then they may be put up with safety, and will keep a long time.

Lastly, the fungues, such as Jew's-cars, and the like, are to be gathered when they are full grown, and strang upon a line, they may dry leismely, or clse they spoil: they must be very well dried before they are put up, clse they will grow mouldy in damp weather; and if once that happen, no art can recover their virtues.

Thus may a druggist's shop of a new kind be filled, and it will consist of as many articles as those which receive their functure from abroad; and there will be this advantage in laving every thing ready; that when custom has made the virtues of the several things familiar, any person may do from his jadgment as the physician in his prescription—mix several things of like virtue together, and not depend upon the virtues of any one singly, when the case requires something of power. These roots and barks powdered, will make as handsome and as efficacions boluses and mixtures as any furnished by the apotherary.

40

Concerning the various Methods of preparing Simples for present Use.

THERE is no form of medicines sent from the apothecary, which may not be prepared from the chesh of our own growth, in the same manner as from foreign drugs. Electuaries may be made with the powders of these larks, roots, and seeds, will conserves of flowers, and of the tops of fresh herbs; and syrups, made from their juices and infusions; the manner of making which is very simple, and shall be subjoined to this clapter, that all may be understood before we enter on the book itself; and in the same manner their boluses may be made, which are only some of these powders mixed up with these, syrups being added : and the inclures of the roots and barks; the method of making which shall be also annexed in a familiar manner.

But beside these several forms of giving them, there are others much more simple, easy, and ready, and these are genetally more efficacious. We shall arrange these under three kinds; juices, infusions, and decoctions. These are the forms of giving the medicines most frequently mentioned in the course of the work, and there is less trouble in them than in the others. They are not indeed contrived for show, nor would they answer the purpose of the apothecary, for his profits would be small upon them; but when the desigu is only to do good, they are most to be chosen of any.

Juices are to be expressed from leaves or roots; and in order to this, they are to be first beaten in a mortar. There is no form whatever in which herbs have so much effect, and yet this is in a manner unknown in the common practice of physic.

These are to be obtained in some plants from the entire herb, as in watercresses, brook-line, and others that have juicy stalks; in others the leaves are to be used, as in nettles, and the like, where the stalk is dry, and yields nothing, but is troublesome in the preparation. When the juice of a root is to be had, it must be fresh taken up, and thoroughly besten. A marble mortar and wooden pestle serve best for this purpose, for any thing of metal is improper: many plants would take a tincture from it, and the juice wold be so impregnated with it, as to become a different medicine, and probably very.

As these juices have sometimes an ill taste, and as some of them are apt to be cold upon the stomach, or otherwise to disagree with it, there are methods to be used to make them sit better upon it; and in some cases these increase their virtues.

When the thick juice, fresh drawn, is too coarse for the person's stomach, it may be suffered to settle and grow clear: a little sugar may be added also in beating the herb, and in many cases, as in those juices given for the scurry, the juice of a Seville orange may be added, which will greatly improve the flavoor.

To the roots it is often proper to add a little white wise in the bruising, and they will operate the better for it. Thus, for instance, the juice of the flower-de-luce root will not stay upon many stomachs alone: but with a little white wine added in the bruising, all becomes easy, and its effects are not the less for the addition. The same addition may be made to some of the colder herbs; and if a little sugar, and, upon occasion, a few grains of powdered ginger, be added, there will be scarce any fear of the medicine disagreeing with the stomach, and its effects will be the same as if it had been bruised and pressed alone.

Infusions are naturally to be mentioned after the juices, for they are in many cases used to supply their place. Juices can only be obtained from fresh plants, and there are times of the year when the plants are not to be had in that state. Recourse is then to be had to the shop, instead of the field ; the plant whose juice cannot be had, is there to be found dried and preserved; and if that has been done according to the preceding directions, it retains a great part of its virtues : in this case it is to be cut to pieces, and hot water being poured upon it, extracts so much of its qualities, as to stand in the place of the other. Often, indeed, the virtues are the same: in some plants they are greatest from the infusion ; but then some others lose so much in drying, that an infusion scarce has any thing. But it is not only as a help in the place of the other, that this preparation is to be used, for infusions are very proper from many fresh herbs; and are of great virtue from many dry ones, of which, when fresh, the juice would have been worth little.

Infusions are the fittest forms for those herbs whose qualities are light, and whose virtue is easily extracted : in this case, hot water poured upon them takes up enough of their virtue, and none is lost in the operation; others require to be boiled in the water. From these are thus made what we call decoctions: and as these last would not give their virtues in infusion, so the others would lose it all in the boiling; it would go off with the vapour. We know very well, that the distilled water of any herb is only the vapour of the boiled herb caught by proper vessels, and condensed to water: therefore, whether it be caught or let to fly away, all that virtue must be lost in boiling. It is from this, that some plants are fit for decoctions, and some for infusions. There are some which, if distilled, give no virtue to the water : and those are fit for decoctions, which will retain all their virtue, as bistort, and tormentil roots, and the like. On the contrary, an infusion of mint, or pennyroyal, is of a strong taste, and excellent virtue; whereas a decoction of these herbs is disagreeable, or good for nothing.

There are herbs also, which have so little juice that it would be impossible to get it out; and others, whose virtue lies in the husks and buds, and this would be income of these is the right way of giving them. Thus mother of thyme is a dry little herb, from which it would be hard to get any juice, and when gotten, it would posses very little of its virtue; ; but an infusion of mother of thyme possess it entirely.

Infusions are of two kinds. They are either prepared in quantity, to be drank cold; or they are drank as they are made, in the manner of tea. This last method is the best, but people will not be prevailed upon tod oit, unless the taste of the herb be agreeable; for the flavour is much stronger hot than it is cold.

Infusions in the manner of tea, are to be made just as tea, and drank with a little sugar; the others are to be made in this manner:

A stone jar is to be fitted with a close cover; the herb, whether frish or dried, is to be cut to pieces; and when the jar has been scalded out with hot water, it is to be put in: boiling water is then to be poured upon it, and the top is to be fixed on: it is thus to stand four, five, or six hours, or a whole night, according to the nature of the ingredient, and then to be poured off clear.

It is impossible to direct the quantity in general for these infusions, because much more of some plants is required than of others: for the most part, three quarters of an ounce of a dried plant, or two ounces of the fresh gathered. The best rule is, to suit it to the patient's strength and palate. It is M

intended not to be disagreeable, and to have as much virtue of | hot, pressing them hard, and the liquor set by to cool : when the herb as is necessary : this is only to be known in each kind by trial; and the virtue may be heightened, as well as the flavour mended, by several additions. Of these, sugar and a little white wine are the most familiar, but lemon juice is often very serviceable, as we find in sage tea; and a few drops of oil of vitriol give colour and strength to tincture of roses. Salt of tartar makes many infusions stronger also than they would be, but it gives them a very disagreeable taste. It is therefore fit only for such as are to be taken at one draught, not for such as are to be swallowed in large quantities time after time.

Among the herbs that yield their virtues most commodiously by infusion, may be accounted many of those which are pectoral, and good in coughs, as coltsfoot, ground-ivy, and the like: the light and aromatic, good in nervous disorders, as mother of thyme, balm, and the like : the bitter are also excellent in infusion, but very disagreeable in decoction ; thus boiling water poured upon Roman wormwood, gentian root, and orange peel, makes a very excellent bitter. It need only stand till the liquor is cold, and may be then poured off for use.

It is often proper to add some purging ingredient to this bitter infusion; and a little fresh polypody root excellently answers that purpose, without spoiling the taste of the medicine.

Several of the purging plants also do very well in infusion. as purging flax, and the like ; and the fresh root of polypody alone is a very good one: a little lemon-juice added to the last-named infusion, does no harm; and it takes off what is disagreeable in the taste, in the same manner as it does from an infusion of senna.

Thus we see what a great number of purposes may be answered by infusions, and they are the most familiar of all preparations. Nothing is required, but pouring some boiling water upon the plants fresh or dried, as already directed, and pouring it off again when cold.

Decoctions are contrived to answer the purpose of infusions, upon plants which are of so firm a texture, that they will not easily yield forth their useful parts. In these the ingredients are to be boiled in the water ; as, in the others, the boiling water was to be poured over them. In general, leaves, flowers, and entire plants, whether fresh or dried, are used in infusions; the roots and barks in decoctions.

An earthen pipkin, with a close cover, is the best vessel for preparing these; for many of those medicines which are little suspected of it, will take a tincture from the metal; and it would be as improper to boil them in a copper pan, (as it is too common a custom,) as to beat the herbs and roots in a metal mortar.

Fresh roots are used in decoction, as well as those which are dried ; and the barks and other ingredients in like manner. When the fresh are used, the roots are to be cut into thin slices, and the barks and woods should be shaved down ; as to the leaves and entire plants, they need be cut but slightly. When dry ingredients are used, the roots and barks are best pounded to pieces; and as to the herbs and flowers, little is to be done to them, and in general, they are best added toward the end of the decoction.

It is always best to let the ingredients of a decoction stand in the water cold for twelve hours, before it is set on the fire, and then it should be heated gradually, and afterwards kept boiling gently as long as is necessary : and this is to be proportioned to the nature of the ingredients. Generally a quarter of an hour is sufficient, sometimes much longer is necessary. They are then to be strained off while they are

they are thoroughly cold, they are to be poured off clear from the settlement, for they always become clear as they cool, and sweetened with a little sugar. Frequently also, it is proper to add to them a little white wine, as to the infusions.

Concerning distilled Waters, and other Preparations to be kept in the House.

THAT spirit is best which is called molosses spirit; it is to be bought at a small price at the distillers; and as to the sugar, the most ordinary loaf kind will do for most purposes : where other is necessary, it will be particularly named.

Few families are without an alembic or still; and that will be of material service. With that instrument the simple waters are to be made, with no expense beside the fire : and it will be proper to keep those of the following ingredients.

Mint-water, peppermint-water, and pennyroval-water, are to be made of the dry herbs. Three pounds of each is to be put into the still, with four gallons of water, and two gallons is to be distilled off. Milk-water is to be made thus : a pound aud half of spear-mint, a pound of rue, half a pound of Roman wormwood, and half a pound of angelica leaves, are to be put into the still with five gallons of water, and three gallons are to be distilled off. Common mint-water is good in sicknesses of the stomach, peppermint-water in colics, and pennyroval to promote the menses. Milk-water is good in fevers, and to make juleps. It used to be made with milk, but that answers no purpose. Only one simple water more need be kept, and that for colics; it is best made of Jamaica pepper: a pound of Jamaica pepper is to be put into the still over night, with three gallons of water; and the next morning two gallons of water distilled off.

It has been customary to keep a great many simple waters, but these are all that are necessary or proper. The other herbs are better to be given in infusion and decoction.

As for cordial waters, they are made as the others, only with the addition of spirit. It may be proper to keep the following; and no more are necessary.

1. Cinnamon-water; which is made by putting into the still a pound of cianamon, a gallon of spirit, and a gallon of water, and the next day distilling off a gallon. This is good in sickness at the stomach, and is a fine cordial.

2. Spirituous milk-water; made from a pound of spearmint, half a pound of angelica, and a quarter of a pound of Roman wormwood, all green. To these is to be put a gallon of spirit, and a gallon of water, and a gallon to be distilled off; to which is to be added a pint of vinegar: this is good to promote sweat, and is used instead of treacle-water, being hetter.

3. Strong pennyroyal water; which is used instead of hysteric water in all hysteric cases, and to promote the menses, is made of a pound and half of dry pennyroyal, a gallon of spirit, and six quarts of water, drawing off a gallon.

4. Aniseed water; which is good in the colic, and is made with a pound of aniseed, a pound of angelica seed, and two gallous of spirit, with one gallon of water, distilling off two gallons. No more of these are necessary : but it may be acceptable to add the making of lavender water, spirit of lavender, and Hungary water, which are preparations of the same kind, and very easy.

Lavender water is made from a pound of fresh lavender flowers, and a gallon of molosses spirit, with two quarts of

made of a pound and half of rosemary tops with the flowers, a gallon of spirit, and a gallon of water, distilling off five pints : and to make the spirit of lavender, or palsy drops, mix three pints of lavender water, and one pint of Hungary-water, and add to this half an ounce of cinnamon, the same quantity of nutmegs, and three drams of red saunders-wood ; these are to stand together till the spirit is well coloured.

This is all the family practitioner will need with distilling : a short account, but sufficient.

As for tinctures, which are a great article with the apothecary and chemist, making a great show, and really very useful; I would have several of them kept, and they are as easily made as the waters, nay, more easily. Molosses spirit is all that is necessary for this purpose.

It would be well to keep tinctures of all roots and barks; which are recommended to be dried in the course of this work, for a tincture will contain more or less of the virtue of every one of these, and be often convenient, where the powder or decoction could not be given. It is needless to enumerate these, and one rule of making serves for them all : two ounces of the ingredient is to be cut into thin slices, or bruised in a mortar, and put into a quart of spirit; it is to stand a fortnight in a place a little warm, and be often shook ; at the end of this time, it is to be taken out, strained off, and made to pass through a funnel, lined with whitish brown paper, and put up with the name of the ingredient.

To these tinctures of roots, barks, and seeds, it would be well to add a few made of foreign ingredients. As,

1. The bitter tincture for the stomach, is made of two ounces of gentian, an ounce of dried orange peel, and half an ounce of cardamom seeds, and a quart of spirit : or it may be made in white wine, allowing two quarts.

2. Tincture of castor, good in hysteric complaints; and made with two ounces of castor and a quart of spirit.

3. Tincture of bark, which will cure those who will not take the powder; made of four ounces of bark, and a quart of spirit.

4. Tincture of soot, for fits; made with two ounces of woodsoot, one ounce of assafætida, and a quart of spirit.

5. Tincture of steel, for the stoppage of the menses : made of flowers of iron four ounces, and spirit a quart.

6. Tincture of myrrh ; made of three ounces of myrrh, and a quart of spirit, good for curing the scurvy in the gums.

7. Tincture of rhubarb; made of two ounces of rhubarb. half an ounce of cardamom seeds, and a quarter of an ounce of saffron, with a quart of spirit.

8. Elixir salutis; made of a pound of stoned raisins, a pound of senna, an ounce and half of carraway seeds, and half an ounce of cardamoms, in a gallon of spirit.

9. Elixir of vitriol ; made of six drachms of cinnamon, three drachms of cardamoms, two drachms of long pepper, and the same of ginger; and a quart of spirit: to a pint of this tincture strained clear off, is to be added four ounces of oil of vitriol : this is an excellent stomachic. Lastly, to these it may be well to add the famous Friar's balsam, which is made of three ouuces of benjamin, two ounces of strained storax, one ounce of balsam of Tolu, half an ounce of aloes, and a quart of spirit of wine, such as is burnt under lamps. This spirit may be made by putting a gallon of molosses spirit into the still, and drawing off two quarts, and this will be useful for spirit of wine and camphire, which is made by dissolving an ounce of camphire in a quart of the spirit. Lastly, we are to add what is called the asthmatic elivir, made with flower of benjamin and opium, of each a drachm, camphire two scruples,

water ; five pints are to be distilled off. Hungary-water is one cunce, and a quart of spirit. This is a gentle opiate. and is much better in families than the strong laudanum.

As to the tinctures made with white wine instead of spirit, a few are sufficient. Steel wine is made of a quarter of a pound of filings of iron, and half an ounce of mace, and the same quantity of cinnamon, put into two quarts of Rhenish. Hiera picra is made of half a pound of aloes, two ounces of Winter's bark, and five quarts of white wine. The first is a restorative cordial and strengthener: the latter is sufficiently known as a purge. Laudanum is made of two ounces of opium, a dram of cloves, and a drachm of cinnamon, and a pint of wine. Viper wine is made of two ounces of dried vipers, and two quarts of white wine : and the tincture of ipecacuanha for a vomit, of two ounces of that root, half an ounce of dry orange peel, and a quart of sack. Lastly, what is called elixir proprietatis is made of aloes, myrrh, and saffron, of each an ounce, sal ammoniac six drachms, and salt of tartar eight ounces, in a quart of mountain wine.

These are all the tinctures and wines that need be kept in a family, whose charity is designed to be very extensive; the expense of the whole is a triffe not worth naming, and the trouble scarce any thing. Books are full of directions in particular for every tincture, as if every one were to be made a different way; but the best method is to give a good deal of time, and frequent shaking, and that will stand in the place of heat in most things of this kind; nevertheless, they should stand in a room where a fire is kept while they are making ; and those which require heat, that is, those that take a colour most slowly, are to be placed nearest to it.

Easy as these are, they are by far the most difficult part of the task, the rest is as it were nothing. Conserves, syrups, and ointments will be wanting; but in the same manner one direction will serve for the making the whole assortment of each, and the ingredients will be at hand. As to plaisters in general, they do more harm than good. Surgeons at this time make very little use of them; and in the course of this work, many herbs will be named, the bruised leaves of which are better than all the plaisters in the world.

Conserves should be made of rue, mint, scurvy-grass, woodsorrel, and Roman wormwood. As to the four first, the leaves are to be picked off from the stalks, and beaten up with three times the weight of sugar. The tops of the young shoots of the latter are to be cut off, and they are to be beat up in the same manner. In the course of this work, many plants will be named, the green tops of which contain their virtue, these may all be made into conserves in the same manner, or as many of them added to those here named as shall be thought proper.

Conserves of the flowers of rosemary, mallows, archangel, and lavender, are to be made also in the same manner, and of red rose buds. These last are to be picked from the husk, and the white heels are to be cut off. They are all to be beat up with three times their weight of sugar; and in the same manner may be made conserves of cowslip flowers, and of those of many other plants mentioned in the following pages.

The outer rinds of Seville oranges and lemons, are also to be made into conserves in the same manner, beating them first to a pulp, and then adding the sugar ; and to these must be added the conserve of hips and sloes, which are to be made in a particular manner. The hips are to be gathered when fully ripe, afterwards set by in a cellar till they grow very soft ; then they are to be laid upon the back of a large hair sieve. a dish being put underneath; they are to be broke with the hand or a wooden pestle, and rubbed about till all the soft matter is forced through the hair-cloth, the seeds and skins oil of aniseed forty drops, liquorice root half an ounce, honey only remaining. This soft matter is to be weighed, and to be

powdered.

Sloes are to be gathered when they are moderately ripe. and they are to be set over the fire in water, till they swell and are softened, but not till the skin bursts; they are then to be laid upon a sieve, and the soft matter driven through, as in the other case; and three times the quantity of sugar is to be mixed with this, that it may make a conserve by beating together.

Syrups are to be made of many jugredients : they may be made indeed of any infusion, with sugar added to it in a due quantity; and the way to add this so that the syrups shall keep and not candy, is to proportion the sugar to the liquor very exactly. One rule will serve for all this matter, and save a great deal of repetition. The liquor, of which a syrup is to be made, may be the juice of some herb or fruit, or a decoction, or an infusion; whichever it be, let it stand till quite clear; then, to every wine pint of it, add a pound and three quarters of loaf sugar, first beat to powder : put the sugar and the liquor together into an earthen pan that will go into a large saucepan; put water in the saucepan, and set it over the fire. Let the pan stand in it till the sugar is perfectly melted, scumming it all the time; then, as soon as it is cold, it may be put up for use, and will keep all the year round.

This being set down as the general method of making the hiquor into a syrup, the rest of the descriptions of them will be easy. They are to be made in this manner. For syrup of cloves, weigh three pounds of clove July flowers picked from the husks, and with the white heels cut off; pour upon them five pints of boiling water. Let them stand all night, and in the morning pour off the clear liquor, and make it into a syrup, as directed above : in the same manner are to be made the syrups of violets and red poppies : but less of the violet flowers will do, and more of the poppies may be added : thus, also, are to be made the syrups of damask roses, peachblossoms, cowslip flowers, and many others which will be recommended for that purpose in this book.

Syrup of buckthorn is to be made by boiling the juice down to half its quantity, with a little cinnamon, ginger, and nutmeg, and then adding the sugar.

The syrups of lemon-juice, mulberries, and the like, are to be made with a pound and half of sugar to every pint of the clear juice, which is to be melted, as in the former manner.

Syrup of garlic, leeks, orange-peel, lemon-peel, mint, and many other things, are to be made of strong infusions of those ingredients, made as before directed, with the first-mentioned quantity of sugar added to them, when they have stood to settle.

Syrup of marshmallows, and of poppy heads, and some others, are to be made in the same manner with the strongest decoctions that can possibly be made from those ingredients, with the same quantity of sugar as is first mentioned.

Syrup of balsam is made by boiling a quarter of a pound of balsam of Tolu, in a pint and half of water in a close vessel, and then making the water into a syrup, with the usual quantity of sugar: and thus may be made syrups of any of the balsams.

Syrup of saffron is made of a strong tincture of saffron in wine. An ounce of saffron being put to a pint of mountain, and this, when strained off, is to be made into a syrup with the usual quantity of sugar.

At one time it was a custom to keep a quantity of syrups of a particular kind under the name of honeys. They were made with honey instead of sugar, and some of them, which had vinegar in the composition, were called oxymels. A few

beat up in a mortar with twice its weight of loaf sugar, first | of the first kind, and very few, are worth keeping, and two or three of the latter, for they have very particular virtues. The way of making them is much the same with that of making syrups ; but, to be exact, it may be proper just to give some instance of it.

Honey of roses is the most useful, and it is to be made of an infusion of the flowers and honey in this manner. Cut the white heels from some red-rose buds, and lay them to dry in a place where there is a draught of air; when they are dried, put half a pound of them into a stone jar, and pour on them three pints of boiling water ; stir them well, and let them stand twelve hours; then press off the liquor, and when it has settled, add to it five pounds of honey, boil it well, and when it is of the consistence of a thick syrup, put it by for use. It is good against sore mouths, and on many other occasions. In the same manner may be made the honey of any flower; or with the juice of any plant thus mixed with honey and boiled down, may be made what is called the honey of that plant. As to the oxymels, they are also made in a very uniform manner. The following are so useful, that it will be proper always to keep them in readiness.

For oxymel of garlic, put half a pint of vinegar into an earthen pipkin, boil in it a quarter of an ounce of carraway seeds, and the same quantity of sweet fennel seeds, at last add an ounce and half of fresh garlic root sliced thin; let it boil a minute or two longer, then cover it up to stand till cold, then press ont the liquor, and add ten ounces of honey, and boil it to a consistence

For vinegar of squills, put into a pint of vinegar three ounces of dried squills ; let it stand two days in a gentle heat, then press out the vinegar, and when it has stood to settle, add a pound and a half of honey, and boil it to a consistence. Both these are excellent in asthmas.

To these also should be added, the common simple oxymel, which is made of a pint of vinegar, and two pounds of honey, boiled together to the consistence of a syrup.

Finally, as to ointments, nothing can be so easy as the making them of the common herbs; and the expense is only so much hog's lard. The lard is to be melted, and the freshgathered leaves of the herb are to be chopped to pieces, and thrown into it : they are to be boiled till the leaves begin to feel crisp, and then the lard is to be strained off. It will be green, and will have the virtues of the herb, and must be called ointment of such an herb. To these I shall take the opportunity of adding the way of making two or three more, which, though not the produce of English herbs, are very useful, and no family should be without them.

1. The white ointment, called unguentum : this is made by melting together four ounces of white wax, and three ounces of spermaceti, in a pint of salad oil, and adding, if it be desired, three ounces of ceness, and a drachm and half of camphire; but it is better, for all common purposes, without these.

2. Yellow basilicon; which is made by melting together yellow wax, resin, and burgundy pitch, of each half a pound, in a pint of oil of olives, and adding three ounces of turpentine.

3. Black basilicon; which is made by melting together, in a pint of olive oil, yellow wax, resin, and pitch, of each nine ounces.

4. The mercurial ointment, which is thus made: rub together, in an iron mortar, a pound of quicksilver, and an ounce of turpentine; when they are well mixed, add four pounds of hog's lard melted, and mix all thoroughly together. The ointment of tutty is prepared with levigated tutty, and as much viper's fat as will make it into a soft ointment; these are only to be mixed together upon a marble, by working them with a thin knife. This is for disorders of the eyes; the foregoing for the itch, and many other complaints, but it must be used cautiously. And those which were before named, for old sores.

Of the same nature with the ointments, are, in some degree, the oils made by infusion of herbs and flowers in common oil. These are also very easily prepared, and an instance or two will serve to explan the making of them all. The most regarded among these is the oil of St. John's-wort, and that is thus made': pick clean a quarter of a pound of the flowers of common St. John's-wort, pour upon them a quart of olive oil, and let them stand together till the oil is of a reddish colour. Oil of elder is made of a pound of elder flowers, which are to be put into a quart of olive oil, and holidel till they are crisp, and the oil is to be then strained off.

3. What is called the green oil, is thus made: bruise in a marble mortar three ounces of green camonile, with the same quantity of bay leaves, sea-wornwood, rue, and sweet majoram; then boil them in a quart of oil of oiles, still they are a little crisp. The oil is then to be poured off, and when cold, put up for use.

These ofts are used to rub the limbs when there is pain and swellings; their virtues will be found at large, under the several herbs which are the principal ingredients : and after one or other of these methods, may be made the oil by infusion, or by boiling of any plant, or of any number of plants, of like virtue.

Lastly, though herbs are now left out of the composition of plasters, even the meiliot being now made without the herb from which it was first named, it may be proper to add the way of preparing a few that are most useful, and ought to be kept in families.

1. The common plaster is thus made; boil together a gallon of oil, five pounds of powdered litharge, and quart and four ounces of water. When the water is boiled away, the rest will be united into a plaster, but it must be stirred all the time: this used to be called diachyloa. To make diachyloa ounces of galbanum, and an ounce of common turpentine, and the same quantity of frankincense. Melt them all together, the gums frat, and then add the plaster.

2. For a strengthening plaister; melt two pounds of the common plaster, and add to it half a pound of frankincense, and three ounces of dragon's blood.

3. For a drawing plaster ; melt together yellow wax and yellow resin, of each three pounds, and a pound of mution suet. This is used, instead of the old melilot plaster, to dress blisters ; and the blister plaster itself is made of it, only by adding half a pint of vinegar, and a pound of Spanish flies in powder, to two pounds of it, just as it begins to cool from melting. The quicksilver plaster is thus made : rub three ounces of quicksilver, what drachm of balasm of subplur, till it no longer appears in globules, then pour in a pound of the common plaster melted, and mix them well together.

A few recipes for making waters without distillation, are added, which being cheap and very serviceable, ought not to be omitted.

1. Lime-water; this is made by pouring gradually six quarts of water, upon a pound of quick lime; when it has stood to be clear, it must be poured off. If a pound of lignum vita: wood, an ounce of liquorice root, and half an ounce of sassafras bark, be added to three quarts of lime-water, it is called compound lime-water, and is excellent in foulnesses of the blood.

2. The blue eye water; this is made by putting a drachm of sal ammoniac into a pint of lime-water, and letting it stand in a brass vessel, till it is of a sky-blue colour.

 Alum-water is made by boiling half an ounce of white vitriol, and the same quantity of alum in a quart of water, till they are dissolved.

Thus have we described all the drug's and compositions that need bekept for family use, or to relieve the neighbouring poor in their greatest of all distresses, that of sickness. The diseases for which these remedies are to be used, will be found enumerated at large under the several heads of the principal ingredients, as described in the succeeding pages. It only remains to say a few words about the manner of putting these things most conveniently together, and we then shall have prepared for all that follows.

Concerning the best Methods of putting Medicines together for present taking.

In the first place, although these several forms of syrups, conserves, and the like, have been named, as what will be sometimes necessary; the great practice in the country will lie in the infusions and decoctions of the fresh plants and roots.

The strength of these infusions and decoctions is to be proportioned to the taste: for as they are made to be swallowed in quantities, if they be made so strong as to be very disagreeable, that end will be defeated: they may be rendered more pleasant by sweetening them with sugar, about an onnce of which is to be allowed to a quart; and occasionally a little white wine, or a small quantity of some of the cortail waters, may be added to them. The dose of either decoction or iafusion, will be in general about half a pint, except where they are intended to purge or vomit; there they must be more carefully and exactly proportioned to the strength, than can be told in this general amore.

Of the simple waters, abont a quarter of a pint is a dose; and of the cordial waters, less than half that quantity. These may be occasionally given alone; but they are mostly intended for mixing with other ingredients.

The tinctures are to be given in drops, from ten to an hundred, according to their strength and nature; but to name a general dose, it is about five and twenty drops. These, however, will be also more serviceable in mixitures, than singly. Of the purging tinctures in wine, and the clixir salutis, three, four, or more spoonfuls, is the dose.

It would be well to keep inctures of many of the roots recommended in nervous cases, as cordials, astringents, and of many other kinds; and also to keep powders of these roots in readiness: and thus the common forms of medicines, as sent from apothecaries, will be very easy.

For julep, six ounces of one of the simple waters, two ounces of one of the compound waters, or those made with spirit, two drachms of a syrup, and fifty drops of a tincture, make a very agreeable one. Thus for an hysteric julep, let the simple water be pennyroyal, the strong water the strong pennyroyal, the syrup that of saffron, and the tincture of castor; and it is a very pleasant julep: and so of all the rest. If a pearl cordial be desired, it is only mixing the simple and strong waters without syrup or tincture, and adding two drachms of sugar, and half a drachm of levigated oster-shells. The apothecaries will not be pleased with thus discissing the mysteries of their profession; but the public good is of more consequence than their pleasure.

Draughts are only little juleps, with more powerful ingredients added to them. An ounce and half of a simple water, three drachms of a strong water, one drachm of a syrup, and forty drops of a tincture, make a draught; but to these may

⁴

be added a simple of some power, to increase the virtue. What waters, tinctures, syrups, or powders, shall be used, will be determined from the case itself.

Boluses are made with these powders in a certain dose. A scruple, or half a drachm, is made into a sort of paste with syrup. The common custom is to cover it with a little leafgold, but this is better let alone : some use leaf-brass, which is abominable.

Electuaries are to be made of powders, conserves, and syrups; they differ from boluses in this, as well as in the size, that the dose is smaller, although the piece taken be as large; which is owing to the conserve, that having in general little virtue in comparison of the other ingredients. This is the form most convenient for medicines that are to be taken for a continuance of time, and the dose of which needs not be so very punctually regarded.

Thus, for an electuary against an habitual looseness, when it exceeds the proper bounds; mix together an ounce of conserve of red roses, and six drachms of syrup of cloves; add to these, two drachms of powdered bistort root, one drachm of powdered tormentil, and half a drachm of toasted rhubarb. This makes an electuary, a piece of which, of the bigness of a nutmeg, taken once in two days, will check the abundance of stools, without stopping the customary looseness entirely : it will also be a pleasant medicine. If a draught of tincture of roses be taken after this, it will increase the power.

In this manner any person may supply the place of the apothecary, to those who could not afford such assistance: and experience is so good a guide, that they will be able in most cases to save the expence of the doctor also; with very little danger of doing harm. The Galenical physic, perhaps, will be found effectual in many more cases, by those who stick to it solely, than they are aware who do not use it: as to the mischief of medicine, that is almost entirely chemical. It would be idle to say that chemical medicines do not do great good ; but they require to be in skilful hands : when the ignorant employ them, death is more likely to be the consequence, than the relief from the disorder any other way.

One useful observation may serve well to close this Introduction. Opiums, and medicines of that kind, to compose persons to rest and to take off pain, will be often necessary; but as they are the most powerful medicines the family practitioner will have to do with, they are the most capable of doing harm : the greatest care will therefore be required in the right use of them.

As there are three different preparations described in this book for answering this purpose, beside the opium, and that solution of it in wine which is called laudanum; these two latter should be used very seldom. A syrup made of the juice of the wild lettuce, is an excellent medicine; the syrup of diacodium, which is made of a strong decoction of poppy heads, is a little stronger than this; and if something more powerful than these is required, there is the asthmatic elixir. One or other of these may almost on every occasion serve the purpose; and it is almost impossible that the use of them should be attended with danger. Let opium or laudanum therefore be very rarely used; perhaps it might be well to say, not used at all; for the others will be able in almost all cases, if not universally, to answer the purpose,

********* Concerning the Virtues of Plants which have not yet been tried.

THE number of English plants, whose virtues are ascertained, scarcely exceeds one thousand, while the catalogue of the same sort of flowers and fruits with those which we know

those which are natives of our own country, as published by Mr. Ray, amounts to many thousands : great numbers therefore remain yet untried, and present an ample field for our researches.

To what purpose can a man devote the hours of his leisure better, than to the discovering, among the number of the unregarded, virtues which may farther supply the catalogue of our own remedies, and make the roots and seeds brought from remote countries less necessary ? What encouragement to the attempt, that there are such multitude of objects for the trial ! and that the discovering but one remedy among them all, for a disease we knew not how so well to cure before, is a source of more true honour, than can be derived from all the useless knowledge in the world.

If any suppose the trial dangerous, they mislead themselves: and to encourage so laudable an undertaking, I shall observe how little is the hazard, and how considerable the advantages, from what we know already.

If a man were to be turned loose upon an island where no person had set foot before, he might dread to taste of any plant he saw, because he might not know but every one he saw was fatal : and supposing him to have got over this fear, the ignorance of the virtues of all would keep him backward : but this is not at all the case with him, who shall at this time set about inquiring into the virtues of plants in England. The poisonous plants, native of our soil, are hardly a dozen, and these are charactered even to the eye, by something singular or dismal in the aspect. They are well known, and he has nothing to do but to avoid them. For the rest, he has so many, whose uses and qualities are already perfectly known, that he has a great foundation to go upon in the search, because he can compare those he does not know with them. Their tastes will go a great way toward informing him; but this is not all, their very outward figures will direct him; for in general those plants which agree in the external aspect, agree likewise in their virtues.

To give an instance in the marshmallow. It is known to work by urine, and to be good against the gravel. We will suppose no more known concerning this kind. A person desirous of extending this useful knowledge, finds that by the taste of the root, which is insipid, and its mucilaginous quality, he might have guessed this to be its virtue, from what he before knew of medicine. The next plant he meets, we will suppose is the common mallow, and afterwards the little white flowered mallow, which lies upon the ground ; he tastes the roots of these, and he finds they are like the other: he will therefore guess that they have the same virtues, and upon trial he will find it is so.

But this is not all : if he had examined the flower of the marshmallow, in what manner it was constructed, and how the little threads grew within it, he would have found that the flowers of these other two mallows were, in all respects, like those of the other; and farther, he would have found, that the seeds of these two kinds were in the same manner disposed in circular bodies : from this he might, without tasting their roots, have been led to guess that their virtues were the same; or having guessed so much from this, he might have been thence led to taste them, and by that have been confirmed in it : but he might be carried farther; he would find the same sort of round clusters of seeds in the hollyoak in his garden; and upon examining the single flowers, he would see they were also alike : and hence he would discover that it was of this kind; and he would rightly judge that the hollyoak also possessed the same virtues.

There is this great use in examining other plants which have

to have virtues, that we may in this way discover plants at home, to supply the place of those we have from other countries. It is certain the sun in warmer climates does ripen the juices of vegetables faster than in ours, but yet we find the plants of the same kind, from whatever part of the world they come, to possess nearly the same kind of virtues; generally indeed they are the same, only differing in degree. Thus all the mallows of Spain and Italy, to bring the trial to the before-named instance, possess the same virtues with the marshmallow, mallow, and hollyoak of England; and the case is the same with those which are truly mallows of the East and West Indies; though this docs not hold good with respect to some of the plants of those countries which have been brought hither under that name. Thus the senega rattlesnake root, which was once much in use amongst us, has heen discovered to belong to a kind of milkwort, or polygala. The roots of the common milkwort of our pastures being tried, have been found to possess the same virtues, though in a less degree. This plant would not have been regarded, if the other had not been found to be of the same kind ; but to that we owe the knowledge of its virtues.

There is this great reason' for seeking in our own climate, plants of the same nature, form, and kind, with those which in other countries afford us remedies—that they are generally of the same kind, and may be fitter for our constitutions; for as it has been before observed, the productions of each respective country, are always best suited to supply the wants of its inhabitants both for food and medicine: and it is certain, that as the sun ripers the juries of plants in hotter countries to more virtue than with us, so it makes men's constitutions more able to bear their effects.

The Chinese will swallow such doses as would poison one of us. This we know in many instances, and it ought to encourage us in the present research; because, if the same doses which agree with them are too much for us, we may also find that other medicines of our own growth, and of the same kind of virtues, though in a less degree, may also be found to agree better with our constitutions. Therefore, notwithstanding that it may be necessary in some cases, and convenient in many, for us to have drugs from abroad, yet in general it will be better for us to be cured by those herbs we may find at home; and they will be found upon trial more sufficient for that purpose than we at present magine. The means are at hand, but we have made very little use of them, proportioned to their number and their value.

The observation already made, that the external form of plants may very well give the hint for a coujecture about their virtues, is much more general than might be imagined. Almost all the plants of the same kinds are of the same virtues. But that is not all; for, in general, those of the same class

possess the same qualities, though different in degree : and this is a proficious help to bina who shall set out upon the generous and useful plan of adding to the number of the useful plants. It is also singular, that what might appear objections in this case, being brought to the trial, will often be found confirmations of the truth there is in the observation.

Thus, suppose a man observing that lettuce is eatable. should inquire into all the plants like lettuce, which are those that have flowers composed of many parts, and have the seeds winged with a white downy matter, to find whether they were eatable; let us examine how he would succeed. The plants of this class native of England, are, the sowthistle, the hawkweeds, the dandelions, goats-beards, succory, and endive, all eatables. The hawkweeds are less agreeable in the taste, but wholesome ; and as to the wild lettuces, those who would bring the opiate quality of the principal of them as an objection, strengthen the observation, for the garden lettuce also has an opiate quality. This wild one possesses it in a greater degree, but still in such a degree, that it is an excellent medicine, not at all dangerous. Its bitter taste would prevent people's eating it, for it is disagreeable ; but its virtues are the same with those of lettuce, only greater. There are some kinds of hawkweed also, which have a bitter milky jnice, altogether like that of this lettuce; and they also have the same opiate quality.

This general observation may be carried a great deal farther. In general, the seeds of unbelliferons plants, that is, those which have little flowers in rounded clusters, each succeded by two seeds, are good against colies; those of carraway, anise, cummin, coriander, and all of that kind, are produced by plants of this figure. In the same manner the verticillate plants, as they are called, that is, those which have the flowers surrounding the stalks, as in mint and thyme, are of a warm nature; and however they differ in degree and circumstance, they have the same general virtues. Farther, such plants as are insipid to the taste and smell, have generally little virtues; and, on the contrary, those which have the most fragrant smell and sharpest taste, have the greatest virtues, of whatever kind.

In general also, those plants which have a strong but an agreeable task, are most worthy to be examined with respect to their virtues; for they are generally the most valuable; and on the contrary, when a very strong taste is also a very disagreeable one; or, in the same manner, when the strong smell of a plant has also something heavy, disagreeable, and overpowering in it; there is mischief in the herb, rather than any useful quality. The poisonous plants of this country are very few; but they are for the most part characterized after this manner : so that they are known as it were at sight, or by the first offer of a trial.

INSTRUCTIONS for finding any Plant, known or unknown, in the following work.

WHEN you have the English name of the Plant, or the Linnean name of the Genus to which it belongs, it will only be necessary to refer to it in the alphabetical order of the Dictionary is hat if you should meet with a Flower or Plant to which you are an entire stranger, you must first determine its Class and Order according to the Rules already laid down in the preceding Introduction; and having found them, inspect the Tubble of Orders and Genera at the end of this Work, observing to which Genus of its Order your Plant belongs. When this is done, you must refer to the description of the Genus by the alphabetical arrangement of the body of the Work; and if that Genus sonation aloy non Species, that is the Plant in question; but if it contain many Species, particular attention must be paid to the circumstances which distinguish these Species; and when you have ascertained to which Section of the Genus (if it be divided into Sections) your Plant belongs, and that stection only includes one Species, which is often the case, you have found the Plant; but if each Section includes several Species, very close attention must be paid to the characteristics of each, as they are in general extremely minute, depending principally upon the shape of the leaves and the roots.

THE

UNIVERSAL HERBAL;

BOTANICAL, MEDICAL, AND AGRICULTURAL

Dictionary.

ABR

ABELE Tree. See Populus. Abelmoschus. See Hibiscus. Abris. See Pinus.

Abroma, a genus in the class Polyadelphia ; order, Dodecandria .- GENERIC CHARACTER. Calix, perianth fiveleaved ; leaflets spear-shaped, acute, spreading, permanent. Corolla, petals five, larger than the calix; claws, obovate. arched concave, hairy at the end, erect, inserted at the base into the nectary ; borders oval, obtuse, spreading, ciliate, contracted at the base into very short, ciliate, recurved small claws, upon which the principal claws are placed. Nectary, short, small, pitcher-shaped, divided into five segments, which are obcordate, hairy, erect, recurved, and arched, alternate with the claws of the petals. Stamina, filaments five, membranaceous, very small, growing on the nectary, between the segments, emarginate-triffd. Antheræ, on each filament three, twin, kidney-form. Pistil, germen almost cylindrical. Styles five, awl-shaped, approximating. Stigmas acute. Pericarp, capsule egg-shaped, membranaceous, veined, fivewinged, five-beaked, five-celled, gaping at top into five parts between the beaks; partitions folded. Seeds, very many, nearly egg-shaped, within an oblique seed-coat, fixed in a double row to the central edge of the partitions, which is thickened, and longitudinally bearded. Receptacle of the seeds, none.—ESENNTIAL CHARACTER. Capsule, five-celled, one-valved, gaping at top; seeds subovate, incom-pletely arilled.—This genus contains the following species: 1. Abroma Augusta, Maple-leaved Abroma, with leaves heart-shaped or angular, sharply serrulate. It is a native of New South Wales and the Philippine Islands; and was introduced into England about 1770. It is propagated by cuttings, but requires a strong heat, and abundance of water. The seeds will not easily ripen with us, and can seldom be obtained in a state fit for vegetation.

2. Abroma Wheleri; *Wheler's Abroma*. Its leaves are spear egg-shaped, sharp-pointed, and slightly toothed : it is unknown in Europe.

Abrotanum. See Artemisia.

ACA

Abrus, a genus in the class Diadelphia ; order; Decandria. -GENERIC CHARACTER. Calix, perianth one-leaved bellshaped, obscurely four-lobed : teeth blunt, the upper one broadest. Corolla, papilionaccous. Banner roundish, entire, ascending; flatted at the sides, longer than the wings and keel. Wings oblong, blunt; keel oblong, sickle-shaped, gibbous, longer than the wings. Stamina, filaments nine, united into a sheath, cloven above, free at the end, unequal, rising. Antheræ oblong, erect. Pistil, germ cylindrical, hairy. Style subulate, rising shorter than the stamina. Stigma, in the form of a head, and small. Pericarp, legume like a rhomb, compressed, coriaceous, double-valved, four or five-celled, sharp-pointed, with a little awl-shaped deflex claw. Seeds, solitary and nearly globular .---- The species in this genus are.

1. Abrus Precatorius, or Jamaica wild Liquorice, which is indigenous in the East and West Indies, Guinea, and Egypt. The seeds of this plant are commonly strung, and worm as ormaments by the natives of these countries. Linnens asys they are extremely deleterious, although they are eaten in Egypt. Is however, authors agree that they are the hardest and most indigestible of all the pulse tribe, producing violent flatulencies in the bowels. This plant may be propagated by seeds which have been soaked twelve or fourteen hours in water, before they are sown, which must be in a good hot-bed in the spring. If sown without soaking, they frequently lie a whole year without vegetating, but will appear in a fortnight, if the seed be good and well soaked, and the bed in a proper temperature of heat. They flower in the second year, and sometimes ripen their seeds in England.

Absinthium. See Artemisia.

Absus. See Cassia.

Abutilon. See Sida.

Accent, a thorn: a genus of the class Tetrandria: order, Monogynia.—GENERIC CHARACTER. Calix, perianth fonrleaved; lealtes ovate, concave, equal, pernanent. Corolla, none, unless the calix be termed one. Stamina, filaments equal, of middle length, opposite to the calix. Antherae, fourcornered, twin, erect. *Pisitil*, germ inferior, obovate, bristled. Style very small, bentin on one side. Stigma, a small, many-cleft, thickish-coloured membrane. *Perianth*, a dry, obovate, one-celled berry, beset with thorns bent backwards. *Sced*, single.—The only species in this genus is the Acæna elongata, a Mexican plant.

ACA

Acadypha, a genus of the class Monzeni; order, Monadelphia.-GENERIC CHARACTER. Male Movers crowded above the females. Calix, perianth three or four leaved; leafter to undish, eorcare, and equal. Corolla, none. Stamina, filaments eight to sixteen, short, erowded, connected at the base. Antherer roundish. Female flowers fewer, below the others, received into a large undivided involucre. Perianth, three leaved; leaftets, subovate, concave, converging, small, permanent. Corola, wanting. Pristil, gern roundish; styles, three: branching, usually three-parted loug. Stigmas simple. Pericary, capsule roundish, three-furrowed, three-celled; the valves gaping two ways. Seeds, solitary, roundish, very large.-ESSENTIAL CHARACTER. Male calix, three of four leaved, no corolla, firon eight to sixteen stamina. Female calix, three-celled. Seed, one.----The species are as follows:

1. Acalypha Virginica; *Virginian Acalypha*; with female involuces, heart-shaped, gashed, leaves ovate-lanceolate, longer than the foot-stalk. It grows maturally in Virginia, and other parts of North America, and even in Ceylon. It is an annual plant, seldom above a foot high, and in its leaves much resembles pellitory. All the culture it requires, is to keep it free from weeds, and to let it remain where sown, as it does not bear removing well. It flowers in August, and the seeds ripen in October.

2. Acalypha Virgata; Janaica Acalypha: has female spikes with heart-shaped involucers, serrate; maked is distinct, naked; leaves spear egg-shaped. It is a native of the warmest countries, and grows plentifully in Jamaica, and is an anneal plant, which seldom exceeds a foot high in England. The leaves are very like those of the annual nettle, and will sting as much when touched. It will not thrive in the open air in this country, but must be sown in pots, and plunged intoloch-leds.

3. Acalypha Indica; Indian Acalypha.—Female involuces, heart-shaped, and slightly notched; leaves ovate, shorter than the petiole. It grows about three feet high, and was discovered in great plenty at Vera Cruz. It inhubits marshy places, is found upon doughilk in the East Indies, and is an annual plant, which flowers in July.

4. Acalypha Villosa; Villous Acalypha.—Female involucres very small, toothed, and extremely villous; spikes elongate; leaves ovate, pointed, serrate, longer than the foot-stalk.

5. Acalypha Australis; South American Acalypha. – Female involucres quite entire; leaves lanceolate obtuse. It is a native of South America.

6. Acalypha Hernandifolia: female spikes very long, in volucres, cordate, serrate; males distinct, naked; leaves subcordate, serrate, on very long petioles. It is a native of the West Indies.

7. Acalypha Corensis: female flowers terminating distinct, involucres three-leaved; males, spikes axillary, involucred; leaves ovate serrate. Grows in the West Indies.

8. Acalypla Lævigata: female spikes with many-parted involucres; male spikes, lax, naked; leaves wedge-ovate acuminate serrulate very smooth. It is found in the West Indies.

9. Acalypha Elliptica: female spikes, with involucres shorter than the germs, ovate-toothed, hirsute; males, naked, lax; leaves elliptic acuminate-toothed. It is a native of the West Indies.

10. Acalypha Reptans: spikes terminating erect, flowers mixed, females lower; involucres cordate serrate; males leafless; leaves ovate serrate; stem creeping. Grows in Hispaniola and Jamaica.

1. Acalypha Tomentosa: female spikes terminating solitary, involucres many-parted; males erect; leaves ovatelanceolate serrate scabrous villous tomentose underneath. It is a native of the West Indics.

12. Acalypha Augustifolia: female flowers subsessile; terminating, involucres serrate; males in spikes; leaves linear serrate. Found in the West Indies.

13. Acalypha Scabrosa: female spikes with cordate gashed involucres; leaves oblong-lanceolate serrate scabrous. It is a native of the West Indies.

14. Acalypha Betulæfolia: female flowers, axillary sessile, involucres cordate crenate; males in spikes; leaves roundish crenate smooth. Is an inhabitant of the West Indies.

These plants have neither use nor beauty to recommend them; they are preserved in botanic gardens for variety's sake.

Acanga. See Bromelia.

Acanthium. See Onopordum.

Acanthus, a genus of the class Didynamia ; order, Angiospermia,-GENERIC CHARACTER. Calix, perianth with leaflets in three alternate pairs, unequal, permanent. Corolla, onepctalled, unequal; tube very short, closed with a beard ; upper lip, none: under lip very large, flat, straight, very broad, three-lobed, obtuse; the length of the upper lip of the calix. Stamina, filaments four, subulate shorter than the corolla, the two upper rather longer, recurved, incurved at the top. Antheræ oblong, compressed, obtuse, the lateral ones parallel, villous before. Pistil, germ conical. Style filiform, length of the stamina. Stigmas two, acute, lateral. Pericarp, capsule subovate with a point, two-celled, two-valved, with a contrary partition; claws alternate, curved, fastened to the partition. Seed ovate, gibbous, single; sometimes two .--ESSENTIAL CHARACTER. Calix, two-leaved, bifid. Corolla, one-lipped, bent down, trifid. Capsule, two-celled. The species of this genus are,

1. Acanthus Mollis; Smooth Acanthus, Brank Ursine, or Bear's Breech : its leaves are sinuate and unarmed. This species is used in medicine, under the name Branca Ursina. The leaves, but especially the roots, abound with a mucilage which is readily extracted by boiling or infusion. Wherever it abounds it is used for the same purposes as the althæa, or the marshmallow (which see) among us. It may be propagated either by seeds, or by parting of the roots. They should be sown towards the end of March, and if the season be favourable, will appear in May ; they only require to be kept six inches asunder, and free from weeds, till autumn, when they should be transplanted whither they are intended to remain. They take deep root, and when once established in a garden, are hard to eradicate. It is said that the leaves of this species of the acanthus, found accidentally growing round a basket covered with a tile, gave occasion to Callimachus to invent the Corinthian capital. It is an inhabitant of Naples, Sicily, Provence, and the Archipelago. The roots and leaves abound with a soft slippery mucilage, which is readily extracted, either by boiling, or infusing them in water; it is of singular efficacy in tickling coughs, catarrhs, defluxions on the lungs, hoarseness, erosions of the bowels, and the stranguary, and for lubricating the urinary passages, in nephritic and calculous disorders. See the Plate.

 Acanthus Carduifolius; Thistle-leaved Acanthus.—Leaves sinuous-toothed, thorny, spike of flowers radical. This was found at the Cape of Good Hope: respecting its culture and propagation, see the preceding species, Acanthus Mollis.

3. Acanthus Spinosus; Prickly Acanthus .- Leaves pinnatifid, thorny. It grows wild in Italy and Provence, and flowers quite entire, evergreen ; said to be a variety of the Cretan from July to September; it requires the same treatment in cultivation as the two preceding species.

4. Acanthus Dioscoridis; Acanthus of Dioscorides .- Leaves lanceolate, quite entire, thorny on the margin. According to Rauwolff, this species, which Linneus supposed to be the genuine species of Dioscorides, grows naturally on mount Lebanon in the East.

5. Acanthus Ilicifolius; Holly-leaved Acanthus .-- Leaves repand, tooth-thorny; stem shrubby, prickly. It is an evergreen, rising about four feet high, very like the common holly. and armed with spines in the same manner, and is a native of the East and West Indies, and of some of the islands in the South Seas. It is too tender to thrive without a stove in England, and can only be propagated by seeds, which do not ripcn in Europe.

6. Acanthus Integrifolius; Entire-leaved Acanthus.- Leaves oblong, entire; stem herbaccous, procumbent. It is a native of the Cape of Good Hope.

7. Acanthus Procumbens ; Procumbent Acanthus .-- Leaves oblong, serrate, and ciliate ; stem procumbent, shrubby. Inhahits the Cane of Good Hope.

8. Acanthus Furcatus; Forked Acanthus .- Leaves oblong, tooth-thorny ; stem shrubby ; bractes terminated by a threeforked thorn. Also a native of the Cape of Good Hope.

9. Acanthus Capensis; Cape Acanthus .- Leaves oblong, toothed, thorny; stem shrubby, erect; bractes terminated by It is, as its name imports, an inhabitant of the a simple thorn. Cape of Good Hope.

10. Acanthus Maderaspatensis; Madras Acanthus .-Leaves four-fold, flowers axillary, calices ciliate. It is a native of the East Indies, and will not thrive in England without a stove.

Acarna. See Cnicus.

Acer, the maple-tree : a genus of the class Polygamia; order, Directa .- GENERIC CHARACTER. Hermaphrodite flowers, calix, perianth one-leaved, five-cleft, acute, coloured, flat and entire at the base, permanent. Corolla, petals five, ovates broader outward, obtuse, scarcely larger than the calix, spreading. Stamina, filaments eight, subulate, short. Antheræ simple ; pollen cruciform. Pistil, germ compressed, immersed in a convex perforated large receptacle. Style filiform, advancing in height daily. Stigmas two or three, pointed, slender, reflex. Pericarp, capsules two or three, growing together at the base, roundish, compressed, each terminated by a very large membranous wing. Seeds solitary, roundish. N. B. The male flowers are the same with the hermaphrodites, except that they have neither germ nor style, but only a bifid stigma .- ESSENTIAL CHARACTER. Calix, five-cleft. Corolla five-petalled. Stamina, eight or ten ; germs two or three, superior. Style, simple. Capsules, two, sometimes three, with one seed in each, terminated by a wing. Males without germ or style. This genus consists of hardy deciduous trees, easily propagated by sowing their seeds soon after they are ripe, in a bed of common earth, covering them half an inch thick with light mould. In the spring they will appear above ground, and if kept clear from weeds, and watered in dry weather, some of the sorts will grow above a foot high the first summer. The autumn or spring following, if they are close in the seed-bed, it will be proper to transplant them into a nursery, in rows at three feet distance, and two feet asunder in the rows. They may remain there three or four years, in which time they will become large enough to plant out for continuance.----The species are,

1. Acer Sempervirens; Evergreen- Maple .-- Leaves ovate, maple. See Acer Creticum, species No. 17 of this genus.

2. Acer Tataricum; Tatarian Maple .- Leaves heart-shaped, undivided, serrate, lobes obscure ; flowers in racemes. It is a native of Southern Russia ; by the Tanais, Volga, &c. The wood is whitish, but with some brownish veins. The seeds, boiled with milk and butter, are used as astringents by the Calmuc Tartars. It is very difficult to raise in England.

3. Acer Pseudoplantanus; Great Maple or Sycamore. Leaves five-lobed, unequally serrate, flowers in racemes. This tree grows wild in mountainous situations; in Switzerland, Austria, Germany, and Italy. In England it is vulgarly called the Sycamore, and sometimes the Mock Plane-tree, and in Scotland it is termed the Plane tree. It was formerly much used for planting walks and avenues, and is excellent for plantations near the sea, or for sheltering other trees from the spray, which they resist with less injury than most trees. In pastures, also, they are least injurious to the grass. The wood was once much in request for trenchers, being very white aud soft. It is still used by turners for bowls, dishes, &c. by saddlers for saddle-trees; and is recommended for cart and plough timber, being light and tough, though inferior to ash. It is a quick-growing wood, thriving wonderfully on warm, sound, rich land, rising so as to make excellent walks and shady bowers ; useful for inward building, where better timber is wanting : and for firing, when wood grows scarce : hence it is generally reckoned proper for underwood, because it shoots fast from the stool, and makes good fuel. In spring and autnmn this species will pour forth from the wounded stem abundance of saccharine inice, in the same manner as the birch; from which Mr. Ray, on the authority of Dr. Martin Lister, says that good wine may be made.

4. Acer Rubrum; Scarlet flowering Maple .- Leaves fivelobed, slightly toothed, glaucous underneath; peduncles very simple and aggregate : of this tree there are two varieties in nurseries, 1. The Virginian scarlet flowering maple, 2. Sir Charles Wager's flowering maple. With us it is propagated for the sake of the scarlet flowers which appear in the spring. In Pennsylvania, where it grows in the swamps, the natives use it for almost all sorts of woodwork; with the bark they dye a dark blue, and make a good black ink. The Canadians tap the tree, and make sugar and treacle from the juice.

5. Acer Saccharinum; American Sugar Maple .-- Leaves five-parted, palmate, point-toothed, pubescent. This tree grows forty feet high. In North America, they top these trees early in the spring, and make a very good sort of sugar in large quantities by boiling the juice. Large tracts of that country are covered with this tree, which yields a sugar equal to the best cane, and in great quantities, with no other labour than what women and girls can bestow, in drawing off and boiling the liquor. Dr. Rush assures us, that this tree is so far from being injured by the tapping, that it has flourished after forty-two annual operations; it is therefore concluded, by judicious persons, that the inhabitants of that country can, not only supply their own demands, but even make sugar for exportation. In all sugar plantations, it will be necessary to cut out the different sorts of timber which grow intermixed with the maple-tree, and even such of that species as are not thriving trees. The timber so cut will serve as fuel for the boilers, and leave openings for the rays of the sun to enter, which improve and enrich the sap. The season for tapping is in February, March, and April, according to the weather. Warm days and frosty nights are the most favourable to a plentiful discharge of the sap. The perforation is made with an axe or an auger, but the latter is preferred. The auger is introtion ; and is afterwards deepened gradually to the extent of Trient ; and near Olon : it is common in many parts of two inches. A spout is introduced about half an inch. and projects from three to twelve inches; it is generally made of the sumach or elder. 'The tree is first tapped on the south side, and afterwards on the north side ; and the sap flows from four to six weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons are placed under the spont to receive the sap, which is taken every day to a large receiver, from whence it is conveyed to the boiler, after having been strained.

6. Acer Dissectum; Cut-leaved Maple .- Leaves manyparted, palmate; the divisions sub-pinnatifid and serrate. It was found by Thunberg in Japan. It flowers in May.

7. Acer Japonicum: Japonese Maple .- Leaves many-parted. gashed, and villous; flowers sub-umbelled. It flowers in April and May, and is a native of Japan.

8. Acer Palmatum; Hand-leaved Maple .-- Leaves palmate, serrate, smooth; flowers in umbels. It flowers in May, and was discovered by Thunberg in Japan.

9. Acer Septemlobum ; Seven-lobed Maple .-- Leaves sevenlobed, smooth ; lobes pointed, regularly and sharply serrate. This species also was seen by Thunberg in Japan.

10. Acer Pictum; Painted Maple .- Leaves seven-lobed, smooth; lobes pointed, entire. It was found by Thunberg, in Japan.

11. Acer Platanoides: Norway Maple .- Leaves five lobed, pointed, sharply toothed, smooth ; flowers in corymbs. This tree grows to a large size. Hanbury says, it is quick of growth, arrives at great bulk, and is one of the best trees for sheltering habitations. Linneus recommends it for walks and plantations; as yielding a juice from which sugar may he made, if it be wounded in the winter; and as cutting out into a white smooth wood, fit for the stocks of guns, and for the joiner and turner. Dr. Hunter observes, that as it is a quick grower, arrives at a great bulk, and answers all the purposes of the sycamore, the raising it for use, as well as ornament and variety, should not be neglected. Norway maple is found on the mountains in the north of Europe, in Germany, Switzerland, Stiria, Carniola, and Savoy.

12. Acer Montanum; Mountain Maple .- Leaves slightly five-lobed, acute serrate; racemes compound; calices hairy. It is a native of North America.

13. Acer Pennsylvanicum ; Pennsylvanian Maple .-- Leaves three-lobed, acuminate, sharply double servate; racemes simple : calices smooth. It is a small tree, which in some situations may be considered rather as a shrub. It is a native of Pennsylvania, Virginia, and Canada. The thickness of the shade, the beauty of the bark, and the tree not being liable to insects, would make it desirable for plantations, were it not for the litter occasioned by the abundance of the leaves and fruit which it produces, and its being subject to be torn by storms: it delights in a firm dry mould

14. Acer Campestre; Common or Small Maple .- This species is chiefly seen in hedgerows and coppices. Its timber is far superior to that of the beech, for all the uses of the turner. particularly dishes, cups, trenchers, and bowls; and when it abounds in knots, as it very frequently does, it is highly esteemed by the joiners for inlaying, &c. The wood is often used by musical instrument makers for its lightness; for gun stocks, on account of its hardness; and it was formerly in great request for tables, on account of its whiteness. This tree will flourish in very coarse land.

15. Acer Opalus; Italian Maple .- Leaves roundish, fivelobed, loosely serrate; capsules ovate, smooth, almost upright. This tree was first discovered at the foot of the Alps, and even in sheltered situations. It requires a moderate stove to pre-2

duced about three quarters of an inch in an ascending direc- afterwards in abundance near Pissevache in the valley of Italy, particularly near Rome and Viterbo. It acquires a considerable stature, and as its leaves are large, and afford a great shade, it is frequently planted on the road side and near habitations, for which purposes it well deserves the attention of ornamental planters, especially as although it be seldom seen in England, it is nevertheless hardy enough to bear the open air of our climate.

16. Acer Monspessulanum; Montpelier Maple .-- Leaves three-lobed, very entire, smooth, annual. Its leaves resemble the common maple, but are of a much thicker substance. smaller, and of a shining green colour. They retain their verdure very late in autumn, which renders this tree more valuable, although it is not common in Eugland. It abounds in the south of France and in Italy.

17. Acer Creticum; Cretan maple .- Leaves three-lobed. very entire, pubescent, perennial. This tree resembles the Montpelier maple, and attains to the same height. Its leaves are distinguished by a thinner texture, and their footstalks are covered with a soft hairy down. When well sheltered they continue green most part of the year. It is a native of the Levant.

18. Acer Trifidum ; Trifid-leaved Maple .- Leaves undivided and trifid, without indentations on the edge. It is of inferior growth, seldom attaining to more than between twenty and thirty feet.

19. Acer Negundo; Virginian Ash-leaved Maple .- Leaves compound, flowers racemed. Three and four pistilla have been observed in the female flower; no corolla, and four or five stamina, in the males. This is a strong-shooting tree, of quick growth, and in Virginia and Carolina is one of the largest trees of this kind. Its leaves fall soon in Autumn, and when planted, it must not be exposed to violent winds, as it is subject to split. The wood is used for the same purposes as the sycamore and Norway maple, but it is soft and brittle. The tree grows to the height of forty feet and upwards, and is fit for large plantations.

20. Acer Pinnutum ; Wing-leared Maple .- Leaves pinnate ; leaflets oblong, quite entire. This is a native of the woods of Cochin-China. It is a middling-sized tree, with spreading branches, white flowers, and a very hard wood.

Acelosa. See Rumex.

Acetosella. See Oxalis and Rumex.

Achania, a genus of the class Monadelphia, order Polyandria .- GENERIC CHARACTER. Calix, perianth double. Outer, many-leaved; leaflets linear, permanent, slightly coalescing at the base. Inner one-leafed, sub-cylindric, streaked half way, five-cleft, permanent. Corolla, almost club-shaped, convoluted. Petals five, obovate oblong, erect, with a lobe at the base on one side, involving the column of stamina, Stamina, filaments numerous, coalescing into a writhed tube. longer than the corolla, free at top, capillary. Antheræ oblong. Pistilla, germ sub-globular, style filiform, the same length with the tube of the stamina, ten-cleft at the top ; the segments spreading. Stigmas headed. Pericarp, berry subglobular, fleshy, five-celled. Seeds solitary, convex on the one side, angular on the other .- ESSENTIAL CHARACTER. Calix double; outer many-leaved. Corolla convolute, berry five-seeded .- Plants of this genus are generally propagated by cuttings; because the sceds do not often ripen herc. These cuttings are placed in pots of light earth, and fixed in a gentle hot-hed, where, if the air be kept from them, they soon take root, and may afterwards be gradually inured to the open air. When placed abroad, they seldom succeed well,

serve them during the winter; and unless kept warm in summer, they will not flower, much less ripen fruit.---- The species are. . 1. Achania Malvaviscus ; Scarlet Achania, or Bastard Hibiscus .- Leaves somewhat scabrous, acuminate; leaflets of the outer calix, erect. It flowers most part of the year, and is a native of Mexico and Jamaica.

2. Achania Mollis ; Woolly Achania .- Leaves tomentose, leaflets of the outer calix spreading. A native of South America, and the West India Islands,

3. Achania Pilosa; Hairy Achania.-Leaves hairy, obtuse, and acute. The flowers are small, and the corolia closed. It is a native of Jamaica.

Achillea, a genus of the class Syngenesia, order Polygamia Superflua, - GENERIC CHARACTER, Calix, common. ovate, imbricate; scales ovate, acute, converging. Corolla, compound radiate; corollets hermaphrodite, tubular in the disk. Females ligulate, five to ten in the ray. Proper of the hermaphrodite, funnel-shaped, five-cleft, spreading. Female obcordate, spreading, trifid ; the middle cleft less than the others. Stamina, in the hermaphrodites : filaments five, capillary, very short; antheræ cylindrical, tubular. Pistil in the hermaphrodites ; germ small ; style filiform, the length of the stamma ; stigma obtuse, emarginate: In the females, germ small, style filiform, the length of the stamina ; stigmas two, obtuse, reflex. Pericarp, none. Calix, scarcely changed; receptacle filiform, elongate, as the disk of the seeds, ovate, twice the length of the calix. Seeds solitary, ovate, furnished with flocks, but having no down. Receptacle, chaffy, elevated ; chaffs lanceolate, the length of the florets, ESSENTIAL CHARACTER. Calix ovate, imbricate. Florets of the ray, about four. Down, none. Receptacle. chaffy .-- Every species of this genus may be propagated by parting the roots either in spring or autumn. Many of them ripen their seeds, and may therefore be increased that way, by sowing them in March or April, and transplanting them at Michaelmas. They will flower the summer following. Some also will grow from slips or cuttings, planted in a shady border in summer. They are in general hardy, and need little care in the cultivation. Those commonly seen in gardens are, the purple variety of common milfoil, the double variety of common sneezewort, called double ptarmica, and woolly milfoil. Whatever merit the Alpine sorts may possess as medicines, it cannot answer to cultivate them with that view in gardens, for they owe their efficacy to their peculiar situation: but they who are desirous of having them for variety, will find that they are very hardy, and will thrive almost in any soil, but that they love an open exposure .-The species are,

* With yellow Corollas.

1. Achillea Santolina ; Larender cotton-leaved Milfoil. Leaves bristle-shaped, toothed; toothlets nearly entire, subulate, reflex .- The leaves of this plant are like those of lavender cotton, which, when rubbed, emit a strong oily odour. It flowers in June and July, and is an inhabitant of the Levant.

2. Achillea Ageratum; Sweet Milfoil, or Maudlin. Leaves lanceolate, obtuse, sharply scrrate .- This plant is a native of Italy, and of the road-sides in Spain. It was brought into England in 1570, but being now seldom used in medicine, it is not cultivated in the gardens for sale; or if asked for, the market people give the thirteenth sort (see Achillea Alpina, No. 13 of this genus) which is a hardier plant and more easily propagated: for though the sweet maudlin will bear cold well, yet wet winters often kill the roots in good ground; although when the plants grow out of the joints of a wall, or in rubbish, they will live many years without care. It has a sweet smell, a bitter taste, and is aromatic. Linneus calls sneeze-wort, and appear in June and July. The leaves are 5.

Allione recommends it in all it obsolete and superfluous. disorders of the nerves, and prefers it before tansy. Culpepper commends it as a *diuretic*, and says that the seeds, as well as an infusion of the flowers in white wine, are excellent for the worms in children, when given in two ounces per dose. Meyrick and Hill agree that "the whole plant has a pleasant smell, and may be used either fresh or dried, but is most efficacious in its recent state. A strong infusion of it, taken for a length of time, is good in obstructions of the liver, and considerably increases the dis juarge by urine.

ACH

3. Achillea Falcata; Sickle-leaved Milfoil. Leaves linear, toothed, obtuse, flat; toothlets crenate.-This species is a native of the East, and is there used in medicine,

4. Achillea Tomentosa; Woolly Milfoil. Leaves pinnate, hirsute; pinnas linear, toothed .- This plant is about a foot high, its whole flower is of a fine vellow colour, with a pleasant aromatic smell. It is often planted in gardens for the sake of variety, as the flowers retain their beauty for a long time. It grows naturally in Spain, the south of France, the Valais, and Italy; but bears the open air very well in England.

5. Achillea Pubescens; Downy Milfoil. Leaves pinnate, leaflets lanceolate, gashed; serrate, wool-bearing beneath. -This plant is a native of the Levant. It has no chaffs tothe receptacle, and in that respect differs from the generic character. This and the following species are easily propagated and cultivated both by roots and seeds ; they are sufficiently hardy to endure the open air, and when intermixed with other plants, form a pleasing diversity by their hoary leaves; and as their flowers are of long continuance, they produce an agreeable coutrast, though not remarkable for beauty in themselves.

6. Achillea Abrotanifolia; Southernwood-leaved Milfoil. Leaves pinuate, super-decompound, divisions linear distant .----It is a native of the Levaut, and flowers in June and July. For the propagation and cultivation of this plant, see the preceding species of this genus.

7. Achillea Bipinnata ; Bipinnate Milfoil. Leaves bipinnate, tomentose, leaflets ovate, eutire .--- A native of the Levant.

8. Achillea Ægyptiaca; Egyptian Milfoil. Leaves pinnate; leaflets obtusely lanceolate, servate toothed .- This plant, which is also a native of the Levant, rises from nine inches to a foot in height. It has finely-cut silvery leaves, which remain all the year; and the plant growing close and low, makes a pretty appearance at all seasons. The flowers appear from Junc to September, and some of them frequently continue the greatest part of the winter. It rarely perfects seeds in England, and is therefore propagated by slips. In a dry soil and a warm situation, it will endure the cold of our ordinary winters in the open air : but being often destroyed in very severe flosts, a few plauts ought to be sheltered under a frame.

* Corolla white in the ray.

9. Achillea Macrophylla; Feverfew-leaved Milfoil. Leaves pinnate, pinnas gash-serrate, the outmost larger, and connected; has many stalks which rise near three feet high, with loose branching corymbs of white flowers, like those of the common sneeze-wort, which they also resemble in smell, but are much pleasanter .- It is a native of the Alps, very hardy, thrives in almost any soil, but loves an open exposure ; flow-

ers in July and August, and deserves a place in gardens. 10. Achillea Impatiens; Impatient Milfoil. Leaves pinnate; pinuas distant, linear lanceolate, acute from the base upwards .- This species is frequent throughout Siberia.

11. Achillea Clavenuze ; Silver-leaved Milfoil. Leaves jagged, flat, obtuse, tomentose .- This plant scarcely rises six inches in height, its flowers resemble those of the common

53

very hoary, something like those of the common wormwood, | it. It is hardy, will thrive with us in almost any soil, and growing close to the ground, and decaying in autumn. It is a native of the Alps, of Switzerland, Austria, Pannonia, and Carinthia. As it never perfects its seeds in England, it is propagated by slips; which should be planted in a dry soil, because much wet in winter will cause it to rot.

12. Achillea Ptarmico ; Sneeze-wort Milfoil. Leaves lanceolate, acuminate, finely serrate .- It grows two feet high, is found wild in all the temperate parts of Europe, and in England in meadows, by the sides of ditches, on the balks of cornfields, in moist woods and shady places. It grows two feet high, has daisy-like flowers, and narrow dentated leaves, from the form of which it is sometimes called goose-tongue. The roots have a biting acrid taste, and so likewise have the young leaves; these, powdered and snuffed up the nose, excite sneezing, and are excellent in inveterate head-aches. A piece of the dried root held in the mouth soon fills it with rheum, and removes the tooth-ache, in the same manner as pellitory of Spain. The young tops are pleasant in the spring, when they are eaten as a salad, and reckoned wholesome. In Siberia a decoction of the whole herb is said to be used with success in internal hemorrhages. When planted in pots so as to confine the roots from creeping, the stalks will grow closer together, and then it makes a tolerable appearance when flowering, which takes place in July and August.

13. Achillea Alpina; Alpine Milfoil. Leaves lanceolate, tooth-serrate, toothlets very finely serrate .--- It is very nearly allied to the preceding species, which it somewhat resembles, but it has longer leaves, more deeply cut on their edges, and of a darker green. It is very hardy, and a native of Switzerland, Savoy, and Siberia.

14. Achillea Serrata; Notch-leaved Milfoil. Leaves linearlanceolate, sessile, tomentose, deeply serrate, jagged at the base.-The flowers resemble those of *sneeze-wort*. They appear in August and September.

15. Achillea Cristata; Slender-branched Milfoil. Leaves linear serrate; serratures transverse crested; stem branched, weak .--- It is a native of the east, and flowers here in July and August.

16. Achillea Atrata; Camomile-leaved, or Black Milfoil. Pinnules comb-like, almost entire, peduncles villous .-- This plant is found on the mountains of Switzerland, the Valais, and Austria. It was introduced by Drs. Pitcairn and Fothergill in 1774, but will not admit of cultivation, nor can be reconciled to a garden whatever pains you take with it.

17. Achillea Moschata; Musk Milfoil, or Swiss Genipi. Leaves pinnate, dotted ; pinnas remote, linear, subulate, almost entire ; rays the length of the calix. This can only be distinguished from the preceding species by its aromatic smell. It is the true genipi of the Swiss, though called genipi batard in Savoy. This plant promises to be of essential efficacy in disorders arising from a debility of the solids ; it is an excellent sudorific, though hot, and frequently injurious in the pleurisy when the fever is high; and it is also a grateful food to all sorts of cattle. Hill says, " the seed is the only part used, and that very rarely." It is said to be good against the head-ache, but we seldom meet with it fresh enough to have any virtue. It is found wild in Switzerland, on the high Alps, and in Savoy, Piedmont, and Austria.

18. Achillea Nana; Dwarf Milfoil. Leaves pinnate, toothed, extremely hirsute, flowers glomerate-umbelled .--- It is a very small plant, and has a fainter smell than the preceding species, for which it is often sold. It grows on the high Alps of Switzerland, the Valais, and Savoy ; and Allione observes, that the higher and colder the situation in which it s found, the thicker is the tomentum or flock which covers Alps.

deserves a place in gardens.

19. Achillea Magna; Great Milfoil or Yarrow. Leaves bipinnate, rather hairy, the divisions linear and toothed ; earlets decussated .- It is a native of Italy, hardy, and requires little culture.

20. Achillea Millefolium; Common Milfoil, or Yarrow. Leaves bipinnate-naked, divisions linear-toothed, stems furrowed towards the top .- This plant has been generally execrated as a noxious weed in pastures : sheep, however, are found to eat it ; and Anderson has even recommended it for cultivation. It is frequently found in our meadows, pastures, and by road-sides. It flowers in June, and the following summer months, until September. It creeps greatly by its roots, and multiplies by seeds, so that it is a troublesome weed in gardens. There is a variety with purple flowers, which are apt to lose their colour by cultivation. The whole plant is used fresh gathered, but the best part is the tops of the shoots; these are to be boiled in water, and the decoction sweetened with fine sugar: though generally neglected, it is an excellent medicine in the overflowing of the menses, bloody fluxes, and bleeding of the piles. It increases the urinary discharges, and removes ulcers of the kidneys or urethra. Sir John Hill says, "the best way of taking it, is in strong decoctions of the whole plant." Linneus recommends the bruised herb fresh, as an excellent vulnerary and styptic, and many foreign physicians still esteem it in hemorrhages. An ointment is made of it for the piles, and it is reckoned good against the scab in sheep. An essential oil is extracted from the flowers, but the plant is excluded from the present medical practice.

21. Achillea Nobilis; Noble Milfoil. Leaves bipinnate, the lower one naked, flat; the upper obtuse, tomentose; the flowers in convex and very crowded corymbs .--- This strongly resembles the common milfoil, but its leaves are not so long or so much cut, they have a pale green colour, and a strong sweet scent when bruised. This scent, as well as its other qualities, are stronger than those of the preceding species. It is a native of Italy, Germany, Switzerland, Narbonne, and Tartary.

22. Achillea Odorata ; Scented Milfoil. Leaves bipinnate, oval, almost naked, corymbs fastigiate, crowded .- Its stem is scarcely a palm in height: it is a native of Spain, Narbonne, Switzerland, &c.

23. Achillea Cretica ; Cretan Milfoil. Leaves linear, pinnas roundish, imbricate, backwards, stem tomentose .- It is, as its name imports, a native of the island of Crete.

24. Achillea Squarrosa; Rough-headed Milfoil. Leaves lanceolate-linear, pinnatifid, pinnas ovate, wedge-shaped, gash acuminate, vertical, stem somewhat villous .- It was introduced into England in the year 1755.

25. Achillea Herbarota; Herbarota Milfoil. Leaves wedgeshaped, entire, toothed at the top .- The whole plant is green, and has a strong smell, like maudlin. It is in general esteem among the peasants of the Alps, and is recommended as a sudorific, against worms, flatulencies, and intermittent fevers.

26. Achillea Ligustica; Marjoram-scented Milfoil. Leaves pinnate, pinnas sharply-toothed, flat, smooth .--- The stems are eighteen inches high, the leaves rather thick and juicy, and, like the preceding species, it has a very strong smell like maudlin.

27. Achillea Tanacetifolia; Tansy-leaved Milfoil. Leaves pinnate ; pinnas laciniate, flat, gashed, and entire .- The stem of this plant is eighteen inches high : it is a native of the Grisons, and not uncommon in the pastures and valleys of the

Achras, a genus of the class Hexandria, order Monogynia. -GENERIC CHARACTER. Calix, perianth six-leaved ; leaflets ovate, concave, erect; outer broader, shorter: inner coloured. Corolla, one-petalled, ovate, of the same height with the calix ; border cut into six subovate flat divisions ; scales at the jaw of the corolla, equal in length to the divisions, narrower, spreading, emarginate. Stamina, filaments short, awl-shaped, at the jaws of the corolla, alternate with the divisions bent inwards; antheræ sharp, Pistil, germ roundish, flatted; style awl-shaped, longer than the corolla. Stigma obtuse. Pericarp, a globose very succulent pome, with twelve cells. Seeds solitary, ovate, shining, scarred on one side, and pointed at the base. ESSENTIAL CHARACTER. Calix, six-leaved. Corolla ovate, sexfid, with six scales, alternate, more within. Pome ten-celled, seeds solitary, with a scar on the edge, and a tail or a process at the top.—The trees of this genus are natives of very warm countries, and cannot be preserved in England unless they are placed in the warmest stoves, and managed with great care .---- The species are.

1. Achras Mammosa; Mammee Sapota .- This has a sixth part less in the parts of fructification, than the other species of this genus. It is also called nippled sapota, or American marmelade; it grows in America, to the height of thirty-five or forty feet, having a straight trunk covered with an ashcoloured bark. The flowers are cream-coloured, and are succeeded by large oval or top-shaped fruit, covered with a brownish skin, under which is a thick pulp of a russet colour, very luscious, called natural marmalade, from its resemblance to marmelade of quinces. This tree is commonly planted in gardens for the fruit, in Jamaica, Barbadoes, Cuba, and most of the West India islands. It is esteemed one of the best timber trees in Jamaica. The bark of this and the following species is very astringent, and is called Cortex Jamaicensis, or Jamaica bark. It is an excellent astringent, but very different from the Jesuits' bark, for which it was mistaken, and given to the negroes, with very ill effect, and has been also tried in England. There is a wild mammee, which bears a fruit of no value, but the tree is straight, tall, and tough, and therefore principally used for masts.

2. Achras Sapota; Common Sapota. Flowers solitary, leaves hanceohate-ovate.—A large, tail, straight tree, without knots or branches, for sixty or seventy feet or more. The fruit, which is wholesome, tastes and smells well; it is larger rough stones, each bigger than a naimond, in the middle; the kernels of which are bitter, and may be used in strengthening emnlisons. This tree is larger and taller than the preceding species.

3. Achras Dissecta; Cloven-flowered Sapota. Flowers rowded, corollas cloven into eight parts, leaves obvate, blundy notched at the end.—This is a lofty tree, with a thick upright trunk. The flowers are white, and all its herbaccons parts milky. In Malabar it is cultivated for the fruit, which is succulent, and of a sweetish acid flavour. The leaves of ginger, are used for cataplasms to tumors. It is supposed to be a native of the Philippine Islands, and also to grow in China; Forster found it flowering in September upon the sistend of Tongataba.

4. Achras Salicifolia; Willow-leaved Sopata. Flowers crowded; leaves lanceolate ovate, acuminate.—This species is called the White Bully-rec, or Galimeta-wood, in Janaica, where it grows to a considerable height, commonly straight and tapering, and most frequently found in the tower lands. The wood is pale yellow, and reckonel good timber, but is

mostly used in such parts of the building as are least exposed to the weather.

Achyrenthes, a genus of the class Pentandria, order Mongynia.-GENREI CHARACTER. Periatin outer, threeleaved, hanceolate, acute, permanent; inner five-leaved, permanent. Carolla, none. Nectary of five valves, surrounding the germ, bearded at the top, concave, caducous. Stamina, filaments filioferm, the length of the corolla. Autherse ovate, incumbent. Pistilla, germ superior, turbinate. Style filiform, the length of the stamina. Stigma bifd, villous. Pericarp, capsule roundish, one-celled, not gaping. Seed single, oblong. ESSENTIAL CHARACTER. Calix, five-leaved. Corolla, none. Stigma bifd. Seeds solitary. These plants have not much beauty to recommend them, they are preserved in botanic gardens, and the greater number must be placed in a stove, to preserve them through the winter.— The species are,

1. Achyranthes Aspera; Rongh Achyranthes, Stem shrubby, erect; calicse relex, pressed to the spike. It is found in Sicily, Malabar, Ceylon, Jamaica, and almost every where within the tropics.—It has been long known in England, and may be raised on a hot-bed from the seeds; and when the plants have acquired strength, they may be removed into the full ground, where the flowers will appear in July, and the fruit in September. If kept in pots, set into a warm greenhouse in winter, they will be two or three years.

 Achyranthes Lappacea; Bnrry Achyranthes. Stem shrubby, diffused, prostrate; spikes interrupted; lateral flowers having a bundle of hooked bristles on each side.—It is a lofty plant, native of Malabar and Ceylon.

3. Achyranthes Muricata; Prickly Åchyranthes. Stem shrubby, patulous; leaves alternate; flowers in remote ovate spikes; calices squarrose.—It is a native of India.

4. Achyranthes Patula; Spreading Achyranthes. Stem shrubby, patulous, pubescent; flowers in orbicular spikes, hedgelog-hooked.—This plant is three feet high. In a state of sleep, the opposite leaves are bent down under the branch, and approximate to the under surface. A native of the East Indies.

5. Achyranthes Alternifolia; Atternate-leaved Achyranthes. Stem herbaceons, erect; flowers in sub-globular burrs. Two stigmas; germ globose. Style purple,—A native of the East Indies.

6. Achyranthes Corymbosa ; Corymbed Achyranthes. Leaves fourfold, linear; panicle, dichotomous corymbed.— This herb is a foot in height, its stem is round and jointed. A native of Ceylon.

7. Achyranthes Dichotoma; Dichotomons Achyranthes. Stems suffruticose, leaves opposite, linear, flat, acute; cyme dichotomous.—It resembles the preceding species, and is a native of Virginia.

8. Achyranthes Prostrata; Prostrate Achyranthes. Stems prostrate, shrubby; spikes oblong; floscules in pairs, with a hooked fascicle on cach side.—The stems of this species are often creeping. It is a native of India.

 Achyramthes Nivea; White Achyramthes. Leaves verticilated, ovate, tomentos; corymls compact, dichotomous; flowers corolled.—This species, which will live in a greenhouse, was introduced into England in 1780, from the Canary Islands. It Howers from May to July.

10. Achyranthes Altissimä, Tall Achyranthes. Sten suffutiose, scandent; panicles terminating and axillary, branched.—The stalks of this species climb up trees to the height of twenty feet. Browne calls it Bastard Hosp-reithe. It is common among low bushes about Spanish Town and Kingston in Jamica, and in the wools of St. Domingo.

11. Achyranthes Polygonoides; Many-cornered Achy-

ACO

date; spikes lax, short; the stems are frequently eighteen inches high .- It is a native of Arabia.

Acia, a genus of the class Monadelphia, order Dodecandria. -GENERIC CHARACTER. Calix, perianth one-leaved, turbinate, curved ; border five-parted, parts roundish, spreading ; the uppermost and two lowest larger; the two middle ones smaller. Corolla, petals five, oblong, rounded; the three upper longer, ascending ; the two lower, shorter. Stamina, filaments twelve, unequal, uniting at bottom in a linear fleshy incubrane, inserted into the calix between the two smaller Antheræ roundish, small. Pistil, germ ovate, petals. above the base adhering by the membrane of the stamina, to a rib internally prominent from the bottom of the calix. Style filiform, curved; stigma, acute. Pericarp, drupe ovate, fibrous, chinked, large. Seed nut-ovate, with a brittle shell. ESSENTIAL CHARACTER. Calix five-parted. Co--Species,

1. Acia Gnianensis; the Guiana Acia .-- Is a tree with a trunk sixty feet in height, and three or four feet in diameter. covered with a smooth gray bark. The fruit is of the size of a walnut, covered with a thick, woody, fibrous, coriaceous skin, of a brown colour, cracking irregularly, and adhering to the stone, which is thin, and easily breaks. It incloses a large kernel of an irregular form, dividing into two parts. The creoles at Cayenne eat it when brought to market in August ; they reckon it good fruit, and extract an oil as sweet as that of almonds from it : they call the tree Coupi. The wood is hard and heavy, of a white colour inclining to yellow.

Acidoton, a genus of the class Monœcia, order Polyandria. -GENERIC CHARACTER. Male flowers; calix, perianth five-leaved ; leaflets ovate-lanceolate, reflex. Corolla, none. Stamina, filaments numerous, thirty-five to forty, placed on a globular receptacle; the outer shorter, the inner longer. Antheræ cordate-ovate, upright, small. Females on the same or a different tree. Calix, perianth six leaved; leaflets linear lanceolate, spreading. Corolla, none. Pistil, germ three-cornered. Style short, acute, thick, trifid at the top. Stigmas tomentose, reflex. Pericarp, capsule three-grained, hirsute, three-celled. Seeds solitary, ovate. ESSENTIAL CHARAC-Male calix, five-leaved. Corolla, none. Stamina TER. fixed to a globular receptacle. Female calix, six-leaved. Corolla none. Style trifid. Capsule three-grained .---- Species,

1. Acidoton Urens .- It is eight or nine feet high, trunk round, straight, and woody, the size of the little finger, covered with a smooth brownish bark. This plant, described by Sloane, seems to have been young, as he never saw either flower or fruit. A native of Jamaica.

Acedoton. See Adelia.

Acynos. See Thymus.

Acuida, a genus of the class Pentandria, order Dicecia .--GENERIC CHARACTER. Male calix, perianth five-leaved ; leaflets ovate, concave, acute, membranaceous on the edge. Corolla none. Stamina, filaments five, capillary, very short. Antherae versatile, bilocular, forked each way. Female calix, involucre many-leaved, linear, deciduous. Perianth twoleaved, linear, very small, permanent. Corolla none. Pistil, germ superior, ovate. Styles five, long, reflex, pubes-cent. Stigmas simple. Pericarp, fruit ovate, compressed, many-angled, furrowed, covered with the succulent calix. Seeds solitary, round, compressed. ESSENTIAL CHARAC-TER. Male calix, five-leaved. Corolla none. Female calix two-leaved, Corolla, noue. Styles five. Seed one, covered with the succulent calix .----- Species.

ranthes. Stem decumbent, four-cornered; leaves ovate-cor- naturally in Virginia, and in some other parts of North America, but is rarely cultivated in Europe, except in some few botanic gardens. It is near of kin to hemp, but there is little beauty in it, and hitherto no use has been made of it.

Aconite, Winter. See Helleborus.

Aconitum, a genus of the class Polyandria, order Trigynia. -GENERIC CHARACTER. Calix, none. Corolla. petals five unequal, opposite, in pairs. 1. The highest helinet-tubed, inverted, the back upwards, obtuse, the top reflected to the base, acuminate, to which top the connecting base is opposite. 2, 3. The two lateral ones broad, roundish, opposite, converging. 4, 5. The two lowest oblong, pointing downwards. Nectaries two, concealed under the first petal, fistulous, nodding; mouth oblique, tail recurved, sitting on long subulate peduncles. Six little, very short, coloured scales, in the same circle as the nectaries. Stamina, filaments subulate, very small, broader at the base, inclining towards the first petal. Antheræ erect, small. Pistil, germs three, (five) oblong, ending in styles the length of the stamina. Stigmas simple, reflex. Pericarp, capsules as many as the styles, ovate-subulate, straight, one-valved, gaping inward. Seeds very many, angular, wrinkled. ESSENTIAL CHARACTER. Calix, none. Petals five, the highest arched, shaped like a hood or helmet. Nectaries two, peduncles recurved. Capsules three or five .- All the species of this genus may be propagated by seeds, which, if sown in a shady situation during autumn, will appear in the following spring. The ground must be kept free from weeds, and the plants watered in dry weather, for the first year, when they may be transplanted to where they are intended to remain; all the attention they will there require, is, to cut down the stalks in autumn, after they have done flowering. They are all hardy perennials, require little care or culture, and, having most handsome spikes of spacious flowers, are very desirable plants for shrub-beries and wilderness quarters.-----The species are,

* With three Capsules.

1. Aconitum Lycoctonum: Great yellow Monk's Hood, or Wolf's-bane. Leaves palmate, multifid, villous. The stem is eighteen inches high or more, very little branched, and leafy .- It is reckoned among the carliest spring flowers of Sweden, where a decoction of the powder of the root is used for destroying flies and other insects. Liuneus says, it is eaten in Medelpadia, a province of Sweden, without injury. It seems, indeed, to be milder than some of the other species, and hence goats and horses are said to eat it. It was cultivated here by Gerard, in 1596. The mountains of Switzerland, Germany, Austria, Carniola, Italy, and Siberia, produce it in a wild state.

2. Aconitum Japonicum ; Japanese Monk's Hood. Leaves trifid palmate; divisions gashed, blunt. The stem is round and smooth, and the spike of flowers short .- It is a native of Japan, and is there called Soo Haso.

3. Aconitum Napellus; Common Monk's Hood, or Wolf'sbane .- Divisions of the leaves linear, broader above, and scored with a line. This species has the root simple, woody, tuberous, unequal; stem erect, firm, covered with leaves eighteen inches high. This plant is allowed on all hands to be a most deadly poison, a criminal having been put to death by taking one drachm of the root. It has nevertheless been so subdued as to become a powerful remedy in some of the most troublesome disorders incident to the human frame. Baron Stoerck began by administering it in violent pains of the side and joints, in glandulous schirrhi, tumors, ulcerous tubercles of the breast, &c. to the quantity of from ten to thirty grains in a dose, of an extract made with 1. Acnida Cannabina; Virginian Hemp .- This plant grows the juice of this plant by a gentle evaporation, and then

ACR

adding two drachms of lump sugar, in powder, to two grains of the extract. Its principal sensible effect was in exciting a copious perspiration. A much larger dose has also been safely administered, but it is recommended to begin with a small quantity. Dr. Murray asserts its chief virtue to be in rhenmatic and other chronic disorders, for which the above extract is the best preparation. It is said to have been serviceable in confirmed venereal cases, and even to have discussed nodes, and cured obstinate ulcers. Its efficacy in the gutta serena has been commended, but probably not with such certainty as in the fore-mentioned disorders. Those which have blue flowers are said to be more potent than those which are vellow or white. It blows in August, and would deserve a place in every garden, were it not for its dangerous nature. The variety of this species, is the most common in our English gardens, being cultivated for the specious appearance of its long spikes of blue flowers. It grows nearly four feet in height, the spikes are above two feet long, and being very hardy, growing in any soil or situation, and multiplying greatly by its roots; it has been allowed a place in most gardens and plantations of shrubs. It ought, however, to be admitted with caution where children and ignorant persons frequent. It flowers in May and June, and the seeds ripen in September.

4. Aconitum Pytenaicum; Pytrenean or Fennel-leaved Monk's Hood or Wolfs-bane. Leaves many-parted, divisions linear, incumbent, and squarrose.—This plant grows wild on the Pyrenese, in Tartary, and Siberia. The spike nods before the time of dowering, which in our gardens is in July; it attains to four feet high, and has a long spike of yellow flowers of a middling size. It may be allowed a place among shrubs, or such parts of a garden as are not frequented by children.

* With five Capsules.

5. Aconitum Anthora; Salutary Monk's Hoad. Flowers with five pistilla; divisions of the leaves, linear.—This plant, though absurdly called Salutary Monk's Hoad, is only poisonous in a less degree than the rest of the same genus. It was supposed to be a remedy against poison, particularly that of the other Aconites; but that dangerous error is now happily exploded. The taste of the root is sweet with a mixture of bitterness and acrimony. The smell is pleasant. It purges vehemently when fresh, but loses its qualities when drived; it is not used in modern practice. Its native places are, the Alps of Switzerland, Savoy, Piedmont, Dauphiny, Austria, Carniola, Siberia, &c.

6. Acconitum Variegatum; Variegated, or Small Falue Monk's Hood. Flowers with five pistills; divisions of the leaves parted half way, broader above.—This species seldom grows more than two feet high. The corollas will change from variegated to plain; it flowers at the end of June, and is a native of Italy and Bohemia.

7. Aconitum Album; White Wolfs-hane, or Monk's Hoad. Howers with five pistila; leaves smooth, three-parted, segments acutely gashed, the claw of the upper petal longer than the side ones.—It is rare in Europe, was brought from the Levant, and is characterized by Mr. Miller as having a tall stem upwards of six feet high, palmate leaves, and large white flower.

 Aconitum Cammarum; Purple Monk's Hood, or Wolf'sbane. Flowers mostly with five styles, divisions of the leaves wedge-shaped, gashed, acute.—It is found wild in Switzerland, Austria, Stiria, Piedmont, &c.; and generally has a stem six feet high.

 Aconitum Uncinatum ; American Monk's Hood, or Wolf's-5. bane. Flowers mostly with five styles, leaves many-lobed, helmet extended very far.—It is a native of Pennsylvania.

Acorus, a genus of the class Hexandria, order Monogynia. —GENERIC CHARACTER. Calie: spatial cylindric, eultrely simple, covered with floscules. Spathe none. Perianth none, concave, loose, thicker at the top, and in a manner truncate. Stamina : filament thickish, a little longer than the corolla. Anthere thickish, twin, terminal, adnate. *Pistilla* : germ gibbous, rather oblong, the length of the stamina. Style none. Stigma, a prominent point. *Pericarp*, a short triangular capsule, attenuated to both ends, obtuse, three-celled. Seeds many, ovate, oblong. ESENTIAL CHARACTER. Spadix eylindric, covered with floscules. Corollas five-petalled, naked. *Studenne*. Capsude three-celled. —Thespecies are,

1. Acorus Calamus; Common Succet Rush. The point of the scape very long and leafly.—This species is distinguished by its long sword-shaped leaves; it has a strong aromatic smell, and a warm, pungent, bitterish taster. The flavour is greatly improved by drying them. The roots are said to have cured agues when the Peruvian bark has failed. No cattle whatever will eat this plant, which grows naturally on the banks of rivers, and in shallow standing waters. It is found wild in many parts of England, grows plentifully in the dyses of Holland, and is common in many other parts of Europe. This plant will succeed very well in a garden if the grown the water. It continues flowering from June till Argust, and multiplies itself fast by creeping roots.

2. Acorus Gramineus; Grass-leaved Sweet Tush, or Chinese Sweet Grass. The point of the stalk searcely extending beyond the top of the spadix.—The whole of this herb has an aromatic smell, for the sake of which it is cultivated. It is probably a native of China, as the Chinese frequently have it in pots about their habitations. It flowers in the spring, must be kept in a dry stove, and does not require a great degree of heat.

Acroatichum, a genus of the class Cryptogamia, order Filees,--GENERIC CHARACTER. The fractifications cover the whole under surface of the frond. Few of these species have yet been introduced into gardens. Those of Europe may be either preserved in pots filled with gaved and lime rubbish, or planted on walls and artificial rocks: but most of them being natives of very hot climates, must be planted in pots, and plunged into the bark pit.

* Frond simple, undivided.

1. Acrostichum Lanceolatum. Fronds linear-lanceolate, acute; shoot climbing.—It is a native of the East Indies and Cochin-China, where it adheres to trees.

2. Acrostichum Citrifolium; Fronds lanceolate-ovate, quite entire, shoot climbing.—A native of America.

 Acrostichum Heterophyllum. Fronds_quite entire, smooth, petiolate; barren ones roundish; fertile linear.— It is found in the woods of the East Indies, Cochin-China, and Africa.

4. Acrostichum Crinitum. Fronds ovate, obtuse, hirsute, crinite above.

 Acrostichum Punctatum. Fronds heart-tongued, acuminate, quite entire, dotted above.—'This species very nuch resembles *Hart's-tongue*. It is a native of China, where it is used medicinally.

6. Acrostichum Spicatum. Frond simple, petiolate, lanceolate, attenuated 10 both ends, quite entire; spike terminal, linear.—Found on the island of Mauritius. Q 7. Acrostichum Lingua. Fronds oblong, obtuse, entire, petiolate, shoot creeping, stipe three cornered, villous, erect. —A native of Japan.

ACR

8. Acrostichum Hastatum. Frond simple hastate.-Also a native of Japan.

* Frond simple divided.

 Acrostichum Septentrionale. Fronds naked, linear-laciniate.—This species grows in tufts, at first sight resembling rushy-grass, on clefts of rocks and old walls, in Yorkshire, Westmoreland, Wales, and Scotland.

10. Acrostichum Australe. Stipes naked, quite smooth, dichotomous at top, with five or six subulate rays, and flowering from the sides.—This much resembles the preceding species, but is more silvery; and is found in the isles of France and E.urbon.

11. Acrostichum Pectinatum. Naked, perfectly simple, spike crescent-shaped on one side, ascending compressed. —A native of the Cape of Good Hope.

 Acrostichum Dichotomum. Naked dichotomous spikes on one side, ascending reflex, compressed.—It is a native of China and the Society Islands.

13. Acrostichum Digitatum. Stipes naked, three-sided, frond digitate, linear, quite entire, equal. Stipe linear, a foot high, smooth, contracted at top.—Native of Ceylon.

14. Acrostichum Ferrugineum. Fronds pinnatifid; pinnas linear, acute, spreading, quite entire, connate; stipe smooth. —This strongly resembles the following species.

15. Acrostichum Polypodioides. Fronds pinnatifid, pinnas linear obtuse, quite entire, spreading, crowned, stipe scaly, —This species has the appearance of common Polypody, and is a native of Jamaica and Virginia.

* Frond pinnate.

16. Acrostichum Aureum. Pinnas alternate, tongue-shaped, quite entire, smooth. The stipes of this plant grow in bundles of a very dark rufous colour, smooth, about the thickness of the little finger, and nine feet in height.—It is a native of Jamaica, Dominica, and the Societ Visles.

17. Acrostichum Rufum. Pinnas oblong, ovate, quite entire, pubescent.—It is eighteen or twenty inches high, leafy almost from the root. A native of Jamaica.

 Acrostichum Punctatum. Leaflets, alternate lanceolate, quite entire, the lowest eared, the upper ones decurrent, the upper surface dotted smooth.—It is a native of the island of Bourbon, and strongly resembles the preceding species.

19. Acrostichum Sorbifolium. Pinnas oblong-ovate, entire, serrate, acute, stipes scaly.—It is found in Jamaica and St. Domingo.

20. Acrostichum Areolatum. Pinnas alternate linear, serrate at top.—A native of Virginia and Maryland.

21. Acrostichum Marginatum. Pinnas oblong, quite entire, waved acuminate, stipes naked.—This is said to be only a barren frond of *Pteris Grandifolio*.

22. Acrostichum Sanctum. Fronds lanceolate, pinnas linear-lanceolate, gash-serrate, the lower serratures largest. —This species is a *Polypodium*.

23. Acrostichum Platyneuron. Pinnas alternate-ovate, crenate, sessile, bowed upwards about a palm in height.—This species, which is a native of Virginia, has the appearance of common Polypody.

24. Acrostichum Trifoliatum. Leaflets ternate-lanceolate. —This species is about a foot high, and is a native of Jamaica.

* Frond subpinnate.

25. Acrostichum Siliquosum. Pinnas alternate, pinnulate upwards, linear, the lower ones two-parted.—A native of Ceylon, supposed to be the same with the following species.

26. Acrostichum Thalictroides. Pinnas alternate, on each side pinnatifid, the barreu ones broader.—Supposed to be the same with the preceding species, and is a native of Ceylon.

27. Acrosticlum Marante. Fronds subbipinnate, pinnas oppositely coadunate, very hirsute underneath, a little toothed at the base.—Its stipes are about seven inches in height, sometimes they reach a foot, they are hairy, and of a blood-red colour. Its fronds are like those of common sphere-wort, and it is a native of the southern countries of Europe.

28. Acrostichum Ilvense. Fronds subbipinnete, pinnas oppositely coadunate, obtuse, hirsute underneath, quite entire at the base.—This has a great resemblance to the foregoing, but it is scarcely so long as the finger, and never so high as seven inches. The stipe is green, and not red. It is allied to the Polypodies by having the fructifications in dots, but they are closely crowded. It is found growing upon rocks in the northeric counties of England, in Scotland, and in Wales, and is sold to be antive of Jamaica.

29. Acrostichum Ebeneum. Pinnas sessile, oblong, sinuate, the uppermost shortest and quite entire.—This is only a young plant of the Acrostichum Calomelanos. See species, No. 34. Native of Jamaica.

30. Acrostichum Furcatum. Dichotomous, leaflets pinnate; pinnas parallel-lanceolate, approximating, quite entire.—This species is a *Polypodium*, and is seldom found in flower. Native of Jamaica.

* Frond bipinnate.

31. Acrostichum Aculeatum. Fronds super-decompound, pinnas bifid, stipes prickly.—This is a species of Trichomanes, and a native of Jamaica.

32. Acrostichum Cruciatum. Fronds super-decompound, pinnas bifid, stipes prickly.-- A native of Dominica.

33. Acrostichum Barbarum. Leaflets opposite, pinnas lanceolate, obtuse, serrate, sessile-alternate. Stipes smooth, upright, and two or three feet high.—This species is a native of Africa.

34. Acrostichum Calomelanos. Pinnas alternate-lanceolate, acuminate, pinnatifid. The stipe is black, but the leaves silvery white underneath.—It is a native of South America and Jamaica.

35. Acrostichum Viviparum. Fronds viviparous, pinnas in pairs, one-sided, pinnules pinnatifid, forked, subulate, being the fructifications on the inner margin.—This species is a native of the isles of France and Bourbon.

 Acrostichum Velleum; Woolly Acrostichum.—Fronds bipinnate; all the pinnas ovate, cordate, gashed on the side, and very hirsute underneath.—A native of Madeira.
Acrostichum Simplex. Fronds entire, smooth, peti-

37. Acrostichum Simplex. Fronds entire, smooth, petiolated, the barren ones lanceolate-acuminate, the fertile ones linear-lanceolate.—This species is a native of Jamaica.

38. Acrostichum Petiolatum. Frouds entire, smooth, petioled; the barren ones linear-lanceolate, the fertile ones linear. —Also a native of Jamaica.

39. Acrostichum Latifolium. Fronds petioled, broad-lanceolate, very smooth, entire, margined; the fruit-bearing ones ovate-lanceolate, shoots creeping.—Native of Jamaica.

40. Acrostichum Villosum. Fronds broad-lanceolate, somewhat crenulate, villous on both sides.-It is a native of Jamaica.

41. Acrostichum Muscosum. Fronds petioled, entire, scaly; the barren ones oblong-lanceolate, blunt, the fertile

ACR

Jamaica.

42. Acrostichum Serrulatum. Fronds linear, toothed, fruit-bearing at the tip, shoots very short, rooting.

43. Acrostichum Graminoides. Fronds naked, linear, subdichotomous, and fruit-bearing at the tip .- A native of Jamaica.

44. Acrostichum Sulphureum. Pinnas alternate ovate, pinnatifid; leaflets retuse serrate .- This also is a native of Jamaica.

Actaga, a genus of the class Polvandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth, four-leaved, leaflets roundish, obtuse, concave, caducous. Corolla: petals four, acuminate to both ends, larger than the calix, caducous. Stamina: filaments usually about thirty, capillary, broader at top. Antheræ roundish, twin, crect. Pistilla : germ superior, ovate; style none; stigma thickish, obliquely depressed. Pericarp: a berry oval globose, smooth, onefurrowed, one-celled. Sceds : very many, semiorbicular, lying over each other in two rows. ESSENTIAL CHARACTER. Calix four-leaved. Corolla four-petalled. Berry one-celled. Seeds semiorbicular in two rows. These plants may be propagated by seeds, which should be sown on a shady border soon after they are ripe, where they can be obtained fresh; for if they are kept out of the ground till spring, the plants will not appear till the year after. As they seldom come all up at the same time, the border should not be disturbed till the following autumn, when they should be transplanted to another shady border, where they may remain to flower. -The species are,

1. Actaea Spicata; Common Black-berried Herb Christopher, or Bane-berry .- Raceme ovate, fruits berried .- This species grows naturally in several places in the north of England. It rises two feet and an half high. It flowers in July, and in autumn ripens its fruits, which are black and shining, about the size of pcas, and very poisonous. Indeed the whole plant is of an acrid and poisonous nature, and therefore though a powerful repellant, and having a root useful in some nervous cases, must be administered with caution. The juice of the berries mixed with alum yields a black dye. Toads seem to be allured by the smell of this plant; but Dr. Withering observes, that this may be owing to its fondness for the same damp shady situations as the toad. There are two varieties of this species, one an American plant with white berries; the other of British origin, and being only distinguished from the rest of the same species by its berries being red instead of black.

2. Actaea Racemosa; American Black or Wild Snake-root. Racemes very long; fruits dry .- The root of this plant is much used in America in many disorders, and is supposed to be an antidote against poison and the bite of the rattlesnake. It is a native of North America, where it is called Black Snake-root, to distinguish it from Common Snake-root. The seeds are annually sent to Europe, and should be sown as soon as the season will permit. It flowers in June, or early in July, but does not perfect seed in England. During the flowering time it makes a good appearance in a garden; and therefore deserves a place in shady borders, or among shrabs, where, if it be not overhung by them, it thrives well, and being hardy, will only require the same care as the shrubs themselves.

3. Actaea Japonica; Japanese Herb Christopher .- Spikes very long; leaflets gashed, palmate, undivided.

4. Actaa Aspera; Rough-leaved Herb Christopher. Stem climbing, leaves lanccolate, rough ; spikes interrupted .- This species is a native of Canton, near China; and its leaves

ones linear-lanceolate .- This species also is a native of being extremely rough, the Chinese use them for polishing, particularly tin-ware.

ADAM'S NEEDLE. See Yucca.

Adansonia, a genus of the class Monadelphia, order Polyandria .- GENERIC CHARACTER. Calix: perianth oneleafed, semiquinquefid, cyathiform; divisions revolute, deciduous. Corolla: petals five, roundish, nerved, revolute, connected by the claws with each other and the stamina. Stamina: filaments united at bottom into a tube, which they crown, expanding horizontally. Antheræ kidney-shaped. Pistilla: germ ovate, style very long, tubulous, variously intorted. Stigmas many, (ten) prismatic, villous, radiate, expanded. Pericarp: capsule ovate, woody, not gaping, ten-celled, with farinaceous pulp, the partitions membranaceous. Seeds numerous, kidney-shaped, rather long, involved in a friable pulp. Observe : This genus is very nearly allied to Bombax; the fructification differing only in the seeds being covered with meal instead of wool or cotton. ESSENTIAL CHARACTER. Calix simple, deciduous. Style very long. Stigmas many. Capsule woody, ten-celled, with farinaceous pulp, and many seeds. This genns is propagated by seeds, which it does not produce in Europe. They must be sown in pots, and plunged into a hot-bed, where they will appear in about six weeks; and soon after be fit to transplant. which should be done, and each removed into a separate pot filled with light sandy earth, and put into a fresh hot bed, observing to shade them until they have taken root, after which they should have free air every day in warm weather. They reach to the height of six feet, and some have even attained to twelve and fifteen feet, but they cannot with us endure the open air .---- The species are,

1. Adansonia Digitata; Ethiopian Sour Gourd, or Monkies' Bread .- This tree was found in Africa of the amazing size of from sixty fire to seventy-eight feet in circumference, but their height was not extraordinary, only from twelve to fifteen feet. The fresh fruit is very pleasant, of an acid flavour, and is eaten with sugar. The pulp or juice mixed with sugar, or a syrup made of it, is used in putrid and pestilential fevers. At Cairo they reduce this pulp to a powder, and use it in the lientery, dysentery, and all sorts of fluxes.

ADDER'S-TONGUE. See Ophioglossum.

Adelia, a genus of the class Diœcia, order Monadelphia. -GENERIC CHARACTER. Male. Calix: perianth oneleafed, three-parted; leaflets oblong, curved back. Corolla none. Stamina : filaments many, capillary, the length of the calix, united into a cylinder at the base. Autheræ roundish. Female. Calix : perianth five-parted ; parts oblong, permanent, Corolla none, Pistil: germ roundish, Styles three, very short, divaricate, stigmas torn. Pericarp: capsule tricoccous, roundish, three-celled. Seeds solitary, roundish. ESSENTIAL CHARACTER. Male. Calix threeparted. Corolla none. Stamina many, united at the base. Calix five-parted. Corolla none. Styles three Female. torn. Capsule tricoccous. The plants of this genus are propagated by seeds, which they do not produce of good quality in England. As the flowers are of little beauty, the plants are seldom found except in Botanic gardens .----- The species are,

1. Adelia Bernardia; Villous-leaved Bernardia. Leaves oblong, tomentose, serrate .- It grows naturally in the island of Jamaica, and is near of kin to the Croton.

2. Adelia Ricinella; Smooth-leaved Bernardia. Leaves obovate, quite entire.- This species grows to the height of eight or ten feet, and has slender flower-stalks, Native of Jamaica.

3. Adelia Acidoton; Box-leaved Adelia. Branches flexu-

ADI

ose, spines genmaccous.—It seldom rises above four feet in pedate; leaflets pinnate; pinnas gibbous before, gashed, fruitheight, and has much the appearance of a young ebony, It flowers in June with us; and in Jamaica, of which it is a naitve, early in April and May.

Advanthera, à genus of the class Decandria, order Monogvina.--GENERIC CHARACTER. Cali:: periantl onelealed, five-toothed, very small. Corolla: five petalled, veilshaped; petals lanceolate, sessile, convex inwards, concave underneath. Stamina: filaments subulate, creet, a little shorter than the corolla. Antileræ roundisk, incumbent, leaving a globoos egland at the outer tip. *Pistil:* germ oblong, gjibbons downwards. Style subulate, the length of the stamina. Stigma simple. *Pricarap:* a legume, long, compressed, membranaceons. *Nedis* very many, roundish, renote. ESENTIAL CHARACTER. Calis five-toolhed. *Pathere.*, Legume membranaceons.-- Species,

1. Adenanthera Pavonina; Leaves smooth on both sides .-This is one of the largest trees in the East Indies, and the timber is in common use on account of its solidity. It flowers in September, bears fruit at the beginning and end of the year, and is never without leaves. Its duration is two hundred years. The natives use the powder of the leaf in their ceremonies, and of the bruised leaves they make a drink, which they esteem good against pains in the loins. The seeds, besides being eaten by the common people, are of great use to the jewellers and goldsmiths, on account of their equality for weights. each of them weighing four grains : they also make a cement by beating them up with water and borax. In England it must be raised from the seeds on a hot-bed, and afterwards placed in the bark stove, where the fine branching leaves will make a handsome appearance. It has never been known to flower in Great Britain.

2. Adenanthera Falcata; Leaves tomentose underneath.— This species is little known, never having been cultivated in England.

3. Adenanthera Scandens; Leaves pinnate, two-paired; leaflets ovate, oblique, smooth; claspers terminal, bliftd.—It has never been cultivated in England, and is therefore little known.

Adhatoda. See Justicia.

Adiantum, a genus of the class Cryptogamia, order Filices. -GENERIC CHARACTER. Fructifications assembled in oval spots at the end of the fronds which are turned back; or at the reflex tip of the frond underneath.

* Frond simple.

 Adiantum Reniforme; Kidney-leaved Maiden-hair, Fronds kidney-shaped, stalked, many-flowered.—It is a native of the island of Madeira, has been cultivated in England, and must be confined to the green-house.

 Adiantum Philippense; *Philippine Maiden-hair*. Fronds kidney-shaped, alternate, petiolate, lobate, many-flowered. —This species is a native of the Philippine Islands.

 Adiantum Repens; Creeping Maiden-hair. Fronds trapezium-shaped, cordate, pinnatifid; divisions lance-shaped, serrate at the tip, the lower ones gashed.—A native of the Isle of France.

* Frond compound.

 Adiantum Radiatum; Rayed Maiden-kair.—Frond digitate, leaflets pinnate; pinnas one-flowered.—This elegant little plant rises by a simple stalk to the height of six or eight inches; it is a native of Jamaica and St. Domingo.

5. Adiantum Pedatum; Canadian Maiden hair. Fronds of Jamaica; and requires a stove in England.

pedate; leaflets pinnate; pinnas gibbous before, gashed, fruitbearing—The leaves of this plant resemble the comb of a cock. It has been cultivated in England, and will live through the winter in the open air, if the season be moderate. It grows naturally in Canada in such quantities, that when the French were in possession of that country, they sent it to France as a package for goods, and the Parisian apothecaries used in Japan and the Society isles, and flowers in August and September.

6. Adiantum Lanceum; Surinam Maiden-hair. Fronds pinnate; pinnas opposite, oblong, the end ones triangularly hastate.—It is a native of Surinam.

 Adiantum Hastatum; Hastate-leaved Maiden-hair. Fronds pinnate; pinnas hastate-trilobate straight.—This plant seldom exceeds six inches in height. It is a native of the Cape of Good Hope.

8. Adiantum Trilobum ; Three-lobed Maiden-hair. Pinnas three-parted, obtuse, gashed, many-flowered.—A native of America.

 Adiantum Serrulatum; Serrate-leaved Maiden-hair. Fronds bipinnate; pinnules deltoid, oblong serate; fructifications solitary, superior.—This species is about six inches high, and a native of Jamaica.

10. Adiantum Caudatum; Tail-leaved Maiden-hair. Fronds pinnate sickle-tailed at the top.—Native of the East Indies and Japan.

* Frond decompound.

11. Adiantum Flabellulatum; Fan-leaved Maiden-hair, Fronds decompound; pinnas alternate, rhombed, rounded, many-flowered, stipes pubescent above.—A native of China,

12. Adiantum Trifoliatum; Ternate-leaved Maiden-hair, Fronds decompound; leaflets alternate, ternate, linear, oneflowered.-Native of America.

13. Adiantum Chusanum; Chinese Maiden-hair-Fronds decompound; pinnas alternate pinnatifid, lobes unequal. Native of China.

14. Adiantum Capillas Veneris; True Maiden-hair. Fronds decompound ; leaflets alternate ; pinnas wedge-shaped, lobed, pedicelled.-This is a native of the South of Europe, and of the Levant, aud is found, though but rarely, in Wales and Scotland, growing wild on rocks; but that which is met with at the druggists is procured from France. The plant is in perfection in the latter end of summer. It may be preserved in pots filled with gravel, lime, and rubbish, in which it will thrive much better than in good earth. It is a very succulent plant, yielding almost its whole weight of juice; but neither its taste nor smell promise any efficacy. although a decoction of the fresh plant is recommended as a gentle diuretic, which removes obstructions of the lungs and other viscera; and, made into a syrup, as an excellent medicine for coughs, hoarsenesses, and other disorders of the breast. Haller says, that if the syrup of Capillaire made from this plant, be good for any thing, it is from the orange-flower water which they put into it; though Sir John Hill asserts, that as we cannot easily have the plant fresh, and it loses a great deal of the virtue in drying: the best expedient is to use the fine syrup of Capillaire, which is made of an infusion of the plant when in its perfection, with fine Narbonne honey. We, continues he, suppose this is a trifle, but barley-water sweetened with it, is one of the best remedies for a violent cold.

 Adiantum Villosum; Hairy-stalked Maiden-hair.— Fronds bipinnate; pinnas rhombed, fructifying before and without; stipe villous.—It is two feet in height, and a native of Jamaica; and requires a stove in England,

ALOE. Barbadoes Aloe.

ADONIS. The Common Adonis, or Pheasant's Eye.

16. Adiantum Pulverulentum; *Dusty Maiden-hair*. Fronds bipinnate; pinnas oval, truncate, before one-flowered, stipe shaggy.-Native of South America.

ADI

17. Adiantum Cristatum; Crested Maiden-hair. Fronds bipinnate; lowest leaflets two-parted; pinnas crescent-shaped, many-flowered above.—Also a native of South America.

18. Adiantum Furcatum; Forked Maiden-hair. Frond bipinnate; pinnas generally two-parted, linear; line of fructification single; stem smooth, and two feet high.—Native of the West Indies.

19. Adiantum Caffrorum; Caffrarian Maiden-hair. Fronds bipinnate; pinnas ovate, gash-tooth letted, chaffy underneath.—Native of Jamaica.

20. Adiantum Fragrans ; Sueet-scented Maiden-hair, Fronds bipinnate; pinnas ovate, sublobed, obtuse, naked underneath.—This species is a native of Madeira. It may be kept with us in a green-house, where alone it has been found able to endure our climate.

21. Adiantum Truncatum: Truncate-leaved Maiden-hair. Fronds with pinnate leaflets; pinnas alternate, wedge-shaped, rather sickle-shaped, truncate, quite entire.—Native of the West Indies.

* Frond super-decompound.

22. Adiantum Clavatum; Clubbed Maiden-hair. Leaflets alternate; pinnas wedge-shaped, quite entire, alternate, oneflowered.-- A native of Dominica.

23. Adiantum Aculeatum; Prickly-stiped Maiden-huir. Pinnas palmate, many flowered, stipe prickly.—It is a native of Jamaica and Dominica.

24. Adiantum Trapeziforme; Rhomb-leaved Maiden-kair, Leadets alternate; pinnas rhombed, gashed, fruit-bearing on each side.—It is a native of New Zealand, and of the countries between the tropics. It has been introduced into England, but cannot be preserved except by a stove; its shning black stalks and oddly-shaped leaves, will there afford an agreeable variety among other exotic plants.

25. Adiantum Hexagonum; Hexagon-leared Maiden-hair. Pinnas hexangular, emarginate, quite entire, one-flowered on both sides.—It is said to be Pteris heterophylla.

26. Adjantum Pteroides; Heart-leaved Maiden-hair.--Pinnas ovate entire, crenulate; stipe polished, seven inches high, purple and smooth.--Native of the Cape of Good Hope.

27. Adiantum Æthiopicum; Cape Maiden-hair. Pinnas rounded, entire crenulate, petioles capillary.—It is a native of the.Cape of Good Hope and Japan.

Frond compound.

28. Adiantum Triphyllum; *Three-leveed Maiden-hair*, Frond three-leveed; leaflets sessile, lanceolate, pinnatifid, crenate.—This is a very beautiful little fern, tender, entirely smooth, a span high, and was found by Commerson at Buenos Ayres in South America.

29. Adiantum Cuneatum; Wedge-leaved Maiden-hair. Frond pinnate; leaflets opposite, subpinnate; pinnas wedgeshaped, retuse, alternate.—This species seems to be little known.

30. Adjantum Pumilum; Diearf Maiden-hair, Frond pinnate; stipe capillary; pinnas alternate, roundish, serrate, the uppermost larger trapezium-shaped, fructifications interrupted.—This plant seldom rises above two or three inches from the root; it is found in dry and rocky places in Jamaica, of which it is a native.

Adiantum Deltoideum; Deltoid-teared Maiden-hair.
Frond pinnate; pinnas alternate, deltoid, obtuse; the uppermost triangular; fruetifications continued above and in front.
—This species is a native of Jamaica.

32. Adiantum Macrophyllum; Large-leaved Moiden-bair, Frond pinnate; pinnas opposite, rhomboid acute, the lower larger, the lowest sub-hastate, reflex; fractifications continue in front and below.—It is a native of Jamaica, and delights in moist and shadky places.

ADO

* Frond decompound.

33. Adjantum Scandens; Climbing Maiden-hair. Leaflets wedge-shaped, equally gashed; stem climbing.—A native of Cochin-China.

34. Adiantum Striatum; Striated Maiden hair. Frond bipinnate; pinnules rigid, sickled-ovate; fructifications superior, interrupted; stipe round, rough.—It is a native of Jamaica.

35. Adiantum Strictum; *Stiff Maiden-hair*. Frond bipinnate; pinnas four-cornered, fastigiate, erect; pinnules alternate, polished, entire; fructificatious superior continued. —Also a native of Jamaica.

36. Adiantum Microphyllum; Small-leaved Maiden-hair, Frond bipinnate; leaflets alternate, oblong, obtuse, crenate, the lowest pinnatifid.—It attains to the height of nine inches, A native of Jamaica, and is found among the rocks by the river near St. Jago de la Vega.

37. Adiantum Dentienlatum; Tooth-leaved Maiden-hair. Pinnas alternate, trapezoid, acuminate, crenate, notches toothletted; fructifications superior, interrupted.—This species is a native of Jamaica.

* Frond super-decompound.

 Adiantum Fragile; Brittle Maiden hair. Frond bipinnate, at top; pinnas obovate wedge-shaped, entire; fructifiations interrupted.—This species is also a native of Jamaica.

39. Adiantum Tenerum ; *Tender Maider-hair*, Pinnules alternate, rhomb wedge-shaped, blunted, gashed; fructifications interrupted.—It is a native of Jannaica, has a black, shining, branched stipe, from fourteen to eighteen inches high, and is found in shady places.

Adiantium Nigrum. See Asplenium.

Adonis ; a genus of the class Polyandria, order Polygynia .--GENERIC CHARACTER. Calix, perianth five-leaved; leaflets obtuse, concave, a little coloured, deciduous. Corolla, petals five to fifteen, oblong, obtuse, shining. Stamina, filaments very short, subulate. Antheræ oblong, inflex. Pistilla, germ numerons, in a head. Styles none. Stigma acute, reflex. Pericarp, none. Receptacle oblong, spiked. Seeds numerous, irregular angular, gibbous at the base, reflex at the top, a little prominent, naked. ESSENTIAL CHARACTER. Calix five-leaved. Petals five or more, without a nectary; seeds naked .- The leaves are multifid in some species, in others biternate. The flowers are terminating, varying in the number of petals, from five to twelve or more ; these are long, narrow, red, or yellow, without any nectary, as in anemone. which genus the adonis flower resembles, though its fruit approaches more to the ranunculus. Three species of this genus are omitted here, as they are not yet decisively ascertained. -The remaining species are,

 Adonis Estivalis, Tall Adonis. Corollas five-petalled, heads of seeds orate.—This species is a native of the southern countries of Europe, and is found among corn. It flowers in May and June, is an annual plant, and if sown in autumn, will appear in the following spring. They thrive best in a light soil, and the seed should be sown where they are intended to remain, as the plant will not bear transplanting.

2. Adonis Antunnalis; Common Adonis, Birds Eye, Pheasant's Eye, Red Maithes, or Red Morocco.—Its stalk is about a foot high, and it is a native of the southern parts of Europe, but grows in Kent by the side of the Medway, between Rochester and Maidstone, where it is met with in great plenty. Among spring corn, there is arrayely a plant of it to be found, which shews the propriety of sowing the seeds in gardens in autumn; for those fields of spring corn, if suffered to remain undisturbed after the harvest, will abound with this plant in the following year. It is supposed to have been conveyed from the garden to the fields by means of the daugheap, as it is not probably of long standing, not being recorded as indigenous by our old botanical writers. Great quantities of the flowers are annually sold in London by the imme of *Red Morecce*. They flower in the beginning of June, and the seeds ripen in August and September. For the mode of propagating thems, see the preceding species.

ADO

3. Adonis Vernalis; Perennial or Spring Adonis. Flower twelve-petalled ; heads of seeds ovale .- This species is a native of Oeland, Switzerland, Austria, Carniola, Silesia, Prussia, Bohemia, the Palatinate, and other parts of Germany, where the root is often used for the true black hellebore. Its large vellow flowers are produced at the end of March or the beginning of April, and the seeds ripen in August, and should be sown soon after, otherwise they seldom succeed. They must be kept free from weeds, and if refreshed with water in dry weather, it will promote their growth. They should remain where sown till the second year, for they make but slow progress when young. The best time to transplant them is in autumn, when they ought to be planted where they are to remain, for if often produced, they will not produce many flowers, and even those will be much the weaker for it. They may be increased by parting the roots either in autumn or spring. Being hardy and easily cultivated, and producing their showy flowers early in the season, they are desirable plants for the garden.

4. Adonis Apennina; Apennine Adonis. Flowers fifteen petalled.—The stem is about a foot and half in height, it is found wild in the Apennines and in Siberia. For its culture and propagation, see the preceding species. (Adonis Vernalis.)

 Adonis Capensis; Cape Adonis. Flowers ten-petalled, heads depressed, leaves biternate, leaflets serrate, heart-shaped. —This species receives its name from being found wild near the Cape of Good Hope.

6. Adonis Vesicatoria; Blister Adonis. Flowers tenpetalled; leaves biternate; leaflets serrate, smooth.—This plant is perfectly smooth, and has hard firm leaves. It is also a Cape Plant, and receives its name from the Africans using it for raising bisters.

Adoxa; a genus of the class Octandria, order Tetragynia. -GENERIC CHARACTER. Calix, perianth inferior, bifid, flat, permanent. Corolla, monopetalous, flat, quadrifid ; clefts ovate, acute, longer than the calix. Stamina, filaments subulate, the length of the calix. Antheræ roundish. Pistilla, germ below the receptacle of the corolla. Styles simple, erect, the length of the stamina, permanent. Stigmas simple. Pericarp, a globose berry, between the calix and the corolla, the calix being united below with the berry, umbilicate, fourcelled. Seeds solitary, compressed. Observe, such is the terminal fructification, but all the lateral ones add a fifth part of the whole number. ESSENTIAL CHARACTER. Calix bifid, inferior. Corolla four or five cleft, superior. Berry four or five-celled, united with the calix .- The roots of plants of this genus may be transplanted any time after the leaves are decayed, till winter. They must be planted in the shade under shrubs; for if they are exposed to the open sun, they will not thrive .---- The following species only has been discovered.

1. Adoxa Moschatellina; Bulbous Fumitory, Hollow Root, Tuberous Moschatell.-It has a perennial root, and grows na-

turally in shady places and woods, as in Hampstead and Charlton woods, dcc. The flowers appear at the end of March, or beginning of April, and the berries ripen in May, soon after which the leaves decay. These and the flowers smell like musk, from whence some have called it *musk crowfost*.

Bigiteroas; a genus of the class Pentandria, order Moncgynia.--GENPERIC CHARACTER. Colit., perianth one-leaved, bell-shaped, half five-cleft, coriaceous, permanent. Corolla, petals five. Stamina, filaments five. Pistil, genu oblong, Style single. Pericarp, capsule bowed, coriaceous, one-celled. one-valved, gaping on the convex side. Seed single. EssExprial. CHARACTER. Calis bell-shaped, half five-cleft. Capsule bow-shaped, one-celled, gaping on the convexside. Seed inverted.— Species,

 Agiceras Majus; the Grater Ægiceras. Leaves ovate, quite entire; legumes long, siekle shaped.—This is a strub about twelve feet high, with several stems, a foot in thickness, putting out many lwigs and suckers. Its flowers have an agreeable small; it is a native of the Molucea Islands.

2. Ægiceras Minus; the Lesser Ægiceras. Leaves ovate, sometimes notched; legumes short, crescent-shaped.—A native of Ceylon.

Ægilops, a genus of the class Polygamia, order Monœcia. GENERIC CHARACTER. Two lateral flowers hermaphrodite. Calix, a large bivalvular gluine, sustaining three flowers; valves ovate, truncate, streaked, with various awns. Corolla, a bivalvular glume; the outer valve ovate, terminated by a double or triple awn; the inner lanceolate, erect, awnless, with the edge bent in longitudinally. Nectary twoleaved ; leaflets ovate, flat, transparent, very small. Stamina, filaments three, capillary, with oblong antheræ. Pis-til: germ turbinate. Styles two, reflex, with hairy stigmas. Pericarp, none. Seeds oblong, convex on one side, grooved on the other, with the inner valve of the corolla adhering to it, and not opening. One male flower between the two former. ESSENTIAL CHARACTER. Calix, a glume, subtriflorous, cartilaginous. Corolla, a glume terminating in a three-fold awn. Stamina three. Styles two. Seed one. -All the species of this genus appear to be annual: they are,

 Ægilops Ovata. Spike awned, all the calices with three awns.—This grass grows wild in the southern countries of Europe.

2. Ægilops Ovata. Spike-awned, all the calices with two awns.—This grass is a native of Crete.

 Ægilops Truncialis. Spike-awned, the lower calices with two awns,—This species of grass grows about Montpelier, Marseilles, Nice, and Smyrna.

4. Ægilops Squarrosa. Spike awl-shaped, longer than the awns.—This species of grass has been found in the Levant by Tournefort, and by Cavanilles in Spain.

Ægilops. See Quercus.

Æginetia. See Orobanche.

1. Ægiphila Martinicensis. Leaves ovate-lanceolate, acuminate, smooth; branches diffused; panicles terminating or axillary, calices smooth .- This is a shrub six feet high, with white flowers, and is found on the edges of woods in the island of Martinico. It flowers in November.

2. Ægiphila Elata. Leaves eliptic, acuminate, membranaceous, panicles terminating, calices pubescent .- This plant is a climber, and frequently rises to the height of six or seven feet or more. It is a native of Jamaica.

Ægopodium; a genus of the class Pentandria, order Digynia GENERIC CHARACTER. Calix, umbel universal, manifold, convex; partial, similar, but flat. Involucre, none. Proper perianth scarcely observable. Corolla, universal, uniform, with every floscule fertile ; particular with five petals, oboyate, concave, inflex at the tip, and equal. Stamina, filaments simple, twice as long as the corolla, with roundish antheræ. Pistilla, germ inferior. Styles simple, erect, the length of the corollas, with headed stigmas. Pericarp, none. Fruit ovate-oblong, streaked, bipartite. Seeds two, ovateoblong, convex, and streaked on one side, flat on the other. ESSENTIAL CHARACTER. Fruit, ovate-oblong, streaked. -One species only is known, viz.

1. Ægopodium Podagraria; Herb Gerard, Gout-weed, Ashweed, or Ground-ash, Wild Masterwort .- This weed is not uncommon in hedges, orchards, &c. It is a perennial plant, and as it is a great creeper, cannot be admitted into gardens without great caution. It requires no care, but to plant it in the shade, and confine the roots, its stem grows two or three feet high. Although it is aromatic, like most umbellate plants, it is not admitted into medical use, nor has it any title to its name of goutweed, though formerly used by the Germans to assuage the pains of the gout and piles. Linneus says it is eaten in Sweden, boiled for greens when tender in the spring. Culnener says, " It is not to be supposed that gout-wort hath its name for nothing, but upon experiment to heal the gout and sciatica; as also joint-aches, and other cold griefs. The very bearing of it about one easeth the pains of the gout, and defends him that bears it from disease !!!" Meyrick and Hill are, however, more reasonable; the former calls the roots and leaves "a good external application for the sciatica and other pains, whether they are employed as a fomentation or a poultice; and though many extol their efficacy in the gout, he says they are well omitted in that complaint, as they are seldom productive of any lasting good effects, and may sometimes be the occasion of much distress and mischief." The latter (Hill) recommends the root, and fresh buds of the leaves, as excellent fomentations and poultices for pains, and says he has seen a good effect from a quantity of the leaves and roots boiled soft together, and applied to the hip in the sciatica, keeping a fresh quantity hot to renew the other as it grew cold, but he advises not to make any use of it for the gout.

Egopricon ; a genus of the class Monœcia, order Monandria. -GENERIC CHARACTER. Male flowers small, in an ovate ament. Calix one-leafed, tubulous, trifid. Corolla, none. Stamina, filaments one, longer than the calix, erect; with an ovate anthera. Female flowers upon the same plant, solitary. Calix and corolla same as above in the male. Pistil, germ ovate, superior ; styles three, divaricate ; with simple permanent stigmas. Pericarp, a globular berry, tricoccous and trilocular within, with a bifid point. (Capsule tricoccous elastic.) Seeds solitary, angular on one side. ESSENTIAL CHARACTER. Male an ament. Calix, common, trifid ; partial tubulous. Anthera four-lobed. Female flowers solitary. Calix as in the male. Corolla, none. Styles three, coadunate at the base. Capsule tricoccous .---- One species only is known.

Branchlets alternate, bent different ways, leafy, flowering at the ends. Bark somewhat wrinkled, except in the younger shoots. -Dalberg noticed it at Surinam, and Aublet in Guiana.

Eschynomena ; a genus of the Diadelphia class, order Decandria.—GENERIC CHARACTER. Calix, perianth one-leafed, bell shaped, sub-bilabiate; lips equal, upper bifid, lower three toothed. Corolla, papilionaceous; benner subcordate, scarcely gaping, large; wings subovate, obtuse, shorter than the banner: keel lunate, acuminate, the length of the wings. Stamina, filaments ten, (single and nine-cleft.) Antheræ small. Pistil, germ oblong, villous, columnar. Style sub-ulate, rising. Stigmas simple, rather obtuse. Pericarp, legume, long, flat, jointed, rough, one celled, opening at the truncate joints. Seeds, solitary between the joints, kidneyshaped. ESSENTIAL CHARACTER. Calix bilabiate. Legume with truncate one-seeded joints .-- All the plants of this genus are propagated by seeds, which should be sown on a hot-bed early in the spring; and when the plants have strength enough to be removed, they should be put each into a separate small pot, filled with light earth, and plunged into a fresh hot-bed, from whence, as they advance in growth, they should be shifted into larger pots, but these pots must not be too large, otherwise the plants will not thrive .---- The species are.

1. Æschynomene Grandiflora; Great-flowered Æschynomene. Stem arborescent, flowers very large, legumes filiform .- It is a shrub from ten to fifteen feet in height, a native of the East Indies, called Pois du Duc de Choiseul by the French. It has been cultivated in England, and is frequent in the gardens at Jamaica; domestic fowls are partial to the seeds. It is difficult to preserve this plant through the winter in this country. The seedling plants should be brought forward on a hot-bed, and then plunged into the bark-bed in the stove, where, if they be tenderly treated, they will survive the winter, and flower in the summer following,

2. Eschynomene Arborea; Arborescent Eschynomene .--Stem aborescent, smooth joints of the legumes semi-cordate, smooth .- This plant attains the height of six or seven feet : it requires the same treatment as the preceding species, flowers early in the summer, and ripens its seeds in the autumn. As their stalks are succulent, they must be kept dry in winter, otherwise they are very apt to rot.

3. Eschynomene Coccinea; Scarlet flowered Eschynomene. Stem arborescent ; leaves pinnate ; leaflets numerous, linear, obtuse, dusty; legumes compressed, equal .-- This species requires the same treatment as the first and second species of this genus. It is a native of the East Indies, and of the islands Ötaheite and Huaheine in the South Seas.

4. Æschynomene Aspera; Rough-stalked Æschynomene. Stem herbaceous, rugged; joints of the legumes rugged in the middle .- This species reaches the height of four or five feet, with a single herbaceous stem, which is in some parts rough. It is a native of the East Indies, and requires the same method of propagation as the first species of this genus.

5. Eschypomene Americana ; Hairy Eschynomene. Stem herbaceous, hispid; joints of the legumes semicordate; leaflets acuminate, bractes ciliate .- The root of this species is annual, its stem one, two, and sometimes even three feet high. It is somewhat sensitive, folding its leaves together during the night, and at the approach of rain. It is found in dry pastures on the south side of the island of Jamaica, of which it is a native. Propagated in England in the same manner as the first species.

6. Æschynomene Indica; Indian Æschynomene. Stem herbaceous, smooth; legumes smooth, swelling on one side, 1. Ægopricon Betulinum .-- This tree is very much branched. | obtuse ; leaflets obtuse .-- It is a native of the East Indies, and may be propagated in England in the same manner as the first species of this genus.

ÆSC

7. Æschynomene Sesban; Egyptian Æschunomene, Stem herbaceons, smooth; legumes cylindric, equal; leaflets obtuse .- It is a native of Egypt, flowers in July and August, and in this country requires the same treatment as the first and second species of this genus, which see.

8. Æschynomene Pumila; Dwarf Æschynomene. Stem herbaceous, smooth ; legumes servate on one side, rough in the middle; leaflets acuminate .- This is an annual plant, a foot and half high, branching at bottom, and a native of the East Indies. For the method of propagating it with us, see the first species.

9. Æschynomene Sensitiva, Stem shrubby, smooth; leaflets obtuse : legumes smooth and even, obtuse ; stipules acute, deciduous .- Native of the West Indies : it flowers in July, and the seeds ripen in October : for the mode of propagation, see the particulars under the description of the Generic Character above.

10. Æschynomene Heterophylla, Stem shrubby, lower leaves ternate ovate, upper pinnate, roundish .- The stem of this species is arboreous, weak, with spreading tomentose branches .- A native of northern Cochin China, and propagated like the preceding species.

11. Æschynomene Lagenaria. Stem herbaceous, leaflets obtuse, in several pairs, legumes muricate,-The stem of this plant, which is a native of marshy places in Cochin China, is there used for stopping bottles, as there are no corks. It is herbaceous, three feet high, upright, thick, round, spongy, and elastic

12. Æschvnomene Connabina. Stem herbaceous: leaflets obtuse, acuminate ; peduncles solitary ; legumes compressed, smooth, and even. -In the East Indies, where it is indigenous, it is treated as hemp, as its name signifies, and may be applied to the same purposes.

Æsculus : a genus of the class Heptandria, order Monogynia .- GENERIC CHARACTER. Calix, perianth one-leafed, ventricose, small, five-toothed. Corolla, petals five, roundish, plaited, and waving about the edge, flat, spreading, claws narrow, inserted into the calix, irregularly coloured. Stamina, filaments subulate, the length of the corolla, declining. Antheræ, ascending. Pistil, gerni roundish, ending in a subulate style. Stigma acuminate. Pericarp, capsule leathery, roundish, three-celled, three-valved. Seeds two, subglobular. Observe, one seed only commonly occurs in the capsule, but, on inspection of the embryos, it is evident that the natural number is two. ESSENTIAL CHARACTER. Calix oneleafed, five-toothed, ventricose. Corolla, five-petalled, irregularly coloured, inserted into the calix. Capsule, three--The species are, celled .---

1. Æsculus Hippocastanum; Common Horse Chesnut. The flowers with seven stamina; leaves digitate, with seven entire leaflets; capsules prickly.-This tree is well known, and was formerly in greater esteem for walks and avenues than at present, which is owing to the litter made by its leaves when falling : it affords, notwithstanding, a noble shade, very early in the year, and no tree has more beauty during the time of its flowering, for the extremities off the branches are terminated by fine spikes of flowers, so that every part of the tree seems covered with them, and being intermixed with the large digitate leaves, they make a noble appearance, continuing in beauty for nearly a month. In Turkey the nuts are ground, and mixed with the provender of those horses which have coughs or are broken-winded. Some assert that swine will fatten on them, and Haller says that sheep have been fed with them whole, and poultry with them boiled, and that agreeable smell. The safest way to avoid all doubt is to cul-

both have done well; but this is disputed by others. The bark may be used to save soap in washing, as it has a saponaceous quality; it has been successfully used in Italy as a medicine for intermittent fevers ; and has answered very well in dyeing several sorts of yellow colours. Notwithstanding the bad character Mr. Miller gives of the timber of this tree, it is said to be useful in making pipes to convey water under ground, as it will last longer than harder woods. Dr. Hunter says it is used for turnery, and is worth sixpence per foot in the north of England. Mr. Hanbury confirms Hunter's account, and adds, that the tree grows speedily to a great magnitude, and sells at such a price as to make it well worth planting for the sake of the timber, and that it ought to be felled in November or December. This species was brought from the northern parts of Asia nearly three centuries ago. and is more common now than it was an hundred years since. These trees are propagated by sowing the nuts early in the spring, but they must be preserved in sand during the winter, otherwise they will mould and rot. They will shoot nearly a foot the first summer, and if they stand close, should be transplanted the next autumn into the nursery, and remain there two years: they should then be removed where they are intended to remain, and well secured by a fence of good stakes against young cattle and violent winds.

2. Æsculus Flava; Yellow flowered Horse Chesnut. Leaves digitate, with five leaflets ; the laminas of the corolla cordate, roundish; the claws twice the length of the calix .- This species flowers in May and June, and is a native of North Carolina

3. Esculus Pavia ; Scarlet Horse Chesnut. Flowers with eight stamina; leaves digitate, with five or six serrate leaflets; capsules smooth ; laminas of the corolla obovate; claws the length of the calix .- This species rises to the height of twenty feet, but does not spread its branches to any extent. The flowers appear in June, and are sometimes succeeded by fruit. but the seeds rarely ripen in England. It grows naturally in Brazil, Carolina, Japan, and several parts of the East, from which countries those who wish to propagate it must procure the nuts, and plant them early in the spring, in pots which must be plunged into a moderate hot-bed. The nursery-men, who propagate this tree for sale, commonly graft or bud it upon common horse chesnut stocks; but as the stock greatly ontgrows the bud or graft, the trees make a bad appearance. and do not last long.

Æthiopis. See Salvia.

Æthusa ; a genus of the Pentandria class, order Digynia .---GENERIC CHARACTER. Calix, umbel universal, the rays gradually shortening towards the middle; partial also spreading, but small. Involucre universal, none; partial placed on the outside, only consisting of three very long, linear, pendulous leaflets. Proper, perianth scarcely observable. Corolla universal nearly uniform, with all the floscules fertile : partial has the petals bent in, heart-shaped, and unequal. Stamina, filaments simple, with roundish antheræ. Pistil, germ inferior. Styles reflex, with obtuse stigmas. Pericarp, none. Fruit roundish, streaked, bipartite. Seeds two, roundish, streaked, except on a third part of the surface, which is plane. ESSENTIAL CHARACTER. Partial involucre halved, three-leaved, pendulous. Fruit streaked .--- The species are.

1. Æthusa Cynapium ; Common Fool's Parsley. Leaves conform .- This species has a stem from one to two feet high, and is a common weed in kitchen gardens, and in a slight degree poisonous. It is easily mistaken for true parsley and chervil when young ; the leaves emit, in a slight degree, a dis-

tivate the curled Parsley, for which this cannot be mistaken. Most cattle eat it, but it is said to be noxious to geese. This is an annual plant, and may be easily restrained in gardens by not suffering it to seed, which it does abundantly.

2. Æthusa Bunius; Coriander-leaved Fool's Parsley. Radical leaves pinnate, cauline, manifold-setaceous. This is a perennial plant, native of the Pyrenees .--- It flowers in July.

3. Æthusa Meum; Spicknel Meu, or Bawd Money. All the leaves manifold setaceous.—This is a perennial plant, rising a foot and a half high. It grows wild in the mountains of Switzerland, Germany, Austria, Carniola, Italy, and Spain ; also in the high pastures of Westmoreland, Cumberland, Lancashire, and Merionethshire. It blossoms in May: the roots and seeds are aromatic and acrid; they are recommended as carminatives and stomachics; in the stone, stoppage of urine, and all uterine disorders; sometimes they are given to cure tertians. Spicknel is an ingredient in therica and mithridate ; and appears to be of the same nature as lovage. It is a powerful diuretic, and remover of obstructions in the viscera, consequently good against the gravel, jaundice, obstructions of the menses, &c. The root is the part to be made use of for these purposes, and an infusion of it is the best preparative; dried and given in powder, it strengthens the stomach, creates an appetite, and is good against the colic. This is a hardy plant, and may be increased by parting the roots at Michaelmas, or sowing the seeds soon after they are ripe, which takes place in July and August. They should have a shady situation and a moist soil.

4. Æthusa Fatua: Fine-leaved Fool's Parsley. All the leaves many-parted, setaceous; leaflets subverticillate; stem many-leaved; sheaths of the petioles narrow; universal involucre many-leaved. This species flowers in August and September; it is not known of what country it is a native.

AFRICAN BLADDER NUT. See Royena.

AFRICAN FLEA-BANE. See Tarchonanthus. AFRICAN MARYGOLD. See Tagetes.

AFRICAN RAGWORT, See Othonna.

Agallocha. See Excoecaria.

Agapanthus, a genus of the Hexandria class, Monogynia order.-GENERIC CHARACTER. Calix: Spathe common, gaping at the side. Corolla : one-petalled, funnel-shaped, regular. Tube cornered, as if composed of six claws. Border six-parted ; parts oblong spreading. Stamina : filaments six, inserted into the throat, shorter than the corolla, declinate. Antheræ kidney-shaped, incumbent. Pistil: germ superior, oblong, three-cornered. Style filiform, length of the stamina, declinate. Stigma simple. Pericarp: capsule oblong, three-sided, three-celled, three-valved; valves navicular, with contrary dissepiment. Seeds: numerous, oblong, compressed, enlarged with a membrane. ESSENTIAL CHARAC-TER. Corolla : inferior, funnel-shaped, hexapetaloid, regular, -Of this genus the following species only is known,

1. Agapanthus Umbellatus ; African Blue Lily .- It is a native of the Cape of Good Hope, and is propagated by offsets, which come out of the sides of the old plants; aud may be taken off at the latter end of June, planted each in a separate pot, and placed in a shady situation, where they can have the morning sun and free air, and be watered twice a week. They only require protection from frost and wet, and as they flower at the end of August, or in the beginning of September, they will frequently continue in beauty till spring.

Agaricus, a genus of the class Cryptogamia, order Fuugi .--GENERIC CHARACTER. Pileus or cap, with gills underneath. Gills differing in substance from the rest of the 6.

plaut, composed of two laminas. Seeds in the gills. In order to cultivate agarici or mushrooms, the small white knobs which are always found near their roots, and are the offsets, or young mushrooms, should be carefully gathered with the earth about them : and as this spawn cannot be found in the pastures except during the mushroom season, you will probably find it in old dunghills where there has been much litter and little wet, also in old hot-beds, shooting out in long strings. The beds for these spawn should be made of dung, with good store of litter, on dry ground, three feet wide at bottom, and long in proportion to the quantity desired. The dung must be laid a foot thick, covered with four inches of strong earth, and upon this two more layers of dung ten inches thick, succeeded by another layer of earth, contracting the sides of the bed like the roof of a house. When finished, the bed should be covered with litter or old thatch. to keep out the wet. In eight or ten days the bed will be moderately warm, and fit to receive the spawn; then the thatch or litter being removed, a covering of rich light earth, about an inch deep, should be laid all over the bed, placing the lumps of spawn upon it, four or five feet asunder, which must be immediately covered with the same light earth, half an inch deep; and the old thatch or litter then replaced, to keep out the wet, as before. In warm weather the mushrooms will probably appear in a month, but if the weather be cold it will be much longer. The great skill is, to keep up a due degree of moisture in these beds; in warm weather showers of rain may be admitted, in winter they must be kept as dry as possible. A bed thus managed, if the spawn take kindly, will remain good for several months, and produce better mushrooms than can be gathered in the fields. When destroyed, the spawn for a new bed may be taken out of it, and plenty of mushrooms may thus be ensured throughout the year. In many parts of Europe several sorts are eaten, which we deem poisonous. Even Agpiperatus, the most acrid and suspicious species of this genus, is eaten in large They season or pickle them quantities by the Russians. with salt in autumn, and eat them in Lent. Caution is nevertheless very indispensable, as several species would be highly injurious, if taken in any considerable quantity. See Fungi. Authors differ exceedingly in their enumerations of the species of this genus.--- The following are the most worthy of notice, viz.

Agaricus Campestris ; Common Mushroom, or Champignon. Gills crowded, irregular, pink changing to liver colour; cap convex; white to brown; stem white, cylindrical; curtain white .- The stem of this species is solid, from two to three inches high, and half an inch in diameter. It is esteemed the best and most savoury of the genus, and is in much request for the table in England. It is eaten fresh, stewed or broiled, and preserved either as a pickle or in powder: the sauce, vulgarly called Catchup, is made from its juice with salt and spices. In contradiction of what is said above, it is asserted, that wild mushrooms, fresh from undunged pastures, are more delicate than those raised on artificial beds; and that those who are much accustomed to them, can distinguish them from each other by the smell. Those artificially raised are certainly more sightly, and more easily procured in a proper state for eating; they are also firmer and better for pickling.

Agaricus Georgii, of Linnæus, resembles this, but is not poisonous, as it is generally supposed. It is very common, and the caps turn yellow, but the gills are always white.

Agaricus Procerus, or Tall Mushroom, which is common in woods and dry hilly pastures, is sometimes exposed to sale in Covent Garden market. It may be easily distinguished

AGA all others by its tallness, bulbous base, and large volva or

ruffle. Agaricus Cæsareus, or Imperial Agaric, is the most splendid of all the species. It is common in Italy, where it is exposed in the markets for sale. The ancient Romans esteemed it one of the greatest luxuries; and Juvenal and Martial have celebrated it as the vehicle whereby Claudius Cesar was poisoned by his wife Agrippina. It was first found wild in this country in the year 1791

Agaricus Orcades; a small pale-brown or buff-coloured mushroom, very frequent in dry pastures, and particularly in fairy rings, which Dr. Withering is satisfied are entirely produced by their growth. It is found in woods and hedges, but is then inferior in flavour. Those from dry pastures are the best, have a pleasant smell, and a most luscious flavour, either stewed alone, or in hashes and ragouts. They make excellent Catchup, and are admirable in the form of a powder. The cap is of a pale brown buff colour, the stem solid and white, an inch and half high, and about the thickness of a crow-quill. It is in season during September and October. but may be so dried as to be in use for the table all the winter.

Agaricus Chantarellus, of Linneus, may be safely eaten, but it is inferior to the preceding species, and is distinguished by its solid stem, often compressed; and by its decurrent, branched, anastomosing gills.

Agathaphyllum; a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth very small, truncate, entire, permanent. Corolla : petals six, ovate, somewhat villose within, inserted into the calix. Stamina: filaments twelve, broadish, very short, alternately placed at the base of the petals, and alternately on the calix. Autheræ roundish. Pistil: germ superior, very small. Style very short. Stigma pubescent. Pericarp: drupe somewhat globose, crowned with the calix. Seed : nut somewhat globose, terminated by a truncate point, half six-celled. Kernel convex, beneath six-lobed, with coriaceous partitions separating the lobes. ESSENTIAL CHARACTER. Calix: superior, very short, toothless. Corolla: six-petalled, somewhat villose. Stamina: alternately inserted into the calix and petals. Drupe juiceless, with a half six-celled nut, and one seed.— The only species known is, 1. Agathophyllum Aromaticum.— This is a large bushy tree,

with a pyramidical head like the clove-tree, and a reddish odorous bark; the wood is hard, heavy, white, with some reddish fibres, and has no smell. Its fruit, which is the size of a large cherry, is shaped like a pear, it cousists of a nut divided into six parts, as a walnut is divided into four, covered with a hard coriaceous shell, and that with a green thin bark very closely adhering to it, both of which are aromatic ; but the nut has an acrid biting taste, which is almost caustic. The tree bears at five or six years age, flowers in January and February, and is ten months in ripening its fruit. The natives of Madagascar gather it before it is ripe, as a spice for the purpose of seasoning their meat. When fresh, it has a fine aromatic smell; and the caustic taste may be diminished by keeping it some months, then throwing it into boiling water for four or five minutes, and afterwards drying it in the sun. The leaves may be prepared as a spice in the same manner.

Agave; a genus of the class Hexandria, order Monogynia. -GENERIC CHARACTER. Calix: none. Corolla: onepetalled, funnel-shaped; border six parted, equal; parts lanceolate erect. Stamina: filaments filiform, erect, longer than the corolla. Antheræ linear, shorter than the filaments, ver-

from the genuine sort by the sponginess of its flesh, and from satile. Pistil: germ oblong, growing thinner towards both ends, inferior. Style, filiform, the length of the stamina, threecornered, stigma-headed. Pericarp : capsule oblong, threecornered, three-celled, three-valved, Seeds : numerous. ESSENTIAL CHARACTER. Corolla: erect, superior. Filaments longer than the corolla, erect .---- The species are,

1. Agave Americana; Common American Agave. Stemless; leaves tooth thorny .- This plant has been long known in England, where it will flower in gardens, but not ripen seed. When they flower they make a fine appearance, and continue a long time in beauty; and if protected from the cold in autumn, will continue to flower for three months in favourable seasons. It has been erroneously said, not to flower until it is an bundred years old; it flowers in a few years in warm countries, but in colder climates, where the growth is slow, it will be much longer before it shoots up a stem. In Portugal and Spain there are hedges of this plant ; it also flourishes about Naples, and in other parts of Italy. The leaves are very useful as a succedaneum for soap: they are cut, and passed (points foremost) between the rollers of a mill, the expressed juice being conducted into wide shallow receivers through a coarse cloth or strainer: it is then placed in a hot sun until reduced to a thick consistence by the exhalation of the aqueous part, after which it is made up into balls with lye-ashes, and will then lather with salt water as well as fresh. This soap may be made by pounding the leaves in a wooden mortar, and reducing them to a consistence by the sun or by boiling. A gallon of juice yields a pound of soft extract: the juice must always be carefully strained, and never combined with tallow or other unctuous materials. The leaves are also used for scouring pewter, and other kitchen utensils, and floors. The inward spongy substance of the decayed stalk is used for tinder. The fibres of the leaves, separated by bruising and steeping in water, and afterwards beating them, make a strong thread for common uses. It is a hardy plant. See the third species.

2. Agave Vivipara ; Viviparous or Childing Agave. Stemless ; leaves toothed .- This never grows to a large size ; it is so tender that it will not thrive out of the stove even in summer: and as it never produces off-sets or suckers from the roots, it cannot be propagated that way except when in flower, when there will be an abundance of them. They require a light sandy earth, and should have little wet in winter. but may be gently watered twice a week in summer, and be allowed a great share of free air. Every summer they must be shifted, but not have large pots, and have fresh earth : unless the roots are confined, the plants will not thrive.

3. Agave Virginica; Virginian Agave. Stemless, herbaceous; leaves tooth thorny .-- This is very like the first sort, but does not rise so high : both sorts have lived in the open air for some years in mild seasons; but in severe winters they are always killed if not sheltered. The third species seldom puts out so many suckers as the first, though it generally produces sufficient for propagation. They should be planted in pots or tubs filled with light sandy earth, and housed in winter with oranges, myrtles, &c.; and during that season should have little wet. They may remain abroad during summer, and until the end of October.

4. Agave Lurida. Subcaulescent : leaves tooth-thorny .---This also greatly resembles the first species, but the leaves are thinner, and their spines blacker. This is propagated like the second species; which see.

5. Agave Tuberosa ; Tuberous-rooted Agave. Caulescent ; leaves tooth thorny .-- Many plants of this species are in English gardens: for the mode of propagating it, see the second species.

AGR

6. Agave Fœtida; *Fetid Agave*. Caulescent leaves, quite entire.—This is propagated in the same manner as the second species; which see.

^A geratum; a genus of the class Syngenesia, order Polygamin & Acquais,-GENERIC CATARACTER. Calix common, oblong; with many lanceolate subequal scales. Carola: compound, uniform. Corollets hermaphronidie, tubulous, numerous, equal, scarcely longer than the calix. Proper monopetalous, finnel-shaped; border quadrifid, spreading. Stamina: filaments capillary, very short. Anthera cylindric, tubular. Pistil: germ oblong. Style filorom, the length of the stamina. Stigmas two, very slender, erect. Pericapy: none. Calix: unchanged. Sced: solitory, oblong, angular, crowned with a chaffy, five-leaved, upright, awned calicle. Raceptack: maked, convex, very small. ESSENTIAL CHA-RACTER. Receptack: guadrifid. ----The species are, oblong, subequal. Corollets: guadrifid. ------The species are,

 Ageratum Conyoides ; Hairy Ageratum, Leaves ovate, stem hairy.—This is an annual root, and tils leaf resembles that of the nettle. It flowers in July and August, is antive of Africa, the islands of America, and the isle of Tanna in the South Seas. The seeds must be sown on a hot-bed in the spring, and should be transplanted after they have taken root. In June they may be inured to the open air; they will begin to flower in July, and continue till the frosts of autumn destroy them.

2. Ågeratum Ciliare. Leaves ovatc, crenate, obtuse; stem smooth. Stem herbaceous, two feet high.—A native of the East Indies, and of China, near Canton.

Ageratum. See Achillea.

Agnus Castus. See Vitex.

Agrimouia ; a genus of the class Dodecandria, order Digynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-cleft, acute, small, superior, permanent, fenced with an outer calix. Corolla : petals five, flat, emarginate ; claws narrow, inserted into the calix. Stamina: filaments capillary, shorter than the corolla, inserted into the calix. Antheræ small, twin, compressed. Pistil: germ inferior, styles simple, the length of the stamina. Stigmas obtuse, Pericarp : none. Calix contracted at the neck, and hardened. Seeds : two, roundish. Observe, the number of stamina is very uncertain, 12, 10, 7. ESSENTIAL CHARACTER. Calix: five-cleft, fenced with another. Petals five, seeds two, at the bottom of the calix. This is a genus of hardy perennial plants, which if kept free from weeds will thrive in any soil or situation. They are propagated by parting their roots in autumn, when their leaves begin to decay, that the young plants may be well established by the spring ; and they should be kept two feet asunder. The seeds sown in autumn will appear in the following spring .---- The species are,

1. Agrimonia Euparoria; Cammon Agrimony, Stem-Jeaves pinnate; the end-lobe periodate; fraits hispid....This plant is only a foot and a half in height; it is a native of woods, shady places, hedges and borders of cornfields in Great Britain, and most parts of Europe. It is perennial, and flowers in June and July. The root in spring is sweet-scented; the fresh-gathered flowers smell like apricots. Kalm informs with the anadians use an infusion of the root in burning fevers with great success. Dr. Hill afirms, that an infusion of six ounces of the crown of the root, in a quart of holing water, sweetened with honey, and half a pint of it drank three times a day, is an effectual cure for the jaundies. He advises to begin with a vomit, afterwards to keep the bowels soluble, and to continue the medicine as long as any symptoms of the disease remain. The leaves, which make a pleas the solut are said to be serviceable in hemorrhages, and

in obstructions of the liver and spleen, are used either fresh or dried. They have been recommended in the jaundice, but are found by experience to be salutary in the diabetes, and incontinence of urine. This plant is also one of the famous vulnerary herbs, and an ingredient in the genuine arquebusade-water. It is frequent, according to Meyrick in dry pastures ; and is a mild corroborant, of great efficacy in all such disorders as arise from a lax habit of body: its roots appear to possess the properties of the Peruvian bark in a very considerable degree, without manifesting any of its inconvenient qualities; and if taken in pretty large doses, either in decoction or powder, seldom fails to cure the ague. The leaves, digested in whey, afford an useful diet-drink for the spring, particularly for such as are troubled with scorbutic complaints. The country people also use them by way of cataplasm in contusions and fresh wounds. If gathered when it is coming into flower, this plant will dye wool of a good bright full nankeen colour; but if gathered in September, the yellow colour will be darker. As it gives a good dve at all times, and is a common plant easily cultivated, it deserves the notice of the dyers : in the Berlin Acts it is recommended for dressing leather. Sheep and goats eat it; but kine, horses, and swine refuse it. There are two varieties of this species, the White Agrimony, and the Sweet-scented Agri-mony, both natives of Italy. The leaves of the latter emit an agreeable odour, and also make a pleasant cooling tea, which is an excellent beverage for persons in a fever.

 Agrimonia Repens; Creeping Agrimony. Leaves pinnate; the end-lobe sessile; fruits hispid.—This plant seldom rises above two feet in height, and it multiplies faster than the common surt, which it strongly resembles.

 Agrimonia Decumbens. Leaves pinnate, hirsute; stem procumbent; fruits every way hispid-hooked.—This species is usually monogynous: it is a native of the Cape of Good Hope.

4. Agrimonia Agrimonoides; Three-leaved Agrimony, Stem-leaves ternate; fruits smooth,—It is found in moist woods and among bushes in Italy and Carniola, where it is a native.

5. Agrimonia Parviflora; Small-flowered Agrimony.— Sten-leaves pinnate; leaflets many, lanceolate; petals half as long again as the calix; fruits hispid. It flowers in July, and is a native of North America.

Agrimonoides. See Agrimonia.

Agrimony Hemp. See Eupatorium.

Agrimony Water Hemp. See Bidens.

Agrostenima ; a genus of the class Decendrin, order Pentagynia.--GENREIC CHARACTER. Calitz, periauth oneleafed, coriaceous, tubulous, five-toothed, permanent. Corolla: petals five: class the length of the tube of the calix; border spreading, obtues. Staminar, filaments awi-shaped, five alternately later than the other five, inserted into each claw of the petals. Authers simple. Pistil: germ ovate. Syles filtion, erect, the length of the stamina. Sigmas simple. Pericarp: capsule oblog, ovate, covered, oneceled, five valved. Seeds very many, kidney-shaped, dotted. Receptacles: free, as many as seeds, the interior ones gradually longer. EssENTIAL CHARCTER. Calix: one-leafed, coriaceous. Petals: five, clawed; border obtuse, undivided. Copute one celled.----The species are,

water, sweetened with honey, and half a pint of it drank three times a day, is an effectual carre for the jaundice. It day is an effectual carre for the jaundice. It day is a constraint of the discreption of the discreptio

The seeds are diuretic; they promote the menses, and are serviceable in the dropsy and jaundice, but the use of them must be continued for a considerable length of time. Hill says, the seeds are used ; they work by urine, and open all obstructions, promote the menses, and are good in dropsy and jaundice: the best way of giving them is powdered, and put into an electuary, to be taken for a continuance of time; for those medicines whose virtues are against chronic diseases, do not take effect at once.

2. Agrostemma Coronaria; Rose Campion. Tomentose. leaves ovate-lanceolate; petals slightly emarginate, crowned, serrate .- This is a native of Italy, the Valais, and Siberia, and is a biennial plant. It has long been an inhabitant of the English gardens, where, by its seed having scattered, it is become a kind of weed. There are three varieties of this species, one with a deep red, another with a flesh-coloured, and the third with a white flower : but all little esteemed, as the double rose Campion, being a fine flower, has turned the others out of most gardens: they propagate themselves best by their seeds.

3. Agrostemma Flos Jovis: Umbellate Rose Campion, or Flower of Jove. Tomentose, petals emarginate, flowers in a corymb .- The flowers, which are of a bright red, appear in July, and the seeds ripen in September. It grows naturally on the Swiss and Piedmontese mountains, and in the Palatinate. This requires a shady situation and moist soil.

4. Agrostemma Cœli Rosa; Smooth Campion, or Rose of Heaven, Smooth, leaves linear-lanceolate, petals emarginate, crowned.-An annual plant, the stem a foot or eighteen inches high; native of Italy, Sicily, and the Levant; and having little beauty, is only preserved in botanic gardens for variety's sake.

Agrostis ; a genus of the class Triandria, order Digynia .--GENERIC CHARACTER. Calix: a one-flowered, bivalve. acuminate glume. Corolla : bivalve, acuminate, one valve larger than the other. Stamina : filaments longer than the corolla, with forked antheræ. Pistil: germ roundish; styles reflex, villous, with stigmas longitudinally hispid. Pericarp: corolla growing to the seed, not gaping. Seed : roundish, pointed at both ends, the corrolla adhering closely to it. ESSENTIAL CHARACTER. Calix : bivalve, one-flowered, a little less than the corolla. Stigmas : longitudinally hispid. This is said to be an artificial genus, the species of which are in general very ill ascertained. For the method of propagating and cultivating these grasses, see the article Grass .-* Awned. The species are.

1. Agrostis Spica Venti ; Silky Bent Grass. The outer petal has a very long stiff awn; the panicle is spreading .--This is from three to four feet high, annual, frequent in sandy corn-fields, and flowering from June to August.

2. Agrostis Interrupta; Interrupted Spike Bent Grass. The outer petal awned; the panicle attenuated, contracted, interrupted .- It is an annual, and native of France, Italy, Switzerland, Carniola, and Germany,

3. Aprostis Miliacea: Millet Bent Grass. The outer petal terminating in a a straight stiff awn of a moderate length .- This resembles the first species, and is a native of Montpellier, Spain, and Siberia.

4. Agrostis Bromoides; Brome-like Bent Grass. Panicle simple, narrowed; corolla pubescent; awn straight, longer than the calix ; culm a foot and half high .- A perennial, growing wild about Montpellier.

5. Agrostis Australis; Southern Bent Grass. The panicle approaching to a spike; the seed ovate, pubescent; awn the length of the calix,-This species is three feet high, and a native of Portugal.

6. Agrostis Arundinacea; Reedy Bent Grass. Panicle oblong, outer petal villous at the base, and furnished with a writhed awn, longer than the calix. Very erect, height sometimes two and sometimes four feet .- It is perephial, and native of many parts of Europe; the Calmuc Tartars weave mats, and thatch their huts, with it. Goats will almost starve rather than eat this species of grass.

7. Agrostis Calamagrostis; Branching Bent Grass. Panicle thickened, whole of the outer petal woolly, awned at the tip; culm branching .- Reaches three feet in height, is a perennial, and native of Germany, Switzerland, and about Verona.

8. Agrostis Serotina : Late Bent Grass. Floscules oblong mucronate : culm covered with very short leaves .- This, species is about a foot high, and was observed by Sequier near Verona.

9. Agrostis Rubra: Red Bent Grass. Flowering part of the panicles very spreading; outer petal smooth; awn terminal, spiral, recurved .- This species is common in Sweden and Scotland.

10. Agrostis Spiciformis; Spiky Bent Grass. Panicle resembling a spike; flowers two, awned; one awn inserted into, the receptacle, jointed and longer than the other, which is straight, and inserted below the tip of the corolla which is rough .- This species is nine inches in height, erect, very smooth, culms perfectly simple. It has been observed in the island of Teneriffe.

11, Agrostis Hirsuta; Hairy Bent Grass. Panicle approaching to a spike ; culm and leaves hirsute, glumes of the corolla awned on the back, and bifid at the tip .- This species is easily distinguished by its shagginess; like the preceding, it is a native of the island of Teneriffe. 12. Agrostris Matrella. The flowers in racemes, onter

valve of the calix bent in, the tip of the keel only gaping. -This differs somewhat from the other species in character. and is found in the sandy lands of Malabar.

13. Agrostis Canina; Brown Bent Grass. Calix elongate : a recurved awn on the back of the petals ; culms prostrate, a little branching.—This species is perennial. * Naked, or Awnless.

14. Agrostis Stolonifera; Creeping Bent Grass. Branches of the panicle spreading, naked ; culm creeping ; calices equal.-This is known by its creeping stems, putting out roots, and producing new plants. It is a native of most parts of Europe, flowering from June to August, and is found in moist meadows.

15. Agrostis Capillaris; Fine Bent Grass, Panicle capillary, spreading, flexuose; calices subulate, equal, smooth, coloured .- An annual species, a native of Lapland, common in pastures and by road-sides.

16. Agrostis Sylvatica; Wood Bent Grass. Panicle contracted; calices equal, those of the barren flower shorter than the corolla, those of the fertile ones twice as long .- It is perennial, and is found in moist woods, as in Bishop's Wood, and Hornsey Wood, near London.

17. Agrostis Alba ; White Bent Grass. Panicle loose ; calices equal; culm creeping; it has purple anthera :- grows in ditches, marshes, and moist meadows, and is perennial,

18. Agrostis Pumila; Dwarf Bent Grass. Panicle on one side; culms erect in bunches .- It is a perennial plant, native of Iceland, Sweden, Germany, Switzerland, of dry places in England, and of Wales and Scotland.

19. Agrostis Minima; Least Bent Grass. Panicle filiform .-- This is an annual spring plant, which flowers early, and ripens its seeds in May. Native of France and Germany, and has been seen in Wales.

contracted, filiform ; flowers linear, valves parallel .- A perennial, and native of the East Indies.

21. Agrostis Virginica; Virginian Bent Grass. Panicle contracted, leaves rolled inwards, subulate, rigid, stauding out .- An elegant little plant, the stalk somewhat compressed, and seldom rising above four or five inches from the root.

22. Agrostis Mexicana; Mexican Bent Grass. Panicle oblong, heaped; calix and corolla acuminate, and nearly equal. Culms numerous, a foot high, smooth, erect .- This species is difficult to determine. It is a native of South America, flowers the second ycar, and has the appearance of Cinna.

23. Agrostis Purpurascens ; Purple Bent Grass. Panicle contracted, elongate ; branches pressed close, upright ; florets unequal, acuminate .--- A native of Jamaica.

24. Agrostis Indica ; Indian Bent Grass. Panicle contracted; racemes lateral, erect, alternate .- A native of India.

25. Agrostis Ciliata; Ciliate Bent Grass. Glume of the calix angular and ciliate .- A native of Japan.

26. Agrostis Panicea; Bearded Bent Grass. Panicle subspiked ; branches and branchlets fascicled ; valves of the calix, and one of the corolla, awned; that of the corolla very short. -This grows in marshes and wet pastures.

27. Agrostis Lenta ; Forked Bent Grass. Spikes subtern, umbellate; floscules awnless, oblong, acute; calveine valves subequal: leaves and sheaths smooth.-It is annual, a native of the East Indies, and flowers in July and August.

28. Agrostis Complanata: Flat-stalked Bent Grass. Spikes umbelled, smooth; outer calvcine valves awned; flatted leaves, and sheaths smooth .- This species is perennial, flowers in July and August, and is a native of Jamaica.

29. Agrostis Pungens; Prickly Bent Grass. Panicle contracted; leaves involute, stiff, pungent; the upper ones obliquely opposite; culm branching .--- Pcrennial, and a native of Arabia, Barbary, and the dry countries near the coast of the county of Nice. The Arabs use it as a medicine for the piles.

30. Agrostis Vinealis; Short awned Bent Grass. Culms ascending; calix coloured; awn nearly straight, from below the middle of the back ; about as long as the calix .- Native of Switzerland, and the north of England.

31. Agrostis Ovata ; Orate-panicled Bent Grass. Outer petal awned below the tip; panicle ovate, contracted, spikeform .- A native of New Zealand.

32. Agrostis Odorata : Sweet Bent Grass. Spikes with the florets pointing one way, heaped together; culm six inches high .- A native of Cochin-China, near the coast. This grass is highly esteemed by the Cochin-Chinese for the permanency of its odour; they dry it to perfume their clothes with.

33. Agrostis Plicata; Plaited-leared Bent Grass. Leaves plaited ; spike linear, awuless. Culm a foot and half high --Native of the suburbs of Canton.

34. Agrostis Cinna. Panicle contracted; flowers acuminate, with one, two, or three stamina ; leaves flat, scabrous.

35. Agrostis Diandra. Panicle elongate, contracted; flowers subulate, two-stamined; leaves convolute .- Native of the East Indies, whence it was sent by Koenig under the name of Cinna.

Agyneia; a genus of the class Monœcia, order Monadelphia .- GENERIC CHARACTER. Male flower below the female. Calix six-leaved ; leaflets oblong, obtuse, equal, permanent. Corolla: none. In the male, instead of filaments, a column shorter than the calix. Three or four antheræ, ob long, growing to the column below the top. In the female flowers, germ of the size of the calix, subovate, obtuse, perforated at top with a six-notched hole; neither style nor stigma. Pericarp supposed to be a tricoccous capsule. ESSENTIAL 6.

20. Agrostis Teuacissima ; Tough Bent Grass. Panicle CHARACTER. Calix : six-leaved. Corolla : none. Male : three antheræ, growing to the rudiment of a style. Female: germ perforated at top; without style or stigma .-----Species, 1. Agyneia Impubes .- Leaves smooth on both sides. An

AIR

erect shrub, a native of China.

2. Agyneia Pubera,-Leaves down underneath. Also a native of China.

Ahouai. See Cerbera.

Ailanthus; a genus of the class Polygamia, order Monœcia. -GENERIC CHARACTER. Male: Calix, perianth oueleafed, five-parted, very small. Corolla, petals five, lanceolate, acute, convolute at the base, spreading. Stamina, filaments ten, compressed, the length of the corolla. Antheræ oblong, versatile. Female: Calix as in the male, permanent. Corolla as in the male. Pistil, germs three to five, curved inwards. Styles lateral, stigmas capitate. Pericarp, capsules as many as there are germs, compressed, membranaceous, sabre shaped, acute, on one of the edges emarginate. Seeds solitary, lens-shaped, bony, close to the emarginature. Hermaphrodite: Calix as in the male and female. Corolla as in the male. Stamina, filaments two or three, as in the male. Pistil, pericarp and seed as in the female. Es-SENTIAL CHARACTER. Male: Calix five-parted. Corolla five petalled. Stamina ten. Female: Calix and Corolla as in the male. Germs three to five. Styles lateral. Pericarp membranaceous, one-seeded. Hermaphrodite: Calix and Corolla as in the male stamina, two to three .---- One species only is known, viz.

1. Ailanthus Glandulosa; Tall Ailanthus .- This tree rises with a straight trunk to the height of forty or fifty feet; the bark is grey, slightly furrowed, and has white marks on it; the young twigs are covered with a fine velvet down. It is a native of China, grows very fast in our climate, and being a handsome and lofty tree, is proper for ornamental plantations. If the bark be wounded, a resinous juice flows out, which hardens in a few days. The wood is hard, heavy, glossy like satin, and susceptible of a very fine polish.

Aira ; a genus of the class Triandria, order Digynia .-- GE-NERIC CHARACTER. Calix, a two-flowered, two-valved glume; valves ovate-lanceolate, acute, equal. Corolla bi-valve; valves like those of the calix. Nectary two-leaved: leaflets acute, gibbous at the base. Stamina, filaments capillary, the length of the flower, with oblong antheræ, forked at each end. Pistil, germ ovate, styles setaceous, spreading, with pubescent stigmas. Pericarp, none. Seed subovate, covered by the corolla. ESSENTIAL CHARACTER. Calix two-valved, two flowered, without any rudiment of a third. For the method of propagation and culture, see Grass .---The species are,

* Naked, or awnless.

1. Aira Arundinacea; Reedy Aira-grass. Panicle oblong, on one side, imbricate; leaves flat .- It is found in the Levant, and in Cochin-China.

2. Aira Minuta; Minute Aira-grass. Panicle loose, almost level-topped, very branching .- This is an annual grass, scarcely an inch high, and a native of Spain.

3. Aira Aquatica ; Water Aira-grass. Panicle spreading, flowers smooth, longer than the calix, leaves flat .- The root of this species is perennial, it runs to a considerable distance in the water, throwing off roots and young shoots as it passes along. It flowers in June and July, but is not worthy of cultivation. The sandy lands near Exmouth, about Northfleet in Kent, and in Yorkshire and Lancashire, produce it.

* Awned.

4. Aira Subspicata; Spiked Aira-grass. Leaves flat, panicle spiked, flowers awned on the middle ; awn reflex, loose,

AIU

Savoy, Denmark, and Lapland.

5. Aira Cæspitosa; Turfy Aira grass .- Leaves flat; panicle spreading; petals villous, and awned at the base; awn straight, short.—The culm of this grass is about a yard high. In marshes it is frequently viviparous, and growing in tufts it occasions irregularities, tussocks, or hassocks, as they are vulgarly called, in meadows. Cows, goats, and swine eat it, but horses are not fond of it. It is perennial.

6. Aira Flexuosa; Heath Aira-grass. Awned; leaves setaceous ; culms almost naked ; panicle divaricated ; peduncles flexuose .- This plant is perennial, a native of heaths, barren pastures, and rocky moors. Horses, kine, and sheep eat it.

7. Aira Montana; Mountain Aira-grass. Leaves setaceous; panicle narrowed; flowers hairy at the base, and awned; awn twisted, and very long.-This is a native of high heaths and barren pastures, it is perennial, and sheep are very fond of it.

8. Aira Alpina ; Alpine Aira-grass. Leaves subulate ; panicle dense : flowers hairy at the base, and awned : awn short, -This species grows on the mountains of Germany, Savoy, and Lapland.

9. Aira Villosa ; Villose Aira-grass. Leaves subulate ; panicle long and narrow; flowers sesquialteral, shaggy, awned; awn straight, short .- Native of the Cape of Good Hope.

10. Aira Canescens; Gray Aira-grass. Leaves setaceous, the upper one involving the panicle at bottom like a spathe .- This may be known at first sight from most other grasses by its paleness. It is a native of sandy shores, the walls of Basil, and the sandy fields of Germany and Piedmont

11. Aira Præcox; Early Aira-grass. Leaves setaceous, sheaths angled; flowers panicle-spiked, and awned at the base .- This species has a sweet taste ; horses and sheep eat it, and cows are very fond of it. It grows in ditches, in wet meadows, and on the banks of streams ; it flowers in June and July.

12. Aira Carvophyllea; Silver Ain z-grass. Leaves setaceous; panicle divaricated; flowers awned, distant .- This is an annual plant, a native of the sandy pastures and heaths of England, France, Switzerland, Piedmont, Germany, and Denmark

13. Aira Antarctica ; South Sea Aira-grass. Leaves flat ; panicle compound, spreading; calices three-flowered; floscules awned in the middle ; awn elongated, straightish .- A native of New Zealand.

14. Aira Involucrata: Involucred Aira-grass. Panicle spreading, involucred, with bristles at the base; floscules awnless .- Native of Spain, on the barren hills near Madrid ; it is annual, and flowers in June and July.

Aitonia; a genus of the class Monadelphia, order Octandria .- GENERIC CHARACTER. Calix: perianth one-leafed, erect, four-parted, short, divided into four ovate sharp segments. Corolla has four, erect, equal, broadly-cvate, concave, very obtuse petals. Stamina: filaments joined as far as the middle; divided above into eight; awl-shaped, furrowed, standing out of the corolla ; and having ovate furrowed antheræ. Pistil: germ superior, smooth, subangular; style one, filiform, of the same length with the stamina; stigma obtuse, undivided. Pericarp: an ovate, dry, mem-branaceous, four-cornered, one-celled, brittle berry; the corners are produced and sharp. Seeds: many, fixed to a column, globular, and smooth. Observe, It varies with five-eleft, ten-stamined, flowers. ESSENTIAL CHARACTER.

-It is perennial, found upon the mountains of Switzerland. Berry dry, anadrangular, one-celled, many-seeded.-Only one species is known, viz.

1. Aitonia Capensis .- This shrub is slow of growth with us, and seldom exceeds three feet in height. It is raised only from seeds, which are sparingly produced in this country : and it must be kept in the greenhouse or cape-stove. When it is of sufficient age, it produces flowers and fruit, which is large, and of a fine red colour through most of the year.

Aiuga : a genus of the Didynamia class, and Gymnospermia order .- GENERIC CHARACTER. Calix: perianth one-leafed, short, cut half way into the five-clefts, with the segments nearly equal. Corolla: monopetalous, ringent; tube cylindric, bent in; upper lip very small, erect, bifid, obtuse; middle division very large and obcordate; side one small, Stamina: filaments subulate, erect, longer than the upper lip; antheræ twin. Pistil: germ four-parted ; style filiform. situation and length as in the stamina ; stigmas two, slender, the lowest shorter. Pericarp : nonc ; the calix, which is converging, fosters the seeds. Seeds: somewhat oblong. Es-sential CHARACTER. Corolla: upper lip very small. Stamina: longer than the upper lip. — The species are,

1. Ajuga Orientalis : Eastern Bugle, Flowers inverted. The stem is a foot and half high: there are several varieties, differing only in the colour of their flowers. It is a native of the Levant, and requires a little protection in winter, and as much free air as possible, except in hard frosts. They are propagated by seeds, and also by offsets ; but the latter is a very slow method.

2. Ajuga Pyramidalis; Pyramidal Bugle. Spike a quadrangular, villous pyramid; leaves approximating; root-leaves very large ; bractes nearly entire. The stem is four or five inches high .- The plant is biennial, and flowers in April. It is a native of Italy, France, Germany, Switzerland, Sweden, Denmark, Wales, and Scotland.

3. Ajuga Alpina; Alpine Bugle. Stem simple, stemleaves equalling the radical ones .- This plant requires a moist and shady situation; it grows naturally on the Alps, and is admitted into some gardens for the sake of variety, where it propagates plentifully by its trailing stalks.

4. Ajuga Genevensis; Geneva Bugle, Leaves downy. streaked with lines, lowermost narrower; calices shaggy; bractes generally three-lobed .- This species nearly resembles the common bugle. It grows wild about Geneva, and in many of the southern countries of Europe.

5. Ajuga Reptans; Common Bugle, Smooth, and creeping by runners .- This species is so plentiful in a wild state, that it is seldom admitted into gardens. Its stalk is six inches high, upright, hairy, and purple. The corolla is blue, coloured with white veins. It flowers from May to June, and grows naturally in woods and moist meadows, in most parts of England, and of the south of Europe. There are two varieties. one with a white, the other with a pale purple flower, growing in different parts of Westmoreland, but they only differ in mere colour from the blue sort. It is numbered amoug cooling and gently astringent vegetables, and is recommended both as an internal and external vulnerary. The leaves, when first chewed, have a sweetish taste, which soon changes into an austere and bitter one. An infusion of them, or their expressed juice, is good for wounds and bruises, whether internal or external, and is also esteemed a good diuretic. The leaves are of a wild astringent corroborating nature, and may be advantageously used in fluxes and all disorders of that kind, as they do not, like many other plants of the same nature, produce costiveness, but rather operate as gentle laxatives. The roots of this plant appear to be more astringent than any Style; one. Caliz: four-parted. Corolla: four-petalled. other part by their striking a black colour with vitriol of iron.

ALC

Some foreign physicians of eminence have recommended a decoction of this herb in the quinsy; it is not employed among us, but is constantly found mixed with the vulnerary herbs imported from Switzerland.

6. Aluga Decumbens ; Japanese Bugle. Decumbent and villous; leaves obovate, toothed .- This plant sends up many stems; it may be propagated in the same manner as the first species.

Aizoon ; a genus of the class Icosandria, order Pentagynia. -GENERIC CHARACTER. Calix: perianth one-leafed, divided into five lanceolate permanent segments. Corolla: none. Stamina: filaments very many, capillary, inserted by bunches into the sinuses of the calix, Antheræ simple. Pistil: germ five-cornered, superior. Styles five, simple; stigmas simple. Pericarp: capsule five-celled, five-valved, swelling, and retuse. Seeds: several, roundish, or kidneyshaped. ESSENTIAL CHARACTER. Calix: five-parted. Petals none. Capsule: superior, five-celled, five-valved .-The species are.

1. Aizoon Canariense; Purslane-leaved Aizoon. Leaves wedge-ovate, flowers sessile .-- This species is an annual plant, and a native of the Canary islands ; it must be raised on a moderate hot-bed in the spring, and when fit to remove, should be carefully planted in a small pot filled with light fresh earth, and plunged into another bed, shaded from the sun, until they have again taken root; after this they must be gradually hardened to the open air, into which they should be removed in June, placing them in a sheltered situation, where they will flower and ripen seed in September, soon after which they die.

2. Aizoon Hispanicum; Spanish Aizoon. Leaves lanceolate, flowers sessile .- An annual plant, whose branches trail on the ground, growing naturally in Spain and Africa; and which, as the flowers have no beauty, is only preserved by those who are curious in collecting rare plants. It is propagated like the preceding species.

3. Aizoon Lanceolatum; Panicled Aizoon. Leaves lanceolate, flowers panicled .- This is of humble growth, and perishes soon after the seeds are ripe; grows naturally at the Cape of Good Hope, and may be propagated in the same manner as the two preceding species.

4. Aizoon Sarmentosum. Leaves linear, filiform ; panicle dichotomous; flowers solitary, peduncled .- A native of the Cape of Good Hope.

5. Aizoon Paniculatum; Panicled Aizoon. Shaggy; leaves lanceolate; flowers sessile; branches erect .- Native of the Cape of Good Hope.

6. Aizoon Perfoliatum ; Perfoliate Aizoon. Downy ; leaves inversely ovate, conjoined, crystalline, dotted; flowers peduncled .- Native of the Cape of Good Hope.

7. Aizoon Glinoides; Hairy Aizoon. Shaggy, herbaceous, procumbent ; leaves ovate ; flowers sessile, distinct .-Native of the Cape of Good Hope.

8. Aizoon Secundum. Shag-hoary, herbaceous, procumbent; leaves ovate; flowers sessile, imbricate, one-ranked. -This species also is a native of the Cape of Good Hope.

9. Aizoon Fruticosum; Shrubby Aizoon. Shrubby, erect, smooth; leaves lanceolate; flowers sessile .--- A native of the Cape of Good Hone.

10. Aizoou Rigidum. Stiff Aizoon. Shrubby, procumbent, downy; leaves ovate; flowers sessile, remote .- A native of the Cape of Good Hope.

Aizoon. See Sedum.

Alaternoides. See Chuytia.

Alaternus, See Rhamnus,

-GENERIC CHARACTER. Calix: none. Corolla: petals six, oblong-oval, permanent; the three outer spreading, the three inner converging. Stamina: filaments shorter than the corolla, three opposite to the inner petals, linear-subulate, complicate a little about the base, then flat; three opposite to the outer petals thicker. Antheræ on the former oblong, fixed to the inflexed tip of the filament below the middle, upright; on the latter, similar but barren, or none. Pistil; germ oblong, triangular; style three-sided; stigma, a triangular pyrainid. Pericarp: an oblong, obtuse, triangular, three-celled, three-valved capsule. Seeds: numerous, flat, lying over each other, and widening outwards. ESSENTIAL CHARACTER. Corolla: six-petalled; the inner ones difform. Stamina: three of the six castrated. Stigma: surrounded by three cusps. The roots of these plants are kept in pots filled with light earth, and sheltered under a hot-bed frame in winter .---- The species are,

* Three Stamina only fertile.

1. Albuca Altissima; Tall Albuca. Interior petals glandulose, and bent in at the tip; leaves subulate, channelled, convolute .--- This species flowers in April and May.

2. Albuca Major; Great Albuca. Interior petals glandulose, and bent in at the tip; leaves linear-lanceolate, flattish. -It is a native of the Cape of Good Hope, and flowers in May.

3. Albuca Minor; Small Albuca. Interior petals glanduiose, and bent in at the tip ; leaves linear-subulate, channelled, -It flowers in May and June.

4. Albuca Coarcta; Channel-leaved Albuca. Interior petals vanited at the tip; leaves smooth, linear-subulate, channelled; peduncles the length of the bractes .- It flowers in May.

5 Albuca Spiralis; Spiral leaved Albuca. Interior petals vaulted at the tip; leaves spiral .-- Native of the Cape of Good Hope.

* All the Stamina fertile.

6. Albuca Fastigiata ; Upright flowered Albuca. Interior petals vaulted at the tip ; leaves smooth ; peduncles very long. This species flowers in May.

7. Albaca Viscosa; Viscose Albuca. Interior petals vaulted at the tip; leaves hairy, glandulose .---- This species flowers in May and June.

8. Albuca Abyssinica; Abyssinian Albuca. Leaves linear, channelled, smooth.

Alcea; a genus of the class Monadelphia, order Polyandria. -GENERIC CHARACTER. Calix: double, each one-leafed; the outer cut half way into six parts, permanent, and very spreading ; the inner cut half way into five parts, larger and permanent. Corolla: five obcordate, emarginate, spreading petals, coalescing at their bases. Stamina : filaments uniting into a sort of five-angled cylinder at bottom, loose at top, and inserted into the corolla ; antheræ almost kidney-shaped. Pistil: germ orbiculate; style cylindric, short; stigmas about twenty, setaceous, the length of the style. Pericarp : many jointed arils in a ring round a columnar flatted receptacle, parting and opening on the inside. Seed: one, flat, kidney-shaped in each aril. ESSENTIAL CHARACTER. Calix double: outer six-cleft. Arils many, one-seeded .--Plants of this genus are propagated by seeds, which should double and the best colours. They must be gathered dry, kept from damp in winter, and sown an inch deep in a bed of light earth in the middle of April. When the young plants have six or eight leaves, they should be transplanted to nursery beds, and placed a foot asunder, observing to water them Albuca; a genus of the class Hexandria, order Monogynia. well until they have taken root; after which they require no

ALE

further care, except to weed them until October, when they may be planted out wherever they are intended to remain. —The species are, westmore and the second secon

ALC

1 Alcea Rosea: Common Holly-lock. Leaves simulatemuglata--Diris species grows naturally in China, whence its seeds are frequently imported, so that they are become very common. They flower from July until September, and often rise to nine feet high in good ground, six feet of which is garaished with dowers, which when *dawbe*, and of a good colour, make a beautiful appearance, especially if the various colours be properly intermixed. Meyrick says, that a decoction of the roots operates by urine, and is serviceable in the stone, gravel, and all other disorders of the urinary vessels, such as the strangury, heat of urine, &c. It is a good ingredient in pontices, fomentations, and clysters, for any of the aforesaid purposes, and appears to possess nearly the same virtues with the marshamallow.

2. Alcea Ficifolia; Fig-Jeared Holly-bock. Leaves palmate.—The seeds of this species were received from Istria, by Mr. Miller: like the common Holly-hock, though a native of warm countries, it is hardy enough to bear the open air of England; and is one of the greatest romaments of our gardens towards the latter end of summer. Both this and the first species require tall stakes to secure them from violent winds, and produce a succession of flowers for two months.

3. Alcea Africana; *African Holly-hock*. Leaves threelobed, crenate; flowers solitary, axillary; both calices sixparted.—The stem of this species rises upright four feet high. It is a native of the eastern shore of Africa.

Alcea. See Malva.

Achemilla : a genus of the class Tetrandria, order Monoguia.—GENERIC CHARACTER. Calix: perianth oneleafed, tubulous, permanent : edge flat, divided into eight segments. Coralle: none. Xaminue: filments erect, awislaped, very small on the edge of the calix : antheræ roundish. Pistil: germ ovate; style filform, length of the stamina, inserted at the class of the germ; stigma globular. Pericarp: none ; the neck of the calix closes and never opens. Sæds: solitary, elliptic, compressed. ESENTIAL CHA-RACTER. Calix: eight-telft. Coralız: none. Sæd: sone: The best way to propagate this genus of plants, is by parting their roots in autumn, that they may be established before the drying winds of spring come on. They require a moist soil and sbady situation, or they will not thrive in the southern parts of England.—The species are,

1. Alchemilla Vulgaris : Common Ladies-Mantle, or Bears-foot. Leaves lobed .- This plant grows naturally in the high pastures of several parts of England, but is not very common near London; it rises about a foot high, and its leaves are scalloped round the edges, resembling the scalloped mantles of the ladies, from which it bas its name. Cows are not partial to it; but horses, goats, and sheep eat it. In Sweden, a tincture of the leaves is given in spasmodic or convulsive diseases: they are also esteemed to be vulnerary, drying, and binding, and are of great force to stop inward bleeding. The root is the most valuable part of the plant; and a strong decoction of it fresh taken up is excellent for immoderate discharges of the menses, the bloody flux, and all other bleedings. Dried and reduced to powder, it answers the same purposes, and is also good for common purges when they continue too long. Some say it has its name from its being used by the women in the north of England, to reduce their breasts to form after they have been swelled with milk, which is effected by an external applica-tion of the leaves. It is a perennial plant.

2. Alchemila Alpina; Cinquefoil, or Alpine Ladies-Mantler, Leaves digitate, serate-This is found growing naturally on the mountains of Yorkshire, Westmoreland, and Cumberland, generally upon moist begy places. It is alsoa native of Sweden, Demmark, the Alps, and other cold parts of Europe, and is admitted into gardens for its elegance. The leaves are of a fine white, and the stem seldom exceeds six inches in height.

3. Alchemilla Aphanoides. Leaves many-parted; stem erect.—This is a small plant, resembling the Aphanes Arvensis or Parsley Piert, and was found in Sonth America by Mentis.

4. Alchemilla Pentaphyllea; Fire-leared Ladies-Mantle-Leaves quinate, multifid, smooth.—This species grows natuturally on the high Alps, as Gotlard, Furica, Speluga, Pilat, &c.; and is only to be found in some few curious botanic gardens in this country.

Alchornea ; a genus of the class Diæcia, order Monadelphia. GENERIC CHARACTER. Male: Calix; perianth three or five-leaved ; leaflets ovate, concave, equal, coloured, deciduous, Corolla: none, Stamina: filaments eight, equal, scarce longer than the calix, slightly connate at the base. Antheræ ovate, upright. Pistil: a rudiment. Female : Calix ; perianth one-leafed, four or five toothed ; teeth equal. small. Corolla: none, Pistil: germ twin, superior. Styles two, very long, filiform. Stigmas simple, acute. Pericarp: capsule berried, two-seeded, two-celled, two-valved. Seeds solitary, large, oblong. ESSENTIAL CHARACTER. Male: Calix ; three or five-leaved. Corolla : none. Female : Calix ; five-toothed. Corolla: none. Style: two-parted. Capsule : berried, dicoccous .---- One species only is known, viz.

 Alchornea Latifolis. Note, This genus was named after Mr. Stainsby Alchorne, apothecary, of London; but there are no particulars of its qualities or use, in Miller's Gardener's Dictionary, edited by Professor Martyn, Lond. 1807.

ALDER-TREE. See Betula Alnus.

Aldroganda ; a genus of the Pentandria class, order Pentagynia.—GENERIC CHARACTER. Caliz: perianth fiveparted, erect, equal, permanent. Carolla: petals five, oblong, acuminate, length of the calis, permanent. Stamina: filaments length of the flowers i authera simple. Pisiti's germ globose; styles very short; stigmas obluse. Pericarp: a globose capsule, with five blunt angles, five-ralved, onecelled. Seeds: ten, longish, fixed to the inner wall of the pericarp. ESSENTIAL CHARACTER. Caliz: five-parted, Petals ive. Capsule five-valved, one-celled, ten-seeded.—— The species are.

 Aldrovanda Vesiculosa. Root perennial, flowers solitary, and the stem seeming to terminate in a peduncle, whilst that continues the stem, or produces a branch from the side. Stamina between the petals. Anthera yellow, twin.—This plant is found in marshes, both in thaly and India.

ALE-COST. See Tanacetum.

Alectra : a genus of the class Didynamia, order Angiospermia.-GENEHIC CHARACTER. Caliz: perinath one-leafed, two-lipped, upper lip two-left, lower three-deft; clefts ovate, obtuse, shorter than the tube. Corolla: one petalled, tubular. Tube by degrees widened a little. Border expanding, five-parted; parts broad-lanceolate, obtuse. Stanimar filaments four, inserted into the tube, foliform; bearded, length of the tube; two of them are a little shorter. Antherae twin. Pizili ; gern ovate. Style filiform, length of the filaments. Stigma incurved, a little thicker than the syle, and of the same length, strated on both sides. Pericarp: capsule ovate obtuse, twin, smooth, two-celled, two-valved. Seeds: solitary, ovate. ESENTIAL CHARACTER. Corolla: bell-shaped. Filaments bearded. Capsule two-celled.

1. Alectra Capensis. Root annual; stem simple, round, striated, erect, villose, a span or a foot in height.—It is a native of the Cape of Good Hope; grows in grassy places near rivers, and flowers in November and December.

ALE-HOOF. See Glechoma.

Alteris; a genus of the class Hexandria, order Monogynia. -GENERIC CHARACTER. Caliz: none. Corolle: onepetalled, ovate, oblong, hexangular, funnel-shaped, semisexfd, very much wrinkled; the divisions lanceolate, acuminate, spreading, erect, permanent. Stamina: filaments awl-shaped, length of the corolla inserted into the base of the divisions; autherw oblong, erect. Pistil: gern ovate; style subalter, length of the stamina; stigma trifd. Pericarp: an ovate; three-cornered, acuminate, three-celled capsule. Szeds: very many. EssERTIAL CHARACTER. Corolla: funnel-shaped. Stamina: inserted into the base of the segments. Capsule: three-celled.—The species are,

 Aletris Farinosa; American Aletris. Stemless; leaves lanceolate, membranaceous; flowers alternate.—A native of America, raredy producing its seeds in England, where it is rare, but may be preserved throughout the winter, if placed unders hot-bed frame. The Americans frequently use it in coughs, and in the pleurisy.

2. Aletria Capenisis, Wared-tarend Aletria. Stemless; leaves lanceolate, waved, splite ovate; flowers nodding... This is a native of the Cape of Good Hope, and howers from November to April in England. This joint must be sheltered in winter, but placed abroad and watered during summer.

3. Aletris Glauca; Glauccus Aletris. Stemless; leaves lanceolate, glaucous; flowers nodding, with a spreading border.—It flowers in january, and is a native of the Cape of Good Hope.

4. Aletris Uvaria; Great Orange-flanered Aletris. Stemless; scape longer than the sword-shaped keeled leaves. —The flowers of this species are of an orange colour, so that when the plants are strong, and produce long spikes, they make a fine appearance. It flowers in Angust and September, will bear mild winters abroad in England, and is propagated by seed sown in pots soon after they are ripe, and sheltered under a common hot-bed frame till the plants appear; after which, they are gradually inured to bear the open air; but they are not able to endure the first winter, during which they must be sheltered until they have acquired sufficient strength to resist the cold. Native of the Cape of Grood Hope.

5. Aletris Pumila; Small Orange flowered Aletris. Stemless; scape shorter than the linear sharply keeled leaves. —This species flowers from September to November, and is a native of the Cape of Good Hope.

6. Aletris Hyacinthoides. All the leaves lanceolate,— This plant requires a warm stove in winter, and will not flower in England unless plunged into a tan-bed, where it will grow to most advantage.

7. Aletris Fragans; Sweet-scented Aletris. Caulescent; leaves lanceolate, loose, — This plant requires the same treatment as the preceding species.

8. Aletris Cochinehinensis. Caulescent; leaves lanccolate-linear, reflex; flowers panieled. Strem shrubby, six feet high, quite simple, upright.—A natives of Cochine Chima, where it is cultivated in gardens; the natives cat the flowers, and use the leaves for dyeing green. It is casily propagated from the side-heads which it puts out after flowering, and which require the same method as the sixth species.

Aleurites; a genus of the elass Monaccia, order Monadelphia.—GENERIC CHARACTER. Male Floreers: Calir; perianth three-eleft, very short; elefts ovate, obtuse. Corolla: petals five, oblong, spreading, obtuse, much longer than the calk. Netary: five scales, somewhat compered, very short at the bases of the petals. Stamina: filaments numerous, sounate into a conic columnar receptacle. Anthere roundish. Female Floreers: few, in the same corymb. Calix, Corolla, Netary: as in the male, but larger. Pistil: germ conic, superior. Style none. Stigmas two, very short. Pericary: berry large; globose, two sceeded. Scels: two, globose, coated with a double bark.——There is only one species known, viz.

1. Aleurites Triloba .--- Its qualities and uses not ascertained.

ALEXANDERS. See Smyrnium.

ALEXANDRIAN LAUREL. See Ruscus.

Algæ. See Cryptogamia.

Alhagi. See Hedysarum.

Alisanders. See Smyrnium and Alexanders.

Alisma : a genus of the Hexandria class, Polygunia order, -GENERIC CHARACTER. Cdir: periamth three-leaved; leafiels ovate, concave, permanent. Corolla: three-petalled. Petals roundish, harge, flat, very spreading. Stamins: filaments awl-shaped, shorter than the corolla; anthere roundish. Pistil: germs more than five; styles simple; stigmas obtuse. Pricarp: coinpressed expusies. Sced: solitary, small. ESSENTAL CHARACTER. Calis: three-leaved. Petals: three. Sceds: several.-To cultivate the European species of this genus, you must either have a piece of water on purpose, or keep the pots or tubs perpetually immersed in water, unless the plants he in wooden frames with partitions filled with earth, so that they can be watered at pleasure.

1. Alisma Plantage; Great Water Plantain. Leaves orate, caute; capsules obtuely triangular.—The flowers of this plant, which grows in watery places, on the banks of pools, lakes, and rivers, are fully expanded about four in the afternoon. It flowers in July and August, and is frequently used by the country people for fallings down of the fundament, and the piles. The puice stops spitting of blood, and bloody urine; and applied to womer's breast, drives up the smilk very soon. The seed is the part used: the plant is to be suffered to stand till the seed is thoroughly rine; it is then to be east up gently, and haid to dry two or three days upon a table; a smart stroke or two will dislode a great quantity of the seeds, which are very good against the overflowing of the nenses, and all other bleedings; and are given in powder in repeated.

2. Alisma Flava. Leaves ovate, acute; peduncles unbellate; capsules globos.—This species grows in Jamaice, Barbadoes, and several places in the warm parts of America, in stagnant waters and swampy places; it would be difficult to preserve this plant in England, since it will not live in the open air, and requires a bog to make it thrive; but it has neither beauty nor use, and is not worthy of eultivation.

3. Alisma Damasonium; Star-headed Water Plantain.— Leaves cordate, oblong; flowers six-pointalled; capsules aushaped.—A native of France, England, and Siberia, found in standing waters, if they are not very deep; but it is by no means so common as the first sort. If it be wanted as a medicine it must be gathered in its natural place of growth, since it is never enluitvated in gardens.

4. Alisma Cordifolia. Leaves heart-shaped, obtuse; flowers twelve-stamined; eapsules hook-pointed. A native both of North and South America.

5. Alisma Natans: Creeping Water Plantain. Leaves ovate, obtuse ; peduncles solitary .-. This is found in ditches in France, Sweden, Germany, and Siberia; also in a lake or two in Wales; and flowers in July and August.

6. Alisma Ranunculoides: Small Water Plantain, Leaves linear-lanceolate : capsules globose and squarrose. The corolla of this plant is bluish, and opens about noon. It is found on marshes and moors, as on Giggleswick Farm, Yorkshire : between Burton and Derby, Bungay, Suffolk ; Ellingham fen. Norfolk ; and is also a native of Sweden. Holland, France, Germany, and Italy.

7. Alisma Subulata. Leaves awl-shaped .- This is a Virginian plant, with a very tender white corolla, and subulate leaves.

8. Alisma Parnassifolia. Leaves heart-shaped, acute: petioles jointed .- It grows to the same height as the first species. The seeds are awned. It is a native of Italy, in the marshes under the Apennines.

9. Alisma Repens. Stems creeping; leaves lanceolate, petioled, acute .- This species flowers in August ; it is a native of Spain, found on the sandy banks of the river Manzanares.

Alisma. See Arnica. Primula. Sinecio.

Alkeuda. See Murtus.

ALKANET. See Anchusa.

Alkekengi. See Physalis.

Allamanda; a genus of the Pentandria class, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-parted; parts ovate, acute. Corolla: one-petalled, funnel-shaped; tube cylindric; border semi-quinquefid, swelling; divisions spreading, obtuse. Stamina: filaments scarcely any: antheræ five, sagittate, converging in the throat of the tube. Pistil : germ oval, surrounded with a ring; style filiform, the length of the tube; stigma headed, contracted in the middle. Pericarp : an orbicular, lens shaped, echinate, one-celled, two-valved capsule. Seeds : very many, imbricate, orbiculate, flat-edged with a membranous ESSENTIAL CHARACTER. Corolla: contorted. wing. Cansule : lens shaped, erect, echinate, one-celled, two-valved, many-seeded .---- The only species known is,

1. Allamanda Cathartica .- A milky shrub, the leaves of which are cathartic; an infusion of which is used at Surinam in the colic. It is found wild there, at Cayenne, and in Guiana, by the sea-side.

ALL-GOOD. See Chenopodium.

ALL-HEAL. See Stachys.

Alliaria. See Erysimum.

ALLIGATOR PEAR. See Laurus.

Allionia ; a genus of the class Tetrandia, order Monogynia. -GENERIC CHARACTER. Calix: perianth-common to three flowers, simple, oblong, five-parted; parts ovate, acute, permanent. Proper obsolete superior. Corolla: proper, one-petalled, funnel-shaped, edge guinguefid, erect. Stamina: filaments setaceous, longer than the corolla, bending to one side : antheræ roundish. Pistil : germ inferior, oblong : style setaceous, longer than the stamina : stigma multifid, linear. Pericarp ; none. Seeds : solitary, oblong, five-cornered, naked. Receptucle : naked. ESSENTIAL CHARAC-TER. Calix: common, oblong, simple, three-flowered; proper obsolete, superior. Corollules irregular. Receptacle -The Species are, naked .---

1. Allionia Violacea. Leaves heart-shaped, calices quinquefid .--- A native of South America.

2. Allionia Incarnata. Leaves obliquely ovate; calices triphyllous .--- This is a native of Peru, and grows on rocks and in sandy soils.

-GENERIC CHARACTER. Calix: spathe common, round-ish, withering, many-flowered. Corolla: petals six, oblong. Stamina ; filaments six, subulate, often the length of the corolla. Antheræ oblong, upright. Pistil: germ superior. short, bluntly three-cornered, the corners marked with a line. Style simple ; stigma sharp. Pericarp ; capsule very short, broad, three-lobed, three-celled, three-valved. Seeds: few, roundish. ESSENTIAL CHARACTER. Corolla: sixparted, spreading; spathe many-flowered; umbel heaped; capsule superior. All the flowering sorts are very hardy. thriving in any soil and situation ; they may be propagated by roots or seeds; the roots should be planted in autumn. the seeds must be sown either in autumn or spring, on a border of common earth : and should be weeded until the following autumn, and may then be transplanted into borders where they are intended to remain. They flower in May, June, and July.

1. Allium Ampeloprasum : Great Round-headed Garlic. Stem-leaves flat; umbel capsule-bearing, globose; stamina three-cusped ; petals with a rough keel. The stem is a foot high or more .- It grows naturally in the East, in Switzerland, in a small island in the Bristol Channel, and flowers in July and August.

2. Allium Porrum; Common Leek. Stem-leaves flat : umbel capsule-bearing, globose; stamina three-cusped; petals with a rough keel ; root coated .- This flowers in April or May. For the cultivation of Leeks see that of Onion species. No. 36. of this genus. Hill recommends an infusion of the roots of the leek, boiled into syrup with honey, as a good medicine in coughs, asthmas, and other disorders of the breast and lungs. He says it answers the same purpose with syrup of garlic, but being milder it may be taken by many who cannot bear that medicine. The juice of leeks is a good diuretic, and will frequently afford relief in the stone and gravel, when most of the usual remedies fail.

3. Allium Lineare; Linear-leaved Garlic. Stem leaves flat; umbel capsule-bearing, globose; stamina three-cusped. twice as long as the corolla .- A native of Siberia, with purple flowers; its leaves are narrower than the common leeks. and its stalk does not rise so high.

4. Allium Rotundum. Great Round-headed Garlic. Umbel subglobose: stamina three-cusped; side-flowers nodding, -The root of this species consists of many purple and black bulbs, crowded between white common sheaths. It is a native of the southern parts of Europe.

5. Allium Victorialis ; Long-rooted Garlie. Umbel rounded ; stamina lanceolate, larger than the corolla ; leaves elliptic .- This species grows on the mountains of Switzerland. Austria, Silesia, and Savoy. The stem is from a foot to eighteen inches in height. The petals are of a dirty white, with a tincture of green.

6. Allium Subhirsutum ; Hairy Garlic, or Dioscorides's Stamina awl-shaped; lower leaves hirsute .- The Molu. flowers are white, and the stem from a foot to eighteen inches high, round, smooth, and solid .- Native of the Levant, Italy, Spain, and Africa. It flowers in May.

7. Allium Magicum ; Homer's Garlic, or Moly. Stamina simple; branches bulb-bearing .- This species grows a foot high, and is preserved by many persons in their gardens for variety's sake, although it has a very strong scent.

8. Allium Obliguum ; Obligue-leaved Garlic. Stamina filiform, thrice as long as the flower; leaves oblique .- This is a native of Siberia, it attains to two feet in height, with a cylindrical stalk.

9. Allium Ramosum ; Branched Garlic. Umbel globose ; Allium ; a genus of the Hexandria class, Monogynia order. stamina awl-shaped ; longer leaves linear-subconvex. The petals of this species are purplish; it grows naturally in Siberia, whence the seeds have been obtained with which most botanic gardens are supplied. They are solely preserved for the sake of variety.

10. Allium Roseum ; Rose Garlic. Umbel 'flat-topped ; petals emarginate ; stamina very short, simple. Flowers large and of a dark purple colour, with white and very short stamina .- It grows naturally abont Montpellier and in Piedmont, in the fields, olive-grounds, and vineyards.

11. Allium Tartaricum; Tartarian Garlic. Umbel flat; stamina simple; leaves semi-cylindrical .- This species rises half a foot high, has a flat and white corolla, with filaments shorter than the petals, and brown antheræ. Native of Siberia.

Stem-leaves flat, Umbel bulb-bearing.

12. Allium Sativum; Common Garlic. Bulb compound; stamina three-cusped .- It is said to be found wild in the island of Sicily. It has many bulbs, commonly called cloves. invested with a white skin : the leaves are linear, long, and narrow, like those of grass. This species is very heating and penetrating, and should not be too freely used. A clove or two of garlic, pounded with honey, and taken two or three nights successively, is good in rheumatic cases. A quart of water, poured boiling hot upon a pound of the fresh root, cut into slices, and suffered to stand upon it in a close vessel for twelve hours, will be strongly impregnated with the smell of garlic, and it is this infusion, with a proper quantity of sugar, which makes the syrup of garlic of the shops. Vinegar and honey greatly improves this medicine as a detergent and remover of obstructions in the breast : this composition is prepared by infusing an ounce and half of the fresh root in half a pint of vinegar, and dissolving in the strained liquor, when at the heat of a water-bath, ten ounces of clarified honey ; to cover the ill smell of the garlic, a little carraway and sweet fennel seed bruised, of cach two drachms, are hoiled for a short time in the vinegar, before the garlic is put in. The garlic itself must on no account be boiled, as its essential oil, in which its whole virtue consists, exhales during that process. Besides the above syrup, which is an invaluable medicine for asthmas, hoarseness, coughs, difficulty of breathing, and most other disorders of the breast and lungs, it is sometimes externally applied in ointments and lotions, to prevent or stop putrefaction, and disperse hard swellings. When bruised, and applied to the soles of the feet, in the low stages of acute disorders, it raises the pulse and gives relief to the head. The principal effects of garlic are, to warm and stimulate the solids of the body, attenuate thick humours, and prevent putrefaction, as above specified. Hence the use of it appears very improper in hot bilious constitutions, where there is already too great a degree of irritation, or where the juices are thin and acrimonious, and the viscera unsound, in which cases it is almost certain to occasion head-aches, flatulence, thirst, and a variety of feverish symptoms. But on the other hand, where the constitution is cold and phlegmatic, its use is frequently attended with happy effects: when people of this last description find themselves troubled with loss of appetite, or with asthmatic complaints, or their stomach and lungs oppressed with tough viscid phlegm, they will generally find relief from the use of this plant. It is a powerful strengthener, and promotes expectoration, removes obstructions of the viscera, increases the urinary evacuation, destroys worms, and is serviceable in dropsies, by removing the water which may be already collected, and preventing its future accumulation. This species is a native of the East, but very common in our gardens, where it flowers in the summer months. Garlic is easily propagated by planting the cloves or obovate, the length of the stamina; the spathe has a very

small bulbs of the root in the spring, with a dibber or in drills, in beds four feet wide, in rows six inches from each other, and four or five inches distant in the rows, taking care to weed them. The leaves should be tied in knots, to prevent their spindling or running to seed; which will greatly enlarge the bulb. Towards the end of July, the leaves will begin to wither and decay, when the roots should be taken up, cleaned, dried in the sun, tied in bunches, and hung up in a dry room, where they will be preserved from rotting, for winter use.

13. Allium Scorodoprasum; Rocambole. Stamina threecusped; leaves crenulate; sheaths two-edged .-- Found wild in Sweden, Denmark, and Hungary; it has compound bulbs, but the cloves are smaller than those of garlic. The stem rises from two to three feet high, and bears many small bulbs at top, which may be used as well as those of the root. Rocambole may be propagated either by the roots or the bulbs produced on the stalks : they should be planted in autumn, especially on dry ground, otherwise their bulbs will not be large. They are to be planted and prepared for use in the same manner as garlic. See the preceding species.

14. Allium Arenarium; Sand Garlic. Stamina threecusped : sheaths columnar : spathe awnless .- This species grows wild in Thuringia, Scania, Denmark, Switzerland, Italy, and Westmoreland. It always grows in a sandy soil; the bulbs and flowers are blue, few in number, and the stamina a little longer than the corolla.

15. Allium Carinatum; Mountain Garlic. Stamina awlshaped ; spathe very long .-- The stem is four feet high, the outer petals are darker in colour than the inner ones, which are yellow, with a line of green, but sometimes purple. The bulb is simple, with very little of the garlic smell or taste. It is found wild in Scania, Germany, Italy, and Switzerland ; also in Westmoreland, about Ramsgate in the isle of Thanet, and between Sandwich and Deal.

Stem-leaves columnar : Umbel cansule-bearing.

16. Allium Sphærocephalon ; Small Round-headed Garlic. Stamina three-cusped, longer than the corolla; leaves semicolumnar; petals red with a darker keel; filaments purple towards the top .-- Native of Italy, Germany, Switzerland, and Siberia.

17. Allium Parviflorum ; Small-flowered Garlic. Umbel globose; stamina simple, longer than the corolla; spathe awl-shaped .- Native of the south of Europe.

18. Allium Descendens; Purple-headed Garlic. Stamina three-cusped, outer peduncles shorter. Two bulbs at the origin of the stalk ; leaves fistnlous, channelled above ; stalk two feet high; sheath quadrifid .- It is a native of Italy and Switzerland.

19. Allium Moschatum : Musk-smelling Garlie. Umbel flat-topped, mostly six-flowered; petals acute; stamina simple ; leaves setaceous .- It seldom attains to a foot in height, has a slender stem, and a dusky white corolla, with brown lines, smelling like musk or civet. It grows wild in Provence, Narbonne, and Spain.

20. Allium Flavium; Sulphur-coloured Garlic. Flowers pendulous ; petals ovate ; stamina longer than the corolla .----A native of the south of France, Italy, and Austria.

21. Allium Pallens; Pale-flowered Garlic. Flowers pendulous, truncated ; stamina simple, equalling the corolla .---This species is two feet high, with a white bell-shaped corolla. It is a native of Italy, Spain, Montpellier, and Hungary.

22. Allium Paniculatum; Panicled Garlic. Peduncles capillary, spread out; stamina awl-shaped; spathe very long. The leaves are awl-shaped and channelled ; the flowers hang on very long, loose, slender peduncles; the petals are purple,

25

long awl-shaped point .- Native of Italy, Austria, Switzerland, | Carniola, Siberia, and the Levant.

23. Allium Vineale : Crow Garlie. Stamina three-cusped -The stem is two feet high. It is a native of Germany. Switzerland, Italy, &c. With us it is frequent in pastures, and communicates its rank taste to the milk and butter. In other countries also, it grows in the vinevards and among the corn

24. Allium Oleraceum: Purple-striped Garlic, Stamina simple; leaves rough, semi-columnar, furrowed underneath. -The stem rises two or three feet high ; very minute white dots, scarcely visible to the naked eye, are scattered over the whole plant. The smell and taste of the bulb is not strong, the flowers are true bell-shaped ; the outer petals more acute, with a green nerve and a blush of purple; inner broader, more obtuse, whiter, and the nerve less prominent. Native of Sweden, Germany, Switzerland, and Italy. In England it is found among the corn, in Westmoreland, Yorkshire, near Bristol, and near Notley in Essex.

25. Allium Pallasii; Pallas's Garlic. Umbel difform; stamina simple, equalling the corolla; style very short .-- The stem is round, a foot and half high, slender, and leafy. Supposed to be a native of Sweden.

Leaves radical; Stem naked.

26. Allium Nutans; Flat-stalked Garlic. Scape two-edged; leaves linear, flat; stamina three-cusped.—This species varies so much in different ages and soils, as scarcely to be known. The cusps of the stamina are obliterated in old plants. Native of Siberia.

27. Allium Ascalonicum; Shallot or Eschallote. Scape columnar; leaves awl-shaped; umbel globose; stamina threecusped .- This species rises from about seven to eight inches high, the petals are blue, with a dark keel, and the antheræ vellow. Hasselgnist found it native in Palestine. The Eschalotte, chalott, or shallot, is propagated by the smaller roofs or offsets, planted in November or February, on beds four feet wide, six inches apart, and two or three deep, requiring no culture, except weeding. At the end of July or beginning of August they will be full grown, but should not be taken up till the leaves begin to wither; and in dry weather, spread them in the sun; and when they are properly dried, clean and tie them up in bunches for use. 28. Allium Senescens; Narcissus-leaved Onion, or Garlic.

Scape two-edged ; leaves linear, convex beneath, smooth ; umbel roundish; stamina awl-shaped .--- It is a native of Siberia, the Alus, Silesia, and the island of Sicily,

29. Allium Odorum : Sweet-smelling Garlic. Scape nearly columnar ; leaves linear, channelled, angular beneath ; umbel flat-topped. Corolla white, sweet-smelling; scape a foot high, round, or with one obscure angle, erect .- Native of the south of Europe, China, Japan, &c.

30. Allium Inodorum ; Carolina Garlic, Scape naked, subtriquetrous; leaves linear, flat-keeled beneath; umbel fastigiate, floriferous; stamina simple,-It flowers in March and April, and is a native of Carolina.

31. Allium Angulosum; Angular-scaped Garlic. Scape two-edged ; leaves linear, channelled, somewhat angular beneath; umbel flat-topped .- It grows in the moist parts of meadows, and is a native of Siberia, Italy, Austria, Switzerland, and Germany.

32. Allium Nigrum; Black Garlic. Scape columnar; leaves linear; umbel hemispherical; petals erect; spathe pointed, bifid .- It is a native of Provence, Italy, Austria, and the neighbourhood of Algiers.

33. Allium Cauadense; Canada Tree Onion. Scape co-

flowers few, pedicelled, whitish; petals oval; filaments simple the length of the corolla, with brownish red antheræ .- Native of North America.

34. Allium Ursinum; Ramsons. Scape three-sided; leaves lanceolate, petiolate; umbel flat-topped; stem a foot high and leafy; corolla white; smell and taste very acrid .- Native of Sweden, Denmark, Germany, Switzerland, Italy, in woods and moist shady places; and with us in England not uncommon.

35. Allium Triquetrum : Three-cornered Molu. Scape and leaves three-sided : stamina simple : leaves resembling those of the burr reed, very much keeled ; netals lanceolate, acuminate, white, with a green keel; stamina and pistil half the length of the petals; antheræ yellow; stigma acute .- A native of Italy and Spain.

36. Allium Cepa ; Common Onion. Scape swelling out below, and longer than the columnar leaves .- The varieties of the common Onion, are, 1. The Strasburgh or Common Oval; 2. the Spanish Silver-skinned and Red-skinned; 3. the Portuguese great Oval Onion ; and, 4. the Tripoli, All these vary from seeds, and there are several intermediate differences not worth enumerating. The virtues of this species are considerable. The common onion has been prescribed in malignant and epidemical distempers. They are very diu-retic, and powerful in cleansing and breaking away any obstructions in the urinary passages. They are likewise very efficacious in removing all oppression from the lungs, greatly promoting expectoration, and relieving asthmas and difficulty of breathing. They are externally employed in cataplasms for suppurating hard tumors. They are excellent to be taken by those who abound in cold watery humours, but very injurious to those of a bilious habit, affecting their heads, eyes, and stomachs. Onions, when eaten plentifully. procure sleep, help digestion, cure acid belchings, remove obstructions of the viscera, increase the urinary secretions, and promote insensible perspiration. Steeped all night in spring water, and the infusion given to children to drink in the sping water, the interstore gradies of the spin of the spin of a little salt, and laid on fresh burns, draws out the fire, and prevents the part from bistering. They are best suited for the use of old phlegmatic people, in cold weather, when their lungs are stuffed, and their breath short. A syrup made of the juice of onions and honey is an excellent medicine in asthmatic complaints. Care should be taken not to eat peeled onions, or pieces of onions, that have been exposed in that state for any considerable time, as very bad effects have followed, though the exact cause is not known. The cultivation of onions and leeks is exactly the same: many persons sow their leeks very thick in beds in the spring ; and in June, after some of their early crops are taken off, they dig up the ground, and plant the leeks out thereon, in rows a foot apart, and six inches asunder in the rows, observing to water them until they have taken root; after which they only require to be weeded: and in good ground, the leeks thus planted, will grow to a large size. To save the leek seed, take the largest and best leeks you have, let them grow in their original place till February, then transplant them in a row against a warm hedge, paling, or wall, eight inches asunder ; and when their stems advance, which will be in May or June, support them with a string, as they are very liable to be broken down, especially when in head; and the closer they are drawn to the fence in autumn, the better the seeds will ripen. They are known to be ripe by the heads turning brown, which should then be cut off, with about a foot or more of the stalk to each, and tie them up in bundles, three lumnar; leaves linear; head bulb-bearing; root perennial; or four heads in each, and hang them up in a dry place, where

ALL

they may remain until Christmas or after, when you may thresh out the seeds for use. The husk is very tough, and makes it difficult to get out the seeds; the best way for those who have but a small quantity, is to rub it hard against a rough tile, which will break the husks, and extract the seeds with great dispatch. The onion is propagated by seeds, which should be sown on good, rich, light ground, well dug, levelled and cleared from weeds, in a dry time, about the latter end of February or beginning of March, when the surface of the ground is not moist, and must not be sown thick, if intended for a winter crop. In cold wet land, it is best to defer sowing till the middle of March, and in very moist rich soils, it may be done any time before the middle of April, but the varly-sown crops bulb or apple best, and grow to the largest size. Nothing should be sown with onions except a little ros lettuce. The seed should be fresh; if above one year old, not one plant in fifty will grow. Six pounds of seed to an acre, or an ounce to a pole, is generally allowed, though most gardeners sow more, because they allow for cuttings or young onions, which they draw out for the market; but this injures the main crop. Six or seven weeks after sowing, they should be gently hoed and weeded, and separated where they grow too close, leaving them at least two inches apart. A month or five weeks after, this must be repeated, cutting out all the weeds, and removing the onions to three or four inches asunder. A month or six weeks afterwards, they must be again hoed and weeded for the third and last time, taking care to cut up all the weeds, and single out the onions to near six inches square, by which means they will grow much larger than if left too close; and this, if well performed, will keep the ground clean till the ouions are fit to pull up, but if weeds re-appear, they must be pulled up by the hand, as the onions will now have begun to bulb, and must not be disturbed by the hoe. Towards the middle of August, the onions will have arrived at their full growth, which is known by their blades falling to the ground and shrinking; they should then, before their necks or blades are withered off, be drawn out of the ground, the extreme part of the blade being cropped off, laid upon a dry spot of ground, and turned every day to avoid their striking fresh root, which they will very suddeuly do in moist weather. In a fortnight they will be dry enough to house, which must be done in perfectly dry weather, after all the earth has been rubbed from their roots, and taking care to mix no faulty ones among them, as that would spoil great numbers. They must not lie too thick. which would bring on sweating and the rot, nor be put in a lower room or ground floor, but in a loft or garret; and the closer they are kept from the air, the better they will keep. Once a month they should be examined, and all the decayed removed, for after all the care you can possibly take in the drying and housing your onions, many, especially in mild winters, will grow; therefore, those who preserve them late in the season, should select a parcel of the firmest, and most likely to keep, from the others, and with a hot iron slightly singe their beards or roots, which will effectually prevent their sprouting; but great care must be taken not to scorch the pulp of the onions, for that will cause them to perish soon The best keeping onions are the Strasburgh kind, after which have an oval-shaped bulb, but seldom grow so large as the Spauish, which are flatter; the white sort is esteemed the sweetest, but varieties of this sort are not lasting, because they always degenerate. To save onion seed, choose the firmest, largest, and best-shaped onions, plant them in rows six inches deep, and nine inches asunder, in a piece of good well dug ground. in a month's time they will appear above ground, and must be well weeded ; and about the beginning 2.

of June, when the heads of the flowers begin to appear, stakes about four feet long must be provided, and driven into the ground, at about six or eight feet apart ; to which you should fasten some packthread, rope yarn, or small cord, which should be run on each side the stems of the onions, a little below their heads, to support them against the wind and rain, which, as they are also ant to fall by their own weight, often beat them down, when the seeds are formed, and the heads heavy; and if the stalks be broken before the seeds have arrived to maturity, they will not be near so good, nor keep so long, as those that are perfectly ripened. The seed is known to be ripe by its changing brown about the end of August; and if not soon cut, the seed will then fall to the ground. When cut, the heads should be spread abroad upon coarse cloths in the sun, sheltering them in the night and in wet weather, and beating out the seeds, which are very easily discharged from their cells, when quite dry. The seeds must be exposed one day more to the sun, and then preserved in bags for use. The scallion or escallion is a sort of onion which never forms any bulbs at the roots, and was chiefly used in the spring for green onions, but is now scarce, and known to few people. It is propagated by parting the roots in spring or autumn, but the latter season is preferable. They are hardy enough to withstand our severest winters, and well deserve a place in all good kitchen gardens. The directions above given are for a general cron of winter onions ; but there are two other crops of this common sort of onion cultivated for the London market; one called the Michaelmas onion, from the thinnings of which they carry young green onions to market in March, for salads, &c. and in the spring they sow more beds in the same manner and for the same purpose, after the Michaelmas onions have grown too large for salads. To have onions for pickling, some seed should be sown in light poor land in the middle of April. It should be thickly sown, and not thinned, except they rise in clusters. They will be fit to take up in August.

37. Allium Moly; Yellow Moly. Scape sub cylindric; leaves lanceolate, sessile; umbel level-topped .- Native of Hungary, or Monte Baldo, about Montpellier, and on the Pyrenées. This was formerly preserved in gardens for the sake of its yellow flowers, but having a very strong garlic scent, most people have rooted it out. It increases plentifully, both by roots and seed. The whole plant smells like garlic, and is, like it, a good remedy in asthmatic complaints. the chincough, and other disorders of the breast. It is also of an opening nature, and removes most obstructions of the viscera.

38. Allium Tricoccum; Three seeded Garlic. Scape naked. semi-columnar; leaves lanceolate-oblong, flat, smooth; umbel globular, seeds solitary .- Native of North America,

39. Allium Fistulosum; Welch Onion, or Ciboule, Scape equalling the columnar; swelling leaves .-- This species is perenuial, and does not form bulbs like the common onion, and are therefore only fit for salads. They are sown about the end of July, in beds of about three feet and a half wide, and appear above ground in a fortnight; they must then be weeded. About the middle of October their blades will die away, and come up again very strong in Jauuary, growing vigorously, and resisting all weathers; by March they will be fit to draw for yonug onions, and are more valued in the market than any other sort at that time in season, as they are extremely green and fine, though they are more like the garlic than the common onion in taste. The roots of these onions, if planted out at six or eight inches distance in March, will produce ripe seeds in autumn, but it will be in small quantities the first year; therefore the same roots should remain Х

ALO

unremoved, which in the second and third year will produce many stems, and afford a good supply of seeds; these roots will continue good for many years, but should be transplanted and parted every second or third year, which will cause them to produce strong seeds.

ALL

40. Alliam Schwoprasun; Circs or Chiers. Scape equaling the columnar; and hidrom leaves—The petals of this species are of a faint purple colour; it has a very strong smell, and is a native of Italy, Switzerland, Sweden, and Siberia. This is a very small sort of onion, which never produces any bubbs, and sclobm grows above six inches high in the blade, which is also very small and slender, and in round bunches; this was formerly in great request for salads in the spring, as being milder than those onions which had stood through the winter; they are propagated by parting their roots, and are also very hardy, and will be fit for use early in the spring.

41. Allium Sibirioum; Siberian Garlie. Scape columnar; leaves semi-cylindric; stamina awl-shaped.—It has white petals, with a greenish keel, and is a native of Siberia.

42. Allium Tenuissimum; Slender-leaved Garlic. Scape columnar, empty; leaves awl-filiform; lueads loose, fewflowered.—A native of Siberia, much eaten by the field mice, who lay up the roots for their winter food.

43. Allium Chanze Moly; Bastard Garlic. Scape scarcely any, naked; capsules drooping; leaves flat, ciliate, —Flowers seven to ten, white, with the outside purplish or greenish. Flowers in January, and is a native of Italy.

44. Allium Graeile; Jamaica Gartic. Scape naked; columnar very long; leaves linear, clannelled; stamina subulate, connate at the base; petals erect, white, the claws uniting below with the stamina, and forming a green tube,—A mative of Jamaica, flowering in February

45. Allium Neapolitanum; Naples Garlie. Scape naked, ancipital; leaves Janccolate, channelled; umbel scattered; corolla white, and spreading; stamina shorter than the corolla.—It is cultivated in gardens in the neighbourhood of Naples, and begins to grow spontaneously about the city; it flowers in March.

Allophyma; a genus of the class Hexandria, order Monogynia-GENERIC CHARACTER. Calix: perianth fourleaved; leaflets orbiculate; two exterior, opposite, smaller by half. Corolla: of four petisls, less than the calix, orbiculate, equal; claws broad, length of the two smaller leaves of the calix. Stamina: filaments filtiorm, the length of the corolla; antheræ roundish. Pistil; germ superior, roundish, with the divisions rolled back. ESENTIAL CHARACTER, Calix: four-leaved; leaflet orbiculate; two opposite smaller. Petals: four, less than the calix. Germ twin. Stigma quadridd.—The species are,

 Allophylus Zeylanicus. Leaves oval, acuminate, quite entire; racemes axillary, very short.—A native of the island of Ceylon.

2. Allophylus Rigidus. Leaves simple, tooth-letted, and spiny; flowers in racemes .--- Native of Hispaniola.

3. Allophylus Racemosus. Leaves ternate; flowers in racemes.—A native of Hispaniola.

4. Allophylus Cominia. Leaves ternate; flowers in panicles; the stem the thickness of the human thigh, rising thirty feet in height, with a smooth ash-coloured bark. Flowers very numerous, whiths yellow, to which succeed small orangecoloured smooth berries, the size of a small pin's head, having a single stone in them, with a thin brittle shell, and a large kernel in proportion to the fruit.—It grows abundantly in Jamaica.

5. Allophylus Ternatus. Leaves ternate serrate; racennes long, terminating.—This is only a shrub five feet in height, with spreading branches. Flowers small, white, with hairy petals, and a neetary of four glands. It is a native of Cochin-China, by the banks of rivers, where the inhabitants use the leaves as a cataplasm in contusions.

ALL-SEED. See Linum, and Chenopodium. ALL-SPICE. See Myrtus. ALMOND African. See Brabeium. ALMOND Dwarf, See Amygdalus. ALMOND Tree. Anifolia. See Clethra.

Alnus. See Betula.

Aloe ; a genus of the class Hexaudria, order Monogynia .---GENERIC CHARACTER. Calix: none. Corolla: onepetalled, erect, sexfid, oblong; tube gibbous; border spreading, small, nectareous at bottom. Stamina: filaments awl-shaped, as long as the corolla, or longer, inserted into the receptacle; antheræ oblong, incumbent. Pistil: germ ovate, style simple, the length of the stamina ; stigma obtuse, trifid. Pericarp: an oblong capsule, three-furrowed, three-celled, and three-valved. Seeds: several, angular, ESSENTIAL CHARACTER. Corolla: erect, with an expanded mouth, and a nectareous base. Filaments inserted into the receptacle. The roots of this genus arc perennial and stoloniferous. Stem none, or else formed from the bases of the leaves : round generally single, seldom branched. Leaves succulent, embracing the stem, in some smooth and even, in others spotted or painted, in others warted; variously disposed. Scape or peduncle bracted, erect, frequently single, seldom branched. -Native place of growth, principally the Cape of Good Hope, all hot climates. The inspissated juice of the various species of aloe is a hot and irritating purgative. The Socotorine aloe is gentler and purer than the others, and is generally the only kind used in medicine. As the drossy resinous part of the aloe is not soluble in water, it has been found, when combined with other mixtures, an excellent preservative against the worm which is so injurious to ships trading to the East or West Indies : one ounce of aloes is sufficient for two superficial feet of plank ; about twelve pounds for a vessel of fifty tons' burthen; and three hundred pounds for a firstrate man of war. It may be incorporated with six pounds of pitch, one pound of Spanish brown, or whiting, and a quart of oil ; or with the same proportion of turpentine, Spanish brown, and tallow. Such a coat will preserve a ship's bottom eight months, and the expence for a first-rate ship will be about eighteen pounds. The same composition may be used in hot countries for preserving rafters, &c. from the wood ant. The soil in which this genus of plants thrive best, is one-half fresh light earth from a common, and if the turf be taken with it and rotted, it is much better; the rest should be white seasand, or road sand, and sifted lime-rubbish, of each of these two a fourth part; mix them together six or eight months at least before the compost is used, observing to turn it over often during that time. The middle of July is the time to shift these plants, which must be done by taking them out of the pots, and opening the roots with the fingers, shake out as much of the earth as possible, and remove all dead or mouldy roots, then fill the pot three parts full with the above mentioned earth, putting a few stones at the bottom to drain off the moisture, and replacing the roots of the plant so as to prevent their interfering with each other, fill the pot almost to the rim with the same earth, observing to shake the plant, that the earth may settle among the roots and keep it steady in the pot, and water it gently, especially in hot dry weather, setting it abroad in a shady place. Towards the end of Sep-

ALO

water them ouce a week in winter, and give them fresh air when the weather is dry. The hardier aloes thrive best abroad in summer, and secured from cold and rain in winter. The tender sorts should always remain in the stove, or be removed to an airy glass-case during summer. Most aloes are increased by offsets, which should be taken from the mother plants at the time they are shifted, and must be planted in very small pots, filled with the same earth as was before directed for the old plants. After planting, let them remain in a shady place for a fortnight, then remove the tender kinds to a very moderate hot-bed, and plunge the pots therein, which will greatly facilitate their taking new root; but observe to shade the glasses in the middle of the day, and to give them a great share of air. Towards the middle of August begin to harden these young plants by taking off the glasses in good weather, and giving them plenty of air, which is absolutely necessary for their growth, and to prepare them to be removed into the house, which must be done towards the end of September; and they will afterwards require the same management as the old plants .---- The species of this genus

1. Aloe Dichotoma; Smooth-stemmed Tree Aloe. Branches dichotomous; leaves swort-shaped, sertate. Trunk round, upright, very stiff, ash-coloured, twelve feet high, about the thickness of a mai's thigh,-mattive of the Cape of Good Hope; where the natives hollow out the trunk to make quivers for their arrows.

 Aloe Perfoliata; Perfoliate Aloe. Stem-leaves toothed, embracing, sheathing; flowers in corymbs, drooping, peduncled, subcylindrical.—Of this species there are the following varieties.

a. Aloc Arborescens; Narrow-leaved Sword Aloc. Leaves embracing, reflex, toothed; flowers cylindrical; stem shrubby. Has a strong naked stem, ten or twelve feet high, with leaves of a sea green colour, and very succentent; the flowers of a bright red, which grow in pyramidal spikes, and are in beauty in November and December.

B. Aloe Africana; Broad-leaved Sword Aloe. Leaves broader, embracing, thorny on the edge and back; flowers in spikes; stem shrubby.—This resembles the preceding species, but has broader leaves, and the flowers grow in looser spikes.

y. Aloe Barbadensis; Barbadoes Aloe. Leaves toothed, upright, succulent, subulate; flowers yellow, hanging down in a thyrse. The flower-stem rises nearly three feet high. -This species, though generally known by the name of Barbadoes aloe, is very common in the other islands of America, where the plants are propagated on the poorest land to obtain the hepatic aloes, which are brought to England, and used chiefly for horses. At Barbadoes, in the month of March, when the plants are a year old, they are cut just above the surface of the earth, and placed in a tub, until their juice is drained off, when they are thrown upon the land by way of manure. The juice will keep several weeks without injury. It is put into boilers, and thickened by a regular fire till of a proper consistency to be ladled out into gourds, or other small vessels fitted for its final reception. As to the sun-dried aloes, which arc most approved for medicinal purposes, very little is made in Barbadoes. The process is, to suspend bladders filled with the raw juice, and open at the top in the sun every dry day until the fluid parts are exhaled, and a perfect resin formed ; which is then packed up for use or exportation. Those lands in the island of Barbadoes, which lie near to the sea, are subject to drought, and are too stony and shallow to plant sugar canes, answer best

tember, in a dry day, remove them into the house again, for the alce plant. The larger stores are renoved, and water them once a week in writer, and give them fresh air frequently formed into a surrounding fence. The lard is when the weather is dry. The handler alces thrive best index is the store of the moved to an airy glass-case during summer. Note that he nother creased by offsets, which should be taken from the mother the the the the store of the stor

> 3. Aloe Socotorina; Socotorine Aloe. Leaves very long and narrow; thorny at the edge; flowers in spikes .-- This is the true Socotorine aloe, which is named from the island of Zocotra or Socotora in the straits of Babelmandel, formerly famous for the extract of this plant. It is of a yellowish brown colour, approaching to purple; and when reduced to powder, is a sort of gold colour. Socotorine aloes may be given in considerable doses, as a scruple, or half a drachm at a time ; and is a very good pnrge, particularly as an aperient, and remover of obstructions in phlegmatic habits. It may be given as a purgative from one to two ounces or more, or may be taken as an alterant in smaller doses, and continued until it has produced a lax habit or soluble state of the bowels. It is an excellent medicine for languid and phlegmatic constitutions ; warming the solids, cleansing the intestines, and attenuating viscid juices in the remoter parts. Spanish liquorice is said to be the most efficacious ingredient of all others, in covering the unpleasant taste of aloes. Equal parts of aloes and Spanish juice dissolved in water, is said to be the most pleasant and useful of all the aloetic purges. Indeed the purgative properties of Socotorine aloes are universally known; and the different preparations of it purify the blood, help digestion, dissipate gross humours, and are friendly to the nervous system in general. They likewise powerfully resist putrefaction, remove obstructions of the viscera, kill worms in the stomach and intestines, cure the jaundice and green sickness, provoke the menses and piles, and prove serviceable in the ague, and all cold watery disorders; but should be forborne by such as have hot bilious constitutions or gravelly complaints. It should not be given to pregnant women, nor to those who spit blood, as in those cases it might prove fatal.

> 5. Aloe Purpurascens; White-spined Glaucous Aloe. Leaves purplish beneath, with small roundish spots at bottom.

> 2. Aloe Glauca; Red-spined Glaucous Aloe. Stem short; leaves embracing, standing two ways; spines on the edges erect; flowers growing in a head.

> 9. Aloe Ferox; Great Hedge-hog Aloe. Leaves embracing, very dark green, beset with spines on every side.—Rises to the height of eight or ten fect, with a strong stem; it has not yet flowered in England, nor does it put out suckers, so that it is difficult to propagate.

. Aloe Saponaria; Great Soap Aloe, and,

x. Aloc Obscurs; Common Song Alae. Leaves broader, potted, thorny at the edge; flowers in spikes.—The first seldom rises above two feet in height; the leaves are very broad at their base, where they closely embrace the stalk, and gradually decrease to a point. The under leaves are of a dark green colour, spotted with white, resembling the colour of soft song. The flowers grow in umbels on the tops of the stalks, are of a leautiful red colour, and appear in August and September. The second has broader leaves, of a lighter green; the edges and spines are copper-coloured, and the flowers grow in lose spikes.

A for Serrulata; Hollow leaved Perfoliate Aloe. Leaves spotted, finely serrate at the edge and the tip of the keel. It seldom rises above a foot high; the leaves, which grow near the ground, are of a sea-green colour, with some white spots; the flowers grow in loose spikes, the tubulous part being red,] and the brim of a light green colour.

u. Aloe Suberecta : Upright Perfoliate Aloe. Leaves flat, almost upright, thorny at the edge and on the lower surface.

v. Aloe Depressa; Short-leaved Perfoliate Aloe. Leaves embracing, thorny on both sides ; flowers in spikes.

E. Aloe Humilis; Dwarf Hedge-hog Aloe. Leaves upright, subulate, radicate, with weak spines all round .- This is a very low plant, never rising into a stem. The flowers, which shew that it belongs to this species, grow on a loose head at the top of the stalk, which is very thick, but seldom a foot high; below their colour is a fine red, but a pale green above.

o. Aloe Mitræformis; Great Mitre Aloe. Grows with an upright stalk to the height of five or six fect : the leaves are of a dark green colour; the tube of the corolla is of a fine red, the brim of a pale green.

m. Aloe Brevifolia; Small Mitre Aloe.

3. Aloe Arachnoides: Cobweb Aloe. Stemless : leaves three-cornered, cusped, ciliate ; flowers in a sort of spike, upright, cylindrical.

a. Aloe Arachnoides Communis : Common Cobweb Aloe. Leaves short, plain, fleshy, triangular at the end; the borders set with soft spines .- Cobweb Aloe never rises from the ground, but the leaves spread flat on the surface ; these are plain, succulent, and triangular toward the end; the borders and keel are closely set with soft white spines. The flowerstem rises about a foot high, is very slender, and has three or four small distant herbaceous flowers.

B. Aloe Arachnoides Pumila; Small Cobweb Aloe, Leaves ovate-lanceolate, fleshy, triangular at the end, with humerous soft spines. A small plant growing near the ground.

4. Aloe Margaritifera: Pearl Aloe. Stemless: leaves three-cornered, cusped, papillose; flowers in racemes, drooping, cylindrical. It is of humble growth, and flowers in several seasons of the year. There is a smaller sort, which has been long preserved in the English gardens.

5. Aloe Verrucosa ; Warted, or Pearl-tongue Aloe. Stem less; leaves sword-shaped, sharp, papillose, distich; flowers in racenies, reflex, club-shaped.—This species produces offsets in plenty, and flowers in several seasons of the year. The flowers are of a beautiful red colour, tipped with green.

6. Aloe Carinata: Keel-leaved Aloe. Stemless: leaves acinaciform, papillose; flowers in racemes, drooping, curved. -The flowers are of a paler colour, and the spikes shorter, than those of the preceding species.

7. Aloe Maculata; Spotted Aloe. Leaves blunt with a point. Almost stemless; leaves acinaciform, smooth, painted; flowers in racemes, drooping, curved .- It varies with large, oblong, white confluent spots; and with small ones. Native of the Cape of Good Hope; flowering from August.

8. Aloe Lingua; Tongue Aloe. Almost stemless; leaves tooth-letted, smooth distich; flowers in racemes, upright, cylindrical.-The flowers are red, in loose spikes, cach hauging downwards, of a red colour at bottom, and green at top, There is a variety of this with leaves much more spotted.

9. Aloe Plicatilis; Fan Aloe. Almost stemless; leaves tongue shaped, even distich; flowers in racemes, pendulous, cylindrical .- This grows to the height of six or seven feet, with a strong stem; the flowers, which are of a red colour, are produced in short loose spikes, and appear at different times of the year.

10. Aloe Variegata; Partridge-breasted Aloe. Almost stemless; leaves in three ranks, painted, channelled; angles spiked, erect; glume smooth; calix surrounded at bottom by cartilaginous; flowers in racemes, cylindrical,-It is a low a ring. It resembles the preceding, but is distinguished from

plant, seldom rising above eight inches high. The leaves are curiously veined, and spotted like the feathers of a partridge's breast. The flowers are of a fine red colour tipped with green.

11. Aloe Viscosa; Upright Triangular Aloe, Subcaulescent; leaves imbricate in three ranks, ovate; flowers in racemes, drooping, cylindrical.-Grows near a foot high, has triangular leaves of a dark green colour: the flowers grow thinly on very slender peduncles, they are of a herbaceous colour, and their upper part turns backward.

12. Aloe Spiralis; Spiral Alor, Subcaulescent; leaves imbricate in eight ranks, ovate : flowers in racemes, curved back. This somewhat resembles the preceding species.

13. Aloe Retusa ; Cushion Aloe. Stemless ; leaves in five ranks, deltoid .- This species receives its name from its very short thick succulent leaves, which are compressed on the upper side like a cushion; the flowers are of a herbaceous colonr.

14. Aloe Spicata; Spiked Aloe. Flowers in spikes, horizontal, bell-shaped ; stem-leaves flat, embracing, toothed .--This very much resembles the second species ; it was observed by Thumberg at the Cape of Good Hope. The flower is full of a purple honey-juice. ... The best and purest hepatic aloe is obtained from this species ; that obtained from Barbadoes is of different degrees of purity, darker, and more bitter and nauseous than the Socotorine kind.

Aloides. See Stratiotes.

Alopecuros. See Betonica.

Alopecurus ; a genus of the class Triandria, order Digynia. Glume: one-flowered, two-GENERIC CHARACTER. valved ; valves ovate-lancolate, concave, compressed, equal, connate at the base. Corolla: one-valved ; valve ovate-lanceolate, concave, the edges united at the base, a little shorter than the calix. Awn twice as long, with a bent joint, inserted into the back of the valve near the base. Nectary : none. Stamina: filaments three, capillary, flattish at the base, longer than the calix. Antheræ forked at each end. Pistil: germ roundish. Styles two, capillary, united at the base, longer than the calix. Stigmas : villous. Pericarp : none. Corolla investing the seed. Seed: ovate, covered. ESSENTIAL CHARACTER. Calix: two-valved. Corolla: one-valved .- For the culture and propagation of this genus see GRASS .---- The species are,

1. Alopecurus Indicus; Indian Fox tail Grass. Spike cylindrical; involucres setaceous, fasciculate, two-flowered; peduneles villous.-Native of the East Indies.

2. Alopecurus Bulbosus; Bulbons Fox-tail Grass. Culm erect ; spike cylindrical ; root bulbous - It rises about a foot high, and has been found in great plenty in a wet salt-marsh near Yarmouth in Norfolk.

3. Alopecurus Pratensis; Meadow Fox-tail Grass. Culm spiked, crect; glumes villous; corollas awuless. Roots perennial; stalks from a foot to eighteen inches, two and even three feet high; the antheræ are frequently purple when in full vigour.—It is a native of most parts of Europe. It is common in the best pastures about London, and produces the spike in April, being one of the carliest grasses. It frequently flowers twice in one season, and the seed may be collected without much difficulty, for it does not quit the chaff, and the spikes are very prolific. This grass is highly worth cultivation on the lands, that are proper for it, as it possesses the three great requisites of quantity, quality, and earliness, in a superior degree to any other.

4. Alopecuris Agrestis; Field Fox-tail Grass. Culm

80

ALS

it, by the great length and slenderness of its spikes, tapering to a point, and usually of a purple colour. The stalk is a foot or eighteen inches high, and it has obtained the name of Mouse-tail in English from the great length and slenderness of the spike, resembling the tail of the mouse. It is every way inferior to Fox-tail Grass, and therefore not worth cultivation. It flowers early, continues flowering till autumn, and comes very quickly into bloom after it is sown.

5. Alopecurus Geniculatus; Flote Fox-tail Grass. Culm spiked, infracted ; corollas awnless ; (awns concealed within the calix) stalk from twelve to eighteen inches high; root perennial .- It is called Black Grass in some places, from the deep purple colour of the spikes; cattle eat it readily, but it is not a profitable grass. It flowers in June.

6. Alopecurus Hordeformis; Barley-like Fox-tail Grass. Raceme simple ; flowers intrenched with awns .- This is an Indian grass, about a foot high, with the pistil longer than the flower; and it has the appearance of barley-grass.

7. Alopecuris Monspeliensis; Bearded Fox-tail Grass. Panicle subspiked ; calices rugged ; corollas awned .- This is an annual, which grows wild in wet pastures, and flowers in June and July.

8. Alopecarus Paniceus; Hairy Fox-tail Grass. Panicle subspiked; glumes villous; carollas awned .- This plant only reaches to five or six inches high ; it grows on dry soils, and is annual, flowering in July.

Alpinia; a genus of the class Monandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, tubulose, three-toothed; leaflets equal, erect, acute. Corolla : monopetalous, tubulose ; tube cylindraceous, short ; border three-parted ; parts nearly equal, oblong. Nectary: connate with the tube of the corolla, two-parted; the lower part forming the lower lip is larger and longer than the parts of the corolla, broadish, spreading, often divided. Stamina : filament proper, none ; but along the upper division of the nectary, forming the upper lip, which is flattish, and the length of the corolla, grows a large anthera, either deeply bifid or entire. Pistil: germ inferior, oblong. Style filiform, often inserted into the fissure of the anthera. Stigma incrassate, obtuse. Pericarp: capsule oval, three-celled, three-valved, crowned with the permanent calix. Seeds : some ovate, angular, covered with a sort of berried aril. ESSEN-TIAL CHARACTER. Calix: three-toothed, equal, tubulose. Corolla: three-parted, equal. Nectary: two-lipped, the lower lip spreading. The species are,

1. Alpinia Racemosa. Raceme terminating, spiked; flowers alternate; lip of the nectary trifid; leaves oblong, acuminate; root fleshy, branched, and having the taste and smell of ginger; the stem from two to five feet high .- It is a native of the West Indies, and must be preserved in a stove, with the pot plunged into a tub of water. When the leaves decay, which is every winter, it may be propagated by parting the roots.

2. Alpinia Occidentalis. Raceme radical, compound. erect ; nectary emarginate ; capsules three-celled ; leaves lanceolate-ovate, very smooth .- It is a native of Jamaica and St. Domingo.

Alsine; a genus of the class Pentandria, order Trigynia. -GENERIC CHARACTER. Calix: perianth five-leaved; leaflets concave, oblong, acuminate. Corolla: of five equal petals longer than the calix. Stamina: filaments capillary; antheræ roundish. Pistil: germ subovate ; styles filiform ; stigmas obtuse. Pericarp : an ovate, one-celled, three-valved ; capsule covered with the calix. ESSENTIAL CHARACcelled, three-valved, ---- The species are, 7.

1. Alsine Media ; Common Chickweed. Petals bipartite; leaves ovate-cordate .- This plant is very generally known : it assumes a diversity of appearances, according to the soil in which it grows. It is commonly given as food to chickens and small birds, and when boiled it exactly resembles spinach: swine, and also many insects, are very fond of it. As a medicine, it contains no active principle, but is frequently applied to swellings, either alone or in poultices. The whole plant, or the juice of it, boiled in a sufficient quantity of hog's lard, makes an excellent cooling ointment. Taken inwardly, it is said this plant is good against the scurvy, and promotes the urinary evacuation. A poultice made of the bruised herb is recommended to remove inflammations arising from blows. Chickweed flowers upright, and open from nine to noon ; but if it rains, the flowers do not open. After rain they become pendant, but in a few days rise again. Chickweed is also a remarkable instance of the sleep of plants : at night the leaves approach in pairs, so as to inclose between their upper surfaces the tender buds; and the two upper leaves but one, at the end of the stalk, are furnished with longer petioles than the others, so that they can close upon the terminating pair, and protect the end of the branch. It is found wild in most parts of the world.

ALS

31

2. Alsine Segetalis. Petals entire : leaves awl-shaped .---It is an annual, and grows in France about Paris, and in Piedmont.

3. Alsine Mucronata. Petals entire, short : leaves setaceous; calices awned; stems erect, a foot high, many together, branching, a little hairy. Petals ovate, white,-It is a native of France and Switzerland.

Alstonia ; a genus of the class Polvandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth inferior. imbricate; scales ovate, very obtuse, concave; the inner ones gradually larger, forming as it were a quadripartite or quinquepartite calix. Corolla: one-petalled, shorter than the calix; tube short; border spreading, divided into eight or ten parts ; divisions equal, in a double row, alternately interior and exterior ; obovate, obtuse, quite entire. Stamina: filaments very many, inserted into the tube very short, imbricate very smooth ; the outer ones longer, linear, attennated at the tip; antheræ orbiculate, furrowed. Pistil: germ superior, ovate, small. Style simple, length of the corolla, filiform, erect; stigma capitate-obovate. ESSENTIAL CHA-RACTER. Corolla: one-petalled, eight or ten cleft, clefts Iternated.— There is only one species, viz. 1. Alstonia Theæformis. This shrub was found by Mutis alternated .-

in South America. It is very smooth, and resembles Bohea tea; its dried leaves also give a greenish colour to the saliva when chewed, and have the same taste as the Chinese tea. The flowers are axillary, three or four together, and sessile ; the calix is very smooth, the scales rounded and green, with a membranaceous edge ; the corollas are white and spreading.

Alstroemeria; a genus of the Hexandria class, Monogynia order .- GENERIC CHARACTER. Calix: none. Corolla: six-petalled, sub-bilabiate; the three outer petals wedge-shaped, retuse, mucronate; the inner, which are alternate with the others, lanceolate; the two lower ones, tabulous at the base, Stamina; filaments awl-shaped, bending down, unequal; antheræ oblong. Pistil: germ inferior, hexangular, truncate : style bending down, filiform, the length of the stamina; stigmas three, oblong, bifid. Pericarp: a roundish six-ribbed mucronate capsule, three-celled, threevalved, valves concave, contrary to the dissepiment. Seeds: very many, globose, covered with raised points, subumbilicate TER. Calix: five-leaved. Petals five, equal. Capsule one- at the tip. ESSENTIAL CHARACTER. Corolla: of six petals, sub-bilabiate; the two lower petals tubulose at the

base. Stamina : bending down .- These plants are all found in South America, and must be kept in a stove in England, where they may be propagated by parting their roots in autumn .---- The species are.

ALT

1. Alstroemeria Pelegrina; Spotted-flowered Alstroemeria. Stem erect ; corollas bell-shaped, straight; leaves linear-lanceolate, sessile. The flowers are whitish, most beautifully stained, and veined with purple and red; they flower from June until October .- This species may be treated as a greenhouse plant ; it will however flower and ripen its seeds better under the glass of a hot-bed frame, where air is freely admitted. It is generally raised from seeds, sown in a pot of light earth in the spring, on a gentle hot-bed, either of dung on tan

2. Alstroemeria Fulchella. Stem erect; corollas reflex, spreading, acute; leaves sessile; pedicles shorter than the involucre .- This much resembles the first species : its petals spread from the base, recurved, acute, alternately less, whitish, red at the tip, streaked or dotted with red at the base; filaments yellow, equal; pistil red, rising; stigma trifid.

3. Alstrocmeria Ligtu; Stripe flowered Alstroemeria. Stem erect : leaves spatulate-oblong ; peduncles of the umbel longer than the involucre ; corolla two-lipped .- This species is remarkable for the largeness and fragrancy of the flowers. which are scarcely inferior to mignionette. It flowers in February and March.

4. Alstroemeria Salsilla. Stem twining; leaves petiolate, lanceolate, acuminate; umbcl branching; peduncles longer; leaves nervose; petioles naked; the outer petals red, the inner greenish

5. Alstroemeria Multiflora. Stem twining ; leaves petiolate, lanceolate, acuminate ; umbel simple; peduncles shorter than the bractes; petals alternate, truncate.-This species is very distinct from the rest.

6. Alstroemeria Ovata. Stem twining ; leaves lanceolate, languinose on the upper surface, lucid on the lower ; corollas tubular. Stem twining, contrary to the sun, slender, hardish, and rising three feet high. Flowers terminating in umbels. Petals approximating into a tube; the three outer scarlet and green at the tip, the three inner green, flattish towards the top, and variegated with black dots .- A native of Peru.

Althæa; a genus of the Monadelphia class, Polyandria order. -GENERIC CHARACTER. Calix: perianth double; outer smaller, one-leafed, unequally novemfid ; divisions very narrow ; inner semiguinquefid ; divisions broader, sharper. Corolla: five-petalled, united at the base, obcordate, præmorse, flat. Stamina : filaments many, juserted into the corolla ; antheræ subreuiform. Pistil: germ orbiculate; style cylindrical, short ; stigmas many, setaceous, the length of the style. Pericarp, consists of arils not jointed, forming a flat ring about a columnar receptacle; they are deciduous, and open on the inside. Seed : one, flat kidney shaped in each aril. ESSENTIAL CHARACTER. Calix: double; outer ninecleft. Arils many, one-seeded .---- The species belonging to this genus are the following.

1. Althwa Officinalis; Common Marshmallow. Leaves simple, downy. This species grows naturally on the banks of rivers, and in salt marshes and ditches, in Cambridgeshire, Norfolk, and Suffolk, on the sea shores of Cornwall, and in Holland, France, Italy, and Siberia. The root is perennial, the stalk annual, growing erect to the height of four or five feet. The flowers appear in July, and the seeds ripen in September. The whole plant, particularly the root, abounds with a mild mucilage, which is emollient in a much greater degree than common mallow. The boiled root is much used as an emollicnt cataplasm, and an infusion of it is very gene- losa. GENERIC CHARACTER. Calix : perianth four-leaved,

rally prescribed in all cases wherein mild mucilaginous substances are useful as a pectoral, and in complaints of a gravelly nature. The infusion is much superior to the syrup kept in the shops. It is kept in most gardens on account of its medicinal qualities, where it blossoms in August. An infusion of it is excellent for blunting and sheathing those sharp and acrimonious humours which occasion tickling coughs. hoarseness, erosions of the stomach and intestines, difficulty. and heat of urine, and for lubricating and relaxing the passages, and for the stone and gravelly complaints. Outwardly applied, it softens and disperses hard swellings. A syrup and ointment of it are kept in the shops, but, as has been above observed, a strong infusion has far more virtues than the syrup; and a ponitice made of the fresh root, with the addition of a little white bread and milk, will prove more serviceable, when applied externally, than the ointment. The common marshmallow may be propagated by sowing the seeds in the spring, or parting the roots in autumn when the stalks decay. The plant should be placed two feet asunder. they will thrive in any soil or situation, but grow larger in moist than in dry land.

2. Althwa Canuabina: Hemp-leaved Marshmallow, Lower leaves palmate, upper digitate. This species has a woody stem, which rises to the height of four or five feet. The flowers are axillary, not so large as those of the common marshmallow, but of a deeper red colour, with a larger calix, -It seldom flowers the first year, unless the summer prove warm; but when the plants survive the winter, they will flower early in the succeeding summer, and produce good seeds, which should be sown in the spring where they are intended to remain, in a sheltered situation and dry soil, or they will not bear an English winter, and transplanting is hurtful to them. In a stouy soil, or in lime rubbish, their growth is stinted. but they become more hardy. They seldom continue longer than two years in England, but they ripen seeds here, and are by no means scarce. It grows naturally in Hungary, Istria. Austria. Carniola, Italy, and by wood-sides in the south of France.

3. Althea Hirsuta; Hairy Marshmallow. Leaves trifid. hairy, hispid, smooth above; peduncles solitary, one-flowered. This is a low plant, with its branches trailing on the ground. If the seeds be sown in April, the plants will flower in July, and the seeds ripen in September. It grows wild in Spain and Portugal.

4. Althaa Ludwigii; Ludwig's Marshmallow. Leaves lobed, naked on both sides ; peduncles collected, one flowered. Peduncles axillary, from two to five, one flowered, the length of the petioles.

5. Althaa Narbonensis: Narbonne Marshmallow. Leaves tomentose on both sides: the lower five-lobed, the upper three-lobed; peduncles solitary, one-flowered. Roots peren-nial, stems annual, from four to six feet high. Corolla purple, rose-coloured, twice as long as the calix .- First discovered near Narbonne; found in Spain; and flowers in August and September.

6. Althæa Corymbosa. Leaves simple, cordate or angular, smooth; peduncles and calices hairy; flowers in corymbs. -A native of Jamaica.

7. Althaa Racemosa. Leaves simple, cordate-ovate, serrate, scabrous on the upper surface, raceme terminating erect. Stems thick, stiff, five feet high, with many branches. Corolla yellow, the fruit composed of five bivalve capsules .- A native of Jamaica.

Althæa Frutex. See Hibiscus.

Alussum ; a genus of the Tetradynamia class, order Silicu-

ALY

oblong ; leaflets ovate, oblong, obtuse, convergent, deciduous. Corolla: four-petalled, cruciform. Petals flat, shorter than the calix, very spreading; claws the length of the calix. Stamina: filaments six, the length of the calix ; two opposite, a little shorter marked with a toothlet. Antheræ from erect, spreading. Pistil: germ subovate; style simple, the length of the stamina longer than the germ. Stigma obtuse. Pericarp : a subglobose, emarginate silicle, with a style the length of the silicle, two-celled ; partitions elliptic, valves elliptical, hemispherical. Seeds fixed to filiform receptacles, issuing forth at the end of the silicle : few, orbicular, ESSENTIAL CHA-RACTER. The shorter filaments marked with a toothlet; silicle emarginate. Every species of this genus may be propagated by seed, and most of them by slips and cuttings. The seeds should be sown in a border of light earth in April; cuttings or slips should be planted in April or May, shaded in the heat of the day, and gently refreshed with water. They seldom survive an English winter, when planted in rich ground ; but in a poor, dry, rubbishy soil, or on old walls, they will abide the cold, and last much longer. The first four species are Undershrubs, the remainder herbaceous.

* Undershrubs.

1. Alyssum Spinosum; Thorny Madaent. The old racemes thorny, naked. It has woody branches rising two foet high, and armed with small spines.—It grows naturally in Italy, Spain, and the south of France; seldom remains more than two or three years with us, and must be often sown to preserve it; but if the seeds be suffered to remain, and fall upon the ground, the plants will rise without any trouble.

2. Alysium Halimitolium; Sweet Madwort. Stems procumben, perennial; leaves lance-linear, acute, quite entire. —It spreads itself upon the ground, and never rises to any height; at the extremities of its branches it produces very pretty tufts of small white flowers, of which the plant is seldom destitute for six or seven successive months. It is a native of the southern countries of Europe.

3. Alyssum Saxatile; Yellow Maducort. Stems shrubby, panicled; leves hanceolate, very soft, repand; petals entire. This plant has a fleshy stalk, seldom more than a foot high; the flowers are of a bright yellow colour.—It is a showy and hardy plant, very suitable to embellish rock-work. The seeds ripen in July, but it is only from young plants that seeds can be expected; for the old plants, or those which are raised form slips or cutings, rarely produce seeds in England.

4. Afyssum Alpestre; *Ialian Madwort*. Stens undershrubby, diffused; leaves roundish, hoary; calices coloured. The flower is yellow, the plant perennial.—It is found on Mount Cenis, and on the mountains of Provence towards Italy.

** Herbaceous.

5. Alyssum Hyperboreum; Northern Madwort. Leaves hoary, toothed; stamina four-forked.—Native of North America.

6. Alyssum Incanum; Hoary Madwort. Stem erect; leaves lanceolate, hoary, quite entire; Rowers in corymbs; petals bidd.—Grows to two feet in height, with small white Rowers. The silicle is entire, oval, and full of brown seeds. It grows naturally in the south of France, in Spain, Italy, Germany, Austria, and Sweden. Chiefly on rocky or gravelly oils. It flowers from June to September, and [the seeds ripen soon after; if these be permitted to scatter, the plants will come up, and require little care.

7. Alyssum Minimum; *Least Madwort*. Stems diffused; leaves linear, downy; silicles compressed. The petals are yellow and submarginate.—It is an annual plant, and grows in Spain.

8. Alyssum Calycinium; Calycine Madwort, Stamina avel-toothed; calices permanent.—Annual, found wild in Austria, Carniola, France, Germany, and Switzerland. The petals are yellow, but turn white with age. It should be sown where it is intended to remain; if thinned, and kept clean from weeds, they will flower in July, and perfect their seeds in autuma.

9. Alyssum Montanum: Monutain Madwort. Stems diffused; leaves sublanceolate, dotted, and echinate.—This is a perennial, and has dark vellow flowers; it grows naturally upon the rocks of Burgundy and other parts of France, and is also found in Germany.

10. Alyssum Campestre; Field Madwort. Stamina guarded with a pair of bristles; calices deciduous.—This much resembles the eighth species; which sec: it is a native of the same countries, and requires the same treatment.

 Alyssum Clypeatum; Buckler-podded Madwort, Stem erect; silicles sessile, oval, compressed fat; petals pointed, linear.—A biennial plant, growing naturally in Spain and Portugal.

*** Silicles inflated, or Calices oblong, closed.

12. Alyssun Sinuaium; Simate-leaved Maduort. Stem herbaccous; leaves hance-deltoid; silicles inflated.—A low spreading plant with flowers of a bright yellow colour. It is annual or biennial; grows by way-sides in Spain, and in the islands of the Archipelago, but will bear the open air of England, in a dry soil and warm situation.

13. Alyssum Creticum; Cretan Madwart. Stem shrubby; leaves lanceolate, a little totted, downy; silicles globular, —This species seldom continues more than two years in England, and in a warm dry situation will live in the open air. The seeds should be sown in Angust soon after they are ripe; and if a few of the plants be potted in October, and sheltered under a frame in winter, they will flower in the following June, and produce good seeds in the same year.

14. Alyssum Gemonense; Gemona Maduori. Stem herbaccons; branches divariated; root-leves obovate, rather downy. Root perennial; flowers of a deep yellow colour; stem four or five inches long.—It has its name from being discovered on the mountain Della Fontana, near Gromona in Italy_ in the clefts of rocks. It flowers in May and June.

15. Alyssum Uriculatum; Bottle Madwort, Stem herbaccous, erect; leaves smooth, lanceolate, quite entire.— This species is well adapted to decorating walls, or rockwork; it grows in the vineyards of Savov, and is a hardy and beautiful perennial, flowering from April to June, at which time it begins to form its curiously infilted pods.

16. Alyssum Vesicaria; Bladder Madwort. Leaves linear, toothed; silicles angular, acute,—This has a trailing stalk, and produces its flowers in loose spikes towards the extremity.

17. Alyssum Deltoideum; Deltoid-kawed Maducort. Stems under-shrubby, prostrate; leeves lance-deltoid; silicles shaggy, Stems woody; flowers of a purple colour; native of the Levant, and rarely producing seed in this country; may be propagated from its trailing branches, which if planted in April will take root and become good plants by the following automn, It is properly a rock plant, being hardy, forming with very little care a neat tuft of flowers; and is very valuable from its beginning to flower in March, and continuing through the summer.

AMARANTH GLOBE. See Gomphrena.

Amaranthus; a genus of the class Monœcia, order Pentandria. GENERIC CHARACTER. Male flowers on the same plants with the females. Calix: perianth five or threeleaved, upright, coloured, permanent; leaflets hanceolate,

acute. Corolla: none. (unless the calix he so termed.) Sta-1 mina : filaments five or three, capillary, from upright, patulous, the length of the calix. Antheræ oblong, versatile. Female flowers in the same racemes with the males. Calix: perianth as in the male. Corolla : none. Pistil: germ ovate; styles three, short, subulate. Stigmas simple, permanent, Pericarp : capsule ovate, somewhat compressed, as is the calix, on which it is placed : coloured, and of the same size, three-beaked, one-celled, cut open transversely. Seed: single, globular, compressed, large. ESSENTIAL CHARACTER. Male: Calix; three or five-leaved, Corolla: none. Stamina; three or five, Female: Calix: three or five-leaved, Corolla: none. Styles : three. Capsule : one-celled, opening horizontally. Seed: one. These plants are generally disposed in nots with cockscombs and other showy plants, to adorn court vards, and other immediate environs of the house. They are tender, and require much care to bring to perfection in England. They are annual herbaceous plants, the flowers Tosely disposed in glomerules or spikes, and are almost all natives of North America, although some are found in the tropical countries of Asia and Africa, and only two in Europe. pical countries —The species are, * With three Stamina. Pullitary

1. Amaranthus Græcizans: Pellitory-leaved Amaranth. Glomerules axillary; leaves lanceolate, repand, obtuse; the stem a span high ; flowers from July to September, and is a native of North America.

2. Amaranthus Albus; White Amaranth. Glomerules axillary; leaves roundish, ovate, emarginate; stem four-cornered, simple : stem greenish white, a span high,-A native of the coast of Pennsylvania, from whence it has migrated into Italy: it flowers in July and August.

3. Amaranthus Deflexus. Spike very short, with few flowers ; leaves rhomb-lanceolate ; capsules not gaping .-- Its native place is unknown.

4. Amaranthus Polygonoides; Spotted-leaved Amaranth. Glomerules three-leaved ; female flowers funnel-shaped ; leaves rhomb-ovate, emarginate .- This species varies in different situations ; in a hot-bed, the stems were a foot high, and in the open air the stem was red. It is found wild by the wayside, and among rubbish, in the tropical countries of Asia, Africa, and America; as in Jamaica, Gniana, Senegal, Guinea, Ceylon, &c. It was brought to England in 1778, and flowers in August.

5. Amaranthus Polygamus; Hermaphrodite Amaranth. Glomerules two-stamined, subspiked, ovate ; flowers hermaphrodite and female; leaves lanceolate; stem upright, eighteen inches high .- It is a native of Guiana, China, and Amboyna, where the inhabitants boil and eat the leaves and stalks in preference to any of the others. Flowers in July and August.

6. Amaranthus Mangostanus. Glomerules subspiked, axillary, solitary; leaves rhomb-roundish .- Native of the East Indies.

7. Amaranthus Inamænus. Glomerules subspiked, threeleaved, axillary, geminate; leaves rhomb-lanceolate; stem a foot and half high; supposed to be a native of Japan.

8. Amaranthus Melancholicus; Two-coloured Amaranth. Glomerules axillary, peduncles roundish ; leaves ovate-lance olate, coloured; stem upright, half a foot high .--- In the open air, the leaves are of a dirty purple on their upper surface, and the younger ones are green ; in a stove, the whole plant is of a fine purple colour. It is well worth a place in a pleasure garden, but is very tender, and requires some art and care to bring them to perfection in England. It is a native of the East Indies and of Guiana, The leaves have two co- that height, green or red, upright, smooth, streaked. There

lours, an obscure purple, and a bright crimson, so blended as to set off each other, and making a fine appearance when the plant is vigorous. See the twenty-third species, for its propagation, cultivation, &c.

9. Amaranthus Gangeticus : Oval-spiked Amaranth. Glomerules in very short spikes, ovate ; leaves ovate-lanceolate. emarginate; stem not more than a foot high .- A native of Bengal, aud the Society Isles, and flowers from July to Sentember.

10. Amaranthus Oleraceus ; Eatable Amaranth. Glomerules axillary, branching ; leaves wrinkled, oblong, very obtuse, emarginate; stem upright, a foot or a foot and half high. even, smooth, round, and white; leaves pale green .- It is a native of Guiana, the East Indies, and Egypt, but is not entitled to a place in gardens on account of its beauty. This and the next species are gathered in India when young, and dressed as we dress spinach ; it flowers in July,

11. Amaranthus Viridis; Green Amaranth. Glomerules axillary, geminate, male flowers trifid, leaves ovate, emarginate ; stem erect, a foot or a foot and half high ; leaves a bright green in open situations, but dusky in the shade .- Native of Brazil; see the preceding species: and flowers in August and September.

12. Amaranthus Tricolor; Three-coloured Amaranth. Glomerules sessile, roundish; stem clasping; leaves lanceolate ovate, coloured; stem upright, a foot and half or two feet in height; leaves blue, with a red point .- It has long been celebrated for the beauty of its variegated leaves, in which the colours are elegantly mixed. Native of Guiana. Persia, Cevlon, China, Japan, and the Society Isles.

13. Amaranthus Lividus; Livid Amaranth. Glomerules subspiked, rounded; leaves elliptic, retuse; stem upright, two feet high, hollow, dark red, smooth, round, deeply streaked or grooved ; leaves dusky green, with pale purple veins; flowers green .- It is a native of Virginia and Guiana.

14. Amaranthus Tristis; Round-headed Amaranth. Glomerules in loose spikes ; leaves subcordate, ovate, emarginate, shorter than the petioles; stem upright, a foot and half high, leaves and flowers green .- Native of China, Cochin, Amboyna, and Brazil, where the young plant is eaten by the natives as the spinach is with us. It flowers from June till August.

15. Amaranthus Blitum; Least Amaranth, or Blite. Glomerules subspiked; flowers three-leaved; leaves ovate, retuse, stem diffused, a span high, upright, streaked, smooth. leaves smooth, green, emarginate, with a very short white point.-Native of all, except the very cold parts of Europe, of Japan, &c. found in cultivated grounds, on dunghills, banks, among rubbish, &c. Culpeper recommends this plant as excellent to restrain the fluxes of blood in either sex; and states, that there is a sort of wild blites, resembling the other wild kinds, but having long and spiky heads of greenish seeds. appearing by their thick setting together, to be all seed, at which fish will bite with great avidity; and adds, that it is much sought after by anglers.

16. Amaranthus Scandens; Climbing Amaranth. Spikes interrupted, compound; spikelets bent in leaves, ovate; stem weak, two feet high .- It resembles the preceding species, and is a native of America.

** With five Stamina.

17. Amaranthus Hecticus. Flowers in simple spikes, axillary, glomerate; leaves ovate, acute; stem red, nearly a foot high .- Its native place is unknown.

18. Amaranthus Hybridus: Clustered Amaranth. Racemes decompound, heaped, erect; leaves ovate-lanceolate; stem two feet high, and double that height in gardens; double

84

AMA

Felix: it flowers from June to September.

19. Amaranthus Strictus. Racemes compound, erect, strict : leaves ovate, concave; stem two feet high or more, obscurely angular .- Place of growth unknown.

20. Amaranthus Lætus. Racemes compound, erect ; leaves ovate, obtuse, mucrouate; stem never exceeding a foot in height ; leaves green, smooth ; the point herbaceous.

21. Amaranthus Cruentus ; Various-leaved Amaranth. Racemes decompound, naked, patulous; leaves lanceolateovate; stem a foot and half or two feet in height, grooved; green with red streaks, smooth, slightly pubescent among the flowers. Native of the East Indies; flowering from June to August

22. Amaranthus Hypochondriacus ; Prince's feather Amaranth. Racemes compound, crowded, erect; leaves oblong, lanceolate, mucronate; stem erect, a foot and half, or two feet high,-It is a native of Virginia, and flowers from July to September; it is now become a common weed, growing upon dunghills.

23. Amaranthus Sanguineus; Spreading, or Bloody Ama ranth. Racemes compound, erect; branches spreading, smooth; leaves oblong acute; stem four feet high; flowers of a bright purple colour, turning darker as the seeds ripen. It flowers from the middle of June until September.-To propagate this species, the seeds should be sown in a moderate hot-bed, towards the end of March. The plants must be transplanted, when large enough, to another moderate hotbed, where they must be watered, and shaded from the sun, till they have taken new root, and then should have free air always during fine weather. At the beginning of June, they may be taken up, with large balls of earth to their roots, and planted some in pots, and others into the borders of the pleasure garden, observing to shade them until they have taken good root, after which they must be frequently watered in dry weather, especially those in pots, which will require it every evening in warm dry weather. These plants are a great ornament to good gardens during the latter part of summer.

24. Amaranthus Paniculatus. Racemes compound ; branches spreading, pubescent; leaves ovate-lanceolate; stem upright, firm, a fathom iu height, grooved .- Native of America.

25. Amaranthus Retroflexus; Hairy Amaranth. Racemes super-decompound, erect; branches pubescent; leaves ovate; stem three feet high .- A native of Peunsylvania, aud a common weed in gardens near London.

26. Amaranthus Chlorostaehys. Racemes compound, nodding ; leaves lanceolate ; stem four feet high .- Its native place of growth unknown.

27. Amaranthus Flavus; Pale Amaranth. Racemes compound, nodding; leaves ovate lanceolate; stem sometimes exceeding four feet high; flowers always green .- The Portuguese cultivate it as a culinary herb.

28. Amaranthus Caudatus ; Pendulous Amaranth, or Lorelies-bleeding. Stem generally two feet high; leaves a bright green colour .- Native of Persia, Ceylon, Guiana, Peru, &c.

29. Amaranthus Spinosus; Prickly Amaranth. Racemes terminating, compound; axils thorny; stem upright, from twelve to eighteen inches high .- In the East and West Indies it is eaten as a green, boiled with basella cordifolia. It is also a native of Guiana and Guinea, and flowers from July to September.

Amaryllis ; a genus of the elass Hexaudria, order Monogynia .- GENERIC CHARACTER. Calix: spathe obloug, obtuse, compressed, emarginate, gaping on the flat side, and withering. Corolla: petals six, lanceolate. Nectary, six very short scales, without the base of the filaments. Stamina: 8

are several varieties. It is found wild in Virginia, and Arabia | filaments six, awl-shaped, with oblong, incumbent, rising antheræ. Pistil: germ roundish, furrowed, inferior ; style filiform, almost of the length, and in the situation, of the stamina; stigma trifid, slender. Pericarp : a subovate, threecelled, three-valved capsule. Seeds : several. ESSENTIAL CHARACTER. Corolla: six-petalled, irregular. Filaments inserted into the throat of the tube, bending down, unequal in proportion or direction. These plants are of the liliaceous or bulbous tribe; most of them have flowers of singular beauty, highly deserving the care and attention of the curious botanist and florist.— The species are, 1. Amaryllis Lutea; Yellow Amaryllis, or Autumnal Nar-

cissus. Spathe undivided, obtuse; flower sessile; corolla bell-shaped, erect, shortly tubular at the base ; stamina erect, alternately shorter .- Its flowers seldom rise above three or four inches high; they are shaped somewhat like those of the large yellow erocus. It flowers in September, and is a native of the south of France, Spain, Italy, and Thrace. It is very hardy, and increases fast by offsets; is a pretty plant, and continues flowering until November, if the frost do not destroy the flowers.

2. Amaryllis Pumilio; Dwarf Amaryllis. Spathe twoleaved, one-flowered; corolla funnel-shaped, equal; segments revolute; stamina bent in, alternately shorter --- Native of the Cape of Good Hope: flowers in November.

3. Amaryllis Atamasco; Atamasco Lily, Spathe bifid, acute; flower pedicelled; corolla bell-shaped, nearly equal, erect, shortly tubular at the base; stamina beat down, equal, The flowers are of a fine carnation colour on the outside at their first appearance, but fade, till they become almost white. They are nearly as large as those of the orange lily, but do not grow above six or eight inches high, appearing at the end of May, beginning of June, and sometimes in August. It is a native of Virginia and Carolina, where it grows plentifully in the fields and woods, making a beautiful appearance when in flower. It may be propagated by offsets from the bulbs; aud if planted in a warm situation, will bear the open air of England.

4. Amaryllis Formosissima; Jacobæa Lily, Spathe undivided ; flower pedicelled; corolla two-lipped, nodding, deeply six-parted; stamina and pistil bent down. Flowers large, of a deep red; the under petals very large; and as the whole flower stands nodding on one side of the stalk, it makes a most beautiful appearance. It is a native of South America. It is propagated by offsets, which may be taken off every year in August; and planted in pots of a middling size, having a moderate degree of warmth, will produce flowers plentifully, especially from March to September.

5. Amaryltis Regina; Mexican Lily. Spathe with about two flowers; pedicels divaricating; corollas bell-shaped, shortly tubular, nodding; throat of the tube, hirsute; leaves lanceolate, patulous .--- Corolla scarlet, with a bottom of a whitish green, the flower-stems seldom rising more than one foot high; it flowers constantly in the spring, when placed in a very warm stove. It is in beauty in February; and, in a moderate temperature of air, will flower in March or April.

6. Amaryllis Purpurea; Purple-flowered Amaryllis. Spathe with about two flowers; corollas somewhat erect, tubular at the base, throat of the tube smooth; leaves linear-lanceolate. -The corolla is large, and of a blood-red purple colour; it is a native of the Cape of Good Hope.

7. Amaryllis Equestris; Barbadoes Lily. Spathe with about two flowers; pedieles erect, shorter than the spathe : tube filiform, horizontal; border spreading open obliquely, and curved upwards; throat hairy .- Native of the West Indies.

8. Amaryllis Reticulata; Flat stalked Amaryltis. Spathe

with about two flowers; corollas tubular at the base and nodding; throat of the tube, smooth; scape compressed; leaves oblong, attenuated at the base.—It flowers in April, and is a mative of Brazil.

9. Amaryllis Belladonna; Belladonna Lily. Corollas somewhat erect, six-petalled; petals flat; scape compressed; leaves sharply channelled, bluntly keeled, very smooth .- It is a very ornamental plant in a garden, the stem rises upwards of two feet high, the flowers are of a soft purple colour, ap pearing about the end of September, or beginning of October, in England; and will continue in beauty a month or longer, in a favourable season. It was originally imported from Portugal; but is a native of shady hills, by the side of streams, in the West Indies. To cultivate this species, remove all the earth to the depth of three feet, from a border close to a wall. with a south-west aspect ; put six inches depth of very rotten dung at the bottom, then replace the original mould to the depth of twenty inches. Plant the roots every way six inches apart, then cover them to the former height of the border. with light sandy earth, and cover the whole three inches deep with rotten tanner's bark, to keep out the frost. This process has been very successful, producing a great many flowers. and making a fine appearance in October.

10. Amäryllis Viliata; Superb, or Ribbard Amaryllis. Flowers peticelled; corollaw swedge funnel-shaped, the ranchis of the outer farnished to the edge of the inner petals; scape round, sligmas grooved.—This species rarely puts forth off sets from the roots, but readily produces seeds by which it is propagated without difficulty. The stem rises to three feet or more, producing from two to five beautiful flowers. It usually blossoms from April to May. Native country unknown.

11. Amaryllis Falcata; Sickle leared Amaryllis, or Criman, Corollas peduncled, erect, six petalled; scape compressed, length of the umbel; leaves flat, pressed to the ground, about the edge sickle-shaped, white, cartilagious, erenate; flowers sweet-scented. Corolla white, with the middle of the bark red.—Naive of the Cape of Good Hope.

12. Amaryllis Ornafa; Cape Coast Lily, or Amaryllis, Flowers sessile; corollas tubular at the base; tube longer than the spathes, and border curved; segments of the border oblong, awned, lowest segments divaricate, concave.—Native of Guinea, flowering in June and July.

13. Anaryllis Longitolia; Long-Laered Amaryllis. Flowers pedicelled, from twelve to twenty in a spathet; corollas tubuar at the base, tube curved, short; segments of the borier lanceolate obtuse; lawes broad, subulate, channelled, flaceid at the tip; flower-stem rarely rising more than three or four inches high; flowers of a deep purple colour, appearing in December-H is a native of the 2acobaa Lily, No. 4, of this genus.

14. Amaryllis Revoluta; Revolute Amaryllis, Flowers perioelled; corollas tubular at the base; tube filform, short, curved; leaves linear, marrow, channelled, long, flaccid from their origin; seque a foot high; flowers weet-scentted, and of a pale red colour, appearing in September,—Native of the Cape of Good Hope.

is. Amaryllis Åurea; Galden Åmaryllis. Flowers pedicelled, somewhat erect; corollas funct/srm, elub-huped, almost six-petalled, segments linear-lanceolate; stamina and style straight; leaves linear, erect, claanalled, with a reflex smooth margin; corolla yellow; scope secared y two feet high. --Ht flowers in August and September, and is a native of China.

16. Amaryllis Orientalis; Broad-leaved African Amaryllis.

Spathe many-flowered; flowers pedicelled, six-parted, considerably shorter than the peduncles, irregular; germs wedgeshaped, angular.

17. Amaryllis Sarniensis; Guernsey Lily. Petals linear. flat; stamina and pistils straightish, longer than the corolla; stigmas parted revolute; leaves dark willow green; scane flattened, twelve or fourteen inches high; corolla, when in its prime, has the colour of a fine gold tissue, wrought on a rosecoloured ground; and when it begins to fade, it is a nink . when beheld in full sunshine, it seems to be studded with diamonds, but by candle-light, the specks or spangles look more like fine gold-dust; when the petals begin to wither, they assume a deep crimson colour .- The flowers begin to come out at the end of August, and the head is usually three wecks in expanding gradually. This beautiful plant is a native of Japan, and has been long naturalized in Guernsey, where it is reputed to owe its introduction to the shipwreck of a vessel returning from Japan, probably before the middle of the last century. The roots are sent over from Guernsey to England, and should be planted in pots filled with fresh, light, sandy earth, mixed with a little very rotten dung, placed in a warm situation, where they must be occasionally watered. The bud will appear about the middle of September, aud must then have the full benefit of the sun, being sheltered from strong winds. When the flowers begin to open, the pots should be removed under shelter, but not kept in too close and warm a place, as that will weaken their colour, and hasten their decay. They will continue in beauty a full month, if properly managed ; and, though they have no scent, they are justly placed in the first rank of the flowery tribe. After the flowers decay, the leaves will continue growing all the winter, and should have fresh air every day in fine weather. The roots should be transplanted every fourth or fifth year, at the latter end of June, or beginning of July, and ought to be replanted into fresh carth.

18. Anarylis Undulata; Waved flower Africen Amaryllis, Petals linear, channelled, waved; stamina and pistil bent down, shorter than the corolla; stagma obsolet; petals toos-coloured.—The flowers have to scent, and expand from November to the beginning of January. Native of the Cape of Good Hone; flowers in England f com April till June.

 Amaryllis Radiata: Snowdrop-leaved Amaryllis. Petals lanceolate waved; stamina and pistil bent down, diverging, twice as long as the corolla; stigma obsolete.—This species flowers in June; its native country not known.

20. Amaryllis Montana. Spaihe many-flowered; leaves linear, subulate; peta's alternate nucronate; stamina and style crect; stem upright; petals blue; seeds ovate oblong, black,--Native of the higher parts of Mount Lebanon.

21. Amaryllis Tubispatha. Spathe one-leafed, tubular, bifid, one-flowered; pednucle twice as long as the spathe; scape erect, four, inches high.—Native of Buenos Ayres.

22. An aryllis Tubiflora. Spathe one-flowered, two-leaved; corolla funnel-haped, with a very long tube.

23. Amaryllis Spiralis. Spathe two-leaved, few-flowered; peduncles filiform, very long; leaves subulate; corolla sixparted; scape twisted at the base.—A native of sandy grounds near the Cape of Good Hope.

24. Amaryllis Maculata. Spathe one-flowered, two leaved, linear; flower pedkneled; stamina and style bent down; scape variegated, with linear spots; corolla bell shaped.—It was found in China by Dombey.

25. Amaryllis Chileusis. Spathe one or two-flowered, one or two-leaved, lanceolate; flowers peduncled; leaves linear. —Has purple flowers, and was found in Chili by Dombey.

26. Amaryllis Ciavata. Spathe one flowered, two leaved,

of Africa.

27. Amaryllis Zeylanica; Ceylon Lily. Spathe manyflowered : corollas reclining ; tube filiform, very long ; segments uncinate. Tube of the corolla of the same rufous colour as the scape. Border white, with lanceolate recurved petals, with a red keel underneath. Filaments and style blood red. Pericarps viviparous.

28. Amaryllis Latifolia. Spathe many-flowered; flowers pedicelled, somewhat reclining, tubular at the base; leaves oblong, lanceolate. Scapes, tube of the flower, and stamina, purple-coloured .- It is a native of the East Indies. This plant may be increased by offsets from its roots, or by the bulbs which succeed the flowers.

29. Amaryllis Cinnamomea. Spathe many-flowered; corollas subhexapetalous, lanceolate, waved ; stamina and pistil erect, shorter than the corolla. Found at the Cape of Good Hope.

Amasonia; a genus of the Didynania class, order Angiospermia .-- GENERIC CHARACTER. Calix: perianth oneleafed, bell-shaped, semigninguefid, acute, equal, permanent. Corolla: one-petalled, tubulous, longer than the calix; border quinquefid, subequal, spreading, small. Stamina : filaments four, at the upper side of the corolla, and longer than it, bending in at the end; two 'of them shorter. Antherae oval, incumbent. Pistil: germ ovate; style in the situation and form of the stamina. Stigmas two, sharp. Pericarn: none. Seeds: an ovate, one-celled nut, of the same length with the calix. ESSENTIAL CHARACTER. Corolla: tubulous : limb small, quinquefid. Nut ovate, one-celled .-There is only one species, viz.

1. Amasonia Erecta. A native of Surinam; the stem herbaceous, three feet in height, round, and quite simple. The flowers in a simple terminal raceme, a foot long with about three upon a pedicle. Bractes ovate, sessile, a little longer than the flowers, which are yellow, nodding, and grow on one side of the stalk.

Amber-tree. Sce Anthospermum.

Ambrosia; a genus of the class Monœcia, order Pentandria .- GENERIC CHARACTER. Male flowers compound. Calix : perianth common, one-leafed, flat, of the same length as the floscules. Corolla: compound, uniform, tubulous, equal, hemispherical. Proper one-petalled, tubulous, funnelshaped, erect, quinquefid. Stamina : filaments very small ; antherm erect, parallel, acuminate, Pistil: Style filiform, length of the stamina; stigma orbiculate, membranaceous. Receptacle common; scarcely any, naked. Female flowers below the Male doubled. Calix: perianth one-leafed, acu-minatc, entire, permanent, the belly five-toothcd, one-flowered. Corolla: none. Pistil : germ ovate, in the bottom of the calix ; style filiform, of the same length with the calix ; stigmas two, setaceous, long, divaricate. Pericarp : a subovate nut, formed from the calix, hardened, one-celled, not opening, crowned, with the five acuminate teeth of the calix. Seeds: single, roundish. ESSENTIAL CHARACTER. Male calix: common, one-lcafed. Corolla: one-petalled, trifid, funnelshaped. Receptucle : naked. Female calix : one-leafed, entire, the belly five-toothed, one-flowered. Corolla ; none. Nut of the hardened calix onc-seeded .--- The species are,

1. Ambrosia Trifida; Trifid-leaved Ambrosia, Leaves three-lobed, serrate .- Grows eight or ten feet high; it is a common weed in North America, and is only preserved by the curious in botany. The seeds, though sown in the spring, seldom come up till the second year, when they may be transplanted into a moist rich soil, every way four or five feet

subulate; corolla club-shaped .-- Native of the southern part | the following spring, provided the ground remain undisturbed.

> 2. Ambrosia Elatior; Tall Ambrosia. Leaves pinnatifid; racemes panicled, terminal, smooth .- It is an annual herbaceous plant. Native of Jamaica, where it is found in barren, sandy, and rocky situations, by the sides of rivers, in the sonthern parts of the island. It flowers there from February till June, but with us from July to the end of August. This plant has the appearance and taste of wormwood; and will thrive, but not produce good seed, in the open air of our climate.

> 3. Ambrosia Artemisifolia: Mugwort-leaved Ambrosia. Leaves bipinnatifid, the first leaves at the origin of the smaller branches undivided, and quite entire. The primary stem is scarcely more than a foot high.

> 4. Ambrosia Maritima; Sea Ambrosia. Leaves multifid; spikes solitary, hairy, subsessile. Rises about two feet and a half high; the leaves emit a strong odour upon being handled; the spikes of flowers are axillary .-- It is not remarkable for beauty, and seldom perfects its seeds in England.

> 5. Ambrosia Arborescens. Tree Ambrosia. Leaves pinnatifid, hirsute; racemes solitary, terminating; stems shrubby, -This species grows to the height of ten or twelve feet, with a woody stem dividing into several branches. It may be propagated by cuttings or seeds; the former planted in a shady border during any of the summer months, and well watered. The secds when sown in the spring soldom appear till the spring following.

> Ambrosinia; a genus of the class Gynandria, Polyandria order .- GENERIC CHARACTER. Male Calix: spathe oneleafed, cowled, convolute at the base, converging at the tip; partition membranaceous, divided into two cells, communicating at top. Corolla: none. Stamina: filaments none. Anthera: very many, solitary, within the hinder cell of the spathe, in the upper part of the partition, digested in a distinct order. Nectaries : two, roundish, concave at the base of the antheræ. Female Calix: spathe common with the males. Perianth : none. Pistil : germ in the anterior cell of the spathe, and the lower part of the partition solitary, roundish. Style cylindrical, shorter than the spathe. Stigma obtuse. Pericarp: roundish, one-celled. Seeds very many, ovate, nestling. ESSENTIAL CHARACTER. Spathe one-leafed, separated by a partition. Stamina on the inner, Pistilla on the onter side of it .---- One species only of this genus has been hitherto discovered, viz.

> 1. Ambrosinia Bassii. Roots perennial, tuberous, acrid. Leaves radical, petiolate, ovate, shining; they appear at the beginning of antumn, and decay in spring. It is a native of Sicily, near Palermo; may be propagated by the root, and requires the protection of a greenhouse.

> Amellus; a genus of the class Syngenesia, order Polygamia superflua. GENERIC CHARACTER. Calix: common, imbricate, roundish. Corolla: compound, radiate. Corollets hermaphrodite, very many in the disk. Females very many in the ray. Proper of the hermaphrodites tubulous, five-cleft. Female ligulate, lax, two or three toothed. Stamina, in the hermaphrodites: germ obovate. Style filiform, the length of the stamina. Stigmas two, filiform. Females very like the hermaphrodites. Pericarp : none. Calix unchanged. Seeds: to the hermaphrodites solitary, chovate. Down: capillary to the females, very like the others. Receptucle : chaffy. ESSENTIAL CHARACTER. Culix : imbricate. Corollets of the ray undivided. Down: simple. Receptacle : chaffy .---- The species are,

1. Amellus Lychnitis; Trailing Amellus. Leaves oppoapart. If suffered to scatter their seeds, they will vegetate in site, lanceolate, obtuse, downy; peduncles one-flowered. This plant rises from two to three feet high, sending out branches on every side, terminated by flower-stalks, each supporting one violet-coloured flower with a yellow disk, which appears in July or August. It grows maturally at the Cape of Good Hope, and is a perennial plant, easily propagated by cuttings, planted during any of the summer months in the shade, and duly watered.

AME

2. Amelius Umbeliatus; Umbelied Amelius. Leaves opposite, three-nerved, downy underneati; fowers umbelied; stem from two to two and a half feet bigh; flowers vellow.— Native of the cooler woods and mountains of Jamaica, where it flowers in summer. It may be propagated by seeds sown in a hot-bed in the spring.

AMERICAN EARTH-NUT. See Arachis.

Amerimmum; a genus of the class Diadelphia, order Decandrim.--G RNERIC CHARCTER. Calific: perimith oneleafed; tube hell-shaped, frie-toothed; techtsharp. Corollar, papilionaceous. Standard: with an oblong claw, roundish, heart shaped, expanding, convex. Winge: hanceolate, shorter than the standard. Keel: short. Stamina: fihaments ten, conjoined. Authera: roundish. Pistiki germ pedicelled, oblong, compressed, leafy, varicose, with lateral veins, within woody, not gaping. Cells disposed longitudinally within. Seeds: solutary, kidney-shaped, thicker at the base, appendicled at the in. Essentral. CharAncTeR. Caliz: twoliped. Legume compressed, leafy, two-valved, gaping. Seeds forw, solitary.----The species are.

 Amerimann Brownei. Unarmed; leaves petioled, alternate, subcordate-ovate; racemes compound, axillary, and lateral.—This shrub rises to the height of ten feet; the flowers, which are white, and have a very sweet secant, come out in great abundance after the rainy season. Native of Carthagena, Jamaica, and Domingo.

2. Amerimum Elecuns; Prickly Amerimum, or Jamaica Ebany, Sujus; leaves subscelle, agercarle, obovate, oblong; pedureles two flowered, — This is common in Jamaica, and is sent to England under the name of ebony; though it is not the true ebony, but a plant of a very different genus. The wood being of a fingerensibility or colours, and polishing well, is much coveted by the instrument makers, as it is also of a very lard and durable nature. It is propagated by seed, which must be procured from its native climate, and sown in pots of light earth early in the surine. The word but not be artheousen air of this country.

Amethystea : a geaus of the class Diandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed; tube bell-shaped, angular, semiquinquefid, subcqual, acuminate, permanent. Corolla: one-petalled, ringent, little longer than the calix; border five parted, subequal; upper lip creet, rounded, concave, two-parted, gaping ; lower threeparted, the sides rounded, erect, shorter : the middle quite entire, concave, the length of the upper lip. Stamina : filaments filiform, approximating under the upper lip, and longer than it; antheræ simple, roundish. Pistil : germ quadrifid ; style size of the stamina; stigmas two, acute. Pericarp: none, but the calix becomes more bell-shaped and spreading. Seeds: four, shorter than the calix, obtuse-angular within. ESSENTIAL CHARACTER. Corolla: quinquend, the lower division more spreading. Stamina: approximated. Calix: subcampanulate. Seeds: four, gibbous. Only one species has as yet been discovered, viz.

 Amethystee Corrules. An annual plant with an upright stalk, about a foot high. Flowers small but of a fine blue colour, making a pretty appearance while they continue. The seeds should be sown in autumn: they will appear in the spring, and only require to be well weeded, and kept from growing to close together. It is an attive of the mountains of Sheria.

Ammennia : a genus in the class Tetrandria, and order Moongynia --GNERAIC CHARACTER. Calk: perianth hellshaped, oblong, erect, with eight streaks and folds, quadramgular, eight-toothed; teath stlernate, bent in, permanent. Corolla: none, or four-petalled; petals vertically ovate, spreading, inserted into the calix. Stamins: filaments (from four to eight) bristly, the length of the calix, into which they are inserted; anthere win. *Pisill*: germ subovate, large, superior; style simple, very short; stigun headed. Pericerp: a roundish, four-celled cagsule, covered with the calix. Seeds: numerous, small. ESVENTAL CHARACTER. Corolls: four-petalled, inserted into the calix. Calix: oneleafed, plaited, eight-toothed, inferior. Capsule: four-celled. ----The species are,

 Ammannia Latifolia; Brand-Jeaved Ammennia. Leaves half-stm-chasping, stalk square, branches erect. Root annual; the stalk grows about a foot high, the leaves are of a pale green, and the petta white.—It is a naive of moist places in Janaica, and can only be raised in a hot-bed from the seeds in England.

2. Anumannia Rumosior; Branching Amaannia. Leaves Infistenc-dasping; stalk square; branches very spreading.— This is an annuai plaut, a native of Virginia and Carolina, rising about a foot high, and will perfect lisseeds in the open air if raised on a hot-bed in the spring, and planted in a warm burder.

 Ammannia Baccifera; Berry-bearing Ammannia. Leaves subperiolate; capsules larger than the calix, and coloured.— A tender, erect, low plant; native of China, and now naturalized in Italy.

4. Ammannia Octandria; Eight-staminedAmmannia. Flowers petaloid, and eight-stamined. Stem erect. Pedmecles axillary, very short, three or one-flowered. Petals blood-red. -Found in the East Indies.

5. Animannia Pinnatifida; Pinnatifid leared Ammannia. Stalks procumbent, rooting, compressed; leaves linear, pinnatifid. Corolla red.—Found in the Isle of Java.

6. Anmannia Deblis; Cluster flowered Ammannia. Leaves lanceolate, attenuated at the base; stem branching; flowers in bundles from the axits; capsules two-celled. An annual plant, petals pale purple.—It flowers in July and August, and is a native of the East Indies.

7. Ammannia Sanguinolenta. Leaves half-stcm-clasping, cordate at the base; flowers subpeduncled, eight-stamined; petal bearing.—Native of Jamaica and San Domingo.

Ammi ; a genus of the Pentandria class, in the order Digypia .- GENERIC CHARACTER, Calix: universal umbel, manifold, frequently of fifty rays, partial, short, crowded. Universal involucre, of many linear, piunatifid, acute leaflets, scarcely the length of the umbel; partial many-leaved; leaflets linear, acute, simple, shorter than its umbellet. Proper perianth scarcely apparent. Corolla: universal uniform, all the floscules fertile; proper of five inflex heart-shaped petals, of unequal size in the ray; almost in the middle of the disk. Stamina : filaments capillary ; antheræ roundish. Pistil: germ inferior ; styles reflex ; stigmas obtuse. Pericarp : none. Fruit roundish, smooth, small, streaked, bipartite. Seeds: two, convex, and streaked on one side, flat on the other. ESSENTIAL CHARACTER. Involucre pinnatifid. Corolla: radiate; all hermaphrodite. Fruit smooth .---- The species are,

i. Anmi Majus; Common Bishop's Weed. Lower leaves pinnale, lanceolate, serrate; upper ones multifid, linear.—It is au annual, and grows in the vineyards and fields in the sonthern parts of Europe and in the east; and is propagated by seeds soon in autumn, where they are to remain. In the spring they must be hoed and thinned like carrots, leaving (them four or five inches asunder, and will afterwards require no further care. It flowers in July, and is common in our The seeds are the only part of the plant used in gardens. medicine; like all other carminatives, they are good against the colic; and are diuretic also, so that they are particularly efficacious in colics arising from the stone in the kidneys and urethra: they also promote the menses.

2. Ammi Copticum. Leaves super-decompound, linear; seeds muricate. Stem smooth, and streaked. Corollas white, equal, five-angular. Seeds aromatic .- Found in Egypt.

3. Ammi Glaucifolium ; Perennial Bishops' Weed. Subdivisions of all the leaves lanceolate.-The stem is from one to two feet high; the plant an annual, and native of the south of France. It is hardy, thrives best on a moist soil, and will grow in any open situation.

Amomum ; a genus of the class Monandria, order Monogynia .- GENERIC CHARACTER, Calix: perianth oneleafed, cylindraceous, unequally trifid. Corolla: monopetalous, funnel-shaped: tube cylindraceous: border threeparted; parts oblong, spreading. Nectary two-leaved, or two-lipped ; lower lip inserted under the upper segment of the corolla, spreading, almost erect, entire, or three-lobed. Stamina : filament none, except the upper lip of the nectary, smaller than the lower, and opposite to it, acuminate or three-lobed at the tip; along the middle, or at the end of which grows longitudinally a large oblong anthera, geminate or divided by a longitudinal furrow into two, which are one-valved. Pistil: germ inferior, oblong. Style filiform, drawn through the suture of the anthera. Stigma turbinate, obtuse, ciliate. Pericarp : capsule fleshy, ovate, three cornered, three-celled, three-valved. Seeds several, covered with a sort of berried aril. ESSENTIAL CHARACTER. Calix: trifid, unequal. cylindric. Corolla: three-parted, unequal, spreading. Nectary two-lipped, almost erect .- All the species of this genus are tender, and require a warm stove to preserve them in this country. In the West Indies, ginger thrives best in a rich cool soil ; in a more clayey soil, the roots shrink less in scald ing. The land laid out for the culture of it, is first well cleared and hoed, then slightly trenched, and planted in March or April; it flowers about September : when the stalks are wholly withered, the roots are fit to take up, which is generally done in January and February .---- The species belonging to this genus are,

1. Amonum Zinziber; Narrow-leaved Ginger. Scape middle-sized; spike ovate; leaves linear-lanceolate. The corolla is a yellowish green .- It is a native of the East Indies, and largely cultivated both there and in the West Indies. The root is less liable to heat the constitution than might be expected. A syrup, made from an infusion of three or four ounces of the root in three pints of boiling water, is kept in the shops. The cases in which it is more immediately serviceable are flatulent colies, debility and laxity of the system, and in torpid and phlegmatic constitutions to excite a brisker action of the vessels. Ginger is a warm and grateful aromatic; it strengthens the stomach, disperses wind, helps digestion, prevents or cures the colic, and is useful in all cold flatulent disorders and weaknesses of the intestines. It is one of the best additions that can be made to rough purging medicines, in order to prevent them from griping in the operation.

2. Amomum Zerumbet; Broad-leaved Ginger or Zerumbet. Scape naked; spike oblong, obtuse; culm four feet high, perennial, straight, and quite simple ; corolla pale .- It is a native of the East Indies, Cochin china, Otaheite, and the other Society Isles. It flowers with us from September 8.

and fomentations. The root is used as warm and good in all nervous cases, its virtues nearly resembling those of zedoary, which is often sold under its name, though in reality it is a much longer and larger root than the zedoary itself.

AMO

3. Amomum Sylvestre; Great Wild Ginger. Scape naked; spike elongate, with oblong ventricose bractes; leaves broad lanceolate. Exactly resembling the foregoing species: it is a native of Jamaica, where it is common in the woods. The root is warm, and gently stimulant; it may be properly administered as a stomachic, and is said to be an alexipharmic.

4. Amomum Mioga ; Japanese Ginger. Scape very short; capsule ovate ; leaves ensiform, acute. Root fusiform, fibrose, aromatic .--- A native of Japan, where it flowers in September.

5. Amomum Cardamomum ; Cardamom. Scape very simple, and short; bractes alternate, loose. Its stalks rise to the height of seven or eight feet in spring, but it has not yet flowered in England. The seeds are the only part used in medicine, and when freed from their husks are a grateful aromatic, warm, but not fiery: not heating and inflaming, like many other seeds of this nature. The seeds should never be separated from their husks till wanted for use, for in that case they lose much of their flavour and virtue. They are an excellent cordial, and peculiarly grateful to the stomach, dispersing wind, creating an appetite, and strengthening the digestive faculties. There is a spirituous distilled water and tincture of them kept in the shops, either of which are more agreeable than the seeds themselves, and equally efficacious. A glass taken after eating flatulent food, is serviceable in preventing or removing that disagreeable eructation or rising, which frequently succeeds. The tincture is also occasionally used as a pleasant warm cordial, as well as for flavouring other medicines. The lesser cardamom seeds are said to be excellent for colics, and disorders of the head, when chewed singly in the mouth; and their taste is not at all disagreeable.

6. Amomum Villosum. Scape short, reclining; bractes linear; fruit villose; culm six feet high; corolla pale .-- The smell of the whole plant is aromatic, mild, and slightly sharp. The fruit has a sweetish and pleasant taste when fresh. It is a native of China, where the seeds are in much request as a medicine.

7. Amomum Medium. Spike cauline, branched; fruit oblong, streaked, valveless. Culm straight, single, eight feet high .--- Native of China, where the seeds are used in agues ; for culinary purposes ; and to increase the strength of any odours whatever.

8. Amomum Globosum. Spike cauline, branched; fruit globose, with an even surface. Culm four feet high .- A natiae of China and Cochin-china, and used medicinally in both countries, in disorders of the bowels.

9. Amomum Hirsutum. Spike cauline, simple, reclining; fruit roundish, hirsute; culm six feet high; the smell and taste very weak .--- A native of Cochin-china, in the woods.

10. Amonium Granum Paradisi; Grains of Paradise. Scape branching, very short .- It is a native of Guinea, and of the islands of Ceylon and Madagascar, from whence we receive the seeds, which are of a warm aromatic nature, much resembling pepper, for which they are frequently substituted in many places. They are but little used in medicine, but might prove useful in cold flatulent disorders, the colic, &c.

11. Amomum Galanga; Galangale. Spike cauline, erect: spathes nearly three-flowered ; capsule three-cornered-ovate, smooth. The culm is perennial, entirely simple, upright, smooth, and six feet high. The smell of the whole plant is aromatic, and it has a biting taste. It is a native of China, and Cochin-china, where it is cultivated, and the roots and to November; and is used in the East externally in cataplasms. seeds used medicinally. The plant was formerly used as a 2 A

89

bitter infusions; but it is now almost wholly laid aside, on account of its unpleasant flavour. The spirituous extract is excessively fiery, and the watery extract very hot and pun-The essential oil has little smell, and no great gent. pungency. An infusion of the root in boiling water, or a tincture made with brandy, is a good medicine in windy complaints, and other disorders of the stomach, as well as for head-aches which arise from some debility or evil affection in that organ. The same root is usually given in the shops for galangale and zedoary.

12. Amomuni Arboreoum. Stem arboreus; fruit calicine. -This tree is ten feet high, has a pale red flower, scarcely any taste or smell, and its use is unknown. The wood is very light, not even fit for the fire. Native of the eastern coast of Sumatra.

Amorpha; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix : perianth one-leafed, tubulous, cyliudrical, turbinate ; mouth erect, five-toothed, obtuse, the two upper teeth larger than the others, perma-nent. Corolla: of one, ovate, concave petal, scarcely larger than the calix, erect, inserted into the calix, between the two larger and upper teeth, and placed at the upper side of it. Stamina : filaments very slightly united at the base, erect, unequal in length, longer than the corolla; antheræ simple. Pistil: germ roundish; style subulate, the length of the stamina; stigma simple. Pericarp: legume lunulate, reflex, larger than the calix, compressed, more reflex at the tip, onecelled, tubercled. Seeds two, oblong kidney-shaped. Es-SENTIAL CHARACTER. Standard of the Corolla, ovate, concave. Wings: none. Keel: none .--- The only species vet discovered is.

1. Amorpha Fruticosa; Bastard Indigo. It rises with many irregular stems to the height of twelve or fourteen feet, branching out with long spikes of purple flowers, but does not ripen seed in England, although it is become very common in all gardens and nurseries. It is propagated by seeds from abroad, and also by laying down young branches in sheltered situations.

Amugdalus: a genus of the Icosandria class, Monogynia order .-- GENERIC CHARACTER. Calix: perianth oneleafed, tubulous, inferior, quinquefid, deciduous; divisions spreading, obtuse. Corolla: of five petals, obloug-ovate, obtuse, concave, inserted into the calix; autheræ simple. Pistil: germ roundish, villose; style simple, length of the stamina ; stigma headed. Pericarp : a drupe, roundish, villose, large, with a longitudinal furrow. Seed : a nut ovate, compressed, acute, with prominent sutures on each side, reticulated with furrows, and dotted with small holes. ESSENTIAL CHARACTER. Calix: quinquefid, inferior. Petals five. Drupe having a shell perforated with pores ; skin pubescent. All the different species of peaches have been originally obtained from the stones, which is the best method of propa gating them. The best sort for sowing is those whose flesh is firm, and cleaves to the stone ; they should be planted in autumn, on a bed of dry earth, three inches deep and four inches asunder, carefully weeded and watered when they come up, until the following spring, when they must be transplanted into a nursery, and placed one foot apart, in rows three feet asunder, observing to lay a little mulch upon the ground to prevent it drying too fast; and if the spring prove dry, watering them once a week. Here they may continue two years, and may be afterwards transplanted where they are intended to remain, to produce fruit. In removing these trees, observe to prune their downright roots, cutting off all bruised parts and small fibres. All the pruning they require acute; the flowers sessile and solitary .-- The wood of this

warm stomachic bitter, and generally made an ingredient in t is the lopping off of decayed or irregular branches, which are very detrimental. The common method of propagation is by inoculating them upon other stocks, such as those of the muscle and white pear, plums, which are most esteemed, also some almond and apricot stocks, for some tender sorts of peaches will not grow upon plum stocks. These stocks should be planted three feet asunder, and one foot apart in the rows. and after two years will be strong enough to bud, which takes place generally about midsummer, or any time in July, when you should make choice of some good cuttings from healthy trees of the sort of fruit you wish to propagate. These cuttings should be taken from the trees in a morning or evening. or in a cloudy day, otherwise they are apt to perspire and miscarry. Much depends upon the choice of trees ; the stock should be of the size of a man's finger, free from moss or canker, the bud of one year's growth only, not such as have been cut down in the spring, and made a second shoot. The best soil for planting is such as is taken from a pasture ground. neither too stiff, and moist, nor over dry, but of a middling nature, such as is termed hazel-loam. It should be dug from the surface of the ground ten inches deep, taking the turf with it; and should be laid in heaps, eight or ten months at least : but if one year before it is used, it will be still better. that it may have a summer's heat and winter's frost to mellow it, during which time it should be often turned, to rot the turf, and break the clods. The trees should always be planted twelve feet asunder, and in good ground fourteen feet. First make a hole wide enough to receive the roots of the tree, then place it down, observing to turn the bud outwards, that the wounded part of the stock may be hid from sight; and let the stein of the tree be placed about four or five inches from the wall, with its head inclining thereto; then fill in the earth with your hands, observing to break the clods, that the earth may fall in between the roots, and gently shaking the tree with your hand, the better to settle, but do not tread it down. In May the shoots should be nailed to the wall, observing to train them horizontally, and cutting off all weak and foreright shoots. In October they must be pruned in proportion to the strength of the tree. Blights are oftener produced by weakness, and want of nourishment, and distempers in the trees themselves, than by the inclemency of the season, which may arise from their being planted in an improper soil. The best method, when the fault is not in the tree itself, is to sprinkle the branches gently with water, which should always be done before noon, in dry weather, and when little dew falls, soon after the blossoming season, when the young-set fruit is tender. When it is grown to the size of a small nut, it will require thinning. The quantity of fruit left on large full-grown trees, ought not to exceed five dozen. and four dozen is sufficient for those of a middling size. In hot and dry seasons, the earth round the stem of each tree may be formed into a hollow bason, six feet in diameter, and covered with mulch; into which once a week or fortnight, according to the heat of the season, eight or ten gallons of water may be poured down round the root of the tree. But the best method is, to sprinkle the same or a larger quantity of water all over the tree like rain, by means of an engine ; which will prevent the fruit from falling off. The culture of the nectarine, is the same as that of the peach, only the buds of the former should be taken from bearing trees, and not from young nursery trees, as is too often done. For further information, as to the propagation and culture of these trees, see the articles INOCULATION and NURSERY .---- The species of this genus are,

1. Amygdalus Persica. All the servatures of the leaves

tree is of a reddish brown colour, darker toward the middle, and fit for the use of the turner. It is of quick growth, and not of very long duration. There are many varieties of this species, the best of which are,-the early purple peach, which is ripe before the middle of August; the large or French Mignon (grosse Mignon) the Chevreuse or Belle Chevreuse ripe towards the end of August; the red Magdalen; Chancellor ; Bellegarde ; Bourdine ; Rossanna ; Rambouillet, and Nivette. Others recommend the small Mignon, Early Newington, Noblesse, Admirable, Royal, Monstrous Pavy, and Swalch. These are the best sorts for planting, but in warm situations one or two trees of the Catharine Peach should be admitted, as it is an excellent fruit in warm seasons. The nectarine is only a variety of the peach tree ; there are twelve sorts, the best of which are Fairchild's early nectarine, the the Elruge Nectarine, the Newington Roman red, and Temple's nectarine. For directions for planting &c. see the preceding article.

2. Amygdalus Communis; The Almond Tree. The lower serratures of the leaves glandulous; the flowers sessile, and in couplets .- This tree grows to the height of twenty feet with spreading branches, but it is scarcely worth considering, in England for the sake of the fruit it produces. It is common in the East Indies, China, and Barbary, where it is a native ; and it is a great object in some part of Italy, and the south of France, as in Provence, and Dauphine, where there are vast plantations of almonds. An almond-tree, covered with blos-soms, is one of the most elegant objects in nature. There are several species and varieties not satisfactorily ascertained. Sweet almonds used in food are difficult of digestion, and afford very little nutriment, unless well masticated. As medicines, they contribute, by their soft unctuous quality, to blunt acrimonious humours in the first passages, and thus sometimes give present relief in the heartburn. On expression, they yield nearly half their weight in oil, which is more agreeable than most of the common expressed oils, and is therefore employed medicinally for allaying acrid juices, softening and relaxing the solids, in tickling coughs, hoarseness, costiveness, nephritic pains, &c. When pounded, in water it unites with the fluid, forming a milky liquor, which is prescribed as a diluent in acute diseases ; and for supplying, in some degree, the place of animal milk, with which it has a great analogy; an ounce of almonds is sufficient for a quart of water, to which gum-arabic is in most cases an useful addition. The pure oil, mixed with a thick mucilage of gum arabic, forms a more permanent emulsion ; one part of gum, with an equal quantity of water, being enough for four parts of oil. Almonds are also useful medicines, for uniting substances with water which will not of themselvcs mix with it. Camphor, and the purgative and other resins, pounded with about six times their quantity of almonds, dissolve in water into a milky liquor, and are thus fit for being taken in a liquid form. Bitter almonds, and emulsions made from them, have been recommended as aperients, resolvents, diuretics, and anthelminthics. These almonds, taken freely in substance, occasion sickness and vomiting : to dogs, and some other animals, they are poisonons. A simple water, strongly impregnated by distillation, with their volatile parts, has been found also poisonous to brutes, and there are instances of cordial spirits flavoured by them being poisonous to man. It is remarkable that the kernels of other fruits, that have any bitterness or particular flavour, appear to be impregnated with a substance of a similar nature to this poisonous principle of bitter almonds. Almonds are distinguished into sweet and bitter, but there is no perceptible difference in the trees which produce them. - Six or eight sweet almonds peeled and eaten,

frequently cure the heartburn. Notwithstanding thenoious gualities of the bitter kind, they are said to destroy worms, and operate as diureties. Sweet almonds blanched, and beaten into an emulsion with barley-water, are of great use in the stone, gravel, strangury, and other disorders of the kidneys, bladder, and bilary ducts.

 Amygdalus Pumila; Double-flowered Dwarf Almond, Leaves veined, wrinkled; branches smooth, two or three feet high; flowers red.—These shrubs make a very agreeable variety among low flowering trees, in small wilderness quarters. Native of Africa: flowering time April.

4. Anygdalus Nana; Common Durarf Almond. Leaves attenuated at the base.—The wood of this little tree is hard. It blooms in April, at which time all the young shoots are covered with flowers, which are of a peach-blosson colour, and make a fine appearance when intermixed with shrubs of the same growth. It is a naive of the northern parts of Asia, particularly abundant in Calmue Tartary, and very frequent on the banks of the Volga.

5. Amygdalus Incana; *Hoary Dwarf Almond*. Leaves lanceolate, serrate, wrinkled, subsessile, white tomentose beneath. It is doubted whether this be any thing more than a variety of the preceding species.

6. Amygdalus Orientalis; Silvery-leaved Almond. Leaves lanceolate, quite entire, silvery, perennial; petiole shorter.— The leaves are silvery, and continue most of the year; the flowers are very small. It was found growing near Aleppo.

7. Amygdalus Cochin-chinensis. Leaves ovate, quite entire; racemes small, subterminal.—This is a large tree, native of the vast woods of Cochin-china.

Amyris; a genus of the Octandria class, Monogynia order, —GENERIC CHARACTER. Caliz: perianth one-leafed, four-toothed, acute, erect, small, permanent. Corolla: of hour, oblong, concave, spreading petals. Stamina: filaments awl-shaped, erect. Antherae oblong, erect, the length of the corolla. Pisiti: germ superior, ovate; style thickish, the length of the stamina; stigma four-cornered. Pericarp: a drupaecous roundish berry. Seed: a round shining nut. ESSENTIAL CHARACTER. Caliz: four-toothed. Petals four, oblong. Stigma four-cornered. Berry drupaecous.—— The species are.

 Amyris Elemifera; Gum Elemi Tree. Leaves ternate, and pinnate, with five lobes, downy underneath.—This tree is six feet high: a resin called gum-demi is from this tree. It is a native of Carolina and Brazil.

2. Amyris Sylvatica.—Leaves ternate, orenate, acute.—A leafy branching shrub, from two to fifteen feet high, found plentifully about Carthagena, in woods near the sea. Flowers in August, and abounds in turpentine of a strong disagreeable smell.

3. Amyris Maritima; Small Shrubby Sweetwood. Leaves ternate, cremulate, obtuse.—A dwarf shrub, branching, with a juice like that of the former species, but pleasanter, and smelling like rue. It grows in very barren coppiecs, in a calcareous rocky soil, both near the sea and on the interior mountains of Jamaica, Hispaniola, and Cuba, flowering from June to September.

4. Amyris Gileadensis; Balsam of Gilead Yræ. Leaves ternate, quite entire; péduncles one-flowercd, lateral.—This is a shrub with purple branches, striated a little, having protuberant buds loaded with balsamic resin; it is, however, doubtful whether it is not the same with the following species.

 Amyris Opobalsamum; Balsam of Mecca Tree. Leaves pinnate, leaflets sessile.—The true opobalsamum is said to be produced from this tree; it is at first turbid and white, of a very strong pungent smell, like that of turpentine, but sweeter,

01

and more fragrant, like mint, varying according to its good-| Leaves awl-shaped; pericarps juiceless .- A shrub with white ness, and of a bitter, acrid, astringent taste ; it becomes thin, light, limpid, and of a greenish hue, and then of a gold colour; after which it grows thick like turpentine, and loses much of its fragrance. Its scarcity has prevented its coming into use among-us; nor are its virtues, probably, superior to those of some of the resinous juices more common in the shops; all these substances being alike in substance and general qualities, though differing in the degree of their pungency, gratefulness, and warmth. It has always been particularly esteemed as a cosmetic, by those who think they can amend what their Creator made. The Eastern women in particular make great use of it; they first go into a tepid bath, till the pores are sufficiently opened, then anoint themselves with a small quantity, as much as the vessels will absorb, after which neverfading youth and beauty are said to be the consequences ! Lady Mary Wortley Montague informs us, that the balm of Meeca, when applied to her face, caused it to become swelled and red during three days, but that her complexion was much mended by the operation. She says, that of the best quality is not easily procured, even at Constantinople, where the women all use it, and have the loveliest bloom in the world !

6. Amyris Toxifera ; Poison Ash. Leaflets pinnate ; leaflets petiolate, plain .- A liquor as black as ink distils from the trunk of this tree, which the Americans say is poison. Birds feed upon the fruit; aud it is a native of America.

7. Amyris Protium .- Leaves pinnate ; leaflets petiolate, waved ; perennial .- Native of the East Indies.

8. Amyris Ambrosiaca. Leaves pinnate, petiolate; panicles crowded, axillary .- The trunk of this tree is thirty feet high, the flowers yellowish white; it is extremely sweetscented, and pours out a very odorous balsam, from the wounded trunk or branches, which is used in the dysentery : the dose is one drachm in red wine; it is also used in houses and churches to burn as a perfume ; and grows in the woods of Guiana and by the sea-shore, flowering and fruiting in September.

9. Amyris Balsamifera ; Sweet Amyris, White Candle wood, or Rosewood. Leaves two-paired .- This species grows to a considerable size, and is one of the most valuable timber trees in the island of Jamaica; the wood is of a clouted ash-colour, of a pleasant smell, heavy, and, bearing a fine polish, is in great repute among entinet-makers. All the parts of this tree are full of warm aromatic particles, and many be used in baths and fomentations. An infusion of the leaves has a very pleasant flavour, is highly cephalic, strengthens the nerves, and is peculiarly restorative to weak eyes.

Anabasis ; a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix : perianth three-leaved ; leaflets roundish, concave, obtuse, spreading. Corolla: fivepetalled ; petals ovate, equal, less than the calix, permaneut. Stamina : filaments filiform, longer than the corolla : antheræ roundish. Pistil: germ roundish, acuminate, ending in two styles; stigmas obtuse. Pericarp: a berry; roundish, surrounded by the calix, dilated. Seeds : single, screw-shaped. ESSENTIAL CHARACTER. Calix: three-leaved. Corolla: five-petalled. Berry one-seeded, surrounded by the calix. The species are,

1. Anabasis Aphylla; Leafless Anabasis. Without leaves, the joints emargiuate; the stem short and roundish; the berry dyes a yellow colour .- It is perennial, and has been found wild on the shores of the Caspian sea.

2. Anabasis Foliosa ; Leafy Anabasis. Leaves subclavate, seldom more than a foot and half high .--- Annual, also found on the shores of the Caspian sea,

3. Anabasis Tamariscifolia ; Tamarisk leaved Anabasis.

branches : native of Spain.

4. Anabasis Spinosissima; Thorny Anabasis. Shrubby; branches without leaves, but full of spines .- A shrub: its native place unknown.

Anacardium ; a genus of the class Polygamia, order Monœcia .- GENERIC CHARACTER. Hermaphrodite flower; Calix: five-leaved : leaflets ovate, concave, coloured, erect, deciduous. Corolla: petals five, lanceolate, acute, three times as long as the calix, upright at the bottom, reflex at the end. Stamina: filaments ten, united at the base, upright; nine of them capillary, shorter than the calix ; one thicker, double the length of the others, lying on the germ in front, Antheræ roundish; in the longer filament large and fertile, in the rest small. Pistil: germ kidney-shaped, obliquely emarginate in front. Style subulate, bent in the length of the corolla. Stigma small, roundish, depressed, concave, Pericarp: none. Receptacle: fleshy, very large, obovate. Seed : nut kidney-shaped, large, at the top of the receptacle ; with a thick shell, cellular within, and abounding in oil. Mala flowers, either mixed with the hermaphrodites, or on a distinct tree. Calix, Corolla, and Stamina, as above. Pistil: germ none, or abortive. ESSENTIAL CHARACTER. Calix: five-leaved. Petals: five, reflex. Anthera: ten, one only fertile. Nut kidney-shaped, on the top of a fleshy receptacle .---One species only is yet known, viz.

1. Anacardium Occidentale; Casheu-nut, Cassu, or Acajou .- This is an elegant tree twenty feet high. The fruit or apple has an agreeable subacid flavour, the juice expressed from it, and fermented, yields a pleasant wine ; and when distilled produces a spirit far surpassing arrack or rum, making admirable punch, and powerfully promoting urine. The nut springs from one end of the apple, and contains, between it and the kernel, an inflammable caustic oil, which will raise blisters on the skin, and has been used with great success in eating off ring-worms, cancerous ulcers and corus, but should be cautiously employed. When fresh, the kernel has a most delicious taste, abounding with a sweet milky juice. When it is old, and ground with cocoa, it makes excellent chocolate. The body of the tree, when tapped, produces a milky juice, which will stain linen indelibly with black ; the thick oil of the shell also tinges it of a rusty iron colour, which can hardly be got out ; and if rubbed over wood, will preserve it from decaying, and might therefore prove an excellent preservative to house timber and ship's bottoms. The tree yields annually five, ten, or even twelve pounds weight, of a fine semitransparent gum, similar to gum-arabic, and not inferior in virtue or quality, except that it has a slight astringency, which perhaps renders it in some respects more valuable. The inside of the fleshy receptacle, which is commonly called the cherry, is stringy, but full of an austere acid but pleasant juice, which the Americans employ in making punch, as we do that of lemons. When the West India ladies imagine their beauty too much impaired by the scorching rays of the sun, they scrape off the outside skin of the nut, and then rub their faces and hands all over with it, which soon after swell and grow black, and in five or six days after the skin has been thus poisoned, it comes off the face and other parts in large flakes. This operation prevents their appearance in public for the full space of a fortnight; at the end of which time the new skin looks as fair as that of a young child. The slaves and negroes in Brazil cure themselves of disorders in the stomach, to which they are very subject, by eating the fleshy parts of the fruit, the acidity of which dissolves the tough humour which prevents the free circulation of the blood and juices, and thus removes the complaint by destroying its

92

cause. It is however necessity, not choice, which leads the] Negroes to the use of this fruit, which they are far from being fond of; but their masters, the Portuguese, deny them every other kind of sustemance. Being constrained to use this food, in a few days they recover from their indisposition, and return to their masters with health and vigour, sufficient to perform the labour usually allotted to them.

Anacyclus ; a genus belonging to the Syngenesia class, order Polygamia Superflua .- GENERIC CHARACTER. Calix: common, hemispherical, imbricate, with many ovate, flat, sharp scales. Corolla : compound, radiate, with numerous hermaphrodite corollets in the disk ; from five to ten females in the ray, scarcely higher than the disk. Hermaphrodites funnel-shaped, with a quinquefid, spreading border. Females with a flatted tube, and an ovate entire border. Stamina : in the hermaphrodites; filaments five, capillary, very short; anthera cylindric. Pistil: germ flatted, stigma bifid, in the hermaphrodites ; with a membrane on each side ; style filiform, the length of the corollet; and two slender reflex stigmas in the floscules. Pericarp : none ; calix unchanged. Seed in the hermaphrodites, solitary, oblong, compressed, naked, or without down; in the females, with a very bold membranaceous wing on each side, and emarginate at top, but without down. Receptacle : chaffy. Chaffs obtuse, with a ESSENTIAL CHARACTER. Receptacle: chaffy. point. Down: emarginate. Seeds in the ray, membranaceous. All the plants of this genus are annual.----The species are,

1. Anacyclus Creticus ; Trailing Anacyclus. Leaves decompound, linear; divisions subdivided, flat .- Native of the islands of the Archipelago.

2. Anacyclus Orientalis; Eastern Anacyclus. Leaves compound, bristly, acute, straight .- This plant has white flowers resembling the chamomile .- Native of the islands of the Archipelago; first discovered by Tournefort.

3. Anacyclus Aureus: Golden-flowered Anacyclus. Leaves bipinnate, roundish, hoary, hollow-dotted ; stems many, seven inches high, and erect .- It is a native of the south of Europe and the Levant.

4. Anacyclus Valentinus; Fine-leaved Anacyclus. Leaves decompound, linear; divisions subdivided, roundish, acute; flowers flosculose .- Grows a foot and half high, with flowers of a bright yellow colour, and a silvery scaly calix. It is a native of Spain, flowering in June and July.

Anagallis ; a genus of the Pentandria class, Monogynia order .- GENERIC CHARACTER. Calix: perianth fiveparted, sharp, permanent ; division keeled. Corolla : wheelshaped, border five-parted; divisions ovate orbiculate, with the claws connected. Stamina : filaments erect, shorter than the corolla, shaggy below; antheræ simple. Pistil: germ globose; style filiform, slightly bending; stigma capitate. Pericarp : a globose, one-celled capsule, opening transversely. Seeds : very many, angular. Receptacle : globose, very large. ESSENTIAL CHARACTER. Corolla: rotate. Capsule : opening horizontally. The four first species are annuals, propagated from seed, which must be sown soon after they are ripe, and sheltered from extreme cold. ---- The species are.

1. Anagallis Arvensis; Common Pimpernel. Leaves undivided ; stem procumbent ; corolla finely notched .- It is an annual plant, with a quadrangular stem and scarlet corollas. with purple bottoms; the blossoms open about eight in the morning, and close in the afternoon, except it rain, in which case they neither open nor close, hence it is called the Shepherd's, or Poor Man's Weather-glass. Cows and goats feed upon it, but sheep reject it. It is common in corn-fields, and in other cultivated places, and blossoms from May till August. 8

is an excellent medicine in feverish complaints, which it relieves by promoting a gentle perspiration. The same simple preparation is much used among country people in the first stages of consumptions; and is often the happy means of checking the disorder, and preventing its fatal consequences. The whole plant, dried and powdered, is good for the falling sickness; and there are, says Hill, many well-authenticated accounts of that dreadful disorder being absolutely cured by

it. A decoction of it in wine, drank in bed, causes sweating, and is a preservative in pestilential and contagious diseases ; a water distilled from it is excellent for sore eyes. The expressed juice is serviceable in the beginning of dropsies, and in obstructions of the liver, spleen, and reins. It brings away stony and gravelly concretions from the bladder and urinary passages, and is good in consumptive cases, ulcerated lungs, and other disorders of the breast. The infusion is best made by pouring boiling water upon it fresh gathered. The dried leaves may be given in powder, or an infusion made of the whole dried plant, but nothing equals the infusion of the fresh plant. This species grows wild in Sweden, Germany, and Switzerland; and with us between Stockwell and Camberwell; near Mitcham in Surry; near Histon in Cambridgeshire; and Bredon-Hill in Worcestershire.

2. Anagallis Monelli; Upright Pimpernel. Leaves undivided : stem erect .- This is a very beautiful small plant, producing great numbers of fine blue flowers in April and May. It is a native of Verona.

3. Anagallis Latifolia; Broad-leaved Pimpernel. Leaves heart-shaped; stem clasping; stem compressed .-- This is very nearly allied to the preceding species; corolla blue; filaments purple; antheræ oblong, yellow; it is a trailing annual plant, and was imported from Spain.

4. Auagallis Linifolia; Flax-leaved Pimpernel. Leaves linear; stem erect; stem three or four inches high .- It grows wild in Spain and Portugal.

5. Anagallis Tenella; Bog Pimpernel, Purple Loosestrife, or Moneywort. Leaves ovate, sharpish; stem creeping; roots perennial; stems numerous; corolla large, pale-red colour, with deeper veins .- Not uncommon on bogs, flowering from June to August. Moneywort is cooling and astringent, excellent against spitting of blood, and in bloody fluxes, for which purposes it is best to give the leaves in powder. The juice of it is a well-known remedy among country people, for overflowings of the menses ; and the roots dried and powdered are good in purgings. It is a good antiscorbutic, and the leaves bruised, and applied to green wounds, speedily heal them.

6. Anagallis Verticellata; Verticelled Pimpernel. Stemleaves verticelled; stem erect, a foot high; corolla a bright blue ; has not yet been cultivated in England.

7. Anagallis Pumila; Dwarf Pimpernel. Stem erect: leaves roundish, acute, sessile .- Annual, and a native of Jamaica.

Anagyris; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth bellshaped ; mouth five-toothed, the upper pair of teeth more deeply divided. Corolla: papilionaccous; standard obcordate, straight, emarginate, broader than the other petals, twice as long as the calix; wings ovate-oblong, flat, longer than the standard ; keel straight, very long. Stamina : filaments parallel, distinct, rising; autheræ simple. Pistil: germ oblong; style simple, rising; stigma villose. Pericarp: an oblong, large, roundish, obtuse legume, a little reflex. Seeds : six or more, kidney-form. ESSENTIAL CHARACTER. Standard and wings shorter than the keel, in a papilionaceous corolla. Fruit ; a legume. These plants may be propagated by laying It is of a cordial sudorific nature, and a strong infusion of it down their tender branches in the spring : if seeds be used,

2 B

March .---- The species are,

1. Anagyris Foetida; Stinking Bean Trefoil. Leaves ovate; flowers axillary .- It is a shrnb eight or ten feet high, with bright yellow flowers, appearing in April and May, and grows wild in France, Spain, Italy, Sicily, and about Smyrna.

2. Anagyris Cretica. Leaves oblong, racemes longer.-A native of Candia, very rare in England.

3. Anagyris Inodora. Leaves pinnate; calices inflated, coloured ; legumes compressed, straight ; racemes terminating, oblong .- An upright shrub, with a white flower, and native of the woods of Cochin-china.

Anastatica ; a genus of the Tetradynamia class, order Siluculosa.-GENERIC CHARACTER. Calix: Perianth fourleaved, deciduous: leaflets ovate oblong, concave, erect, deciduous. Corolla tetrapetalous cruciform ; petals roundish, flat, spreading ; with claws nearly the length of the calix, but more spreading. Stamina: filaments six, subulate, the leugth of the calix, form erect spreading : antheræ roundish. Pistil : germ bifid, very small; style subulate, the length of the stamina, permanent; stigma capitate. Pericarp : a very short silicle; partition ending in a subulate point, oblique and longer than the silicle itself; the valves parallel, making a cell of the lower half, but standing out from the upper, rounded, concave, gaping, oblique; hence having the form of a sheep's hoof. Seeds solitary, roundish. ESSENTIAL CHARACTER. Silicle retuse, crowned at the edge with valves twice as long as the partition. Style intermediate, pointed, oblique. Cells one-seeded .--- These plants are annual, and can only be propagated by seeds sown in a hot-bed in the spring .---- The species are.

1. Anastatica Hierochuntica. Common Anastatica, or Rose of Jericho. Leaves obtuse ; spikes axillary, very short ; silicles hoofed, thorny .- This curious plant, if taken up before it is withered, and kept entire, may be preserved many years in a dry room : and afterwards, if the root be placed a few hours in a glass of water, the buds of flowers will swell, open. and appear as if newly taken out of the ground. It grows naturally on the coasts of the Red Sea, in the sandy parts of Palestine, and near Cairo,

2. Anastatica Syriaca: Surian Anastatica. Leaves acute: snikes longer than the leaf; silicles ovate, beaked .-- It flowers in May and June, and is a native of Austria, Stiria, Carniola, Svria, and Sumatra.

ANCHOVY PEAR. See Grias.

Anchusa ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER, Calix; perianth five-parted. oblong, round, acute, permanent. Corolla; monopetalous; funnel-shaped; tube cylindrical, the length of the calix; limb semi-quinquefid, from crect expanding, obtuse; throat closed with five small scales, convex, prominent, oblong, converging. Stamina: filaments very short, in the throat of the corolla : antheræ oblong, incumbent, covered. Pistil: germs four ; style filiform, the length of the stamina ; stigma obtuse, emarginate. Pericarp none; but the calix enlarged. and erect, contains the seeds in its bosom. Seeds: four, oblongisa, obtuse, gibbose. ESSENTIAL CHARACTER. Corolla funnel-shaped, the throat closed with an arch of scales. Seeds: engraved at the base .- All the species of this genus may be propagated by seeds, sown in the autumn upon a bed of light sandy earth, and removed from theuce in the spring to beds planted at two feet distance, watering them till they have taken root, after which they will require no further care If the seeds of the common sorts be permitted to scatter themselves, the plants will rise in plenty .---- The species are, 1. Anchusa Officinalis; Officinal, or Garden Alkanet, or

they must be sown on a moderate hot-bed at the beginning of Bugloss. Leaves lanceolate, spikes imbricate, pointing one way. Stem from a foot to eighteen inches high. Corolla purple, and sometimes white .- They appear in June, July, and August. Bees are very fond of the tube of the corolla : it appears to be nearly similar to borage : the leaves are less juicy, and the roots more mucilaginous : these, with the leaves and flowers, are ranked among the articles of the materia medica. It is in great esteem in China, for gently promoting the eruption in the small pox. Bugloss shares with borage the credit of being a cordial; but perhaps neither of them have any great title to the character. It is used, like borage, in cool tankards; for there is no way of making any regular preparation of it that is possessed of any virtues.

2. Anchusa Angustifolia; Narrow-leaved Alkanet. Racemes almost naked, in pairs. Grows two feet high in gardens, but seldom more than one when wild. The flowers are small and of a red colour : it is found wild in Germany and Switzerland : flowering in July and August by way-sides, and the borders of ploughed fields. The great Bocrhaave recommended the juice of this plant in the pleurisy and maniacal cases.

3. Anchusa Italica ; Italian Alkanet. Leaves lucid, strigose; raccmes two-parted, two-leaved; flowers somewhat unequal, bearded at the throat. Roots biennial, stem erect. four feet high or more.

4. Anchusa Undulata; Waved Alkanet. Strigose, leaves linear toothed, pedicles less than the bracte, fruit-bearing calices inflated. Height three feet, leaves stiff, rough, six or seven inches long; corollas a fine blue colour .- A native of Spain and Portugal.

5. Anchusa Tinctoria: Duer's Alkanet, Downy, leaves lanceolate, obtuse, staming shorter than the corollas .- This greatly resembles the Garden Alkanet, and is cultivated in the south of France for the deep purplish red colour of the roots. It gives a fine deep red to oils, wax, and all unctuous substances, as well as to spirit of wine. It grows about Montpellier, in Silesia, Spain, and Italy.

6. Anchusa Virginica: Virginian Alkanet. Flowers scattered, stem smooth. Seldom rises a foot high, and where it abounds, the ground seems covered with bright yellow flowers. Native of North America.

7. Anchusa Lanata : Woolly Alkanet. Leaves villose, calices shaggy, stamina longer than the corollas. Stem single, a foot high; corolla blue .- Found near Algiers.

8, Anchusa Sempervirens; Evergreen Alkanet. Leaves ovate, peduncles two-leaved, racemed. Corollas blue, stems at the sides of the crown of the root hispid .- Found wild in Spain and Italy, and in various parts of England, by roadsides, among rubbish, and from the joints of old walls. It flowers from May through a great part of the summer, and is perennial. Kine, horses, sheep, and goats, are said to eat it; and it has the same qualities as the first and second species.

9. Anchusa Barrelieri ; Barrelier's Alkanet. Leaves ovate lanceolate; stem erect, peduncles racemed, pointing one way. Root pale red; stein angular; corolla azure .- Found in Piedmont.

10. Anchusa Paniculata; Panicled Alkanet, or Bugloss. Leaves lanceolate, strigose, quite entire; panicle dichotomous divaricate; flowers peduncled; calices five-parted, with subulate segments .- It is biennial, flowers in May and June, and is a native of Madeira.

Ancistrum, a genus of the class Diandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leaved, turbinate, truncate, four-toothed; teeth cylindric, awned, erect, terminating in four reversed hooks. Corolla superior, one-petalled, "funnel-shaped, with a very short tube, and a spreading quadrifid border. The divisions nearly equal, obuse the length of the tube. Stamina: filaments fastened to the base of the tube, longer than the corolla, expilary; an thera roundisb. Pisitl: germen oblong; style filirorm, the length of the corolla; stigma penci shaped. Pericarp, none, but the calix, in the bottom of which is the fruit. Seed, single, oblong. ESENTIAL CHARAFER. Calix; four-leaved. Corolle, none. Stigma, many-parted. Drupe, dry, bispid, one-celled.—The species are,

 Ancistrum Decombens. Stems decumbent; peduncle scapeform, solitary; flowers in a globular beat; leaflets wedge-form, deeply serrate, hairy beneath; seed covered with the thickened calix.—It is a native of New Zealand, and remarkable for the yellow awns to the calix, resembling fox's nails.

2. Ancistrum Lucidum; Shining Ancistrum. Stems subdemerged; peduncles scape-form; spikes ovate; leaflets oblong, quite entire, acute, subfascicled.—It flowers in May and June, and is a native of the Falkland Isles.

3. Ancistrum Latebrosum; *Hairy Ancistrum*. Stems demerged; peduncles scape-form; spikes elongate; leaflets oblong, gashed, villose; fruits armed on every side.

Andrachne, a genus of the class Monœcia, order Gynandria .- GENERIC CHARACTER. Male. Perianth five-leaved, equal, marcescent. Corolla: petals five, cmarginate, slender, shorter than the calix. Nectary. Leaflets five, semibifid, herbaceous, one within each petal, and less than it. Stamina: filaments five, small, inserted into the rudiments of each style, antheræ simple, Female, Calix : perianth five-leaved, equal, permanent. Corolla: petals none. Nectary, as in the male. Pistil : germ superior, globose ; styles three, filiform, twoparted ; stigmas globose. Pericarp : capsule globose, trilobate, three-celled ; cells bivalved, the size of the calix; seeds in pairs, rounded on one side, triangular, and obtuse on the other. ESSENTIAL CHARACTER. Male. Calix, fiveleaved. Corolla five-petalled. Stamina five, inserted into the rudiment of the style. Female. Calix: five-leaved. Corolla none. Styles: three. Capsule three-celled. Seeds: two. -The plants of this genus are propagated in England by seeds sown upon a hot-bed in March ; they are very tender, ripening their seeds in August or September, and decaying soon after .---- The species are,

1. Andrachne Tclephoides. Procumbent and herbaceous. It grows wild in Italy and the Archipelago, and is a low trailing plant.

2. Andrachne Fruticosa. Erect, shrubby. Fourteen feet high, with small white flowers.—A native of the East Indies, China, and of Vera Cruz, in New Spain.

 Andrachne Arborea. Stem arborescent; leaves ovate, obtuse, hoary underneath.—This species has a strong woody stem rising more than twenty feet high, and is a native of Camprachy.

ANDRACHNE. Sce Arbutus.

Andrameda, a genus of the class Decandria, order Monogmia – GENRIC CHARACTER. Periamh, five-parted, acute, very small, coloured, permanent. Corolla monopetalos, campanulate, quinquefdi clefts, reflex. Stamina: filaments subulate, shorter than the corolla, and scareely fixed foit; anthere two-hored, nodding. Pietli germ roundish; style cylindric, longer than the stamina, permanent; stigna ohume. Pericarp: casput roundish, hive-cornered, fivecelled, five-valved, opening at the corners; partitions contrary. Seeds very many, roundish, shining. ESENTIAL CHARACTER. Colin five-parted. Corolla ovate or campa malte, quinquefd at the edge. Capsule superior, five-celled, with the partitions from the middle of the valves.-Most of the plants of this genus are hardy decidoous shrubs, delight-

ing in moist ground. They are propagated by their creeping roots, which putting up suckers at a distance, may be taken off withroots, and transplanted where they are designed to remain; for they will not bear frequent removals.—— The species are,

AND

1. Androineda Tetragona. Peduncles solitary, lateral; corollas bell-shaped; leaves opposite, imbricate, obtuse, revolute.—Grows in Siberia and Lapland.

2. Andromeda Hypnoides. Peduncles solitary, terminal, corollas bell-shaped; leaves crowded, awl-shaped.—This is found in Denmark, Siberia, and in the Lapland Alps, where it covers great tracts of ground, adorning them with its beautiful red flowers.

3. Andromeda Cerea. Peduncles axillary, two-leaved, one flowered; leaves alternate, ovate, serrate.-Native of Otaheite.

4. Andromeda Cœrulea. Peduncles aggregate; corollas ovate, leaves scattered, linear, obtuse, flat.—Found in Swcden, Denmark, Lapland, and Siberia.

5. Andromeda Mariaua; Maryland Andromeda. Peduncles aggregate, branched; corollas ovate-cylindrical; leaves oblong-ovate, quite entire, deciduous.—Native of North America. There are two varieties belonging to this species.

6. Andromeda Ferruginea; Rusty Andromeda. Peduncles aggregate, axillary; corolla subglobose; leaves elliptic, quite entire, beneath scaly-scariose.—Native of North America.

7. Audromeda Holifolia ; Marsh Andromeda. Peduacles aggregate ; corollas ovate ; Leaves alternate, lanceolate, rerolute.—This elegant little shrub is from six to eight inches and a foot high, with a red ealix and pink coloured corolla. It flowers about the end of May, and is a native of America, and of furf bogs in the northern countries of Europe. There are several varieties of this species.

8. Andromeda Bryantha. Flowers corymbed ; leaves elliptic ; stem prostrate.—It comes up in thick clumps, like wild thyme, on the rocks of Kamtschutka.

9. Andromeda Daboecia; Irish Whorts, or Cantabrian Heath, or Trailing Andromeda. Racemes pointing one way; Bowers quadrifd ovate; leaves alternate, lanceolate, revolute, —Grows only in the Irish bogs, and flowers in June and July.

10. Andromeda Droseroides; Clammy Andromeda. Racemes pointing one way; leaves linear, hairy, viscid.—A native of the Cape of Good Hope.

11. Andromeda Paniculata; *Panicled Andromeda*. Racemes terminal, panicled; corollas roundish; leaves ovate, rather entire.—Native of Virginia.

12. Andromeda Japonica. Racemes panicled, cylindric, bracted; leaves elliptic, reflex, serrate at the t p.—This is a tree flowering in December, and a native of Japan.

 Andromeda Arborea; Tree Andromeda, or Sorrel Tree, Racemes terminal; corollas rather downy; leaves elliptic, pointed, tooth-letted.—A shrub from twelve to twenty feet high, native of Virginia and Carolina.

14. Andromeda Racemosa; Branching, or Pennsylvania Andromeda. Racemes terminal, simple, bracted; corollas cylindric; leaves oblong lanceolate, serrate.—It flowers in July, and is a native of Pennsylvania.

15. Andromeda Axillaris; Notch-leaved Andromeda. Racemes axillary, simple; corollas oblong; leaves ovate, acnte, serrulate.—Native of Carolina, flowering from May to August.

16. Andromeda Coriacca; *Thick-leaved Andromeda*. Racemes axillary, simple; leaves ovate, very entire, very shining; brauchlets three-cornered.—Flowers in July and August: a native of North America.

17. Andromeda Acuminata; Acute-leaved Andromeda. Racemes axillary, simple; leaves ovate-lanceolate, acuminate, serrate.—A shrub fonr feet high, flowering in July and August: and a native of North America.

AND

18. Andromeda Calyculata; Colycled Andromeda. Peduncles solitary, axillary, pointing one way; bractes two; leaves oval; scaly, dotted, obsoletely serulate.—A low sbrub growing upon mossy land in Sweden, lugria, Siberia, and North America. There are several varieties of this species.

19. Andromeda Anastomozans. Racemes crowded, leafy; leaves ovate, slightly serrate, anastomosing underneath, and dotted.—Native of New Granada.

20. Andromeda Rupestris. Leaves oblong, alternate, serrulate.-Native of New Zealand.

21. Andromeda Salicifolia; Willow-leaved Andromeda. Racemes pointed one way, naked; corollas subcylindrical; leaves lanceolate, acute, quite entire.—Found in the island of Mauritius.

22. Andromeda Buxifolia; *Box-leaved Andromeda*. Racemes pointing one way, naked; corollas subcylindrical; leaves cordate, ovate, quite entire, with a little dagger point. —Native of the isle of Bourbon.

23. Andromeda Fasciculata. Peduncles aggregate; leaves alternate, ovate, lanceolate, obtuse, slightly crenulate, coriaceous.—A native of Jamaica.

24. Andromeda Jamaicensis. Peduncles aggregate; corollas ovate, transparent; leaves alternate, broad-lanceolate, obtuse, entire, beneath ash-coloured, membranaceous.—A native of Janaica.

25. Andromeda Octandra. Peduncles aggregate; corollas cylindric quadrifid; leaves alternate ovate-lanceolate, entire, membranaceous.—Also a native of Jamaica.

Andropogon ; a genus of the class Polygamia, order Monœcia.-GENERIC CHARACTER. Hermaphrodite flowers sessile. Calix; a glume, one-flowered, two-valved, oblong, obtuse, cartilaginous, awnless; the outer valve concave, flat, tish at the back, embracing the inner, which is narrower, with its edges. Corolla ; a two-valved glume, less, and more slender than the calix : outer valve smaller, frequently very small, within the inner valve of the calix, sharp or bifid at the end, in most of the species awned; awn terminating, or from the cleft to the glume, long with a bent joint and twisted at bottom; the inner valve lanceolate, doubled at the edges. Nectary : two-leaved ; leaflets thickish, diaphanous. Stamina: filaments three, capillary very tender: antheræ oblong, forked at both ends, incumbent. Pistil: germ oblong; styles two, capillary; stigmas oblong, feathered. Pericarp, none; glumes of the corolla and calix involving and inclosing the seed. Seed : solitary, oblong, covered ; armed with the awn of the corolla, which easily falls off. Male. Flowers peduncled, single or in pairs to each hermaphrodite. Calix, Corolla, and Stamina, as in the others, only that the corolla has no awn. ESSENTIAL CHARACTER. Hermaphrodite. Calix: glume one-flowered. Corolla: glume awned at the base. Stamina; three. Styles; two. Seeds; one. Male. Calix and Corolla the same. Stamina ; three .- Few of the species of this genus have been cultivated in England; the greater part of them would require a stove, since they are natives of the East and West Indies .---- The species are,

1. Andropogon Caricosum. Spike solitary, imbricate; seeds shaggy; awns naked contorted.—Native of Amboyna and Japan.

2. Andropogon Contortum. Spike solitary; male flowers awnless on the back of the spike; female flowers on the belly of it, twice as long as the males, with twisted approximating awns longer than the whole spike,—Native of the East Indies.

3. Andropogon Crinitum. Spike solitary, shaggy; awns naked, jointed, very long.—A native of Japan. 4. Andropogon Divaricatum Spike oblong; flowers woolly, remote, divaricate; awn flexuose, naked.-Native of Virginia.

5. Andropogon Gryllns. Peduncles of the panicle entirely simple, three-flowered; the hermaphrodite floscule sessile, awned, ciliate, bearded at the base. Culm three feet high. —It is a native of Piedmont and Switzerland.

6. Andropogon Saccharoides. Branches of the panicle single, florets in pairs, hermaphrodite, awned, sessile, the other awnless, pedicled, withering, pedicle and rachis woolly.— Naive of Jamaica.

 Andropogon Nutans. Panicle nodding; awns twisted, polished; glumes of the calix shaggy.—Found in Virginia and Jamaica.

8. Andropogon Ciliatum. Panicle nodding; onter calix many-flowered, ciliate; awns contorted, hairy.—It flowers in September, and is a native of Japan.

9. Andropogon Serratum. Panicle loose; one floscule, sessile, villose at the base; the other pedicled, with the pediclc villose, and shorter than the calix.—Native of Japan.

10. Andropogon Cotuliferum. Paniele spreading villose; awn twisted, naked; pedicles clubbed or swelling at topa and hollowed like a saucer or dish.—This grass is singular in having all the pedicles hollow at the top to receive the flower, It is found in Japan.

11. Andropogon Cymbarum. Panicles scattered; bractes boat-form; flowers transverse, awned, three-fold. Culms three feet high.—A native of the East Indies.

12. Andropogon Squarrosum. Pauicle crowded; glumes awl-shaped, rugged. Culms smooth, leaves rugged.—A native of Ceylon, where the natives make fans of it for its pleasant smell.

13. Andropogon Prostratum. Peduncles in five-flowered umbels without calicles, the hermaphrodite floscule awned. —Native of the East Indies.

14. Andropogon Fastigiatum. Spikes of the panicle solitary; peduncles elongate, subfastigiate; rachis woolly; floscules awned; male fertile.—Native of Jamaica.

15. Andropogon Alopeuroides. Pauicle loose; rachis woolly; a twisted awn to each floscule.--Native of Virginia and Jamaica.

16. Andropogon Distachyum. Spikes two, terminal. Culm undivided.—A foot high, said to grow wild in Switzerland.

17. Andropogon Schemanthus; Seret Ruch, or Camelz Hay. Spike of the panicle conjugate, oxic, oblong; rachis pubescent; floscules assaile with a twisted awa. This species is cultivated in the gardens of China and Cochin-china, where the inhabitants employ it to season their nerat. We receive it in bundles from Turkey. When in perfection, it has a warm, bitterish, and not unpleasant, taste, with an agreeable smell. It was once employed as a warm stomachic and remover of obstructions, but has been superseded by more common aromatics...H is a native of Araba and India.

 Andropogon Virginicum. Spikes of the panicle conjugate; peduncles simple; rachis woolly; floccules awnless, the male one wanting.— About six feet high, and a native of America.

19. Andropogon Bicorne; Fox-tail Grass. Spikes of the panicle conjugate; peduacles branching very nuch; rachis woolly; awn caducous, male floscule wanting.—This is found upon dry hills in the East Indies.

20. Andropogon Hirtum. Spikes of the panicle conjugate ; calices shaggy.—A native of Portugal, Italy, Sicily, and Smyrna.

21. Andropogon Insulare. Panicle loose, smooth; floscules double, awnless; one pedicle shorter; calices woolly. AND

flowers.

22. Andropogon Barbatum. Spikes digitate ; calices permanent; corollas ciliate. Culni a foot high .- Found in the East Indies.

23. Andropogon Pubescens. Spikes digitate; calices subtriflorous, outer petals awned; keel and edge of the hermaphrodite flower ciliate .- This species is perennial, flowers from July to September, and is a native of Jamaica.

24. Andropogon Nardus; Nard, or Spikenard. Branches of the panicle super-decompound, proliferous. This is said to be used as a spice among the Orientals : as brought to us, it is a congeries of small tough reddish-brown fibres. forming a bunch about the size of a finger, and is moderately warm and pungent, accompanied with a flavour which is not disagreeable. The whole plant has a strong aromatic odour; but both the smell and the virtues reside principally in the husky roots, or lower part of the stalks, which in chewing have a bitter, warm, biting taste, accompanied with a slight degree of that glow in the mouth which cardamoms occasion. The Hindoos call it Fever restrainer, from the virtues they attribute to it in that disease. They infuse about a drachm of it in half a pint of hot water, with a small quantity of black pepper. This serves for one dose, which they repeat three times a day. It is esteemed as a powerful medicine in all kinds of fevers, whether continued or intermittent; and a work attributed to Galen, informs us that a medicine, composed of this and some other aromatics, was found useful in long-protracted fevers, which are the cases in which modern practitioners employ medicines of this class. The ancients highly valued it as a luxury as well as a medicine, it being the favourite perfume which they used at their baths and feasts ; and, from the following words of Horace, it appears that it was so valuable, that as much of it as could be contained in a small box of precious stone, was considered as a sort of equivalent for a large vessel of wine; and, according to the custom of antiquity, a handsome quota for a guest to contribute towards an entertainment :-

" ----- Nardo vina merebere.

" Nardi parvus onyx eliciet cadum."

Hor, lib. 1v. car. xii. v. 16, 17.

" To purchase wine with spikenard dost thou ask? " A tiny box will bring a teeming cask."

25. Andropogon Muticum. Spikes digitate, mostly three ; floscules alternate, scssile, awnless. Culms seven inches high .- A native of the Cape of Good Hope.

26. Andropogon Ischæmum. Many digitate spikes ; floscules sessile, awned and awnless ; pedicles woolly .- This species is found upon mountains and hills, and in dry situations, in the southern parts of Europe.

27. Andropogon Fasciculatum; Many-spiked Andropogon. Spikes fascicled, very many, smooth ; calices twoflowered; valves acute, smooth, and even, the outer like petals and awned, the inner floscule barren .- Native of Jamaica, flowering from July to September,

28. Andropogon Polydactylon. Spikes fasciled, outer petals awued, those of the lower floscule ciliate, bearded .--Native of Jamaica.

29. Andropogon Glaucum, Panicle leafy ; involucels and calices two-flowered; calices of the sessile flowers threevalved, of the peduncled ones two-valved. Culm filiform, a foot high, leafy .- It is a native of the East Indies.

30. Andropogon Serratum. Spike simple, imbricate, with two rows of awned sessile flowers, and two of awnless pedicelled ones; calices one-valved .- Native of Bengal.

31. Andropogon Incurvatum. Spikes filiform, subdigitate, 9.

--- Native of Jamaica, and frequently deficient in the male | flowers twin, the female pedicelled and awned, the male sessile and awnless ; calices one-valved .- Found near rivers in Tranquebar.

AND

32. Andropogon Binatum. Spikes twin, woolly, one valve of the calices acuminate, the other truncate, three-toothed, the larger petal awned. Seen in the East Indies.

33. Andropogon Aciculatum. Panicle contracted, upright, peduncles three-flowered, male flowers two-pedicelled, acuminate, female sessile awned .- It is a native of barren places in the East Indies.

34. Andropogon Bladhii. Spikes about eight, hermaphrodite, floscule sessile, awned, neuter, peduncled, ciliate, awnless .- Native of China.

35. Andropogon Provinciale. Spikes fascicled, smooth ; floscules alternate, subsessile, directed one way, awned; root annual, culms a foot high, leafy, branched at the base .- A native of the south of France.

Androsace ; a genus of the class Pentandria, order Monogynia,-GENERIC CHARACTER. Calix: involucre, manyleaved, many-flowered, very small. Perianth onc-leafed. five-cornered, semiquinquefid, acute, erect, permanent. Corolla: monopetalous, salver-shaped; tube ovate, involved in the calix; border flat, five-parted; divisions ovate, oblong, obtuse, entire; throat beset with glands. Stamina : filaments very short, within the tube ; antheræ oblong, erect, included. Pistil: germen globose; style filiform, very short; stigma globose included. Pericarp : capsule globose, sitting on a flat calix, one-celled, opening into five parts at the top. Seeds : very many, roundish, gibbous on one side, flat on the other. Receptacle : erect, free. ESSENTIAL CHARACTER. an involucre to the umbel. Tube of the corolla ovate, with a glandulous mouth; capsule one-celled, globose .- These are low plants with small flowers, and only require to be kept free from weeds, and to be sown in a shady situation. They seldom appear the first year, but if permitted to scatter themselves, often succeed better than when sown. The annual sorts perish as soon as the seeds are ripe; but the others will live in an open border for several years .---- The species are,

1. Androsace Maxima; Oval-leaved Androsace. Perianths of the fruit very large. Root annual, slender. Flowers in April and the beginning of May, the seeds ripen in June, and the plants perish soon after .- It grows naturally among the corn in various parts of Germany and Italy.

2. Androsace Elongata; Cluster-flowered Androsace. Leaves lanceolate-toothed : fruiting umbel elongate : corollas shorter than the angular calix .- Native of Austria, near Vienna, growing up to the very suburbs. Its flowers, which are white, appear in May, and the seeds are perfected in June.

3. Androsace Septentrionalis; Tooth-leaved Androsace. Leaves lanceolate, toothed, smooth; periantlis angular, shorter than the corollas .- Native of mountainous situations on all parts of the Continent.

4. Androsace Villosa; Hairy Androsace, Leaves hairy; perianths shaggy. Tube of the corolla yellow, spreading into a white border, which at length becomes purple .--- Common in the Swiss Alps, in the mountains of Austria and Carniola, and the Pyrenees of Spain. Flowers in July and August.

5. Androsace Lactea; Grass-leaved Androsace. Leaves lanceolate-smooth; umbel many times larger than the invo-lucres. Root perennial, tube of the corolla yellow, with yellow glands at the throat; segments obcordate, large, emarginate, snow white .- Place of growth and time of flowering the same as the fourth, or preceding species.

6. Androsace Carnea; Awl-leaved Androsace. Leaves awl-shaped; smooth umbel, cqualling the involucres. Corollas flesh-coloured,-Native of the Alps and Pyrenees,

2 C

7. Androsace Filiformis. Leaves ovate-toothed, petioled ; rays of the umbel capillary; corollas exceeding the bellshaped calix. Corolla white .- A native of Siberia.

Androsæmum. See Hypericum.

Andryala; a genus of the class Cryptogamia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix : common, many-parted, short, rounded, villose; scales very many, subequal, subulate. Corolla: compound, imbricate, uniform: Corollula : hermaphrodite, numerous, equal. Each ligulate, linear, truncate, five-toothed. Stamina: filaments five, capillary, very short. Anthera : cylindrical, tubulose. Pistil: germ ovate. Style filiform, the length of the stamina. Stigmas two, reflex. Pericarp: none. Calix: converging globose. Seeds : solitary, ovate. Down capillary, the length of the calix. Receptacle: villose, flattish. ESSENTIAL CHA-RACTER. Receptacle: villose. Calix: many-parted, subequal, rounded. Down: simple, sessile .- Every species in this genus may be propagated from seeds ; those of the hardy sorts should be sown in spring, wherever they are to remain The second, third, fourth, and fifth species require the pro rection of a green-house, where they will flower all the summer, and frequently produce seeds fit for propagation. The perennials are increased by their creeping roots. These plants require no culture but occasional thinning and weeding.

1. Andryala Integrifolia; Hoary Andryala. Lower leaves rancinate; upper ovate-oblong, tomentose. The flowers are vellow, like sow-thistle .- It flowers in July, and seeds in September. There is a variety of this species; both are annuals. and natives of the southern parts of Europe.

2. Andryala Cheiranthifolia; Various-leaved Andryala. Leaves runcinate ; upper ones lanceolate, entire ; down glan duliferous. Perennial, three feet high, full of milk. Flowers yellow, scarce, nodding.-Native of the island of Madeira. 3. Andryala Pinnatifida; Pinnatifid-leaved Andryala.

Leaves tomentose, pinnatifid ; calices tomentose, hairy, hairs rather stiff .-- Flowers in July and August, and is a native of the Canary Islands, where, and in Madeira, it and two varietics of the same species are found.

4. Andrvala Crithmifolia: Samphire-leaved Andrvala. Leaves pinnate, linear, tomentose .- Native of Madeira.

5. Andryala Ragusina; Downy Andryala. Leaves lanceolate, undivided, denticulate, acute, tomentose, flowers solitary .- This plant has a yellow flower terminating every branch in June and July, and being very hoary, makes a pretty appearance among others whose leaves are green. It will not bear the open air, except in a dry soil and warm situation. It has been found in Spain, in Algiers, and at the Cape of Good Hope.

6. Andrvala Lanata: Woolly Andrvala. Leaves oblongovate, slightly toothed, woolly; peduncles branching .--- A biennial, with a large yellow flower, which appears in June, and is followed by the seeds in August .- Native of the south of Europe.

Anemone; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla: petals in two or three rows, three in a row, somewhat oblong. Stamina: filaments numerous, capillary, half the length of the corolla : antheræ twin, erect. Pistil : germina numerous in a head; styles acuminate; stigmas obtuse. Pericary; none. Receptacle globular or oblong, hollowed and dotted. Seeds very many, acuminate, retaining the style. ESSENTIAL CHARACTER. Calix: none. Petals: six or nine. Seeds : many .- Most plants of this genus are hardy perennials, and may be propagated both by seeds and roots .---- The species are,

late flower. Leaves three-lobed, quite entire,-This flower lies a year complete with all its parts within the bud, and is one of the most eminent beauties of the spring. The flowers appear plentifully in February and March; and the double sorts. which have fairer and more durable flowers than the single ones, make a beautiful appearance upon the borders of a pleasure garden. The single sorts produce seed annually, which should be sown in pots of light earth at the beginning of August, placed so as to have only the morning sun upon them till October, and then removed into the full sun for the winter season. In March they must be replaced in a shady situation, and frequently be watered in dry weather. In the following August they must be transplanted into a border of good fresh loamy earth, facing the east, where they must be placed six inches asunder each way, and have the earth pressed closely to their roots, otherwise the worms will draw them out of the ground. They will shew their flowers in the following spring; but it will be three years before they flower strongly. You may then venture to judge of their quality, and if you find any double flowers, or any of a different colour from the common sorts, they should be taken up and transplanted into the flower garden, where they should continue two years at least before they are taken up or parted; for where they are often removed and parted, they are very subject to die, but if undisturbed for many years, they thrive exceedingly, and produce large roots. The double flowers never produce seeds, and are therefore propagated by parting their roots in March, placing them where they can enjoy the morning sun, in a strong loamy soil. They will grow any where, except in very hot places, and are not injured by cold.-There are many varieties of this species, as 1. single and double blue. 2. Single and double red or peach-coloured. 3. Single and double white. 4. Single and double variegated red and white. 5. Single and double violet-coloured. 6. With striped leaves. This is an astringent plant, but is never-theless neglected. It is found wild in Sweden, Denmark, Switzerland, France, Spain, Italy, and other parts of Europe.

2. Anemone Patens: Woolly-leaved Anemone. Peduncles involucred, leaves digitate, multifid, seeds tailed. Corolla white.--A native of Siberia and Lower Lusatia. This and the following eight species are propagated by seeds in nearly the same manner as the Hepatica, No. 1. which see. They must not be exposed to the forenoon sun in the spring, and they require a loamy soil, as they are apt to decay in light ground during summer.

3. Anemone Sulphurea. Peduncle involucred ; leaves triply pinnate, hairy, flat, acutely gashed; seeds tailed.-See the preceding species.

4. Anemone Baldensis. Peduncle involucred : seeds tailed : leaves luternate, shaggy. The corolla has eight or ten white petals, shaggy on the outside and reddish .- It grows wild in Switzerland.

5. Anemone Vernalis. Peduncle involucred, leaves pinnate, flowers erect, seeds tailed. Flower red without, white within .- Found growing in woods and barren sands bordering upon the mountains of Sweden, Germany, and Switzerland.

6. Anemone Cernua. Peduncle involucred, leaves pinnate; flowers nodding ; seeds tailed .- Found flowering early in the spring near Jedo in the island of Japan.

7. Anemone Pulsatilla; Pasque flower. Peduncle involucred; petals straight; leaves lupinnate; seeds tailed. The corolla is a specious purple .- It grows wild in the dry soils of almost every country upon the European continent, and upon the chalky downs of England; as, Gog-magog hills, Barnacle-1. Anemone Hepatica; The Hepatica, which has subcalicu- heath, near Stamford, about Leadstone-hall, near Pontefract,

ANNONA. The Papaw

near Charlbury in Oxfordshire, Hexham, Bury, and Newmarket.—It flowers in April, and derives its Italian name, *putastilla*, from the downy seed being beaten about by the wind. There is one variety with double, and another with white flowers. It is an aericl plant, and will raise bisters; the distilled waters produce vomiting, and cannot therefore be safely given in disorders of the langs.

8. Anemone Pratensis; *Meadow Änemone*. Peduncle involucred; petals reflex at the tip; leaves bipinnate.—This species is common in barren stony fields of Oeland and Scania; also in Denmark, Germany, and Piedmont.

9. Anemone Alpina; Alpine Anemone. Peduncle involucred ; stem-leaves ternate, connate, super decompound, multifid; seeds shagey, tailed. Flower almost the size of the tuilb, white with a tinge of purple, and pubescent on the outside.—H grows wild on the Alps, Mount Jura, and in Austria.

 Anemone Apiifolia. Peduncle involucred; stem-leaves ternate, connate, super-decompound, multitud, very slender, extremely hairy underne-th. Stem simple, about a span high; flower large and of a sulpilureous colour, without any smell. — A native of the Leonitme Alps.

11. Anemone Coronaria : Narrow-leaved Garden Anemone. Radical leaves ternate, decompound; involucre leafy; with a leafy stem and tailed seeds .-- This species is a native of the Levant, particularly of the Archipelago, where the borders of the fields are covered with it of all colours ; but the flowers are single, and have been doubled by culture. Modern seedsmen reckon from one hundred and fifty to two hundred sorts of this flower, the principal colours of which are white, red, and purple, and in some these are curiously intermixed. The prevailing colour of English raised anemonies is red; though we have received from France great variety of blues and purples, which are exceedingly fine flowers, and make a beautiful variety, when intermixed with those of English growth. A double anemone, in order to be a fine one, should have a strong upright stem, about nine inches high; the flower two to three inches in diameter, the outer petals firm and horizontal, except a little turning up at the end ; while the smaller petals within these should lie gracefully over each other so as to form an elegant whole. The plain colours ought to be brilliant and striking, the variegated tints clear and distinct. Twelve months before you want to use it, mix a quantity of light sandy loam, or hazel mould, taken with the turf to the depth of ten inches, but no more ; add a third part of rotten cow-dung, and lay the whole in a heap, turning it once a mouth, taking out all the stones, and breaking every clod, but on no account sift it. After the year has expired, at the beginning of September prepare your bed by laying this earth six or eight inches above the surface of some ground, whereon you have previously laid the rakings of your heap to drain off the moisture, and upon that four or five inches deep of rotten neat's dung, putting your prepared earth upon the top. lf the soil be wet, lay the bed a little round to shoot off the water; but if dry, bring it nearly to a level. Plant the forward flowers at the latter end of September, those of a middle season any time in October, at the time of some gentle showers, and cover them from the winter frosts, by arching the beds over with hoops, and laying mats and garden cloths upon them. They will flower in the beginning of April, and contimue for three weeks or more, according to the mildness of the weather, and the care taken to screen them from the sun. The leaves will begin to decay in June, they must soon after be taken up, cleared from decayed stalks, washed clean, and spread upon a mat in a shady place until they are perfectly

min in bags. Observe, in planting the roots, to distribute the different colours, which will greatly increase their beautiful appearance by the contrast with each other. No good florist, however, who has garden-room, should omit to sow the seeds: he should provide himself with a quantity of good single or poppy anemones of the best colours, having more leaves than common, with other good qualities, and plant them early in the beginning of August, either in pots, beds, or tubs of light earth, taking care to rub the seeds between his hands with a slight mixture of dry sand, to separate and prevent them from adhering together; and after sowing them as equally as possible over the bed, taking a strong hair brush. and sweeping it gently over the whole bed, observing not to brush off the seeds, by which he will leave no lumps, and make the distribution complete. Light earth, to the depth of one quarter of an inch, may then be sifted over the seeds; and mats laid over the whole, if the weather be hot and dry. They may be occasionally but sparingly watered, and should always be exposed to gentle showers. In ten weeks the plants will appear; they will be very liable to suffer, if not protected from the frosts of the first winter, and from too much wet, together with the piercing winds of February and March : a low reed-fence on the north and east sides of the bed will be very useful. As the spring advances, they may be thinned if necessary; and as soon as their green leaves decay, you must sift the earth of the bed with a very fine sieve, till you have taken out all the roots you can find; and then level the bed, and let it remain till the next year, when you will again find a plentiful crop from those roots which will unavoidably have escaped you in the sifting. The before-mentioned young roots must be cleaned and dried, as above prescribed for the older plants; but when replanted, the former should be put into the ground three weeks before the latter, that they may gather strength and flower abundantly in the succeeding year. The single or poppy anemones, in favourable seasons and warm situations, will flower through most part of the winter and spring, and from their peculiar beauty well deserve admittance into every flower-garden. They need little culture; it will be often enough to take them up every other year, and when they are taken up, they should be replanted very early in the autumn, otherwise they will not flower till the spring. The seeds of these flowers must be gathered daily as they ripen, otherwise they will soon be dispersed by the winds .--This species was cultivated in France, long before it was known in England or Holland.

12. Anemone Hortensis: Broad-leared Garden Amenone. Leares digitate; seeds woolly; leafy stem and tailed seeds, —This was formerly called hard-leared anemone by the Walloons, who imported the roots. It is found wild with single flowers in Italy, Provence, and Germany. It was discovered with red and purple flowers near the Rhine, and in many parts of Italy and Switzerland, and also in Austria. There are many varieties of this species, to enumerate which would be as tedious as useless. For the culture and propagation of this species, see the preceding species, No. 11. the detail respecting which, is equally applicable to the proper management of both.

 Anemone Palmata. Leaves heart-shaped, sublobate; calix six-leaved, coloured. Stem leafy; seeds tailed. The petals are yellow without and orange within.—Found near the Tagus in Portugal.

14. Anemone Sibirica. Stem one-flowered ; involucre, leafy, obtuse. Flower naked ; seeds tailless .-- Found in Siberia.

be taken up, cleared from decayed statks, washed clean, and spread upon a mat in a shady place until they are perfectly more. Potuncle maked: seeds rounded, shagey, awnles, dired, and should then be hume up out of the reach of ver- Flower naked; seeds rounded, sha a simple degance, resembling the snowdrop, which forms a pleasing contrast with the more showy flowers of the garden. It has large while flowers, which appear in May, and produce seeds in June, standing on the tops of the flower-stalks, which sometimes grow two together, but generally single.—It as native of many parts of Germany, and has been seen in Sweden, Alsace, and Siberia.

16. Anemone Fragifera. Peduncle naked; seeds roundish, woolly, awnless, tailless; gashes of the leaves acute lanceolate, flowers naked. Without smell; solitary, deciduous, hirsute; pale purple flowers, and native of Carinthia.

17. Anemone Virginiana; Virginian Aneuone. Peduncles alternate, very long; fuit cylindric; seeds shaggy, awnless. Flower naked; seed tailless. Flowers green like the calix, appearing in May and June. It produces abundance of seeds, and may be readily propagated that way.

18. Ånemone Decapetala; Ten petalled Anemone. Stem one-flowered; flower ten-petalled; leaves ternate, lobate, radical. Flower naked; seed tailless. Corolla small and white, with ten petals.—It is found in Brazil.

19. Anemone Pennsylvanica; *Pennsylvanian Anemone*. Stem dichotomous; leaves sessile; stem clasping, the lowest ternate, trifid, gashed. Flower naked; seed tailless.—Native of Canada and Pennsylvania.

20, Anemone Dichotona. Stem dichotomous; leaves sessile, all opposite; stem clasping, trifid, gashed. Flower naked; seed tailless. Root creeping far and wide. Leaves opposite, horizontal. Corollas purplish underneath. Stem a foot high.—A native of Canada and Siberia. 21. Anemone Trifolia. Leaves ternate, ovate, entire, ser-

21. Anemone Trifolia. Leaves ternate, ovate, entire, serrate; stem one-flowered, flower naked; seed tailless. Corolla six-petalled and white.—Flowers at the end of April, and grows in the woods of France, Carniola, and Siberia.

22. Anemone Quinquefolia. Leaves quinate, oval, serrate; stem one-flowered; flower naked; seed tailless.—Native of Virginia and Canada.

23. Anemone Nemerosa; Wood Anemone. Seeds acute, tailless; leaflets gashed; stem one-flowered; flower naked. Root perennial, creeping; height of the plant ten inches; the usual colour of the flower white. It grows in woods among bushes, in hedges, and in pastures of most parts of Europe. It almost covers the ground with its flowers in some of the woods of England during March, April, and May. In fine clear weather the blossoms are expanded, and become so erect as to face the sun : but in wet weather, and in the evening, they are closed and hang down. As the paper in which dried specimens of this plant had been preserved was stained brown, it might probably be useful as a dye. It is acrid, and slightly poisonous. Linneus informs us that cattle brought from open to woody pastures, and eating of this plant, have afterwards had the bloody flux, and voided bloody urine. When the flowers become double, the wood anemone is cultivated by the gardeners; and were the same pains taken with it as with the foreign anemones, it would in all probability soon stand higher in the estimation of the florist. The roots may be taken up when the leaves decay, and transplanted into wildernesses, where they will greatly increase if not disturbed; and in the spring, before the leafing of the trees, the ground will be covered with their flowers. This plant is also called the Wind Flower. The juice snuffed up the nose, or the root held in the mouth, excites a discharge of cold watery humours from the head and parts adjacent. The leaves bruised, and applied to ulcers and running sores, cleanse, and dispose them to heal. Some authors recommend it in suppressions of the menses; but it is too acrid in its nature for internal use, and might be fatal in unskilful hands.

24. Anemone Appenina; Mountain Wood Ammone. Seeds acute, tailless; leaflets gabaid; petals hanceolate, numerous; flowers naked. This flowers at the same time as the Wood Amemone (No. 23) and makes as fine variety when intermixed with it. Double flowers of both sorts have been obtained from seeds. It may be propagated by offsets from the root, and will flourish in almost any situation. Flower upright, of a pale blue colour and sweet smell; petals oblong, from twelve to fifteen, disposed in three rows.—Native of the Appenines near Rome, and of Wimbledon, Harrowon-the-Hill, a wood by Luton Boe, Bedfordshire, and near Berkhampsteed in Hertfordshire, England.

25. Anemone Ranunculoides; Yellow Wood Anemone, Seeds acute, tailless; leaflets gashed; petals roundish; stem mostly one-flowered; flower naked. This flower has a yellow corolla, and grows wild in almost all parts of the European continent. In Great Britain it has been found near King's Langley in Herts, and Wrotham in Kent.

26. Anemone Narcissiflora; Narcissus flowered Anemone, Flowers umbelled, maked; seeds oval, depressed, maked, tailless. Flowers white within, reddish without, forming a salver-shaped corolla. It grows wild on the mountains of Austria, Switzerland, and Siberia.

27. Anemone Fasciculata. Flowers umbelled, collected, naked; leaves multifid; seeds tailless.—Found in the mountains near the Baikal lake; first observed in the Levant.

28. Anemone Thalictroides; Meadow Rue-leaved Anemone. Flowers umbelled, naked; stem leaves simple, verticillate; radical leaves, biternate; seeds tailless. The corolla is white, and it is a wild native of Virginia and Canada.

Anethum : a genus of the class Pentandria, order Digynia. —GENERIC CHARACTER. Colix : umbel universal and partial, manifold. Involuce neither universal nor partial. Perianth proper, obsolete. Corolla: universal, uniform; floscules all fertile: proper petials five, involute, entire, very short. Stamina: filaments capillary: antherae roundish. Pisiti: germ inferior. Styles approximating, obsolete. Stigmas obtuse. Pericarp: none. Fruit suborate, compressed, striated, bipartile. Sceds: two; suborate, margined, comvex and striated on one side, flat on the other. ESSENTIAL CHARACTER. Fruit: suborate, compressed, striated. Petals involuted entire.—The species are.

1. Anethum Graveolens; Common Dill. Fruit compressed. Dill differs from fennel, which it otherwise greatly resembles, in having an annual root, and a smaller and lower stem: it has a peculiarly strong and aromatic smell. The bruised herb is anadoyne and resolvent ; and the seeds being aromatic, and containing an ethereal oil, are useful in flatulencies, for which purpose they rub the bellies of children with the oil prepared by infusion; the essential oil is also good for the colic. The seeds are warm to the taste, and have a strong, disagreeable, aromatic smell. Given in doses of a drachm, they disperse wind in the stomach, help digestion, and cure the colic. They likewise operate by urine, and are said to be an infallible cure for the chincough, but probably without foundation. Culpeper says, that the seeds being roasted or fried, and used in oils or plaisters, dissolve imposthumes, and dry up all moist ulcers. The decoction, whether of herb or seed, which must be first bruised, he also prescribes as "a gallant expeller of wind, and provoker of the terms." A distilled water, drawn off to the quantity of a gallon from a pound of seeds, was ordered in the London Pharmacopoeia ; and occasionally made the basis of carminative draughts and juleps, having a more agreeable flavour than the seeds themselves. Together with this water arises a considerable quantity of essential oil, which is given from one 5

100

101

to three or four drops, or more, as a carminative, and in | There is the same difference in the preparations from them : hiccoughs .- This plant is propagated by sowing the seeds soon after they are ripe in autumn, in a light soil, where they are to remain, allowing them eight or ten inches room to grow. When they appear, hoe them in the same manner as onions, leaving them every way eight or ten inches asunder, and clearing them from weeds. When the seeds begin to form, cut up those intended to be put into the pickle for cucnmbers, leaving those that are for seed till ripe, when you must cut, and spread them upon a cloth to dry, and then beat out for use. If the seeds be suffered to fall upon the ground, the plants will appear in the spring without any further care .- It is an annual, growing wild among the corn in Spain and Portugal, and also upon the coast of Italy.

2. Anethum Segetum. Three stem-leaves, fruits oval. Corolla flosculous vellow .- An annual plant, and a native of Portugal.

3. Anethum Faniculum; Fennel, or Finckle; of which there are three varieties, viz.

Fœniculum Vulgare, or Common Fennel;

Fœniculum Dulce, or Sweet Fennel;

Faniculum Azoricum: Azorian Fennel, or Finochio. Fruits of both the species and varieties ovate. The first, or Common Fennel, flowers in July, and ripens seed in autumn, and though not a native of England, but of Germany, Spain, Italy, Madeira, and China, has sown itself so plentifully in many places where it has been introduced, that it is now become common upon our chalky cliffs, near Gravesend, and other parts of Kent, in Sussex, near Marazion in Cornwall, and inland near Nottingham castle, Spetchly in Worcestershire, and Burwell in Cambridgeshire. The Sweet Fennel seeds are imported from Germany and Italy, and are by some preferred to the common sort, being much sweeter. The best time to sow the seeds of these two is soon after they are ripe; the plants will come up in autumn or the following spring, and as they will grow in any situation, only require to be thinned when too close, and kept free from weeds. The third sort, or Finochio, though a favourite salad herb of Italy, is not much liked, and therefore little cultivated in England, where it seldom survives the cold of winter. It has very short stalks, swelling just above the surface of the ground, to four or five inches broad and two inches thick, which being the tender part, is eaten when blanched with oil, vinegar, and pepper, as a cold salad. The seeds are narrow. crooked, and of a bright yellow colour, with a strong smell like aniseed, and a very sweet taste. They should be sown in light rich earth early in March, and will be fit for use in July. Sow the seeds about two inches apart, in shallow drills eighteen inches asunder. As soon as the plants appear, remove the weeds with a hoe, and thin them occasionally until they are at least seven or eight inches asunder. When the plants begin to swell in the stem above the surface of the ground, they must be earthed up like celery to blanch, which will make them very crisp and tender. You may sow successive crops until July, after which it will be too late for them to come to perfection. In case of sharp frosts in autumn, they may be covered with peas-haulm, which will screen them from the cold, and preserve them for winter use. A small bed will suffice for a moderate family, but it will require a bed twenty feet long and four broad to supply a large one. The tender buds of fennel are eaten in salads, and the boiled leaves as a sauce to fish, and also raw with pickled fish. In Spain, they are put up with olives and pickled pork. The seeds of Common Fennel are warmer than those of the Sweet Fennel, but less sweet, and not of so grateful a flavour. 9.

the spirituous tincture of sweet fennel is yellowish; of this greenish. The distilled leaves impregnate water with a grateful flavour, and yield a considerable portion of essential oil. An extract made from them by rectified spirit is by no means a despicable aromatic. The essential oil procured from the seeds expels wind, and increases the urinary evacuation, but is not of a heating nature. The roots taken up early in the spring have a pleasant sweetish taste, with a slight aromatic warmth, and are ranked among aperient roots. Hill recommends a decoction of it made with common water, when given in large quantities, as operating by urine, and relieving the gravel and jaundice. Meyrick says a strong decoction of the root is a good medicine in the jaundice, dropsy, and all other disorders arising from obstructions of the viscera. The seeds reduced to powder, and taken every morning fasting. are said to preserve the sight from decaying, and to restore it when impaired. A decoction of them is good in the small pox and measles; it likewise relieves shortness of breath, and other complaints of the lungs, and promotes urine and the menses. The seeds applied externally in poultices, are found to be useful in dispersing hard swellings in any part of the body. Culpeper remarks, that fennel is boiled with fish to correct the phlegmatic tendency of that kind of food, though few persons know why they use it, as it is a very ancient custom. He recommends the leaves or seeds to be boiled in barley-water, and drank, as good to increase the quantity and improve the quality of nurses' milk ; when boiled in water for the hiccough, and for heat of the stomach and loathing, and boiled in wine as an antidote for those who have eaten poisonous herbs or mushrooms. A pound of sweet fennel seeds impregnates a gallon of water strongly with their flavour, in distillation. A great quantity of mild, sweetish, and yellowish essential oil, like that of aniseeds, floats on the surface of the water, and like it also congeals by a slight cold into a white mass like butter. These seeds also contain a considerable quantity of expressed oil, which is extracted by digestion in rectified spirit, along with the aromatic matter of the fennel. but rises to the surface upon inspissating the filtered functure : the concentrated extract retains much the greatest part of both taste and smell. These seeds of the sweet fennel, according to Hill, are less acrid, and therefore more proper for internal use than those of the common fennel, and are the only part fit for use. They are excellent for the colic, and, when externally applied in poultices, to disperse hard swellings,

Angelica ; a genus of the class Pentandria, order Digynia, -GENERIC CHARACTER. Calix: universal; nmbel manifold, roundish; partial; when flowering exactly globular. Universal involucre three or five-leaved, small : partial eightleaved, small. Proper perianth five-toothed, scarcely observable. Corolla: universal uniform; floscules all fertile; partial petals five, equal, lanceolate, flattish, incurved, caducous. Stamina : filaments simple, longer than the corolla ; antheræ simple. Pistil: germ inferior ; styles reflex ; stigmas obtuse. Pericarp : none. Fruit roundish, angular, solid, bipartite. Seeds : two, ovate ; flat on one side and margined ; convex on the other, scored with three lines. ESSENTIAL CHARACTER. Fruit roundish, angular, solid, with reflex styles. Corollas equal, with petals bent inwards .- Ever species of this genus may be increased by seed; they are all hardy biennial or perennial plants, viz.

1. Angelica Archangelica; Garden Angelica. The odd leaflet of the leaves lobed .- The stalks of this plant were formerly blanched and eaten as celery. The Norwegians make bread of the roots, and the young shoots are greatly esteemed 2 D

by the Laplanders. In gardens near London, through which small streams of water run, great quantities of this plant are propagated, the tender stalks of which are cut in May for the confectioners, who have a great demand for it as a sweetmeat. The roots form one of the principal aromatics of European growth, though little regarded at present; the other parts of the plant have the same flavour, but their active principles are far more perishable. Though the seeds, which come nearest to the roots, can scarcely be kept till the spring after they are gathered, they are the only part of the plaut used, and that only in compound spirit of aniseed. Every part of this plant is full of medicinal virtue, but the roots and seeds possess the highest degree. They are cordial, sudorific, and stomachic, and of great efficacy in pestilential disorders, and contagions of every kind, in all cold flatulent complaints, and seldom fail of removing the ague, if taken three or four times repeatedly on the approach of the fit. A scruple of the dried root in powder, or ten grains of the seed, is a moderate dose. The roots and stalks are sometimes candied, and are then more palatable, and equally efficacious.-Of this plant Hill says, Every part is fragrant, when bruised, and every part is used in medicine. The root is long and large; that of our own growth is used fresh, but the fine fragrant dried roots are brought from Spain. The whole plant possesses the same virtues, and is cordial and soporific ; it has always been famous against pestilential and contagious diseases. The root, the stalks candied, the seeds bruised, or the water distilled from the leaves, may be used; but the seeds are the most powerful, and they are also an ingredient in many compositions. Culpeper prescribes also a water distilled in a glass from the root steeped in wine, as more effectual than the water of the leaves, and in two or three spoonfuls at a time, to ease all paius produced by cold or wind, if the body be not costive; and taken with some of the root in powder, for the pleurisy and all other diseases of the lungs and breast; such as coughs, phthisic, and shortness of breath, for which he remarks, that a syrup of the stalks will be found equally good. This plant flowers with us from June till August, and delights in a moist soil. To propagate it, sow the seeds soon after they are ripe; when they are six inches high, transplant them three feet asunder upon the sides of ditches or pools of water, where they will not fail to thrive. The second year they will flower, and if you wish to continue the root, they must be cut down in May, which when repeated will continue them for three or four years; but if they come to seed they will perish soon after. Where they are cultivated for the seeds, there should be fresh plantations every year .- It is a native of the northern parts of Europe.

2. Angelica Sylvestris; Wild Angelica. Leaflets equal, ovate-lanceolate, serrate. Has a smooth stem six inches high; it is perennial, and very common in moist woods and hedges by the sides of rivers, flowering in July and August. -This herb yields a good yellow dye, and may be safely used as a medicine instead of the garden angelica; but as it only possesses its virtues in an inferior degree, it has been long neglected.

3. Angelica Verticillaris. Leaves very much divaricate; leaflets ovate, searate; stem verticilled with peduncles: six feet high; flowers green .- A native of Italy and Silesia.

4. Angelica Atropurpurea; Purple Angelica. The outermost pair of leaves coadjoined; the terminal leaf petioled. Stem six feet high .- A native of North America.

5. Angelica Lucida; Shining Angelica. Leaflets equal, ovate, gash-serrate. Stem from one to two feet high; petals and of a hot aromatic flavour .- It flowers in June, ripens its seeds in August, and is a native of Canada.

6. Angelica Ražulii. Leaves bipinnate; leaflets lanceolate. serrate, decurrent. Stem three feet high; corollas a bright purple before unfolded, afterwards white .- Native of the Appenines and Piedmontese mountains,

Angelica Tree. See Aralia.

Anguina. See Trichosanthes,

Anguria ; a genus of the class Monœcia, order Diandria. -GENERIC CHARACTER. Male flowers. Calix: monophyllous, quinquefid, swelling at the base; divisions lanceolate, short. Corolla: pentapetalous, spreading, growing to the border of the calix. Stamina : filaments two, opposite, inserted into the calix; anther creeping up and down. Female flowers. Calix and Corolla as in the Male. Stamina: filament as in the male, but without antheræ. Pistil: germen inferior, oblong; style semibifid; stigmas bifid, acute, Pericarp: a pome oblong, quadrangular, trilocular. Seeds: very many, oval compressed, nestling. ESSENTIAL CHA-RACTER. Male. Calix five cleft. Corolla: five-petalled. Female: Calix and Corolla same as the Male. Pome inferior, two-celled, many-seeded .---- The species are,

1. Auguria Trilobata. Leaves three-lobed .- This plant has a very shining appearance, and is a native of Carthagena in South America, flowering there in June.

2. Auguria Pedata. Leaves pedate, serrate. This is a perennial plant, which climbs trees to the height of twenty feet, by means of tendrils. The flowers, which are destitute of smell, and have orange-coloured petals, appear in December,

and the fruit ripens in September.—Native of St. Domingo. 3. Anguria Trifoliata. Leaves ternate quite entire.—Native of St. Domingo,

Aniseed Tree. See Illicium.

Anisum, or Anise. See Pimpinella.

Annona; a genus of the class Polyandria, order Polygynia .- GENERIC CHARACTER. Calix: perianth three-leaved. small; leaflets cordate, concave, acuminate. Corolla: petals six, cordate, sessile; the three alternate, interior ones less. Stamina : filaments scarcely any : antheræ very numerous, placed on the receptacle. Pistil: germen roundish. placed on a roundish receptacle; styles none; stigmas obtuse, numerous, covering the whole germen. Pericarp a berry very large, roundish, clothed with a scaly bark, onecelled. Seeds: very many, hard, ovate, oblong, placed in a ring, nestling. ESSENTIAL CHARACTER. Calix: threeleaved. Petals: six. Berry many-seeded, roundish with a scaly bark .- These plants require a bark stove and careful management, plenty of air in warm weather, and to remain constantly in the tan-bed. They have flowered, but never borne fruit in England, where they are only preserved for the beauty of their leaves. They have been known to reach the height of twenty feet, but seldom exceed twelve or fourteen. The earth in which they are planted should be light and rich, and the tan-bed frequently turned over and refreshed, keeping the stove in which these plants are placed at the Ananas heat, as marked upon the botanical thermometers. The fruits of this genus are highly esteemed by the natives of the countries where they naturally grow, for their cooling and wholesome qualities, and are frequently given to sick people.---- The species are,

1. Annona Muricata. Rough-fruited Custard Apple, or Sour Sop. Leaves oval-lanceolate, smooth, acute; fruits muricate; petals ovate, the interior ones obtuse, shorter. This tree is twelve, fourteen, or twenty feet high. Flowers coriaceous, yellow .- It is common in every savanna of Jaof a dirty white or very pale yellow colour. Seeds brown, maica, flowering in the spring. The large succulent fruit is agreeable to new comers, and over-heated habits; but so commonly used, especially by the negroes, that the better sort of people refuse it for its vulgarity. The smell and taste of the fruit, flower, and whole plant, very much resemble those of black currants.

2. Annona Tripetala; Broad-leaved Custard Apple. Leaves ovate, acute, pubescent beneath; flowers three-petalled; petals lanceolate, coriaceous, tomentose .- A large tree of South America, producing a fruit highly esteemed by the Peruvians.

3. Annona Squamosa; Undulated Custard Apple, or Sweet Sop. Leaves oblong-acute, smooth; fruits obtusely scaled : outer petals lanccolate, inner ones minute .- A small tree of eight feet high; flowers green without and whitish within. A native of both Indies, where the fruit, which is sweet, is eaten.

4. Annona Reticulata; Netted Custard Apple, Leaves oblong, lanceolate, acute, smooth; fruits ovate; reticulateareolate; outer petals lanceolate, inner minute,-This species attains to the height of twenty-five feet or more. A native of both Indies, where some say the fruit is much esteemed, and others that it is never caten.

5. Annona Hexapetala; Long-leaved Custard Apple. Leaves elliptic-oblong, acute, smooth; petals spatulate equal, acute .- Native of China, and cultivated in the East Indies.

6. Annona Palustris; Shining-leaved Custard Apple. Leaves oblong, rather obtuse, smooth ; fruits areolate. This tree seldom exceeds six feet high : grows wild in soft marshy places of Jamaica-Its wood is so very soft, even after it is dried, that it is frequently used instead of corks, and is hence universally called Cork-wood by the natives, who also call the fruit the Alligator Apple, which, though sweet-scented aud not ill-tasted, is not eaten, because it is said to be a strong narcotic.

7. Annona Triloba; Trifid-fruited Custard Apple. Leaves elliptic, acute, smooth; flowers pendulous, campanulate; calices ovate ; petals many, oval. Every part of this tree has a rank, if not a fetid smell; and the fruit is relished by few except negroes. It grows in a fat soil, and low shady swamps, -It is a native of the Bahama islands, also of Carolina, Maryland, and Virginia; and the seeds are frequently brought to England by the title of Papaw Tree. It will thrive in warm situations in the open air of this country.

8. Annona Glabra; Smooth Custard Apple. Leaves lanceolate, ovate; fruits connoid, smooth. This tree attains the height of sixteen feet, and bears a very sweet eatable fruit, which is the food of guanas and other animals .- Native of North America.

9. Annona Asiatica ; Asiatic Custard Apple. Leaves lanceolate, smooth, shining, marked with lines .- Native of the East Indies and of China, where it is cultivated; but the fruit, which is an oblong conical berry, filled with a whitish, sweet, eatable pulp, is inferior in flavour to the third sort.

10. Annona Africana; African Custard Apple. Leaves lanceolate, pubescent .- Notwithstanding its name Africana, it is said to be a native of America.

Anolta. See Bixa.

Anserina. Sce Potentilla.

Anteuphorbium. See Cacalia.

Anthemis; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER.. Calix: common hemispherical; scales lincar, subequal. Corolla: compound radiate ; corollules hermaphrodite, tubular, numerous, in a convex disk : females more than five in the ray. Pro-

of the female, ligulate, lanceolate, sometimes three-toothed. Stamina, in the hermaphrodites : filaments five, capillary, very short : anthera cylindrical tubular. Pistil, in the hermaphrodites : germen oblong ; style filiform, the length of the stamina; stigmas two, reflex in the females, germen oblong; style filiform, the length of the hermaphrodite; stigmas two, revolute. Pericarp : none. Calix unchanged. Seeds: solitary, oblong: down margined, or none. Receptacle : chaffy, convex, or conical. ESSENTIAL CHARACTER. Receptacle : chaffy. Down : none. Calix : hemispherical, nearly equal. Floscules of the ray more than five .- Some plants of this genus are annuals, others perennials, and all, except the fifteenth and nineteenth species, are hardy enough to bear the open air. They are propagated by seeds sown upon poor land in the spring : they flower in July, and only require to be weeded and kept well asunder, as they are generally bushy, and require room .---- The species are,

* With a discolour, or white Ray.

1. Anthemis Cota. Chaffs of the flowers rigid, pungent: the largest flower of this genus .- An annual; native of ploughed fields in Italy and Spain.

2. Anthemis Altissima; Tall Chamomile. Erect with leaves pinnate; the bases of the pinnas rough, with a reflex toothlet. Annual; growing wild in the south of France, Spain, and Italy.

3. Anthemis Maritima; Sea Chamomile. Leaves pinnate, toothletted, fleshy, naked, dotted; stcm prostrate; calices rather tomentose. The flowers have the smell of feverfew: they flourish in July and August .- It grows wild about Montpellier, in Italy, and in England.

4. Anthemis Tomentosa; Downy Chamomile. Leaves pinnatifid, obtuse, flat, peduncles shaggy, leafy; calices tomentose .- Native of the coasts of Greece, Italy, and France.

5. Anthemis Mixta; Simple-leaved Chamomile. Leaves simple, jagged, toothed .- An annual, growing wild in Italy and France.

6. Anthemis Alpina; Alpine Chamomile. Leaves toothpinnate, quite entire, lincar; stem villose, one-flowered; petals ovate, chaffs sphacelate .- Percnnial, native of Italy.

7. Anthemis Chia; Cut-leaved Chamomile. Leaves pinnatifid, jagged; peduncles naked, subvillose .--- Seen in the isle of Chios.

8. Anthemis Nobilis: Common, or Sweet Chamomile, Leaves pinnate-compound, linear, acute, subvillose .- It abounds in most of the dry commons of Surry, aud in Cornwall, flowering in July and August .- The leaves and flowers have a strong but not ungrateful smell, with a very bitter nauseous taste, especially the flowers, which are more aromatic than the leaves. If they be carefully dried, the taste and smell will not diminish but improve. The single flowers only should be kept, because the white florets of the ray, which are multiplied in the double flowers, are almost tasteless ; and yet double flowers are the only sort ever found in the shops! An infusion of the flowers is often used as a stomachic and antispasmodic, but in large quantities it excites vomiting. Large doses of the powdered flowers have cured agues, even where the bark has failed. Both leaves and flowers are very useful in antiseptic fomentations and poultices. From their antispasmodic powers, they are frequently found to relieve pain, whether internally or externally applied. The decoction is used for clysters, as well as in fomentations, which, with poultices made of the flowers, often prove beneficial in putrid sore throats. Independently of its general virtues as a bitter, it is good in different kinds of the colic, particularly in such as arise in flatulencies or cold. It per of the hermaphrodite funnel-shaped, five toothed, crect : is also recommended in hysterical and hypochondriacal disorders, in the gravel, and intermittent fevers. The dose of exciting sneezing .-- It is a native of the Levant, and southern the dried flowers in substance is from ten or twelve grains to half a drachm, or more ; in tea, two or three drachms. The expressed juice is an excellent remedy for the strangury, asthma, jaundice, and dropsy; and the flowers are much used in conjunction with other ingredients of a similar nature to promote perspiration. Culpeper says, that bathing with a decoction of chamomile removes weariness and eases pain, to whatever part of the body it is applied; and that the flowers boiled in posset-drinks provokes sweating, and bringeth down women's courses. Syrup of the juice of chamomile, with the flowers in white wine, he also recommends for the jaundice and dropsy, and a decoction of the flowers in lee, as good to wash the head in disorders of the brain. This plant may be increased by planting slips a foot asunder in the spring; as it is hardy, it will soon cover the ground, and the gardener would do well to prefer the single-flowered kind for the reasons above given.

9. Anthemis Arvensis; Corn Chamomile. Receptacles conic; chaffs bristle-shaped; seeds crown-margined; leaves thinly downed .--- It flowers in June and July, and is a common weed amongst corn in most parts of Europe.

10. Anthemis Austriaca; Austrian Chamomile. Receptacles conic; chaffs oblong, mucronate; seeds naked; leaves bipinnate, woolly-villose, Root annual. It has a bitter taste, flowers the whole summer, and is found by way sides, in corn-fields, and sometimes covering fallow grounds in Austria.

11. Anthemis Cotula; Stinking Chamomile, or Mayweed. Maithes, Maithen, or Mather. Receptacles conic : chaffs bristly; seeds naked; leaves smooth. An annual plant, the whole of which is so extremely fetid as to blister the skin of those who handle it. Loeselius avers, that it drives away fleas, is offensive to bees, and is given as a medicine to sheep troubled with the asthma. An infusion of the root is good in hysteric disorders, and promotes the menses. The herb boiled till it becomes soft, and then applied by way of poultice, is an excellent thing for the piles. It has been little used as a medicine; but decoctions of it are said to have been successfully used as a bath or fomentation for the piles and hysteric suffocations. Mr. Ray says, it has been beneficially administered in scrophulous cases. It is a common weed, flowering from May to August, and abounding by way-sides, on dunghills, and in corn-fields; and farmers are little aware of the vast fertility of this and some other weeds, which they first suffer to exhaust their dunghills, and afterwards to be distributed with them over their fields.

12. Anthemis Pyrethrum; Spanish Chamomile, or Pellitory of Spain. Stems simple, one-flowered, decumbent; leaves pinnate multifid. Root perennial, as big as a man's finger, the colour of horse-radish, white within, of an acrid biting taste. When chewed, it excites a glowing heat, with a discharge of saliva, which relieves tooth-ache and rheumatic affections of the face: it is also recommended in lethargic complaints, and paralyses of the tongue. Lewis says, the roots having a hot pungent taste when chewed in the mouth, by stimulating the salival glauds, promote a flow of viscid humours from the head and the adjacent parts, and frequently by this means relieve the tooth-ache, head-ache, lethargy, and palsy of the tougue. It is also successfully given in small doses for paralytic and rheumatic complaints. In palsies, its stimulation alone will sometimes restore the voice. According to Culpeper, an ounce of the juice taken in a draught of Muscadel an hour before the fit of the ague comes on, will remove it at the second or third time of taking it; and the powder of the herb snuffed up the nostrils removes the head-ache by melling of the snows, and flowering in April and May.

parts of Europe.

** With a concolour, or yellow Ray.

13. Anthemis Valentina; Purple-stalked Chamomile. Stem branching; leaves pubescent, tripinnate, bristle shaped; calices villose, peduncled .- It grows naturally in Spain, Portugal, and Provence, and is supposed to be the same which Dioscorides recommends as good for the jaundice, and to restore the skin to a good colour.

14. Anthemis Repanda; Repand-leaved Chamomile. Leaves simple, ovate-lanceolate, repand, crenate .-- Native of Spain and Portugal.

15. Anthemis Trinervia; Three-nerve-leaved Chamomile, Lcaves ovate, serrate, three-nerved, opposite petiolate; receptacle conic .-- Found in South America.

16. Anthemis Americana ; American Chamomile. Leaves triternate; peduncles terminal, longer than the branch .---Native of America.

17. Antheris Tinctoria; Yellow Chamomile, or Ox-eye. Leaves bipinnate, serrate, tomentose underneath; stem corymbed .--- A native of dry open pastures in Germany, and of Sweden; where, Linneus says, it is much used in Gothland for dying yellow. A decoction of the fresh herb with ale is given as a remedy for the jaundice; it operates by urine. This plant may be casily increased by sowing the seeds upon a bed of common earth in spring, and transplanting them three feet asunder, when they are strong enough to remove. Some of the flowers are white, some sulphur-coloured, and some of a deep yellow; and in large open spots they form a pleasing variety from June till November, which is the time they continue to flower .- The Levant seeds produce the tallest plants and largest flowers,

18. Anthemis Arabica; Arabian Chamomile. Stem decompound; calices branch-bearing; root annual .- A native of Arabia ; its flavour is bitter and aromatic, but far weaker than the common chamomile. Unless the seeds be sown in autumn, they will seldom be reproduced in perfection in England.

19. Anthemis Odorata; Shrubby Chamomile. Leaves pinnatifid at the tip; peduncleselongate; calices membranaceous; ray barren .- Native of the Cape of Good Hope; flowering from April to June.

Anthericum ; a genus of the class Hexandria, order Mouogynia .- GENERIC CHARACTER. Calix: none. Corolla: petals six, oblong obtuse, spreading very much. Stamina: filaments subulate erect; antheræ small, incumbent, fourfurrowed. Pistil: germen obscurely three-cornered; style simple, the length of the stamina; stigma obtuse, three-cornered. Pericarp: capsule ovate, smooth, three-furrowed, three-celled, three-valved. Seeds: numerous, angular. Es-SENTIAL CHARACTER. Corolla: six-petalled, expanding. Capsule: ovate .--- All the plants of this genus are perennial, and may be increased by offsets or suckers, or by seeds planted during autumn on a bed of light sandy earth in a warm situation. They require covering with straw or peasehaulm in severe weather, and will last several years if not destroyed by frost .---- The species are,

1. Anthericum Floribundum; Thick-spiked Anthericum. Leaves flat, smooth, linear-lanceolate, acute; scape simple; raceme many-flowered, cylindric, compact ; pctals spreading ; stamina smooth. Leaves channelled; filaments generally smooth .- Native of the Cape of Good Hope; flowering in March and April.

2. Anthericum Scrotinum. Leaves flattish; scape one-flowered; filaments generally smooth .- A vernal plant, which appears in Switzerland and on Snowdon in Wales, after the

104

3. Anthericum Græcum. Leaves flat, channelled ; scapes | simple: flowers corymbed; filaments woolly. Filaments generally smooth .- Native of the Levant.

4. Anthericum Planifolium. Leaves flat, channelled; scape and filaments woolly, the latter generally smooth .-- Native of Portugal, where it flowers in April.

5. Anthericum Revolutum ; Curled-flowered Anthericum. Leaves flat, channelled; scape branched; corollas revolute; filaments generally smooth .- Native of the Cape of Good Hope.

6. Anthericum Ramosum; Branching Anthericum. Leaves linear, subulate, flat, channelled ; scape branched ; peduncles solitary; corollas flat; pistilla straight; filaments generally smooth .- The flowers, which are generally white, watch from seven in the morning to three or four in the afternoon. Native of Sweden, France, Switzerland, and Austria.

7. Anthericum Elatum; Tall Anthericum. Leaves flat, channelled; scape branched; peduncles aggregate; corollas flat ; filaments generally smooth .- The flowers are white and handsome when fully blown: they appear in August and September. It is a native of the Cape of Good Hope.

8. Anthericum Trifforum; Three flowered Anthericum. Leaves channelled, sword-shaped; scape simple; bractes remote, three-flowered; filaments generally smooth .- It flowers in November, and is a native of the Cape of Good Hope.

9. Anthericum Canaliculatum; Channelled Anthericum. Leaves rather fleshy, hairy, sword shaped, triquetrous, channelled on the narrow side ; scape simple ; filaments generally smooth .- Flowers in April; a native of the Cape of Good Hope,

10. Anthericum Albucoides; Striped-flowered Anthericum. Leaves linear, channelled, smooth, with a cartilaginous edge; scape simple; filaments generally smooth .- Flowers in August; native of the Cape.

11. Anthericum Liliago; Grass-leaved Anthericum. Leaves flat, channelled; scape perfectly simple; corollas flat; pistil bending down; filaments generally smooth .- Native of Italy, Switzerland, Germany, France, and Denmark.

12. Anthericum Liliastrum; Savoy Anthericum, or Spiderwort. Leaves flat, channelled ; scape perfectly simple ; corollas bell-shaped; stamina bending down; filaments generally smooth .- It grows wild upon the mountains of Switzerland and Savoy.

13. Anthericum Spirale,-Scape spiral ; filaments generally smooth .- A leafless native of the Cape of Good Hope.

14. Anthericum Putescens; Shrubby Anthericum. Leaves fleshy, columnar; stem shrubby; filaments bearded .-- Native of the Cape of Good Hope

15. Anthericum Alooides; Aloe-leaved Anthericum. Leaves fleshy, subulate, flattish; filaments bearded .--- Also a native of the Cape of Good Hope.

16. Anthericum Asphodeloides; Glaucous-leaved Anthericum. Leaves fleshy, subulate, semicolumnar, upright and stiff; filaments bearded .- Comes from the Cape of Good Hope.

17. Anthericum Annuum; Annual Anthericum. Leaves fleshy, subulate, columnar; scape subracemed; filaments bearded .- - It is found at the Cape of Good Hope,

18. Anthericum Hispidum; Hairy-leaved Anthericum. Leaves fleshy, compressed, hispid; filaments bearded: antheræ yellow .--- A native of the Cape of Good Hope.

19. Authericum Ossifragum ; Lancashire Anthericum, or Asphodel. Leaves sword-shaped; filaments woolly .- It grows wild on the bogs of the northern countries of Europe, and in Lancashire, and other northern counties; in Cambridgeshire, in Norfolk, on Putney heath ; and flowers in July and August.

20. Anthericum Calyculatum, Leaves sword-shaped, pe-Ω.

-Grows wild in Lapland, Sweden, Denmark, Siberia, Switzerland, and in several places in Scotland.

21. Anthericum Japonicum. Leaves sword-shaped, convolute, smooth; scape branching, angled; flowers racemed, nodding .--- Native of Japan, China, and Java.

22. Anthericum Filiforme; Thread leared Anthericum. Leaves filiform, rather cylindric, rough ; filaments smooth ; petals lanceolate,-Found at the Cape of Good Hope; and flowers in April.

23. Anthericum Flexifolium. Leaves subplate, smooth. flexuose; stem branching .-- Found at the Cape of Good Hope.

24. Anthericum Muricatum. Leaves fleshy, compressed. muricated, streaked.

25. Anthericum Latifolium. Leaves fleshy, wide, swordshaped, smooth ; raceme very long ; stem simple.

26. Anthericum Cauda-felis. Leaves channelled, swordshaped ; scape simple ; raceme oblong .- Native of the Cape of Good Hope.

27. Anthericum Triquetum. Leaves filiform, triquetrous, shorter than the simple scape ; raceme ovate.

28. Anthericum Ciliatum. Leaves sword-shaped, fleshy, subtriquetrons, ciliate; scape simple; raceme very long.

29. Anthericum Falcatum. Leaves fleshy, sword-shaped, sickled, smooth ; stem branching, racemed.

30. Anthericum Contortum. Leaves flat, sword-sbaped ; stem branching ; flowers very remote.

31. Anthericum Scabrum. Leaves triquetrous, serrulate; stem branching, rugged; fruit bearing peduncles, recurved, -Found at the Cape of Good Hope.

32. Anthericum Squameum. Scape imbricate, with membranous tumid scales. - Native of the Cape.

33. Anthericum Cirratum. Leaves lanceolate, flattish : scape panicled; leaves bearded, bicirrate .-- Native of New Zealand.

34. Anthericum Adenanthera. Leaves linear, ensiform, connate at the base; a gland between the filament and anther. -Native of New Caledonia.

Anthistiria; a genus of the class Polygamia, order Monœcia, -GENERIC CHARACTER. Calix: glume four-valved. three or four-flowered; valves equal, oblong, flat, blunt, leathery, erect, expanding. Hermaphrodite floscule sessile. Males pedicelled, very like the hermaphrodite. Corolla: glume two-valved; valves lanceolate, acute, awnless, the outer larger. Stamina: filaments three, short, filiform; antheræ oblong, erect. Pistil, in the hermaphrodite : germen oblong, from the base a twisted awn; styles two; stigmas clubshaped, hairy. Pericarp: none, except the closed calix. Seed : oblong, smooth, marked with a furrow. ESSENTIAL CHARACTER. Cleft at the base into four equal divisions. -----There is only one species discovered, viz.

1. Anthistiria Ciliata. Root annual ; culms a foot high.

Anthoceros ; a genus among the Algæ, in the class Cryptoganija.

Antholuza: a genus of the class Triandria, order Monogynia,-GENERIC CHARACTER. Calix: spathes two-valved. alternate, imbricate, separating the flowers, permanent. Corolla: petal one, gradually dilated from the tube into a compressed ringent throat; upper lip straight, slender, very long; furnished with two short divisions at the base; under lip shorter, trifid. Stamina: filaments long, slender, under the upper lip; antheræ acnte. Pistil: germen inferior; style filiform, situation and length of the upper stamina; stigma trifid, capillary, reflex. Pericarp : roundish, three-cornered. three-celled, three-valved. Seeds: many, triangular. Esrianths three-lobed; filaments smooth; flowers three-pistilled. SENTIAL CHARACTER. Corolla: tubular, irregular, re-2 E

ANT

ANT

curved. Capsule: inferior.—Plants of this genus are propagated by offsets, or by seeds sown soon after they are ripe, in pots of light earth, plunged into an oid tan-bed which has lost its heat, and is shaded doring hot weather from the heat of the day. They must be kept two years under glasses, and may then be transplanted into small separate pots, placed during summer in the open air, but in winter must go back to the hot-bed frame. The flowers are ornamental; and as the plants do not require much culture, they deserve a place in every good garden. The seeds are very seldom perfected in Europe, and every one of the species is a native of the Cape of Good Hope.—They are,

i. Antholyza Ringens; Narrow-leaved Antholyza. Lips of the corolla divaricate, throat compressed.—The flowers are red, and appear in June; the seeds ripen in September.

2. Antholyza Plicata; *Plaited-leaved Antholyza*. Leaves plaited; stem branching, hirsute; corolla ringent, shorter than the stamina.—The stamina are shorter than those of the first species.

3. Antholyza Cunonia; Scarlet-flowered Antholyza. Corollas straight, the two outer lobes of the five-parted lip broader and ascending .- This flower is of a beautiful scarlet colour, and flowering about the latter end of April or beginning of May, makes a fine appearance. Plant it in pots of light earth, which may remain in the open air till October, and must then be sheltered under a glass-case, or hot-bed frame, where the leaves will grow throughout the winter, and the stalks arise and flower in spring. Water them sparingly once a week in winter, in spring oftener; and when the flowers are past, remove them into the open air to perfect their seeds . these ripen at the latter end of June, the stalk then decays, and remains inactive until September. As soon as they decay, take them up, keep them in a dry room, till the end of August, and then plant them again. It may also be easily in creased by offsets, which require the same treatment : both seeds and offsets should be planted in the middle of August, where they can enjoy the morning sun.

4. Antholyza Äthiopica; Broad-leaved Antholyza. Corollas incurvate, the two alternate lobes of the five-parted lip spreading, larger, and lanceolate; corolla tubulous, scarlet.

5. Antholyza Meriana; Red flowered Antholyza. Corollas funnel-shaped; leaves linear.—This and the sixth species are propagated by offsets from the roots, which require the same treatment as the third species, which see. It flowers in April and May.

6. Antholyza Merianella; *Dwarf Antholyza*. Corollas funnel-shaped; leaves linear.—The flowers are larger, and later in appearing, but of the same colour with the fifth species.

7. Antholyza Lucidior. Radical leaves, with filiform base, broad-awled, furrowed at top; stem simple, leafy, spiked; style the length of the stamina and corolla.

Anthora. See Aconitum.

Anthespermum; a genus of the class Polygamia, order Dioccia, or Dioceia Tetrandria.-GENERIC CHARACTER. Male calix: perianth one-leafed, conical, quadrifid, beyond the middle divisions ovarte-oblong, revolute, obluse, a little coloured. Corolla: none, unless the calix be so termed. Stamina: filaments four, capilary, erect, the length of the calix, inserted into the receptacle; anthera twin-oblong, fourcornered, obluse, erect. Franki calix and corolla as in the male. Pisitli: gennen inferior, ovate, four-conrered; styles two, recurved; stigmas simple. ESSENTAL CHARACTER. Calix: four-parted. Corolla: none. Stamina: four. Pistil: two. Gremen: inferior; male and female in the same or a distinct plant.-These plants are propagated by cutting placed in a border of light earth, during my of the summer

months; or if planted in pots, plunged into a very moderate hot-bed, they will sooner take root, and be of surer growth. Afterward they should be taken up will the earth that will adhere to their roots, and replanted in a pot of light sandy earth, which may bear the open air until October, but must then be removed under shelter for the winter, during which they must be sometimes watered, and have fresh air admitted. The first and second sorts may be raised from layers: they are all natives of the Cape of Good Hone.

1. Anthospermum Æthiopicum : Amber-tree. Leaves polished. --The beauty of this shrub consists in its small evergreen leaves, which grow as close as heath, and emit a very fragrant odour when bruised between the fingers.

 Anthospermum Ciliare. Leaves ciliated along the keel and edge; root perennial and woody.

 Anthospermum Herbaceum. Leaves six, polished ; stem herbaceous ; flowers axillary.

Anthocamthum; a genus of the class Diandria, order Digyna.—GENERER. Calitz FER. Calitz glume one-diowered, two-valved; valves ovate, acuminate, concave; the inner one larger. Corollie; glume one-flowered, two-valved; the length of the greater valve in the calix; each valve emitting an awa from the lower part of the back, one of them jointed. Neatury: two-leved, very slender, cylindric; leaflets subovate, embraching. Stamina: filaments two, capillary, very long; anthera oblong, forked at both ends. *Pistil:* germen oblong; styles two, filform; sigmas simple. *Pericary*; glume two-valved, one-flowered. Corolla: glume two-valved, acuminate. Sced: sone.—For the propagation and culture of this genus, see Grass.

1. Anthoxanthum Odoratum; Sweet-vernal Grass, Spike oblong-ovate; flowers longer than the awn, on short peduncles ; root perennial, odorous ; colour of the spike pale yellow. -This is the grass which gives that delightful sweetness of scent to new-mown hay, from which it has derived its specific name odoratum, sweet-scented : from the earliness of its flowering, it has obtained the other English name of vernal or springgrass. It will grow on any soil, but prefers that which is moderately dry, having, according to some, a great tendency to curl its leaves in rich ground. It is common in woods and pastures, and in the middle of May is in full bloom ; the seed, which is never very abundant, ripens in June, and separates easily when rubbed. Cattle of all sorts are fond of it, and in good meadows it grows to a considerable height, forming a thick tuft of tender succulent leaves at the bottom, though in point of crop it is not so productive as some other grasses. As the best mutton comes from places where it abounds, it is probably a good grass for sheep pastures : especially as it is found on all grounds, from the driest and sandiest to the most stiff and moist, and even in bogs. It is very easy to gather, and abounds plentifully in the best meadows about Hampstead and Hendon, near London. It retains its odour for a long time, and Boccone says, that a distilled water is prepared from it, as the vehicle of some perfumes.

2. Anthoxanthum Indicum. Spike linear; flowers sessile, shorter than the awn.-Native of the East Indies.

3. Authoxanthum Crinitum. Panicle spike-form, cylindrical, awned, the awns long, spreading, loose.--Native of New Zealand.

Anthriscus. See Scandix.

Anthyllis ; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. Caliz: perianth one-leafed, ovate-oblong, swelling, villose; the mouth five-toothed, unequal, permanent. Corolla: papilionaceous; banner longer;

1. Anthyllis Tetraphylla: Four-keared Anthyllus, or Kidmy/feth. Leaves pinnate, with four lobes; flowers lateral. —An annual plant, with yellow flowers, appearing in July, and producing seeds in September. It is a native of France, Spain, Portugal, Italy, and Sicily, where it is a weed in arable land. With us it should be sown upon a bed of light earth in spring, wherever it is to remain, and will only require thiming and weeding. If the plants be suffered to seatter their seeds, they will come up with the first warmth of spring.

2. Anthyllis Vulberaria; Common Ladies' Finger, or Kidney Vetch. Leaves pinuate, unequal; head double.—Native of most parts of Europe, and flowers from May to July. This and the following species may be propagated by seed sown either in autumn or spring. There are several varieties.

3. Anthyllis Moniana, Mountain Anthyllis, or Kidney Petch. Leaves pinnale, equal; head terminal, one ranked, flowers oblique.—Both this and the preceding species are found wild in several parts of Europe; in Pembrokeshire, and Anglesen in Wales, and in the Isle of Man; they abound greatly in the best meadows of the Pyrences; and are recommended as an excellent pasture for sheep.

4. Anthyllis Cormicina. Leaves pinnate, unequal; heads solitary.—Native of the south of France, Switzerland, Austria, Carniola, Italy, and Spain.

4. Anthyllis Laioides. Leaves three-parted; calices prismatic, fascieled, the length of the legumes.—Native of Spain, 6. Anthyllis Gerardi. Leaves pinmate, unequal, peduncles lateral, longer than the leaf-heads leafless.—It grows wild upon the sea-shores of Provence.

7. Anthyllis Quinqueflora; *Five-flowered Anthyllis*. Leaves ternate, linear, head five-flowered. Corollas yellow.—A native of the Cape of Good Hope.

8. Anthyllis Involucrata. Sub-herbaceous; leaves ternate, petiolate, stipuled, sword-shaped; flowers in a head.—Native of the Cape of Good Hope.

9. Anthyllis Linifolia. Leaves ternate sessile, sword-shaped; flowers in a head. Flowers yellow.

10. Anthyllis Barba Jovis; Silcery Anthyllis, or Jupiter's Bord. Leaves pinnate, equal, tomentose; flowers in a head. —This is sometimes called Silcer Bush, from the whiteness of its leaves. It is a shrub often growing ten or twelve feet high, with flowers of a bright yellow colour; a native of the south of France, Spain, Portugal, Italy, and the East. It may be propagated either by seeds or cuttings, sown or planted in post filled with light earth, and placed under a frame to protect them from the winter's frost. They may be planted during any of the suumer norths.

11. Anthyllis Heterophylla. Leaves pinnate, the floral leaves ternate,—Grows naturally in Portugal and Spain, and may be propagated by cuttings in the same manner as the tenth species.

12. Anthyllis Visciflora. Leaves digitate-pinnate; calices shaggy. Corolla yellow.—Seen at the Cape of Good Hope.

14. Anthyllis Hermanniæ; Lavender-leaved Anthyllis.

Leaves ternate, sub-peduncled; calices naked.—Six feet high, a native of Greece, Crete, and Palestine, and may be propagated by cutting in the same manner as the tenth species.

ANT

15. Anthyllis Erinacea; Prickly Anthyllis. Spinose leaves simple.—Grows nine feet high, native of Portugal and Spain. It is propagated by seeds only, and will survive mild winters in the open air, but hard frosts destroy it.

16. Anthyllis Tragacanthoides. Shrubby; leaves pinnate, tomentose; petioles spinescent; flowersjin racemes.-Native of Mount Lebanon.

17. Anthyllis Indica. Shrubby; leaves pinnate, equal, smooth; raceines oblong subterminating. Corolla white.----Native of the Cochin-chinese mountains.

Antichorus; a genus of the class Octandria, order Monoguia.--GENERIC CHARACTER. Cali:: perianth fourleaved, very much expanded; leaflets lanceolate, acuminate, deciduous. Corolla: petals four, oborate, obtuse, the length of the calix. Stamina: filaments setaceous, erect, shorter than the corolla; anthera roundish. Pistil: Germen superior ovate; style cylindric, the length of the stamina; sigma obtuse. Pericarp: capsule subulate, four-celled, four-valved, Seeds: very uamy, truncate, placed over each other in four rows. ESSENTIAL CHARACTER. Calix: four-leaved, Petals: four. Capsule: superior, subulate, four-celled, fourvalved. Seeds: very many. One species only has been hitherto discovered, yiz.

 Antichorus Depressus.—It resembles the Corchorus, and is a small procumbent annual plant, with yellow flowers, and a native of Arabia.

 Antidesma Alexiteria.—This is a middle-sized tree, the bark of which is used for making ropes. A decortion of the leaves is reputed to be an antidote against the bite of serpents, It is a common evergreen in Malabar, where the fruit, which it continues to bear to the age of seventy years, is much esteemed for its pleasant cooling qualities.

2. Antidesma Acida. Leaves obovate ; spike solitary.----Native of the East Indies.

3. Antidesma Scandens. Leaves palmate, serrate; stem climbing.-Stem shrubby; native of China, near Canton.

Antirrhinum: a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth five-parted, permanent; divisions oblong, the two lower more gaping. Corolla: monopetalous, ringent; tube oblong, gibbous; limb bilabiate : upper lip bifid, reflex on the sides; lower trifid, obtuse; palate convex, usually closed by a prominency between the lips, produced from the under lip ; the throat being concave beneath. Nectary at the base of the corolla, produced downwards, prominent. Stamina : filaments four inclosed under the upper lip, nearly of the same length with the corolla, yet two are shorter; autheræ converging. Pistil: germen roundish; style simple, of the length and in the situation of the stamina ; stigma obtuse. Pericarn ; capsule roundish, obtuse, two-celled, of different form and aperture in the different species. Seeds : very many. Re-

ANT ceptacles : reniform, solitary, affixed to the partition. ESSEN-TIAL CHARACTER. Calix: five-leaved. Corolla: with the base produced downwards, and nectariferous. Capsule: two-celled.

1. Antirrhinum Cymbalarica ; Ivy-leaved Toud-flax. Leaves heart-shaped, five-lobed, alternate; stalks procumbent. Root perennial; and is a native of Italy, but now become common upon walls in and near London. The whole plant is smooth, and has a disagreeable smell, with a white flower: it flowers from June until October, and is well adapted to ornament rock-work, which if moist, it will soon cover with a thick tapestry. When once established it is hard to eradicate, and will thrive in any situation.

2. Antirrhiuum Elatine; Sharp-pointed Toad-flax, or Fluellin. Leaves hastate, alternate; stalks procumbent. Root annual, whitish: the whole plant is hairy, and varies with blue and yellow flowers .- It grows wild in corn-fields in Italy, Germany, France, Switzerland, and England, and flowers with us from July till October. It is the bitterest plant of the whole genus; and the expressed juice, or distilled water, is said to check foul old ulcers, disposing them to heal. It is likewise a good medicine for internal bruises, for inflammations of the eyes, the bloody flux, and other hæmorrhages, such as the overflowing of the menses. The leaves bruised, and applied with barley-meal to watery eyes, that are hot and inflamed by defluxions of the head, is said to be very Culpeper informs us, that this herb was origiefficacious. nally named the Female Speedwell ; and gravely adds, that it received its present name of Fluellin, from the gratitude of a Welsh gentleman whose nose it had preserved from the dreadful ravages of the venereal disease. But notwithstanding he avers, if taken inwardly it may cure that disorder, its antivenereal virtues are entirely unknown at the present day; though he is probably correct, in calling it a herb of a fine cooling and drying quality. The seeds ripen in autumn, and if sown or permitted to scatter at that time, will produce an abundant crop.

4. Antirrhinum Spurium; Round-leaved Toad-flax, or Fluellin. Leaves ovate, alternate ; stalks procumbent-Grows wild in the fields of Germany, Eugland, France, and Italy. See the third or preceding species.

5. Antirrhinum Cirrhosnm. Tendrilled Toad-flax. Leaves hastate, alternate; stems spreading; petioles every where tendrilled .- Annual, and a native of Egypt.

6. Antirrhinum Ægyptiacum; Ægyptian Toad flax. Leaves hastate, alternate; stem erect, very branching; peduncles stiffish. Corolla yellow, with a purplish dotted palate .--- A native of Egypt.

7. Antirchinum Triphyllum; Three-leaved Toad-flax. Leaves alternate, ovate .-- An annual plant, with yellow flowers; native of Spain and Portugal; and seldom ripens its seed in England, where it flowers in July. Its seeds should be sown in spring ou the borders of the flower-garden where they are to remain. Thin and weed them when they come up, which is all the culture they require.

8. Antirrhinum Trionithopnosum. Leaves in fours, lanceolate; stem erect; branching flowers peduncled .- It has large purple flowers, and is a native of Portugal and America.

9. Autirrhinum Purpureum; Purple Toad-flax. Leaves quaternate linear; flower-bearing stem erect, spiked. Root perennial; corolla all purple .- Native of Italy, about Naples, and at the foot of Mount Vesuvius, flowering from July till September. The seeds of this and the three following species, if permitted to scatter, will produce plenty of young plants without any further care: they prefer a dry soil, and when placed upon an old wall, they will come up, and endure louger than abon the ground. They may be increased by parting the roots.

10. Antirrhinum Versicolor; Spike-flowered Toad-flar Leaves linear lanceolate; the lower ones ternate; stem erect. spiked .--- A native of the southern countries of Europe, resembling common toad flax. See the ninth species.

11. Antirrhinum Repens; Creeping Toad flax. Leaves linear, crowded, below quaternate; calices equalling the capsule .- It has a perennial root, and pale blue flowers, destitute of scent, which appear in July, and seed in autumn. Native of France, Italy, and England, in Hertfordshire, and about Henley in Oxfordshire. See the ninth species.

12. Antirrhinum Monspessulanum; Montpellier Toad-flax. Leaves linear, filiform, succulent, scattered, crowded; stem erect; spur shorter than the calix. Root perennial; flowers a pale blue colour and sweet smell.—Found near Montpellier in the south of France, and in England near Penryn in Cornwall. See the ninth species.

13. Antirrhinum Sparteum ; Branching Toad-flax, Leaves awl-shaped, channelled, fleshy; the lower ones ternate; stem panicled, and corollas very smooth. Stem a foot high, corolla yellow, flowering in May and June, and very common in a dry sandy soil about Madrid .- It may be sown in spring like other hardy annuals, but will flower earlier if raised in the autumn.

14. Antirrhinum Bipunctatum ; Dotted-flowered Toad-flax. Leaves linear, smooth; the lower ones quaternate; stem erect, panicled ; flowers spike-headed .- Stem seven inches high; it is an annual plaut, growing wild in the corn-fields of France, Spain and Italy, and producing a yellow flower in May and June,

15. Antirrhinum Triste; Dark-flowered Toad-flax. Leaves linear scattered, the inferior ones opposite; nectaries awlshaped; flowers subsessile. Corolla very dark purple, capsule shaped like the human skull.—Native of Spain; flowering during most of the summer months, when it is easily propagated by cuttings, which if watered and shaded will soon take root, and may be afterwards planted in pots filled with light fresh undunged earth, which may have plenty of free air in mild weather, but must be sheltered in winter,

16. Antirrhinum Supinum ; Procumbent Toad-flax. Leaves subquaternate, linear; stalk diffused; flowers racemed; spur straight .- Native of sandy grounds in France and Spain.

17. Antirrhinum Arvense; Yellow Corn Toad-flax. Leaves sublinear, the lower ones quaternate; calices hairy, viscid; flowers spiked; stem erect.

18. Antirrhinum Pelisserianum; Violet-coloured Toad-flax. Stem-leaves linear, alternate ; root leaves lanceolate, ternate ; flowers corymbed; root annual; corolla purple with a white palate, marked with obscure purple veins .- Native of France and Italy. The seeds ripen in autumn, at which time they should be sown.

19. Antirrhinum Saxatile; Rock Toad-flax. Leaves lanceolate-linear, scattered, villose; the inferior, quaternate; stem decumbent; flowers spiked; root perennial; corolla full yellow, with two orange spots at its opening, and two upon the palate .- Native of Spain.

20. Antirrhinum Viscosum; Clammy Snapdragon, Rootleaves quaternate, lanceolate; stem-leaves linear, alternate; calices villose, approximating the stem .- Native of Spain.

21. Antirrhinum Multicaule; Many stalked Toad flax. Leaves quinate, linear, fleshy; flowers headed .- There are two varieties of this annual plant, one with a deep yellow, and the other with a sulphur-coloured flower. It is a native of Sicily and the Levant. See the ninth species.

22. Antirrhinum Glaucum. Leaves quaternate, awl-shaped, fleshy; stems erect; flowers spiked .- An annual, with a yellow corolla; native of the south of Europe and the Levant.

Leaves 23. Antirrhinum Alpinum; Alpine Toad-flax. quaternate, linear-lanceolate, sea-green; stem diffuse ; flowers racemed, with a straight spur .- Root perennial, having an elegant flower of a fine violet purple colour, with a rich gold colour in the centre, and which blows most part of the summer. It has a bitter disagreeable taste, and is a native of moist rocky places in the Alps. This beautiful flower may be propagated by cuttings as well as seeds, which it does not produce plentifully in England. It succeeds best in a pot or on a rock-work.

24. Antirrhinum Bicorne ; Horned Toad-flax, Leaves opposite, ovate-oblong, serrate; stem erect; flowers racemed; capsules two-horned .- An annual, native of the Cape of Good Hope.

25. Antirrhinum Villosum. All the leaves opposite, ovate, villose; stems simple; flowers opposite, lateral.-Observed in Spain.

26. Antirrhinum Origanifolium. Leaves mostly opposite, oblong; flowers alternate .--- Annual, growing wild upon the Pyrenees, and near Marseilles.

27. Antirrhinum Pinnatum. Leaves opposite, pinnatifid; stem erect; flowers racemed .- Native of the Cape.

28. Antirrhinum Minus : Lesser Toad-flax. Leaves mostly alternate, lanceolate, obtuse ; stem very much branched, diffuse .- The corolla is small, the tube and upper lip violet, the beard and chin whitish, and the throat closed with a pile of orange hairs. Annual, flowering from June till September, and growing wild in corn-fields, dry pastures, and upon walls in most parts of Europe.

29. Autirrhiuum Dalmaticum. Leaves alternate, heartshaped; stem clasping .- The flowers, which are of a deep yellow colour, appear in July, but seldom produce ripe seed in England; it is a native of Crete and Armenia. It is propagated by seed, sown early in the spring, upon a border of light earth, removing them, when they come up, to pots of light sandy earth placed in the shade, till they take root, and under hot bed frame after October to preserve them from the frost. It will endure more cold than any of the other species.

30. Antirrhinum Hirtum; Hairy Toad-flax. Leaves lanceolate, shaggy; flowers spiked, the upper leaf of the calix largest.—Annual; with a pale yellow flower, with a few dark stripes, and the chaps of a gold colour. Native of Spain. See species, No. 7.

31. Antirrhinum Genistifolium; Broad-leaved Toad-flax. Leaves lanceolate, acuminate ; panicle wand-like, flexuose .--Native of Siberia, Lower Austria, Switzerland, Dauphine, and Piedmont. See the ninth species.

82. Autirrhinum Junceum; Rush stalked Toad-flax. Leaves linear, alternate ; stem panicled, wand-like ; flowers racemed. -Discovered in Spain. See the ninth species.

33. Antirrhinum Linaria; Common Yellow Toad-flax, or Calves-snout. Leaves lanceolate-linear, crowded; stem erect; spikes terminal, sessile ; flowers imbricate .- Root perennial ; flowers yellow with orange palates. It grows wild in most parts of Europe upon banks by road sides, and in dry pastures, flowering from June till August. In Worcestershire it is called Butter and Eggs. It abounds in an acrid oil, that is almost empyrheumatic; and when inwardly given, excites nausea, purges, and increase of urine. It is recommended in dropsical cases ; and the distilled water or juice of the plant, put into the eyes, is said to remove inflammations ; but it is most useful when applied as a cataplasm with lard for the piles. The fresh tops are used ; an infusion of them works by urine, and has beeu recommended by some in the jaundice, and other diseases arising from obstructions in the viscera; but Hill says, we have so many English plants that excel in 10.

this particular, and the taste of the infusion is so far from agreeable, that it is not worth while to have recourse to it, Withering prescribes an infusion of the leaves as both diuretic and purgative, and informs us that an ointment prepared from them gives relief in the piles. A decoction of the whole plant, in all, purges briskly, operates by urine, and is frequently found serviceable in the jaundice and incipient dropsies. The juice of the leaves is good for inflammatious of the eyes, and cleanses old ulcerous sores. The plant is very apt to spread so as to become troublesome, and therefore is seldom admitted into gardens. The flowers however make a pretty appearance, and are well worth retaining in pots.

ANT

Leaves lanceolate, three-34. Antirrhinum Linifolium. nerved; flowers racemed; peduncles distinct, shorter than the bracte. Corolla yellow .- It is perennial, and found upon the sea-coasts of Italy

35. Antirrhinum Chalepense; White-flowered Toad-flax. Leaves linear-lanceolate, alternate ; flowers in racemes ; calices longer than the corolla ; stem erect .- An annual, flowering in July, and ripening seed in autumn. Native of Sicily, Italy, and France.

36. Antirrhinum Reflexum. Leaves ovate, smooth; peduncles axillary, fruit-bearing, elongate, recurved ; stem procumbent. Root annual. Corolla white .- It flowers in May and June, and is common in vineyards and gardens about Messina, and has been found in Barbary.

37. Antirrhinum Pedunculatum. Leaves linear, remote: flowers panicled; peduncles longer than the leaf, stiff, and upright .--- Corollas yellow. Found in Spain.

38. Antirrhinum Lagopodioides. Leaves scattered, soft, recurved at the tip ; spikes ovate, villose .- Native of Siberia. 39. Antirrhinum Aphyllum. A capillary scape .- Found near the Cape of Good Hope.

40. Antirrhinum Majus ; Great Rock Toad-flax, or Snapdragon. Corollas tailless; flowers in spikes; calices rounded. Root biennial; stem a foot, eighteen inches, two, and even three feet high .- There are several varieties of this species, and the differences in the colour of the flowers are endless; the most common are red, yellow, purple, white; red with white and vellow mouths; white and red; vellow and red; yellow and white; purple and white; purple, with yellow mouths, and scarlet dotted with gold colour. Native of the southern countries of Europe, growing in hedges, and on rocks, and ruins. In England it flowers during June and July, and grows on walls, Dover cliffs, and between Northfleet and Gravesend. In Russia they express an oil from the seeds of this plant, which is little inferior to oil of olives. All its varieties are raised from seed sown in April or May upon a dry soil, and transplanting them to large borders in July, where they will flower in the following spring. Any of the sorts may be continued by planting cuttings in the summer months, which will easily take root. They resist the cold of winter well, require little attention, and are pretty ornaments, well worthy of admittance into every garden. Whenever these plants are intended for rocky barren soils, or to grow upon walls, sow the seed early in March, and all the further trouble they require is merely to keep them free from weeds: they will begin to flower in July, and continue till the frost sets iu.

41. Antirrhinum Orontium; Small Toad flax, or Calvessnout. Corollas tailless ; flowers subspiked ; calices longer than the corolla .- Stem seldom more than a foot high, corollas a bright purple, with a little yellow, and sometimes white spur, very short. It is a poisonous annual plant, native of England, growing in a light soil, in corn-fields and vineyards, aud flowering in July and August, and is seldom admitted into gardens.

2F

109

42. Antirrhinum Papilionaceum. Corollas tailless ; flowers axillary; calices papilionaceous; leaves fleshy. Native of Persia.

43. Antirrhinum Asarina; Heart-leaved Toad-flax. Corollas tailless; leaves opposite, heart-shaped, crenate; stems procumbent .-- Native of Italy, and the sonth of France; a low trailing annual plant.

44. Antirrhinum Molle; Woolly-leaved Toad flax, or Snapdragon. Corollas tailless; leaves opposite, ovatc, tomentose; stems procumbent .- Native of Spain; corollas villose, white, with a yellow palate; the upper lip streaked with red.

45. Antirrhinum Unilabriatum. Corollas tailless, with two calices; leaves alternate, pinnate; stem panicled .-- Found ncar the Cape of Good Hope.

46. Antirrhinum Bellidifolium; Daisy-leared Toad-flax. Root-leaves tonguc-shaped, toothed, marked with lines ; stemleaves parted, quite entire .- A biennial, or at most triennial plant, with a blue corolla. Native of Spain, Italy, and the south of France; also found near Geneva. Propagated by seeds sown where they are to remain, upon a border of light earth, and to be thinned and weeded when they appear in the following spring, which is all the culture they require.

47. Antirrhinum Canadense; Canada Toad-flax. Leaves linear, alternate; lower lip spreading and flat .-- Native of Virginia and Canada.

48. Antirrhinum Micranthum ; Small flowered Toad flax. Stem herbaceous, upright, lower leaves in fours, upper ones alternate; flowers very small; spur short interior .- Root annual; corolla smallest of all the species, and white. Native of Spain, near Madrid, where it flowers in March and April.

49. Antirrhinum Reticulatum; Reticulate Toad-flax. Lcaves linear, channelled, scattered, those on the radical shoots generally in fives; calix hairy; flower-stalks shorter than the bractes .- Root percunial; flowers very beautiful, variable in colour, and without scent. Discovered in Algiers.

50. Antirrhinum Pygmæum; Dwarf Toad-flax. Leaves sagittate ; peduncles capillaceous. Corolla yellow.

51. Antirrhinum Ærugincum, Lower leaves in fours, linear; flowers in racemes, the upper leaflet of the calix twice as long as the rest.-An annual, with a yellow corolla ; it is a native of Spain.

52. Antirrhinum Hexandrum. Leaves opposite, cordateovate, serrate; peduncles axillary; one-flowered .- Native of Otaheite in the South Seas.

Apactis; a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla: four-petalled. Petals roundish, crenate, concave, unequal; two opposite broader. Stamina: filaments from sixteen to twenty. Pistil: germen superior; style one. ESSENTIAL CHARACTER. Corolla: four-petalled. Calix: none .---The only species known is,

1. Apactis Japonica .- A tree erect and very branching.

Apargia; a genus of the class Syngcnesia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix: common, imbricate, oblong; scales several, linear, parallel, unequal, longitudinal, incumbent Corolla: compound, imbricate, uniform ; corollets hermaphrodite, numerous, equal. Proper : monopetalous, ligulate, linear, truncate, five-toothed. Stamina: filaments five, capillary, very short. Anthera cylindric, tubular. Pistil: germen subovate. Style filiform, length of the stamina. Stigmas two, recurved. Pericarp: none. Calix: oblong, straight. Seeds : solitary, oblong, striated. Down sessile (in the central seeds somewhat striped) plumose ; rays chaffy beneath. Receptacle naked, subvillose.

linear, parallel, unequal scales. Down plumosc, subsessile, Receptacle naked, subvillose.----The species are,

1. Apargia Hispida. The whole calix upright; leaves lanceolate toothed, hispid, with forked bristles; scape oneflowered, naked .- It is very common in meadows and pastures, where it flowers in May; the flowers open at four in the morning, and close at three in the afternoon.

2. Apargia Hirtor. The whole calix upright, smooth: leaves toothed, rough with hairs that are undivided ; scape smooth, without any floral leaf; outer seeds without down .--The whole of this plant is much smaller than the first species. It is a native of Germany, Switzerland, France, and Spain, and is frequent on Hampstead-Heath, Barnes-Common, and other commons near London.

3. Apargia Danubialis. The whole calix upright, smooth; leaves toothed, smooth; scape one-flowered, almost naked. -It flowers in June, and is found in meadows on the islands in the Danube.

4. Apargia Tuberosa. Calix acute, hirsute; leaves runcinate, scabrous,-Native of meadows in Tuscany and the sonth of France.

5. Apargia Autumnalis. Stem branched, almost naked : peduncles scaly; leaves lanceolate, toothed, quite entire, smooth .-- Root perennial; florets yellow on both sides, the tubular part a little hairy. The flowers open at seven in the morning, and close at three in the afternoon; they appear from July until October. This plant is common in pastures; horses, goats, and swine are said to eat it, but cows and sheep to refuse it. Old English writers call it Yellow Devil's Bit; Small Hare's Hawk weed; or Small Hawk-weed with bitter roots.

6. Apargia Pyrenaïca. Peduncles scaly ; leaves lanceolate, with very few teeth ; calices villose, root-end bitten .- Root perennial, florets yellow. Found by Dr. Solander in the mountains of Lapland; and since that, in mountainous parts of the south of Europe, and both in Wales and Scotland. It flowers in July.

7. Apargia Taraxaci. Peduncles somewhat sealy at the top; leaves entire or pinnatifid, smooth; calix woolly; rootend bitten.

Aphanes ; a genus of the class Tctrandia, order Digynia, or class Monandria, order Monogynia .- GENERIC CHARAC-Calix: perianth one-leafed, tubular, permanent; TER. mouth flat, eight-parted. Corolla: none. Stamina : filaments four, erect, subulate, very small, placed on the month of the calix ; anthera roundish, or one, twin. Pistil : germen ovate; style filiform, the length of the stamina, inserted into the base of the germen; stigma headed. Pericarp: none. Calix: containing the seeds in the bottom, converging at the mouth. Seeds: ovate, acuminate, compressed, the length of the style. ESSENTIAL CHARACTER. Calix: eight-cleft. Corolla: none. Seeds: two, naked .- The only species is,

1. Aphanes Arvensis: Parsley Piert. An European annual plant, growing in fallow fields and dry pastures, and flowering from May to August. As a medicinc, the whole plant is to be made use of, and it is best when fresh gathered, in which state it is easy to obtain it, as it abounds in cornfields and dry gravelly places. A strong infusion of it is beneficial in the gravel, as it operates powerfully by urine, cleansing the kidneys and urinary passages from all sabulous concretions in a short time. It is likewise good in the janndice, and other complaints arising from obstructions of the liver or any other viscera; and many people fancy that it has the power of dissolving the stone in the bladder; but this is No medicine has ever yet been supposing too much. ESSENTIAL CHARACTER. Calix: subimbricate, with found to have that effect, and unhappily it is much to be

7

feared there never will; those substances being of too firm and compact a nature to be dissolved by any thing that the bladder can bear without being irreparably injured. Culpeper calls this plant a very good salad herb, and says it were well that the gentry would pickle it up as they pickle up samphire, for their use all the winter, because it is a very wholesome herb, and it may be kept either dried or in a syrup. He prescribes a drachm of the powder of it in white wine, to carry off zavel from the kidneys insensibly and without pain.

Aphyllanthes; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. Colix: glumes univalve lanceolate, several imbricate. Corolla: petalasis, ovate, spreading in the border; claws slender, erect, converging into a tube. Stamina: filaments setaceous, shorter than the corolla, inserted into the throat; antheræ oblong. Pisitil: germen superior, three-cornered, turbinate; style filiform the length of the stamina; sligmas three oblong. Pericarp: capsule turbinate, triangular, trilocular. Seeds: ovate. EssentTAL CHARACTER. Corolla: six-petalled. Filaments: inserted into the throat of the corolla. Capsule: superior; glume of the calix univalve, imbricate.....One species only is known,

1. Aphyllanthes Monspeliensis. Root creeping.—Grows wild in barren pastures and rocky places, about Montpellier and Nice.

Aphyteia; a genus of the class Monadelphia, order Triandria.—GENERIC CHARACTER. Calix: perianth monophyllous, semitrifid, funnel shaped, large, fleshy, erect, permanent. Corolla: rudiments of three petals growing to the divisions of the calix; or rather none. Stamina: filaments connate at bottom, short; anthera convex, cordate, striated. *Pistil:* germen inferior; style thickish, short; stigma threecornered, channelled. Pericarp: berry one-celled. Seeds numerous, nestling. ESSENTIAL CHARACTER. Calix: large, funnel-shaped, semitrifid. Petals three, inserted into the throat of the tube in the calix, and shorter than it.— The only known species belonging to this genus is,

1. Aphyteia Hydnora. A vegetable wilhout leaves, stem, or root, being parasitical, terrestrial, consisting of a fructification only.—The smell of the flower and ripe fruit is not unpleasant. The latter is much liked by foxes, and caten both raw and roasted by the Hottentots. This plant is parasitical at the root of *euphorbia*, and was first observed in the parched sandy plains at the Cape of Good Hope.

Apios. See Glycine, and Euphorbia.

Apium ; a genus of the class Pentandria, order Digyna:-GENERIC CHARACTER. Calix: nmbel universal, of fewer rays; partial of more. Involucer universal small, of one or more leaflets; partial, similar; proper perianth obsolete. Corolla: nniversal, uniform; floscules almost all fertile; proper petals roundish, inflex, equal. Stamina: filaments simple; anthera roundish. Pistil: germen inferior; styles reflex; sigimas obtuse. Pericarp: none. Fruit ovate, striated, splitting in two. Seeds: two, ovate, striated on one side, plain on the other. ESSENTIAL CHARACTER. Fruit ovate, striated. Involuce one-leafed. Petals: equal.----The species are,

1. Apium Petroselinum; Parsley. Stem-leaflets linear; involucels minute; stems round, smooth, striated; flowers yellow.—It is a biennial plant, cultivated for culimary use. Parsley roots are sometimes used in decoctions, and supposed to be aperient and diuretic, but liable to produce flatulencies. In distilling large quantities, two or three drachms of essential oil separate from two hundred pounds; the leaves, which are warmer but not so sweet as the roots, yield about ten drachms from the same quantity. The seeds are warmer and more aromatic than any other part, and are accounted to be

carminative, resolvent, and diuretic, and are recommended for destroying eutaneous insects in children. In distillation. three pounds yield above an ounce of essential oil. Parsley is said to be fatal to small birds, and is accused of causing epilepsies, or of increasing them where before existing, and also of injuring the eyes. A ponitice of the leaves is reported to be resolvent and discutient, if applied to glandular tumors: and also to be an efficacious remedy for the bites or stings of poisonous insects. A decoction of the leaves has been considered as excellent in cases of the stone. Independently of its uses at table, the seeds disperse flatulencies in the stomach, and relieve those who are troubled with the colic. A strong decoction of the roots is a powerful diuretic, and is excellent in obstructions of the viscera, and such disorders as arise therefrom; and when drank for some time, will bring away gravel and other sabulous concretions from the kidneys and bladder, and is very serviceable in the jaundice and dropsy. The distilled water of parsley, says Culpeper, is a familiar medicine with nurses, to give their children when they are troubled with wind in the stomach or belly. The leaves, laid to inflamed eyes, also are very efficacious; and when fried in butter, and applied to women's breasts, which are hard through the curdling of their milk, will give speedy relief; and also remove black and blue marks produced by blows or falls. The common and the curled, which is a variety of the common parsley, must be sown early in spring, and, if for medicinal use, should be thinly sown. They only require hoeing and weeding. It is sown by skilful persons in fields, about the end of February, for the use of sheep, and is a sovereign remedy to preserve them from the rot, provided they are fed twice a week for two or three hours each time. One bushel of seed will sow an acre of land.

2. Apium Graveolens; Smallage, or Celery. Stem-leaves wedge-shaped; corollas small and white. It is biennial, flowering in ditches and marshes, from July to September. The fresh roots, especially in their native watery places, are fetid, acrid, and supposed to be noxious. They lose the greatest part of their ill flavour, and become sweetish when dried, and in that state have been used for decoctions as aperients and diuretics. The seeds have been sometimes used as carminatives and aperients; they have a moderately strong grateful smell, and a warm bitterish taste. Culture corrects its noxious qualities, and renders it mild and esculent. The lower part of the stem and leaf-stalks blanched, by being covered up with earth, are eaten either raw, stewed, or boiled in soups, and are excellent antiscorbutics. A strong decoction of the roots operates by urine, and is good in fits of the stone or gravel : the seeds are of a warm carminative nature, and operate more powerfully by urine than any other part of the plant. Culpeper recommends the juice, with honey of roses and barley-water, as good to gargle within ulcerated sore throats; and says, that the seed kills worms, and sweetens a stinking breath. Smallage is a common weed by the side of ditches and brooks of water. The seeds should be sown soon after they are ripe, on a moist spot of ground ; and when the plants come up, they may either be transplanted into a moister soil, or hoed out, and left to remain six or eight inches asunder.

Aphuda ; a genus of the class Polygamia, order Monecia. —GENERIC CHARACTER. Calix: involucre common, univalve; valve ovate, concave, terminated by a very short point or leaflet; two-flowered, the inferior flower sessile in the short, glumaceous, linear, flat, vertical footstalks, on one of wi, ch sits the superior flower, on the other a very short indiment of a flower. Flower inferior, hermaphrodite, almost entirely lying hid between the footstalks. Calix : involucre proper, univalve; valcelet lanceolate, compressed, rigid, doubletoothed at the tip, smooth, embracing the flower with its margins beneath; opposite to the common involucre. Glume one flowered, two-valved; valvelets membranaceous, transparent, shorter than the involucre; the exterior navicular, gibbous on the back, keeled, contracted towards the tip, acuminate, the interior ventricose, somewhat sharp, smaller. Corolla: glume bivalve, membranaceous, extremely thin, transparent; valve exterior, navicular, compressed, smooth, hyaline, gibbous on the back, bifid, acute, awned below the tip, hid within the exterior valve of the calix, and shorter than it; the interior lanceolate, flat, acute, doubled together at each margin, the exterior rather longer. Nectary very small, twoleaved, truncate, rounded, hyaline. Stamina : filaments three, capillary. Antheræ linear, bifid on each side. Pistil: germen oblong, small. Styles two, capillary, upright, longer than the germen. Stigmas oblong, villose, spreading, protruded on each side from the flower. Pericarp : none. Corolla cherishes the seed, gapes, and drops it. Seed: ovate-oblong, compressed, smooth. Flower superior, smaller. Calix : glume two-flowered, two-valved ; valves lanceolate, broadish, flat, sharp, nervose, nearly equal; one floscule fe-male, the other male, or neuter. Corolla: of the female glume bivalve; valves membranaceous, hyaline; the exterior ventricose, cornered, sharp-pointed; the interior lanceolate, narrower, shorter, obtuse. Glume of the male bivalve ; valves lanceolate, membranaceous, hyaline; the exterior somewhat ventricose, sharp; the interior narrower, shorter. Nectary in both as in the inferior flower. Stamina of the male, as in the inferior flower. Pistil of the female as in the inferior flower. Pericarp and seed of the female, as in the inferior flower. ESSENTIAL CHARACTER. Calix: glume common, bivalve; female floret sessile, males peduncled. Male Calix: none. Corolla: bivalve. Stamina: three. Female calix : none. Corolla : bivalve. Style : one. Seed : one, covered .---- The species are,

1. Apluda Matica. Leaves lanceolate; all the flowers awnless.-Native of India.

2. Apluda Aristata. Leaves lanceolate; male flowers awnless; one at the end sessile and awned,---Native of India.

3. Apluda Zeugites; *Mountain Reed Grass*. Leaves ovate; male flowers awnless; one at the end sessile and awned.—This curious little plant is a native of Jamaica.

 Apluda Digitata. Spikes digitate ; flowers pointing one way.—A lofty East Indian grass.

Apocumumi; a genus of the class Pentandria, order Digynia—CEXPRETC CHARACTR. Cality: perianth one-leafed, five-parted, acute, short, permanent. Carolla: monopetalous, bell-shaped, semiquinquefid (i divisions revolute. Neetary of five glandular oval corpuscles, surrounding the germen. Stamitar: filamentis very short; anthera oblong, ereet, acute, bind at the base, converging. Pistil: germen two, ovate; styles short; stigma roundish, bind at the tip, nunricate, gloed to the antherz. Periarp: fellicles two, long, acuminate, one-valved, one-celled. Stedis: numerous, very small, rowned with a long down. Receptacle: subulate, very long, rough, free. ESEENTAL CHARACTER. Corolla: belishaped. Nectaries five, alternate with the stamina—The first three species are propagated by parting the roots in light dry soil. The fourth will bear the open air in a warm situation and dry soil: all the rest are tender, and must be constantly kept in a hot-house, plunged into a tam-bed. They arely seed in England, but are an ornament at all seasons,

retaining beautiful green leaves throughout the year. The species are,

1. Apocynum Androssemifolium; Tutsan-tened Dog? Bane. Stem straightish, herbaceous; leaves ovate, smooth on both sides; eynes terminating; root perennial; corolla white.—This plant is said to kill the flies that alight upon it. The Canadian French say, that it is poisonous to some persons, but harmless to others. Kahn relates, that the saw a soldier whose hands were blistered all over, merely from plucking it; whereas he frequently rubbed his own bands with the juice, without feeling any inconvenience. Native of Virginia and Canada; flowering from July till September.

2. Apocynum Caunabinum; *Hemp Dog's-bane*. Stem straightish, herbaceous; leaves oblong; cymes lateral, longer than the leaf.—Native place and flowering-time, same as No. 1.

3. Apocynum Hypericifolium; St. John's Wort-leaded Dog's bane. Stem straightish, herbaceous; leaves oblong, cordate, smooth; cymes shorter than the leaf; root perenniaj; flower smill, scentles, and white.—The whole plant is smooth, and abounds in milk. Flowers in June and July. Native of North America.

4. Apocynum Venetum; Spear-leaved Dog's-bane. Stem straightish herbaceous; leaves ovate-lauceolate; root pereunial.—It varies with purple and with white flowers, which appear in July and August. Found in the Adriatic Islands.

5. Apocynum Minuthm; Petty Dog's-bane. Stem prostrate; leaves hastate.-Found at the Cape of Good Hope.

6. Apocynum Filiforme; *Thread-leaved Dog's bane*. Stem prostrate, herbaceous; leaves filiform; flowers umbelled.— Native of the Cape of Good Hope.

 Apocynum Frutescens; Shrubby Dog's-bane. Stem erect, shrubby; leaves lanceolate, oval; corollas aente, vilose at the throat.—Native of the East Indies, Ceylon, and the coast of Guinea. Flowers small, in losse bunches, and of a purple colour.

8. Apocynum Reticulatum; Net-leared Dog's-bane. Stem twining, perennial; leaves ovate, veined.—The leaves of this species are of a dark and very shining green, with a beautiful uet of milky veins.—Native of the East Indies, and Cochinchina.

 Apocynnm Lineare; Linear-leaved Dog's-bane. Stem twining, herbaceous; leaves linear, flat; umbels axillary, compound.—Both this and the next species are natives of the Cape of Good Hope.

10. Apocynum Triflorum ; Three flowered Dog's bane. Stem twining, herbaceous ; leaves lanceolate ; umbels axillary, two or three flowered. See No. 9.

11. Apocynum Juventas; Renovating Dog's-bane. Stem twining, shrubby; leaves ovate, hairy; reaemes dichotomous; flowers greenish yellow colour.—A native of Cochin-china, where the country physicians imagine the root of this plant to refresh the animal spirits to such a degree, as by long continued use to endow old age with all the strength and vigour of youth.

12. Apocynum Alterniflorum; Alternate-flowered Dog'sbane. Stem climbing, shrubby; leaves ovate, acuminate, smooth; axils alternate, umbelliferous; flowers pale and scentless.--Native of the islands near Canton in Cochin-china.

13. Apocynum Africanum; *African Dog's-bane*. Stem suberect, shrubby; leaves ovate-oblong; peduncles two or three-flowered; stem eight feet high; flower pale.—Found in a sandy plain upon the coast of Zanguebar in Africa.

14. Apocynum Scandens; Climbing Dog's-bane. Leaves oblong, cordate, stiff; flowers lateral; stem shrubby, twining, APP

abounds near Carthagena, in New Spain, and flowers in August and September; it has smooth shining green leaves.

15. Apocynum Nervosum; Nerve-kaied Dog's-hone-Leaves ovate, nerved; cymes lateral; folwers yellow, large; tabe very long; stem shrubby, climbing.—Has a climbing woody stalk, with bright yellow flowers. Native of New Spain, near Carthagena.

16. Apocynum Cordatum; Heart-leaved Dog's-bane. Leaves oblong-cordate, pointed, sessile; flowers lateral; stem climbing .- This and the following species are natives of Vera-Cruz, in New Spain : they both have climbing stalks, and will mount the highest trees ; even in English hot-houses they have ascended plants twenty feet high. The down of these plants is greatly esteemed in France, for stuffing easy chairs, and making warm light quilts for persons afflicted with the gout ; hence, in the south of France, where it will thrive and produce seed in the open air, there are many plantations of these plants for the sake of the down. As these plants are plentiful in the uncultivated parts of Jamaica, abundance of the down might be procured from thence; and if it were only to become fashionable, would soon become vendible in England. They require no cultivation ; the only trouble would be, to collect the down, which on some of the large podded sorts is produced in great quantities.

17. Apocynum Villosum; Villose.flowered Dog's-bane. Leaves cordate, smooth; flowers villose, lateral, or long peduncles; stem climbing. See the foregoing species.

Aponogeton ; a genus of the class Dodecandria, order Tetragynia .- GENERIC CHARACTER. Calix : none, except a spathaceous scale, surrounding the outer side of the flower : simple, sessile, ovate, obtuse, entire, upright, smooth, coloured. Corolla: none. Stamina: filaments eleven to nineteen, in the upper flowers fewer, inserted between the spathe and the capsules, subulate, smooth, white, many times shorter than the spathe. Pistil: germina usually four, seldom three or five; styles none; stigmas subulate, bent in. Pericarn; capsules four, seldom three or five, ovate, subulate, acute, gibbous on the outside, flat on the inner side, smooth, onecelled. Seeds : in each capsule three, affixed to the base of it, sessile, obovate, very blunt, subcompressed, smooth. Es-SENTIAL CHARACTER. Calix: an ament. Corolla: none. Capsule : three-seeded .. These plants belong to the greenhouse or cape-stove, and may be increased by offsets from the bulbs .---- The species are,

 Aponogeton Monostachyon; Single-spike Aponogeton.
Spike simple; leaves cordate-oval.—Common in fields that are flooded for rice in the East Indies.

2. Aponogeton Distachyon; Broad-kened Aponogeton, Spike bifd; leaves linear, oblong, floating; bractes entire; flowers many stamined.—Found at the Cape of Good Hope, It bears while flowers almost all the year round; they have a very fragrant smell.

 Aponogetum Angustifolium; Narrow-leaved Aponogeton. Spike bifd; leaves linear-lanceolate, erect; bractes two-parted; flowers six-stamined—Flowers almost all the year.

Apple, Custard, See Annona. Apple, Love: See Solanum, Apple, Mad. See Solanum, Apple, Pine. See Bromolla. Apple, Purple. See Annona. Apple, Sour. See Annona. Apple, Thren. See Datura. Apple, Itree. See Arnona. Apple, Itree. See Annona. Apple, Water. See Annona. Apple, Water. See Annona. Apple, Solar. See Prunus. 10, Aquarta; a genus of the class Tetrandria, order Monogria.-GENREIC CHARACTER. Caliz: perianth monophyllous, permanent; tube bell-shaped; limb subquadrifd, expanding; two opposite divisions obsolete. Corolla: mouopetalous, rotate; tube very short; limb quadrifd; divisions lincar, widely spreading. Stamina: filaments short; anthera erect, very large, linear. Pistil: germen ovate; style filiorm, declined, the length of the corolla; stigma simple. Pericarp: herry globular, one celled. Seeds: very many.compresed. ESSENTAL CHARACTER. Caliz: bellshaped. Corolla: wheel-shaped, with finear divisions. Berry: mny seeded.----One species only is known, viz.

1. Aquartia Aculeata. A perennial aculeate plant, with a white inodorous flower. In St. Domingo, of which Jacquin says it is a native, it flowers and bears ripe fruit in October. Native of South America.

Aquilaria ; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, permanent; tube bell-shaped; border five-cleft; clefts ovate, acute, flat, spreading. Corolla: none. Nectary one-leafed, pitcher-shaped, length of the tube of the calix, half five-cleft; clefts bifid, obtuse. Stamina : filaments ten. alternate to, and shorter than, the clefts of the nectary. Anthere oblong, versatile. Pistil: germen ovate, on a very short pedicle, superior. Style, none. Stigma simple. Pericarp: capsule on a very short pedicle, obovate, woody, twocelled, two-valved; with the partition contrary and bipartite. Seeds: solitary, oblong. ESSENTIAL CHARACTER. Calix: five-cleft. Corolla : none. Nectary: pitcher-shaped, half five-cleft, with bifid clefts. Capsule : superior, woody, twocelled, two-valved. Seeds : solitary .---- The only species discovered is.

1. Aquilaria Ovata. Leaves alternate, ovate, mucronate. -This is a huge tree, the wood of which is white and inodorous; it has the name of lign-aloes, or wood alors, from its bitter taste. No part of this plant is poisonous; the aroma which it produces arises from a disease; and the perfume made of the wood is bighly esteemed by the oriental nations. From its bark the common writing paper of the Chinese is made. The perfume is said to be good in vertigo and palsy; the powder restraius vomiting and fluxes, and particularly lienteries, by its astringent and corroborating power. Three kinds of this wood are used in the shops; they are called, Calambac, Common Lign-Aloes, and Calambour. The first is the finest and most resinous, the last is almost a mere chip, and the second a middling kind. They all have the property of acting as cordials, and strengthening the stomach. but in different degrees, and are not much used.

Aquilegia: a genus of the class Polyandria, order Pentagynia. GENERIC CHARACTER. Calix: none. Corolla: petals five, lanceolate, ovate, flat, spreading, equal. Nectaries five, equal, alternate with the petals, each horned, gradually broader upwards, with an oblique mouth, ascending outwardly, annexed inwardly to the receptacle, produced below into a long attenuated tube, with an obtuse top. Stamina : filaments thirty to forty, subulate, the outer ones shorter : antheræ oblong, erect, the height of the nectaries. Pistil: germina five, ovate-oblong, ending in subulate styles, longer than the stamina : stigmas erect, simple. Chaffs ten, wrinkled. short, separate, and involving the germina. Pericarp: capsules five, distinct, cylindric, parallel, straight, acuminate, one-valved, gaping from the tops inward. Seeds : very many. ovate, keeled, annexed to the gaping suture. ESSENTIAL CHARACTER. Caliz: none. Petals: five. Nectaries, five, horned between the petals. Capsule: five, distinct.—These plants should always be raised from seeds, since the old plants 2 G

are spit to decay. Sow them in a nursery hed in Angust or September; they will appear in spring, and in May should be transplanted, eight or nne inches every way apart, upon heds of good fresh undunged earth, where they will flower in antumn. To insure good flowers, let them flower in the nursery, and then select the best for transplantation; but the best way is to sow fresh seeds every year. Take care that no seeds of the plain sorts are mixed with the variegated kinds, or they will cause the whole to degenerate.— The species are,

1. Aquilegia Viscosa; Clammy Columbine. Stem almost naked, with viscid hairs, aud one or two flowers; leaves subtrilobate. Root perennial; stem a foot high.—Native of the south of France, and the mountains of Piedmont.

2. Aquilegia Vulgaris; Common Columbine. Nectaries blue, yellow at the tip, and incurved .- In a wild state, the flowers are usually blue; red and white is common about Berne in Switzerland, and also in Norfolk. Double flowers have been found in the Pays de Vaud. Native of most parts of Europe, in woods, hedges, and bushes. It is perennial, and the flowers vary much by culture; with us they appear in June, and are blue, white, red, purple, flesh-coloured, ashcoloured, chesnut-coloured, and striped or variegated blue and purple, blue and white, and red and white. The root, herb, flowers, and seed, are recommended as medicines upon good authority, but the plant itself is of a suspicious tribe; and Linneus says, that children have lost their lives by an over-dose of it. The sensible qualities of the seeds, says Lewis, afford little foundation for their supposed virtues in the jaundice, measles, and small-pox, as they only differ from the cold seeds in being somewhat more mucilaginous, with a disagreeable relish. The virtues ascribed to a tincture of the flowers, as an antiphlogistic, and for strengthening the gums, and deterging scorbutic ulcers in the mouth, are better founded. The tincture is made with an addition of the vitriolic acid, and differs little from our tincture of roses. Notwithstanding this, Hill observes, that the seeds operate by sweat and urine, open obstructions of the viscera, and are good in the jaundice, in fevers, and in the small pox and measles, to throw out the pustules. A decoction of the leaves is good for sore throats, and a tincture of the flowers in brandy is recommended by Tournefort as an excellent gargle for scorbutic affections of the gums. Culpeper informs us, that the Spaniards eat a piece of the root in a morning fasting, many days together, when troubled with the stone.

3. Aquilegia Alpina; Alpine Columbine. Nectaries straight, shorter than the lanceolate petal; root biennial; corolla blue...-Flowers in May and June, and is said to be found in Westmoreland, but is a native of the Swiss and Savoy Alps.

4. Aquilegia Canadensis ; Canadian Columbine. Nectaries straight; stamina longer than the corolla ; root perennial; corolla red without, aud yellow within.—Native of North America; flowering in April, and ripening seeds in August. It flowers a month sooner than the other sorts.

 Aquilegia Viridiflora; Green-flowered Columbine. Nectaries straight, thickened, and a little bent in at the tip; stauma nearly equal to the corolla; root peremnial.—It flowers in May, ripens seed in July, and was found by Professor Pallas m Siberia.

Aquilicia. See Leca.

Arubis ; a genus of the class Tetradynamia, order Siliquosa. —GENERIC CHARACTER. Caliz: perianth four-leaved, decidnous; leaflets from parallel converging; two opposite larger, ovale-oblong, acute, a little prominent at the base,

gibbose, concave; the two others linear, erect. Corolla: four-petalled, cruciform; petalls spreading, ending in claws the length of the calix. Nectaries four; each from a little vcale, within the bottom of the calix, four whice as long; an there cordate, rect. Pistl; germen columnar, the length of the stamina; style none; sigma obluse, entire. Pericarp silique: compressed, very long, linear, unequal, with swellings at the seed; valves almost the length of the partition. Seeds very many, roundish, compressed. ESSENTIAL CHARACTER. Nectareous glands four; ione within each leaflet of the calix, like a refex scale.—They are all hardy plants, producing seed plentifully, thriving in any situation, or permitting them to scatter themselves.—The species are,

1. Arabis Alpina; *Alpine Wall-cress*. Leaves stem-clasping, toothed; perennial.—Native of the Alps, and other European mountains, upon rocks, and in woods and caverns.

2. Arabis Lucida; Shining Wall-cress. Leaves stem-clasping, shining; perennial.—A native of Hungary.

3. Arabis Grandiflora; Great-flowered Wall-cress. Stem naked; perennial, with a white corolla.—It is a native of Siberia.

 Arabis Thaliana; Common Wall-cress. Leaves petiolate, lanceolate, quite eutire.—This flowers in March and April, seeds in May, and is common upon walls, and among corn in sandy soils.

 Arabis Bellidifolia ; Daisy-leared Wall-cress. Leaves subdentate, the radical ones obovate, those of the stem lanceolate ; root perennial ; the flowers confined, inodorous, appearing in May and June.—Native of moist places, near the Alps, and in Austria.

6. Arabis Lyrata; Lyrate leaved Wall-cress. Leaves smooth, the radical lyrate; the stem-leaves linear; root annual; flower white—Native of North America.

7. Arabis Hispida; Rough Walleress. Leaves wedge-shaped, sublyrate, hispid; the stem-leaves half stem-clasping, lanceolate; siliques stiff, ancipital; root perennial; petals white.—Native of the south of France, Switzerland, and Austria: observed also upon Mont Saleve in Savoy, near Geneva, by Mr. Ray, and upon St. Vincent's rocks near Bristol: it flowers in May.

8. Arabis Halleri; *Haller's Wall-cress*. Stem-leaves sublyrate, those on the branches lanceolate, gashed; stem erect, six inches high.—Native of Germany, Carniola, and Piedmont.

9. Arabis Canadensis; Canadian Wall-cress. Stem-leaves lanceolate, toothed, smooth; flowers pendulous,-Native of North America.

10. Arabis Pendula; *Pendulous Wall-cress*. Leaves stemclasping; siliques ancipital, linear; calices subpilose; stem nearly a foot high; corolla white.—A native of Siberia.

11. Arabis Turrita; Tower Walkeres. Leaves stemclasping : siliques bending down, flat, linear; calices subrugose; root biennial; stem from nine inches to one and two feet high.--Native of Austria, Switzerland, and Dauphinyy It flowers with us in June, and grows in abundance upon the walls of St. John's College at Cambridge, and of Magdalen College at Oxford.

12. Arabis Saxatilis. Stem erect; leaves stem-clasping, lanceolate, toothed; siliques the length of the raceme; root annual; umbel of flowers terminating, nodding; stem a palm or a palm and a half high.—Found upon rocks, in most parts of the south of Europe.

13. Arabis Scabra, Root-leaves roundish, scabrous,

toothed; stem-leaves embracing, hirsute; stem six inches high; petals milky white.--Native of the south of Europe. 14. Arabis Serpyllifolia. All the leaves elliptic, quite en-

tire; stem flexuose; biennial.—A native of Dauphiny. 15. Arabis Recta. Stem straight; leaves rectangularly toothed, and sessile; siliques from erect spreading.—The flowers are white: it grows upon rocks and walls about Grenoble in France.

Arach. See Atriplex.

Arachis ; a genus of the class Diadelphia, order Decandria. GENERIC CHARACTER. Calix: perianth two-parted, gaping; upper lip ovate, semitrifid; the intermediate division rather larger, emarginate; under lip lanceolate, concave, acute, rather longer. Corolla: papilionaceous, resupine. Banner roundish, flat-deflex, very large, emarginate, longer than the calix; wings free, subovate, shorter than the bauner; keel subulate, incurved, the length of the calix, very slightly bifid at the base. Stamina : filaments ten, all united at the bottom, subulate, the length of the keel; anthera alternately roundish and oblong. Pistil : germen oblong ; style subulate, the length of the germen, ascending ; stigma simple. Pericarp: legume ovate-oblong, columnar, valveless, gibbous, torulose, veined, coriaceous, one-celled. Seeds : two, oblong, obtuse, gibbous, truncate at one end. ESSENTIAL CHARACTER. Calix: bilabiate. Corolla : resupine. Filaments connected, legume, gibbous, torulose, veined, coriaceous. The seeds must be sown upon a hot-bed in the spring, and kept under glasses till the middle of June, when, if the weather prove warm, they may be gradually exposed to the air. It multiplies very fast in hot countries .---- The species are,

1. Arachis Hypogaa; Common Earth or Ground Nuct. Stem herbaccous, procumbent. Stem herbaccous, annual, three feet high; flowers gold-coloured.—Native of the East Indies, and much cultivated in China and Cochin-china. All the European settlements of America now abound with this plant: in South Carolina the inhabitants roast the nuts, as they are called, and use them for chocolate. In the eastern countries they are a substitute for almonds, and abound in a thin limpid oil, nuch used for lamps in Cochin-china, where, though inferior in flavour, it supplies the place of oil of olives for culinary use.

2. Arachis Fruticosa; Shrubby Earth or Ground Nut. Stem shrubby, upright.— Flowers of a yellow colour; native of the East Indies, in Tranquebar, and the island of Ceylon.

Availa; a genus of the Pentadrina class, order Pentagynia. GENERIC CHARACTER. Caliz: Involucer very small, of a globular umbellule. Perianth five-toothed, very small, superior. Corolla: petals five, ovate, acute, sessile, reflex. Stamina: filaments five, subulate, the length of the corolla; anthera roundish. Pistil: germen roundhis, inferior; styles very short, permanent; stigmas simple. Pericarp: herry roundish, striated, crowned, five-celled. Seeds: solitary, hard, oblong. ESSENTIAL CHARACTER. Flowers in an umbellule, with an involver. Caliz: five-toothed, superior. Corolla: five-petalled. Berry: five-seeded.——The species are,

 Aralia Spinosa; Thorny Aralia, or Angelica Tree. Arborescent; stem and leaves prickly.—Bisse eight or ten feet high, and is a native of Virginia. It is propagated by seed, which is easily procured from North America. Sow them in pots of light earth as soon as they arrive, and plunge them during autumn either in an old tab bed or a warm border, and cover them with pease-haulun, if the winter be severe. When they appear, water and weed, but do not disturb them the first sesson. They are also casaily increased by the roots.

2. Aralia Pentaphylla; Five-leaved Aralia, Arboreus

prickly; leaves quinate.-Native of Japan; flowering in May and June.

ARB

3. Aralia Chinensis; Chinese Aralia. Shrubby; stem and petioles prickly; leaflets unarmed, villose.—Native of Malabar, found in China and Cochin-china.

 Aralia Japonica; Japanese Aralia. Shrubby; leaves lobate; stem unarmed, six feet high; flowering in November and December, has no involucre, and is a native of Japan.

5. Aralia Racemons: *Berry-bearing Aralia*. Stem leafy, herbaceous, smooth.—Height three or four feet. The French and Indians of Canada eat the berries, and use both the leaves and toots as salads and potherbs. This and the next sort should have their seeds sown soon after they are ripe in autom, and weeded when they appear during the summer; and in the next autumn they may be transplanted where they are to remain. The roots also may be parted in autumn, and planted well asunder; they are hardy plants, and will grow any situation. The flows are are of a main.

6. Aralia Nudicaulis; Naked-stalked Aralia. Stem naked; leaves in pairs, ternate.—For the height of the stalk, colour of the flower, and mode of propagation, see No. 5.

7. Aralia Cordata; *Heart-leaved Aralia*. Herbaceous; stem angular, unarmed; leaves simple, heart-shaped.--Native of Japan.

8. Aralia Octophylla; Digitate-leared Aralia. Stem arboreous, unarmed; leaves digitate, with eight leaflets; panicle umbelled.—A tree ten feet high, with a yellow flower sprinkled with red. It is cultivated in Cochin-china, where it is a native, and used medicinally in dropsical cases.

 Aralia Palmata; Palmate-leaved Aralia. Stem scandent, prickly; ieaves five-lobed; umbels simple, lateral; stem shrubby; flower white.—Native of China; where the bark is employed in cutaneous and dropsical disorders.

Araticu Ponhe, or Muricata. See Annona.

Arbor Crepitans. See Hura.

Arbor Vitæ. See Thuja.

Arbutus; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. Caliz: perianth five-parted, obtuse, very small, permanent. Corolia: monopetalous, oate, fattish at the base, diaphanous, with a quinqueid month; divisions obtuse, revolute, small. Stanina: filaments ten, subulae, swelling, very slender at the base, affixed to the edge of the base of the corolla, and half the length of it; anthere slightly bifd, nodding. *Pisiti*: germen sub-globalar, on a receptacle marked with ten dots; style cylindric, the length of the corolla; stigma thickish obtuse. *Pericary:* berry rounded, thy-celled. Steeds: small, how. ESSENTIAL CHARACTER. Caliz: five-parted. Corolla: oxtet, diaphanous at the base. Caravale: five-celled.—The species are.

1. Arbutus Unedo; Common Strawberry Tree. Stem arboreous; leaves oblong lanceolate; panicles, smooth, nodding. -It rises to the height of twenty or thirty feet, and forms a great ornament, both with its flower and fruit, when other trees are past their beauty. There are two varieties, the red and double-flowered strawberry tree; the flower of the common sort is white. The best way of propagating them is from seed. Gather the fruit when perfectly ripe, which is from the middle of November till the end of December, and mix it with dry sand to preserve it until the time of sowing. The surest way of raising the plants, is to sow the seed in pots in December, plunging them into an old bed of tanner's bark which has lost its heat, and covering the bed with glasses. If the seeds be good, the plants will come up in the beginning of April, and must be often, but sparingly watered, and kept free from weeds. During the first summer shade them from the heat of the day, and in the beginning of Octoearth ; when they are two or three feet high, in April, shake gravely complaints, although they are not noticed by medithem out of the pots, and replant them upon the open ground cal practitioners. Whatever may be the ultimate decision as where they are to remain. This tree delights in a moist soil, to its medical properties, the whole plant is certainly very seldom producing much fruit in a dry ground.

2. Arbutus Laurifolia; Laurel-leaved Strawberry Tree. Stem arborescent; leaves oblong, acuminate to both ends, sharply serrate, smooth; racemes axillary, one-ranked, sessile, solitary .-- Native of North America.

3. Arbutus Andrachne; Oriental Strawberry Tree. Stem arboreous; leaves oval, quite entire, and serrate; panicles pubescent, erect .-- A middle-sized tree. Common in Crete, and between Aleppo and Antioch ; it has also been seen near Athens, and in the fruit-market at Smyrna,

4. Arbutus Ferruginea; Long-flowered Strawberry Tree. Stem arborescent; leaves oblong, obtuse, smooth, quite entire; racemes terminal .- Found in America.

5. Arbutus Mucronata; Pointed-leaved Strawberry Tree. Stem shrubby; leaves alternate, ovate, serrate, pointed; peduncles axillary, one-flowered. This a very stiff shrub, found in Terra del Fuego.

6. Arbutus Pumila; Dwarf Strawberry Tree. Stems diffused; leaves alternate, distich, oblong, quite entire; flowers lateral, solitary .-- A low shrub with nodding flowers ; a native of Terra del Fuego.

7. Arbutus Acadiensis ; Acadian Strawberry Tree. Stems procumbent; leaves ovate, subserrate; flowers scattered; berries many-seeded .- It never produces fruit in England, but grows naturally upon swampy land in Acadia, and other northern parts of America.

8. Arbutus Alpina; Alpine Arbutus. Stems procumbent; leaves rugose, serrate .- This is a very common plant in Sweden, Denmark, Switzerland, Dauphiny, Savoy, Siberia, and many of the highlands of Scotland; flowering in May in a dry barren soil.

9. Arbutus Uva Ursi; Trailing Arbutus, or Bearberry. Stems procumbent ; leaves quite entire .- This shrub abounds in most parts of the continent, and in heathy, mountainous, and rocky places, throughout the highlands; also, near Hexham, in Northumberland. The leaves have been greatly celebrated as a remedy in stony and gravelly complaints. The dose is half a drachm of the powder of the leaves, every morning, or twice or thrice daily. De Haen relates, after great experience of this medicine in the hospital of Vienna, that suppurations, though obstinate and of long continuance, in the kidneys, ureter, bladder, urethra, scrotum, and perinæum, where there was no venereal taint, nor marks of calculi, were in general completely cured by'it; that even of those who had a manifest calculus, several found permanent relief, so that long after the medicine had been left off, they continued free from pain or inconvenience in making water, though the catheter shewed that the calculus still remained: that others, who seemed to be cured, relapsed on leaving off the medicine, and were several times successively relieved by again repeating its use; while others obtained from it only temporary and precarious relief, the complaints being often as severe during the operation of the medicine as when it was not used. The trials made of it in this country have not answered the general expectation. Some have had their complaints entirely removed, others have thought them aggravated by it. But though it frequently fails of performing a cure in those dreadful maladies, stone, gravel, &c. it many times alleviates the symptoms, and procures intervals of ease when all other means are ineffectual; which is a matter of no small moment, and certainly entitles it to some notice. It is probably not superior upon the whole to other vegetable astringents, some of which

ber transplant them singly into small pots filled with light have long been successfully used by the country people in serviceable in dyeing an ash-colour, but particularly in tanning leather. In this view it well deserves attention in those countries, the Highlands and Western Islands of Scotland for instance, where whole mountains are covered with this trailing shrub, and they have scarcely timber sufficient for their economical purposes. The berries are food for grouse and other game.

10. Arbutus Thymifolia; Thyme-leaved Arbutus. Stems procumbent; leaves oval, acute, obscurely serrate, strigose underneath; flowers axillary, eight-stamined.-Very abun-dant in the swamps of North America, where the berries are used for tarts and other kinds of pastry, for which purpose the London confectioners import and employ them ; but they are inferior to cranberries of our own growth. Great quantities of them preserved are exported to the West Indies, and all parts of Europe.

Arbutus, Trailing. See Epigea. Archangel. See Lamium. Archangel, Brown-leaved. See Melittis. Archangel, Yellow. See Galcopsis. Archangelica. See Angelica.

Arctium : a genus of the class Syngenesia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix : common, globular, imbricate; scales lanceolate, ending in long subulate prickles, reflex and hooked at the end. Corolla: compound, tubular, uniform; corollula hermaphrodite equal. Proper : monopetalous, tubular; tube slender, very long; limb ovate, quinquefid ; divisions linear, equal. Stamina : filaments five, capillary, very short; anthera cylindric, tubular, the length of the corolla, five-toothed. Pistil: germen oblong, with a villose top; style filiform, longer than the stamina; stigma bifid, reflex. Pericarp: none. Calix: converging. Seeds: solitary, vertically pyramidal, with the two opposite angles obliterated, gibbous on the outside; down simple, shorter than the seed. Receptacle : chaffy, flat ; chaffs seta-ESSENTIAL CHARACTER. Calix: globular; the ceous. scales furnished at the end with inflected hooks .-- These plauts are readily increased by seeds, but will not flower till the second year, and the roots decay when the seeds are per--The species are, fected .---

1. Arctium Happa; Common Burdock, Burr, or Clotburr. Leaves cordate, unarmed, petioled ; root biennial ; stem three feet high; corolla purple, with a white tube .- It is very common by road-sides, on rubbish, and ditch banks, throughout Europe; flowers in July and August, and also abounds in Japan. In England, few animals except the ass will touch it; birds feed upon the seeds; and snails, slugs, and some sorts of caterpillars, on the leaves. Boys catch bats by throwing the prickly heads up into the air. The stems are eatable, if stripped of their rind before the flowers appear, either boiled or raw, with oil and vinegar. Some excellent physicians think a decoction of the root equal if not superior to that of sar-. saparilla. Two ounces of the dried root are boiled in three pints of water till one pint is wasted, and a pint or more of this liquid is taken warm every day. A strong infusion of the roots operates powerfully by urine, aud is good in the jaundice and dropsy. The decoction above mentioned is also serviceable in the gravel, stone in the kidneys and bladder, and venereal disorders; also for consumptive and asthmatical habits. The roots are said to be sudorific, and useful in fevers ; but its virtue in operating by urine is its greatest value. The herb being burnt green between the time of

flowering and seeding, in a hole made in the ground, without | hermaphrodites none; - in the females solitary, roundish, vilsuffering the flame to escape, three pounds of the ashes produced sixteen ounces of very white alkaline salt, as good as the best potash. There are many varieties of this common plaut, differing in colour, and size, and smoothness or woolliness of the heads. The most remarkable of which is the Woolly-headed Burdock, which differs only in having the leaves whiter beneath, the heads more compact, and the florets of a bright red colour, but principally in having the calix all over beautifully netted with a fine down.

2. Arctium Personata ; Cut-leaved Burdock. Leaves decurrent ciliate-spiny ; root-leaves pinnate ; stem-leaves oblong ovate; root biennial, black, woody .- Flowers in July and August : native of Switzerland, Austria, Silesia, and Siberia. 3. Arctium Carduelis. Leaves pinnatifid, prickly; root

perennial .- Found in the mountains of Upper Carniola and Silesia.

Arctopus ; a genus of the class Polygamia, order Dircia. -GENERIC CHARACTER. Male Calix: umbel universal, iong, unequal ; partial shorter, more abundant. Involucre universal, five-leaved, short; partial, five-leaved, the length of the umbellule. Perianth: five-parted, very small. Cotolla: universal, uniform; proper petals, five, entire, oblong. Stamina: filaments five, setaceous, longer than the corolla : antheræ simple. Pistil : germen none ; styles two, setaceous, longer than the stamina ; stigmas simple. Pericarp : abortive. Female, or Androgynous, on a distinct plant. Calix: umbel partial, with sessile floscules. Involucre partial, one-leafed, four-parted, spreading, spiny at the edge, many-Corolla : proper of the disk male, flowered, very large. several as in the male; of the ray female, four pentapetalous. Stamina : to the males of the disk as in the male. Pistil: to the females, germen subulate, hispid, under the receptacle of the floscule; styles two, reflex, permanent; stigmas simple. Pericarp : none. Involucre converging with spines. Seeds to the females solitary, cordate, acuminate, bent ontward, hispid above, bilocular, the size of the involucre. ESSENTIAL CHARACTER. Male umbel, compound. Invo-lucre five-leaved. Corolla: five-petalled. Stamina: five. Pistil: two abortive. Androgynous, umbel simple. Involucre, four-parted, spiny, very large, containing very many male floscules in the disk, and four female ones in the ray. Male petals, five. Stamina: five. Female petals, five; styles two. Seed one, bilocular, inferior. --- The only species known is,

1. Arctopus Echinatus; Prickly-leaved Arctopus. A handsome plant from the Cape of Good Hope.

Arctostaphyllos. See Vaccinium.

Arctotheca. See Gorteria and Arctotis.

Arctotis; a genus of the class Syngenesia, order Polygamia Necessaria .- GENERIC CHARACTER. Calix: common, roundish, imbricate; lower scales more lax, subulate; middle ovate; inmost oblong; scariose, rounded and concave at the end. Corolla: compound radiate; corollules hermaphrodite, very many in the disk. Females ligulate, near twenty, longer than the diameter of the disk. Proper of the bermaphrodites funnel-shaped ; border quinquefid ; ends reflex, equal; of the females ligulate, lanceolate, very finely three-toothed; tube very short. Stamina of the hermaphrodites : filaments five, capillary, very short ; antheræ eylindric, tubular, five-toothed, the length of the corolla. Pistil of the hermaphrodites-germen scarcely visible; style cylindric, a little longer than the corolla; stigma simple ;---of the females, germ ovate, four-cornered, villose, crowned with its proper calvele ; style filiform ; stigmas ovate, oblong, thickish, erect. Pericarp : none. Calix : unchanged. Seeds in the 10.

lose, crowned with a calvcle usually of five leaves; leaflets ovate, spreading. Receptacle : villose or chaffy, flattish, ESSENTIAL CHARACTER. Receptacle, villose or chaffy. Down, with a five-leaved crown. Calix: imbricate, with scales scariose at the end. All the plants of this genus are natives of the Cape of Good Hope, and may be taised from seed sown in a warm border of light earth in the middle of April, and may also be propagated by cuttings or slips from the roots, in which way they should be often renewed. Some of them require to be sheltered in the green-house during winter. * Receptacles villose.

ARD

1. Arctotis Calendulacea; Marygold-flowered Arctotis. Radiant florets, twelve-fold nearly entire. There are several varieties of this species; they are all natives of the Cape of Good Hope,

2. Arctotis Serrata. Radiant florets barren ; leaves lanceolate, undivided, tooth-serrate; corolla yellow.

3. Arctotis Tenuifolia. Radiant florets barren; leaves linear, undivided, naked. Perennial.

4. Arctotis Grandiflora; Great-flowered Arctotis. Radiant Arctois Grandmine, Orcarfource Arctois, Radiant forets fertile; leaves pinnatifid, tooth-letted, cobwebbed, three-nerved. Flowers from March till May. Biennial.
Arctois Plantaginea; Plantain-leaved Arctois. Ra-

di-florets-fertile ; leaves lanceolate ovate, nerved, toothletted ; stem clasping, Perennial.

6. Arctotis Argentea; Silvery Arctotis. Radiant florets fertile ; leaves lanceolate linear, quite entire, tomentose .--- A biennial plant with yellow flowers.

7. Arctotis Angustifolia. Radiant florets fertile ; stem creeping, cobweb-like; leaves lyrate, with two teeth on each side .- Ray of the corolla purple; the whole plant white.

8. Arctotis Aspera; Rough Arctotis. Radiant florefs fertile; leaves pinnate-sinuate, villose; divisions oblong, toothed. Stiff, perennial .- There are several varieties of this species.

* Receptacle chaffy.

9. Arctotis Paradoxa; Chamomile-leaved Arctotis. Radiant florets barren; chaff's coloured, longer than the disk; leaves bipinnate, linear ; chaffs elongate, coloured, almost the length of the ray.

10. Arctotis Scariosa : Southernwood-leaved Arctotis, Radiant florets barren; chaffs equalling the florets of the disk; leaves decompound ; stem shrubby.

11. Aretotis Paleacea; Chaffy Arctotis. Radiant florets barren, chaffs equalling the florets of the disk ; leaves pinnate. linear .- Flowers from April to August.

12. Arctotis Dentata; Fine-leaved Arctotis. Radiant florets barren; leaves pinnate; pinnas pinnatifid-indented .--- An annual, flowering in July.

13. Arctotis Anthemoides. Chaffs shorter than the florets; leaves supra-decompound, linear .--- Very like Chamomile.

14. Arctotis Tenuifolia. Radiant florets barren ; leaves linear, undivided, smooth ; corolla yellow.

15. Arctotis Acaulis; Dwarf Arctotis. Peduncles radical: leaves lyrate.—A low plant, with fine large yellow flowers, Arcturns. See Celsia. Arcuation. See Layers and Laying.

Ardisia : a genus of the class Pentandria, order Monogynia. GENERIC CHARACTER. Calix : perianth one-leafed, five-cleft; clefts subulate. upright, coloured, permanent, Corolla : one-petalled. Tube short, length of the calix. Border, five-parted, parts lanceolate, acute, spreading, at length reflex. Stamina: filaments five, subulate, upright. Anthera acute, upright, bifid at the base, converging at top round the style. Pistil : germen superior, ovate, very small ; style subulate, longer than the stamina, upright, at length ascending Stigma simple, acute, permanent. Pericarp: berry roundish, large. Seed : single, roundish, covered with a hard brittle bark, like a nut. ESSENTIAL CHARACTER. Calix: five cleft. Corolla : one-petalled, five-parted, reflex ; stigma simple ; berry roundish, one seeded .---- The species are,

ARE

1. Ardisia Excelsa; Laurel-leaved Ardisia or Aderno. Racemes axillary, simple; leaves obovate, cartilaginous-ser-rate at the edge,-Native of Madeira.

Flowers terminating, panicled; 2. Ardisia Zeylanica. leaves ovate, subpetioled, quite entire; stem arboreous,-Native of Ceylon, where the berries, which are esteemed cooling and refreshing, are given in ardent fevers.

3, Ardisia Tinifolia. Flowers panicled; leaves elliptic, entire, nerved ; stem arboreous .- A tree thirty feet high, and native of Jamaica.

4. Ardisia Coriacea. Flowers panicled; leaves oblong, entire, veinless, coriaceous .- Native of the West Indies.

5. Ardisia Serrulata. Flowers panicled; leaves ovate, lanceolate, acuminate, wrinkled ; stem shrubby, pubescent,-Native of St. Domingo.

6. Ardisia Lateriflora. Racemes lateral or axillary, compound; flowers umbelled; leaves oblong, acuminate, quite entire; stem shrubby.

7. Ardisia Parasitica. Racemes axillary, simple ; leaves sessile, lanceolate-ovate, marked with lines ; stem shrubby .--Native of Montserrat.

Arduina; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fiveparted, erect, acute, small, permanent. Corolla : one-petalled, funnel-shaped. Tube cylindrical, a little curved inwards at top. Border, five parted, acute, spreading. Stamina : filamenta five, simple shorter than the tube, and inserted into the lower part of it; anthera oblong, within the throat of the corolla. Pistil: germen superior, ovate; style filiform, the length of the tube. Stigma bifid, thickish. Pericarp berry, globular, oval, two-celled. Seeds : solitary, oblong, hard. ESSENTIAL CHARACTER. Corolla: one-petalled; stigma bifid ; berry two-celled ; seeds solitary .---- Only one species is known, viz,

1. Arduina Bispinosa; Two-spined Arduina.-A low shrubby plant, seldom rising more than five feet high. The flowers are small, white, and have an agreeable smell, but seldom come to seed in England. Native of the Cape of Good Hope. It may be increased by cuttings planted in July, and shaded from the sun, and must be screened by the hot-house during autumn and winter.

Arealu. See Ficus Religiosa.

Areca ; a genus of the class Palmæ, order Monœcia Enneandria .- GENERIC CHARACTER. Male flowers, Calix : spathe bivalve; spadix branched. Proper perianth, threeleaved. Corolla : petals three, acuminate, rigid. Stamina : filamenta nine, the three outer longer than the rest. Female flowers in the same spadix. Calix : spathe common with the males. Proper perianth, three-leaved. Corolla : petals three, acuminate, rigid. Pericarp : berry subovate, fibrose, surrounded at the base with the imbricate calix. Seed : ovate. ESSENTIAL CHARACTER. Corolla: three-petalled. Male, nine stamina. Female, a drupe, with an imbricate calix. For the propagation and culture, see Palms.

1. Areca Catechu. Fronds pinnate ; leaflets folded back, opposite end bitten. This palm is forty or fifty feet high, the trunk six or eight inches in diameter. The fruit does not fall off even when ripe. The Indians call it Chotool, and present it to all their guests green when it can be procured, and stripped of the outer rind, but otherwise dried. They are sontinually chewing it, and swallowing their saliva tinctured - Native of the Swiss and Pyrenean mountains,

with the juice, which is esteemed to be an excellent anti-scorbutic for the gums, and a strengthener of the stomach and appetite. It is also used in constipations of the bowels, and in worm cases. A decoction of the nuts is employed in dyeing, and is supposed both to set and enliven the colours. A native of the East Indies and of China.

2. Areca Oryzeformis. Fronds pinnate; leaflets smooth, three-nerved .- A straight slender palm, ten feet high, and only an inch and half in diameter .- Native of Cochin-china, and Amboyna.

3. Areca Oleracea; Cabbage tree. Leaflets quite entire, -This is the loftiest of the American palms. The West Indians cut off the green crop of the trunk, take out the white heart of two or three inches in diameter, consisting of the leaves closely folded together, and eat it raw with pepper and salt, or fried with butter; it has somewhat the taste of an artichoke. The best cabbage is obtained when the tree is. young. The outward part of the tree is used for lathing, and boards for out-houses; the seeds serve to feed the wild hogs in the season, and the spathes are frequently made into mats. by the Negroes.

Areira. See Schinus.

Arenaria ; a genus of the class Decandria, order Trigynia. -GENERIC CHARACTER. Calix: perianth five-leaved; leaflets oblong, acuminate, spreading, permanent. Corolla: petals five, ovate, entire. Stamina : filamenta ten, subulate, five alternately interior. Antheræ roundish. Pistil: germen ovate ; styles from erect reflex ; stigmas thickish. Pericarp: capsule ovate, covered, one-celled, three or six-valved. Seeds very many, kidney-shaped. ESSENTIAL CHARACTER. Calix : five-leaved, expanding. Petals : five, entire. Capsule one-celled, many-seeded. ---- Species: Most of these plants are natives of mountainous situations in Europe, but are neither large nor brilliant enough to be generally cultivated in gardens, though many of them are neat elegant plants. 'The perennial sorts may easily be increased by slips or parting the roots, though both these and the annuals may be increased by seeds. They require little care, being all hardy plants.

1. Arenaria Peploides ; Sea-sandwort, or Chick-weed. Leaves ovate, acute, fleshy; root perennial.—Common on sandy coasts in the north of Europe; as, near Sheerness in Kent, Yarmouth in Norfolk, Southwold in Suffolk, and Leith in Scotland : it flowers in June and July.

2. Arenaria Tetraquetra ; Square Sandwort. Leaves pointed, recurved; flowers aggregate .- Native of the Pyrenean and Arragon mountains ; flowering in July or August,

3. Arenaria Biflora ; Two-flowered Sandwort, Leaves obovate, obtuse; stems procumbent; peduncles two-flowered, lateral .- Native of the high Alps of Savoy and Switzerland.

4. Arenaria Lateriflora; Side-flowering Sandwort. Leaves ovate, obtuse ; peduncles lateral, two-flowered .- Discovered in Siberia.

5. Arenaria Trinervia; Plaintain-leaved Chickweed, or Sandwort. Leaves ovate, acute, petiolate, nerved .- This. species has an annual root, and is not very common, growing only in and about woods, and flowering in March and April.

6. Arenaria Ciliata ; Ciliate Sandwort. Leaves ovate. nerved, ciliate, acute, biennial; flowering from March till August .- Found upon Mount Cenis, and in the turf of the mountains of Dauphiny, and by Sir Joseph Banks in Iceland.

7. Arenaria Balearica; Majorca Sandwort. Leaves ovate, shining, rather fleshy; stem creeping; peduncles one flowered, perennial.-Native of Majorca and Minorca.

8. Arenaria Multicaulis ; Many-stalked Sandwort. Leaves. ovate, nerveless, sessile, acute ; corollas larger than the calix. 9. Arenaria Serpyllifolia; Least Chickmeed, or Thymeleaved Sandwork. Leaves subvacts, acute, sessile; corollas shorter than the calix.—A next little annual plant, common upon walls, among rubbish, and in dry barren places, not only in Europe, but Japan; flowers from May to August.

10. Arenaria Triflora; Three-flowered Sandwort. Leaves lance-subnlate, ciliate; branches mostly three-flowered; petals marked with lines, obtuse: perennial.—Found upon rocks in the south of Europe.

11. Arenaria Montana; Mountain Sandwort. Leaves linear-lanceolate, rugged, barren; stems very long, procumbent.--Native of Spain, and the south of France.

12. Arenaria Rubra; Purple Spurrey, or Sandwort. Leaves linear, the length of the internodes, annual; corolla purple, appearing in June and July, and frequently continuing till September.—Sheep and goats dislike this plant.

13. Arcnaria Media ; Middle, or Downy Sandwort. Leaves linear, fieshy ; stipules membranous; stem spuebscent. — The flower, which appears in June and July, is purple, and open at noon. It is found plentifully on the shell coast of the isle of Shepey, and is also a native of Germany and France.

14. Arenaria Bavarica; Bavarian Sandwort. Leaves semi-cylindric, fleshy, obtuse; petals lanceolate; peduncles terminal, mostly binate: perennial.—Native of Bavaria, Monte Baldo, and Little St. Bernard.

15. Arenaria Gypsophiloides. Leaves linear, radical ones bristly; panicle subpubescent; petals lanceolate: perennial. --Native of the Levant.

16: Arenaria Saxatilis; Rock Sandwort. Leaves subulate; stems panicled; leaftets of the calix ovate, obtuse, perennial; petals white.—Native of France, Germany, Switzerland, Caruiola, and Siberia.

17. Arenaria Verna; Vernal Mountain Sandwort, or Chickneed. Leaves subulate; stems panicled; calices pointed, striated; petals oval and white: it flowers from May till August.—Found upon mountains in Dauphiny, Savory, Austria, and Gereat Britain, as, near the Land's End in Cornwall, about Kendal, Settle, and Matlock; at Arthur's seat near Chinburgh; near Holywell, St. Asaph, and Llanberys in Wales.-

18. Arenaria Hispida ; Hispid Sandwort. Leaves subulate, hispid underneath. Native of Montpellier.

19: Arenaria Juniperina; Juniper Sandwort. Leaves subulate, thorny; stem erect; calices striated; capsules oblong; root perennial.—Native place unknown.

20. Arcnaria 'Tenufofia ; Fine-lored Chickneed, or Sand-wort. Leaves subulate; stem panicled; capsules erect; petals shorter than the calix, and hanccolate; root peremial.—Native of almost every country in the north of Europe ; it is found in England upon Gog-magog Hills, and the borders of Triplow heath in Cambridgeshire; near Bury in Suffolk; near Cley in Norfolk; Cornbury quary, near Charlbury in Oxfordshire, Malvern hill in Worcestershire; and at Eattersea and Deptford, near London: it flowers in June and July.

22. Aremaria Striata; Striated Sandwort. Leaves linear, erect, pressed to the stem; calices oblong, striated.—It flowers from July to August, and is a native of Switzerland.

23. Arenaria Fasciculata; Cluster-flowering Sandwort. Leares subulate; stem erect, stiff; flowers fascicled; petals very short; root annual.—It flowers in August, and is a maine of the south of France, the Alps, of Piedmont, and Austria.

24. Arenaria Grandiflora; Great-flowered Sandwort, Leaves subulate, flat, stiff; the radical ones crowded; stems: one-flowered; root perennial.—Native of the South of France, near Geneva, Mont Cenis, the Vaudois, and Carniola.

25. Arenaria Austriaca; Austrian Sandwort. Stemsundershrubby, prostrate, then herbaceous and erect: leaves subulate; flowers twin; petals emarginate: percential.—Native of the mountains of Austria, Switzerland, and Piedmont.

26. Arenaria Liniflora; *Flax-flowered Sandwort*. Stemserect, branching below, and under-shrubby; leaves subulate; flowers twin: perennial.—Native of the south of Europe.

27. Arenaria Recurva. Radical leaves heaped; recurred, subulate; stem simple, bearing about three flowers; root biennial.—Native of Provence, and of rocky pastures in the high Alps; of the Vaudois in Piedmont; also of the highest-mountains of Switzerland.

28. Arenaria Obtusa. Leaves linear, flat; obtuse; calices* viscid: perennial.-Native of the high Swiss Alps:

29. Arenaria Lanceolata. Leaves lanceolate, three-nerved; acute; calices lanceolate, three-nerved; root perennial, darkcoloured, tough, with a very few fibres, creeping.

30. Arenaria Dianthoides. Leaves linear, scabrous at they edge; flowers capitated; bractes ventricose; longer than the peduncles; root woody, perennial.—Found by Tournefort: in Armenia.

31. Arenaria Cucubaloides. Leaves linear, scabrous at the edge; panicles dichotomous, pubescent; petals obovate; root perennial.—Found by Tournefort in Armenia.

Arethusa ; a genus of the class Gynandria, order Diandria. -GENERIC CHARACTER. Calix: spathe leafy. Perianth none. Corolla: ringent. Petals five, oblong, subequal, two outer, all converging into a helmet. Nectary one-leafed, tubular at the base, within the bottom of the corolla, twoparted ; lower-lip reflex, broad, wrinkled, the length of the petals, hanging down forwards; upper-lip linear, very tender, fastened to the style, lobed at the top, Stamina : filamenta? two, very short, sitting on the top of the pistil; anthera ovate; compressed, covered with the folding of the inner lip of the nectary. Pistil: germen oblong, inferior; style oblong, incurved, clothed with the inner-lip of the nectary; stigmer funnel-shaped. Pericarp: capsule oblong-ovate; one-celled, three-valved, gaping at the angles. Seeds numerous, accroses ESSENTIAL CHARACTER. Nectary tubular, within the The first three are hardy, and will endure the rigour of our climate; the next three must be kept in the cape-stove, and the last in the bark-stove:-----The species are, 1. Arethusa Bulbosa; Bulbous-rooted Arethusa. Root

1. Arethusa Bulbosa; Bulbous-rooted Arethusa. Root globose; scape sheathed; spathe two-leaved.—This and the two two next species are natives of bogs in North América.

2. Arethusa Ophioglossoides; Adder's and Tongue-leaved Arethusa. Root fibrous; leaf of the scape oval; spathaceous; leaflet lanceolate: see No. 1.

3. Arethusa Divaricata; Lily-leaved Helleborine, or Arethusa. Root subpalmate; leaf of the cape and leaflet of the spathe lanceolate, the outer petals rising: see No.1.

4. Arethusa Capensis; Cape Arethusa. Bub round 3: stem two-leaved, simple, one-flowered.—Found at the Cape: of Good Hope.

5. Arethusa Villosa; Villose Arethusaw Bulb round; leaves ovate, ciliate, pubescent.—Found also at the Cape of Good Hope.

6. Arethusa Ciliaris; Ciliated Arethusa. Root fleshy; leaf kidney-shaped, orbiculate; lip ciliate,-Also a native of the Cape of Good Hope.

7. Arethusa Biplumata; Two feathered Arethusa. Scape

sheathed; spathe cowled, the two lower petals elongated; bearded on the upper side ; roots fascicled or in bundles.

ARE

Aretia ; a genus of the class Pentandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth one-leafed, bellshaped, semiquinquifid, bluntish, permanent. Corolla: monopetalous, salver-shaped; tube ovate, the length of the calix, contracted at the neck; limb five-parted, divisions obovate. Stamina: filaments five, conic, in the middle of the tube very short ; antheræ erect, sharpish, within the throat of the corolla. Pistil: germen roundish ; style filiform, the length of the tube; stigma flat-headed. Pericarp: capsule onecelled, five-valved. Seeds: five. ESSENTIAL CHARACTER. Corolla: salver-shaped, five-cleft, tube ovate; stigma flatheaded. Capsule: one-celled, globular, with about five seeds. -These little Alpine plants are rather difficult to preserve; they require a shady situation, where the seeds should be sown as soon as ever they can be procured. They may be also propagated by offsets or slips, and by parting the roots. -The species are.

1. Aretia Helvetica; Imbricate Aretia. Leaves imbricate ; flowers subsessile ; root perennial .-- Native of the western Swiss Alps, and of Dauphiny.

2. Aretia Alpina ; Linear-leaved Aretia. Leaves linear. spreading ; flowers pedunculated .- Found in various parts of Switzerland, and in Austria. There are two varieties of this species ; the first has white flowers with a purple eye, and the second forms beautiful tufts of red flowers, which grow upon Mount St. Bernard, at the height of almost two miles above the level of the sea!

3. Aretia Vitaliana ; Grass-leaved Aretia. Leaves linear. recurved; flowers subsessile .- A very small plant, native of the Pyrences, and high Alps between the Valais and Italy: flower of a deep vellow : it is also found in Dauphiny.

· Argan. See Sicteroxylon.

Argemone ; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth threeleaved, roundish; leaflets rounded with a point, concave, caducous. Corolla: petals six, roundish, from erect spreading; larger than the calix. Stamina : filaments numerous, filiform, the length of the calix; antheræ oblong, erect. Pistil: germen ovate, five-angled ; style none ; stigma thickish, obtuse, reflex, quinquefid, permanent. Pericarp : capsule ovate, five-angled, one-celled, half-valved. Seeds: nu-merous, very small. Receptacles: linear, fastened to the angles of the pericarp, not gaping. ESSENTIAL CHARAC-TER. Corolla: six-petalled. Calix: three-leaved. Capsule: half-valved .- The seeds of this first species must be sown upon a bed of light earth in the spring, where they are to remain. They must be thinned till each is four inches apart from the rest. The species are,

1. Argemone Mexicana; Prickly Argemone, or Poppy. Capsules six-valved ; leaves spiny .- This is called the yellow thistle in the West Indies, where it is a troublesome weed in cultivated lands. The whole plant abounds with a milky juice, which turns to a fine bright vellow in the air, and when reduced to consistence, is not distinguishable from gamboge; and in very small doses, it is probably equally efficacious, for dropsies, jaundice, and cutaneous eruptions. It is reckoned very detersive, and generally used in diseases of the eyes ; but the infusion is looked upon as a sudorific and resolutive, which may be most successfully applied. The seeds are said to be a much stronger narcotic than opium. The inhabitants of the sugar colonies think them an excellent remedy in diarrhœas and bloody fluxes; they have a pungent warm taste, but it is not immediately perceived by the palate. They work both by stool and vomit, and have been adminis | bivalve ; valves linear-subulate, membranaccous, equal. Co-

tered in the dry belly-ache: but we have much better medicines for both these disorders, though this may be successfully given when the parts are relaxed or weakly, or the disorder proceeds from indigestion, which is frequently the case in hot climates.

2, Argemone Armeniaca. Capsules three-valved .- Discovered in Armenia by Tournefort.

3. Argemone Pyrenaica. Capsules four-valved : stem naked .- Native of the Pyrenees.

Argophyllum ; a genus of the Pentandria class, Monogynia order .- GENERIC CHARACTER. Calix: perianth short, quinquefid; divisions sharp. Corolla: petals five, lanceolate, spreading, three times greater than the calix. Nectary : five-angled, pyramidal, open at the top, consisting of many converging papillis, connate at the base. Stamina : filaments five, subulate, inserted into the receptacle; shorter than the nectary ; antheræ ovate. Pistil : germen turbinate, fastened at the bottom to the calix, flat above ; style filiform, the length of the nectary ; stigma globular. Pericarp : capsule hemispherical, flat above, growing to the calix; three-celled, opening into three parts. *Sceds*: very many, globu-lar, porons. ESSENTIAL CHARACTER. Capsule three-celled. Nectary pyramidal, five-angled, the length of the corolla .---- One species only is known, viz.

1. Argophyllum Nitidum. A perennial, found in New Caledonia.

Arguzia. See Messerschmidia.

Argyrocome. See Baccharis.

Argythamnia; a genus of the class Monœcia, order Tetrandria .- GENERIC CHARACTER. Male flowers. Calix: perianth four-leaved ; leaflets lanceolate, erect. Corolla : petals four, lanceolate-ovate, ciliate on the margin, shorter than the calix. Nectary, four glands between the petals, roundish, depressed. Stamina: filaments four, longer than the petals, approximated at the base, dilated. Antheræ simple. Pistil: rudiment of a style. Female flowers in the same raceme under the male ones. Calix: perianth five-leaved, leaflets lanceolate. Corolla: none. Pistil: germen ovate, somewhat three-cornered ; styles three, spreading, half.twocleft ; each of the clefts bifid ; stigmas lacerate. Pericarp : capsule tricoccous, three-celled, six-valved. Seeds : solitary, roundish. ESSENTIAL CHARACTER. Male. Calix: fourleaved. Corolla: four-petalled. Female. Calix: five-leaved. Corolla: none. Styles dychotomous. Capsule tricoccous. with solitary seeds .---- The only species known is,

1. Argythamnia Candicans .- A shrub seldom rising above five feet high, and common upon the lower hills and gravelly soils of Jamaica.

Aristea ; a genus of the class Triandria, order Monogynia, -GENERIC CHARACTER. Calix: spathes bivalve. Corolla : petals six, oblong, spreading, nearly equal. Stamina : filaments three, filiform, shorter than the petals. Antheræ oblong, erect, incumbent. Pistil :: germ inferior, threecornered ; style filiform, longer than the filaments, declinate. Stigma funnel-form, gaping, simbriated on the margin, somewhat three-cornered, Pericarp: capsule oblong, three-cornered, three-celled, three-valved. Seeds : very many. Es-SENTIAL CHARACTER. Petals: six; style declinate; stigma funnel-form, gaping. Capsule : inferior, with many seeds .---- The only species yet discovered is,

1. Aristea Cyanea ; Grass-leaved Aristea .- A plant three or four feet high ; native of the Cape of Good Hope.

Aristella. See Stipa.

Aristida ; a genus of the class Triandria, order Digynia. -GENERIC CHARACTER. Calix: glume one-flowered, ARI

ralla; glume bivalve, thicker than the calix; outer valve linear, converging longitudinally, hirsute at the base, terminated by three awns, tube equal, patulous; inner valve lanceolate, sharp, very short, wrapped within the outer valve. Nectary two-leaved; leaflets lanceolate obtuse. Stamina : filaments capillary; antheræ oblong. Pistil: germen turbinate; styles capillary; stigmas villose. Pericarp: none. Glume converging, involving, gaping. Seed : one, filiform, the length of the corolla, naked. ESSENTIAL CHARACTER. Calix: two-valved. Corolla: one-valved, with three terminal awns .---- The species are,

1. Aristida Adscensionis. Panicle branching ; spikes scattered; corollas one-valved; culms in tnfts .- Native of Jamaica, in dry sands.

2. Aristida Americana. Panicle simple; corollas twovalved, one with dorsal, the other with terminating awns; culm half a foot high .- Native of Jamaica.

3. Aristida Plumosa, Panicled; the middle awn longest and woolly; culms villose .--- Found in America.

4. Aristida Arundinacea. Panicled ; corollas two-valved, middle awn longer, smooth ; culms four feet high, narrow, even, full .- It was found in the East Indies.

5. Aristida Gigantea. Panicle elongated, loose, oneranked; calices one-flowered; awns of the corolla subequal, straight .-- A very lofty, branching, and smooth grass, found upon the island of Teneriffe.

6. Aristida Hystrix. Panicle divaricated, very spreading; Flowers quite simple, smooth; awns straight, divaricated .- A creeping, stoloniferous, smooth grass, observed in Malabar.

Aristolochia ; a genus of the class Gynandria, order Hexandria .- GENERIC CHARACTER. Calix : none. Carolla : monopetalous, tubulous, irregular; base swelling, subglobular, torulose; tube oblong, hexagon, cylindric; limb dilated, extended below into a long tongue. Stamina : filaments none; antheræ six, fastened at bottom to the stigmas, four-celled. Pistil: germen oblong, inferior, angular; style scarcely any; stigma subglobular, six-parted, concave. Pericarp : capsule large, six-angled, six-celled. Seeds : several, depressed, in cumbent. ESSENTIAL CHARACTER. Stigmassix. Caliz: none. Corolla: monopetalous, tongue-shaped, entire. Cap sule : six-celled, inferior .- All the plants of this genus are natives of hot climates, and are propagated hy seed procured from their native countries; sown in small pots of light earth as soon as they arrive, and if it be autumn or winter, they must be plunged into tan in the bark-stove, between some large plants to screen them from the sun, as they delight in shade. In March they must be removed into a hot-bed frame, where the plants will appear in May. Roots perennial .-The species are,

1. Aristolochia Bilobata; Two-lobed Birthwort. Leaves two-lobed; stem twining; stem filiform, subdivided, round, smooth .--- It flowers from November until January, and covers the trees and shrubs in Dominica and Hispaniola.

2. Aristolochia Trilobata; Three-lobed Birthwort. Leaves three-lobed ; stem twining ; flowers very large, bagged at the base; tongue linear, very long .- A climbing plant, with an aromatic stem. The roots of this and the tenth species are accounted warm attenuants, and active diuretics and stomachics; they are administered in infusions, and greatly used among the slaves of Jamaica, where they naturally grow. This species abounds most on the north side of the island, and is therefore called Contrayerra of the North-side. It is also a native of the South American continent.

3. Aristolochia Pentandria; Five stamined Birthwort. Leaves c ordate, hastate, subtrilobate; stem twining; bracte cordate, embracing .- Native of America. 11.

4. Aristolochia Peltata; Peltated Birthwort. Leaves kidney-shaped, subpeltate ; stem twining ; root woody, corky, perennial .- It flowers in February and March, and is a native of St. Domingo, in very dry coppices, and also of the continent of South America.

ARI

5. Aristolochia Maxima; Greatest Birthwort. Leaves oblong, acuminate; stem twining; peduncles many-flowered; stem corky next the root .- Found near Carthagena in New Spain.

6. Aristolochia Bilabiata ; Two-lipped Birthwort. Leaves cordate, tongue-shaped, obtuse ; stem twining ; corollas twolipped .- Flowers in spring, and is found upon a calcareous soil, in the hedges of Hispaniola ; it is also a native of South America.

7. Aristolochia Erecta; Upright Birthwort. Leaves lanceolate, sessile, subhirsute; stem erect; peduncles solitary, one-flowered, flowers very long; rises three feet high, with an upright stalk ; flowers of a dark purple colour .-- It was discovered at La Vera Cruz, in New Spain.

8. Aristolochia Arborescens; Tree Birthwort, Leaves cordate, lanceolate; stem erect, shrubby .-- Called Snakeroot in North America, where it naturally grows to the height of two feet,

9. Aristolochia Caudata; Tailed Birthwort. Leaves cordate, obtuse, emarginate at the tip; lobes incumbent, liptailed.-Native of America.

10. Aristolochia Odoratissima; Sweet-scented Birthwort. Leaves cordate ; stem twining, shrubby ; peduncles solitary ; lip of the corolla very large .- It has a long round geniculated root, as thick as a finger; the whole plant has a very strong and very grateful smell. In Jamaica, where it naturally grows, it is called Contrayerva of the South-side, to distinguish it from the second species, which see,

11. Aristolochia Sipho; Broad-leaved Birthwort. Leaves cordate, petioled; flowers solitary, border trifid, equal; bracte ovate ; stem twining, shrubby .- A tall twining shrub, flowering in June and July: a native of North America.

12. Aristolochia Anguicida; Snake-killing Birthwort, Leaves cordate, acuminate ; stem twining, shrubby ; peduncles solitary; stipules cordate; root long, thick, pale coloured ; corolla purple .- If the juice of the root, mixed with the saliva, be put into the mouth of a serpent, he may be safely handled, but will recover himself after some hours; several of the other species are said to produce the same effect. Native of Mexico and the West Indies.

13. Aristolochia Maurorum; Moorish Birthwort. Leaves hastate, quite entire; stem weak, simple; flowers solitary, recurved .- This plant has an unpleasant smell : seen in olivegrounds near Aleppo.

14. Aristolochia Indica; Indian Birthwort. Leaves cordate, rather acute; stem twining; peduncles about three, longer than the petiole; stem shrubby .- A native of the East Indies, and Cochin-china. It is bitter, but has not much smell, and is thought to be an attenuant, and remover of obstructions.

15. Aristolochia Bœtica ; Spanish Birthwort. Leaves cordate, rather acute; stem twining; pedancles about three, longer than the petiole ; root very long, pale-coloured, acrimoniously astringent .- It is an evergreen, flowering in January and February, and a native of Spain.

16. Aristolochia Sempervirens ; Evergreen Birthwort. Leaves cordate, oblong, acuminate, waved; stem weak; flowers solitary; roots many, slender, odorous .- It flowers in May and June, and is a native of the isle of Candia.

17. Aristolochia Serpentaria; Virginia Birthwort, or Snake-root. Leaves cordate, oblong, flat; stems weak, 2 I

flexuose, round; flowers solitary; root a congeries of small fibres, of a yellow colour, and aromatic smell and taste... It is a warm diaphoretic and diuretie; it is recknowd one of the principal alexipharmics. It is given in substance from a few grains to a scruppe or half a darchm; in decoction or infusion, to a drachm or upwards. A tincture of it is prepared by digesting three ounces in a quart of spirit of wine eight day; and a spiri-alexiterial water, mixed with one-sixth it squantity of distilled water. It is also an ingredient in the compound tincture of bark. Native of Virginia and Carolina.

 Aristolochia Pistolochia. Leaves cordate, crenulate, netted underneath, petioled; flowers solitary; roots round, numerous.—Native of the south of France, Switzerland, and Spain.

19. Aristolochia Rotunda; Raund-rooted Birthuort, Leaves cordate, subscsile, obtuse; stam weak; flowers solitary.—This has long tap-roots, shaped like those of carots, lt is a mative of the south of Europe, and of Japan, and flowers at the same time in both, from June through the autumn. The root, which is the only part used, is a rough and disagreeable medicine; it often offends the stomach, but is an excellent drug for promoting the necessary evacuations after delivery. There are two kinds of birthwort, tools kept in the shops; the one called the long birthwort, but is rough and in the round, but in a less degree, and are therefore less regarded; see species 20 and 22.

20. Aristolochia Longa; Long-rooted Birthwort. Leaves cordate, petioled, obtuse; stem weak; flowers solitary; fruits ovate .- Native of the south of Europe and Japan. Mevrick informs us, that it will sometimes resist the severity of an English winter in the open air, and that it flowers with us at the latter end of summer. He adds, the roots are kept in the shops, and many authors represent them as being of an extremely hot and pungent nature; but such as are commonly met with among the druggists, exhibit no very striking qualities of that kind. On first chewing them when dry, scarcely any taste is perceptible; but they soon fill the mouth with a nauseous bitterness, which remains for a long time. As a medicine, they heat, stimulate, cut and attenuate a tough phlegm, and promote the fluid secretions in general; but their principal efficacy consists in removing feminine obstructions, and promoting the necessary evacuations after delivery ; from which it is probable the plant received its name. The dose is from a scruple in weight to upwards of a drachm. A decoction of them is recommended to be used externally as a fomentation, for cleansing and healing wounds and ulcers, and in cutaneous disorders. They have likewise been recommended as powerful alterants in gouty complaints : but whoever has been attentive to their effects, must have observed, that in some cases they are improper : see the 22nd species. Simon Paulli informs us, that the long birthwort roots, applied as an epithem or fomentation, were found remarkably serviceable in stubborn ulcers of the legs.

21. Aristolochia Hirsuta; Rough Birthwort. Leaves cordate, rather obtuse, shaggy; flowers solitary, pendulous, recurved, subtruncate.—The whole plant is bitter, the flower scentless; it has been recommended for the gout. Native of the island of Scio or Chios.

22. Aristolochia Elematitis; Common Birthwort. Leaves cordate; stem erect; flowers axillary, crowded.—It has an erect stem, from two to three feet high, simple, striated, round, and smooth, and is found all over the continent of Europe. It is found in a wood two miles from Thorndon in Essex, near

| Maidstone and other places in Kent, near Stuston in Suffolk and in the hedges at Whittlesford in Cambridgeshire. The roots have an aromatic smell, and a warm bitterish taste; they are celebrated as warm attenuants and deobstruents. particularly in suppressions of the uterine purgations. The dose is from a scruple to a drachm and upwards. Boerhaave observes, that the pituitous gout, as he calls it, is often relieved by an infusion of these roots in spirit of juniper berries, sweetened with sugar, and taken to the quantity of a spoonful at a time; but that in other kinds of the gout, and in subjects of a tender constitution, this medicine produces loss of appetite, a weakness of the stomach, and a languidness more distressing than the gout itself: a powder composed of this and other similar materials, which was prescribed by the ancients as an antiarthritic, and has again come into esteem, has produced complaints of the same kind,

23. Aristolochia Scandens. Leaves cordate, on very long petioles; stem climbiug; flowers terminal, on very long peduncles.—This species grows naturally near Tolu in New Spain.

24. Aristolochia Conferta. Leaves cordate, petioled; stem climbing; flowers axillary, crowded.—Discovered at Campeachy in New Spain.

25. Aristolochia Bracteata. Leaves cordate, obtuse; stem weak; flowers solitary; bractes cordate, petioled.—Native of the East Indies, where it is used as a medicine.

26. Aristolochia Obtusata. Leaves cordate, rounded at the tip, three-nerved, beneath netted and tomentose; stem twining; peduncles solitary.—Native of the Caribbee Islands.

27. Åristolochia Grandiflora. Leaves broad, cordate; stem twining, subherbaccous; peduncles solitary, lip of the corolla very large, with a very long tail.—It bears very large flowers, seldom under five or six inches round the margin; very common in St. Annis, Jamaica.

Aristatelia; a genus of the class Dodecandria, order Monogynia. – GNERIE CHARCTER. *Calific:* perinnth oneleafed, five-parted; divisions lanceolate, concave, acute, upright. *Corollars* petuls five, wedge-shaped, concave, erect, lying over each other at the sides, scarcely longer than the calix. *Stamina:* filaments fibren, very short; anthrea longer shorter than the germen. *Pistil:* germen superior, roundish, rather three-concret; style filliorn, longer than the corolla; stigma three, recurved. *Pericorp:* berry subglobular, obtusely three-concred, style. *Event Starters*. *Calif. Starter Concevel. Corolla: Koveptalled. Berry:* threecelled. *Seeds:* two in each cell.——One species only is known.

 Aristotelia Macqui; Shining-leaved Aristotelia—A small shruh, native of Chilii, where the inhabitants make a wine from the berries, which are slightly acid, and eatable, and given in malignaut fevers. Dombey, while in Chili, used it successfully against the plague. It flowers in April and May, and is lardy enough to bear the open air in general, though severe winters will probably kill it, unless protected by a green house.

Arrite; a genus of the class Syngenesia, order Polygamia Superflua,—CENEREC CHARACTER. Callix: common imbricate, shorter than the ray of the corolla; leadies hanceolate, the length of the calls, erect. Corolla; compound, radiate. Corollules: hermaphrodite in the disk, very numerous. Females in the ray, about twenty. Proper of the hermaphrodite tubular, erect, five-clefi, equal. Female lanceolate; very long, three-toothed, spreading. Stamina to the hermaphrodites. Filamenta subulate, erect; anthera cylindric, to the females. Filamenta subulate, erect; anthera none. Pitality germen obloog; svbe simple, the length of the stamina; signa bind. Pericorp: none. Cala: unchanged. Seda: solitary.oblong. Down: simple, in the hermaphrodite, pubescent, long. Receptacle: naked. ESSENTIAL CHARAC-TER. Receptacle: naked. Down : simple; corollules of the ray have five finaments without antherae. The European sorts, which are hardy, require a most shady situation, and may be propagated by parting the roots in autumn, when the stalks begin to decay, or by seeds sown soon after they are ripe in autumn, for those sown in spring often fail; but if the seeds are permitted to scatter, they will appear of themselves, and only require to be kept free from weeds. The other species must be kept in pots under a frame or in a dry slove; they may be increased by seeds, cuttings, or parting the roots. —The species are,

1. Arnica Montana; Mountain Arnica. Leaves ovate, entire; stem-leaves twin, opposite; root perennial, and aromatic; the whole plant is acrid, and has a strong scent .--The flowers follow the sun; goats are fond of it, but cows refuse to touch it. In Smaland they snuff the powder of the leaves up the nostrils, and smoke them as tobacco. In Germany it is esteemed a specific for resolving coagulated blood, occasioned by falls or bruises, and is recommended in obstinate chronical disorders; but it appears to be too violent in its operation for general use. Dr. Collin, of Vienna, recommends beginning with an infusion of one drachm of the herb in flower morning and evening, gradually increasing the dose to half an ounce, and keeping the body open. Infused in small beer, and taken as common drink, it is reported to have removed the chronical rheumatism of the loins; and in one or two doses, taken two hours before the fit, to have put a stop to intermittents of long standing. Bergius tried this infusion, and also the powder of the root, in quartan agues, without success. Allionis relates, that the palsy was cured by the flowers, but that his patients could not endure the quantity of the infusion of them which Dr. Collins above recommends; and that he never gave more than three drachms, and divided them into several doses. Villars celebrates the arnica as one of the best remedies of the vegetable kingdom ; as eminently diuretic and tonic ; as a febrifuge, antiparalytic, and antiarthritic. He says, that all parts of it may be used in infusion or decoction ; in a dose of half a grain, or, if given in substance, less, especially at the beginning, because it is apt to discourage patients by giving them the heartburn. How many sick, he exclaims, have I benefited, and even cured of the dropsy, by this simple remedu! It flowers in July in Great Britain, and is a native of most parts of Europe, and of Siberia.

 Amica Scorpioides; Alternati-leared Arnica. Leaves alternate, toothed.—The root and the whole plant has a strong disagreeable smell, especially in the shade, and exposed to the north. Native of Switzerland, Savoy, Dauphiny, and Austria.
Amica Doronicam. Leaves alternate, subsertate, oblong, rough.—Natives of the high Alps of the Grisons, of Dauphiny, Piedmout, and Austria.

5. Arnica Maritima; Sea Arnica. Leaves lauceolate, the lower ones serrate; stem leafy, many-flowered.—Native of Kamtschatka and North America.

6. Arnica Crocea; Saffron-flowered Arnica. Leaves ovate, repand, toothletted, tomentose underneath.—Native of the Cape of Good Hope.

7. Arnica Ciliata; Ciliate-leaved Arnica. Leaves stemelasping, ovate, toothed, ciliate, smooth; stem simple, oneflowered; flower terminating red, the size of a small pear.

8. Arnica Japonica; Japonese Arnica. Leaves gash palmated, tooth letted; flowers terminal, sub-binate.—Flower red.

ART

 Arnica Palmata; Palmate-leaved Arnica. Leaves gash-palmated, toothed; flowers panicled.—Native of Japan.
Arnica Gerbera. Leaves pinnatifid; lobes rounded. —Native of the Cape of Good Hope.

11. Arnica Coronopifolia. Leaves pinnate; divisions linear.—Native of the Cape of Good Hope.

12. Arnica Oporina. Shrubby; leaves lanceolate, callous, crenate, tourentose beneath; peduncles one flowered, solitary, terminating scaly.---Native of New Zealand.

Arnotto. See Bixa.

Arrow-Head. See Sagittaria.

Arrow-headed Grass. See Triglochin.

Arrow Root, Indian. See Maranta.

Arsesmart. See Polygonum.

Artedia ; a genus of the class Pentandria, order Digynia. GENERIC CHARACTER, Umbel universal, spreading, flat, manifold. Partial, small, similar. Involucre universal, about ten-leaved; leaflets ovate, oblong; three-bristled at the end, nearly the length of the umbel; partial, two or three-leaved, verging outwards; leaflets linear, pinnate, longer than the umbellule. Corolla: universal, difform, radiate. Floscules of the disk abortive. Proper of the disk male; petals five, cordate; inflex, erect-of the ray, hermaphrodite, with similar petals, but the outmost larger. Stamina: filamenta five, capillary in all the flowers; anthera simple, roundish. Pistil of the ray: germen small, inferior; styles reflex ; stigmas simple. Pericarp : none. Fruit roundish, compressed, leafy-scaled on the edge, bipartile. Seeds: two, oblong, set about the edge with roundish spreading scales. ESSENTIAL CHARACTER. Involucre pinnatifid. Floscules of the disk male. Fruit rough with scales .---- The only species known is,

 Artedia Squamata.—An annual plant, and a native of the East, producing a large unbel of while flowers in July. If the seed be sown where they are to remain upon a warm border in antunun, and the plants kept six or eight inches apart, and clear from weeds, they will intrive: but to secure their seeding in England, they should be raised in a hot-bed, and kept in a green honse.

Artemisia ; a genus of the class Syngenesia, order Polygamia Æqualis,-GENERIC CHARACTER. Calix: common, roundish, imbricate, scales rounded, converging, Corolla; compound; corollula hermaphrodite, tubular, several in the disk. Females almost naked in the circumference. Proper of the hermaphrodite funnel-shaped; border five-cleft. Stamina, in the hermaphrodites: filaments capillary, very short : anthera cylindric, tubular, five-toothed. Pistil, in the hermaphrodites: germen small; style filiform, the length of the stamina; stigma bifid, revolute. Females, germen very small: style longer than in the hermaphrodites; stigma smaller. Pericarp: none. Calix : scarcely changed. Seeds : solitary, naked. Receptacle: flat, naked, or villose. ESSEN-TIAL CHARACTER. Receptacle: subvillose, or almost naked. Down : none. Calix : imbricate with rounded, converging scales. Corolla of the ray none .- Most of the numerous plants of this genus are hardy perennials, and may be increased without much difficulty, by seeds, by parting the roots, and by slips or cuttings.

* Shrubby, erect.

 Artemisia Verniculata. Leaves acerose, crowded, very small, panicle racemed; flowers sessile.—Native of the Cape of Good Hope: it requires a light soil in a green-house, and may be there increased by slips or cuttings.

ARN

2. Artemisia Capillaris. Leaves simple, capillaceous. Flowers white, inodorous, small, appearing in October.---Na--

tive of Japan, and cultivated in China and Cochin-china. 3. Artemist Judaica. Leaves obovate, obtuse, lobed, small; flowers panieled, pedicelled.—Native of Judea, Arabia, Caramania, the Mogul country, and China. The taste is bitter, but the eastern nations use both the leaves and seeds in medicine as tonics: stomachies, and anthelminities.

4. Artemisia Æthiopica. Leaves palmate, linear, very munte, panicled, racencel ; flowers sessile.—Native of Spain and the Cape of Good Hope. This and the fifth, sixth, and seventh species must be sheltered from frost under a frame during winter. They are easily propagated from cuttings.

5. Artemisia Contra. Leaves palmate, linear, minute, panicled, racemed; flowers sessile. Found in Persia, see No. 4.

6. Artemisia Abrotanum; Southernwood. Leaves setaceous, very branching .- It seldom rises above three or four feet high. Common Southernwood, which is merely a variety of this species, is bitter and aromatic, with a very strong smell. It is not much in use, but promises considerable effects, outwardly, in discussing contusions and humours; inwardly, for destroying worms, and in disorders peculiar to the female sex. It may have great efficacy in catarrhal malignant fevers, by its quality of promoting perspiration, which it possesses in a very high degree. A table-spoonful of the expressed juice may be given, half an ounce of the decoction, or a whole ounce of the infusion of the herb. In the present practice it is seldom used, except as an ingredient in discutient and antiseptic fomentations. A strong decoction of the leaves destroys worms; but it is a very nauseous medicine. The leaves are also esteemed as a good ingredient in fomentations, for easing pain, dispersing swellings, and stopping the progress of gangrenes. The top of the young branches, beaten into a conserve with three times their weight of sugar, are rendered less unpleasant to take, and in this form are good for all nervous disorders, and in all hysteric complaints. Culpeper says, that the distilled water was formerly given for the stone. It is held by all writers, ancient and modern, to be more offensive to the stomach than wormwood. The branches of it dye wool a deep yellow. See the fourth species.

7. Artemisia Arborescens; Common Narrow-leaved Treewormwood. Leaves tripinnatifid, silky, cinereous; leaflets linear; flowers globose; flower-bearing branchlets simple.— Native of Piedmont; see No. 4.

 Artemisia Argentea; Broad-leaved Tree-wormwood. Leaves bipinnatifid, silky, white; leaflets lanceolate-linear; flowers globose; flower-bearing branchlets wandlike.—Native of Madeira.

9. Artemisia Arragoniæ. Leaves linear, bipinnate, hoary; flowers racemed.—Scarcely a foot high.

10. Artimisia Messerschmidii. Leuves linear, multifid; racemes erect, slender, loose.-Found in Tartary.

 Artemisia Tatarica. Lower leaves bipinnate; pinnas equal; upper leaves pinnate, linear; racemes erect, loose, many-flowered.—Native of Tartary.
Artemisia Nitrosa. Lower leaves finely multifid; up-

 Artemisia Nitrosa. Lower leaves finely multifid; upper entire, obtuse; corymbs erect, hoary, oblong, spiked, sessile.—Native of Siberia.

13. Artemisia Lerchiana. Lower leaves piunate, short, finely divided; pinnas, palmate; upper leaves linear, undivided; corymbs sessile, very copious, spiked, oblong.—Native of Russia.

14. Artemisia Tenella. Leaves short, very finely multifid; panicles slender, loose, leafy; peduncles one or two-flowered. Native of Spain.

15. Artemisia Pauciflora. Branches virgate, filiform; corymbs one-ranked, spiked, subsessile.--Native of the banks of the Volga.

ART

16. Artemisia Italica. Leaves tomentose, loosely pinnate ; pinnas long, linear ; root-leaves dotted ; spikes dense ; flowers erect.--Native of Italy.

17. Artemisia Hispanica. Leaves loosely pinnate; pinnas long, linear; spikes very dense; calices oblong.—Native of Spain.

18. Artemisia Gmelini. Leaves doubly pinnate, obtuse, linear; corymbs green, roundish, nodding.

10. Artemisia Lobellu. Leaves petiolate, palmate, multifid, linear; the upper ones single, angular.—The flowers are of a fine yellow; and the whole plant, which is a native of Piedmont, the Genoese Alps, and Dauphiny, is remarkable for a strong, balsamic, camphorated smell.

20. Artemisia Santonica; Tartarian Southermuood, or Wormsed. Procumbent before flowering. Stem-leaves pinnate, multifid; branches undivided; spikes one-rauked, reflex; flowers with five florets.-Native of Tartary, whence the seeds are brought to England, and used in worm cases: they are recknoed a good balsamic, tonic, and stomachic medicine. It will grow with us in a dry soil and sheltered situation. The seed supplied by our druggists is frequently mixed with the unripe flowers; they are an excellent medicine against worms, and are best given in treate after reducing them to powder. An infusion of them is a good stomachic medicine, and may be used in all cases where bitters are likely to be serviceable. For persons of delicate palates they may be powdered and made into boluses.

21. Artemisia Campestris; Field Southernwood, Leaves multifd, linear; stens procumhent, wandlike.—It grows at Elvedon or Elden, in Suffolk, between Newmarket and Lynn, also near Barton Mills and Thetford, and in most parts of Europe. It flowers in August, and has the same qualities, in a less degree, as garden southernwood. Linneus recommends an infusion of it in the pleurisy.

22. Artemisia Palustris; *Marsh Southernwood*. Leaves linear, pinnate, quite entire; flowers glomerate, subsessile. --Native of Siberia.

23. Artemisia Erithmifolia; Samphire-leaved Southernwood. Leaves compound, divaricate, linear, fleshy, smooth; stem rising, panicled.—Native of the sandy shores of Portugal; flowering from May till Angust.

24. Artemisia Vallesiaca; Downy Southernwood. Leaves pinnate, many-parted, filiform, tomentose; flowers sessile, erect, subcolumnar, having few florets.—Native of Spain, Piedmont, and the Valais. It flowers in July and August, and sheep feed upon it.

25. Artemisia Maritima; Sca Wormwood. Leaves many-parted, tomenose; racemes drooping; females, florets three, —It has a strong smell of camphor when wild, but it diminishes upon cultivation. It is used as an ingredient in distilled waters. A conserve of the tops is made by beating them with thrice their weight of fine sugar; and they are used as an ingredient in the decoction for fomentations. It is less unpleasant, but not so strong, as common wormwood; and though not so valuable as an antisceptic or anthelminibic, is more eligible as a stomachic. The tops fresh gathered, and the whole plant dry, are used. In the shops and markets, it is used; all of the virtues of which it posserses, but it is more disagreeable than it, and less so than the common wormwood, see No. 3.0. It is friendly to the stomach, strengthening it, and expelling wind. It is a common ingredient in the biter

125

alone; boiling water poured upon it, and suffered to stand till it is cold, and then strained off, is an excellent medicine to procure an appetite. Put into white wine, it also gives a pleasant bitter flavour, with the same virtues. It is common about ditches, in salt-marshes, and wherever salt-water comes.

26. Artemisia Glacialis ; Silky Wormwood. Leaves palmate, multifid, silky; stems ascending; flowers glomerate, level-topped .- Flowers in July and August. Native of Switzerland, the Valais, Austria, Dauphiny, and Piedmont. It may be propagated by the side-shoots, planted in a shady border, during any of the summer months, where it will strike root if watered, and in the autumn may be transplanted where it is intended to remain : see No. 28.

27. Artemisia Rupestris; Creeping Wormwood. Leaves pinnate; stems ascending; flowers globose, nodding; receptacle pappose; receptacle hairy .--- Native of mountainous situations in most parts of Europe; very hardy, and easily increased by cuttings. See No. 28.

28. Artemisia Spicata; Spiked Wormwood, Root-leaves biternate; stem ascending, spiked; flowers erect .- Native of the Alps, of Switzerland, Austria, Piedmont, and Dauphiny. Under the name of Genipi, this and the two preceding species are in great request among the inhabitants of the Alps, for restoring a suppressed perspiration, pains of the sides, and intermittent fevers. They are an useful medicine, where diaphoretics are employed, as in rheumatism, intermittent and catarrhal fevers; but arc dangerous in the pleurisy, though they are used indiscriminately by the peasauts in all inflammatory disorders.

29. Artemisia Anethifolia ; Dill-leaved Wormwood, Leaves multifid, very slenderly divided ; corymbs roundish, nodding, one-ranked, loosely spiked,-Native of Siberia.

30. Artemisia Pontica ; Roman Wormwood. Leaves manyparted, tomentose beneath; flowers roundish, nodding; receptacle naked; root creeping .- The bitterness of this plaut is so mixed with a kind of aromatic flavour, as scarcely to be disagreeable; and it appears to be more eligible than either common or sea wormwood, as a stomachic and corroborant ; for which purpose, a conserve of the tops has been greatly recommended, and is, undoubtedly, an elegant and useful preparation. It will grow in any moderately moist soil, and may be propagated, by parting its creeping roots, in the middle of October, and planting them two or three feet asunder. Native of Germany.

31. Artemisia Austriaca ; Austrian Wormwood. Leaves many-parted, tomentose, hoary; flowers oblong, nodding; receptacles naked; stems upright, annual .- Native of Austria.

32. Artemisia Annua ; Annual Wormwood. Leaves threefold, pinnate, smooth on both sides; flowers subglobose, nodding; receptacle, smooth, conical .- An annual. Native of Siberia and China: it has a most agreeable scent, which it retains a long time after it has been dried. Loureiro, who introduced it into Portugal, where plants ten feet high have been produced from the seeds, recommends a decoction of the leaves and flowers in hectic fevers, the dysentery, and putrid ulcers.

33. Artemisia Tanacetifolia; Tansy-leaved Wormwood. Leaves bipinnate, underneath tomentose, shining; pinnas transverse; racemes simple; root perennial .- This annual has no perceptible odour; and is a native of very lofty situations in Dauphiny, Piedmont, and Siberia.

34. Artemisia Absinthium ; Common Wormwood. Leaves compound, multifid; flowers subglobose, pendulous; receptacle villose .- It flowers from July until October, and is found wild in the rocky places, road sides, rubbish, and farm-11.

yards of almost every part of Europe. The leaves and flowers are very bitter; the roots are warm and aromatic. It produces a considerable quantity of essential oil in distillation, sometimes two ounces from ten pounds, which is used both externally, and internally to destroy worms. The leaves put into sour beer soon destroy the acescency; they also resist putrefaction, and are therefore a principal ingredient in antiseptic fomentations. A weak infusion of them forms a good stomachic ; and with the addition of fixed alkaline salt, produced from the burnt plant, is a powerful diuretic in some dropsical cases. The ashes yield a purer alkaline salt than most other vegetables, excepting bean-stalks, broom, and the larger trees. Linneus mentions two cases, wherein an essence prepared from this plant, and taken for a considerable time, forbidding the use of wine and acids, prevented the formation of stones in the kidneys or bladder; and though, like other bitters, it will weaken the action of the nervous system, in these instances it did not produce that effect. The plant steeped in boiling water, and repeatedly applied to a bruise, will speedily remove the pain, and prevent the swelling and discoloration of the part. An infusion of it given to a nurse makes her milk bitter, and it gives a bitterness to the flesh of sheep that eat it. Wormwood leaves give out nearly the whole of their smell and taste both to aqueous and spirituous menstrua; the cold water infusions are the least offensive. A bitter of little or no particular flavour may be extracted from it, either in a solid form, or in that of a watery or spirituous solution. The spirituous extract seems preferable as a vermifuge. Meyrick informs us, that a slight infusion of the tops of this plant, is excellent for most disorders to which the stomach is subject, creating an appetite, promoting digestion, and preventing sickness after meals; but will produce the contrary effect if made too strong. The flowers, dried and powdered, destroy worms more effectually than worm seed, and are excellent in agues. The expressed juice of the leaves operates by urine; and though insufferably nauseous, it is good in the jaundice and dropsy. There are two other kinds of wormwood recommended; the Roman, see No. 39. and the Sea Wormwood, see No. 25. which possess the same virtues in a less degree, and therefore all three may be indiscriminately used. Common wormwood is easily propagated by parting the roots, by slips, or by seeds, sown in the autumn, soon after they are ripe; or if they be permitted to scatter. the plants will spring up without further care.

35. Artemisia Vulgaris; Mugwort. Leaves pinnatifid, flat, gashed, tomentose underneath ; racemes simple, recurved ; ray five-flowered .- Found wild all over Europe, China, and Japan, on the borders of fields and ditch-banks, by way-sides, in waste places, and about farm-yards. It flowers with us in August and September. The Moxa (see No. 41.) of Japan, is, according to Thunberg, prepared from this species. The leaves are collected in June, dried in the shade, and beat in a mortar till they become like tow: this substauce is then rubbed between the hands, till the harder fibres and membranes are separated, and there remains nothing but a very fine cotton, which the Japanese use for tinder; and twice in a year, young and old, rich and poor, are indiscriminately singed with it, either to prevent disorders, or cure the rheumatism. Mugwort has been chiefly recommended for promoting the uterine evacuations, and abating hysteric spasms : for which purposes infusions of it have been drank as tea, and used as a bath. It appears to be one of the mildest substances used in such cases, and may perhaps be of service where medicines of more activity would be improper. The flowery tops are considerably stronger than the leaves. used in some countries as a culinary aromatic, and a decoc-2 K

tion of it taken for the ague. A woman who had been afflicted with hysteric fits for many years, and had taken as safectida and æther without obtaining any relief, was cured in a few days by taking a drachm of the powdered leaves four times daily. The Chinese bruise the leaves, and apply them to fresh wounds, which they soon heal. It is, says Hill, an excellent medicine in hysteric complaints, and in all obtruetions of the viscera, for which a strong infusion is most serviceable. Meyrick informs us, that a decoction of it, sweetened with honey, eases the most violent coughs, and is good in sciatic pains. An ointment, made of the juice of the leaves and hog's lard, disperses wens, and hard knots and kernels about the neck and throat. Culpeper observes, that the herb itself taken fresh, or the juice of it, is an especial remedy for removing the bad effects of taking too much opium. A decoction made with chamomile and agrimony, he assures us, will remove all the pains of the sinews and the cramp, by bathing the affected part with it. No quadruped seems to feed on this plant; which may be raised by slips, cuttings, or parting the roots. There are several varieties of this species.

36. Artemisia Pectinata. Leaves pinnate, pectinate, smooth, sessile; flowers axillary, solitary, sessile, having firm florets. -This is an elegant and exceedingly fragrant plant, with an annual root, and an upright herbaceous stem about eight inches high .- Found in the dry lands of Dauria.

37. Artemisia Integrifolia; Entire-leaved Mugwort. Leaves simple, lanceolate, tomentose underneath, quite entire, or with one or two teeth ; female florets five .- Native of Siberia ; it is as hardy as the common mugwort, and multiplies as fast.

38. Artemisia Japonica; Japonese Mugwort. Leaves simple, smooth ; those on the branches lanceolate and entire, on the stem oblong and trifid; flowers racemed, nodding .-Native of Japan.

39. Artemisia Corulescens: Lavender-leaved Wormwood. Stem-leaves lanceolate, entire; root-leaves multifid; female florets three .- Found in the southern parts of Europe upon the sea coast, and upon the coast of Lincolnshire, near Boston. It flowers from August to October.

40. Artemisia Dracunculus; Tarragon. Leaves simple, lanceolate, smooth, quite entire; root perennial,-Native of Siberia and Tartary; it flowers in August. It is generally used in Persia, to excite an appetite at their meals; and the French employ it frequently in salads to correct the coldness of other herbs. The leaves, which have a fragrant smell and an aromatic taste, make an excellent pickle. This plant is very hardy, and propagates greatly by its creeping roots, or may be nultiplied very fast by planting the young shoots in the same manner as mint, and if well watered in dry weather, they will soon spread and meet.

41. Artemisia Chinensis; Chinese Mugwort, Leaves simple, tomentose, obtuse, lanceolate ; the lower ones wedgeshaped, three lobed .- Native of China and Siberia. This is the species from which the Moxa is prepared in China, where the natives term it the physician's herb, and employ it in hemorrhages, dysenteries, pleurisies, and disorders of the stomach; girdles of the down are recommended in the sciatica, and those who are afflicted with the rheumatism in the legs, quilt their stockings with it. The common mugwort is more efficacious for making Moza than this sort. Moza is celebrated in the East for preventing and curing many disorders, by being burnt on the skin; it produces a dark-coloured spot, the exulceration of which is promoted by applying a little garlic, and the ulcer is either healed up when the eschar separates, or kept running, as circumstances require. A fungous substance found in the fissures of old birch-trees, is used by the Laplanders for the same purpose; and cotton impregnated the East Indies. The fruit, which ripens in December, is

with a solution of nitre, and then dried, will answer the end as well as the Moxa. All these applications are only means of producing an exulceration of the skin, and its consequence a drain of humours.

42. Artemisia Maderas Patana; Mudras Wormwood. Leaves simple, lyrate-sinuate; stems procumbent; flowers pedunculate, solitary, globose, opposite to the leaves .- Native of the East Indies, flowering in July and August.

43. Artemisia Minima; Least Wormwood. Leaves simple wedge shaped, repand; stem procumbent; flowers axillary, sessile .- Native of China : a minute, annual plant.

44. Artemisia Littoralis. Procumbent, strigose; leaves spatulate, serrate-toothed, simple ; calices naked, pedicelled. -Found in the East Indies.

Artichoke. See Cynara.

Artichoke of Jerusalem. See Helianthus.

Artocarpus; a genus of the class Monœcia, order Monandria .- GENERIC CHARACTER. Male flowers. Calix: none. Ament cylindrical, all covered with florets. Corolla: two petals each, oblong, concave, blunt, villose. Stumina: filament single within each corolla; filiform the length of the corolla; anthera oblong. Female flowers, on the same tree. Calix and Corolla noue. Pistil: germina very many, connected into a globe, hexangular. Style to each filiform : stigmas single, or two, capillary, revolute. Pericarp : fruit ovate-globular, compound, muricate. Seeds: for each germen solitary, oblong, covered with pulpy arils, placed on an ovate receptacle. ESSENTIAL CHARACTER. Male ament. Calix: none. Corolla: two-petalled; style one; berries one-seeded, connected, and forming a roundish muricated fruit. These are milky trees. Those varieties which bear seeds may be propagated by them, sown in a pot of rich earth, and plunged in the bark-bed. Those which have no seed in the fruit may be increased from suckers, in which they abound very much, or by layers .---- The species are,

1. Artocarpus Incisa; Bread-fruit Tree. Leaves gashed. Capt. Cook observes, that this tree is about the height of a middling oak ; its leaves are frequently a foot and a half long, deeply sinuated like those of the fig tree, which they resemble in consistence and colour, and in exuding a milky juice when broken. The fruit is of the size and the shape of a child's head, and the surface is netted not much unlike a truffle ; it is covered with a thin skin, and has a core about as big as the handle of a small knife; the eatable part lies between the skin and the core; it is white as snow, and somewhat of the consistence of new bread. It must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid with a slight sweetness, resembling that of the crumb of wheaten bread, mixed with Jerusalem artichoke. As it is not in season at all times of the year, by reducing it to a sour paste called mahie, they supply that defect. The tree is not only useful for food, (three trees yielding sufficient nourishstripped off the suckers, and formed into a kind of cloth. This plant is distributed very extensively over the East Indian continent and islands, as well as in the innumerable islands of the South Sea. It was imported into the West India islands about the year 1793, where it has been most successfully established. The principal varieties are, that producing fruit with seeds, and that without; the former may be considered to be the tree in a wild state, as the want of seed is probably occasioned by cultivation.

2. Artocarpus Integrifolia; Indian Jaca Tree. Leaves entire .- This is about the same size or rather larger than the bread-fruit tree; it is a native of Malabar, and other parts of
eaten, but esteemed difficult of digestion: it is also pickled, or cut in slices, and boiled or fried in palm-oil. The nuts are eaten roasted, and the skin next them is used instead of the areca nut in chewing betel. The wood of the tree is employed in building. Thirty varieties of this fruit are enumerated in Malabar.

Arum ; a genus of the class Gynandria, order Polyandria. -GENERIC CHARACTER. Male flowers ; on the same spadix as the females, closely heaped between a double row of threads. Calix : spathe one-leafed, very large, oblong, convolute at the base, converging at the top ; the belly compressed, coloured within. Spadix club shaped, quite simple, a little shorter than the spathe, coloured, fenced at bottom with germiua, and shrivelling above them. Perianth proper, none. Corolla: none. Nectaries thick at the base, ending in threads or tendrils, in two rows issuing from the middle of the spadix. Stamina: filament none; each anthera sessile, four cornered. Female flowers : on the lower part of the spadix, close to each other. *Calix*: spathe and spadix common to them with the males. Perianth proper none. Corolla : none. Pistil : germen each obovate. Style none. Stigma bearded, with villose hairs. Pericarp : berry globular, one-celled. Seeds several, roundish. ESSENTIAL CHA-RACTER. Spathe one-leafed, cowled. Spadix naked above, female below, stamineous in the middle. The arums are all perennial, herbaceous plants, mostly natives of hot climates : their roots are fleshy, hot, and acrid, but in many species eatable,----The species are,

* Without Stems.

1. Arum Crinitum ; Hairy-sheathed Arum. Leaves pedate, compound, with the lateral segments involute ; spathe hairy within; spadix ramentaceous above .- The flower of this plant smells very strong of carrion, by which flies are enticed to enter, but when they attempt to retreat, the reversed hairs prevent them, and they are there starved to death. In England it flowers in March, and is a native of Minorca.

2. Arum Dracunculus; Long-sheathed Arum, or Common Dragon. Leaves pedate, compound; leaflets lanceolate, quite entire; lamina ovate, longer than the spadix .-- The flower is shaped like the common arum, having a very long spathe of a dark purple colour ; standing erect, with a large spadix of the same colour; so that when it is in flower, it makes no unpleasing appearance, but it has so strong a scent of carrion that it cannot be endured. It grows naturally in most of the southern parts of Europe, and is prescrved in gardens to supply the markets. It appears to be similar in medicinal virtues, as in botanical characters, to common arum, but rather more pungent, and therefore might be used in the same cases in which the latter only is generally employed. It is very hardy, growing in any soil or situation. The offsets from the roots propagate very fast ; the time to transplant it is in autumn, when the leaves decay.

3. Arum Dracontium ; Short-sheathed Arum, or Green dragon. Leaves pedate, compound ; leaflets lanceolate, quite entire, longer than the spathe, which is shorter than the spadix .- It grows about eight or nine inches high : flowers with us in June, and grows in moist places in Virginia and New England. The root of this, as well as that of the common dragon, is acrimonious and purgative. The whole plant. while fresh, is of an almost insupportably acrid taste, but loses the greatest part of that quality in drying. It was formerly much esteemed for its supposed officacy in malignant fevers, the small-pox, and other disorders; and was also supposed to be a noble sudorific and resister of poison, but is at

plant in gardens ; they must have a moist shady situation, or they will not thrive.

4. Arum Venosum ; Purple flowered Arum. Leaves pedate, compound ; leafiets suboval, quite entire; lamina lanceolate, longer than the spadix .- Native country unknown; it flowers in March.

5. Arum Pentaphyllum; Five-leaved Arum. Leaves quinate, compound .- Native of the East Indies and China. The root is accounted warm, attenuant, and deobstruent, and is given in the epilepsy, convulsions, obstructions of the uterus, bites of venomous animals, and other disorders in the East. 6. Arum Triphyllum; Three-leaved Green-stalked Arum,

Leaves ternate ; lamina lanceolate, acuminate, the length of the spadix; without stems; leaves compound.-Grows ten inches high, in Cochin china. This and the two following species are propagated by offsets. They will live in a shcl-tered situation in the open air, or if the surface of the ground be covered with tan, to keep out the frost in winter; and they will thrive better in the full ground than in pots.

7. Arum Atrorubeus : Three-leaved Purple-stalked Arum. Leaves ternate, compound ; lamina ovate, shorter by half than the spadix .- Native of Virginia, flowering with us in June and July: see the sixth species.

8. Arum Ternatum. Leaves compound, ternate; recentacle longer than the spathe. Found in Japan, flowering in May and June; see the sixth species.

9. Arum Colocosia: Eguptian Arum. Leaves simple. peltate ovate, repand, semibifid at the base .-- Native of the Levant, Egypt, Sicily, and Italy, near Salerno, where it is esteemed a wholesome food, and though not very delicate. is frequently eaten in the East. The roots when young are sometimes eaten raw, the roots and petioles are boiled. This and the tenth, eleventh, twelfth, thirteenth, fourteenth, and sixteenth species, are easily propagated by the offsets which they put out plentifully from their roots; these must be planted in pots filled with light earth, and plunged into a hotbed, to promote their taking root; and if they be afterward continued in the bark-stove, they will make greater progress, and produce larger leaves.

10. Arum Bicolorum ; Two-coloured Arum. Leaves peltate, sagittate, coloured ou the disk, simple spathe contracted in the middle, subglobular at the base ; lamina roundish, acuminate, upright, somewhat convolute.-Cultivated in Madeira, flowers in June and July : see the ninth species.

11. Arum Esculentum; Esculent Arum, or Indian Kale. Leaves peltate, ovate, quite entire, simple, emarginate at the base .- It is very frequent in China and Cochin-china, in shallow waters by the sides of rivers and marshes, and is a common food there, the root and tender petioles being eaten boiled. The bruised leaves are applied to tumors, and imagined to be an autidote for poisonous bites. It is also a native of, and frequently cultivated in, Japan, where the sliced roots and stalks are put into soups and broths. It is found in all the islands of the Southern Ocean, except those which are drowned or desert; and is cultivated every where within the tropics, and even in the northern extremity of New Zealand. The natives of the South Sea islands bestow great pains on the culture of this root; for in the first months of its growth it succeeds best when the ground is inundated; but afterwards it should be laid dry, which they do by means of ditches dug round the fields. The root, which is the common food in many of the islands, is extremely acrid, and when eaten raw will excoriate the mouth, but baked in hot ashes, loses its acrimonious quality, and becomes mild and well-tasted : it is, however, heavy upon a weak stomach, and tends to propresent very little regarded. It is difficult to preserve this duce costiveness. The leaves are extremely soft, glaucous,

natives instead of dishes : see the ninth species.

12. Arum Macrorhizon; Long-rooted Arum. Leaves peltate, cordate, repand, simple, two-parted at the base .- This species is distinguished by its great size. It is a native of China and Cochin-china, the East Indies, Cevlon, and the islands of the Southern Ocean ; and, as well as the foregoing species, is eaten by the natives, after the roots are deprived of their acrimony by dressing : see the ninth species.

13. Arum Peregrinum. Leaves simple, cordate, obtuse, mucronate, angles rounded .- Native of America: see the ninth species.

14. Arum Divaricatum. Leaves cordate, hastate, divaricate, simple .- Native of Malabar and Cevlon : see the ninth species.

15. Arum Trilobatum ; Three-lobed Arum. Leaves sagittate, trilobate, simple; flower sessile .- Native of Ceylon, Amboyna, Japan, and Cochin-china. It flowers here in May and June, and is propagated by offsets, which come out in abundance when the plants are in health. They are very impatient of cold, and must be placed in the tan-bed of the bark-stove.

16. Arum Sagittæfolium ; Arrow-leaved Arum. Leaves simply sagittate, triangular, the angles divaricate, acute.-Native of the Spanish West Indies, China, and Cochin china, where it is esteemed a wholesome green when boiled; and where the common European vegetables are with difficulty procured, this proves a good succedaneum: see the ninth species.

17. Arum Maculatum; Common Arum. Leaves simple, hastate, quite entire, spadix club-shaped .--- Native of all except the most northern parts of Europe, growing in shady places, on the banks of ditches, and flowering in May. The berries ripen at the close of summer. The fresh roots and leaves are extremely acrid; on first tasting them, they seem to be merely mucilaginous and insipid, but they soon affect the tongue for several hours, with a pungency as if it had been pricked with needles, which sensation may be allayed by milk, butter, or oil. When dried, they become farinaceous and insipid, in which case they might be used for food in case of necessity; and by boiling or baking would probably afford a mild and wholesome nourishment, as well as those sorts which are natives of hot climates. The berries are devoured by birds; and it has been supposed that they, particularly pheasants, eat the roots. These, when dried and powdered, are used by the French as a wash for the skin, and sell under the name of cypress powder, at a high price, being an excellent and innocent cosmetic. Starch may also be made from them, but the hands are liable to be blistered in using it. They have occasionally been substituted for soap. When newly dried and powdered, the root has been given as a stimulant, in doses of a scruple and upwards; but in being reduced to powder, it loses much of its acrimony; and there is reason to suppose, that the compound powder, which takes its name from this plant, owes its virtues chiefly to the other ingredients. The pulvis ari compositus, or powder composed of arum, is therefore discarded from the London dispensatory, and instead of it a conserve is inserted, made by beating half a pound of fresh root with a pound and half of fine sugar. In the medicine recommended by Sydenham against rheumatisms, the acrid antiscorbutic herbs are largely joined with it. Dr. Lewis orders the fresh root to be beaten with a little testaceous powder, and mixed with an equal quantity of gum-arabic, and three or four times as much conserve, and thus to be made up into an electuary; or else to

and covered with a very fine silky nap, and are used by the ceti, adding any watery liquor, and a little syrup, to form an emulsion ; two parts of the root, two of gum, and one of spermaceti. In these forms he has given the fresh root from ten grains to upwards of a scruple, three or four times a day ; it generally occasioned a sensation of slight warmth, first about the stomach, and afterwards in the remoter parts; manifestly promoted perspiration, and frequently produced a plentiful sweat : several obstinate rheumatic pains were removed by this medicine, which he therefore recommends to further trial Chewed in the mouth, it has been known to restore the speech in paralytic cases ; and made into a conserve, it is efficacious in the scurvy and the rheumatism ; it likewise increases the urinary secretion, and is good in the gravel. But in whatever form it is used, the roots should be fresh, for it loses the greatest part of its efficacy in drying, and becomes insipid. It grows naturally in woods, and is seldom admitted into gardens. Both this and the large Italian variety propagate very fast by offsets from the root, and will thrive in any soil or situation. The best time to transplant these, is soon after the seeds are ripe, for by the end of October they will be putting out new fibres. There are also two other varieties.

18. Arum Virginicum; Virginian Arum. Leaves simple, hastate, cordate, acute, angles obtuse .-- Grows wild in wet places in Virginia, Carolina, Pennsylvania, &c. The savages boil the spadix with the berries, and devour it as a great The berries, when raw, have a harsh pungent taste, dainty. which they lose in a great measure by boiling.

19. Arum Proboscideum ; Apennine Arum, Leaves simple, hastate; spathe declinate, filiform, subulate .- Native of the Apennines. This and the two following species flower in April, and multiply fast by offsets in a shady situation, but seldom produce seeds in England.

20. Arum Arisarum: Broad-leaved-hooded Arum, or Friar'scowl. Leaves simple, cordate, oblong, aperture of the spathe ovate .-- Native of woods in the south of France, Italy, Spain. Portugal, and Cochin-china : see the nineteenth species.

21. Arum Pictum; Painted Arum. Leaves simple, cordate, painted with coloured veins. See the nineteenth species.

22. Arum Ovatum. Leaves simple, ovate-oblong ; spathe scabrous .- Native of the East Indies.

23. Arum Tenuifolium; Grass-leaved Arum, or Narrowleaved Friar's-cowl .-- It grows naturally about Rome, Montpellier, and in Dalmatia and the Levant.

24. Arum Cannæfolium. Leaves simple, lanceolate, veinless; parasitical upon trees .- Native of Surinam.

** Caulescent.

25. Arum Arborescens; Tree Arum. Straight; leaves sagittate .- Native of South America. This and the following remaining species of this genus are propagated by cutting off the stalks into lengths of three or four joints, which must be laid to dry for six weeks or two months; for if the wounded part be not perfectly healed over before the cuttings are planted, they will rot and decay. Plant them in small pots of light sandy earth, plunged into a moderate hot bed of tan, taking care that they have little wet, until well rooted and then some of them may be placed in a dry stove, and others plunged into the tan-bed in the bark-stove, where they will grow fastest and flower most.

26. Arum Seguinum; Dumb-cane Arum. Nearly upright; leaves lanceolate, ovate.-This species grows naturally in the sugar islands and other warm parts of America, chiefly in the low grounds. The whole plant abounds in an acrid juice, so that if a leaf or a part of the stalk be broken, and applied to the tip of the tongue, it occasions a very be rubbed with a thick mucilage of gum arabic and sperma- painful sensation, and such an irritation of the salivary ducts,

ARU

that they presently swell so that the person cannot speak ; concrete white substance, called tabaheer, or tabashir, an from this quality, and its being jointed, they call it/duth-can in Janaka, where it is said they sometimes cruelly rub the is commonly found in what are called the female or large bamboos, which, on shaking, are found to contain a fluid, staks is used for a beter purpose, to bring sugar to a good grain, when the juice is too viscid, and cannot be brought to plant is recommended by way of fomentation in dropsie; it pertainly must be a strong resolutive, which cannot fail to be find the treater of this streagthen and stimulate the relaxed fibres in such cases.

27. Arum Hederaceum ; *Ivy-leared Arum*. Radicant ; leaves cordate, oblong, acuminate ; petioles round.—Native of the West Indies : see the twenty-fifth species.

29. Arum Lingulatum ; Tongui-laured Arum. Creeping ; leaves cordate, lanceolate ; petioles edged with membranes. -Native of the West Indies, where it climbs the trees with great case, and grows more succulent and invariant towards the top : see the twenty-fifth species.

29. Arum Auritum; *Ear-leared Arum*. Radicant; leaves ternate, those on the side one-lobed.—Native of the West Indies; see the twenty-fifth species.

30. Arnm Indicum; *Indian Arum*. Nearly upright; leaves ovate, bifid at the base, rounded, spadices axillary.—Native of the East Indies, and cultivated in Cochin-china, where the stalk is boiled and eaten.

31. Arun Cucullatum; Cowled Arum. Upright; leaves peltate, cordate, with the ears cowled.—Native of the suburbs of Canton.

32. Arum Spirale; Spiral Arum. Stemless; leaves lanceolate; spathe spiral, sessile.-Native of Tranquebar in the East Indies.

Aruncus. See Spiræa.

Arando; a genus of the class Triandria, order Digynia.-GENERIC CHARACTER. Calis : glume one or many-flowered, two-valved, erect; valves oblong, acuminate, awnless, one shorter. Corolla: two-valved; valves the length of the calix, oblong, acuminate; from their base arises a lanugo almost the length of the flower. Nectary two-leaved, very small. Stamina: finamenta three, capillary. Anthera forked at both ends. *Pistli*: germen oblong. Styles two, capillary, reflex, villose. Stigmas simple. Pericary: none. Cosula: adheres to the seed without gaping. Scel : single, oblong, acuminate at both ends, furnished with a long down (pappus) at the base. ESENTIAL CHARACTER. Colis:: two-valved. Florets heaped, surrounded with wool.......The species are,

1. Arundo Bambos; Bambu, or Bamboo-cane. Calices manyflowered ; spikes in threes, sessile. The highest and the last of all the bamboos, covered very thick with spines. The bamboo cane grows naturally almost every where within the tropical regions, and there is perhaps scarcely any plant which serves such a variety of domestic purposes. The houses of the meaner people in the East Indies are almost entirely composed of it, and it is said to be strong and perfect after lasting an hundred years. Bridges, masts for boats, boxes, cups, baskets, mats, and a great variety of other utcnsils and furniture, both domestic and royal. Paper is also made from it by bruising it, and steeping it in water, and thus forming it into a paste. It is the common fence for gardens and fields, and is frequently used as pipes for conveying water. The leaves are generally put round the chests of tea which are sent to Europe from China, as package, fastened together so as to form a kind of mat. The tops of the tender shoots are frequently pickled in the West ladies. In the cavities or tubular parts of the bamboo, is found, at certain seasons, a 11.

article which the Arabian physicians hold in great estimation: it is commonly found in what are called the female or large bamboos, which, on shaking, are found to contain a fluid, which after some time gradually lessens, and then they are opened, in order to extract the tabasheer. The nature of this substance is very different from what might have been expected in the product of a vegetable. Its indestructibility by fire, its total resistance to acids, its uniting by fusion with alkalies, in certain proportions, into a white opaque mass, into a transparent permanent glass ; and its being again separable from these compounds, entirely nuchanged by acids, &c.; seem to afford the strongest reasons for considering it as very nearly identical with common silicious earth. As to the medical virtues of this part of the plant, though in great esteem as a drug among the orientalists, it is not regarded in modern Europe. Loureiro informs us, that the bark, buds, and root, are used. The leaves, he says, are cooling, emolhent, and resolvent; their decoction is good in fevers, coughs, pains of the throat, &c. the thin bark is cooling and agglutinant, and a gentle astringent: it is good in feverish heats, hamorrhages, nauseas, and vomitings : the roots and buds are attenuating, and promote urine, and purify the blood, and are used for disorders of the kidneys, bladder, and urethra, wandering pains, obstructions, and in venereal cases: from the fresh roots, mixed with tobacco leaves, and betel, in equal portions, and infused and macerated for some days in oil, is prepared an ointment of great efficacy in discussing hard and schirrhous swellings. In England, it must be preserved in a warm stove; and, as the roots spread very wide, it should be planted in a large tub. filled with rich earth : this must be plunged into a hot-bed in the bark-stove, and be well supplied with water. It may be propagated by slips from the roots, which should be taken off in the spring, that they may be well established before winter. There are many varieties of this species, with one of which the Turks make their writing pens.

2. Arundo Donax; Cultivated, or Evergreen Red. Calicies five-flowered; panicle diffused; culm shrubly.—Native of the South of Europe, Sibera, Egypt, and Cochin-china. It will bear the cold of our winters in the open ground, provided it be planted in a soil not too wet, and laving in severe winters a little mulch to the roots. It is propagated by parting the roots early in the spring, before they begin to shoot, and will in a year or two, if the ground be good, make very large stools, from each of which eight or ten canes are produced. It never flowers in England.

3. Arundo Phragmites ; Common Reed. Calices fiveflowered ; panicle loose .- It flowers from July till September, and ripens its seeds in October and November. It is very common by the sides of rivers, in ditches, and large standing waters. In automu, when the leaves begin to fall, and the stems are changed brown, it is cut for making screens in kitchen-gardens, and for many other uses, as thatching, for which it is more durable than straw for ceilings, and to lay across the frame of wood work, as the foundation for plaister floors. The panicles are used by the country people in Sweden, to dye wool green, and the root has been recommended as answering the same purposes as Dog's grass, or triticum caninum. According to Hill, the inice of the fresh root excites the menstrual discharge powerfully, but not violently : it likewise increases the urinary evacuation, and is serviceable in stranguries and the gravel.

4. Arundo Epigejos; Small Reed-grass. Calices oneflowered; panicle erect; leaves smooth underneath.-Native of many parts of Europe, and flowering in July.

 Arundo Calamagrostis ; Wood Reed-grass. Calices 2 L. one-flowered, smooth; corollas woolly; culm branched; root perennial, creeping.—Native of most parts of Europe, in moist woods and hedges; flowering in June and July.

ASA

6. Arundo Arenaria; Sca Reed.grans. Calices one-flow: ered; leaves rolled inwards, dagger.pointed, and pungent.—A native of sandy coasts in Europe and America; flowering in June and Juy. By means of its creeping roots it helps very much to consolidate driving sands, which gather about it in hills or banks, and are thus prevented from dispersing over and impoverishing the adjoining fields. The Dutch have profited by their knowledge of this fact; and Mr. Woodward informs us, that it is planted about wells in Norfolk, to aid in repelling the sea. The country people know it by the name of Sea Matveed, Marema, and Helme. They cut and bleach it for making mats; and where it is plentiful, houses are thatched with it.

7. Arundo Conspicua. Calices one-flowered; panicle loose, from erect spreading; awn of the outer petal reflex, and very long.---Native of New Zealand.

 Arundo Agrestis. Flowers six-stamined; panicle spiked; spikelets heaped; lower branches of the culm very spiny; calices one-flowered.—Native of mountains and dry desert places in Cochin-china.

9. Arundo Mitis. Flowers six-stamined; paniele erect, contracted; spikes long imbricate; culm very even narmed; calies one-flowered.—It is cultivated in the fields and hedges of Cochin-china; and being divided into_long thin pieces, is used for weaving into hats, coffers, baskets, and a variety of very elegant utensils.

10. Arundo Multiplex, Flowers six-stamined; spikes interrupted; spikelets in whorls; culm divided; calices oneflowered.—Used in the cultivated parts of the northern provinces of Cochin-china, where it is used as fence-work or hedges to separate gardens.

11. Arundo Bengalensis. Calices two-flowered ; panicle erect, with three-flowered pedicles .-- Native of Bengal.

12. Arundo Piscatoria. Calices one-flowered; spike terminating; culm branched; leaves minute.—Native of Cochin-china; being very tough, and tapering towards the end, it is very fit for fishing-rods.

13. Arundo Dioica. Calices one-flowered ; spikes in bundles, compound ; spikelets linear.—Native of woods in Cochin-china.

14. Arundo Colorata; Reed Canary Grass. Calices one-fowered, keeld; corollas smooth with two languinose pencils at the base; leaves flat.—This is a native of Europe, on the banks or rivers and ditches; howering in July and August. It is used to thatch ricks and cottages, for which purpose it is more durable than straw. In the province of Scania, they mow it twice a year, and their cattle eat it. The texture is so lard that it must be cut young, if cattle be expected to touch it. There is a cultivated variety of this grass in our gardens, with beautifully striped leaves. The sirpes are generally green and white; but sometimes they have a purplish cast. This is called Ladie's Laces, Painted Grass, or Ribband Grass.

Asarabacca. See Asarum.

Assrum; i a genus of the class Dodecandrin, order Monogynia.—GENERIC CHARACTER. Calit: perianth oneleafed, bell-shaped, three or four cleft, coriaceous, coloured, permanent; clefts erect, bent in at the top. Corolla: none. Stamina: j fundenta twelve, subulate, half the length of the Calit: ament Subtract of the calit; style cylindric, the length of the stamin; stjums stellate, six-parted is parts reflex. Pericapre capsule the South Sea.

corjaccous, within the substance of the calix, mostly six-celled. Scads: several ovate. Essential CHARCTER. Calix; three or four cleft, placed on the germen. Corolla: none. Copulat: confaccous, crowned.—These plants delight in a most shady situation, and may be increased by parting the roots in autumn.—The species are,

1. Asarum Europæum; Common Asarabacca. Leaves kidney-shaped, blunt, in pairs .- A native of many parts of Europe, in woods and shady places; flowering in April, and May. With us it has been found only in Lancashire. The root powdered, and taken to the amount of thirty or forty grains, excites vomiting ; and when coarsely powdered, it generally purges. The powder of the leaves is the basis of most cephalic snuffs, which occasion a considerabledischarge of mucus from the nostril, without much sneezing; and sometimes proves useful in disorders of the head; but should be administered with caution, as alarming symptoms have been sometimes known to succeed an imprudent use of them. An infusion of one or two drachms of the leaves vomits. Allioni gives a particular account of the qualities of asarabacca, and seems to have a high opinion of it, especially in obstinate intermitteuts, and above all in the quartan ague. Others entirely reject it, as too acrid when fresh, and too insinid when dry. The Pulvis Asari Compositus, or Powder of Asarabacca, is composed of equal guantities of the dried leaves of asarum, marjorum, and marum, and of the dried flowers of lavender. The powdered root, taken to the amount of thirty or forty grains, is a rough emetic ; and the leaves powdered, and snuffed up the nose, occasion a considerable discharge of mucus from the head without exciting much sneezing. The salutary discharge occasioned by snuffing a grain or two of this powder up the nose, will sometimes continue for two or three days together; and a single dose has been known to remove a palsy of the mouth and tongue. It is an excellent medicine in soporific distempers, and those disorders of the head which proceed from a redundancy of viscid matter; but the patient should carefully avoid cold during the operation, as it might subject him to inflammations of the face, and other alarming consequences. The dried roots or leaves, according to Meyrick, taken in large doses, vomit and purge violently, but in smaller doses they operate safely and effectually by urine, and are of great efficacy in obstructions of the menses, the jaundice, and the dropsy.

 Asarum Canadense; Canadian Asarabacca. Leaves kidney-shaped, nucronate.—Native of Canada; flowering from April to July. Too much wet in winter will cause this species to rot.

3. Asarum Virginicum; Sweet-seented Asarabacca. Leaves heart-shaped, bluut, smooth, petioled.—This seldom thrives well if it be too much exposed to the sun in summer, and should be planted so as to have only the morning sun.—Native of North America.

Asarina ; a genus of the class Dieceia, order Monandria. —GENERIC CHARACTER. Male flowere, Calis: ament filiform; floscules scattered, sessile; perianth a very short scale. Corolla: none. Stamina : filamenta single, very short; anther oblong, from spreading recurve, four-furrowed, large. Female flowers in a different plant. Calis: as in the male. Corolla: none. Pistil: germen globose; style none; stigma flat, three-lobed; growing to the germ. Pericarp: drupe. Seeds: single. ESENTIAL CHARACTER. Calis: ament, filtorm. Corolla: none. Male, anthera worm-shaped. Female, style none; stigma three-lobed.— One species only has been hitherto discovered, viz.

 Asarina Polystachya.—A native of the Society Isles, in the South Sea. Ascium; a genus of the class Polyandria, order Monogyma.-Gis REIC CURARCER. Calix: periatuh five-leaved; leaftets roundish, concave, coriaceous, coloured on the margin. Corolaz, petals five, ovate, acute, larger than the calix, inserted into the receptacle. Stamina: fitamenta very many, short, three-sided, inserted into the receptacle; anthera oblong. Platil: germen ovate; style very short; stigmn headed. Periarp: on-celled. Seeds ; very many. Gorolla: five-petalled. Berry: one-celled, with very many seeds.---Oly one species is yet known.

1. Ascium Norantia.-This tree is a native of Guiana.

Asclepias ; a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix: perianth five-cleft, sharp, very small, permanent, Corolla: monopetalous, flat or reflex, five-parted; divisions ovate, acuminate, slightly bending with the sun; nectaries five, growing to the tube of the filamenta below the anthera, fleshy or cowled, protruding from the bottom a sharp horn bending inwards. Stamina : filamenta five, collected into a tube, swelling at the base; anthera oblong, upright, two-celled, terminated by an inflex membrane lying on the stigma, having a reversed wing on each side, growing broader downwards, with its edge contiguous to the next. The pollen is collected into ten corpuscles, inversely lanceolate, flat, hanging down into the cells of the anther by short threads, frequently flexuose; which are annexed by pairs to five cartilaginous twin tubercles, each placed on the tip of the wings of the authera, adhering to the angles of the stigma between them. Pistil; germina two. oblong, acuminate ; styles two, subulate ; stigma common to both, large, thick, five-cornered, covered at the top by the apices of the anthera, umbilicate in the middle. Pericarp : Follicles two, large, oblong, acuminate, swelling, one-celled, Seeds: numerous, imbricate, crowned with one-valved. down ; receptacle membranaceous, free. ESSENTIAL CHA-RACTER. Contorted ; nectaries five, ovate, concave, putting out a little horn. The North American and European species of this genus are hardy enough to bear the open air ; and therefore are proper for large borders in pleasure grounds, and to mix with shrubs. The other species require the protection of the green house or stove ; and all of them are tall perennials, flowering from June to August or September, mostly dying down to the root in autumn. They should have little water, especially in winter, for as they abound with a milky juice, much wet will rot them. They may be propagated by seeds, where these can be obtained, or by cuttings; the hardy sorts may be increased by parting the roots. The species are.

1. Asclepias Undulata; Waved-leaved Swallow-wort. Leaves sessile, oblong, lanceolate, waved, smooth; petals ciliate.—Native of the Cape of Good Hope, and flowers here in July.

2. Asclepias Crispa; Curled-leaved Swallow-wort. Leaves cordate, lanceolate, waved, scabrous, opposite; umbel terminal.—Native of the Cape of Good Hope.

3. Asclepias Pubescens; Pubescent Swallow wort. Leaves ovate, veiued, naked; stem shrubby; peduncles villose; flowers purple.—Native of the Cape of Good Hope.

4. Asclepias Volubilis; *Twining Swallow-wort*. Leaves ovate, quite entire, acuminate; stem arboreous, twining; umbels erect.—Native of Malabar and Ceylon.

5. Asclepins Asthmatics; Asthmatic Suallow-wort. Leaves petiolate, oordate ovate, above smooth, quite entire; stem shrubby, twining, hirsute; umbels few-flowered.—Found in Ceylon, where the root is esteened a good medicine in asthmatic disorders.

6. Asclepias Gigantea; Curled; flowered Gigantic Swatlow.wort. Leaves obovate-oblong; petioles very short; seg: ments of the corolla reflex, involute; flowers white.—Native of the East and West Indies.

7. Aselepias Syriaca; Syrian Swallow-wort. Leaves oval, tomentose underneath; stem quite simple; umbels nodding,—It flowers in July, and is a native of North America.

8. Asclepias Amona; Oral-leaved Swallow-wort. Leaves ovate, rather hairy underneath; stem simple; umbels and nectaries erect.—The flowers, which appear in July, are of a bright purple colour, but are not succeeded by pods in Englaud.—It is a native of North America.

10. Asclepias Variegata; Variegated Swallow-wort, or Wisank. Leaves ovate, wrinkled, naked; stem simple; umbels subsessile; pedicles tomentose.—Flowers in July; native of North America.

11. Asclepias Curassavica; Curassoa Swallow-wort, Bastard Ipecacuanha. Leaves lanceolate, smooth, shining; stem simple; umbels erect, solitary, lateral .- Mr. Miller avers, that the roots of this plant have been sent to England for ipecacuanha, from which however they may be easily distinguished, the true ipecacuanha having jointed fleshy roots which run deep into the ground. The juice of this plant, made into syrup with sugar, has been observed to kill and bring away worms wonderfully, even when most other vermifuges have failed ; it is given to children in the West Indies, from a tea-spoonful to a table-spoonful. The juice and pounded plant are applied to stop the blood in fresh wounds, and is said to be a powerful astringent in such cases. The root, dried and reduced to powder, is frequently used by the Negroes as a vomit; and hence its name of Wild or Bastard Ipecacuanha.

12. Asclepias Nivea; White or Almond-leaved Swallowwort. Leaves ovate-lauceolate, smoothish; stem simple; umbels erect, lateral, solitary.—Native of North America.

13. Asclepias Incarnata; *Flesh-coloured Swallow-wort*, Leaves lanceolate; stem divided at top; umbels erect, twin, —Native of North America.

Asclepias Decumbens; Decumbent Swallow-wort.
Leaves villose; stem decumbent.—Native of North America.
Asclepias Lactifera; Milky Swallow-wort. Leaves

ovate; stem erect; umbels proliferous, very short.-Native of Ceylon.

16. Asclepias Vincetoxicum; Officinal Swallow-wort, or Tame-poison. Leaves ovate, bearded at the base; stem erect; umbels proliferous .- Native of most parts of the continent of Europe. It was formerly imagined to be an alexipharmic, and hence its name of Vincetoxicum, Tame poison, absurdly composed of a Latin and a Greek word. It has been also recommended in dropsical cases, and disorders peculiar to women, but is disused in the present practice, and is too suspicious a plant to be internally taken, except with great caution. The external application for foul ulcers, abscesses of the breast, and scrofulous tumors, is more plausible. The root is the part to be used : an infusion of it, fresh gathered, removes obstructions, increases the urinary discharge, and is good in the jaundice ; dried, and given in powder, it promotes perspiration, and is good against fevers, the small-pox, measles, and other eruptive complaints. No animal, except the goat, is said to eat it, though Linnæus affirms that the horse will crop it after it is frost-bitten. The down or cotton may be used for stuffing cushions, pillows, &c .---- There are several varieties of this species.

17. Asclepias Nigra; Black Swallow-wort. Leaves ovate, bearded at the base; stem twining a little at top.-It is rather

ASP

about Nice, and in Spain.

18. Asclepias Arborescens; Arborescent Swallow-wort, Leaves ovate; stem shrubby, subvillose; corolla white,-Native of the Cape of Good Hope.

19. Asclepias Fruticosa; Shrubby or Willow leaved Swallow-wort. Leaves linear-lanceolate; stem shrubby .--- It flowers from June to September; a native of the Cape of Good Hope.

20. Asclepias Repanda; Repand Swallow-wort. Leaves revolute, repand, hairy .--- Native country unknown.

21. Asclepias Sibirica; Siberian Swallow-wort. Leaves linear-lanceolate, opposite or in threes ; stem decumbent .--Native of Siberia, where it flowers in July and August.

22. Asclepias Verticillata; Verticillate Swallow-wort. Leaves linear, verticillate; stem erect .- Native of North America.

23. Asclepias Rubra; Red Swallow-wort. Leaves ovate; umbels many, from the same common peduncle .- Native of Virginia.

24. Asclepias Tuberosa; Tuberous Swallow-wort. Leaves lanceolate; stem divaricate, hairy .- The flowers are of a bright orange colour. It flowers from the end of July until September, sometimes ripening seeds in England; and is a native of North America.

25. Asclepias Filiformis; Narrow-leaved Swallow-wort. Leaves filiform; stem erect; umbels lateral, elongate-peduncled .- Found at the Cape of Good Hope.

26. Asclepias Grandiflora; Great-flowering Swallow-wort. Leaves petiolate, oblong, hairy; stem simple, hirt erect; Bowers axillary, pedunoled. — Found at the Cape of GoodHope. 27. Asclepias Carnosa; Fleshy-leaved Swallow-wort.

Leaves ovate, fleshy, very smooth .- It is a native of China.

28. Asclepias Scandens; Climbing Swallow wort. Leaves oblong-lanceolate, subhirsute; stem shrubby, climbing; umbels lateral, compact; flowers sulphur-coloured,-Native of Carthagena in South America.

29. Asclepias Precera; Bell-flowered Gigantic Swallowwort. Leaves obovate-oblong; petioles very short; corol-las subcampanulate.-Native of Persia.

30. Asclepias Parviflora; Small-flowered Swallow-wort. Leaves lanceolate, acuminate, smooth, opposite, drawn to a point at the base: stem suffruticose, upright; umbels lateral, solitary .- Native of Cochin-china and East Florida.

31. Asclepias Linaria; Toad flax leaved Swallow wort. Leaves scattered, subulate, channelled ; umbels lateral, manyflowered .- Native country unknown; flowers from August to October.

32. Asclepias Mexicana ; Mexican Swallow-wort. Leaves six together in whorls, lanceolate ; flowers umbelled .-- Native of Mexico; also flowering from August until October.

33. Asclepias Fusca. Stems creeping; leaves cordate, lanceolate; umbels axillary in pairs .- Native of Cochinchina, growing in waste places and upon old walls.

34. Asclepias Viminalis. Stem suffruticose, twining, filiform ; leaves opposite, lanceolate, smooth ; umbels lateral, many-flowered .- The whole plant is of a dark green colour, full of milk, and is very common in the larger inland woods of Jamaica.

Ascyrum; a genus of the class Polydelphia, order Polyandria .- GENERIC CHARACTER. Calix: perianth fourleaved; the outer leaflets opposite, very minute, linear; the inner heart-shaped, large, flat, erect; all permanent. Corolla: petals four, ovate; the outer opposite, very large; the inner less. Stamina: filamenta numerous, bristle-shaped, slightly united at the base in four parts ; anthera roundish. Pistil germen oblong; style scarcely any; stigma simple. Pericarp:

rare, being only found in the south of France, the mountains | capsule oblong, acuminate, one-celled, two-valved, inclosed by the larger leaves of the calix. Seeds : numerous, small, roundish, fixed to the edge of the valves. ESSENTIAL CHA-RACTER. Calix: four leaved. Petals: four. Filamenta many in four divisions .---- The species are,

1. Aseyrum Crux Andreæ; Common Ascyrum, or Saint Andrew's Cross. Leaves ovate ; stem round ; panicle dichotomous .- Native of North America; flowering in July and August.

2. Ascyrum Hypericoides. Leaves oblong ; branches ancipital .- An elegant little shrub, seldom above three feet in height. Native of South Carolina, Maryland, and the cooler mountains of Jamaica.

3. Ascyrum Villosum. Leaves hirsute; stem stiff, and straight .- Reaches three feet in height; and grows naturally in Virginia.

Ash, Common, Flowering, and Manna. See Fraxinus.

Ash, Mountain. See Sorbus.

Ash-weed. See Ægopodium. Asp or Aspen Tree. See Populus.

Aspalathus ; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix: perianth oneleafed, five-cleft; divisions acuminate, equal, except that the upper is larger. Corolla : papilionaceous; banner compressed, ascending, obovate, generally hirsute on the outside, obtuse with a point; wings lunulate, obtuse, spreading, shorter than the banner; keel bifid, conformable with the wings. Stamina ; filamenta ten, uniting into a sheath, gaping longitudinally at top, ascending; anthera oblong. Pistil: germen ovate ; style simple, ascending ; stigma sharp. Pericarp : legume ovate, awnless. Seeds : generally two, kidnev-shaped. ESSENTIAL CHARACTER. Calix: five-cleft: the upper division largest; legume ovate, awaless, with about two seeds. With few exceptions, the plants of this genus are natives of the Cape of Good Hope; few of them have been cultivated in Europe, but they may be propagated by seeds obtained from thence, and sown in light earth as soon as they arrive. When they come up, transplant them into separate pots of light earth, and plunge them into a moderate hot-bed. till they have again taken root, after which they may be gradually innred to the open air in summer, but in autumn and winter they must be carried into the green-house .--The species are,

1. Aspalathus Spinosa; Thorny Aspalathus. Leaves fascicled linear, naked, surrounding a genumaceous spine.

2. Aspalathus Verrucosa; Warted Aspalathus. Leaves fascicled, filiform; buds warted, tomentose, naked.

3. Aspalathus Capitata; Headed Aspalathus. Leaves fascicled, linear, sharp ; flowers headed ; bractes naked.

4. Aspalathus Glomerata; Glomerate Aspalathus. Leaves fascicled, linear, sharp, villose, bent inward; flowers headed; divisions of the calix ovate; corollas smooth.

5. Aspalathus Astroites; Starry Aspalathus. Leaves fascicled, subulate, mucronate, smooth; stem villose; flowers scattered .- This has the appearance of juniper.

6. Aspalathus Chenopoda. Leaves fascicled, subulate, mucronate, rough with hairs ; flowers headed, very hirsute.

7. Aspalathus Albens; White Aspalathus. Leaves fascicled, subulate, silky, spreading at top; bunches of flowers scattered.

8. Aspalathus Thymifolia; Thyme-leaved Aspalathus. Leaves fascicled, subulate, unarmed, smooth, very short, flowers alternate.-The leaves resemble those of thyme.

9. Aspalathus Ericifolia; Heath leaved Aspalathus. Leaves fascicled, linear, unarmed, hirsute; flowers alternate; calices linear.

10. Aspalathus Nigra; *Black Aspalathus*. Leaves fascieled, linear, rather obtuse; flowers headed, spiked, pubescent.

11. Aspalathus Carnosa; Fleshy Aspalathus. Leaves fascicled, almost columnar, obtuse; calices subpubescent, sharp; corollas smooth. Corolla yellow.

12. Aspalathus Ciliaris; Ciliate-leaved Aspalathus. Leaves fascicled, filiform, scabrous; flowers terminal, sessile; bauners pubescent. Corolla yellow, with an ash-coloured banner.

13. Aspalathus Genistoides; Broom-like Aspalathus. Leaves fascicled, filiform, polished; calices subracemed, pendulous; they and the corollas smooth, and yellow.

14. Aspalathus Hystrix; *Porcupiue Aspalathus*. Leaves fascicled, filiform, rigid, spiny, silky; flowers lateral, sessile, solitary; corollas villose.

15. Aspalathus Galioides. Leaves fascicled, linear, polished; peduncles two-flowered, elongate, leafy at the cnd.

16. Aspalathus Retroflexa. Leaves fascicled, subulate, smooth, very small; branches filiform, very spreading; flowers solitary, terminal. Keel of the corolla tomentose.

17. Aspalathus Uniflora; One-flowered Aspalathus. Leaves fascicled, linear, unarmed, smooth; stipules sharp, permanent; flowers solitary; divisions of the calices boat-shaped.

18. Aspalathus Araneosa. Leaves fascicled, bristleshaped, unarmed, hispid; flowers headed. Banner hairy on the outside.

19. Aspalathus Asparagoides. Leaves fascicled, setaceous, rather hairy; calices leaf-shaped, the length of the corolla, solitary; banner scarcely pubescent.

20. Aspalathus Sericea; Silky Aspalathus. Leaves fascicled, lanceolate, silky; peduncles terminal, two-flowered; banner almost naked.

21. Aspalathus Canescens; Hoary Aspalathus. Leaves fascicled, subplate, tomentose-silky; flowers lateral; banners pubescent. Corolla yellow, with a hoary pubescent banner.

pubescent. Corolla yellow, with a hoary pubescent banner. 22. Aspalathus Heterophylla; Various-leaved Aspalathus. Leaves of the branches fasciled, of the branchlets ternate, linear, rough with hairs; spikes terminal; calix and corollas villose.

23. Aspalathus Indica; Small-flowered Aspalathus. Leaves quinate sessile; peduncles one-flowered.—Native of the East Indies.

24. Aspalathus Cretica; Ever-green Aspalathus. Leaves trinate, wedge-shaped, smooth; the lateral ones shorter; stipules obsolete; flowers headed.

25. Aspalathus Quinquefolia; Five-leaved Aspalathus. Leaves in fives, sessile; peduncles spiked.—Native of the Cape.

26. Aspalathus Tridentata; Three-toothed Aspalathus. Leaves trine-lanceolate, smooth; stipules three-toothed, mucronate; flowers headed.—Native of the Cape of Good Hope.

27. Aspalathus Pilosa; Hairy Aspalathus. Leaves tern linear, villose; heads terminal, very hairy; corollas pubescent.

28. Aspalathus Anthylloides. Leaves trine, lanceolate, equal, subpubescent; stipples none; heads terminal.

29. Aspalathus Laxata; Loose-leaved Aspalathus. Leaves tern linear, villose; flowers in bunches of five; calices woolly; stems prostrate, round; corolla smooth and yellow.

30. Aspalathus Argentea; Silvery Aspalathus. Leaves trine, linear, silky; stipules simple, mucronate; flowers scattered, tomentose.

31. Aspalathus Callosa; Callous Aspalathus. Leaves trinc, subulate, equal; stipules roundish, callous; flowcrs spiked, smooth. 12. 32. Aspalathus Orientalis; Letant Aspalathus. Leaves ternate-lanceolate, pubescent; flowers in bunches of five; calices pubescent; stems crect, angular.—Found in the Levant.

33. Aspalathus Mucronata. Leaves tern, polished; branches acuminate; flowers in racemes; corollas smooth.

34. Aspalathus Pinnata; Pinnate-leaved Aspalathus. Leaves pinnatc-quinate, obcordate; peduncles headed.

35. Aspalathus Pedunculata; Small-leaved Aspalathus, Leaves fascicled, subulate, smooth; peduncles filiform, twice the length of the leaf.—It flowers in August.

36. Aspalathus Candicans; Fair Aspalathus. Leaves trine and fascicled, filiform, silky; flowers sublateral; banners naked.

37. Aspalathus Arborea; Tree Aspalathus. Leaves pinnate-quinate; racemes terminating.—It is a middling-sized tree.

Apprograms, a genus of the class Hexandria, order Monogynia.--GENERIC GHARACTER. Calis: none. Corolla: petals six, cohering by the clavs, oblong, erected into a tube; three alternately interior, reflex at the end, permanent. Stamina: filamenta six, filiform, inserted into the petals, erect, shorter than the corolla; anthera roundish. *Pistil*: germen turbinate, three-cornered; style very short; stigma a prominent point. *Periaerps*: herry globular, unbilicated with a point, three-celled. Seeds: two, round, angular, on the inside smooth. EssetTrat. CTARCTER. Corolle: six-parted, erect; the three inner petals reflected at the end. Berry three-celled, two-seeded.----The species are,

1. Asparagus Officinalis: Common Asparagus, or Sperage, Stem herbaceous, round, erect; leaves setaceous; stipules alike .-- It is propagated by seeds, sown broad-cast, but not too thick, on a level bed of good rich earth, in the beginning of March : the bed must be afterwards trodden all over, to bury the seed. Keep it clear of weeds during the following summer, and towards the latter end of October, when the aulm is quite withered, you may spread a little rotten dung, about two inches deep, over the surface of the ground, which will preserve the young buds from being injured by the frost-In the following spring the young plants will be fit to remove. Prepare the ground by trenching, and burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at least six inches above the level of the ground, and level the whole, after taking out all the large stones. In the beginning of April, with a narrow-pronged dung-fork, carefully fork up the roots, shaking them out of the earth, and separating them from each other, observing to lay their heads even, then range a very tight line across the plot of ground, throwing out by it a trench six inches deep, into which trench you may lay your roots, spreading them with your fingers, and placing them upright against the back of the trench, that the buds may stand forward, and be about two inches below the surface of the ground, and at twelve inches' distance from each other; then with a rake draw the earth into the trench again, laying it very level, which will preserve the roots in their right position. Then remove your line a foot farther back, and proceed as before. A small crop of onions may be sown at the same time, treading in the seeds, and raking the ground level. Six weeks after planting, you must cut up the weeds with a small hoe, and thin the onions wherever they rise in bunches, cutting up those onions which grow near to the asparagus shoots. This must be three times repeated, until the onions are fit to be pulled up, which is commonly in August, and is known by the falling down and withering of their greens. Some persons cuttheir asparagus for use, in the second spring after planting, but it is better to defer it till the third year. 2M

134

In the summer of the second year keep them free from weeds. digging the alleys between them in October, and forking the beds towards the end of the following March ; observing every other year to lay some rotten dung from a melon or cucumber bed, all over the beds, burying some in the alleys; also at the time for digging them up. When they appear about four inches above ground, you may then cut them sparingly, only taking the larger buds, and suffering the small to run up to strengthen the roots ; for the more you cut, the greater will be the increase of buds, but they will be smaller, and the roots sooner decay. A very prevalent error is that which has long prevailed with those people who will not dung their asparagus beds, because they think that the dung communicates a strong rank taste to the asparagus. This is a great mistake, for the sweetest asparagus grows upon the richest ground, and it is the poor land that occasions that rank taste so often complained of; the sweetness of asparagus being also proved by experiment to arise from the quickness of its growth, which is always proportionable to the goodness of the ground, and the warmth of the seasons. Eight rods of ground will be sufficient to supply a small family, and double that quantity for a large one. Some persons, who delight in having early asparagus, force it in the following manner, They provide a quantity of good roots, either of their own raising or purchased from such eardeus as plant for sale, such as has been two or even three years ont from the seed-bed; and having fixed upon the time at which they would wish to have their asparagus fit to cut, they prepare a quantity of new horse-dung about six weeks before, which is thrown into a heap for ten days or more in order to ferment, and having some sea-coal ashes mixed with it, they turn it over into a heap, where it must lie another week, when it will be fit for use. They then dig out a trench in the ground where they intend to make the bed, a foot and a half deep, of the width of the frames which are designed to cover it, and the length proportioned to the quantity which they design to raise : if it be only to supply a small family, three or four lights at a time will be sufficient, but for a larger family, six or eight lights will not be too much: they then lay down the dung into the trench, working it very regularly, and beating it down very tightly with a fork, laying it at least three feet in thickness, or more, when the beds are made in December; upon this they put the earth, taking great care to break the clods and lay it level, beginning at oue end to lay the roots against a little ridge of earth, raised about four inches high, and as close as possible to each other, in rows, with their buds standing upright, with a small quantity of fine mould between every row, observing to keep the crown of the roots exactly level. When you have finished laying your beds with roots, you must lay some stiff earth up to the roots, on the outsides of the bed, which are bare, to keep them from drying; and thrust two or three sharp-pointed sticks about two feet long, down between the roots in the middle of the bed at a distance from each other. The use of these sticks is to inform you what temper of heat the bed is in, which you may find by drawing up the sticks, and feeling the lower part : and if after the bed has been made a week, you find it does not heat, you may lay a little straw or litter round the sides, and also upon the top, which will greatly help it; or if you find it very hot, so as to endanger scorching the roots, it will be advisable to let it remain wholly uncovered, and to thrust a large stick into the dung on each side of the bed in two or three places, to make holes for the great steam of the bed to pass off, which in a short time will reduce the bed to a moderate heat. After the bed has been made a fortnight, you must cover the crowns of the roots with fine earth about two inches thick,

and when the buds begin to appear above ground, through that earth you must again lay on a fresh quantity, about three inches thick; so that in the whole it may be five inches above the crowns of the root, which will be sufficient. Then you must make a band of straw, or long litter, about four inches thick, which must be fastened round the sides of the bed, that the upper part may be level with the surface of the ground ; this must be fastened with straight sticks about two feet long, sharpened at the points to run into the bed : and upon this band you must set your frames, and put your glasses thereon; but if, after your bed has been made three weeks. you find the heat decline, you must lay a good lining of fresh hot dung round the sides of the bed, which will add a fresh heat thereto; and in bad weather, as also every night, keen the glasses covered with mats and straw ; but in the day-time let it be all taken off, especially whenever the sun appears, which, shining through the glasses, will give a good colour to the asparagus. A bed thus made, if it work kindly, will begin to produce buds for cutting in about five or six weeks, and will hold about three weeks in cutting; if rightly planted with good roots, it will produce in that time about three hundred buds in each light; so that where it is proposed to be coutinued until the season of natural asparagus, a fresh bed should be made every three weeks, until the beginning of March. from the time of the first bed being made; but if the last bed be made about a week in March, it will last till the season of natural asparagus : for the last beds will come a fortnight sooner to cut after making, than those made about Christmas; and the buds will be larger, and better coloured. as they will then enjoy a greater share of the sun.' The best ground for planting asparagus, to have large roots for hotbeds, is a moist rich soil; but for those intended for a natural produce, a middling soil, neither too wet nor too dry : yet a fresh sandy loam, when well dunged, is preferable to any other.

 Asparagus Declinates; Long-leared Asparagus. Stem unarmed, round; branches declined; leaves setaceous.—This species is ligher than the common sort, the leaves also are twice as long, and more abundant; the stem is annual. Native of the Cape of Good Hope.

3. Asparagus Palcatus; Sickle-lared Asparagus. Prickles solitary, reversed; branches rokud; leaves ensiform, falcated. Stem round and branching; leaves linear or swordshaped, sharp, narrow at the base, smooth.—A native of Cevion.

4. Asparagus Retrofractus; Larch.leared Asparagus, Prickles solitary; brancheszound, reflected, and retrofracted; leaves setaceous, fascicled.—It has very crooked irregular stalks, shrubky, and rising regibt or ten feet high, putting out several weak side-branches, having long narrow leaves of them coming out in clusters like those of the larch tree; under each of these clusters is placed a single sharp thorn. The stalks continue several years, and the leaves retain their greenness through the winter. It flowers in August and September, and is a native of the Cape of Good Hope.

5. Asparagus Æthiopicus. Prickles solitary, reversed; branches angular; leaves lauceolate, linear.—This resembles the third species, and is a native of the Cape of Good Hope.

6. Asparagus Asiaticus ; Slender stalked Asparagus. Prickles solitary ; stem erect ; branches filiform ; leaves fascicled, setaceous.—It is a native of Asia.

 Asparagus Albus, White Asparagus. Prickles solitary; branches angular, flexuose; leaves fascicled, triquetrous, awnless, deciduous. The spines are straight, spreading, or reflex.—It is a native of Spain and Portugal.

8. Asparagus Acutifolius ; Acute-leaved Asparagus. Stem

unarmed, angular, shrubby; leaves needle-shaped, rather rigid, perennial, mucronate, equal .- This has white crooked shrubby stalks, which rise four or five feet high, but have no spines on them; the leaves come out in clusters like those of the larch-tree: they are very short, and end in sharp prickles, so that they are troublesome to handle. It is a native of Spain, Portugal, and the Levant.

9. Asparagus Horridus; Thorny Asparagus. Leaflets shrubby, five-cornered ; prickles four-cornered, compressed, striated. The spines are about the length of a finger .- It is a native of Spain.

10. Asparagus Aphyllus ; Prickly Asparagus. Stem unarmed, angular, shrubby; leaves subulate, striated, unequal, diverging .- The flowers are small, and of an herbaceous colour : the berries are larger than those of the common sort, and are black when ripe. Native of the south of Europe.

11. Asparagus Capensis; Cape Asparagus. Spines in fours; branches aggregate, round; leaves setaceous; root tuberous; stems shrubby, filiform, flexuose; spines spreading, a little recurved, very acute .- Native of the Cape of Good Hope.

12. Asparagus Sarmentosus; Linear-leaved Asparagus. Leaves solitary, linear-lanceolate ; stem flexuose ; prickles recurved .- It sends out many weak climbing branches, which rise about five or six feet high from the root ; the shoots are armed with short crooked spines, which are so closely set on, that it is difficult to touch the branches. The roots, which are long, fusiform, many, whitish, fleshy, of a sweetish pleasant flavour, are eaten in Ceylon, where it grows naturally, with broth or milk, and the inhabitants appear to be very foud of them.

13. Asparagus Verticillaris ; Whorl leaved Asparagus. Leaves verticillate .- It was found by the French botanist Toarnefort in the Levant, about Derbent, and in other parts of the East.

Asperugo ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-cleft, erect, with unequal toothlets, permanent. Corolla: one-petalled, funnel shaped; tube cylindrical, very short; border semiquinquefid, obtuse, small; throat closed, with five convex, prominent, converging little scales. Stamina : filamenta five, in the throat very short ; anthera obongish, covered. Pistil: germs four, compressed; style filiform, short ; stigma obtuse. Pericarp : none. Calix : very large, erect, compressed ; lumellas flat, parallel, sinuate. Seeds : four, oblong, compressed, distant by pairs. ESSENTIAL Calix of the fruit compressed ; lamellas CHARACTER. flat-parallel, sinuated .- All these plants, except the second species, being perennial, may be increased by the roots as well as by seeds. The first sort will prosper under the shade of shrubs in wilderness quarters. The fifth must have the protection of a green-house, and does not continue many years, but it may be increased both by seeds and cuttings. The eighth growing naturally in chalk, and most of the others being natives of rocky places, require a dry open situation.

1. Asperugo Procumbens; Procumbent Asperugo. Calices of the fruit compressed ; root annual ; corolla scarcely exceeding the calix, deep blue, often white -- It is found in roads and among rubbish at Newmarket, Boxley in Sussex, Holy Island, and near Purfleet, flowering in April and May. Horses, goats, sheep, and swine eat it, but kine are not partial to it. It may be easily propagated by seeds sown in autunin; or, if they be permitted to scatter, the plants will come up of themselves.

the fruit swelling ; root annual, columnar, the thickness of a quill, red ; stem half a foot high or more ; flowers void of scent; petals pale yellow, and the scales of the throat yellow. -It flowers from June to August, and is a native of Egypt. It may be raised by seeds, but they must be sown in a moderate hot-bed. The plants will flower in the open air in summer, but they must be housed in winter.

ASP

Asperula ; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth small, four-toothed, superior. Corolla : one-petalled, funnel-shaped; tube cylindric, long; border four-parted; divisions oblong, obtuse, reflex. Stamina : filamenta four at the top of the tube; antheræ simple. Pistil: germ twin, roundish, inferior ; style filiform, bifid at top ; stigmas headed. Pericarp: two dry globular united berries. Seed : solitary, roundish, large. ESSENTIAL CHARACTER. Corolla: onepetalled, funnel-shaped. Seeds two, globular .---- The species are.

1. Asperula Odorata; Sweet-scented Woodroof. Leaves eight in a whorl, lanceolate; flowers in bunches, peduncled; root perennial, slender, jointed, yellowish, creeping a little below the surface, and sending out many small fibres .- Native of many parts of Europe, in woods, and shady places, flowering in May, and sometimes in April. 'The scent is pleasant, and when dried, this plant diffuses an odour like that of vernal grass, or anthox anthrum odoratum. It is said to give a grateful flavour to wine; and when kept among clothes, not only to impart an agreeable perfume to them, but to preserve them from insects: cows, horses, sheep, and goats, are reported to eat it. Since it is known to contain an acrid principle with much fixed alkaline salt, it is thought by some that it may be useful in obstructions of the liver and biliary ducts, although modern practitioners generally reject it. A strong decoction of the green herb opens obstructions of the viscera, and is good in the jaundice ; it likewise strengthens the stomach, and is often taken as a cordial.

2. Asperula Arvensis; Blue or Field Woodroof. Leaves six in a whorl ; flowers sessile, terminal, aggregate ; root aunual, slender, with a yellow bark ; corollas blue, with streaks of darker blue ; germs smooth .- The roots dye a fine red colour. It flowers in July, and is a native of France, Germany, and various parts of Italy.

3. Asperula Taurina; Broad-leaved Woodroof, Leaves four in a whorl, ovate, lanceolate, revolute, bluntish, pubescent; roots percunial, red, branching, intertwined .--- Flowering from April till June, and a native of Switzerland and Italy.

4. Asperula Crassifolia; Thick-leaved Woodroof. Leaves four in a whorl, oblong, lateral, revolute, bluntish, pubescent; the flowers are few, in terminating bunches; corollas pubescent on the outside .- Native of Crete and the Levant ; flowering in June.

5. Asperula Calabrica; Calabrian Woodroof. Leaves four in a whorl, oblong, lateral, revolute, bluntish, pubescent .---This is an undershrub, about a cubit high, prostrate, and extremely fetid in all its parts, which, with its shrubby stalks and leaves in pairs, sufficiently distinguishes this species. It flowers during most of the summer, and some part of the autumn, and is a native of Syria, between Aleppo and Antioch. and also of Calabria and Sicily.

6. Asperula Tinctoria ; Narrow-leaved Woodroof, Leaves linear, the lower six, the middle four in a whorl; stem flaccid; most of the flowers trifid ; corolla white ; the whole plant is green and smooth .- In Gothland the roots arc used instead of madder for dyeing wool of a red colour .- It is a native of 2. Asperugo Ægyptiaca; Egyptian Asperugo. Calices of Sweden, Germany, Switzerland, France, Carniola, and Siberia.

7. Asperula Pyrenaica; Pyrenean Woodroof. Leaves four in a whorl, lanceolate linear; stem erect; flowers generally trifid ; roots perennial ; flowers red .- Native of the Pyrenees and about Basil.

ASP

8. Asperula Cynanchica; Squinancy Wort, Leaves four in a whorl, linear, the upper ones opposite; stem erect; flowers quadrifid; roots perennial; stems from four inches to a foot and half in length, prostrate, hard, numerous, branching dichotomously .- The corollas are blush-coloured, elegantly marked with red lines; sometimes they are white. The flowers have a sweet smell, rarely perceived like those of the woodroof. It is found in France, Germany, Switzerland, Carniola, Italy, and the Levant: it abounds in many parts of England, on chalk downs, as, about Dartford in Kent; in Epsom downs Hertfordshire, Gog-magog hills, Newmarket heath, Swaffham in Norfolk, Armingale wood near Norwich, and on the Sussex downs. It flowers from June till August, This plant had formerly a great reputation for curing the quinsy, for which it was both internally and externally applied : it is now entirely obsolete.

9. Asperula Aristata; Awn-flowered Woodroof, Leaves linear, rather fleshy; the lower ones four in a whorl; flowers subtern-awned; stem upright; flowers pale yellowish, placed parallel, with the divisions bluntly awned .- Native of the south of Europe.

10. Asperula Lævigafa: Shining Woodroof. Leaves four in a whorl, elliptic, nerveless, smoothish; peduncles divaricate, trichotomous; seeds scabrous; stems simple, smooth, spreading; leaves subpetioled, obtuse, spreading, scarcely ciliate; flowering branches horizontal, bifid; two small lanceolate bractes; flowers usually in threes, peduncled, white .-- It flowers in June and July, and is a native of the south of Europe.

11. Asperula Hexaphylla; Six-leaved Woodroof. Lcaves six in a whorl, linear; flowers umbelled, terminal, subsessile; root perenuial; stems sometimes branching at the base, but generally simple; corollas purple, white within, the segments a little revolute ; seeds oblong, compressed ; the whole plant is smooth. It grows in the fissures of the rocks near Tende.

Asphodelus ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix : none. Corolla : one-petalled, six-parted ; divisions lanceolate, flat, spreading. Nectary six very small valves, converging into a globe, inserted into the base of the corolla. Stamina: filamenta six, subulate, inserted into the valves of the nectary, bowed, alternately shorter. Antheræ oblong, incumbent, rising. Pistil, germ roundish, within the nectary ; style subulate, in the same situation with the stamina; stigma truncate. Pericarp: capsule globular, fleshy, three-lobed, three-celled. Seeds several, triangular, gibbous on one side. Observe : the filamenta decline in some, and are bowed outwardly in others. ESSENTIAL CHARACTER. Corolla six-parted. Nectary: six-valves, covering the germ .---- The species are,

1. Asphodelus Luteus ; Yellow Asphodel, or King's Spear. Stem leafy ; leaves three-sided, striated .- The roots are composed of many thick, yellow, fleshy tubers, joined into a head at the top, whence arise strong round single stalks, nearly three feet high, covering their whole length with long, three-cornered, boat-shaped leaves, of a sea-green colour; the upper part of the stalk is adorned half way with yellow star-shaped flowers, which begin to open at bottom, so that on the same spike there is often a succession of flowers during a full month from the time of its beginning to flower, which is in June or towards the end of May. It is a native of Sicily, multiplying very fast by roots which will soon overspread a large border, if permitted to remain, or if the side-shoots are not taken off. lines along the under disk of the frond .-- Whoever desires to

2. Asphodelus Ramosus; Branched Asphodel, or King's Spear. Stem naked, leaves ensiform, keeled, smooth .- The flowers are star-shaped, white, with a purple line running longitudinally along the outside of each segment; they grow in long spikes, flowering successively, from the bottom upwards, appearing in the first part of June, and producing seed in autumu. It is a native of the south of Europe; immense tracts of land in Apulia are covered with it, and it affords an excellent food for sheep. It does not increase very fast by roots, nor should it be often transplanted, for that, will weaken it, so that the flower-stems will not rise so tall, or produce so many flowers, as when left undisturbed for some vears; the best way therefore is to propagate it by seeds, which should be sown soon after they are ripe, on a warm border of light fresh earth ; in the spring the plants will appear, when you should carefully clear them from weeds, and in dry weather they must be frequently watered : if this be done at

the following Michaelmas, the plants will be strong enough to bear transplanting, at which time you must prepare a bed of fresh earth in the flower nursery, into which you should plant the roots, at about six inches' distance every way, observing to plant them so low as that the top of the roots may be three or four inches under the surface of the bed; and some old tan or dung should be spread over the surface of the ground, to keep out the frost; in this bed they may remain one year, during which time they should be kept clear from weeds: by which time, the roots having acquired strength enough to produce flowers the following year, in autumn, when their leaves are decayed, they should be carefully taken up, and transplanted into the flower garden, observing to place them in the middle of the borders, amongst other hardy kinds of flowers, where, being properly intermixed, they will create an agreeable variety, and continue a long time in flower. The flowers are pretty ornaments for a flower garden, and the plant requires little trouble to cultivate it. Motherby recommends the bruised root to be applied to scrophulous swellings, which, he says, it will speedily dissolve and disperse. This plant is of an acrid, heating, diuretic quality; and, taken internally, is said to be particularly useful in removing obstructions of the menstrual discharge : it has likewise gained the credit of being an excellent antispasmodic.

3. Asphodelus Fistulosus; Onion-leaved Asphodel. Stem naked ; leaves stiff, subulate, striated, subfistulose.-The roots are composed of many fleshy yellow fibres. The leaves spread out from the crown of the root close to the ground, in a large cluster; they are convex on their under side, but flat above, and hollow. The flower-stalks rise immediately from the root, and grow about two feet high, dividing upwards into three or four branches, which are adorned with white starry flowers, having purple lines on the outside, which appear in July and August, and ripen seed in October, soon after which the plants decay. It grows naturally in the south of France, and the island of Crete; is an annual plant, and propagated by seeds only, which should be sown in the autumn, when they will be more certain to grow than if sown in the spring: when the plants are up, they will require no other trouble but to keep them clean from weeds, until they have put out four or five leaves, when they should be carefully removed to the place where they are designed to remain. If the seeds are permitted to scatter, the plants will come up without care, and those which are not removed will be the strongest plants, and produce a great number of flowers.

Asplenium; a genus of the class Cryptogamia, order Filices. -GENERIC CHARACTER. Fructifications disposed in right ASP

cultivate any of these ferns, must have walls, rocks, or heaps of stones, to set the hardy species in ; or pots may be filled with loamy undunged earth, or saud gravel and lime rubbish for that purpose, placing them in the shade. Hart's-tongue has been raised from seed, but every species of the genus may be increased by parting the roots. Some of the foreign sorts must be placed under a common frame in winter ; and it is evident, that such as are natives of the West Indies, and other hot climates, require the protection of a stove .---- The species are,

* Frond simple.

1. Asplenium Rhizophyllum; Root-leaved Spleenwort: Fronds cordate, ensiform, undivided, top filiform, rooting; root fibrose .- The ends of the fronds bend down to the ground, and there throw out roots, by which means this species of fern propagates itself.

2. Asplenium Hemionitis ; Mule's Tongue, Mule's Fern, of Spleenwort. Fronds cordate hastate, five-lobed, quite entire; stipes smooth and even .- It is a low fern, nearly allied to hart's-tongue, not above six inches in height, with a fibrous root. Native of Madeira, and the south of Europe.

3. Asplenium Scolopendrium ; Hart's tongue Spleenwort. Frond cordate lingulate, quite entire ; stipes birsute ; root black, hard, covered with scales, and emitting numerous strong black fibres .- The fronds are greatly subject to variation, and hence several varieties have been noticed by authors, as the curled, curved, clustered, and branching hart's-tongue. It is a native of most parts of Europe, in shady lanes, on walls and rocks, in wells, and damp caverns. Common in the north of England, and is in full seed from September till November. The leaves, which were recommended as apericnts and corroborants, in obstructions of the viscera, have been principally used in apozems and infusions. Ray recommends the plant, from his own experience, as a good medicine against convulsive disorders; but it is discarded from the present practice, although the common people indeed still use an cintment made with the leaves of this plant, as also with those of ophioglossum, or adder's-tongue, in burns and scalds. According to Hill, the expressed juice of the plant, taken in small quantities, for a considerable length of time, is an excellent medicine in obstructions of the viscera. and has been known to cure many of the most obstinate chronic disorders, when all other means have proved ineffectual.

4. Aspleuium Nidus ; Bird's-nest Spleenwort, Fronds lanceolate, quite entire, smooth .- The leaves are two fect long, and six or seven inches wide. It roots into the tops of trees. The leaves come out in a circle, are erect, and form a kind of umbel, in the middle of which birds make their nests. Native of Java, and the Society Isles.

5. Asplenium Serratum; Servate-leaved Spleenwort. Fronds lanccolate, serrate, subsessile. - The root consists of brown fibres, sending up cight or nine fronds. Native of woods in the inland parts of Jamaica.

6. Asplenium Plantagincum; Plantain-leaved Spleenwort. Fronds ovate-lanceolate, subcrenate; stipe four-cornered. The margin of the fronds is even, and the stipe smooth. Native of Jamaica.

7. Asplenium Lanceum ; Lance-leaved Spleenwort, Frond elliptic, entire, smooth ; stine round, scaly,--- It differs from the third species, in having a lanceolate frond, not cordate. Native of Japan.

8. Asplenium Bifolium; Double-leaved Spleenwort, Fronds pinnate ; leafiets lanceslate, subsinuate, conuate,--- Native of South America, 12.

** Frond pinnatifid.

9. Asplenium Ceterach; Common Spleenwort, or Miltwaste. Lobes alternate, confluent, obtase. - Native of most parts of Europe, on old walls, and in the clefts of moist rocks; as, about Bristol, Bury, in Suffolk; Heydon, in Norfolk; Asheridge, in Hertfordshire ; near Malham, Tarn, and many other places in the northern counties. It is in seed from May till October. It has been recommended as a pectoral. and as an aperient in obstructions of the viscera ; and an infusion of the leaves has been prescribed for the gravel. It was recommended by the ancients for the various disorders of the spleen; and, although rejected from modern practice, is prescribed by Meyrick to be administered in a strong decoction of the whole plant for all obstructions of the liver and spleen, which it will remove, if persevered in ; and is also excellent in those disorders which arise from the same cause.

10. Asplenium Obtusifolium ; Blunt-leaved Spleenwort. Fronds subpinnate; pinnas obtuse, sinuate, decurrent, alternate .--- Native of South America.

*** Frond pinnate.

11. Asplenium Nodosum; Knotted-stalked Spleenwort, pinnas opposite, lauceolate, quite entire .--- Native of the West Indies, and Cochin-china.

12. Asplenium Salicifolium; Willow-leaved Spleenwort. pinnas sickle, lanceolate, crenate, from the base upwards angular; height a foot and half .--- Native of Jamaica and the Antilles.

13. Asplenium Trichomanes; Common Maiden-hair, Pinnas roundish, crenate; roots small, consisting of brown capillary fibres .- Native of Europe, in the crevices of rocks and walls, and in shady places among stones. It is in seed from May to October. The country people sometimes give a tea or syrup of it, for coughs and other complaints of the thorax. A little of the syrup, mixed with water, makes a very pleasant draught. That which is brought from abroad has orange-flower water in it : but several different ferns are used for syrup of capillaire.

14. Asplenium Viride; Green Spleenwort. Pinnas roundish, crenate, truncate at the base .- Native of moist rocks on the mountains of Yorkshire, Westmoreland, and North Wales.

15. Asplenium Ebenenm; Ivory-stiped Spleenwort. Pinnas lanceolate, subfalcate, serrate, eared at the base; stipe very glossy, simple .-- Native of North America.

16. Asplenium Dentatum; Tooth-leaved Spleenwort, Pinnas wedge-shaped, obtuse, crenate, emarginate .- Native of South America, and the West Indies.

17. Asplenium Marinum; Sea Maiden-hair, or Spleenwort Dwarf Sea-fern. Pinnas obovate, serrate, gibbous above, obtuse, wedged at the base; fronds from three inches to a foot in length, but commonly about six inches .--- Native of Sussex, Devonshire, Cornwall, Cumberland, Lancashire, Scotland, and Wales, on rocks of the sea-coast.

18. Asplenium Cultrifolium; Sickle-leaved Spleenwort, Phinas sickle, lanceolate, gash-serrate, from the base downwards angular .- Native of the island of Martinico.

19. Asplenium Rhizophorum. Fronds rooting at top; pinnas ovate, repand, somewhat eared; very small ones, remote, quite entire .- This seldom grows above ten or twelve inches in length, and is always found with the top bending towards the ground .- Native of Jamaica.

20. Asplenium Monanthemum; One-flowered Spleenwort, Pinnas trapezium-shaped, obtuse, serrate, entire behind ; one line of fructification ; fronds numerous, ascending, a foot high, frequently twisted, linear, lauceolate, acute, very smooth .-Native of the Cape of Good Hope.

21. Asplenium Ruta Muraria; Wall-rue, Tentwort, White 2 N

Spleenwort. Fronds alternately decompound ; leaflets wedgeshaped, crenulate .- It seeds from June till October, and is a native of Europe, in the fissures of walls and rocks. It was formerly employed as a medicine in coughs and obstructions, but is now wholly out of repute.

ASP

22. Asplenium Alternifolium. Alternate-leaved Spleen-Fronds simply pinnate; leaflets alternate, wedgeprort. shaped, gashed above.-It differs from *wall* rue in having the stems more simple. Native of Switzerland and Austria.

33. Asplenium Adiantum Nigrum. Black Maiden-hair. Fronds subtripinnate; leaflets alternate; pinnas lanceolate, gash-serrate .- In the leafing of this fern there are varieties. It seeds from April till October, and is a native of Europe, found in the fissures of rocks, and old walls, or among stones in shady places.

24. Asplenium Trichomanes Ramosum; Branched Maiden-hair. Fronds doubly pinnate; pinnas obovate, crenate; lower leaflets smaller.

25. Asplenium Marginatum ; Margined Spleenwort. Pinnas opposite, cordate, lanceolate, submarginate, quite entire. -Native of South America.

26. Asplenium Squamosum; Scaly-stiped Splcenwort. Pinnas acuminate, gashed ; stipe scaly .- Native of South America.

27. Asplenium Striatum; Striated Spleenwort. Pinnas pinnatifid, obtuse, crenate; the terminal one acuminate .-Native of South America.

28. Asplenium Erosum ; Lacerated Spleenwort, Pinnas trapeze-oblong, striated, erose, eared at the base. Height from fourteen to eighteen inches. Stype black and simple. -Native of Jamaica.

29. Asplenium Japonicum; Japonese Spleenwort. Pinnas acute, gash-pinnatifid, serrulate; stipe sealy .-- Native of Japan.

30. Asplenium Resectum; Half-leaved Spleenwort. Pinnas trapezium-shaped, acuminate, gash-crenate, entire behind. Frond a foot high, lanceolate, acute, smooth .- Found in the Isle of Bourbon

31. Asplenium Bulbosum; Bulbous-rooted Spleenwort. Pinnas lanceolate, slightly crenate; root bulbous. Fructifications in oblique parallel lines .- Native of the mountains of Cochin-china, where the root is eaten.

32. Asplenium Proliferum. Fronds subsessile, broad-lanceolate, the first leaves obovate, rooting at the end .- Native of Jamaica.

33. Asplenium Pumilium. Frond ternate ; leaflets threeparted, gashed .- Native of Jamaica and Martinico.

34. Asplenium Dimidiatum. Pinnas trapeze-oblong, acuminate, angular upwards, entire and flat downwards .- Native of Jamaica.

35. Asplenium Fragrans. Fronds subtripinnate; leaflets alternate; piumas lanceolate, broadish, serrate at the tip.-Native of Jamaica.

36, Asplenium Grandiflorum. Pinnas alternate, lanceolate, subserrate, at the base rectangular above, rounded below .- Native of Jamaica.

37. Asplenium Dissectum. Pinnas lanceolate, gash-serrate, tailed at the tip .- Native of Jamaica.

38. Asplenium Præmorsum. Frond tripinnatifid ; pinnas somewhat wedge-shaped; pinnules erose-toothed at the top. -Native of Jamaica.

39. Asplenium Cicutarium. Frond tripinnate, very smooth, the upper ones pinnatifid, leaflets lanceolate, entire. -It has a solid black root, covered with a hairy moss towards its top, whence rise nine or ten leaves, about three inches high Native of Jamaica.

40. Asplenium Flaceidum. Fronds pinnate; leaflets alternate, remote, pinnatifid, linear, stiff .- Native of New Zealand.

41. Asplenium Lucidum. Fronds pinnate ; leaflets opposite, oblong-ovate, acuminate, serrulate .- Native of New Zealand.

42. Asplenium Polyodon. Fronds pinnate; leaflets trapezoid, acuminate, acute, doubly serrate .- Native of New Zealand.

43. Asplenium Obliquum. Fronds pinnate ; stipes scaly ; leaflets oblong, opposite, acuminate, serrate, the outer margin shorter .- Native of New Zealand.

44. Asplenium Obtusatum. Fronds pinnate; leaflets opposite, oblong, obtuse, serrate .- Native of New Zealand.

45. Asplenium Tenerum. Fronds pinnate ; leaflets rhomb-

oblong, obtuse, gash-serrate, ---Native of New Zealand, 46. Asplenium Caudatum. Fronds pinnate; leaflets pin-natifid, linear, bristle-shaped at the tip; segments blunt, gash-serrate at the tip; stipe rough with hairs .- Native of New Zealand.

47. Asplenium Bulbiferum. Fronds subbipinnate; leaflets decurrent, oblong, obtuse, pinnatifid ; fructifications proliferous .- Native of New Zealand.

Assafatida. See Ferrula.

Assonia ; a genus of the class Monadelphia, order Dodecandria.-GENERIC CHARACTER. Calix: perianth double. Outer, three-leaved, unilateral, deciduous. Inner, oneleafed, five-parted ; parts lanceolate, acute, reflex. Corolla: petals five, roundish, narrowed at the base, spreading, withering, affixed to the pitcher of the stamina. Stamina : filamenta fifteen, filiform, upright, shorter than the corolla, conjoined at the base into the form of a pitcher. Antheræ oblong, subsagittate, erect; five, linear-lanceolate, somewhat erect, coloured, petal-formed, straps between the stamina, proceeding from the pitcher. *Pistil*: germen roundish, fivefurrowed ; style simple, longer than the stamina, permanent ; stigmas five, recurved. Pericarp : capsule subglobose or turbinate, five-celled; cells separable, bivalve. Seeds : solitary, or in pairs, subovate. ESSENTIAL CHARACTER. Calix : double, outer one-leafed or three-leaved, inner one-leafed. Corolla ; five-petalled without any tube affixed to the pitcher of stamina. Filamenta connected in the form of a pitcher, with petal-shaped straps between them. Style one or five, Capsule five-celled. Seeds : not winged. For the propagation and culture of plants of this genus, see Hibiscus and -The species are, Pentapetes .-

1. Assonia Populnea. Leaves cordate, ovate, acuminate; flowers corymbed .- This is a middle-sized tree, the wood of which is sweet-scented, and blue in the centre, and bccomes very hard when it has arrived at a certain age. It is a native of hilly woods in the Isle of Bourbon, where it flowers in May.

2. Assonia Palmata. Leaves cordate, palmate, smoothish; lobes seven, acute, serrate-crenate ; flowers corymbed; stem arboreous, branched .- Flowers in May and June; native of the Isle of Bourbon.

3. Assonia Acutangula. Leaves cordate, roundish, threecusped, crenate, at first tomentose; flowers racemed; stem arboreous; fruit shaped like a pear .- Native of the Isle of Bourbon.

4. Assonia Angulata. Leaves cordate, roundish, angular at top, serrate-toothed, tomentose ; umbels numerous ; common peduncles shorter than the petiole; fruit globular .--- Native of the Isle of Bourbon.

5. Assonia Tiliæfolia. Leaves cordate, roundish, aeute, crenate; flowers raceme-corymbed; corolla an inch in diameter .- Native of the Isle of Bourbon.

6. Assonia Tomentosa. Leaves cordate, roundish, crenate, tomentose, with almost circular veins; flowers umbelled.---Native of Madagascar.

7. Assonia Punctata. Leaves ovate-lanceolate, long, quite entire, tomentose underneath, rugged with dots in the upper surface.—Native of the Isle of Bourbon.

8. Assonia Decanthera. Leaves ovate, acuminate, repard, cremate, smooth; stamina five, two-anthered; flowers small, umbelled; corolla small, scarcely three lines in diameter; stem arborescent, with a brown furrowed bark.—One seed in each cell of the fruit. Native of Madagascar.

9. Assonia Umbellata. Leaves cordate, ovate, oblong, acuminate, repand, smooth; flowers umbelled, globular.-Native of the Isle of Bourbon, where ropes are made of the bark. 10. Assonia Orata. Leaves ovate, toothed, five-nerved,

tomentose; style very small.-Native of the Isle of Bourbon.

11. Assonia Ferruginea. Leaves ovate-oblong, sevennerved, ferruginous beneath; petioles, peduncles, and calices, tomentose; stem arborescent, from eight to ten feet high; the branches; especially the younger ones, clothed with a rufous map; fruit tomentose, roundish, five-comered.—Native of the isle of Mauritius.

Aster ; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix: common imbricate, the inner scales prominent a little at the end, the lower ones spreading. Corolla: compound radiate; corollules hermaphrodite, numerous in the disk. Females ligulate, more than ten in the ray. Proper, of the hermaphrodite, funnel-shaped, with a five-cleft spreading border; of the female ligulate, lanceolate, three toothed, at length rolling back. Stamina: hermaphrodite, filamenta five, capillary very short; anther cylindric, tubulous, Pistil : hermaphrodite, germ oblong; style filiform, the length of the stamina; stigma bifid, spreading :- females, germ and style the same ; stigmas two, oblong, revolute. Pericarp : none. Calix: scarcely changed. Seeds: solitary, oblong, ovate; down capillary. Receptacle: naked, flattish. ESSENTIAL CHARACTER. Receptucle: naked. Down: simple. Corolla : ray more than ten. Calix : imbricate, lower scales spreading.-In the numerous species of this genus, the far greater part are hardy, herbaceous, fibrous-rooted, autumnal, flowering, showy perennials, with annual stems, from one to five feet in stature. America has furnished a considerable number of them; and they are particularly adapted to adorn large borders and plantations of shrubs, in the latter season. Only two are annuals, five natives of Europe, and the first four species from the Cape, are shrubby plants of the green house. ---- The species are.

* Shrubby.

1. Aster Taxifolius; Yew-leaved Starwort. Undershrubby; leaves decurrent, subulate, channelled, ciliate; flowers terminal .- It produces no seeds in England, but may be propagated by cuttings any time during the summer. These should be planted in small pots filled with light earth, and plunged into an old hot-bed; where if they be shaded from the sun, and gently watered, they will put out roots in six weeks, when they may be placed in the openair, and in about a month after they should be separated, each into a small pot filled with light sandy earth. In October they must be removed into the green-house, and placed where they may enjoy as much free air as possible, but be secured from frost or damps, either of which will destroy them, so that they are much easier preserved in a glass-case, where they will enjoy more light and air than in a green-house; but they must not be placed in a stove, for artificial heat will soon destroy them. Native of the Cape of Good Hope.

 Aster Reflexus; Reflected leaved Starwort. Shrubby; leaves ovate, subimbricate, recurved, serrate-ciliate; flowers terminal.— For the propagation and culture of this plant, see the preceding species. Native of the Cape of Good Hope.

AST

3. Aster Crinitus. Somewhat shrubby; leaves ovate-oblong, acute, tomentose underneath; calices terminated with a hair. Ray of the flower blue.—For the propagation and culture of this plant, see the first species. Native of the Cape of Good Hope.

4. Aster Fruticosus; Skrubby Starwort. Shrubby; leaves linear, dotted; peduncles one-flowered, naked.—For the propagation and culture of this plaut, see the first species. Native of the Cape of Good Hope.

** Herbaceous, entire-leaved, Peduncles naked.

5. Aster Tenellus; Brielly-leaved Starwort. Leaves filtiom, prick-leilate; calicies hemispheric, with equal leatlets. Disk of the corolla yellow; ray blue; often, and especially in the night, rolled back.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the first species of this genus.

6. Aster Alpinus; Alpine, or Great Blue Montain Starword. Leaves subspatulate, rough with hairs, quite entire; stems simple, one-flowered. Calix equal; stem-leaves two, seldom three; sometimes the ray of the flower is white--II to seldom rises above nine inches high on the Alps, and when transplanted into a garden, not above sixteen. It flowers in June, and grows wild on the Alps and Pyrenees. There are two varieties of this species; one also a native of the Alps, the other of Austria.

7. Aster Sibiricus; Siberian Starnort. Leaves lanceolate, almost stem-clasping, serrate, hairy, scabrous; calices lax; leaflets lanceolate, acuminate, leavy, hispid. Ray of the corolla blue.—It flowers in August, and is a native of Siberia.

8. Aster Tripolium : Sea Starwort, Leaves linear-lancenlate, quite entire, fleshy, smooth, three-nerved, calycine; leaflets submembronaceous, obtuse; root perennial.-It is found in the Isle of Wight ; flowers sometimes occur without any ray, and sometimes the ray is white. It is a native of salt marshes on the sea-coast of Europe, and by inland salt lakes in Germany and Siberia. It is frequent about Bristol, and not only on the coast, but in the interior parts of the kingdom. where Dr. Hokes, with good reason, supposes that its presence indicates the existence of salt-springs. It flowers in July and August. Morison observes, that in the morning the flowers being expanded, appear blue; the blue florets quickly vanishing, and the disk remaining, they then appear yellow ; in the evening, these go off, and the white down of the seeds shows itself: it thus undergoes a triple change in the course of the day, and hence derives its name of Tripolium.

9. Aster Amellus: Italian Starwort. Leaves oblong-lanceolate, entire, scabrous ; branches corymbed; calices imbricate, subsquarrose, leaflets obtuse, the inner membranaceous, coloured at the end .- The stems grow in large clusters from the root, and each of them branch at the top into eight or ten peduncles, each terminated by a single large flower, having blue rays with a yellow disk. It flowers in August or September, and in mild seasons will often continue till the middle of November. It grows naturally in the valleys of Italy, Sicily, and Narbonne ; also in Austria, Carniola, Germany, and Switzerland, and is very common about Bienne. The leaves and stalks being rough and bitter, the cattle seldom browse upon them, so that they remain in the pastures after the grass is eaten bare, and make a fine appearance when full of flowers. This species is propagated by parting the

AST

AST

roots, soon after the plant is out of flower; for those which are removed in the spring, will not flower so strong in the accceeding antumn. The roots should not be removed oftener than every third year, where they are expected to produce many flowers.

10. Aster Divaricatus; Divaricate Starwort. Branches divaricate; leaves ovate, serrate; foral leaves quite entire, rather obtuse; stem-clasping; stems rough, about two feet high, dividing towards the top into many forked branches, diverging from each other.—The flowers grow almost in an ambel, and appear in the beginning of September. Native of Virginia.

*** Herbaceous, entire-leaved, Peduncles scaly.

11. Aster Hyssopifolius; Hyssopicaucd Starworf. Leaves linear-lanceolite, drawn to a point at the base ; quite entire, stiff; branchlets corymbed, fastigiate; leaflets frequently linear, inhireate; calleces inhireater; stem a foot high; eight purple florets in the ray; pistil yellow. Native of North Ameri.a.

12. Aster Dumosus; Bushy Starwort. Leaves linear, quite entire, smooth, those on the branchlets very short; branches panicled; calices cylindric, closely imbricate. Stems upright, two feet high.—Native of North America,

13. Aster Ericoïdes; Heath-leared Starwort, Leaves linear, quite entire, very smooth, those of the branchlets subulate, approximating, those of the stem elongated; calices subsquarrose; leaflets acute; stem smooth, three feet high, —Native of North America.

14. Aster Tenuifolius; *Fine-leared Starwort*. Leaves sublinear, quite entire; peduncles leafy; stem five feet high, slender, angular, smooth, not branching much.—Native of North America.

15. Aster Linarifolius; Satory-leared Starwort, Leaves linear, quite entire, mucronate, seabrous, stiff, upper ones lax, remote; calices inbricate, branches fastigate; stem purplish; flowers terminal, solitary, few.—Native of North America.

16. Aster Linifolius; Flaz-leaved Starsort. Leaves linear, quite entire, roughish; branches corymbed; fastigiate, with small leaflets; calices imbricate; rays about equal to the disk; stem from two to three feet high.—Native of North America.

 Aster Aeris. Leaves lanceolate, linear, stiff, quite entire, flat; flowers corymbed, fastigiate; peduncles leafy.— It grows naturally in the south of France, and in Italy, Spain, and Hungary.

18. Aster Concolor. Leaves ovate, sessile, quite entire; stem quite simple; raceme terminal.—Native of Virginia.

19. Aster Rigidus; Stiff-leaved Starwort. Leaves linear, alternate; flowers terminal, solitary; leaves small, stiff, frequent; stem woody, weak, not branching, terminated by one specious flower.—Native of Virginia.

20. Aster Nove Anglie; New England Starwort. Leaves hanceolate, quite entire, cortate, stem-classping, hairy; calices longer than the disk, loose; leaflets 'inear lanceolate, nearly capal; stem hispid; stems many, for feet high, brown, terminated by large purple violet flowers, growing in a loose panicle, and expanding in August. The peduncles are so short, as scarcely to appear among the flowers. Native of New England, and Virginia.

21. Aster Undulatus; Waved Starwort. Leaves serrate, hairy, waved, lower cordate; petioles winged, dilated at the base; branchlets virgate; calices imbricate; stem hispid.— Native of North America.

22. Aster Grandiflorus; Catesby's Starwort. Leaves stemclasping, linear, quite entire, hispid, ciliate, those of the

branches and calix reflex; each branch is terminated by a large blue flower.---Native of Virginia.

**** Herbaceous, Leaves servate, Peduncles smooth.

23. Aster Cordifolius; Heart leaved Starwort. Leaves heart-shaped, acute, fuely serrate, underneath hairy; petioles almost simple; branches panicled; stem rongh with hairs.— Native of America, and of the northern parts of Asia.

24. Aster Puniceus; Red-stalked Starwort. Leaves stemchasping, lanceolate, serrate, subscabrous; branches panicled; calices surpassing the disk; leadets linear-lanceolate, nearly equal; stem lispid.—Flowers on single peduarcles, forming a corymb at top, and of a pale blue colour; they appear in September. Native of North America.

25. Aster Annuus ; Annual Starnort. Leaves somewhat hairy, the lower ones subovate, serrate; the upper lanceolate; calices hemispheric; leaflets subequal, strigose.—The seeds of this plant will seatter, and come up without care; annual, A native of North America.

26. Aster Vernus; Vernal Starwort. Root leaves lanceolate, quite entire, obtuse; stem almost naked, filiform, a little branching; peduncles naked,---Native of Virginia.

27. Aster Indicus; Indian Starwort. Leaves ovate-oblong, scrate; floral leaves oval, lanceolate, quite entire; branchlets one-flowered; flowers terminal, solitary, --Native of Japan and China, flowering from August till October.

28. Aster Lævis; Smooth Aster. Leaves stem-clasping, oblong, quite entire, shinning ; root-leaves subserrate; branches simple, bearing about one flower; calices imbriente; peduacles leafty, subdivided; leaflets somewhat wedge-shaped, acate, thickened at the end; stem smooth; ray of the corolla blue, --Observed by Kalm in North America.

20. Aster Mutabilis; Variable Starwort. Leaves almost stem-clasping, lanceolate, serrate, glossy, drawn to a point below; branchlets virgate; calices somewhat leafy, lax; stem smooth.—Flowers at the end of October.

30. Aster Tradescanti; Tradescant's Starwort. Leaves lanceolate, serrate, sessile, smooth; the middle branches virgate; calices closely imbricate; stem round, smooth.—The ray of the corolla is first white, and afterwards becomes purplish. Native of Virginia.

31. Aster Novi Belgii; New Holland Starwort. Leaves almost stem-chasping, lanceolate, smooth, but scabrous about the edge, the lower serrate; branches subdivided; calices loosely inbricate, leaflets linear-lanceolate; stem round, smooth.—The flowers appear at the latter end of August. Native of Virginia and Pennsylvania.

32. Aster Tarchiforus; Late, flowering Starwort. Leaves essile, lanceolate, drawn to a point at the base, serrate smooth; calices lax; leaflets lanceolate, linear, subequal, smooth.— Flowers in England, from July to September. Native of North America.

33. Aster Miser; Small White-flowered Starwort. Leaves sessile, lanceolate, subserrate, smooth; calices imbricate; leaflets acute; disk equal to the rays.—Native of North America.

34. Aster Macrophyllns; *Broad-leaved Blue Starwort*. Leaves serrate oblong; the upper ovate, sessile, those on the stem cordate, petioled; upper petioles winged.—Native of North America.

35. Aster Chinensis; Chinese Slarwort, China Aster, Leaves ovate, anguhar, toolted, petiolate; calices expanding, leafy, terminal.—The flowers of this species are the larged and handsomest of any belonging to the genus; the disk yellow, at first flat, then convex; the floscules of the ray broad and long, and searcely notched at the end. It came originally from China to Europe, and is an annual plant, prooriginally from China to Europe, and is an annual plant, pro-

AST

warm border, or rather upon a gentle hot-bed, just to bring up the plants; for they should be inured to the open air as soon as possible, which will prevent them from being drawn up very weak ; when they are three inches high they should be taken up, and planted in a bed of rich earth, at six inches distance every way, observing to shade them from the sun till they have taken new root; and if the season proves dry, they must be often refreshed with water. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flowergarden, where they are designed to remain, or into pots to adorn court-yards, &c. The plants should be taken up carefully, with large balls of earth to their roots, and the ground dug up and well broken with the spade, where the holes are made to receive the plants; and after they are planted with the earth closed about their roots, there should be some water given them to settle the earth, which should be done, if possible, when there is no rain, for then the plants will soon take new root, and require no further care, except to keep them clear of weeds. In August they will flower, by which time, if the ground be rich, they will be about two feet high, and furnished with many side branches, each terminated by a large radiated flower, forming one of the finest autumnal ornaments of the flower-garden. The seeds ripen in the beginning of October, and should be gathered when they are perfectly dry. In order to preserve the varieties with double flowers, those which grow upon the side branches, being commonly fuller of leaves than the flowers on the main stem, should always be preserved for seeds.

36. Aster Tataricus; *Tatarian Starwort*. Root-leaves lanceolate-ovate, serrate, scabrous; stem few-flowered; ray of the corolla blue. Native of Siberia.

37. Aster Hispidus; *Shaggy Starwort*. Lowest leaves oblong, crenate, scabrous; stem-leaves lanceolate, entire, ciliate; stem scabrous; stem erect, a foot high.—Native of Japan.

38. Aster Scaber; Rugged Starwort. Leaves oblong, serrate, scabrous; peduncles panicled; stem a foot high.— Native of Japan.

30. Aster Glaber; *Peach-leaved Starwort*. Leaves oblong, lanceolate, acute, serrate; stem branching; flowers terminal; calices linear, erect.—Native of North America; flowers in October.

40. Aster Serotinus; Late-flowering Blue Starwort, or Michaelmas Daity. Leaves oblong, acute, broader at the base, half stem-chasping; stems numerous, three feet and a half high, shooting out many lateral branches, terminated by pretty large flowers, very pale blue, tending to white.—Imported from Virginia.

41. Aster Precox; Early Starwort. Leaves oblong, acute, scabrous, sharply-toothed, half stem-clasping; stem erect, hairy; flowers orymbed; calices hairy, erect; stems a foot and half high; flowers large and blue, appearing in July.—Native of the Alps and Pyrenees.

42. Aster Altissimus; Lofty Starwort. Sce Aster Puniceus; Red-stalked Starwort.

43. Aster Ramosissimus; Branching Starwort. Leaves linear-lanceolate, stiff; stem very branching, spreading; flowers placed regularly one above another; peduncles leady; flowers small, pale, and purple, appearing in November.— Native of North America.

44. Aster Umbellatus; Umbelled Starwort. Leaves lanceolate, drawn to a point at the base, quite entire, about the edge scabrous; branches corymbed, fastigiate; ray of the 12.

pagated by seeds, which must be sown in the spring on a | flowers, which appear in July and August, white.—Native of warm border, or rather upon a gentle hot-bed, just to bring | Nova Scotia.

45. Aster Nervosus; *Three-nerved Starwort*. Leaves linear-lanceolate, acute, nerved; stem simple; flowers terminal, in a kind of umbel.—Native of Pennsylvania.

46. Aster Paniculatus; *Panicled Starwort*. Lower leaves ovate, half stem-clasping at the base; upper leaves lanceolate, small; stem panicled; branches one-flowered; peduncles leafy.—Height four feet: native of North America.

47. Aster Latifolius. Leaves linear, lanceolate, smooth, htree-nerved; flowers corymbed, terminal.—The stems put out side-branches toward lhe top, which grow creet, forming a loose spike of large blue flowers, expanding about the end of October; height four feet. Native of Canada.

48. Aster Procumbens; Procumbent Starwort. Leaves ovate, loothed; stem procumbent; peduncles naked, axillary, one-flowered; the calx is sealy—This species cannot endure the open air of England. The seeds must be sown in a hotbed; and the plants will require a stove to protect them during the winter.

49. Aster Holosericeus. Herbaceous; leaves oblong, lanceolate, serrate, underneath silver-silky; scapes oneflowered, leafy.—Native of New Zealand.

50. Aster Coriaceus. Herbaceous; leaves ovate, quite entire, furrowed above, woolly underneath; scapes oneflowered, leafy, woolly.--Native of Zealand.

51. Aster Cymbalariae ; Cymbalaria-leaved Starwort. Shrubby ; leaves ovate, sinuate, rough with hairs ; calices inbricate, rough with hairs.—It flowers most of the summer, and is a native of the Cape of Good Hope.

52. Aster Nemoralis; Wood Starwort. Leaves linear lanceolate, drawn to a point at the base, somewhat scabrous ; branches filiform, one-flowered ; calices lax imbricate; leaflets earche ; stem a foot high; ray of the flower blue, disk white, --It flowers in August and September. Native of Nova Scotia.

53. Aster Paludosus; Marsh Starwort. Leaves linear, stem.clasping, erect, quite entire, very smooth, scabrous at the edge; peduncles almost naked, calices squarose; ray blue, large; disk yellow.—Flower appearing in September and October. Native of the swamps of Carolina.

54. Aster Patens ; Spreading Hairy-stalked Starnort, Leaves oblong, entire, acute, cordate, almost stem-clasping, scabrous; branches spreading, elongated, few-flowerel; calices imbricate, subsquarrose; stem rough with hairs; ray of the flower pale blue; disk tawny.—Native of Virginia, flowering in September and October.

55. Aster Foliolosus; *Ledjy Starwort*. Lcaves lanceolate, linear, quite entire, smooth, those on the branchlets spreading very much; calices inbicate; leaflets acute; stem pabescent.—It flowers in October, and is a native of North America.

56. Aster Multiflorus ; *Small-leared Starwort*. Leaves linear, quite entire, smoothish ; branches one-ranked ; calices imbricate, squarrose; scales somewhat leafy, acute; stem pubescent; ray white.—It flowers in September and October, and is a native of North America.

57. Aster Salicifolius; Willow-leaved Starwort. Leaves linear, lanceolate, quite entire, smooth; calices imbricate, lax; stem glossy; stem the height of a man; ray of the flower bluish flesh-colour,—Native of North America.

58. Aster Æstivus; Labrador Starwort. Leaves lanceolate, almost stem-clasping, quite cutire, smooth, scabrous about the edge; calices lax, with equal leaflets; ray blue...-Native of North America: flowers in July and Angust.

59. Aster Junceus; Slender-stalked Starwort. Leaves 2 O of the branchlets lanceolate; branches virgate; calices imbricate; stem smoothish; stem four feet high; ray slightly flesh-coloured; disk elevated, pale yellow .--- It flowers in October, and is a native of North America.

AST

60. Aster Pendulosus ; Pendulous Starwort. Leaves elliptic, lanceolate-serrate smooth, those of the branchlets rather remote; branches very much divaricated, pendulous; stem pubescent; ray of the flower white; disk yellow, changing to ferruginous .- It flowers in October. Native of North America.

61. Aster Diffusus; Diffuse Starwort. Leaves elliptic, lanceolate, serrate, smooth, proportioned; branches spreading; calices imbricate; stem pubescent; ray white, flower-ing in September.-Native of North America.

62. Aster Divergens; Spreading Downy-stalked Starwort. Leaves elliptic, lanceolate, serrate, smooth, those on the stem linear, lanceolate, elongated ; branches spreading ; calices imbricate; stem pubescent; ray white, shorter than the calix : disk reddish .- Native of North America.

63. Aster Corymbosus; Corymbed Starwort. Leaves cordate, smooth, acuminate, all finely serrate; petioles simple; branches fastigiate ; stem smooth .- It flowers in September, and is a native of North America.

64. Aster Spectabilis; Showy Starwort. Leaves lanceolate, somewhat scabrons, the lower serrate; branches corymbed; calycine leaflets lax, leafy, nearly wedge-shaped, sharpish, squarrose; stem two feet high, ray blue .- It flowers in August and September, and is a native of North America.

65. Aster Radula; Rough Starwort. Leaves lanceolate, serrate, acuminate, wrinkled, very scabrous; calices imbricate; leaflets lanceolate, obtuse .- It flowers in September, and is a native of Nova Scotia.

Astragalus ; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. Calix: perianth one-leafed, tubular, five-toothed, acute; lower toothlets gradually less. Corolla: papilionaceous; banner longer than the other petals, reflex on the sides, emarginate, obtuse, straight; wings oblong, shorter than the banuer ; keel length of the wings, emarginate. Stamina : filamenta diadelphous simple, and novemfid, almost straight ; antheræ roundish. Pistil: germ nearly columnar; style subulate, ascending; stigma obtuse. Peri-carp: legume two-celled, the cells bent to one side with a longitudinal bifid septum parallel to the valves. Seeds: kidney-shaped. ESSENTIAL CHARACTER. Legume, twocelled, gibbous .- Every species of this genus may be raised from seeds; these should be sown in April on an open border of light earth, the annual sorts where they are to remain, the perennials to be transplanted to the places for which they are destined. They are in general hardy, and require no other care but to draw the plants out where they come up too thick, leaving them a foot and half or two feet asunder, and to keep them clean from weeds .---- The species are,

* Stems leafy, erect, not prostrate.

1. Astragalus Alopecuroides ; Fox-tail Milk Vetch. Caulescent; spikes cylindric, subsessile; calices and legumes woolly .- The flowers, which are yellow, are produced in June or July, and ripen the seeds in September .- Native of Spain and Siberia.

2. Astragalus Christianus. Caulescent, erect; flowers glomerule, subsessile from all the leafy axillas .- The flowers are large, and of a bright yellow colour; they appear in July, and in very favourable seasons are succeeded by seeds in England, and will only succeed when planted in a warm border. It is a native of the Levant.

lanceolate, linear, sessile, smooth, the lowest subscrrate, those | duncles very long; leaflets emarginate.-From the axils come out long peduncles supporting a head of purple flowers, which appear in July, but are rarely succeeded by pods in England. This species must be raised on a moderate hot-hed in the spring, and when the plants are fit to remove, they should be each put into a small pot filled with light earth, and plunged again into the hot-bed, shading them from the sun till they have taken root; after which they should have free air admitted to them daily, in proportion to the warmth of the season, and should be frequently and gently watered. In May they should be removed to a sheltered situation, where they may remain till October, when they should be placed under a common frame. In the spring they may be turned out of the pots, and planted in a warm border, where they will flower, and sometimes produce seeds. If the winter prove very severe, a little old tan should be laid over the roots, which will effectually preserve them.

4. Astragalus Pilosus; Pale-flowered Milk Vetch. Caulescent, erect, hairy; flowers in spikes; legumes subulate, hairy; root woody, perennial .- It flowers from June till August; the corolla is of a light yellow colour. Native of the Valais, SIberia, Thuringia, and Austria.

5. Astragalus Sulcatus; Furrowed Milk Vetch. Caulescent, erect, smooth, striated, stiff; leaflets linear-lanceolate, acute; legumes three-sided; root perennial, woody; corollas pale violet; seeds many, brown, shining, round, kidneyshaped .- It flowers in the open air in June and July, and ripens seed in August. It is a native of Siberia.

6. Astragalus Galegiformis ; Goat's Rue-leaved Milk Vetch. Caulescent, stiff, smooth; flowers in racemes, pendulous; legumes three-sided, mucronate at both ends ; root perennial. -It flowers in June or July, ripens seed in autumn, and is a native of Siberia. To cultivate this plant you must place it. in an open situation and dry soil.

7. Astragalus Chinensis. Caulescent, stiff, smooth ; flowers in racemes, pendulous; legumes ovate, inflated, mucronate at both ends .- The colour of the calix is greenish yellow; of the banner pale yellow, streaked with green at the base; of the wings and keel, white with yellow tips; the flower itself finally becomes white. It is a native of China, as its name imports. For the propagation and culture of this species, see the third species of this genus.

8. Astragalus Onobrychis; Purple-spiked Milk Vetch. Caulescent, procumbent, diffused ; spikes peduncled, banner twice as long as the wings; leaflets linear; corollas red.--Flowers in June and July. Native of Austria.

9. Astragalus Uliginosus; Violet-coloured Milk Vetch. Caulescent, almost upright; flowers in spikes; legumes almost upright, naked, tumid, round, flatted; point reflex.-It flowers from June till August. Native of Siberia.

10. Astragalus Carolinianus ; Carolina Milk Vetch. Caulescent, upright, even; peduncles in spikes; legumes ovate,. cylindric, acuminated by the style; root perennial .- It flowers in July and August; but unless the season be warm, seldom ripens seed in England. Native of Carolina. For the culture and propagation of this plant, see the third species of this genus.

11. Astragalus Aster; Rough Milk Vetch. Caulescent, stiff, even, roughish ; flowers in spikes, on elongated pedun-cles ; legumes oblong .-- Native of Astracan.

** Stems leafy, diffuse. 12. Astragalus Canadensis; Woolly Milk Vetch. Caulescent, diffuse ; legumes subcylindric, mucronate ; leaflets al-3. Astragalus Capitatus. Caulescent; heads globular; pe- culture of this species, see the third species of this genus.

13. Astragalus Cicer; Bhaddered Milk Petch. Caulescent, prostrate : legumes subglobular, inflated, mucronate, hair; ; root thick, sweet; corollas pale yellow,—It flowers in July, and the seeds ripen in autum. This species is recommended to be cultivated as the food for cattle. It is a native of Italy, Austria, Switzerland, and Germany.

14. Astragalus Microphyllus; Small Round-podded Milkwetch. Caulescent, erect, expanding; leaflets oval; calices rather tumid; legumes roundish; corollas yellow, twice as long as the calix.—Native of Siberia and Germany, flowering in June and July.

15. Astragalus Glycyphyllus; Wild Liquorice, or Liquorice Yetch. Caulescent, prostrate; legumes subtriquetrous, bowed; leaves oval, longer than the peduncle; corolla geenish yellow.—The leaves are sweet with a mixture of bitteness, and do not seem to be agreeable to cattle, at least, the plant in its wild state is left untouched; otherwise this being the largest of the European species, it might have been desirable to cultivate it. Native of most part of Europe, in woods, hedges, and pastures, especially in a calcarcous soil. Its flowers appear in June, its seeds in September. It spreads much at the root in gardens.

16. Astragalus Hamosus; Duarf Yellow; flowered Milk Yetch: Caulescent, procumbent; legunes subulate, recurved, smooth; leaflets obcordate, villose underneath; root annual; flower of a pale yellow colour.—Native of Messina and Montpellier.

17. Astragalus Contortuplicatus; Waze-podded Milk Vitek. Caulescent, procumbent; legumes writled, channelled, villoge.—This is an annual plant, and varies wonderfully in size and height in different soils. Native of Siberia. 18. Astragalus Besticus; Triangular-podded Milk Vetch.

18. Astragalus Bosticus: Triangular-podded Milk Vr(th. Caulescent, procumbent; spikes peduncled; legumes prismatic, straight, three-sided, hooked at top.—Annual, flowering in July, and ripening seeds in autumn.—Native of Spain, Portugal, and Sicily.

19. Astragalus Laxmanni. Caulescent, procumbent; spikes elongated; legumes oblong, three-cornered, marked with a furrow, nucronate, villose; root perennial, branching; corolla pale blue; antheræ yellow.—It flowers in June and July, and is a native of Siberia.

20. Astragalus Stella. Caulescent, diffuse; heads peduncled, lateral; legumes straight, subulate, mucronate; corollas bluish purple.—Native of Montpellier.

21. Astragalus Sesameus; *Starry Milk Vetch*. Caulescent, diffuse; heads subsessile, lateral; legumes subulate, reflected at the point.—It is an annual plant, flowering in June and July, and a native of France and Italy.

22. Astragalus Austriacus; Austrian Milk Vetch. Caulescent, prostrate, smooth, striated, weak; leaflets sublinear, emarginate; legumes round; root perennial, woody; flowers small, and without smell; they appear in May and June.

23. Astragalus Leontinus. Caulescent, prostrate ; legumes ovate, villose ; flowers spiked, erect.—This plant has no smell. Native country unknown.

24. Astragalus Pentaglottis. Caulescent, procumbent; legumes headed, folded back, compressed, converging, crested, with a reflected point.—It flowers in the beginning of August, and bears seed at the end of the same month. Native of Spain.

25. Astragalus Epiglottis; Heart-podded Milk Vetch. Coulescent, procumbers; legumes headed, esssile, nodding, cordate, nucronate, folded back, naked.—The plant is an anunal, with largish flowers of a deep purple colour. It flowers in July, and ripens seed in autumn. Native of Provence, Spain, Portugal, and of mountainous woods in the Levant. 26. Astragalus Hypoglotis; Purple-mountain Milk Vetch. Caulescent, prostrate; legumes headed, ovate, folded back, compressed, hairy with a reflex point; root perennial; corolla bluish, purple, large, and landsone.—Native of sandy and chalky pastures, flowering from May till July. It varies with naked leaves and white flowers. It requires a shady situation and a strong soil.

AST

27. Astragalus Syriacus; Syrian Milk Vetch. Caulescent, procumbent; heads peduncled; flowers reflected; legumes tomentose, ovate-oblong.—Native of Siberia.

28. Astragalus Arenarius. Subcaulescent, procumbent; flowers subracemed, erect; leaves tomentose; root perennial, filiform; corolla blue, without blue streaks.—Native of Scania, in loose sand.

29. Astragalus Glaux; Small Milk Vetch. Caulescent diffuse; heads peduncled, imbricate, ovate; flowers erect; legumes ovate, callous, inflated.—Native of Spain.

30. Astragalus Sinicus; Chinese Astragalus, Caulescent, prostate; unbels peduncled; legumes prismatic, three-sided, ercet, subulate at top; root annual.—The flowers appear in July and August, and the seeds ripen in autumn, It grows naturally in China. For the propagation and culture of this species, see the third species of this genus.

31. Astragalus Alpinus; Alpine Milk Vetch. Caulescent, procumhent; howers pendulous, racemed; legumes acute at both ends, hairy; stems rather more than a foot high; flow-ers specious, loose; hanner the length of the kedt, blue with deeper-coloured lines, while at the base; wings stilf; short, narrow, hooked, white; keel white, with a broad obtuse beak. --Native of the mountains of Switzerland and Lapland.

32. Astragalus Ammodytes. Caulescent, undershrubby; flowers twin; legumes ovate, twin, woolly.—Native of the sandy hills of southern Siberia.

33. Astragalus Trimestris; Egyptian Milk Vetch. Subcaulescent; scapes mostly two-flowered; legumes hooked, subulate; two-keeled; root annual.—Native of Egypt, flowering in June and July, and ripening its seeds in August. This requires to be planted in a warm horder.

*** Scape naked, without a leafy Slem.

34. Astragalus Verticillaris. Leaflets aggregate, semiverticilled.—Native of eastern Siberia, beyond the lake Baikal.

35. Astragalus Montanus. Nearly stemless; scapes longer than the leaf; flowers loosely spiked, erect; legumes ovate, with an inflected point.—Native of the mountains of Spain. This plant requires a shady situation and a strong soil.

36. Astragalus Vesicarius. Scapes longer than the leaves; flowers loosely spiked; calices and legumes inflated, hirsufe; root perennial; banner of the corolla purple; wings yellow. --Native of Dauphiny and Siberia.

37. Astragalus Physodes. Scapes equal to the leaves; legumes inflated, subglobular, naked; root perennial, creeping. Flowers purple, appearing in June.—Native of Siberia. It requires a shady situation and a strong soil.

 Astragalus Caprinus. Scape erect; leaflets ciliate; legunes ovate, tumid, villose; root perennial, creeping; flowers pale, yellow, very fragrant.—Native of Barbary and Russia.

30. Astragalus Uralensis; Silky Milk Fetch. Scape erect; longer than the leaves; legumes subulate, inflated, villose, erect; root long, woody; flowers pale, violetcolour.—Native of Dauphiny, Carinthia, the Pyrences, and Siberia; also of mountainous pastures in Scotland. It requires an open situation and dry soil.

40. Astragalus Monspessulanus; Montpellier Milk Vetch. Scapes declining, the length of the leaves; legumes subulate,

AST

AST

round, rather bowed, smooth; root very large, woody, sweet. -Native of the south of France, the lower Valais, and the Grisons.

41. Astragalus Incanus. Scapes declining; leaflets tomentose ; legumes subulate, rather bowed, hoary, incurved at top ; root perennial .- Native of the south of France.

42. Astragalus Campestris; Field Milk Vetch. Calices and legume villose ; leaflets lanceolate, acute ; scape decumbent; corollas pale yellow .- Native of Switzerland and Germany.

43. Astragalus Depressus ; Dwarf White-flowered Milk Vetch. Scapes shorter than the leaf; legumes nodding; leaflets subemarginate, naked; corollas small, white; keel purple at the tip .--- Native place unknown.

44. Astragalus Uncatus. Scapeless; legumes subulate, hooked, longer than the leaf; leaflets obcordate .- It flowers in July and August, and the seeds ripen in autumn, and is found growing naturally in the neighbourhood of Aleppo.

45. Astragalus Exscapus; Hairy-podded Milk Vetch. Scapeless ; legumes woolly ; leaves villose, flowery, numerous, radical, subsessile, first pale and afterwards full yellow .-Native of Hungary.

Stem woody.

46. Astragalus Tragoides. Nearly stemless; flowers radical, numerons, subsessile; corollas yellow .- Native of Switzerland, Siberia, and Armenia.

47. Astragalus Tragacantha; Goat's Thorn. Trunk arborescent; petioles becoming spinescent; root large, woody, and branching; corollas long, stiff, of a pale violet colour .-Native of Switzerland, Mount Ætna, Mount Olympus, and of the sea-shore near Marseilles. Mr. Miller describes four varieties of this species. From this plant is gathered the gum called gum-tragacanth, so much used in various preparations of the Materia Medica. It differs from all other known gums, in giving a thick consistence to a much larger quantity of water, and in being difficultly soluble, or dissolving only imperfectly. When put into water, it imbibes slowly a great quantity of the fluid, swells into a large volume, and forms a soft but not fluid mucilage. The demulcent qualities of this gum are to be considered as similar to those of gum-arabic. It is seldom given alone, but frequently in combination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted. It gives name to an officinal powder, and may be propagated by seeds, if they can be procured from abroad, in the same manner with the others. They should be carefully taken up when large enough to transplant, and some of them reset in small pots filled with fresh earth, placed in the shade until they have taken root, after which they may be removed into an open situation, where they may remain till the end of October, when they should be placed under a common frame, to shelter them from severe frosts, and allow them free air in mild weather. The remainder of the plants may be set on a warm dry border. The plants in pots may be preserved a year or two under frames in winter, and then being taken out of the pots, may be planted in a lean dry soil and warm situation; but as they are sometimes destroyed by hard winters, it will be proper to keep a few plants in pots, to be sheltered in winter, in order to preserve the species. These plants may also be increased by slips, and as they rarely produce seeds in this country, the latter method is generally used here. The best time for this work is in April, just as the plants begin to shoot, at which time the tender branches should be slipped off, and their lower parts divested of the decayed leaves; then they should be planted on a very moderate hothed, which must be covered with mats, to screen them from

the heat of the sun by day, and the cold by night. These slips should be frequently but gently watered, until they have taken root; after which they may be exposed to the open air, and in very dry weather they must be refreshed with water. On this bed they may remain until the following spring, being covered with mats in very severe weather. In April they may be transplanted, either into pots filled with light sandy earth, or into warm borders, where, if the soil be dry, gravelly, and poor, they will endure almost the severest cold of our climate, but if planted in a very rich soil, will often decay in winter.

48. Astragalus Fætidus. Stemless; leaves prostrate, viscid, sharply linear ; scapes erect with few flowers .- Native of Dauphiny and of Mount Cenis.

49. Astragalus Halleri. Scapes leafless; leaves ovatelanceolate, smooth ; legumes inflated, hirsute, erect .- Native of the mountains of the Valais, and of Piedmont bordering on it.

50. Astragalus Vulneraroides. Stemless, hirsute; scapes longer than the leaves ; legumes inflated, ovate in heads .----Native of Mount Cenis.

51. Astragalus Tenuifolius ; Upright Milk Vetch. Caulescent, erect ; spikes peduncled ; banner twice as long as the wings; leaflets linear .- Flowers in July and August; a native of Siberia.

52. Astragalus Virescens; Green-flowered Milk Vetch. Caulescent, erect; legumes bent back; peduncles manyflowered, longer than the leaf; leaflets lanceolate, acute .- It flowers in June, and is a native of Siberia.

53. Astragalus Garbancillo. Stem shrubby, upright; pinnules ovate-oblong, somewhat tomentose; peduncles naked, elongated .- It is reported to be very hurtful to cattle, Native of Peru.

54. Astragalus Hispidus. Caulescent, procumbent ; leaflets and legumes ovate-oblong, hispid; corollas shorter than the calix ; seeds very few, kidney-shaped .- Native of Mount Libanus.

55. Astragalus Emarginatus. Almost stemless; scapes very long; heads globose; legumes woolly; stem scarcely any, herbaceous; seeds very few, nearly kidney-shaped .--Native of Mount Libanus.

56. Astragalus Lanatus. Stemless, with a naked scape, the length of the leaves; legames in close spikes, woolly, half cordate, three-sided, subulate; leaves villose; corolla yellow; flowers in a close spike; seeds few, kidney-shaped. -Native of Mount Libanus.

57. Astragalus Lencopheus, Caulescent, procumbent; legumes subcylindric, straight, smooth; leaflets obcordate, villose underneath .- Native country unknown.

58. Astragalus Deflexus. Subcaulescent, prostrate; scape twice as long as the leaf ; legumes gaping ; leaves pectinate, right-angled,-Native of the loftiest mountains of Siberia.

59. Astragalus Unifultus. Suffruticose, procumbent; stipules solitary, stem-clasping, opposite to the leaves bifid .--Native of Peru.

Varius. Caulescent, fruticulose up-60. Astragalus right; flowers in loose spikes; legumes linear; stipules fuliginose downwards .- This is a hoary little shrub, about a cubit high, with flowers subsessile, purple, and nine lines in length. Stem upright, round, branched from the base. Native of Siberia.

61. Astragalus Aristatus. Suffruticose, prostrate; leaves hairy; petioles spinescent; calices awned .- Native of Switzerland and Provence.

62. Astragalus Pugniformis. Shrubby, procumbent; heads stem-clasping, tomentose; petioles and leaves pun-

145

gent and smooth.—This species is remarkable for the largeness of the heads or balls of flowers, which are almost as large as those of the first species.—Native of the Levant.

63. Astragalus Echinoides. The leaves are minute; the flowers small, white, with a purple line on the banner; peduneles axillary, short, two-flowered.—Native of Crete or Candia.

Astrantia; a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix: umbel universal, with very few rays (often three); partial with very numerous ones. Involuere universal, with leaflets doubled to the ray ; partial with leaflets (about twenty) lanceolate, spreading, equal, coloured, longer than the umbellule. Perianth proper, five-toothed, acute, erect, permanent. Corolla: universal, uniform; floscules of the ray abortive. Proper with petals five, crect, inflex, bifid. Stamina : filamenta five, simple, the length of the corollule; anthera simple. Pistil: germen oblong, inferior ; styles two, creet, filiform ; stigmas simple, spreading. Pericarp: fruit ovate, obtuse, erowned, striated, bipartile. Seeds: two, ovate-oblong, covered with the crust of the pericarp, wrinkled. ESSENTIAL CHARAC-TER. Partial Involucres, laneeolate, spreading, equal, longer, coloured. Flowers, very many, abortive. All the plants of this genus, except the fourth species, are very hardy, and may be propagated either by sowing their seeds, or by parting their roots. If from seeds, they should be sown in autumn soon after they are ripe, on a shady border; and when the plants are come up, they should be carefully weeded, drawing out some wherever they are found to be too close, in order that the others may have room to grow, until Michaelmas, when they should be transplanted where they are to remain, which should always be in a moist soil and a shady situation. They should be planted three feet asunder, as their roots will spread to a considerable width, if they be permitted to remain long in the same place. They require no other culture but to keep them clear from weeds, and every third or fourth year to be taken up at Michaelmas, and their roots parted, and planted again. They are seldom preserved except in botanic gardens, as there is no great beauty in the flowers .---- The species are,

1. Astrantia Major; Great Masicrowort. Leaves fivelobed, lobes triffed; stem eighten inders bigh,—It is a native of the mountains of Switzerland, where it was found ahundantly flowering in August. It is singularity has long obtained for it a place in our gardens, where it flowers in June and the succeeding months of summer. The whole plant has a warm aromatic taste, but little is known respecting its virues, except that it is a violent purgative.

2: Astrantia Carniolica. Leaves five or seven-lobed, simple or biffs; root nearly of the thickness of the little finger, about an inch long, praemorse, dark brown, having an aromatic balamic swell, with a taste at first slightly aromatic but nauseous, and afterwards acrid. The whole plant is smooth, --Native of Carniola ; flowering in July and August.

 Astrantia Minor; Little, or Alpine Masterwort. Leaves digitate serrate. This seldom rises a foot high.—Native of the Alps, and Alpine valleys of Switzerland, but not of the lower mountains.

4. Astrontia Ciliaris. Leaves lanceolate, serrate, eiliate; stem simple, a foot high.—Native of the Cape of Good Hope. This species always require to be protected by a dry stove in winter.

5. Astrantia Epipactis. Leaves five-parted, obtuse, serrate; flowers in a head, yellow.—Native of Idria, Gorizia, and also of Hungary.

Astronium ; a genus of the class Dioccia, order Peutandria .- GENERIC CHARACTER. Male, Calix: perianth five-leaved, coloured, small; leaflets ovate, coneave, obtuse, spreading. Corolla: petals five, ovate, very obtuse, flat, spreading very much. Nectary five, roundish, very small glands in the disk of the flower. Stamina : filamenta five, subulate, spreading, the length of the corolla; antheræ oblong, incumbent, Female, Calix : perianth five-leaved, eoloured ; leaflets oblong, concave, obtuse, converging. Corolla: petals five, subovate, obtuse, concave, erect, less than the ealiy, permanent. Pistil : germen ovate, obtuse ; styles three, short, reflex ; stigmas subcapitate. Pericarp: none. Calix increased, coloured : its leaflets at first expanded into a pendulous star, at length dropping the seed. Seed : one, oval, the length of the ealix, lactescent. ESSENTIAL CHARAC-TER. Male, Calix: five-leaved. Corolla: five-petalled. Female, Calix: five-leaved. Corolla: five-petalled. Styles, three. Seed : one .---- The following is the only species yet discovered.

1. Astronium Graveolens. An upright tree, from twelve to thirty feet in height, abounding every where in a slephtly glutinous terchinthine juice, which has a disagreeable swell. After the fruits in the female, and the flower in the male plants, have fallen off, new branches are put forth, having un-equally pinnate leaves on them, with three pair of leadets, smooth-veined, three inclues in length. Panietes lax, half a foot long in the males, but a foot and half long in the females, seattered on the outnost twigs; flowers small, red. The callees are expanded into stors, nine lines in diameter. Native of the woods about Carthagena in New Spain, flowering in May and June, and fruiting in July.

Atamasco Lily. Sce Amaryllis.

Athamanta : a genus of the class Pentandria, order Digynia .- GENERIC CHARACTER. Calix: umbel universal, manifold, spreading; partial, has fewer rays. Involucre uni-versal, many-leaved, linear, a little shorter than the rays; partial linear, equal with the rays. Perianth proper, obscure. Corolla: universal, uniform; floscules all fertile. Proper, with five petals, inflex, emarginate, a little unequal. Stamina: filamenta five; capillary, the length of the corolla; antheræ roundish. Pistil : germen inferior : styles two, distant : stigmas obtuse. Pericarp: none; fruit ovate-oblong, striated, bipartile. Sreds : two, ovate, convex on one side, striated; on the other flat. ESSENTIAL CHARACTER. Fruit, ovate-oblong, striated. Petals, inflex, emarginate.-These plants are propagated by seeds, which should be sown in autumn, on an open hed of light dry ground; and when the plants come up in the spring, they should be kept clean from weeds, and thinned where they are too close, so that they may have room to grow till the following autumn, when they should be carefully taken up, and planted at about a foot distance, in a bed of light sandy earth, where the roots will continue several years ; except the cighth species, which is annual, and the ninth, which probably requires some shelter, but has not yet been cultivated with us .---- The species are,

 Atlamanta Libanotis; Mountain Spignel, or Stone Parsley. Leaves bipinnate, flat; nubel hemispherical; seeds hirsute; root perenuial.—Native of Denmark, Sweden, Germany, Switzerland, Austria, Carniola, the south of France, and ou Gog magog hills near Cambridge.

2. Athamantic Cervaria; Broad-taired Spignel, or Black-Hart Root. Leaves pinnate, decussated, gash-angled; seeds, nucled; root perennial, thick, very long, annulated, full of resinous juice, sweet-smelling, will a bristle-shaped crown.— This plant is recommended in the gout, and in Stiria they use it in intermittent fevers. Native of the mountains of France, 2P ATH

Switzerland, Germany, Austria, and Carniola. It flowers in until they have taken new root; after which they should be July and August.

 Athamanta Sibirica; Sibrrian Spignel. Leaves pinnate, gash angled; stem two feet high, round, and scarcely streaked; corollas red underneath.

4. Athamanta Condensata; Close-headed Spignel. Leaves sublipinnate; leaflets inbricate downwards; unibel lensform; root perennial; stem simple, a foot high; antherae aid receptacles of the florets, purple.—Native of Siberia.

5. Atlamanta Orcoselinum; Divaricated Spignel, or Monutain Porley. Leadingt Subarriant, root perennial, thick, aromatic, resincus, crowned with bristles. Petals, white, with a blush of rosc-colour.—It is gratefully aromatic and deserves to be better known. Native of the continent of Europe, but not of Great Brisian.

6. Athananta Sicola; Flixneed leared Spignel. Lower leaves shining, primordial; numbels subsessile; seeds hairy.— This is a percential plant, sending up from the root several upright stems, nearly three feet high. The flowers are white, and are succeeded by oblong woolly fruit. Native of Sicily.

7. Athamanta Creteusis; Cretan Spignel, or Candy Carrot. Leaflets linear, flat, hirsute; petals two parted; seeds oblong, hirsute .- The whole plant is villose in a wild state ; when cultivated in a garden, the leaves become succulent, brittle, and very shining. Petals white. It flowers in June, was found by the celebrated English botanist, Mr. Ray, upon the highest parts of Mount Juna. It is a native of the southern parts of Europe. The seeds have been occasionally employed as carminatives, and were supposed likewise to be diuretic and emmenagogue : lately they have been little used, except as ingredients in theriaca and mithridate. Waller, however, judges it to be much superior to the common Daucus, or wild carrot, in medicinal efficacy. It was celebrated anciently as a specific in the stone; and it will scarcely be credited, that Vau Helmout seriously affirms, that it has even cured the water in a well of this disorder.

8. Athamanta Annua; Annual Spignel. Leaves manyparted; divisions linear, roundish, acuminate.—Annual; a native of Candia.

9. Athamanta Chinensis. Seeds membranaceous, striated ; leaves super-decompound, polished, multifid ; umbel not much expanded, white.--Native of China.

 Athamanta Rupestris. Leaflets bristle-shaped, recurved, smooth; all the flowers fertile; stem eighteen inches bigh, branching, subvillose, finely streaked; petals white, cqual.--Native of Carniola and Dauphiny.

Athanasia; a genus of the class Syngenesia, order Polygamia Æqualis.-GENERIC CHARACTER. Calix: common, imbricate, ovate; scales lanceolate, pressed close, Covolla: compound, uniform, longer than the calix. Corollules hermaphrodite, equal, numerous. Proper, funnel-form ; border five-eleft, acute, erectish. Stamina : filamenta five, capillary, short ; anthera cylindric, tubular. Pistil: germen oblongish; style filiform, a little longer than the stamen; stigma bifid, ohtnse, Pericarp : none. Calix : unchanged. Seeds : solitary, oblong ; down chaffy, of very short bristles; receptacle chaffy; chaffs lanceolate, longer than the seed. ESSENTIAL CHARACTER. Calix: imbricate. Down: chaffy, very short; receptacle chaffy. The perennial Cape sorts of Athanasia are easily propagated by cuttings during the summer months. If these are planted either in pots or upon an old hot-bed, and closely covered with glasses, shading them, in the heat of the day, and refreshing them with water when they require it, they will put out roots in five or six weeks ; and in two months they may be taken up and planted in pots filled with light earth, and placed in a shady situation,

removed to a sheltered situation, mixing them with other exotic plants, where they may remain till the middle or end of October, according as the season proves favourable; then they should be removed into a dry stove or glass case, where they may enjoy as much free air as possible, but secured from frost, with which management they will thrive, and produce plenty of flowers; but where they are drawn weak in winter. they will not appear sightly. The annual Cape sort is propagated by seeds when they can be obtained good : they should be sown on a moderate hot-bed the latter end of March ; when the plants are come up, they should have air. in proportion to the warmth of the season, admitted to them, to prevent their drawing up weak; and so soon as they are big enough to remove, they should be transplanted on another gentle hot-bed, at three inches' distance, observing to shade them until they have got fresh root ; after which they must have air and water, and by the end of May, the plants will have acquired strength enough to be transplanted into the open air; when some may be planted in pots, to place among other exotic plants in summer, and the other into warm borders, where they will flower all the autumn; but unless the season is very warm, they will not ripen seeds. The European species may be propagated by planting slips or cuttings during the summer months, in the same way as the African sorts; some of the plants should be put into pots to be placed under a hot-bed frame in winter; the others may be planted in a warm border, where, if the winter proves favourable, they will live, but they rarely survive cold winters. -The species are,

1. Athanasia Squarrosa; Cross-leaved Athanasia. Peduncles one-flowered, lateral; leaves ovate recurved.—Native country unknown, supposed to be the Cape of Good Hope.

2. Athanasia Sessiflora; Sessifl-flowered Athanasia. Peduncles one-flowered, shorter than the leaf; leaves linear, hairy.--Native of the Cape of Good Hope.

3. Athanasia Pumila; *Dwarf Athanasia*. Peduncles one-flowered, longer than the leaf; leaves linear, hairy.—A very small plant; found by Thunberg at the Cape of Good Hope.

 Athanasia Crenata; Notch-leaved Athanasia. Flowers solitary, terminal; leaves linear; stem shrubby.—Native country unknown.

5. Athanasia Uniflora; One-flowered Athanasia. Flowers solitary, terminal, sessile; leaves obovate, imbricate, smooth. --Native of the Cape of Good Hope.

6. Athanasia Capitata; *Hairy Athanasia*. Fowers terminal, subsessile; leaves lanceolate, hirsute; flowers discoid and flosculose.—Native of the Cape of Good Hope.

7. Athanasia Maritima; Sea Athanasia, Cud-weed, or Cotton-weed. Peduncles two flowered; leaves lanccolate, create, obluse, tomentose; root perennial, woody, putting out many fibres, which spread near the surface.—The flowers are produced towards the end of the branches, upon short peduncles, and are of a bright vellow colour. The whiteness of the leaves and branches, makes a pretty appearance. Native of the south of Europe, on the sea coast; found also in the isle of Anglesea, Cornwall, isle of Shepry, near Pool in Dorsetshire, and Landguard fort in Essex.

 Athanasia Genistifolia; Broom-leaved Athanasia. Corymbs simple; leaves lanceolate, undivided, naked, crowded; corymbs small, with three or four subsessile flowers.

9. Athanasia Pubescens; Villose-leaved Athanasia. Corynhs simple; leaves lanceolate, undivided, villose.—It rises six or seven feet high, with a shrubby stem; the flowers are yellow, and the seeds do not ripen in England.

10. Athanasia Annua ; Annual Athanasia. Corymbs sim-

ple, contracted : leaves pinnatifid, toothed ; root annual; flowers large, bright, yellow; appearing in July and August, but rarely producing seed in this country. There is a variety of this species, which is a tender plant, with a single grooved stem.

 Athanasia Trifurcata; Trifid-leased Athanasia. Corymbs simple; leaves three-lobed, cuueiform; stem shrubby, five or six feet high, dividing into many irregular branches.— The flowers are of a bright vellow colour, and appear in August, but are seldom succeeded by ripe seeds in Eugland.

12. Athanasia Crithmifolia; Samphire-leaved Athanasia. Corymbs simple; leaves semitrifid, linear; stem shrubby; flowers of a bright yellow colour.

13. Athanasia Linifolia; *Flax-leaved Athanasia*. Corymbs simple; leaves linear; stem simple, round, smooth, like that of flax.—Found at the Cape of Good Hope.

14. Athanasia Dentata; Tooth-focared Athanasia. Corymbs compound; leaves recurred, the lower linear, toothed, the upper ovate-serate; stem low, shrubby, branching, seldom rising litre feet ligh, --Flowers pale yellow; they appear early in summer, and if the season prove favourable, will be succeeded by ripe seeds in autumn.

15. Athanusin Parviifora; Scall/flowered Athanasin. Corymbs compound: leaves plumate, linear.—It has roundish buuches of bright yellow flowers; some of the peduncles sustain but one, others two, https://fowers.upon.each; they appear in the beginning of July, and continue in succession till late in autums; those which come early in the season will riper their seeds in winter. Native of the Cape of Good Hope.

16. Athanasia Pinnata. Corymbs dense, compound; leaves pinnate, linear, tomentose; leaves crowded with five or seven pinnas.—Native of the Cape of Good Hone.

17. Athanasia Pectinata. Coryinb compound; leaves pinnate, smooth.—Found at the Cape of Good Hope, by Thunberg.

18. Athanasia Dentata. Corymb compound; leaves lanceolate, toothed, serrate.—Native of the Cape of Good Hope.

19. Athanasia Filiformis; Fine-leaved Athanasia. Corymb compound; leaves linear, smooth, spreading.—Found at the Cape of Good Hope, by Thunberg.

20. Athanasia Cinerca; Lavender-leaved Athanasia. Corymb compound; leaves linear, tomentose, entire.—Native of the Cape of Good Hope.

Athenæa: a genus of the class Octandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, coloured, five-parted; parts oblong, acute, erect, spreading at top. Corolla: none. Stamina: filamenta eight, filiform, erect, of which five are of the length of the calix, the three alternate ones a little shorter ; antheræ sagittate ; eight plumose bristles, shorter than the filamenta, growing together with them to a gland surrounding the germ. Pistil: germen superior, ovate, surrounded at the base by an annular gland. Style : setaceous, longer than the stamina; stigma depressed, five-parted. Pericurp: capsule globose, one celled, threevalved; valves somewhat fleshy. Seeds : three to five, rounded, covered with a pulpy-coloured membrane, affixed to the receptacle in the bottom of the capsule. ESSENTIAL CHA-RACTER. Calix : coloured, five-parted ; corolla none. Bristles, eight, feathered between the filamenta ; stigma fiveparted; capsule globose, one-celled, three-valved. Seeds three to five .---- The only species known, belonging to this genus, is,

1. Athenza Guianensis. A branching shrub; stem four or five inches in diameter, covered with a wrinkled gray bark. The flowers come out in bundles from the axils, and upon the tubercles of the stem and branches, each on a small pedancle; their calix is white, and there is no corolla; capsule green, with a tinge of violet. The seeds are covered with a pulpy viscid membrane of a scatter colour. The bark, leaves, and fruit, are sharp and arcmatic. The last are called *eaffrdiable*, or devil's coffee, by the creates. It is a native of Cayenne, and the neighbouring continent of Gniana, in a sandy soil, a quarter of a league from the sca-shore, flowering and hearing fruit in September.

ATR

Atractylis; a genus of the class Syngenesia, order Polygamia Æqualis .-- GENERIC CHARACTER. Calix: outer many-leaved, linear, larger, roughened, permanent, imprisoning the common one; common, ovate, imbricate : the scales oblong, very many, lanceolate, converging, unarmed. Corolla : compound, radiate; corollules hermaphrodite, numerous, tubular in the disk ; hermaphrodite numerous, tubular in the disk : hermaphrodite ligulate in the ray; proper of the disk funnel-form, five-cleft; of the ray ligulate, flat, five toothed. Stamina : filamenta five, capillary, very short ; anthera cylindric, tubular. Pistil of the disk : germen very short ; style filiform, the length of the stamina; stigma bifid: of the ray, very like that of the disk, but obscure and withered. Pericarp none. Calix converging. Seeds: turbinate, compressed. Down plumose. Receptacle: villose, flat. ESSENTIAL CHARACTER. Corolla: radiated : corollules of the ray five-toothed .- All the species of this genus, except the first, second, and third, are strangers to the European gardens; and whenever they are introduced, will require the protection of a green-house or stove. — The species are, 1. Atracts is Gummifera; Gummy-rooted Atractylis.

Flower stemless; root perennial, sending out many narrow leaves, which are deeply sinuated, and armed with pines on their edges .- These lie close to the ground, and between them the flower is situated. The florets on the border arewhite, but those which compose the disk are of a yellowish colour. It is a native of Italy, and the islands of the Archipelago, but never perfects seeds in England. The roots, if wounded when fresh, yield a viscous milky juice, which concretes into tenacious masses, whitish, and resembling wax. It was formerly chewed for the same purpose as mastich. It is propagated by seeds, which must be obtained from the countries where they grow naturally: these should be so sown upon a border of light earth, in a warm situation, early in April ; and when the plants come up, and are fit to transplant, they should be thinned, and those which are drawn out may be transplanted, leaving the others two feet asunder : after which, the only culture they require is, to keep them clean from weeds in summer, and in winter, to cover the roots with some old tanner's bark, to prevent the frost from penetrating the ground.

2. Atractylis Humilis; Dowar/ Atractylis. Leaves tooth-sinnatel; flowers radiated, fenced with an expanding involucre; stem herbaceous; stem near a foot high.—The roots will live two or three years; it flowers in Junc, but unless the summer be warm and dvy, it will not perfect seeds in England. It is a native of France and Spain; propagated in the same manner as the first species.

3. Attactylis Cancellata; Netted Attractylis. Involuces latticed, hellying, linear, toothed; calices ovate; flowers flosulous.—It is an annual, seldom rising more than eight or unie inches high; it is curiously netted over, and is narrow at the top, but swelling below, containing many florets of a purplish colour. It is a native of Spain, Sieity, and other wara parts of Europe; flowers with us in July, and if the season he dry and warm, will ripen its seeds in September.

4. Atractylis Lancea; Lance-leaved Atractylis. Involu-

leaves smooth .- Native of Japan.

ATR

5. Atractylis Ovata; Orate-leaved Atractylis. Involucres pinnate; leaves ovate, ciliate, smooth; flower terminating. solitary .- Native of Japan.

6. Atractylis Oppositifolia; Opposite-leaved Atractylis. Leaves opposite; the leaves, and even the calix, tomentose underneath .- Native of the Cape of Good Hope.

7. Atractylis Purpurata; Purple-flowered Atractylis. Leaves hastate, runcinate; receptacle naked .-- Found by Mutis in New Granada.

8. Atractylis Mexicana; Mexican Atractylis, Leaves oblong, quite entire; stem shrubby; stipules none; corolla purple .- Found in Mexico.

Atragene; a genus of the class Polyandria, order Polygynia; -GENERIC CHARACTER. Perianth four-leaved ; leaflets oval, spreading, obtuse, deciduous. Corolla : petals twelve, linear, very narrow at the base, obtuse, spreading. Stamina: Filamenta very many, very short. Antheræ oblong, acuminate, shorter than the calix. Pistil : germina very many, oblong. Styles villose, permanent. Stigma simple, the length of the antheræ. Pericarp : none. Seeds: very many, end-ing in a hairy tail. ESSENTIAL CHARACTER. Calis: fourleaved. Petals: twelve, Seeds: tailed .---- The species are.

1. Atragene Japonica ; Japonese Atragene. Erect, leaves opposite, triternate; leaflets ovate, gashed .- It has all the appearance of anemone, but is referred to this genus on account of the number of petals. Never cultivated in England. Native of Japan.

2. Atragene Alpina ; Alpine Atragene. Leaves doublyternate, serrate, outer petals four fold ; stcms many, branching, diffused, long, angular, smooth, brown, prostrate on the rocks, or scandent ; petals dirty white, usually twelve. This may be increased by cuttings or layers. In a strong soil, and trained against a wall, it will rise to the height of five or six feet. The flowers appear early, and if the season prove favourable, they make a handsome figure ; but as this plant is apt to put ont leaves very early in the spring, it is frequently nipped by the frosts, as are many plants and trees of Siberia and Tartary. Native of the high Alps of Switzerland.

3. Atragene Capensis; Cape Atragene. Leaves ternate; leaflets gashed, toothed, outer petals five-fold; scape simple, six or seven inches long .- Native of the Cape of Good Hope.

4. Atragene Tenuifolia; Fine-leaved Atragene, Leaves doubly pinnate ; pinnales linear, entire .- Found at the Cape of Good Hope, by Thunberg.

5. Atragene Zeylanica; Ceylonese Atragene. Tendrils two-leaved; this is caulescent, and scandent; panicle terminating, composed of a twice trifid peduncle, bearing commonly nine peduncled distinct flowers. Native of the island of Ceylon.

Atraphaxis ; a genus of the class Hexandria, order Digynia .- GENERIC CHARACTER. Calis: perianth two-leaved; leaflets opposite, lanceolate, coloured, permanent. Corolla : petals two, roundish, sinuate, larger than the calix, permauent. Stamina: filamenta six, capillary, the length of the calix. Antheræ roundish. Pistil: germen compressed. Style none. Stigmas two, capitate. Pericarp: none. Calix inclosed, including the seed. Seed : one, roundish, compressed. ESSENTIAL CHARACTER. Calix : two-leaved. Petals : two, sinuate. Stigmas : capitate. Seed : one .-The seeds of these plants not ripening seeds in England, they are propagated by cuttings, during any of the summer months. In winter they must be screened from hard frost, which com-

cres pinnate ; leaves lanceolate, ciliate, smooth ; stem leafy ; | monly destroys such as are planted in the air.---- The species are,

ATR

1. Atraphaxis Spinosa ; Prickly-branched Atraphaxis. Branches spiny .- This shrub rises four or five feet high, sending out many weak lateral branches, armed with spines, and garnished with small, spear-shaped, smooth leaves, of an ash colour. The flowers come out at the end of the shoots in clusters, each consisting of two white petals, tinged with purple, included in a two-leaved calix, of a white herbaceous colour. They appear in August. Native of Armenia, Siberia, and Persia.

2. Atraphaxis Undulata ; Ware leaved Atraphaxis. Without spines .- This species sends out many slender branches, trailing on the ground ; leaves small, oval, about the size of those of knot-grass, waved and curled on their edges, embracing the stalk half round at their base, and placed alternate ; stems several, shrubby, and scarcely a foot high. Native of the Cape of Good Hope.

Atriplex ; a genus of the class Polygamia, order Monœcia. -GENERIC CHARACTER. Hermaphrodite flower. Calix: perianth five-leaved, concave, permanent; divisions ovate, concave, membranaceous at the edge. Corolla: none. Stamina : filamenta five, subulate, opposite to the leaves of the calix, and longer than them. Antheræ roundish, twin. Pis-til: germen orbiculate. Styles two-parted, short. Stigmas reflex. Pericarp : none. Calix : closed, pentagon, with the angles compressed; deciduous. Seed: one, orbicular, depressed. Female flower on the same plant. Calix: perianth two-leaved ; leaflets flat, erect, ovate, acute, large, compressed. Corolla: none. Pistil: germen compressed. Style two-parted. Stigmas reflex, acute. Pericarp : none. Valves of the calix very large, cordate, including the seed between them. Seed : one, orbiculate, compressed. ESSENTIAL CHARACTER. Hermaphrodite. Calix: five-leaved. Corolla: none. Stamina: five. Style: two-parted. Seeds one, depressed. Female calix : two-leaved. Corolla none. Stamina none. Style two-parted. Seed one, compressed. -The species are,

1. Atriplex Halinns; Tall Shrubby Orache, or Spanish Sea Purslane, Stem shrubby; leaves deltoid, entire; root perennial, woody, dividing into many branches; the whole shrub white; flowers small, purplish at the ends of the branches: seeds small, brown .- It grows in hedges near the sea, about Nice, also in Spain, Portugal, and Sicily. Ray says that he found it in great plenty about Messina. Although this shrub is not proper for hedges, for which it was introduced, it may have a place in wilderness quarters, where it will serve to thicken, and the silver-coloured leaves will add to the variety, among other shrubs of the same growth. It will grow eight or ten feet high, and if suffered to grow wild without pruning, will spread several feet in compass, and sometimes produce flowers. This, and the second and third species, may be increased by cuttings, planted in any of the summer months on a shady border; where, if they be duly watered, they will soon take root, and be fit to transplant the Michaelmas following, when they should be planted where they are to remain: for they do not succeed well in transplanting, especially when they are grown large and woody.

2. Atriplex Portulacoides; Dwarf Shrubby Orache, or Common Purslane. Stem shrubby ; leaves obovate .- This is a low undershrub, soldom rising above two feet and a half, or at most three feet high, but becoming very bushy. The leaves are narrow, and of a whitish colour. The branches generally recline, are angular, and of a whitish green. The leaves are glaucous, opposite, petioled, generally elliptic, some obtuse, others lanceolate. The flowers are yellow, and

10

terminate the branches in clustered spikes. It is found wild on the shores of the European ocean, and in salt marshes, flowering in July and August. It may be introduced into plantations among other low shrubs, and if planted on a poor gravelly soil, will abide several years, and make a pretry diversity. For the culture and propagation of it, see the first species.

3. Atriplex Glauca. Stem undershrubby, procumbent: leaves orate, sesile, quite entire : the lower ones subdentate : stem the thickness of a finger, covered with an ash-coloured bark, and divided into declining branches, three or four feet long, subdividing into other shorter ones. The leaves are thickish, from silver inclining to glaucous. At each axil of the upper branchlets come out three or four hermaphrodite flowers, with a few females among them of a yellowish colour. Native of France and Spain.

4. Atriplex Rosea. Stem herbaceous ; leaves hoary, serrated; fruits quadrangular, toothed; stem erect, a foot and half or two feet high, somewhat angular, white, smooth, very branching, the branches alternate, subdividing all diffused flowers in close sessibe balls at the axils—It is an annual plant, native of the southern countries of Europe. For the culture and propagation of it, see the first species.

5. Atriplex Sibirica; Siberian Orache. Stem herbaceous; leaves deltoid, angular; the calices of the fruit muricated on the outside,—The leaves are silvery beneath, and the flowers white. An annual plant, and a native of Siberia.

6. Atriplex Tatarica; Tartarian Orache. Stem herbaceous; leaves deltoid, sinuate-toothed, waved alternate; stem about six feet high.

7. Atriplex Hortensis; Garden Orache. Stem erect, herbaceous; leaves triangular; root annual; stem three feet high, and more, thick, shining .- It is a native of Tartary. There are three or four varietics of this, differing only in the colour of the plants; one is of a deep green, another of a dark purple, and a third with green leaves and purple borders. It is used of many, says Parkinson, boiled and buttered, to make the stomach and belly soluble, and is put among other herbs into the pot, to make pottage. There are many dishes of meat made with it while it is young; for being almost without savour, it is the more convertible into what relish any one will make it, with sugar, spice, &c. It was formerly cultivated in the kitchen-gardens, as a culinary herb, being used as spinage, and is now by some persons preferred to it, though in general it is not esteemed among the English ; but the French cultivate this plant for use. The red orache is formed to dye wool of a good olive colour. This must be sown for use early in the spring, or at Michaelmas, soon after the seeds are ripe, at which time it generally succeeds better than when it is sown in the spring, and will be fit for use at least a month earlier. These plants require no other culture, but to hoe them when they are about an inch high, to cut them down when they are too thick, leaving them about four inches asunder, and also to cut down all the weeds. This must be done in dry weather, otherwise the weeds will take root again, and render the work of little When the plants are grown about four inches or no use. high, it will be proper to hoe them a second time, in order to clear them from weeds ; and if you observe the plants are left too close in any part, they should then be cut out. If this be well performed, and in dry weather, the ground will remain clean until the plant is fit for use. Where it is sown on a rich soil, and the plants are allowed a proper distance, the leaves will be very large, and in that the excellence of the herb consists. It must be eaten when young, for when the stalks become tough, they are good for nothing. The secds 13.

will ripen in August, when the plants may be cut or pulled up, and laid on a cloth to dry; after which the seeds may be beaten out, and laid up in bags for use.

8. Atriplex Laciniata; Jagged Sca Orache. Stem herbaccons; leaves deltoid, toothed, silvered underneath...-The whole plant is covered with a skin that peels off, and is of a gray hoary colour. It is an annual, flowering in July and August, and is a native of the sea-shores of Europe.

9. Atriplex Hastata; Broad-leaved Wild Orache, vulgarly Fat-hen. Stem herbaceous; valves of the calix in the female flowers large, deltoid, sinuated ; root annual.-It varies with an erect and decumbent stem; with leaves sinuatetoothed, toothed and entire. It varies much according to age and situation; on dunghills it is very strong and luxuriant, by road-sides it is weaker, and its branches are long and procombent; in wet places it becomes more upright, and the leaves are very mealy on the under side, particularly when it grows on the sea-shore ; at other times they are altogether smooth. In its young state, this plant is frequently eaten instead of spinach. Birds are very fond of the seeds, but cattle do not seem much to like the plant. In gardens, and other cultivated grounds, it is a very troublesome weed ; it should not therefore be suffered to grow and seed on dunghills.

10. Atriplex Patula; Narrow-leaved Wild or Spreading Orache, Stein herbaceous, expanding; leaves subdelloid, lanceolate; calices of the seeds toolhed in the disk; root annual.—Native of Europe, in waste places, on ditch-hanks, and in cultivated grounds, flowering in August.

 Atriplex Littoralis; Grass-larged Sea Orache. Stem herbaceons, erect; all the leaves linear, quite entire; root annual.— Native of the sea-coasts of Europe, flowering in August : found at Ramsgate in Kent; Yarmouth, Blakeney, and Wells, in Norfolk.

12. Atriplex Pedunculuta; Pedancled Orache, Stem herbaccous, divaricated ; leaves lanceolate, obtuse, entire; calices of the female flowers peduncled; stem much branched. --Native of the sea-shores of Denmark and England; as, near Boston, in the isle of Thanet; near Yarmouth, Lynn, &c. It flowers from July till September.

 Atriplex Marina; Serrated Sea Orache. Stem herbaceous, erect; leaves linear, serrate.—It is an annual plant, native of Sweden and England; on sea-shores and in waste places, flowering in August.

 Atriplex Albicans; White Orache. Stem shrubby, erect; leaves hastate, quite entire, acute, spikes terminating. —Native of the Cape of Good Hope: flowers in June and July.

Arops ; a genus of the class Pentandria, order Monogrna-GENERER. CHARACTER. Colfars perianth one-leafed, ive-parted, gibbous; divisions acute, permaneta. Corollar, one-petalled, bell-shaped; tube very short; border ventricose, ovate, longer than the calix; mouth small, five-cleft, spreading; divisions subequal. Shumine; filamenta five, subulate, from the base of the corolla, and of the same length with it, converging at the base, above diverging outwards, bowed. Antheræ thickish, rising. *Pisidl*; germen semiorate. Style filiform, the length of the stamina included. Signa headted, rising transcelle, pelong. *Pericarp*: berry globular, sitting on a large calix, two-celled. Receptacle fielshy, convex on both sides, reniform. Seeds very many, reniform. ESENTIAL GHARACTER. Corolla: bell-shaped; stamina distant; berry globular, two-celled.

1. Atropa Mandragora; *Mandrake*. Stemless; scapes one-flowered.—It has a long taper root, like a parsnep, which runs three or four feet deep in the ground; it is sometimes 2 Q. 150

single, and at others divided into two or three branches, almost of the colour of the parsnep, but a little darker : immediately from the crown of the root arises a circle of leaves, which at first stand erect, but when grown to their full size, spread open, and lie upon the ground; they are more than a foot in length, and are four or five inches broad in the middle, growing narrow towards both ends, of a dark green colonr, and a fetid seent: among these come out the flowers, each on a scape about three inches long; they are five-cornered, of an herbaceous white colour, spreading open at top like a primrose, having five hairy stamina, and a globular germen, supporting an aul-shaped style, which becomes a globular soft berry, when full grown as large as a nutmeg, of a yellowish green colour, when ripe full of pulp. Haller adds, that the leaves are ovate-lauceolate, and waved about the edges; that the flowers have a tinge of violet; and that a circular gland surrounds the germen produced into two horns. The roots have been supposed to bear a resemblance to the human form, and in the old Herbals are figured as male, with a long beard, and female with a prolix head of air. Mountebanks carry about fictitious images, shaned from roots of bryony, and other plants cut into form, or forced to grow through moulds of earthenware, as mandrake roots. It was fabled to grow under the gallows, where the matter falling from the dead body, gave it the shape of a man; to utter a great shrick or terrible grean at the digging up; and it was asserted, that he who would take a plant of mandrake, should in common prudence tie a dog to it for that purpose, for if a man should do it himself, he would surely die soon after. The bare mention of such fables, are a sufficient confutation of them, nor would they have been mentioned here, had it not been for the allusions to them which occur in ancient authors. The whole plant is fetid, and reputed to be poisonons, though in small doses it was used medicinally, and particularly as an opiate. Native of Spain, Portugal, Italy, and the Levant. It flowers with us in March, and the seeds ripen in July. Mandrake is propagated by seeds, which should be sown upon a bed of light earth, soon after they are ripe, for if they are kept until the spring, they seldom succeed well; but those which are sown in autumn, will come up in the spring, when they should be carefully cleared from weeds ; and in very dry weather, they must be refreshed with water, which will greatly promote their growth. In this bed they should remain till the end of August, when they must be taken up very carefully, and transplanted into the places where they are to remain : the soil should be light and deep, for their roots run far down; but if the soil be wet, they are often rotted in winter, and if it be too near gravel or chalk, they will make little progress; but where the soil is good, and they are not disturbed, the plants will grow to a large size in a few years, and will produce great quantities of flowers and fruit. These plants should have a warm situation, otherwise in severe winters they will be destroyed.

2. Atropa Beliadonna; Deadly Nightshade, or Deadle, Sten herbaccous; leaves ovate, entire; peduncles one-flower-ed.—Deadly nightshade has a perennial, thick, long, branching root, sending out strong, lerbaccous, wright, round, trichotonous, branching stems, from three to five feet, and sometimes six feet in height, frequently tinged with purple: the branches are dichotonous. The root leaves are often a foot long, and five inches broad; the stem-leaves are peitoled, acute, soft, dusk green above; and paler green beneath, a little hairy on both sides, and fattish to the touch, chang ing to a purple colour in the autum; there are generally two leaves at each branch, one smaller than the other, running down along the short petiole.

one-flowered, flowers large, nodding, void of seent; calix dirty green ; eorolla lurid ; within dusky, purple, and streaked, with a yellow variegated base, without greenish red, or dusky brown : berry large, at first green, but when ripe of a beautiful shining black colour, full of purple juice, with roundish dotted channelled seeds immersed in the pulp; and a glandular ring surrounding it. Seopoli observes, that there are two tubereles between the cells of the antheræ; that the stigma is two-lobed ; that the berry sits on the stellate calix, is very succulent, obtuse, marked with small dots, and has two heart-shaped receptacles to which the seeds adhere. When this plant was found to differ from the solana or nightshades, it received the Italian name of belladonna, which was given it, according to some, because it was used as a wash among the ladies, to take off pimples and other excrescences from the skin; or, according to others, from its quality of representing phantasms of beautiful women to the disturbed imagination. The qualities of this plant are malignant, and it is extremely deleterious in all its parts. Numerous instances have occurred of the berries proving fatal, after eausing convulsions, delirium, &c. Buchanan relates the destruction of the army of Sweno the Dane, when he invaded Seotland, by the berries of this plant, which were mixed with the drink which the Scots, according to truce, were to supply the Danes with. The Danes were so inebriated thereby, that the Scottish army fell on them in their sleep, and slew such numbers, that there were scarcely men enough left to carry off their king. A remarkable case is related by Mr. Ray, of the dilatation of the pupil of the eye, caused by a part of a leaf of this plant applied outwardly, and which took place successively on the repetition of the experiment. With respect to the berries, they have frequently been fatal to ehildren ; and if a considerable number are caten, to grown persons likewise. The symptoms are said to occur in less than half an hour after taking them, and consist of vertigo, great thirst, delirium, swelling and redness of the face, &c. The general sensibility of the system is said to be weakened to a great degree, so that the stomach will bear a far larger dose of emetic medicines than it would otherwise have done. Vinegar, liberally drank, has been found efficacious in obviating the effects of the poison. Dr. Hill relates a very remarkable case, which occurred under his own observation. A labourer found some of the plant in the park of a nobleman, where he was repairing the pales; he eat heartily of the berries, and gave some to two of his children. After two hours he grew giddy, and unable to stand ; was extremely thirsty; complained of dreadful pain in his breast, and difficulty of breathing. He afterwards fell into violeut ravings, which continued, with slight intervals, during great part of the night. All this time he was also afflicted with a very painful strangury. He recovered, however, some time afterwards, without the assistance of medicine, but both the children died in the course of the night. The leaves are said to have been sometimes successfully applied in cancerous tumors. The iugenious Dr. Milne, in his Indigenous Botany, has very properly remarked, that nature has been more parsimonious in her warnings with respect to this plant, than to others of the same natural family. Neither the smell nor the taste is offensive ; and if the colour of the flowers proves in some degree a repellent, that of the fruit, on the other hand, is in an equal degree, at least, attractive and inviting. Accordingly, belladonna, notwithstanding its deleterious nature, is not totally excluded from the precincts of physic: nay, some diseases, and those of the most malignant kind, have been known to yield to the anodyne and antispasmodic virtues of this plant, when administered with caution, after

resisting the force of medicines, more innocent indeed, but of less powerful efficacy. Bergius relates, that he has often given relief in epilepsy and convulsion by the internal use of the powder of the leaves, taken in doses of from one to four grains, twice a day; and Gesner, in his Medical Epistles, recommends the expressed juice of the berries, boiled with sugar into a syrup, and given a tea-spoonful at a time, as excellent in every case requiring an opiate, and as peculiarly efficacious in the cure of the dysentery. It was some time ago supposed to be a specific in cancerous complaints, and in the Philosophical Transactions, there is a well-attested case, of a woman that was cured of a cancer in her breast, by taking a tea-cupful of an infusion of the dried leaves every morning. The malady at first grew worse, but after persevering some time in the use of the medicine, the symptoms abated, and in about half a year she was perfectly well. The infusion was made by pouring ten tea-cupsful of boiling water on twenty grains of the dried leaves, and letting it stand to infuse all night in a warm place. In consequence of this it was tried in many of our hospitals, and frequently mitigated the symptoms, but without effecting the cure. The leaves externally applied are cooling and softening; they are good against the ringworm, and tetters, and against hard swellings. This plant is a native of Europe, particularly of Austria and England, in church-yards and on dunghills, skulking in gloomy lanes, and uncultivated places : in other countries it is said to be common in woods and hedges. With us, it is not so common as in a wild state, but that the places where it has been found may be set down. About Fulborn, in Cambridgeshire; near Wisbeach, in the isle of Ely : Hollaud, in Lincolnshire : between Temsford-mills and Welwyn, in Herts; Charley forest and Grace Dieu, in Leicestershire; north Luffenham, in Rutland; Satton Cofield, in Warwickshire ; Clifton Hill, near Nottingham, and Mansfield in the same county ; and in Westmoreland. Mr. Miller observed it in Woodstock park, in Oxfordshire; and in Uppark in Hampshire. In the counties round London it is not very common; it has, however, been remarked about Rochester, between that and Maidstone, and near Feversham in Kent, about Harefield and More Park near Rickmansworth, at Jorking in Surrey; and by old Gerarde in Highgate. It may be propagated both by its roots and by seeds. It loves a shady situation, but on account of its deadly poison, is rarely admitted into gardens. It should by no means be suffered to grow where children or common people resort. because they are likely to be attracted by the splendid black colour of the berries.

S. Atropa Physaloides ; Perurian Deadly Nightshade, or Blue-flowered Atropa. Stem herbaceous; leaves sinuate, angular; calices closed, acute angular; root fibrous, annual; stem two feet high, spreading, erect; branches angular .--The stem, though herbaceous, is very strong, in our gardens four or five feet high, and of a purplish colour, dividing into several branches, spreading out wide on every side ; leaves oblong, deeply sinuate, deep green ; peduucles short ; calix large, bell-shaped ; corolla large, of the open bell-shape, of a light blue colour ; berries about the size of common cherries, inclosed in a large swelling bladder, having five sharp angles. It flowers in July, and the seeds ripen in autumn ; and if permitted to scatter, the plants will come up in the following spring; or if the seeds be sown on a bed of rich earth in the spring, the plants will rise easily, and may be afterwards easily transplanted to the borders of the pleasure garden, where they must be allowed room, for if the ground be good, the plants will grow very large.

4. Atropa Solanacea. Stem shrubby; peduncles solitary;

corollas bell-shaped; I caves suborate; stem six feet high; i shrabhy, somewhat branching and angular; ealth bell-shaped, five cleft; corolla three times larger than the calix.—Native of the Cape of Good Hope. It may be propagated by seeds, which should be sown in the spring, on a hot-bed; when they are fit to remove, they should be each put into a separate small pot, filled with loamy earth, and shaded until they take root.

5. Atropa Arborescens; Tree Atropa. Stem shrubby; peduncles crowded; corollas revolute; leaves oblong.—This is a small tree, a nutive of South America and Jamaica, on the temperate mountains, flowering in autumn. The betries are commonly full of some worm. It must be kept in the barkstove, or it will not thrive well in England.

6. Atropa Trutescens; Shrubby Atropā. Stem shrubby; peduncles crowded; leaves cordate-ovate, obtusc.—This rises with a shrubby stem to the height of six or eight feet, and divides into many branches; leaves alternate round, in shape like those of the storax tree. The flowers come out between the leaves upon short peduncles, and are shaped like those of deadly nightshade, but much smaller, of a dirty yellowish colour, with a few brown stripes; they are never succeeded by berries in England. It is a native of Spain, and may be planted with other hardy exotic plants, in a sheltered situation, from whence it must be removed in October, into the green-house.

7. Atropa Herbacea; *Herbaccous Alropa*. Stem berbacoosa; leaves ovate, nerved, with waved edges; root perennial.—The flowers come out from between the leaves, on short peduncles; they are white, and shaped like those of leadly nightshade, but smaller. It flowers in July and August, but seldom ripens its fruit in England. It must be kept in a bark-stove, or it will not thrive in this country.

8. Atropa Procumbens : Wheel-flowered Atropa. Stem procumbent, herbaceous; leaves twin, unequal, ovate, smooth; flowers in nmbels; root annual; corolla herbaceous; leaves, whice-labaped, spreading very much, the border five-cornered, rolled back a little with sharp angles.—Native of Mexico: cultivated in the royal garden at Madrid, where it flowers and fruits in October. It must be kept in the bark-stove, or it will not thrive well in this country.

Aubletia ; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth fiveleaved, rigid, spreading, coloured within, pubescent without, deciduous, five-parted; parts linear, lanceolate, acute, with thick margins, which before flowering are contiguous, Corolla: pctals five, roundish, oblong, smaller than the calix, with very short claws. Stamina : filamenta very many, very short. Antheræ ovate-oblong, outwardly gibbous, gaping on the inner side, foliaceous at the tip, acute; the exterior ones sterile, lanceolate, ending in a foliaceous point; shorter than the corolla. Pistil: germen roundish, depressed. Style long, striated, gradually thickening, slightly incurved. Stigma spreading, perforated, ten-toothed. Pericarp : capsule large, orbiculate, depressed, coriaceous, echinate, ten-celled, gaping at the base. Seeds very many, small, roundish, somewhat compressed. Receptacle of the seeds fleshy. ESSEN-TIAL CHARACTER. Calix five-leaved. Corolla five-petalled. Capsule many-celled, echinate, with many seeds in each cell .--The species are,

 Aubletia Tibourbou. Leaves acutely serrate, hirsutc.— This is a middling-sized tree, with a trunk seren or cight feet high, about a foot in diameter, and an irregular chopped soft thick bark, fibrous and fit for making ropes. Aprila is the Brasilian name, though it is called tibourbou by the Caribbees. Aublet found it in flower and fruit from August till October. It is a native of Brazil, Guiana, the islands of the calix ; culms from two to three feet in height, very slen-Cavenne, and Tobago.

AVE

2. Aubletia Petoumou. Leaves elliptic, acute, serrulate, hoary beneath .- This is a large tree, being often forty feet high, and a foot and a half or more in diameter, with a brown thick filamentose bark, fit for making cordage ; the wood is light, and of a white colour; corolla yellow. It bears flowers and fruit in October, and is a native of Guiana, in the vast forests of Linemari,

3. Aubletia Aspera. Leaves quite entire, pubescent beneath ; fruit compressed .- Also a large tree from thirty to forty feet high, and a foot and half or more in diameter, with a grayish, irregular, thick, filamentose bark, proper for making cordage: the wood is light and white; corolla yellow, four or five-petalled. Native of Guiana, and the island of Cayenne ; flowering and bearing fruit in the month of May.

4. Aubletia Levis. Leaves quite entire, smooth on both sides ; fruit rough, depressed .- This is a middling-sized tree, its trunk being from ten to twelve feet in height, and cight or ten inches in diameter, with a smooth, thin, greenish bark; the wood is white, tender, and so light, that the trunk may be easily carried in one hand; corolla greenish. Native of Guiana; flowering and bearing fruit in the month of May.

Aucuba; a genus of the class Monœcia, order Tetrandria. -GENERIC CHARACTER. Male flowers. Calix : perianth one-leafed, truncate, obscurely four-toothed, villose, very short, permanent. Corolla : four-petalled. Petals Petals ovate, acute, spreading, underneath concave, hairy, above convex; deciduous. Stamina: filamenta four, inserted into the receptacle among the petals, thick, erect, very short. Antheræ ovate, twin, with four furrows. Receptacle planoconvex, with a square hole impressed upon the middle. Female flowers on the same Tree. Calix and corolla as in the male. Pistil: germen inferior. Style thick, short. Stigma simple, capitate. Pericarp: nut ovate, one-celled. ESSEN-TIAL CHARACTER. Male calix: four-toothed. Corolla: four-petalled. Berry : one-seeded. Female nectary : none. Nut one-celled .---- The following species alone is known ;

1. Aucuba Japonica. A large tree; branches and subdivisions dichotomous, smooth rather fleshy, divaricate, erect, angular, scarred from the falling of the leaves : leaves aggregate at the tops of the branches ; petiolate, opposite oblong, sharp, remotely serrate, smooth, pale underncath, a hand'sbreadth long, nerved; flowers terminal, panicled; panicle trichotomous, superdecompound; peduncles and pedicles villose ; bractes lanceolate .- Native of Japan.

Avena ; a genus of the class Triandria, order Digynia .--GENERIC CHARACTER. Calix: glume generally manyflowered, two-valved, loosely connecting the flowers; valves lanceolate, acute, ventricose, loose, large, awnless. Corolla two-valved; lower valve harder than the calix, the size of the calix, roundish, ventricose, acuminate at both ends, emitting from the back an awn spirally twisted, reflex as at the kneejoint. Nectary two-leaved ; leaflets lanceolate, gibbous at the base. Stamina: filamenta three, capillary. Antheræ oblong, forked. Pistil: germen obtuse. Styles two, reflex, hairy. Stigmas simple, Pericarp: none, Corolla most firmly closed, grows to the seed, and does not gape. Seed : one, slender, oblong, acuminate at both ends, marked with a longitudinal furrow. ESSENTIAL CHARACTER. Calix two-valved, many-flowered; awn from the back of the corolla, jointed, twisted. For the propagation and culture of the grasses belonging to this genus, see Grass .---- The spe-cies are,

1. Avena Siberica; Siberian Cat-grass. Panicled; ca-

der .- It flowers in July and August. Native of Siberia.

AVE

2. Avena Elatior ; Tall Oat-grass. Panicled ; calices two-flowered ; hermaphrodite ; floscule almost awnless, male awned; root perennial; germen villose .- It is common on banks, in hedges, on the borders of fields, aud sometimes of meadows, especially wet ones; flowering in June and July. It is an early grass, very productive, and yields a plentiful aftermath. The stem and leaves are by no means coarse, but soft, tender, and of a pleasant taste; and it may be propagated with facility. It is cultivated in some places abroad, aud may perhaps be no bad substitute for meadow fox-tail grass.

3. Avena Stipiformis. Panicled ; calices two-flowered ; awns twice the length of the seed ; culm branching ; culms a foot high, often reclining smooth, with brown joints .- Native of the Cape of Good Hope.

4. Avena Pennsylvanica; Pennsylvanian Oat-grass. Panicle attenuated ; calices two-flowered ; seeds villose ; awns twice the length of the calix .- Observed in Penusylvania by Kalm.

5. Avena Læflingiana; Spanish Oat-grass. Panicle contracted ; floscules in pairs, hirsute ; one peduncled with two awns at the top, the middle awn longest; root aunual, capillary .- Found iu a dry soil near Madrid, and at the Cape of Good Hope.

6. Avena Sativa; Cultivated Oat. Panicled; calices twoseeded ; seeds very smooth, one-awned ; root annual, fibrous. -No botanist has been able to ascertain satisfactorily the native place of growth of this or any other sort of grain now commonly cultivated in Europe. There are three sorts of oats cultivated in England, viz. the white, the black, and and the brown, or red oat; to which we may add the blue. the Poland, the Friezland or Dutch, and the Siberian or Tartarian oat. The white sort is the most common about London, makes the whitest meal, and is chiefly cultivated where the inhabitants live much upon oat-cakes. The black is more cultivated in the northern parts of England, and is esteemed a hearty food for horses. The red oat is much cultivated in Derbyshire, Staffordshire, and Cheshire, but is rarely seen in any of the counties near London; though, as it is a very hardy sort, and gives a good increase, it would be well worth propagating, especially in strong land; the straw is of a brownish red colour, as is also the grain, which is very full and heavy, and esteemed better food for horses than either of the former sorts. The blue oat is said, in Merrett's Pinax, and Ray's Synopsis, to have been sown about Kighley in Yorkshire. It is probably the same with what is cultivated in Lincolnshire, under the name of Scotch grays. The Poland oat has a short plump grain, but the thickness of the skin seems to have brought it into disrepute among the farmers. The grains are mostly single, it has no awn, and the straw is short. Friezland or Dutch oats affords more straw, and is thinner skinned. The grains are mostly double, the larger one sometimes awned, with the awn placed high. Siberian or Tartarian oat, is, according to Mr. Marshall, a distinct species, unnoticed by Linneus. Each flower frequently contains three perfect florets, never less than two, with a pedicelled rudiment of a third. The oat is a very profitable grain. and esteemed the most wholesome food for horses, being sweet, and of an opening nature; other sorts of grain are apt to bind, which is injurious to labouring horses; but if they be fed with this grain soon after it is housed, before it has had a sweat in the mow, or has been otherwise dried, it is as bad on the other hand, for it is then too laxative. This grain is a great improvement to many estates in the north of Englices one-flowered ; seeds hirsute; awns thrice the length of land, Scotland, and Wales; for it will thrive on cold barren

AVE

soils, which will produce no other sort of grain; it will also thrive on the hottest land; in short, there is no soil too rich or too poor, too hot or too cold, for it; and in wet harvests, when other grain is spoiled, this will receive little or no damage ; the straw and husks being of so dry a nature, that if they be housed wet, they will not heat in the mow, or become mouldy, as other grain usually do ; it is therefore of great advantage in the northern parts of England, and in Scotland, where their harvest is generally late, aud the autumns wet. The meal of this grain makes tolerably good bread, and is the common food of the country people in the north. In the south it is esteemed for pottage and other messes, and in some places they make beer with it. The best time for sowing oats is in February or March, according as the season is early or late; and sometimes I have known them sown in April, upon cold land, and they have been early ripe. The black and red oats may be sown a month earlier than the white, because they are hardier. In the papers of the Bath Agricultural Society, there is an experiment made, in order to ascertain the effect of early sowing, Black oats were sown on the 27th and 28th of February, The which is a month sooner than the common practice. quantity sown was four Winchester bushels to the acre. The land was a mellow, deep, sandy loam, on which potatoes had grown. The produce was ninety-eight bushels and a quarter to the acre. The success, however, is not wholly imputed to early sowing, but partly to good deep tillage. White oats, sown the last week in May, have produced seven quarters to the acre. In Hertfordshire, they do not put them in till they have done sowing barley: in Suffolk, on the con-trary, they are sown before barley. The former practice is seemingly the best, this oat being more tender. Mr. Marshall gives the blowing of the sallow as a direction for the time of sowing this grain. Oats are often sown on land which has in the preceding year produced wheat, rye, or barley. The common method is to plough in the stubble about the beginning of February, and sow the oats and harrow them in ; but they must be harrowed the same way as the furrows lie, for if it be done crosswise, the stubble will be raised on the surface; but this is not a good method of husbandry, for when there is time to plough the stubble in autumn, it will rot in winter, and then giving the land another ploughing, and a good harrowing just before the oats are sown, it will make the ground finer, and better to receive the grain. Oats are also sown upon land when it is first broken up, before the ground is brought to a tilth for other grain, and are frequently put in upon the sward with one ploughing; but it is much better to give the sward time to rot before the seed is sown, for the roots of the grass will prevent those of the corn from striking downwards. Most people allow four bushels of oats to an acre, but I am convinced that three bushels are more than enough; the usual produce is about twenty-five bushels to an acre, though I have sometimes known more than thirty bushels. This indeed is no very great crop, forty bushels and upwards being no very unusual produce, but not from sowing thin. With respect to the proper quantity of seed to be sown, practical men differ widely in opinion. Mr. Young is decidedly of opinion, that the quantity of the seed should be proportioned to the poverty of the ground; yet there are not wanting others, who say, that poor soils ought not to be loaded with too much seed, and that six or seven bushels an acre would utterly destroy cold clay lands. On a rich soil, oats are very apt to run to straw, if sown thin; and one capital advantage which arises from sowing thick, is, that the weeds are thereby effectually smothered. 13.

7. Aveda Nuda; Naked Oat, Pilcorn, or Pillis. cled: calices three-flowered : receptacle exceeding the calix : petals awned at the back ; the third floscule awuless .- This is nearly allied to the cultivated oat, differing in little else except that the grains quit the husks, and fall naked when they are ripe. Mr. Ray informs us, that in his time it was cultivated abundantly in the farther part of Cornwall, where it fetched no less a price than wheat. It is still sown there in the poorest croft land, that has been tilled two or three seasons before with potatoes, and for the uses of the poor, answers all the purposes of oatmeal. It is a small yellow grain, and accounted superior to any other nourishment for fattening calves. Mr. Miller says, that the naked oat is less common than the others, especially in the southern parts of England; but in the north of England, Scotland, and Wales, it is cultivated in plenty. This sort, according to Worlidge, is esteemed, because the grain thrashes clean out of the husk, and need not to be carried to the mill to be made into oatmeal or grist. An acre of ground does not yield so many bushels of these, as of the common oats, because the grain is small and naked, and goes near in measure; but what is wanting in the measure, is supplied in value. Naked oat is called pillis, or pilez, according to the orthography in Borlase; or pill-corn, from its quality of depositing the husk or chaff : pill, which we now write peel, being formerly put for the outer coat of any sort of fruit.

8. Avena Fatua; Bearded Wild Oat, or Haer. Panicled; calies three-flowered; all the floxcules awned, and bairy at the base; root annual.—It is taller than the cultivated oat, the culm or strave being commonly three, and frequently four feet in height; it is erect, firm, leafy, smooth, with four joints or knots; sheaths streaked, smooth; the seed has a hairy covering. This is one of our most destructive annual weeds, and is too frequently so prevalent among barley, as almost to choke it. The seed ripens, and falls before harvest, thus filling the ground, in which it will he seeral years without repeated fallowing, or by laying down the land to grass. The awns of this species are sometimes used for hygrometers; and the seeds instead of artificial flies, in fishing for trout.

10. Avena Pubescens: Soft Oat-grass. Subspikel; eaves flees subtriforous, upper florets larity at the base; leaves flat, pubescent; root perennial.—This grass is hardy, early, and productive. Native of Portugal, France, Germany, Siberia, and England, where it grows in dry and chalky soils.

11. Avena Sterilis; Great Wild Oat, or Barded Oatgrass. Panieled; calices five-flowered; the outer flowcules and awns hairy at the base, the inner ones awnless; root annual; culms three or four feet high, round, upright, smooth; flowers pendulous; anthree oblong, pale yellow, scarcely emerging from the corolla; germen oblong, round, hirsute.— Native of Barbary and Spain.

12. Avena Flavescens, Yellow Oat-grass. Paniceloose; calices three dowered, short, all the florets awned; it has a perennial creeping root.—This grass is found in most pastures, especially high ones, in soome neadows, and frequently on banks by road-sides. In many of our counties it forms the principal part of the finest pasturage on the lawus; and in some meadows contributes to the goodness as well as greatness of the crop.

13. Avena Hispida. Panicled; calices three-flowered, 2 R

AVE

hairy; culms a foot high, upright, smooth. A native of the | Cape of Good Hope.

14. Avena Capensis. Panicle contracted : calices threeflowered, subulate; corolla pubescent; middle awn twisted, curved ; root creeping .- Native of the Cape of Good Hope.

15. Avena Purpurea. Panicle contracted; calices twoflowered, ovate; corollas villose; outer glume bifid; awn terminal, beut in.-Native of Martinico.

16. Avena Lutea. Panicle spreading : calices two-flowered, subulate ; corollas naked, three-awned, middle awn flexuose .- Native of Martinico.

17. Avena Lupulina. Panicle contracted, ovate; calices three-flowered, lanceolate; corollas villose; outer glume bisubulate; middle awn reflex .- Native of the Cape of Good Hope.

18. Avena Fragilis; Brittle Oat-grass. Spiked; calices four-flowered, longer than the floret; root annual .- Native of Spain and Portugal.

19. Avena Pratensis; Meadow Oat-grass. Subspiked; calices five-flowered : florets smooth : leaves channelled. smooth ; root perennial .- Native of Europe and Siberia, on dry pastures and heaths, flowering in July.

20. Avena Spicata. Spiked ; calices six-flowered, longer than the outer petal, which is awned and forked at top; flowers six, sessife, upright.-Native of Pennsylvania.

21. Avena Bromoides. Subspiked ; spicules binate, onepeduncled ; awns divaricate ; calices eight flowered ; height two feet; culm round, scarcely the thickness of a needle. Native of Switzerland, and the neighbourhood of Montpellier.

22. Avena Strigosa. Panicled; calices two-flowered; corolla smooth at the base; outer valve ending in two awns, shorter than the valve, and with a bent awn from the back ; root annual; culm and leaves bare; seeds hairy .- Native of Europe.

23. Avena Aurata; Golden Oat-grass. Calices twoflowered; panicle sparse, erect; corollas golden, villose at the base .- This is a handsome grass; culms nine inches high. Whilst the plant is young, the calix is greenish; the corolla shining pale yellow, but when arrived at maturity, the whole culm, calix and corolla, are of a resplendeut goldcolour. Native of the Alps of Switzerland aud Piedmont.

24. Avena Scheuchzeri. Locustas round, five-flowered, pubescent at the base ; peduncles branching ; culms from six to twelve inches in height .- Native of the Alps of Switzerland, Savoy, and Piedmont.

25. Avena Filiformis. Panicle erect, very slender; calices one-flowered ; awns twice the length of the calix .- Native of New Zealand, and Eastern Island.

Avenues ; in Gardening, are walks of trees leading to a house, and are generally terminated by some distant object. These were formerly much more in request than at present, there being few old seats in the country, but had one or more of these avenues; and some had as many of them as there were views from the house: but of late, these are with good reason disused; for nothing can be more absurd, than to have the sight contracted by two or more lines of trees, which shut out the adjacent grounds, whereby the verdure and natural beauties of the country are lost; and where the avenues are of a considerable length, even though their breadth be proportionable, they appear at each end to be only narrow cuts through a wood, which never can please any person of real taste; and when the road to the house is through the avenue, nothing can be more disagreeable ; for in approaching the house, it is like going through a narrow lane, where the objects on each side are shut out from the view; and when viewed from the house, it at best has only the appearance of a road, which being extended to a great length in a straight line,

turnings, so as seldom to be seen to a great extent ; but as these avenues must be made exactly straight, when the trees grow to any size, they entirely break the view, whatever way the sight is directed through them ; and if this is in a park, the lawn of grass through which the avenue is planted, is thereby entirely deprived of the beauty which it naturally would afford, if left open and well kept; therefore, whenever the situation of a house will admit of a large open lawn in front, the road to the house should be carried round at a proper distance ; and if it be carried sometimes through trees, and serpented in an easy natural way, it will be much more beautiful than any stiff formal avenue, how large soever made. But as there may be some persons so much wedded to the old way of laying out and planting grounds, as to prefer avenues to the most beautiful disposition of lawns, woods, &c. I shall mention the usual methods of designing and planting them, that have been esteemed the best .- The usual width allowed to these avenues was generally as much as the whole breadth of the house and wings; but if they are planted twelve or fourteen feet wider, they will be the better; because, when the trees are grown to any considerable size, they will spread and overhang so as to contract the view : and as for such avenues to woods or prospects, they ought not be less than sixty feet in breadth; and because such walks are a long time before they are shady, it will be convenient to plant another row on each side, rather than to lose the stateliness that the main walk will afford in time by being broad, where any thing of a prospect is to be gained. As to the distance, the trees should not be planted nearer one another than thirty-five or forty feet, especially if they are of a spreading kind ; and the same distance if they are for a regular grove. The trees proper for planting avenues, are English elm, the lime-tree, the horse chesnut, the common chesnut, the beech, and the abele. First, The English elm is approved for all places where it will succeed, (and that it will do in most places, except in very wet and cold shallow lands ;) because it will bear cutting, beading, lopping, in any manner whatsoever, and probably with better success than any other tree. Secondly, The lime-tree : this is approved by others, because it will do well in any tolerable soil, if the bottom be not bot and gravelly; and because of the regular shape it has in growing, the agreeableness of its shade, and the beautiful colour of its leaves. Thirdly, The horse-chesnut is also to be used in such places as are very well defended from strong winds ; because wherever it grows freely, if it be not skilfully managed now and then by cutting, the branches are subject to split down. This tree is valuable on account of its quick growth, the earliness of its coming out, the nobleness of its leaves, and the beauty of its flowers; being a fine plant both for shade and ornament. This delights in a strong hearty soil, but will do well in any tolerable ground, if good care be taken in the planting of it; but wherever these trees are planted in avenues, they should be placed thirty feet asunder, that their heads may have room to spread, otherwise they will not appear so beautiful. Fourthly, The common chesnut will do well in a proper soil, and will rise to a considerable height, if planted close together; but if it be planted singly, where the tree can take its own natural shape, it is rather inclined to spread and grow globous, than tall. Fifthly, The beech is recommended by some; but this seldom succeeds well after transplanting, without extraordinary care; though it arrives to a very large tree in many places in England, where it grows naturally, and is the most tedious and troublesome to raise to any tolerable size in a nursery way. Sixthly, The abele; this indeed grows more dispersed, and looser in its is not near so beautiful as a common road, where it is lost by the head than any of the former, and consequently is worse for

trees for avenues, because it is the quickest in growth of all the forest trees, and will thrive tolerably well in almost any soil, and particularly in wet ground, where few of the beforementioned trees will thrive, and this seldom fails in transplanting. Seventhly, The oak ; but this is seldom used in planting avenues, because it requires so long a time to raise it up to any tolerable stature in the nursery way; nor is it apt to thrive much after it has been transplanted, if it had arrived to any considerable size. As for the alder, ash, platanus, and sycamore, they are but rarely used for planting avenues.

Averrhoa; a genus of the class Decandria, order Pentagynia. -GENERIC CHARACTER. Calix : perianth five-leaved, erect, small; leaflets lanceolate, permanent. Corolla: petals five, lanceolate, the lower part erect, the upper spreading. Stamina : filamenta ten, setaceous, alternately the length of the corolla, and shorter. Antheræ roundish. Pistil: germen oblong, obscurely five-cornered. Styles five, setaceous, erect. Stigmas simple. Pericarp : pome turbinate, fivecornered, five-celled. Seeds: angular, separated by mem-ESSENTIAL CHARACTER. Calix: five-leaved; branes. petals five, expanding above; pome five-cornered, five-celled. -The species are,

1. Averrhoa Bilimbi. Trunk naked, fruit-bearing; pomes oblong, obtuse-angled .- This tree is only about eight feet in height, with few reclining branches. It is a native of Goa and many parts of India, both within and without the Ganges. Burman describes it as a beautiful tree, with green fleshy fruit, filled with a grateful acid juice; the substance and seeds not unlike those of cucumber : it grows from top to bottom at all the knots and branches. They make a syrup of the juice, and a conserve of the flowers, which are esteemed excellent in fevers and bilious disorders. This and the following species are singular for the fruit growing upon the trunk itself, below the leaves. The flower resembles that of geranium, but the fruit is widely different. The flowers are red purple, on oblong small racemes, adhering to the trunk. The fruit is a pome, five-celled, and containing many seeds.

2. Averrhoa Carambola. Axillas of the leaves fruit-bear-ing; pomes oblong, acute-angled.—This is a tree above the middle size, with spreading branches, and a very close head; pome the size of a hen's egg, acutely five-cornered, five-celled, many-seeded; the rind is yellow, thin, and smooth; the pulp clear, watery, in many sweet, in others acid, with scarcely any smell : seeds small, oblong, angular, flatted, and brown. Rheede relates, that the carambola is twelve or fourteen feet in height, scarcely a foot in girth, with a rough brown bark ; that it bears three times a year from the age of three to fifty; that the root-leaves and fruit are used medicinally, either alone or with areca or betel leaves; that the latter, when ripe, are esteemed delicious; unripe, are pickled; and that they are also used in dyeing, and for other economical purposes. Burman informs us, that the acid juice of this plant is not so pleasant as that of the first species ; that the fruit is rather larger, and is used for the same purposes; and that it is a very beautiful tree. See the first species.

Avicennia ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth fiveparted, permanent ; leaflets subovate, obtuse, concave, erect, increased by three scales. Corolla : monopetalous : tube bell-shaped, short ; border bilabiate ; upper lip square, emarginate, flat; lower trifid, divisions ovate, equal, flat. Stamina: filamenta four, subulate, erect, the two front ones rather shorter, bent back to the upper lip. Antheræ roundish, twin. Pistil: germen ovate; style subulate, erect, the

defence; but yet is not to be left out of the number of | sion bent down. Pericarp: capsule coriaceous, rhomboidal, compressed, one-celled, two-valved. Seed : one, large, the form of the capsule, constructed of four fleshy folds, germinating. ESSENTIAL CHARACTER. Calix: five-parted. Corolla : bilabiate, upper lip square. Capsule : coriaceous, rhomboidal, one-seeded .---- The species are,

> 1. Avicennia Tomentosa. Leaves cordate-ovate, tomentose underneath .- This tree agrees mostly with the mangrove, rising not above fifteen or sixteen feet high ; its trunk is not so large, having a smooth whitish green bark. Native of the East and West Indies. Dr. Patrick Browne, says, that it is frequent near the sea, both on the north and south side of Jamaica, growing in low moist ground.

> 2. Avicennia Nitida. Leaves lanceolate, shining on both sides; height forty feet .-- Native of Martinico.

> 3. Avicennia Resinifera. Leaves ovate-lanceolate, tomentose underneath .- The green-coloured gum, so much esteemed by the natives of New Zealand, and which is so very hot in the mouth, is supposed to be the produce of this tree. Native of New Zealand

Awl-wort. See Subularia.

Axyris; a genus of the class Monœcia, order Triandria. -GENERIC CHARACTER. Male flowers in an ament. Calix : perianth three-parted, spreading, obtuse. Corolla : none. Stamina : filamenta three, capillary, spreading. Antheræ roundish. Female flowers scattered. Calix : perianth five-leaved, concave, obtuse, converging, permanent, the two outer leaflets shorter. Corolla: none. Pistil: germen roundish. Styles two, capillary ; stigmas acuminate. Pericarp : none. Calix closely involving the seed with its three larger leaflets. Seed : one, ovate, compressed, obtuse. Es-SENTIAL CHARACTER. Male Calix: three-parted. Corolla: none. Female Calix: two-leaved. Corolla: none. Styles : two. Seed : one .---- The species are,

1. Axyris Amaranthoides; Simple-spiked Axyris. Leaves ovate; stem erect; spikes simple; leaves rugged, with stellate hairs .- Annual; a native of Siberia.

2. Axyris Hybrida. Leaves ovate; stem erect; spikes conglomerate .- An annual plant, and a native of Siberia.

3. Axyris Prostrata. Leaves obovate; stem subdivided; flowers capitated : stem much branched, six or seven inches high .--- An annual plant, a native of Siberia.

Ayenia; a genus of the class Gynandria, order Pentandria .- GENERIC CHARACTER. Calix: perianth one-leafed, five parted ; parts ovate oblong, acute, coloured in the middle, reflex, withering. Corolla pentapetalous; petals five, united at the top to the nectary into a flat star ; claws capillary, very long, bowed outward ; borders obcordate, resupinate, with a clubbed point at the top, turned upward. Nectary bell-shaped, sitting on a cylindric erect column shorter than the calix ; border five-lobed, lobes elevated, above flattish, with a longitudiual furrow, excavated underneath, and sharp. Stamina: filamenta five, very short, inserted into the margin of the nectary, on the top of the ribs, between the divisions of the border, each bent downwards archwise, through a notch at the end of each petal. Antheræ roundish, under the borders of the petals. Pistil, germen roundish, five-cornered, at the bottom of the nectary; style cylindric; stigma obtuse, five-lobed, ten-valved, elastic. Seeds : solitary, rather oblong, gibbous on one side, angular on the other. ESSENTIAL CHARACTER, Monogynous, Calix: five-leaved, Petals : united into a star, with long claws. Antheræ: five under the star. Capsule : five-celled .- These plants are propagated by seeds, sown upon a moderate hot-bed early in the spring ; when they come up, and have four leaves, they length of the stamina; stigma bifid, acute; the lower divi- should be transplanted on a fresh hot-bed, to bring them forward; part of them may be planted in small pois, and the others on the bed; those in the pots should be plunged into a hot-bed of tanner's bark; they must be shaded until they have taken new root, and then they must have free air admitted to them every day, in proportion to the warmth of the season; they require to be frequently watered in warm weather, but they should not have it in too great plenty. The plants should continue all the summer in the hot-bed, where they must have a good share of air; for those which are fally exposed to the open air will not thrive, and if they be too much drawn, they do not flower well. The plants will live through the winter in a moderate stove; but as they perfect their seeds well the first year, few persons care to continue the old plants.—The species are,

 Ayenia Pusilla; Smooth Ayenia. Leaves cordate, smooth, many of the flowers being abortive.—Linneus suggests, that they may possibly be of different sexes. The flowers continue to succeed upon the same plant from July till winter. Native of Peru.

2. Ayenia Tomentosa. Leaves ovate-roundish, tomentose; leaflets of the calix lanceolate, acute, permanent; antheræ three,---Native of South America.

3. Ayenia Magna. Leaves cordate, pubescent; germen of the flowers sessile.—An upright shrub, five feet high. Native of Carthagena, and other places of South America.

 Ayenia Lævigata. Leaves ovate, entire, smooth ; germen pedicelled ; nectary ten-cleft, radiated.—Native of Jamaica.

Azdaz; a genus of the class Pentandria, order Monogynia. —GENERIC CHARACTER. Caliz: perianth five-parted, acute, erect, small, coloured, permanent. Corolla: monopetalous, bell-shaped, semiquinquedid, the sides of the divisions bent in. Stamina: filamenta five, filiform, inserted into the receptacle, free. Anthera simple. Piotif: german roundish. Style filiform, the length of the corolla, permanent. Stigma obtuse: Pericarp: capalle roundish, five-celled, five-valved. Scel: many, roundish. ESENTIAL CHA-RACTER. Corolla: bell-shaped. Stamina: inserted into the receptacle. Capaule: five-celled. — The species are,

1. Azalea Pontica; *Pontic Azalea*. Leaves shining, lanceolate, smooth on both sides; racemes terminal.—Native of Pontus, never hitherto cultivated in Europe.

 Azalea Indica; Indian Azalea. Flowers subsolitary; calices hairy.—Native of the East Indies, never cultivated in Europe.

3. Azalea Nudiflora ; Naked-flowered Azalea. Leaves tive of the woods of Cochin-china.

ovate; corolla hairy; stamina very long. Grows naturally in shade, and upon moist ground, in most parts of North America, from whence many of the plants have been sent, of late years, to England, and several of them have produced their beautiful flowers in the gardens of the curious. They must have a moist soil and a shady situation, otherwise they will not thrive. They can only be propagated by shoots from their roots, and laving down their branches, for they do not produce seeds here; and if good seeds could be obtained, they would be difficult to raise, and a long time before they would flower ; but when they are in a proper situation, their roots extend, and put out shoots which may be taken off and transplanted. When any of them are laid down, it should be only the young shoots of the same year, for the old branches will not put out roots. The best time for this, is at Michaelmas, and if they are covered with some old tan to keep out the frost, it will be of great use to them. The autumn is also the best time to remove the plants, but the ground about their roots should be covered in winter to keep out the frost ; and if this be every year practised to the old plants, it will preserve them in vigour, and cause them to flower well.

4. Azalea Viscosi; Viscid Zzalea. Leaves scabrons at the edge; corollas with glutinous hairs.—This is a low shrub, rising with several slender stems, nearly four feet high. The Bowers have much the appearance of honeysuckle, and are as agreeably scented. They appear in the middle of July, but are not succeeded by seeds in England. It is a native of woods and moist places in North America. For its propagation and culture, see the third species.

5. Azalea Lapponica; Lapland Azalea. Leaves with excavated dots sprinkled over them.—This is a divaricated shrub, six or seven inches high. It is, like the sixth species, a low plant of little beauty; and growing naturally on boggy ground upon the mountains, is difficult to keep in gardens.

6. Avalea Procumbent : Procumbent Avalea. Branches diffusely procumbent ; calis purple, a little shorter than the corolla, five-cleft almost to the base ; corolla bright, rose-cloar, or pale scarlet.—Native of the mountains of Europe, and also found in the highlands of Scotland. For its culture and propagation, see the fifth species.

7. Azaléa Punctata; Dotted Azalea. Leaves rugged about the edge; flowers dotted, heaped.—This shrub is five feet high, upright, and branched; corolla white; calix whitish, dotted with red, as are also the corolla, anthere, and germen. Native of the woods of Cochin-china.

BAC

BACCHARIS; a genus of the class Syngenesia, order common, cylindric, inbricate; scales linear, acute. Corolla: componed, equal; corollules hermaphrodite and female mixed; proper to the hermaphrodite nunef-form, five-cleft; to the females scarcely apparent, almost none. Stamina: filamenta five, capillary, very small. Anthere eyindric, tubular. Pietili: germen ovate. Style filform, the length of the flower; signa bifid. Pericarp: none. Calix: unchanged. Seeds solitary, very short, oblog; down simple. Receptacle: naked. ESSENTAL CHARCTER. Calix: inbricate, cylindric. Florets: female, mixed with hermaphrodites. Down: simple. Receptacle: naked. Most of the plants of this genus are shrubby: the flowers are disposed commonly in corymbs.—The species are,

BAC

1. Baccharis Iverfolia; Peruvian Plonghumat's Spikenard. Leaves lanceolate, longitudinally tooth-serrate.—This plant grows to the height of five or six feet. It is a native of America, flowering in July and Angust. This is a manageable shrub: it may be propagated by cuttings planted in a shady border, during any of the summer months, or by seeds sown on a common border in the spring. These seeds ripen well in this country, and if permitted to scatter on the ground, the plants will lowen up in the following spring. It is pretty hardy, and will live abroad in mild winters, if planted in a warm situation; but it is usually kep in the green-house, and placed abroad in summer; it requires much water in warm weather.

2. Baccharis Neriifolia; Oleander-leaved Ploughman's Spikenard. Leaves lanceolate, serrate, in the upper part
with one or two toothlets .-- This is difficult to propagate, for the cuttings with great difficulty take root; and it is very rare to find the shoots near the roots to lay down, so that in Holland they lay down the entire head of young plants, slitting the smaller branches in the same manner as is practised for carnations, laving them into the ground and forking them down to prevent their rising ; these, when duly watered, put out roots in one year, when they may be taken off, and planted in small pots filled with light earth, and placed in the shade till they have taken new root ; after which they may be placed in a sheltered situation in summer, but in winter must be kept within the protection of the green-house.

3. Baccharis Arborea. Leaves elliptic, lanceolate, quite entire, naked, petioled; height three feet; trunk the thickness of the human arm; the largest of the genus; seeds streaked .- Observed by Koenig in woods on the island of Joanna.

4. Baccharis Halimifolia; Sea Purslane-leaved Ploughman's Spikenard, or Groundsel Tree. Leaves obovate, emarginate crenate in the upper part .--- This is a herbaceous kind of shrub, six, seven, or eight feet high : it flowers in October, and is a native of Virginia, and other parts of North America. This sort may be propagated by cuttings, which should be planted in April or May, upon a shady border, and duly watered in dry weather, until they have taken root; and at Michaelmas, they will be fit to transplant where they are to remain ; this will live in the open air, and is never injured by the cold of our ordinary winters, but severe frost will sometimes destroy it. It was cultivated in 1688 by Bishop Compton.

5. Baccharis Dioscorides. Leaves broad, lanceolate, toothed, sessile, stipuled; stems shrubby, six feet high, weak, a little hairy, much branching, luxuriant.

6. Baccharis Indica. Leaves obovate, toothletted, petioled ; branches with raised streaks .- Native of Ceylon, and the Cape of Good Hope.

7. Baccharis Brasiliana. Leaves ohovate, entire, scabrous, sessife, veined underneath; stem somewhat angular; down ferruginous .--- Native of Brazil.

8. Baccharis Feetida .--- Leaves lanceolate, serrate-toothed; corymbs leafy .-- This rises with a woody stem six or seven feet high. It is a native of Carolina, and some other parts of North America. It may be propagated by cuttings, planted towards the end of May; if shaded and duly watered, they will put out roots in two months, when they should be potted, that they may be sheltered under a frame in winter.

9. Baccharis Chinensis. Leaves lanceolate, quite entire, tomentose beneath, petioled ; peduncles many-flowered, axillary .- An undershrub, three feet high, upright, simple, round ; flowers yellow, oblong. Native of China.

Bacopa ; a genus of the class Pentandria, order Monogy-Bia .- GENERIC CHARACTER. Calix: perianth one-leafed, five-parted, two of the parts oblong, concave, acute, the two inferior deflex, ovate, acute; the single superior one broader. roundish, undulated. Corolla: one-petalled; tube short, towards the orifice a little enlarged ; border five-parted, parts ovate oblong, obtuse, equal, spreading. Stamina : filamenta five, inserted into the tube of the corolla. Antheræ sagittate. Pistil: germen ovate, compressed, below incrusted by the calix growing to it. Style short; stigma headed. Pericarp : capsule one celled. Seeds : very many, extremely small. ESSENTIAL CHARACTER. Corolla: with a short tube, spreading at top. Stamina : inserted into the tube of the corolla. Stigma : headed. Capsule : one-celled .-The only species known, is,

14.

dric, succulent, knotty stems; leaves opposite, stem-clasping, or rather connate, thick, oblong, concave, sharp, smooth; flowers solitary, peduncled, alternate from the axils; below the calix there is a pair of fleshy bractes on the long peduncle; corolla blue .- It puts forth roots from the knots, both as it runs along the ground, and as it lays on the surface of the water. Native of the island of Cavenne, on the borders of rivulets, flowering and fruiting in December. The French inhabitants call it herbe-aux-brulures, on account of its cficacy in curing burns.

Bactris ; a genus of the class Moncecia, order Hexandria, -GENERIC CHARACTER. Male Flower. Calix : spathe universal, one-leafed ; spadix branched. Periauth one-leafed, three-parted, small; parts lanceolate, concave, coloured. Corolla: one-petalled, three-cleft; tube short, clefts ovate, acute, erect. Stamina : filamenta six, subulate, erect, of the length of the corolla, inserted into the middle of the tube, Antheræ oblong, incumbent. Female flowers few, in the same spadix, intermixed with the male ones. Calix : spathe the same as in the males. Perianth one-leafed, bell-shaped, three-toothed, sharp-pointed, coloured, very small, permanent, Corolla : one-petalled, erect, three-toothed, permanent. Pistil: germen ovate, large; stylc very short; stigma headed, obscurely three-cleft, Pericarp : drupe coriaceous, roundish, fibrous, succulent, sharp-pointed with the style. Seed : nut roundish, depressed on each side, marked on the sides with three holes; kernel solid. ESSENTIAL CHARACTER. Male, Calix three-parted. Corolla: one-petalled, three-Stamina: six. Female Calix: one-leafed, threecleft. toothed. Corolla: one-petalled, three-toothed. Stigma: obscurely three-cleft. Drupe: coriaceous.----The species are.

1. Bactris Minor. Fruit roundish ; root creeping ; flowers without scent, very slightly tinged with yellow .-- Fruit dark purple, the size of a common cherry, containing an acid juice, of which the Americans make a sort of wine. They are also eaten raw, but are not pleasant. Canes are made of the stem. which are dark coloured, shining, jointed, and very light. Native of Carthagena in South America.

2. Bactris Major. Fruit ovate .- This commonly grows to the height of twenty-five feet, and the trunk to two inches or more in diameter. Fruit the form and size of an egg, acuminate, with the style fibrous, succulent, covered with a dark, purple, coriaceous coat, of which the natives make a vinous liquor. The nut is large, of a dark colour, ovateoblong, with an acuminate trifid apex, and three obscure holes, two above the middle, and the third higher ; kernel oblong, blunt at both ends, cartilaginous, solid. Native of Carthagena in South America.

Bæckia ; a genus of the class Octandria, order Monogynia .-- GENERIC CHARACTER. Calix: perianth one-leafed, funnel-form, five-toothed, permanent. Corolla : petals five, roundish, patulous, inserted into the calix. Stamina : filamenta eight, of which six arc equal, two solitary, very short, bent in. Antheræ subovate, small. Pistil: germen roundish. Style filiform, shorter than the corolla. Stigma capitate. Pericarn ; cansule globular, crowned, four-celled, four-valved. Seeds some, roundish, angular on one side. ESSENTIAL CHARACTER. Calix : funnel-form, five-toothed. Corolla: five-petalled. Capsule : globular, four-celled, -The only species belonging to this genus, hithercrowned .--to discovered, is,

1. Bæckia Putescens .- This is a shrub which has the babit of southernwood, with wand-like branches, and opposite short simple twigs; leaves opposite, linear, sharp, smooth, 1. Bacopa Aquatica. This plant puts forth several cylin- quite entire ; flowers axillary, solitary, on a naked peduncle, 2 S

BAL the length of the flower, much shorter than the leaves. Native of China, and called there tiongina.

Baobotrys; a genus of the class Pentandria, order Monogynia .-- GENERIC CHARACTER. Calix: perianth double, exterior three-leaved ; leaflets roundish, concave, smaller. Inferior one-leafed, bell-shaped, short, inferior, growing to the germen, five-cleft; clefts ovate, permanent, converging after flowering and crowning the fruit. Corolla: one-petalled. tubular; tube very short; border five-cleft, erect; clefts rounded, very short. Stamina : filamenta five, very short, in the middle of the tube. Antheræ heart-shaped. Pistil: germen globose, half superior. Style cylindric, very short, permanent ; stigma obtuse, tuberculated. Pericarp : berry globose, somewhat dry, one-celled, growing to the calix. Seeds : several, angular, affixed to a columnar receptacle in the bottom of the berry. ESSENTIAL CHARACTER. Corolla: tubular, with a five cleft border. Calix: double, onter two-leaved; inner one-leafed, bell-shaped; berry globose, one-celled, growing to the calix, many-seeded .----- The obly species hitherto discovered is.

1. Bæobotrys Nemoralis .- Native of the isle of Tanna, in the South Seas.

Ballota ; a genus of the class Didynamia, order Gymnospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, tubular, salver-shaped, five-cornered, oblong, tenstreaked, erect, permanent, equal; month acute, patulous, plaited, five-toothed; involucre of linear folioles under the whorls. Corolla: monopetalous, ringent; tube evlindric, the length of the calix; upper liperect, ovate, entire, crenate, concave; lower trifid, obtuse; the middle segment larger, emarginate. Stamina : filamenta four, the two shorter subulate, bending towards the upper lip, and shorter than it. Antheræ oblong, lateral. Pistil: germen quadrifid; style filiform, in the same situation and form with the stamina. Stigma slender, bifid. Pericarp: none. Calix : unchauged, fostering the seeds in its bosom. Seeds: four, ovate. Es-SENTIAL CHARACTER. Colix: salver-shaped, five-toothed, ten-streaked. Corolla: upper lip crenate, concave .--- The European sorts being common stinking weeds, are never introduced into gardens .---- The species are,

1. Ballota Nigra; Stinking or Black Horehound, Leaves cordate, undivided, serrate ; calices acuminate ; corolla purple, twice the length of the calix; filamenta brown. It is a perennial plant, common in most parts of Europe, in waste places and hedges, flowering in July. It is recommended in hysterical cases. In Gothland, it is an universal remedy in disorders incident to cattle ; but the Swedish plant is not supposed to be the same with ours. This, says Meyrick, is one of those neglected English plants, which are possessed of great virtues, though they are but little known, and still less regarded. An infusion of the green leaves, or a conserve made of the fresh-gathcred tops, is one of the best remedies for hypochondriacal and hysteric complaints. It likewise promotes the menses, and is good in low-spiritedness, and all the numerous train of nervous disorders. The flowers are sometimes found white.

2. Ballota Alba; White-flowered Black Horehound. Leaves cordate, undivided, servate ; calices subtruncate .- This has a pale stem and white corollas, with rounded cordate veined leaves. It is a native of Sweden.

3. Ballota Lanata; Woolly Black Horehound. Leaves palmate toothed; stem woolly; stems covered with a white wood; corollas extremely hirsute, pale yellow, white on the outside .- It is a hardy plant, a native of Siberia, towards China.

4. Ballota Suaveolens; Sweet-smelling Black Horehound. Leaves cordate; spikes leafy; calices truncate; awns linear;

root annual; stem upright, shrubby at bottom, branched, hirsute ; branches almost upright, villose. Browne says, that it commonly rises to the height of three or four fect : and that it is a very grateful cephalic and alexipharmic. It is a very odorous plant, and the people of St. Domingo use it in their warm baths. A native of the West Indies : it requires the protection of a stove.

5. Ballota Disticha; Betony-leared Black Horehound. Whorls halved, two-parted, half-spiked ; stem pubescent .--Native of the East Indies, and must be placed in a stove in England.

6. Ballota Pilosa. Leaves ovate, crenate, tomentose; whorls hairy; calices ten-toothed; stem perennial, four feet high .- Native of Cochin-china, and will not live without a stove in this country.

Baltimora ; a genus of the class Syngenesia, order Polygamia .- GENERIC CHARACTER. Calix: common, cvlindric ; leaflets seven, lanceolate, erect, the interior ones shorter. Corolla : compound, radiate ; corollules hermaphrodite, of the disk many; females of the ray five; proper of the hermaphrodites funnel-form, with a five-cleft tomentose border; of the females ligulate, ovate, trifid; the middle ones less, Stamina : in the hermaphrodite. Filamenta five ; anthera cylindric. Pistil: in the hermaphrodite. Germen obscure; style short; stigma none. In the females, germen oblong, crowned with a toothed deciduous calicle; style filiform, very short; stigmas two, filiform, longer than the corollule. Pericary: none; calix unchanged. Seeds: in the hermaphrodite, none ; in the females three-sided, naked, gibbous at the top. Receptacle : chaffy. ESSENTIAL CHARACTER. Calix : cylindric, many-leaved ; ray of the corolla five-Down : none. Receptacle : chaffy,---- One speflowered. cies only is yet known,

1. Baltimora Recta. An annual plant, with a stem two feet high, four-cornered, upright, green, with the sides deeply channelled, and the angles rugged .- Native of Maryland, near Baltimore ; it flowers in June and July.

Bambusa; a genus of the class Hexandria, order Monogynia .-- GENERIC CHARACTER. Calix: none, except glume-like bractes scattered, often three under each spikelet, oblong ovate, sharp-pointed, concave, keeled, unequal, shorter than the floscules; two opposite, the third leaning on the flat side of the spikelet; spikelets lauceolate, distichous, compressed, sharp, nearly five-flowered. Corolla: glume twovalved ; valve inferior, oblong, ventricose, acuminate, towards the tip keeled and streaked; interior lanceolate, flat, ciliate, a little longer than the inferior, and projecting from it. Nectary two leaved, flat at the interior side of the germen; leaflets ovate, acuminate, bearded at the tip, membranaceous. Stamina: filamenta six, capillary, almost the length of the corolla. Antheræ parallelopiped, two-cleft at the base, Pistil: germen oblong; style capillary, two-cleft; stigmas feathery. Pericarp: none. Seed: single, oblong .-- For the rest, see Arundo Bambos, and Nastus.

Banara; a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, six-parted, permanent, parts ovate. Corolla: petals six, rounding concave, spreading, three times larger than the calix, inserted into the receptacle. Stamina : filamenta fifteen and more, capillary, length of the corolla, inserted into a glandule surrounding the germen. Antheræ roundish. Pistil: germen somewhat globose, seated in a glandule; style filiform, of the height of the stamina; stigma headed. Pericarp : berry globose, but little succulent, one-celled, crowned by the permanent style. Seeds : very many, very small, cornered, striated. ESSENTIAL CHARACTER. CaBAN

lix: six-parted, permanent. *Corolla:* six petalled. *Germen:* seated on a glandule; stigma headed; berry globose, one-celled, many-seeded.——The following species only has been hitherto found,

 Banaria Guianensis.—This is a tree of ten feet or more in height, and about seven inches in diameter, with a grayish bark, and a whitish light wood. The corolla is yellow, and the berry black. Native of the island of Cayenne, flowering in May, and bearing finit in July.

Baneberry. See Actan.

Banisteria ; a genus of the class Decandria, order Trigynia .- GENERIC CHARACTER. Calix: perianth five-parted, very small, stiff, underneath with tubercles, permanent, Two melliferous glands are under each division of the calix, except one; they are therefore eight in number. Corolla, petals five, orbieulate, very large, spreading, crenate ; claws oblong, linear. Stamina : filamenta ten, very small, coalescent at bottom. Antheræ simple. Pistil : germen three, winged, coalescent ; styles three, simple; stigmas obtuse. Pericarp: capsules three, running out into a long wing, one celled, marked at the sides with small appendicles, not gaping. Seeds : solitary, covered, toothed on the lateral edge. Es-SENTIAL CHARACTER. Calix : five-parted, with melliferous pores at the base on the outside. Petals: roundish, with claws ; stigmas leaf shaped. Seeds : three, winged with membranes .- These plants, being all natives of hot countries, cannot be preserved in England, unless they are kept in a bark-stove. They are propagated by seeds, which must be procured from the countries where they grow naturally. These seeds should be fully ripe when gathered, and put into sand or earth, in which they should be sent to England, otherwise they will lose their vegetative quality; for from a large parcel of these seeds, which were sent over in papers, as fresh as they could possibly arrive here, very few plants were raised, and those did not appear till the second year ; therefore, when the seeds arrive, they should be immediately sown in pots, and if it happen in autumn or winter, the pots should be plunged into a hot-bed of tanner's bark, where the heat is very moderate, and secured from frost and wet till spring, when they must be removed to a fresh hot-bed, which will bring up the plants; but if they should not appear the first year, the pots should be preserved till the next spring, to see if the seeds will grow. When the plants come up, they must be put into separate pots, filled with light earth, and plunged into the bark-bed, after which they must be treated like other tender plants from the same countries. ---- The species are,

1. Banisteria Angulosa. Leaves sinuate, angular; corolla sulphur-coloured.—Native of the island of Dominique, where Plumier first discovered it, and also of Hispaniola.

2. Banisteria Purpurea. Leaves ovate ; spikes lateral ; seeds erect, Mative of the Caribbee Islands.

3. Banisteria Laurifolia. Leaves ovate, oblong, rigid, racemes terminal.—Native of Jamaica and Hispaniola.

4. Banisteria Longifolia. Leaves oblong, acuminate, rigid, shining; panicle terminating; branches spreading very much. Native of the West Indies.

5. Banisteria Benghalensis. Leaves ovate-oblong, acuminate; racemes lateral; seeds spreading; corollas blue,—Native of the East and West Indies.

6. Banisteria Dichotoma. Leaves ovate; branches dichotomous; corolla of a golden scarlet colour, spreading.—First observed in the island of Martinico.

7. Banisteria Fulgens. Leaves subovate, tomentose underneath; racemes brachiate; peduncles umbelled.—Native of Jamaica and Barbadoes.

8. Banisteria Brachiata. Leaves subovate; branches brachiate; seeds narrower within.—The flowers are produced in loose spikes at the ends of the branches; are first of a gold colour, and fade to a scarlet; these are succeeded by slender thin seeds, and for the most part single.—Native of Carthagena.

9. Emisteria Aculeata. Leaves pinnate; leaflets oblong, obtuse; flowers spiked; stem branching, prickly.—The flowers grow in long loose spikes at the end of the branches, are succeeded by single seeds, and are as large as those of the greater maple. Native of Tolu.

 Banisteria Cœrulea. Branches tubercled; leaves ovate, acute, coriaceous; racemes axillary; corolla blueish. —Native of Jamaica and Dominica.

11. Banisteria Nitida. Leaves ovate oblong, quite entire, shining beneath, panicle terminating, leafy.-Native of Brazil.

 Banisteria Chrysophylla. Branches tubereled; leaves ovate, acute, with a golden nap on the lower surface; wings very long.—Found near Rio Janeiro in Brazil.

13. Banisteria Muricata. Leaves ovate, acute, tomentose beneath; racemes axillary; capsules muricate. – Native of Peru.

14. Banisteria Leona. Branches tubercled; leaves ovate acuminate, coriaceous; flowers panicled.—Native of America, and found also at Sierra Leone.

16. Banisteria Emarginata. Leaves ovate, subcordate, emarginate, cuspidate at the end, tomentose on the lower surface; flowers raceme corymbed; flowers terminating; corolla yellow.—Native of America.

 Banisteria Quapara. Leaves ovate, tomentose beneath; flowers in corymbs; seeds erect; corolla yellow, with unēqual petals; seeds lens-shaped.—Native of Guiana, on the borders of meadows, flowering in August.

18. Banisteria Sinemariensis. Leaves ovate, acuminate ; fowers in corymbs, yellow, wings gradually widening—This is a shrub with a trunk five feel high; the fifth petal is larger than the rest, and fringed. Native of Guiana, on trees, by the sides of meadows and fields, flowering and fruiting in August.

19. Banisteria Orbiculata. Stem twining; leaves orbiculate beneath, tomentose, and silky; petioles biglandular; germina united; styles three; stigmas leafy, short.—Native of Janaica, Guadaloupe, and St. Domingo.

20. Banisteria Ciliata. Leaves cordate, roundish, eared, smooth, ciliate.-Native of Brazil.

21. Banisteria Anriculata. Stem twining : leaves subsagittate, smooth, with rounded lobes ; flowers in umbels ; stem slender.—Native of Rio Janeiro.

22. Banisteria Ovata. Stem twining; leaves ovate, acute, quite entire; flowers in umbels, involucres stipuled; corolla red, sulphur coloured.-Native of the island of Dominique.

23. Banisteria Palmata. Stem twining; leaves palmate, tomentose beneath; petioles biglandular; leaves divided into five acute parts, the middle one longest.—Native of St. Domingo.

24. Banisteria Sagittata. Stem twining ; leaves sagittate, large, tomentose ; petioles biglandular.—The leaves have one tooth on each side towards the tip.—Native of St. Doningo.

Banksia: a genus of the class Tetrandria, order Monogynia: named after Sir Joseph Banks, P. R. S. who first discovered it.—GENERIC CHARACTER. *Calis:* periath oneleafed, four-tleft, inferior. *Corola:* one-petalled; tube cylindric, very short; border very long, four-partled; parts linear, acute. Stamina: filamenta none. Antheræ four, lanceo- claws; partition contrary. Seeds: two, compressed, roundlate, sessile in the cavity of the parts of the corolla. Pistil: ish. ESSENTIAL CHARACTER. Calix: four-parted. Stagermen superior, minute ; style filiform, stiff, longer than the corolla; stigma pyramidate, acute. Pericarp: capsule ovate or globose, woody, one-celled, two-valved. Seeds : two. obovate, convex on one side, flat on the other, terminated by a very large membranaceous veinless wing. ESSENTIAL CHARACTER. Calix : four-cleft, inferior. Corolla: fourparted ; tube very short ; border very long, linear-lanceolate. Antheræ sessile in the cavity of the parts of the corolia. Capsule : two-seeded, one-celled, two-valved .- Some of the species of this genus have flowered and seeded in England. They have not yet been increased any other way but by seeds. These, and the plants in general from the South Seas, are hardy, considering their climate, and may be treated much in the same manner with the Cape plants. They covet abundance of air, and flourish best near the front of the dry-stove. -The species are,

1. Banksia Serrata; Serrate-leaved Banksia. Leaves linear, attenuated into the petiole, equally servate, truncate at the end with a point .- This is the most handsome species of the genus. The leaves are at the ends of the branches, confluent, scattered, seven or eight inches long, narrow, smooth, coriaceous, flat, spreading much, surrounding the ament, which is very large, thick, columnar, obtuse, erect; flowers much spreading, ascending, the borders pubescent on the outside, and hoary. Native of New South Wales.

2. Banksia Integrifolia ; Entire-leaved Banksia, Leaves wedge-form, quite entire, white, tomeutose underneath .-- Native of the South Sea islands.

3. Banksia Ericæfolia ; Heath-leaved Banksia. Leaves approximating, acerose, truncate, emarginate, smooth .--- The leaves of this are very small. Native of New South Wales.

4. Banksia Dentata; Tooth-leaved Banksia. Leaves oblong, attenuated into the petiole, curved, flexuose, toothed, teeth ending in a spinule, white underneath .- The flowers in this species are smaller than in the others. Native of New South Wales.

5. Banksia Pyriformis; Pear-fruited Banksia. Flowers solitary; capsules ovate, pubescent; leaves lanceolate, very entire, smooth .- Native of New South Wales.

6. Banksia Gibbosa : Gibbons-fruited Banksia. Flowers solitary ; capsules ovate, gibbons, wrinkled; leaves columnar. -Native of New South Wales.

7. Banksia Musculiformis; Muscle-fruited Banksia. Flowers solitary ; capsules ovate, conical, muscle-shaped, pointed with tubercles on the outside ; leaves obovate, emarginate .--Native of Amboyna.

8. Banksia Spinulosa; Prickly-leaved Banksia. Leaves linear, revolute, with a little sharp point, and with spinous denticulations towards the top .- Native of New South Wales.

Barbadoes Bastard Cedar. See Cedrela.

Barbadoes Cherry. See Malpighia.

Barbadoes Gooseberry. See Cactus Pereskia. Barbadoes Wild Olive. See Bontia.

Rark beds. See Hot-beds.

Bark, Jesuit's. See Cinchona.

Barleria ; a genus of the class Didynamia, order Angiospermia,-GENERIC CHARACTER. Calix : perianth fourparted, permanent; two opposite leafiets larger. Corolla: monopetalous, funnel-form, quinquefid, subequal; the fifth division deeper. Stamina: filamenta four, filiform, two very short, capillary. Antheræ the upper oblong, the lower withered. Pistal : germen ovate ; style filiform, the length of the stamina; stigma bifid. Pericarp : capsule acute, flat, qua | Native of South America. See the fifth species.

lanceolate at the tip, internally hollowed by a little cavity, drangular, two-celled, two-valved, gaping elastically at the mina: two, far less than the others. Capsule, quadrangular, bilocular, bivalvular, elastic without the claws. Seeds : two, -Barlerias being all natives either of the East Indies or South America, require the protection of the bark-stove,----The species are.

1. Barleria Longifolia. Spines of the whorls six-fold; leaves ensiform, very long, scabrous; flowers in whorls, axillary .- Native of the East Indies.

2. Barleria Solanifolia. Spines axillary; leaves lanceolate, toothletted ; flowers blue, and have more of the form of the labiate flowers, than any of the other species .- Native of Panama. The roots of this species will continue three or four years, but after the second year the plants grow too rambling, and the lower parts of the branches being naked. are not so sightly as the young plants ; therefore a succession of these should be raised, and the old ones turned out. They are propagated by seeds, which will sow themselves in the pots which are near them in the stove, when the plants are once obtained; but where the seeds are received from abroad, they must be sown upon a hot-bed in the spring : and when the plants are fit to remove, they must be each planted in a separate pot, and plunged into a hot-bed of tanner's bark, where they must constantly remain, and be managed in the same manner as other tender exotics from the same countries, giving them water frequently in summer, and letting the fresh air to them every day in warm weather. but in winter they should have less water, and be kept warm. They flower from June to November, and their seeds ripen soon after.

3. Barleria Hystrix. Spines axillary, twin, simple: leaves quite entire, lanceolate, ovate.-The stem is wand-like, not firm. Native of the East Indies.

4. Barleria Prionitis. Spines axillary, pedate, four-fold ; leaves quite entire, lanceolate, ovate; stem herbaceous, round, stiff .- Native of the East Indies. It has flexible perennial stalks, which, if cut off during the summer, and made into lengths of six or eight inches, and planted in pots, plunging them into a hot-bed, and duly watered and shaded from the sun, will soon put out roots; so may be planted each in a small pot, and plunged into the tan-bed in the stove; for although this sort may be kept in a dry stove through the winter, yet the plants will not grow near so fast, nor will their leaves be so large, as those which are plunged into the bark. By this means the plants may be propagated in plenty; but as they rarely produce flowers in England, so two or three plants will be sufficient to maintain the species.

5. Barleria Buxifolia. Spines axillary, opposite solitary; leaves roundish, quite entire .- This will produce seed in England, provided the plants are kept in the tan-bed in the stove, and may therefore be propagated by seeds, which should be sown in the hot-bed, and the plants afterwards treated in the same manuer as those of the fourth species.

6. Barleria Noctiflora. Spines axillary, branching ; leaves lanceolate, quite entire, cuspidated ; bractes ovate, scariose; tuhe elongated; flowers blue, and expanding during the night .- Observed near Tanjour in the East Indies.

7. Baleria Cristata. Leaves oblong, quite entire, two leaflets of the calix broader ciliated, and two linear acute :> stem round; corolla blue, erect, spreading.

8. Barleria Coccinea. Unarmed ; leaves ovate, tootletted, petioled ; stem smooth, four feet high ; flowers scarlet, in. whorls at the joints, appearing from July till September .--

9. Barleria Pungens. Unarmed; leaves ovate, acute, pungent ; bractes ciliated .- Found at the Cape of Good Hope. 10. Barleria Longiflora. Unarmed ; leaves ovate, silky ;

bractes cordate, scariose; corollas very long .- Observed on the mountains of St. Thomas in Malabar.

11. Barleria Procumbens. Unarmed; leaves lanceolate, erenate, hispid; heads terminating; flowers yellow -- Native of China, near Canton.

Barley. See Hordeum.

Barnadesia ; a genus of the class Syngenesia, order Polygamia Æqualis. - GENERIC CHARACTER. Calix: common, somewhat ventricose, spreading at the tip, imbricate ; scales imbricate, gradually longer from base to tip : the inferior or exterior ovate, closely imbricate, sharp, pungent; the superior or interior subulate, flat, spreading, pungent. Corolla : compound, rayed. Corollets hermaphrodite, tubular, very few, remote in the disk ; ligulate in a simple series in the ray. Proper to the inferior, funnel-form ; tube very short, border hairy, five-parted, parts erect, converging; proper to the latter ligulate, lanceolate, spreading at the base, incurved at the tip, and split, outwardly very hairy ; tube longer than the calix. Stamina : filamenta five. Antheræ cylindric, tubular. Pistil: germen ovate; style filiform, longer than the stamina; stigma bifid; clefts spreading, ovate rounded. Pericarp none; calix converging. Seeds : very many, ovate, hairy ; hairs reversed. Down of the flowers of the disk bristly ; rays subulate, stiff, broken backwards, naked, or covered with extremely minute hairs. Of the radial flowers long, erect, spreading, many-rayed, feathery, soft. Receptacle: flat, villose, without chaff. ESSENTIAL CHA-RACTER. Calix naked, imbricate, pungent. Corolla: radiate. Down of the ray feathered, of the disk bristly, broken backwards .----- Of this genus the following species only has yet been discovered,

1. Barnadesia Spinosa. This is a shrub with very smooth branches, set with a pair of thorns at their origin, which at first were stipules; they are patulous, brown, and smooth; leaves alternate, simple, ovate, quite entire, sharp, flat, veined, somewhat hairy on both sides, whitish underneath; petioles very short ; stipules in pairs, small, subulate ; flowers panicled, terminating ; calix pubescent .-- The flower is singular, in having two sorts of down. Native of South America. Barrenwort. See Epimedium.

Barreria ; a genus of the class Syngenesia, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, five-toothed, small. Corolla: one-petalled, five-parted; parts oblong, acute, convex beneath, concave above, with a double pit; the superior ovate, bifid, the wedge-shaped one trifid, excavated for the reception of the stamina. Stamina: filamenta five, ascending, linear, wider above, thick, triangular, bordered, curved. Antheræ erect, four-cornered, marginated, coalescing into the form of a mill-wheel; each, in the closed flower, answering, together with the filamenta, to the pits of two of the petals. Pistil: germen roundish; style short; stigma trifid. Pericarp and Seeds: not ascertained. Es-SENTIAL CHARACTER. Calix five-toothed, very small. Corolla: five-parted. Style: short. Stigma: trifid .----The only species known is, 1. Barreria Guianensis.—This tree rises forty or fifty feet

in height, and is two feet and a half in diameter ; the bark is ash-coloured, and the wood is reddish brown, hard, and compact : the flowers, which appear in November, are in small axillary spikes, alternate, and almost sessile. Native of Guiana, in the extensive forests near the banks of the river Sinemari, fifty leagues from its mouth.

Barringtonia ; a genus of the class Monadelphia, order moreland. 14.

Polyandria .-- GENERIC CHARACTER. Calix : perianth two leaved, superior ; kafets roundish, concave, coriaceous, permanent. Corolla: petals four, equal, ovate, spreading, coriaceous, larger than the calix. Nectary couic, tubular, coating the base of the style, toothed at the tip; teeth several, unequal. Stamina : filamenta very many, monadelphous (or conjoined from the very base into a cylinder seated on the receptacle) capillary longer than the corolla. Autherae roundish. Pistil : germen inferior, turbinate ; style filiform, length of the stamina; stigma simple. Pericarp: drupe large, ovate, conic, quadrangular, crowned by the calix. Seed: nut long, ovate, outwardly wrinkled, fibrose, four-celled. Kernels ovate, wrinkled. ESSENTIAL CHARAC-TER. Calix : simple, two-leaved, superior, permanent : fruit a dry four-cornered drupe, inclosing a nut, one to four-celled. -The only species known is,

1. Barringtonia Speciosa; Laurel-leaved Barringtonia. -This is a lofty tree, and the handsomest in the whole equinoctial flora, with its thick shady bunches of leaves, and its large handsome purple and white flowers, every where mixed with them. The flowers open at night, and fall at sun-rise: the birds also pluck them off, and the ground about these trees is perfectly covered with them. The seed mixed with bait, inebriates fish in the same manner as the cocculus-indicus, &c. It grows within the tropics, especially on the shores of the ocean, and at the mouths of rivers in the East Indies, from the southern coasts of China, through the Molucca isles to Otaheite, and the other Society Isles, the Friendly Isles, &c. It is cultivated in the governor's garden at the island of St. Helena.

Bartsia ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, tubular, permanent; mouth obtuse, two lobed; lobes emarginate, coloured at the top. Corolla: monopetalous, fingent; upper lip erect, slender, entire, lougest; lower re-flex, trifid, obtuse, very small. Stamina: filamenta four, bristle-shaped, the length of the upper-lip, two somewhat shorter. Antheræ oblong, approximating under the top of the upper lip. Pistil: germen ovate, style filiform, longer than the stamina ; stigma obtuse, nodding. Pericarp : capsule ovate, compressed, acuminate, two-celled, two-valved ; partition contrary to the valves. Seeds : numerous, angular, small. ESSENTIAL CHARACTER. Calix : two-lobed, emarginate, coloured. Corolla: coloured, less than the calix; upper lip longest. Capsule: two-celled.

1. Bartsia Coccinea : Red Bartsia. Leaves alternate. linear, two-toothed on each side .- This most beautiful plant has a stem entirely simple; it has been found in Maryland, Virginia, and New York.

2. Bartsia Pallida; Pale-flowered Bartsia. Leaves alternate, lanceolate, quite entire; floral leaves ovate, toothed; root fibrose; corolla purple,-Native of Siberia and Hudson's Bay.

3. Bartsia Viscosa ; Viscid Bartsia, or Yellow Marsh Eyebright. Upper leaves alternate, serrate ; flowers distant, lateral ; stem a foot high, upright, cylindric, simple, hirsute ; corolla yellow. The whole plant is clammy. It is an annual, native of France, Italy, and Britain ; in the marshes of Cornwall, Devonshire, Lancashire, and Staffordshire; and of Argyleshire in Scotland; flowering in July and August.

4. Bartsia Alpina; Alpine Bartsia. Leaves opposite, cordate, obtusely serrate; stem simple, six or seven inches high, hard, villose, obtusely quadrangular; corollas reddish, blueish, or purple .- Native of the mountains of Lapland, Switzerland, Savoy, Monte Baldo, and near Orton in West-

2 T

9. Bartsia Gymnaudria.—Two-stamined; leaves radical, two-fold, petioled; stem mostly two-leaved, one-spiked; spike linear, obtuse; whorls bracted, collected; stem three or four inches high, round, upright, smooth, entirely simple; corolla pale blne.—It grows within the arctic circle, on the north side of the frozen rocks in Kamtschatka, where there is no other vegetation.

Basella; a genus of the class Pentandria, order Trigynia. -GENERIC CHARACTER. Calix: none. Corolla: sevencleft, pitcher-shaped, the two outer divisions broader, one within the rest, converging above, fleshy at the base. Stamina : filamenta five, subulate, equal, fastened to the corolla, and shorter than it. Antheræ roundish. Pistil: germen superior, subglobular; styles three, filiform, the length of the stamina; stigmas oblong, on one side the tops of the styles. Pericarp: corolla permanent, closed, fleshy, counterfeiting a berry. Seed : single, roundish. ESSENTIAL CHA-RACTER. Calix: none. Corolla: seven-cleft; two opposite divisions shorter, at length berried. Seed : one. These plants are propagated by seeds, which should be sown on a hot-bed in the spring; and when they are fit to remove, they should be each planted in a separate pot filled with rich earth, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotics. They may also be propagated by cuttings, which should be laid to dry a day or two after they are taken from the plants, before they are planted, that the wound may heal; otherwise they will rot. These cuttings must be planted in pots filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, where they will take root in a fortnight or three weeks' time, when they should be treated in the same manner as the seedling plants ; but as these rise so easily from seeds, it is seldom they are propagated any other way, be-cause they are plants of short duration. They climb to a considerable height, and send forth a great number of branches, so that they should have a place near the back of the stove, where they may be trained up to a trellis, or fastened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them, and be very injurious to the other plants; whereas, when they are regularly trained to a trellis, they will have a good effect in adding to the variety. They flower from June till antumn, and the seeds ripen in September and December.---The species are.

1. Basella Rubra; Red Malubar Nightshade. Leaves flat; peduncles simple.—The flowers of this plant have no great beauty, but the plant is preserved for the odd appearace of the stalks and leaves. It is a native of the East Indies, Amboyna, Japan, &c. A beautiful colour is drawn from the berries, but when used for painting, does not continue very long, but changes to a pale colour; thought this beautiful colour might be fixed, so as to become very useful, for the juice of these berries has been used for staining calicoses in India.

2. Basella Alba; White Malabar Nightshade. Leaves oblong, and flaccid; the stalks, flowers, and fruit, are smaller than those of the first species. Native of China and Amboyna.

3. Basella Lucida; Shining Malabar Nightshade. Leaves subcordate; peduncles crowded, branching.—Native of the East Indies.

4. Basella Nigra. Black Malabar Nightshade, Leaves round, ovate; spikes lateral; stem perenail, twining, slender, round, succulent, branched; Bowers purple and white, lateral, few, in simple, long, solitary spikes.—This is a native both of China and Cochin, in the bedges and fences of their gardens. Basil. See Clinopodium.

Basnia; a genus of the class Dodecandria, order Monognia.--GEN REIC CHARACTER. Cali: periault fourleaved; leafiels coriaceous, ovate, permanent. Corolla: mopetalous, bell-shaped; tube inflated; ovate, fleshy; border shorter than the tube, eight-parted; divisions ovate, almost upright. Stamina: filamenta sixteen, eight below the jaws, and eight in the middle of the tube. Anthera linear, sagitate, acute, vilose on the inside, shorter than the corolla. Pistli: germen superior, ovate; style subulate, twice as long as the corolla; tugina acute. Pericary: druge fleshy, milky. Scads: nuts five, oblong, three-conreed. ESSNTIAL CHA-RACTER. Calis: four-leaved. Corolla: eight-cleft; tube inflated. Stamina: sixteen. Druge: five-seeded.----The species are,

1. Bassia Longifolia. Leaves ovate, lanceolate; peduncles axillary. This is a lofty tree, with the outmost branches recurved, thickish, and covered with a gray down. Native of Malabar and Ceylon.

2. Bassia Dubia. Seed large, half-moon shaped, flatted like alens, smooth, shining, of a dark chesnut colour, except an oblong, rugged, unbilical area, which is pale, and almost white.—The shell is thick, stony, and very hard. Native country not ascertained.

3. Bassia Obovata. Leaves obovate; peduncles heaped, terminating.-Native of the isle of Tanna in the South Seas.

Basoria ; a genus of the class Pentandria, order Monogyma-GENERER. Calar: perianth one-leafed, permanent, five-parted, parts ovate, acute. Corolla: onepetalled ; tube very short; border five-cleft, spreading; clefts ovate, acute, larger than the calix. Stamina : filamenta five, inserted into the tube of the corolla, and opposite to is clefts. Anthera ovate. Pitfil: germe ovate, sitting on a glandule; style short; stigma thickish, obtuse. Pericapy: berry ovate, knobbed. Steeds: very many, kidney-shaped, girt with a membrane nestling in a pulp. ESSENTAL CHA-RACTER. Corolls: five-cleft, spreading, with a very short tube. Berry : orate, knobbed, with many seeds.——The only species known, belonging to this genus, is,

1. Bassovia Sylvatica. Stems herbaccous, three or four feet high, branched ; leaves alternate, ovate, acute, smooth, quite entire, on a petiole about an inch in length; the largest are ten inches long, and four and a half broad; flowers in axillary corymbs, green, and very small.—Native of Guiana, in wet forests, flowering and fruiting in June.

Butatas. See Convolvulus. Batis; a genus of the class Diœcia, order Tetrandria.-GENERIC CHARACTER. Male, Calix : ament pyramidal ; scales one-flowered, four-fold, imbricate. Corolla : none. Stamina : filamenta four, erect, longer than the scales of the ament. Antheræ oblong, twin, incumbent. Female, on a separate plant. Calix: ament common, fleshy, containing some floscules congloberated into an ovate quadrangular body; involucre two-leaved. Corolla: none. Pistil: germen quadrangular, fastened to the ament ; style none ; stigma two-lobed, obtuse, villose. Pericarp : berry conjoined with the rest, one-celled. Seeds : four, triangular, acuminate. ESSENTIAL CHARACTER, Male: ament four-fold, imbricate. Calix and Corolla : none. Female ament ovate ; involucre two-leaved. Calix and Corolla : none ; stigma twolobed, sessile; berries conjoined, four-seeded.----The only known species is,

 Bais Maritima.—This is a shrub about four feet ligh; fruits yellow, or greenish yellow. The whole plant is very salt to the taste; and it is burnt for barilla at Carthagena. Naive of the Caribbee islands, and the neighbouring continent. It is very common in all the salt-marshes on the south side of Jamaica.

Baukinia ; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oblong. gaping longitudinally on the lower side, reclining on the other, gaping also five ways at the base, with five cohering leaflets above, deciduous. Corolla : petals five, oblong, waved, with attenuated reflected tops expanding ; the lower ones a little larger, the upper one more distant, all with claws placed on the calix. Stamina : filamenta ten, declining, shorter than the corolla, the tenth much the longest. Antheræ ovate, always on the tenth, seldom on the rest. Pistil: germen oblong, sitting on a pedicle. Style filiform, declining; stigma obtuse, rising. Pericarp : legume long, subcolumnar, one-celled. Seeds : many, roundish, compressed, placed according to the length of the legume, ESSENTIAL CHARACTER. Calix: five-cleft, deciduous. Petals: expanding, oblong, with claws, the upper one more distant, all inserted into the calix .- These plants being all natives of hot countries, will not thrive in England unless they are kept in the bark-stove. They are propagated by seed, which must be procured from the countries where they grow naturally, for they do not perfect their seeds in England, ---- The species are,

 Bauhinia Scandens; Climbing Mountain Ebony. Stem cirrhiferous.—It is a native of both Indies, but has not produced flowers in England. The flowers are at first whitish, but turn to a yellowish colour.

2. Bauhinia Aculeata; Prickly-talked Mountain Ebony, Stem prickly-nelt rises to the height of sixteen or eighteen feet in Jamaica, where, as well as in the other sugar islands, it grows plentifully. The stalks are terminated by several long spikes of yellow flowers, which are succeeded by bordered pods, about three inches long, containing two or three swelling seeds; these pods are glutinous, and have a strong balsamie scent, as have also the leaves when bruised, whence from its strong odour, which somewhat resembles the common savin-tree, the Americans call it the Indian savin-tree.

3. Bauhinia Divaricata; Dwarf Mountain Ebony. Leaves smooth, lobes divaricated, acute, two-nerved; petals lanceolate.—This a low shrub; seldonı rising more than five or six feet high, dividing into several branches. Flowers in a simple upright racenee. Corolla white. The flowers have a

very agreeable scent, appear most part of the summer, and are one of the greatest beauties of the hot house. The pods are taper, about four inches long, and contain four or five dark-coloured seeds. It flowers from June till September, and grows naturally in great plenty on the north side of the island of Jamaica. This sort has several times produced pods in the Chelsea garden, but they have never come to maturity. The seeds should be brought over in their pods; which will preserve t'em good. These must be sown in pots filled with light fresh earth, and plunged into a moderate hotbed of tanner's-bark; if the seeds be good, the plants will come up in about six weeks, and in a month after will be fit to transplant, when they should be carefully shaken out of the seed-pot, so as not to tear off the roots, and each planted into a separate small pot filled with light loamy carth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root, after which they should have fresh air admitted to them every day in warm weather. In the autumn they must be placed in the bark-stove, and treated in the same way as other tender exotics, giving them but little water in winter. As these plants frequently flower, they deserve a place in the stove.

4. Banhinia Ungulata. Leaves ovate ; lobes parallel. Native of America.

5. Bauhinia Variegata ; Variegated Mountain Ebory, Calices one-leaded, bursting: petals assistie ovate ; lobes of the leaves ovate obtuse. The flowers are large, and grow in losoe panicles at the extremity of the branches, of a purplish red colour, marked with white, and the bottom yellow.—It grows naturally in both indies.

6. Bauhinia Purpurea; Purple Mountain Ebony. Leaves subcordate, two-parted, rounded, tomentose underneath. The corolla is of a very ref purple.—Native of the East Indies, where it flowers the whole year. 7. Bauhinia Tomentose; Downy Mountain Ebony.

7. Bauhinia Tomentosa; Downy Mountain Ebony. Leaves cordate; lobes semiorbiculate, tomentose. Flower scentiless.—Native of the East Indies.

8. Bauhinia Acuminata; Sharp-leaved Mountain Ebony. Leaves ovate; lobes acuminate, semiovate; stamina white.— Native of the East Indies.

 Bauhinia Emarginata. Stem prickly; leaves cordate with round lobes, tomentose underneath.—The flowers grow at the extremity of the brauches, and are large, and of a dirty white colour. Native of New Spain.

white colour. Native of New Spain.
10. Bauhinia Rotundata. Stem prickly; leaves subcordate, two-parted, rounded; flowers scattered, --Native of Carthagena in New Spain.

11. Banhinia Aurita; Long-cared Mountain Ebony. Leaves subtransverse at the base; lobes lanceolate, porrected, three-nerved; petals lanceolate.—Native place unkuown. It flowers in September.

12. Bauhina Porrecta; Smooth Broad-leaved Mountain Ebong. Leaves conduct; lobes porrected, acute, threenerved; petals lanceolate.—This tree rises to about fifteen feet in height. The wood is very hard, and veined with black, whence its name of Ebony. It grows on the hills in all parts of Jamaica, and Mowers in July.

13. Bauhinia Candida; White-leaved Mountain Ebony. Leaves cordate, pubescent underneath; lobes ovate, obtuse; calices atteonated upwards, and elongated.—It flowers in May and June, and it is a native of the East Indies.

Begonia ; a genus of the class Monœcia, order Polyandria. -GENERIC CHARACTER. Male Flowers. Calix: none. Corolla: petals four (in Begonia Octopetala six to nine) of which two opposite ones are larger, commonly roundish (in Begonia Ferruginea all nearly equal, oblong.) Stamina : filamenta numerous (fifteen to one hundred) inserted into the receptacle, very short, sometimes united at the base. Antheræ oblong, erect. Female flowers, usually on the same common peduncles with the males. Calix : none. Corolla : petals in most species five, in some six ; in others perhaps four, commonly unequal. Pistil: germen inferior; three-sided, in very many winged; styles in most three, bifid; stigmas six. Pericarp ; capsule in most three-cornered, winged, threecelled, opening at the base by the wings; some are two-celled, and others perhaps one-celled. ESSENTIAL CHARAC-TER. Male Calix : none. Corolla : many-petalled. Stamina: numerous. Female Calix: none. Corolla: many petal-led, superior. Capsule winged, many-seeded. The plants of this genus increase readily by cuttings; and if kept in the bark stove prove highly ornamental, being much esteemed both for the beanty of the flowers and the singularity of the leaves. Where there is no bark-stove, they will be found to do very well over the flue of the dry stove .---- The species are.

1. Begonia Nitida. Shrubby, erect; leaves very smooth, unequally cordate, obscurely toothed, largest wing of the capsule roundish ; corolla flesh or rose coloured .- It is an elegant shrub, flowering here from May till December. Native of Jamaica.

2. Begonia Isoptera. Caulescent; leaves smooth, semicordate, obscurely toothed ; wings of the capsule almost equal, parallel ; seeds numerous, small .- Native of Java.

3. Begonia Reniformis. Caulescent ; leaves kidney-shaped, angular-toothed; the largest wing of the capsule acuteangled, the others parallel, very small .- Native of Brazil in the dry clefts of the rocks.

4. Begonia Erminia. Caulescent : leaves cordate, acuminate, serrate; the largest wing of the capsule sickle-shaped, the rest obliterated .- Native of Madagascar, on stones and rocks by brooks.

5. Begonia Crenata. Caulescent; leaves unequally cordate, roundish, obtuse, crenate toothed ; capsules two-celled ; flowers pale red .- Native of the island of Salsette in the East

6. Begonia Tenuifolia. Caulescent; leaves unequally cordate, ovate, acute, angular, obscurely toothed; capsules twocelled .- Native of Prince's Island, near Java

7. Begonia Ferruginea. Caulescent; leaves unequally cordate, toothed; petals of the male flower, oblong, nearly equal; flowers blood-red, nodding. Found in New Granada.

8. Begonia Grandis. Caulescent ; leaves unequally cormale corolla purple .--- Native of Japan.

9. Begonia Macrophylla. This is two feet high, and a native of the islands in the West Indies.

10. Begonia Acutifolia. Caulescent: leaves semicordate, angular-toothed ; the largest wing of the capsule obtuseangled, the others acute-angled .- Native of Jamaica.

11. Begonia Acuminata. Caulescent; leaves hisped, semicordate, acuminate, unequally toothed; the largest wing of the capsule obtuse-angled, the others acute-angled.-Found in the Blue Mountains in Jamaica.

12. Begonia Humilis. Caulescent, upright, leaves hisped. semicordate, doubly serrate; wings of the capsule rounded, a little unequal .- Native of the island of Trinidad

13. Begonia Hirsuta. Caulescent; leaves hispid, semicordate, doubly serrate; the largest wing of the capsule obtuseangled, the others parallel and very small; corolla white .-Observed on the rocks of Guiana, in South America.

14. Begonia Urtico. Caulescent, radicant; leaves hispid on both sides, unequally ovate, doubly serrate ; capsules three, horned at the base; flowers usually in pairs, a male with a female, males blood-red; no stamina; no rudiment of a pistil .- Found by Mutis in New Granada.

15. Begonia Scandens. Scandent, radicant ; leaves ovate, roundish, obscurely toothed, the largest wing of the capsule obtusely angled, the others parallel and very small .- Native of Guiana, of Jamaica, and of the Isle of France.

16. Begonia Tuberosa. Creeping; leaves unequally cordate, angular toothed; wings of the capsule parallel .- Native of Amboyna, the Moluccas, and Celebes.

17. Begonia Rotundifolia. Creeping; leaves reniform, roundish, crenate ; stems thick, cylindric, naked, with small permanent stipules, between which they are marked with scars from the fallen leaves, slightly crenate, green, and shining above, white beneath, on pretty long petioles. From the end of each stem arises a peduncle, or rather scape, longer than the leaves, bearing an umbel-shaped panicle of red monœcous flowers at the top .- Native of South America, on rocks and trees.

18. Begonia Nana. Stemless: leaves lanceolate; scape with about two flowers .- Native of Madagascar, on rocks and trunks of trees.

19. Begonia Tenera. Steinless, leaves unequally cordate, flowers umbelled .- Native of Ceylon.

20. Bigonia Diptera. Stemless; leaves unequally cordate; peduncles dichotomous; one wing of the capsule very large, another narrow, and the third obscure .-- Native of the island of Joanna, in shady places by the sides of mountains.

21. Begonia Octopetala. Stemless; leaves cordate, fivelobéd ; peduncles dichotomous ; root tuberous, viscid, purple within .- Found on the mountains of Luna.

22. Begonia Malabarica. Stems lierbaceons; peduncles axillary, short, subtriflorons ; fruits berried. Native of Malabar.

23. Begonia Repens. Stews creeping, rooting at the joints; leaves one-eared; peduncles axillary, long, many-flowered. Native of St. Domingo.

Bejaria ; a genus of the class Dodecandria, order Monogynia .-- GENERIC CHARACTER. Calix : perianth one-leafed, gibbous downwards, subventricose, seven-cleft; divisions subequal, ovate, acute, converging, small; the outer ones broader, permanent. Corolla : petals seven, oblong, broader above, obtuse, patulous, inserted into the receptacle. Stamina: filamenta fourteen, subulate, rather shorter than the corolla, alternately less. Antheræoblong, incumbent. Pistil: berry juiceless, seven-cornered, depressed, umbilicate, date, angular, serrate; wings of the capsule a little unequal; seven-celled. Seeds: numerous, columnar, oblong, imbricate. ESSENTIAL CHARACTER. Calix: seven-cleft. Petals: seven. Stamina : fourteen ; berry seven-celled, many-seeded. -The species are,

1. Bejaria Æstuans. Leaves lanceolate; flowers in racemes .- This is a shrub twelve feet in height, with roundish spreading branches; corolla flesh-colour. Native of Mexico and New Granada.

2. Bejaria Resinosa. Leaves ovate ; flowers heaped ; eorolla purple, very resinous or viseid .-- Found in New Granada

Belladonna. See Amaryllis and Atropa.

Bell-flower. See Campanula and Canarina.

Bellis ; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Common hemispherie, upright; leaflets ten to twenty, in a double row, lanceolate, equal. Corolla: compound, radiate; eorollules hermaphrodite, tubular, numerous in the disk ; female ligulate, more in number than the leaves of the calix in the ray. Proper of the hermaphrodite funnel-form, five-eleft; of the female ligulate, lanceolate, scarcely three-toothed. Stamina: of the hermaphrodite ; filamenta five, capillary, very short. Antheræ eylindric, tubular. Pistil: germen ovate, of the hermaphrodite; style simple; stigma emarginate; of the female, style filiform ; stigmas two, patulous. Pericarp : none. Calix: unchanged. Seeds: solitary, obovate, compressed; down none. Receptacle: naked, conical. ESSENTIAL CHARACTER. Calix: hemispherie, with equal scales. Seeds : ovate, with no down. Receptacle : naked, conical. -The species are,

1. Bellis Perennis; Perennial or Common Daisy. Scape naked .- It is a native of most parts of Europe, in pastures; flowers almost all the year, and shuts up very close every night, and in wet weather. The taste of the leaves is somewhat acrid, notwithstanding which, it is used in some countries as a potherb. The roots have a penetrating pungency. It is ungrateful to eattle, and even to geese : although it occupies a large share of pasture lands, to the exclusion of grass aud profitable herbs. It has been much recommended as excellent for fresh wounds externally, and against inflammatory disorders, &c. internally, but it is now wholly out of use. Meyrick, however, recommends a strong decoction of the roots, as an excellent medicine in scorbutic complaints: but says, the use of it must be continued for a considerable length of time before its effects will appear. Some persons give the roots, boiled in milk, to keep puppies from growing; but they have no such effect. The varieties of this speeies are : the double white, red, white and red striped, variegated, scallet, and pied; double-quilled, or with fistular florets; double eoek'scomb-shaped, white red, and speekled; proliferous, childing, or hen and chicken daisy. The common wild daisy being a troublesome weed in pasture lands, and the lawns and grass walks in gardens, is never cultivated. The garden daisies flower in April and May, when they make a pretty variety, being intermixed with plants of the same growth; they should be planted in a shady border, and a loamy soil, without dung, in which they may be preserved without varying, provided the roots are transplanted and parted every autumn; which is all the culture they require, except keeping them clear from weeds. These were formerly planted for edgings to borders, but they are very unfit for this purpose, because where they are fully exposed to the sun, they frequently die in large patches, whereby the edgings become bald in many places.

2. Bellis Annua; Annual Daisy. Stem somewhat leafy. inches high, with an upright stalk, hairy leaves on the lower part, but the upper part naked, and supporting a single cave, alternate, smaller, coloured, deciduous. Corolla: pe-

14.

flower like that of the common daisy, but smaller. Native of Sieily, Spain, about Montpellier, Verona, and Nice.

Bellium; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix : common, simple, with very many equal boat-shaped leaflets. Corolla: compound, radiated; in the ray female, ten or twelve; in the disk hermaphrodite, very many; proper of the hermaphrodite funnel-shaped, quadrifid, erect; of the females ellipticemarginate, ligulate. Stamina, in the hermaphrodite : filamenta four, short. Antheræ cylindrie. Pistil, in the hermaphrodite : germen turbinate ; style filiform ; stigma bifid, oblong: in the females, germen turbinate; style very short; stigma bifid, minute, Pericarp : none ; ealix unchanged, Seeds : turbinate; crown chaffy, eight-leaved, rounded; down with eight single awns. Receptacle : naked, eonic. ESSEN-TIAL CHARACTER. Calix: with equal leaflets. Seeds: conie with a chaffy eight-leaved crown, and awned down, Receptacle : naked .---- The species are,

1. Bellium Bellidioides. Seapes naked, filiform .- Native of Italy, about Rome, and in the island of Majorca. It has the habit of the daisy, but differs essentially from it in having a down to the seed ; ray white ; disk yellow.

2. Bellium Minutum. Stem leafy .- This is one of the minutest of plants; stem capillary, an inch in length; the whole plant smooth and ascending. Native of the Levant.

Bellonia : a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, superior, semiquinquefid, permanent; divisions laneeolate, acute. Corolla: monopetalous, wheel-shaped; tube very short ; border flat, semiquinquefid, obtuse, large. Stamina : filamenta five, subulate, erect, very short. Antheræ erect, converging, short. Pistil: germen inferior ; style subulate, straight, longer than the stamina ; stigma acute. Pericarp : capsule turbinate, ovate, wrapped up in the calix, and beaked with its eonverging divisions, one-celled. Seeds : numerous, roundish, small. ESSENTIAL CHARACTER. Corolla: wheel-shaped. Capsule : one-celled, inferior, many-seeded, beaked with the ealix .- The plants of this genus are propagated by seeds, which should be sown early in the spring, in a pot filled with light fresh earth, and plunged into a hotbed of tanner's bark, observing to water it frequently, as the earth appears dry; but you must be careful not to wash the seeds out of the ground. When the plants are come up half an inch high, they should be carefully transplanted into pots filled with light fresh earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root, after which time they should have air admitted to them every day, when the weather is warm; they must also be frequently watered : they must be constantly kept in the stove, and should have a large share of free air in warm weather ; but if they are set abroad, they will not thrive in this climate .--- The species are,

1. Bellonia Aspera. Leaves ovate, serrate; flowers co-rymbed, terminating.—This is a shrub ten or twelve feet iu height, said to be very common in the warm islands of Ameriea.

2. Bellonia Spinosa. Thorny; leaves ovate, angular, tooth-serrate ; peduneles axillary, one-flowered .-- Discovered by Swartz in Hispaniola.

Benjamin Tree. See Laurus. Bennet Herb. See Geum.

Bent Grass. See Agrostis.

Berberis ; a genus of the class Hexandria, order Mono--This is a low annual plant, seldom rising more than three gynia.-GENERIC CHARACTER. Calix: perianth sixleaved, patulous; leaflets ovate, with a narrower base, con-2 U

tals six, roundish, concave, erect, expanding, scarcely larger than the calix. Neetary two, small, roundish, coloured bodies, fastened to the base of each petal. Stamina: filamenta six, erect, compressed, obtuse. Anthere two, fastened on each side to the top of the filamenta. *Pistil*: germen eyindie, the length of the staminar; style none; sigma orbiculate, broader than the germen, surrounded with a sharp edge. *Pericarp*: berry cylindric, obtuse, unbilicated, with a point, one-celled. *Scads*: two, oblong, cylindric, obtuse. ESEN-TIAL CHARCTER. *Calix*: six-leaved. *Petals*: six, with two glands at the claws. *Style*: none; berry two-seeded. ——The species are.

1. Berberis Vulgaris; Common Berberry, Peduncles racemed; spines triple .- The common berberry is a shrub rising to the height of eight or ten feet; it is a native of the castern countries, and now of most parts of Europe, in woods, coppices, and hedges. It is found in a chalky soil in England, particularly about Saffron-walden in Essex. The flowers appcar in May, and the fruit ripens in September. The varie-ties of this species are not worth enumerating. The leaves of this shrub are gratefully acid: the smell of the flowers is offensive when near, but pleasant at a certain distance : the berries are so very acid that birds seldom touch them. The berberry, however, is cultivated for the sake of the fruit, which are pickled, and used for garnishing dishes, and being boiled with sugar, form a most agreeable rob or jelly; they are used likewise as a sweetmeat, and are put into sugarplums or comfits. The roots boiled in lye yield a yellow colour; and in Poland they dye leather of a fine yellow colour with the bark of the root. The inner bark of the stems will also dye linen of a fine yellow, with the assistance of alum. Cows, sheep, and goats, are said to eat it ; horses and swine to refuse it. The fruit of the berberry is considered as a mild restringent acid, agreeable to the stomach, and of efficacy, like other vegetable acids, in hot bilious disorders, and in a putrid disposition of the humours. According to Prosper Alpinus, the Egyptians employ a diluted juice of the berries in ardent and pestilential fevers. Their method is to macerate them in about twelve times their quantity of water, and let them stand for about twenty-four hours, and then to add a little fennel-seed. The liquor is then pressed out and strained, and sweetened with sugar, or syrup of citrons, roses, &c. and given plentifully as a drink. A concrete, similar to cream of tartar, may be obtained from the juice, by mixing it with lemon juice, in the proportion of two pounds of berberry juice, and two ounces of lemon juice, and digesting them in a sand-heat for two days, and then gently evaporating the filtered liquor to one-half, and setting it in a cellar for some days. The tartar incrustates the sides of the vessel, and is a grateful medicine in febrile disorders : in fact, it is the essential salt of the berberry. The berries of this shrub are also made into an agreeable jelly, by boiling them with an equal weight of fine sugar to a proper consistence, and then straining it. As the leaves are also acid, they have been sometimes employed for the same purposes as the fruit, and have been introduced as an ingredient in salads. The celebrated naturalist Mr. Ray. successfully employed the inner yellow bark, which is austere and bitterish, in the form of a decoction or other liquors, as a gentle pargative in the jaundice. It is also said to be a good lotion for the itch, and other cutaneous eruptions. Insects of various kinds are remarkably fond of the berberry flowers. Linneus observed long since, that when bees, in search of honey, touch the filamenta, they spring from the petal, and strike the antheræ against the stigma, and thereby explode the pollen. The purpose which this curious con-

| trivance of nature is intended to answer is evident : in the original position of the stamina, the antheræ are sheltered from rain by the concavity of the petals ; thus probably they remain, till some insect, coming to extract honey from the base of the flower, thrusts itself between the filamenta, and almost unavoidably touches them in the most irritable part; thus the impregnation of the germen is performed ; and as it is chiefly in fine sunny weather that insects are on the wing, the pollen is also in such weather most fit for the purpose of impregnation. It is generally propagated by suckers, which are put out in great plenty from the roots ; but these plants are very subject to send out suckers in greater plenty than those which are propagated by layers; therefore the latter method should be preferred. The best time for laying down the branches is in autumn, when their leaves begin to fall; the young shoots of the same year are the best for this purpose ; these will be well rooted by the next autumn, when they may be taken off, and planted where they are designed to remain. Where this plant is cultivated for its fruit, it should be planted single (not in hedges, as was the old practice) and the suckers every autumn taken away, and all the gross shoots pruned out; by this method the fruit will be much fairer and in greater plenty, than upon those which have been suffered to grow wild : a few of these shrubs may be allowed to have place in wildernesses, or plantations of shrubs, where they will make a pretty variety; but they should not be planted in great quantities near walks which are much frequented, because their flowers emit a very strong disagreeable odour.

2: Berberis Cretica; Cretan or Bas-leaved Berbergy, Peduncles submibleld; joines triple.—This never rises more than three or four feet high in England. It flowers in April and May, and is a native of Crete or Candia, and also of Japan. This sort may be propagated by laying down the branches in the same manner as the first species; but when the young plants are taken off, they should be planted in pots, and sheltered under a frame in winter, till they have obtained strength, when they may be turned out of the pots, and planted in a warn situation.

Bergera : a genus of the class Dodecandria, order Monogynia-GENBRIE CHARACTER. Calitz, perianth five-parted, very snall, acute, spreading, permanent. Corolla : pedias five, oblong, bluntish, spreading. Stamina: filamenta ten, five alternately shorter. Antherre round. Pisiti's germen roundish, superior; style filiform, club-shaped; stigma turbinate, shining, with transverse grooves. Pericarp: berry subglobular, one-celled. Seeds: two. ESSENTAL CHA-RACTER. Calit: five-parted. Pedias' ive. Berry : subglobular, one-celled, with two seeds.——The only species hitherto discovered is,

1. Bergera Kœnigu.-This is a very leafy tree, with the bark of Alder. Native of the East Indies.

Bergia; a genus of the class Decandria, order Pentagynia.— GRNERIC GRARACTER. Cali:: perianth fiveparted, spreading; leaflets lanceolate, permanent. Corolla: petals five, oblong, spreading, the length of the calix. Stamina: filamenta ten, bristle-shaped, of middling length. Anherer roundish. Pistl: genner roundish, superior; styles five, very short, approximating; stigmas simple, permanent, periang): capsule simple, subglobular, mucronate, with five little swellings, five-celled, five-valved; valves ovate, flat, opening along the furrows, permanent, spreading very widely. Seads: numerous, minute. ESSENTIALCHARACTER. Casteds: very nany.—The Repeties are, Seeds: very nany.—The species are, in whorls .- A native of Tranquebar in the East Indies. 2. Bergia Glomerata. Leaves obovate, crenulate; flowers glomerate .- Native of the Cape of Good Hope.

Bermudas Juniper. See Juniperus.

Berry-bearing Alder. See Rhamnus Frangula.

Bertiera ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth turbinate, five-toothed. Corolla : one-petalled ; tube short ; mouth villose; border five-cleft; clefts ovate, acute, spreading, Stamina: filamenta five, very short, inserted into the tube beneath the orifice. Antheræ linear, erect. Pistil: germen roundish, inferior, crowned by a gland ; style filiform ; stigma two-plated. Pericarp : berry globose, crowned by the teeth of the calix, two-celled. Seeds: very mauy, roundish, affixed to the dissepiment. ESSENTIAL CHARACTER. Calix: turbinate, five-toothed. Corolla: tube short, with a villose mouth; berry globose, inferior, two-celled, manyseeded .---- The only known species is,

1. Bertiera Guiauensis .- This is a shrub six or seven feet in height, the thickness of the human arm ; branches opposite, knotty, tomentose. Found in the wood of Aroura in Guiana, flowering and fruiting in the month of June.

Besleria ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth oneleafed, five-parted, acuminate, erect, loose, with reflected tops. Corolla: monopetalous, ringent; tube the length of the calix, roundish, gibbous on one side at the base, and at the top; border five-cleft; divisions roundish, the lowermost largest, the two upper less divided. Stamina : filamenta four, within the tube of the corolla, of which two are a little shorter. Antheræ oblong, twin, hanging down on each side. Pistil: germen globular, sitting on a glandular body, which embraces it and is permanent, cordate, where the corolla is gibbous ; style subulate, erect ; stigma bitid, obtuse, Pericarp: berry subglobular, one-celled ; partition two opposite semiovate laminas. Seeds numerous, round, very small, nestling, fixed to the inner surface of the berry. ESSENTIAL CHARACTER. Calix: five-parted, berry subglobular, manyseeded .- These plants grow naturally in the warm parts of America. The seeds should be sown on a hot-bed, early in the spring, and when the plants are come up half an inch high, they should be each transplanted into a small pot filled with light fresh earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root, after which time they should have air and water in proportion to the warmth of the season, and the heat of the bed in which they are placed .---- The species are,

1. Besleria Melittifolia. Peduncles branching; leaves ovate .--- Native of South America.

2. Besleria Lutea. Peduncles simple, crowded; leaves lanceolate.-Native of Martinico, Jamaica, &c. 3. Besleria Cristata. Peduncles simple, solitary ; calices

serrate, erected .--- Native of woods and moist mountains in Martinico.

4. Besleria Bivalvis. Calices bivalve, torn .- Observed at Surinam.

5. Besleria Biflora. Peduncles two-flowered ; involucre caducous, inflated ; leaves ovate, quite entire .- Native of the island of Otaheite.

6. Besleria Cymosa. Peduncles cymed; pedicles with little bractes ; leaves ovate, crenate .- Native of the island of Tanna.

Beta ; a genus of the class Pentandria, order Digynia .--GENERIC CHARACTER. Calix: perianth five-leaved, con-

1. Bergia Capensis. Leaves lanceolate, or elliptic; flowers | none. Stamina : filamenta five, subulate, opposite to the leaves of the calix, and of the same length with them. Antheræ roundish. Pistil: germen in a mauner below the receptacle ; styles two, very short, erect ; stigmas acute. Pericarp : capsule within the bottom of the calix, one-celled, deciduous. Seed : single, kidney-form, compressed, involved in the calix. ESSENTIAL CHARACTER. Calix: five-leaved. Corolla : none, Seed : kidney-form, within the substance of the base of the calix .---- The species are,

1. Beta Vulgaris; Red Garden Beet. Flowers heaped; leaflets of the calix toothed at the base,-There are four seminal varieties, for the best is very subject to change and to degenerate in our climate. It is a native of the sea-coast of the southern parts of Europe. The roots of red beet are boiled, sliced, and eaten cold by themselves, or in salads ; are used as garnish to dishes, and as a pickle. The greenleaved sort is most esteemed ; the roots being the largest and tenderest. Martial has justly marked the beet for its fatuity It is said to be prejudicial to the stomach, and to afford little nourishment: taken in quantity, it tends to loosen the belly. The juice both of the roots and leaves is said to be a powerful errhine, occasioning a copious discharge of mucus, without provoking sneezing. A good sugar may be obtained from the juice of the fresh roots. This species is frequently sown with carrots, parsneps, or onions, by the kitchen-gardeners near London, who draw up their carrots or onions when they are young, whereby the beets obtain room to grow, when the other crops are gathered ; but if the other crops are not removed in time, it will be better to sow them separately. This sort requires a deep light soil, for as their roots run deep in the ground, so in shallow ground they will be short and stringy. The seeds should be sown in March, but the plants should not be left nearer than a foot apart, or in good land a foot and a half, for the leaves will cover the ground at that distance. The roots will be fit for use in the autumn. and continue good all the winter; but in the spring, when they begin to shoot, they will be hard and stringy: a few roots may be left for seed, or some of the fairest roots transplanted to a sheltered spot of ground, where they may be defended from strong winds, which frequently break down their stalks, if they are not well supported, especially when the seeds are formed, which becoming heavy as they increase in bulk, are apt to weigh down the tender stalk upon which they grow. The seed will ripen in September, when the stalks should be cut off, and spread on mats to dry, and afterwards threshed out and cleared, and put up in bags for use.

2. Beta Cicla ; White Garden Beet. Flowers three-fold ; leaflets of the calix unarmed at the base .- The lower leaves of this sort are thick and succulent, and their footstalks are broad : for these it is cultivated ; the leaves being boiled as spinach, or put into soups, and the stalks and midrib of the leaf being eaten as asparagus : it affords both food and medicine. The juice of the fresh root is an excellent remedy for the head-ache, and that species of the tooth-ache in which the whole jaw and side of the face is affected. The method of using it, is to snuff it up the nose in order to provoke sneezing, and a discharge of humours from the head and parts adjacent. This sort is commonly sown by itself, and not mixed with other crops. It must be sown in the beginning of March, upon an open spot of ground, that is not very moist; the seeds should be sown thinly, because the plants require room to spread; for when they are too close, the leaves being small and full of fibres, will be unfit for the purposes designed. When the plants have put out four leaves. they should be hoed, as is practised for carrots, carefully cave, permanent ; divisions ovate, oblong, obtuse. Corolla ; cutting up all the weeds, and also the plants where they are

BET

too near each other, leaving them at least four inches asunder: if this be done in dry weather, all the present weeds will be destroyed; but as young weeds will soon appear, in three weeks or a month's time the ground should be a second time heed over, to cut up the weeds, and thin the plants to a greater distance; for by this time they will be past danger, and should not be left nearer than six inches.

3. Beta Maritima; Sca Beet. Flowers double, a twin; leaflets of the calix even, not toothed.—It is a native of Holland, and is found plentifully about Nottingham, and on the seacoast, and in the salt marshes of Great Britain.

4. Beta Patula; Spreading Beet. Flowers heaped; all the leaves linear lanceolate; branches divaricated. It flowers in August.—Native of the island of Madeira.

Betel, or Betle. See Piper.

Betonica ; a genus of the class Didynamia, order Gymnospermia .- GENERIC CHARACTER. Calix : perianth oneleafed, tubular, cylindric, five-toothed, awned, permanent. Corolla: monopetalous, ringent; tube bent in, cylindric; upper lip roundish, entire, flat, erect; lower trifid; middle division broader, roundish, emarginate. Stamina : filamenta four, subulate, the length of the throat; two shorter, inclined to the upper lip. Antheræ roundish. Pistil : germen fourparted ; style, form situation and size of the stamina ; stigma bifid. Pericarp : none. Calix : fostering the seeds in its bosom. Seeds : four, ovate. ESSENTIAL CHARACTER. Calix : awned. Corolla : upper lip ascending, flattish ; tube cylindric. All these plants flower in May and June, and ripen their seeds in August. They may be propagated by seeds, or by parting the roots. They require a shady situation and a moist stiff soil, in which they will thrive better than in rich ground. The best time to transplant and separate the roots, is in autumn; but the seeds should be sown in the spring, upon a shady border, and when the plants come up, they will require no other care but to keep them clean from weeds, and to thin them where they are too close.----The species are.

1. Betonica Officinalis; Wood Betony. Spike interrupted : helmet of the corolla entire ; middle division of the lower lip emarginate; calices smoothish. There are two varieties of this species .- Betony, says Linneus, was formerly much used in medicine, but it is discarded from modern practice. When fresh, it intoxicates; the leaves when dry excite sneezing : sheep eat it, but goats refuse it. The leaves and flowers, according to Lewis, have a herbaceous, roughish, and somewhat bitterish taste, with a weak aromatic flavour. An infusion or light decoction of them may be drank as tea; or a saturated tincture, in rectified spirits, may be given in laxity and debility of the viscera. The sneezing quality of the dried leaves seems to be merely owing to the rough hairs on them. The roots are bitter and very nauseous: in a small dose they vomit and purge violently. Meyrick informs us, that many people have been cured of inveterate head-aches, which resisted every other remedy, by daily breakfasting on a tea made of the leaves and tops of this herb; he says, the dried leaves are often smoked as tobacco, in disorders of the head and stomach, and that the young leaves, beaten into a conserve, are beneficial in the jaundice, falling-sickness, palsy, gout, and dropsy; as also in colds, coughs, wheezing, shortness of breath, and sharp defluxions on the lungs. A strong decoction of the plant kills worms, removes obstructions, takes away stitches and other pains in the back and sides, and eases the colic. Bruised, and applied to green wounds, it quickly heals them, and draws thorns, splinters, and other bodies, out of the flesh. The root, inwardly taken, excites vomiting .- It is a native of

woods, heaths, and pastures, among bushes; flowering from the beginning of July to September.

2. Betonica Orientalis; Oriental Betony. Spike entire, middle division of the lip of the corolla quite entire.—First discovered in the Levant.

 Betonica Alopecurus; Fox-tail Betony. Spike leafy at the base, helmet of the corolla bifid.—Native of the mountains of Savoy, Piedmont, Austria, Carniola, Silesia, and Provence.

4. Betonica Hirsuta: Hairy Betony. Spike leafy at the base, helmet of the corolla entire.-Native of the Alps, Appenines, and Pyrenees.

5. Betonica Heraclea. Spike with woolly calices; teeth filiform; leaves lanceolate, naked; stem and leaves almost smooth; corollas yellow.—Native of the Levant.

6. Betonica Stricta; Danish Betony. Spike oblong; helmet of the corolla entire, middle division of the lower lip notch-waved; calices hairy.-Native of Denmark.

7. Betonica Incana; *Hoary Betony*. Spike interrupted; helmet of the corolla bifid; middle division of the lower lip notched; tube tomentose, bent in.—Native of Italy.

Betula; a genus of the class Monœcia, order Tetrandria .-GENERIC CHARACTER. Male Flowers: in a cylindric ament. Calix : ament imbricate on every side, loose, cylindric ; consisting of tree-flowered scales, in each of which are two very minute scales, placed at the sides. Three equal floscules, fixed to the disk of each scale of the calix ; perianth in each one-leafed, small, entire, three or four-parted ; divisions ovate, obtuse. Corolla: none. Stamina : filamenta to each four, very small. Antheræ twin. Female Flowers: in an ament of the same plant. Calix : ament cylindric or roundish, imbricate, with two-flowered scales. Corolla: none. Pistil: germen proper, ovate, compressed, very small, twoseeded. Styles two, setaceous; stigmas simple. Pericarp: none. Ament under each scale cherishing the seeds of two florets. Seeds : solitary, ovate. ESSENTIAL CHARACTER. Male, Calix : one-leafed, three-cleft, three-flowered. Corolla: four-parted. Female, Calix: one-leafed, subtrifid, twoflowered; seed with a winged membrane on each side,----The species are.

1. Betula Alba; Common Birch Tree. Leaves ovate, acuminate, serrate. This tree is known at first sight by the silvery colour of its bark: it is of a middling or rather inferior size among other forest trees. The wood of birch is very white; women's shoe-heels and pattens, and packing cases, are made of it. It is planted along with hazel, to make charcoal for forges. In the northern parts of Lancashire they make a great quantity of besoms with the twigs, for exportatiou. The bark is of great use in dyeing wool yellow, and particularly in fixing fugacious colours. For this purpose it is best to use it dry, and to disbark trees of eighteen or twenty years' growth, at the time when the sap is flowing. The trees should stand, and be cut down the following winter. The black American birch may be applied equally well to the same purpose. The Highlanders of Scotland use the bark for tanning leather, and for making ropes; and sometimes they burn the outer rind instead of candles. With the fragments dexterously braided, the Laplanders make themselves shoes and baskets; they use large thick pieces, set out with a hole in the middle, to fit the neck for a surtout to keep off the rain. The Russians, Poles, and Norwegians, cover their houses with it, laying turf three or four inches thick over. In Kamtschatka they make hats and drinking cups of it. The wood was formerly used by the Scotch Highlanders for their arrows; but now by the wheel-wright, and for most rustic implements ; by the turner, for trenchers, bowis, ladles, &c.

and when of a proper size, it will make tolerable gates, rails, &c. In France it is generally used for wooden shoes. It affords good fuel, some of the best charcoal; and the soot is a good lamp-black for printers' ink. The small branches serve the Highlanders for hurdles and side-fences to their houses. Moxa is made of the yellow fungous excrescences of the wood, which sometimes swell out from the fissures. The leaves afford good fodder to horses, kine, sheep, and goats. The seeds are the favourite food of the siskin, or aberdevine ; and the tree also furnishes food for a variety of insects. The vernal sap of the birch-tree is well known to have a saccharine quality, and to make a wholesome diuretic wine. In the beginning of March, while the sap is rising, and before the leaves shoot out, bore holes in the bodies of the largest trees, and put fossets therein, made of elder sticks with the pith taken out, setting vessels under to receive the liquor. If the tree be large, you may tap it in four or five places at a time; and thus from several trees you may draw several gallons of juice in a day. If you do not obtain enough in one day, bottle up close what you have, until you have extracted sufficient for your purpose, but the sooner it is boiled the better. Boil the sap as long as any scum rises, skimming it all the time. To every gallon of liquor put four pounds of sugar, and boil it afterwards half an hour, skimming it well, then put it into an open tub to cool, and when cold, tun it into the cask ; when it has done working, bung it up close, and keep it three months; then either bottle it off, or draw it out of the cask when it is a year old. This juice is an excellent medicine against the scurvy, and other similar disorders. It removes obstructions, promotes urine, and, if taken pretty freely, loosens the belly. Fermented with yeast, it yields a vinous liquor, which is far from being unpleasant, and is said to be good for the stone and gravel. The leaves and bark of the tree, resolve, clcan, and resist putrefaction A decoction of them may be advantageously employed to bathe cutaneous eruptions with, and is also serviceable in the dropsy. This tree deserves to be planted in parks and ornamental woods. to increase the variety, and its fragrant smell after rain instly entitles it to a place in the wilderness. The stem being straight, the bark smooth and white, and the foliage neat, the birch has a picturesque appearance, when properly placed in ornamental plantations; either in the openings here and there, to show the foliage and hanging down of the twigs; or within, to display its silvery bark through the gloom. Though it is in the lowest esteem as a timber tree, it may yet deserve to be cultivated, not merely as an ornament, but for its various uses; especially as it will grow to advantage upon barren land, where better trees will not thrive : it will flourish in moist springy land, or in dry gravel and sand, where there is little surface; upon ground which produced nothing but moss, these trees have succeeded so well as to be fit to cut in ten years after planting, when they have been sold for nearly ten pounds the acre standing, and the after-produce has been considerably increased; and as the woods near London have been grubbed up, the value of these plantations has advanced in proportion : therefore those persons who are possessed of such poor land, cannot employ it better than by planting it with these trees, especially as the expense of doing it is not great. The best incihod to cultivate it is to furnish yourself with young plants from the woods where they naturally grow; but in places where there are no young plants to be procured, they may be raised from secds, which should be carefully gathered in the autumn, as soon as the scales under which they lodge begin to open, otherwise they will soon fail out and be lost : the seeds being small, should not be buried deep in the ground, a quarter of an inch is sufficient. 15.

They should be planted in autumn, in the shade, where they will thrive better than when they are exposed to the full sun; for in all places where there are any large trees, the seeds fall, and the plants come up well without care; so that if the young plants are not destroyed by cattle, there is generally plenty of them in all the woods where there is any of these trees. If the plants take kindly to the ground, they will be fit to cut in about ten years ; and afterward they may be cut every seventh or eighth year, if they are designed for the broom-makers only; but where they are intended for hoops, they should not be cut oftener than every twelfth year. The expense of making these plantations, in places where the young plants can be easily procured, will not exceed forty shillings per acre, and the after-expense of clearing, about twenty shillings a year more; so that the whole will not be more than three pounds; and if the land so planted be of little value, the proprietor cannot make better use of his money; for when the wood is cut, it repays the expense with interest, and a perpetual stock upon the ground. The several varieties of this species are of too trifling a nature to be here enumerated.

2. Betula Nigra; Black Virginia BirchTree. Leavesthomborate, acute, doubly sertate, pubescent underneath, entire at the base; scales of the strobiles villose; segments linear equal.—Although this species has been hitterto propagated chiedly for ornamental plantations, it is to be looped that if will be admitted anong our forest trees, for it is equally hardy with the European white birch, and attains to a much greater size, growing upwards of sixty feet high. There are also several varieties of this species, which grow more vigorusly than the common sort, thriving on the most barren ground, and may be cultivated to great advantage in Engrand, in the same manner as the first species; which see.

3. Betula Lenta; Canada Birch. Leaves cordate oblong, acuminate, serrate. It grows to sixty feet or more in height.— The liquor flowing from its wounds is used by the inhabitants of Kamschatka without previous fermentation; with the wood they build skdges and cances; and they convert the bark into food by stripping it off when green, and cutting it into long narrow pieces, like vermicelli, drying it, and stewing it with their caviar. Of this species, which is propagated in the same manner as the first, there are also several varieties not worth noticing.

4. Betula Nana; Smooth Dwarf Birch. Leaves orliquidate, centac,—This is an utright shrub, seldom above two or three feet high: trunk hard and stiff, with a roughish bark, like that of the elm, of a russet or blackish purple colour. It flowers in May, and is a native of the northern parts of Europe. This plant, the leaves of which, according to Linneus, dye a better yellow than the common birch, is of signal use in the economy of the Laplanders. The branches formish them with their bed and their chief fuel; and the seeds are the food of the parmigan, which makes as considerable apart of their sustenance. The mova also is prepared from it, which they consider as an efficacious remedy in all painful diseases.

5. Betula Pumila; American or Hairy Dwarf Birch. Leaves obovate, crenate.—It is a native of North America, cultivated only in the gardens of the curious.

6. Betuka Ålaus ; *Àlder*. Peduncles branched ; leaves roundish, weige-form, very obtase, glutinous; a xils of the veins villose underneath.—Though this species appears generally as a shrub; it will grow to a considerable tree, thirty-five of forty feet in height. It is a native of Europe, from Lapland to Gibrarlar, and of Asia, from the White Sea to mount Caucasus, in wet and boggy grounds, and on the banks of rivers;

flowering with us in March and April. varieties of which our limits will not admit; but there is a long leaved alder from America, which grows to thirty feet in height, and merits a place in all plautations. The branches are slender, smooth, numerous, and dark brown, or purple. The leaves are long, and free from the clamminess of the commort sort: they sometimes continue on the tree even in December, and it has then the appearance of an evergreen. The wood of the alder is valuable for piles, pipes, pumps, sluices, and in general for all works intended to be constantly under water. It is said to have been used under the Rialto at Venice ; and we are told that the morasses about Ravenna were piled with it, in order to lay the foundations for building upon. In Flanders and Holland it is raised in abundance for this purpose. It serves also many domestic and rural uses, as for cart-wheels, spinning wheels, milk vessels, bowls, spoons, small trays, trenchers, and other turnery ware, troughs, handles of tools, clogs, pattens, and wooden heels. The roots and knots furnish a beautiful veined wood for cabinets. The Scotch Highlanders often make chairs of it, which are very handsome, and the colour of mahogany. The wood which has lain in bogs is black like ebony. It is very generally planted for coppice wood, to be cut down every ninth or tenth year for poles; and the branches make good charcoal. The bark is used by dyers, tanners, and leather dressers; also by fishermen for their nets. Both this and the young shoots dye yellow, and, with a little copperas, a yellowish gray, very useful in the demi-tints and shadows of flesh in tapestry. The shoots cut in March will dye a cinnamon colour; and a fine tawny, if they be dried and powdered. The fresh wood yields a dye the colour of rappee snuff. The catkins dye green. The bark is used as a basis for blacks : an ounce of it dried and powdered, boiled in three quarters of a pint of water, with an equal quantity of logwood, with solution of copper, tin, and bismuth, six grains of each, and two drops of solution of iron vitriol, will dye a strong deep boue de Paris. The leaves have been sometimes employed in tanning leather. The Laplanders chew the bark, and dye their leather garments red with their saliva. The whole tree is very astringent. Motherby says, a decoction of the bark of the alder has been often known to cure agues, and is frequently used by country people, to repel inflammatory tumors in the throat, and parts adjacent. According to Tournefort, the peasants on the Alps are frequently cured of rheumatic complaints, by being covered with bags full of the heated leaves. The bark possesses a considerable degree of astringency, and a decoction of it may be advantageously employed to bathe swellings and inflammations. It dycs woollen of a reddish colour, and, with the addition of copperas, black. A late popular writer very gravely assures us, that if the leaves are strewed in a chamber infested with fleas, they will all immediately come together upon them, and be so entangled by the clamminess on their surface, that they may be easily destroyed. But surely it would be an equally effectual method of getting rid of these troublesome bed-fellows, to apply a decoction of the leaves, as a celebrated quack advised the purchasers of his nostrum to do with it ; namely, to catch them by the skin of the neck, which must of course compel them to gape, and then pour a little of the liquid down their throats. The alder makes good hedges by the sides of streams and ditches, and in all wet morassy soils, and serves to keep up the banks; but if it be planted in a low meadow, it is said that the ground surrounding it will become boggy; whereas if ash be planted, the roots of which penetrate a great way, and run near the surface, the ground will become firm and dry. The branched ; leaves obovate, acute ; veins and their axils vil-

There are many | shade of alder seems to be no material impediment to the growth of grass. The boughs cut in summer, spread over the land, and left during the winter to rot, are found to answer as a manure; clearing the ground in March of the undecayed parts, and then ploughing it. The fresh-gathered leaves are covered with a glutinons liquor, in which fleas are said to entangle themselves, as birds do in lime. Linneus says, that horses, cows, sheep, and goats, eat it, but that swine refuse it. The tongues of horses feeding upon it are turned black, and it is supposed by some persons not to be wholesome for them. The alder delighting in a very moist soil, where few other trees will thrive, is a great improvement to such lands. It is propagated by layers, cuttings, or truncheons about three feet in length. The best time for planting truncheons is in February, or the beginning of March ; they should be sharpened at one end, and the ground should he loosened with an iron crow before they are thrust into it, that the bark may not be torn off. They must be planted at least two feet deep, to prevent their being blown out of the ground by strong winds, after they have made their shoots. The plantations should be cleared at first of tall weeds; but when the trees have made good heads, they will require no farther care. If you raise them by layers, this operation must be performed in October, and by the October following they will have taken root sufficiently to be transplanted. They should be set at least a foot and a half deep in the ground; and their tops must be cut off to about nine inches above the surface, which will occasion them to shoot out many branches. In planting alders for coppices, it is much better to raise them from young trees than from truncheons. To obtain a quantity of these plant-suckers, and head them down for stools, lay the shoots the succeeding autumn, and in twelve months they will have taken root ; then remove and plant them in rows ; in one or two years, they may be planted where they are to remain. If the coppice is to be on boggy or watery ground, they may be removed from the nursery, and planted three feet asunder in holes previously prepared. There they may stand six or seven years, when half the trees may be taken away, and the rest cut down for stools. Every uinth or tenth year will afford a fall for poles.

7. Betula Incana ; Hoary Alder. Peduncles branched ; leaves roundish, elliptic, acute, pubescent underneath ; axils of the veins naked; stipules lanceolate .-- It grows naturally in dry sandy soils, and may perhaps be cultivated with the birch, where land is of little value, as an under-wood, and may be propagated either by layers or cuttings, as well as by seeds, where they can be obtained. Native of the Alpine and Subalpine parts of Switzerland, of Dauphiny, of eastern Siberia, and of the islands beyond Kamschatka.

8. Betula Populifolia ; Poplar-leaved Birch. Leaves deltoid, drawn out to a long point, unequally serrate, very smooth ; the scales of the strobiles having roundish sidelobes; petioles smooth .- Native of North America.

9 Betula Papyracea ; Paper Birch. Leaves ovate, acuminate, doubly serrate; veins hirsute underneath .-- Native of North America.

10. Betula Excelsa; Tall Birch. Leaves ovate, acute, serrate; scales of the strobiles having the side-lobes rounded; petioles pubescent, shorter than the peduncle .- Native of North America.

11. Betula Oblongata; Turkey Alder. Peduncles branched; leaves oval, somewhat obtuse, glutinous; the axils of the veius marked underneath .- This is very common in Austria and Hungary.

12. Betula Serrulata; Notch-leaved Alder. Peduncles

170

lose underneath ; stipules oval, obtuse .- Native of Pennsylvania.

13. Betula Crispa; Curled-leaved Alder. Peduncles branched; leaves ovate, acute, somewhat waved; veins hairy underneath; axils naked; stipules roundish, ovate.—Native of Newfoundland and Hudson's Bay.

14. Betalu Daurica. Leaves ovate, acuminate, serrate, hairy on the nerve.—This species, when young, is scarcely to be distinguished from our common birch, except by the leaves : it does not grow so tall, and the runk does not exceed a foot in diameter : the wood is hard, yellower than that of the common sort, and in old trees marbled with brown and gray towards the middle : it is tougher, and therefore more fit for the use of the wheelwright: it is also used for making charceol. Native of Dauria.

15. Betula Fruticosa. Leaves rhomboid-ovate, equally serrate, smooth.—It abounds in marshes, and on rocky mountains, and in the cold regions of eastern Siberia, especially towards the lake Baikal.

Bidaws; z genus of the class Syngenesia, order Polygania Equalis.—Ge SNERIC CHARACTER. Caliz: common, inbricate, erect; leaflets often equal, oblong, channelled, concave. Corola: compound, uniform, tubular: corollates here der fivecleft, erect. Stamina: filamenta five, capillary, very short. Anthere sylindric, tubular. Pisidi z germen oblong; style simple, the length of the stamina; stigmas two, oblong, reflex. Periarger zone, Calix: unchanged. Seeds: solitary, obluse angular; down with two or more awns, oblong, straight, aonte, rough, hooked backwards. Receptacle: fall, chaffy; chaffs decidrous, flattish. ESSENTIAL CHARAC-TER. Calix: imbriate. Corolla: sometimes, but seldom, with a floscule or two in the ray. Seed: crowned with erect seabous awns. Receptacle: fally.—The species are,

1. Bidens Triparitia; Trifd Wate Heng Agrimony, or Berr Margach. Leaves trifd; calcies somewhat leaf; seeds erect; root annual.—This plant dyes a deep yellow: the yarn or thread must be first steeped in a lume water, then dried and steeped in a decoction of the plant, and afterwards boiled in the decoction. The seeds have been sometimes known to destroy gold fail by adhering to their gills and jaws. As it is found by a chemical analysis to possess much the same qualities as verbeina acwalla, it is probable that it might have the same good effects in expelling the stone and gravel: it grows readily in wet situations.

2. Bidens Minima. Leaves lanceolate, sessile; flowers and seeds erect.—This, like the first species, prospers in a wet soil.

3. Bidens Nodiflora; Sessile/flowered Bidens. Leaves oblong, quite entire, one-toothed; stem dichotomous; flowers solitary, sessile.—Native of the East Indies. It must be sown upon a moderate hot-bed in the spring, and afterwards treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June, soon after which the plants decay.

4. Bidens Tenella. Leaves linear; peduncles capillary; calices mostly four-leaved; seeds erect, five-fold.—It is an annual, a native of the Cape of Good Hope, and must be cultivated in the same manner as the preceding species.

5. Bidens Cernua; Drooping Water Hewp Agrimony, or Bar Marygodd. Leaves lanceolate, stem chasping; flowers nodding; seeds erect; root annual.—Native of most parts of Europe. Found at Dichingham in Norfolk, and Tarporley in Cheshire; it is frequent in Ireland : it flourishes in wet situations.

6. Bidens Frondosa; Smooth-stalked Bidens. Leaves

pinnate, serrate, marked with lines, smooth; secds erect; calies leafy; stem polished.—H grows naturally in Virgunia, Maryland, and Canada, where it is often a troublesome weed. It is easily propagated by seeds sown in the spring; in an open situation, where, if they be permitted to scatter, the plants will come up the following spring; and two or three of them are to be transplantcd where they are to grow, and after they are rooted, will require no further care.

7. Bidens Pilosa; Hairy Bidens. Leaves pinnate, somewhat hairy; stem will bearded joints; calices will a simple involucre; seeds diverging.—Native of America, and the island of Tongataboo in the South Seas. See the third species.

 Bidens Bipinnata; Hemlock-leaved Bidens. Leaves bipinnate, gashed; calices involucred; corollas half radiated; seeds diverging.—Native of Virginia. For its cultivation, see the sixth species.

9. Bidens Nivea; Sanney Bidens. Leaves simple, cordate-oute, acuminate; branchels trichotomous, serrate; flowers hemispherical; peduncles clongated.—Native of Jamaica, in elevated pastures, and on the sea: coast of the southern parts. It is propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pop, pluoged into a fresh hot-bed, and treated as other tender plants from the same countries : in automn, they must be placed in the barkstove, and will generally live some years with management.

10. Bidens Verticillata. Leaves oblong, entire, lower ones entire, upper ones opposite; flowers verticilled.—Native of Vera Cruz in South America. For the cultivation of this plant, see the preceding species.

11. Bidens Scandens. Leaves opposite, ovate, acuminate, serrate; stem climbing, shrubby; flowers panicled, ovate.— Native of the cooler mountains of Jamaica, and of Vera Cruz. See the ninth species.

 Bidens Bullata; Various-leated Bidens. Leaves ovate, serrate; lower ones opposite, upper ones ternate, the middle larger.—Native of America, found also wild in Italy. See the third species.

 Bidens Hirsuta. Lcaves opposite, ovate-lanceolate, entire, tomentose, hirsute; stem climbing, shrubby; peduncles opposite, diverging, many-flowered; annual.—Native of Jamaica. See the ninth species.

14. Bidens Odorata. Stem four-cornered, branching very much; leaves connate, bipinnate; pinnules wedge-trifid, smooth; seeds rugged; root annual.—It is a native of Mexico. See the minth species.

Bignonia; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth oneleafed, erect, cup-form, five-cleft. Corolla : monopetalous. campanulate; tube very small, the length of the calix; throat very long, ventricose beneath, oblong-campanulate; border five-parted, the two upper divisions reflex, lower patulous. Stamina : filamenta four, subulate, shorter than the corolla. two longer than the other two. Antheræ reflex, oblong, as it were doubled. Pistil: germen oblong; style filiform, situation and form of the stamina ; stigma capitate. Pericarp : silique two-celled, two-valved ; partition membranaceous, parallel, thickened at the sutures. Seeds : very many, imbricate, compressed, membrane-winged on both sides. ESSEN-TIAL CHARACTER. Calix: five-cleft, cup-form. Corolla: throat bell-form, five-cleft, ventricose beneath. Silique; twocelled. Seeds: membrane-winged .-- These are exotic trees or shrnbs, and may be raised from seeds sown on a moderate hot-bcd in the spring. They should be soon inured to the Leaves open air, to prevent their being drawn up weak. They may

also be increased by cuttings, and some of them by layers. lets cordate; stem murieated .- Native of Campeachy. See The species are,

BIG

1. Bignonia Catalpa; Common Catalpa Tree. Leaves simple, cordate; stem erect; seeds winged with membranes .- 'The branches dye wool a kind of cinnamon-colour. Thunberg mentions, that the Japanese lay the leaves on parts of the body affected with pains, supposing them to be beneficial to the nerves; and that a decoction of the pods is esteemed useful in the asthma. The seeds of this tree are usually imported from South Carolina. The seedling plants should be placed abroad in the beginning of June, in a sheltered situation, till autumn, when they should be placed under a common frame, to screen them from frost in winter; but in mild weather they must be fully exposed to the open air. The following spring these may be taken out of the pots, and planted in a nurserybed in a warm situation, where they may remain two years to get strength, and be afterwards planted where they are designed to remain. These plants, when young, are frequently injured by frost, for they shoot pretty late in autumn, so that the early frosts often kill the extremity of their branches; but as the plants advance in strength, they become more hardy, and are seldom injured but in very severe winters. It is late in the spring before these trees come out, which has often caused persons to believe they were dead, and some have been so imprudent as to cut them down on that supposition, before the tree was well known. It may also be propagated by cuttings, which should be planted in pots in the spring, before the trees begin to push out their shoots, and plunged into a moderate hot-bed, observing to shade them from the sun in the middle of the day, and refresh them occasionally with water, which must not be given them in too great plenty. In about six weeks these will have taken root, and made shoots above, so should have plenty of air admitted to them constantly, and hardened by degrees to bear the open air, into which they should be removed, and treated in the same manner as the seedling plants, and the spring following planted out into a nursery-bed, as is before directed. The catalpa delights in a moist soil, where it will make great progress, and in a few years produce flowers.

2. Bignonia Tomentosa. Leaves simple, cordate, tomentose beneath; flowers axillary, panicled .- Native of Japan.

3. Bignonia Sempervirens; Carolina Yellow Jasmine. Leaves simple, lanceolate; stem twining .- It grows naturally in South Carolina, where it spreads over the hedges, and at the season of flowering, perfumes the air to a great distance. In Virginia, where it grows only in some parts, and not very plentifully, the inhabitants call it yellow jasmine, probably from the sweet odour of its flowers. The young plants are impatient of cold, so must be sheltered in the winter until they have obtained strength, when they should be planted against a warm wall, and in winter protected from frost by a covering of mats, and the ground about their roots covered with tan.

4. Bignonia Unguis. Leaves conjugate: tendril very short, bowed, three-parted .- Native of the West Indies. It will live in the open air, if planted against a wall that has a south aspect, and sheltered in very severe frost.

5. Bignonia Æquinoctialis. Leaves conjugate, cirrhose; leaflets ovate-lanceolate; peduncles two-flowered; siliques linear .- Native of New Spain. See the fourth species.

6. Bignonia Paniculata. Leaves conjugate, cirrhose; leaflets cordate-ovate ; flowers raeemed ; peduncles three-flowered .- It will not thrive in this country except kept in the bark stove. Native of South America.

7. Bignonia Crucigera. Leaves conjugate, cirrhose ; leaf-

preceding species.

8. Bignonia Capreolata ; Four-leaved Trumpet-flower. Leaves conjugate, eirrhose ; leaflets eordate lanceolate ; bottom leaves simple .- Native of Virginia and Carolina, See the eighth species.

9. Bignonia Pubescens. Leaves conjugate, cirrhose ; leaflets cordate-ovate, pubescent beneath,-It grows naturally in Virginia, and several other parts of America. When this sort is planted in the full ground against a wall, the roots should be covered in autumn with some old tanner's bark, to keep out the frost in winter; and in very severe frost, the branches should be covered with mats, to prevent their being destroyed.

10. Bignonia Triphylla; Three-leaved Trumpet-flower. Leaves ternate; leaflets ovate, acnminate; stem shrubby, erect.-See the sixth species. Native of South America. 11. Bignonia Pentaphylla; Hairy Five-leaved Trumpet-

flower. Leaves digitate ; leaflets quite entire, obovate .- Native of Jamaica. See the sixth species. 12. Bignonia Leucoxylon. Smooth Five-leared Trumpet-

flower, White Wood, or Tulip flower. Leaves digitate ; leaflets quite entire, ovate, acuminate.—It will take root from cuttings planted during summer in pots, and plunged into a bark-bed : the wood is very hard and white. Native of Jamaica

13. Biguonia Radiata; Ray-leaved Trumpet-flower. Leaves digitate; leaflets pinnatifid .- Native of very dry sand in Peru.

14. Bignonia Radicans; Rooting or Ash-leaved Trumpetflower. Leaves pinnate ; leaflets gashed ; stem with rooting joints .- Native of Carolina. This kind is hardy enough to thrive in the open air; but as the branches trail, they must be supported ; it is therefore usually planted against walls or, buildings, where, if the branches have room, it will spread to a great distance, and rise very high ; it is therefore very convenient for eovering unsightly buildings. It may also be trained up against the stcms of trees, where, by proper management, it will make a fine appearance when in flower. It is propagated by seeds, but the young plants so raised, do not flower in less than seven or eight years; therefore those which are propagated by cuttings, or layers from flowering plants, are most esteemed, because they will flower in two or three years after planting. The old plants also send out many suckers from the roots, which may be taken off, and transplanted where they are to remain, for they will not transplant safely if they be old. The culture necessary for these plants, after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to about two feet along, that young shoots may be obtained for flowering the following summer. These plants are of long duration.

15. Bignonia Stans; Branching-flowered Trumpet-flower. Leaves pinnate; lcaflets serrate; stem ereet, firm; flowers racemed .- Native of all the sugar islands in the West Indies, chiefly in a dry rocky or gravelly soil. It is propagated by seeds sown on a hot-bed, and the plants afterwards transplant-ed into separate small pots, filled with light fresh earth, and plunged into a fresh hot-bed; in the autumn they must be removed into the bark-stove, and during the winter should have but little water, but in summer they must be frequently refreshed with it, but not in too great plenty. The plants should constantly remain in the bark-stove, and be treated in the same manner as other tender plants from hot countries. The third year from the seed they will flower, but they do not produce seeds in England.

Published by Nuttall, Fisher & Dison, Liverpool. 1816.

BIS

acuminate, serrate; stem twining ; calix semiquinquefid .--Native of Japan.

17. Bignonia Chelonoides. Leaves unequally pinnate; leafiets ovate, quite entire, acuminate, pubescent; corollas bearded, with the rudiment of a fifth stamina .- This is a large tree, with a whitish ash-coloured bark. The fresh flowers immersed in water, give it a pleasant odour, and in the East Indies, of which it is a native, they sprinkle it over the temples in a morning, to correct the stagnant air.

18. Biguonia Spathacea. Leaves unequally pinnate ; leaflets ovate, rough with hairs; calix one-leafed, spathed; corolla salver-shaped .--- Native of Malabar, Java, and Ceylon, in woods near waters.

19. Bignonia Peruviana. Leaves decompound ; leaflets gashed; stem with tendrils at the joints .- This species elimbs by tendrils, which come out from the joints of the branches. Native of America.

20. Bignonia Indica; Indian Trumpet-flower. Leaves bipinnate ; leaflets quite entire, ovate, acuminate .- This is a large tree with ascending branches. Native of the East Indies.

21. Bignonia Cœrulea. Leaves bipinnate ; leaflets lanceolate, entire .-- Native of the Bahamas.

22. Bignonia Longissima; Wave-leaved Trumpet-flower. Leaves simple, oblong, acuminate; stem erect; seeds woolly. -This beautiful tree is now cultivated in many parts of Jamaiea, especially in the low lands and savannas, where it seems to thrive very luxuriantly. It grows to a considerable size, and is generally looked upon as an excellent timber-tree. Its numerous flowers, and slender siliques, add a peculiar grace to its growth. Native of the West Indies.

23. Bignonia Echinata. Climbing; lower leaves ternate, upper bijugous cirrhose; fruits echinate,-This is a rambling shrub, climbing to the tops of trees, by its very long and numerous branches; corolla flesh-coloured. Native of the West Indies, Carthagena, and Guiana.

24. Bignonia Pentandra. Leaves bipinnate; stamina five, with two antheræ on each ; calix fleshy coloured, five-toothed .--- Native of Cochin-china, near rivers.

25. Bignonia Alliacea. Leaves conjugate ; leaflets elliptic, entire, coriaceous; peduncles five-flowered, axillary; calices entire .- This plant obtained its trivial name from the strong seent of garlic, which betrays it from afar. It is a native of the West Indian islands, and the forests of Cayenne and Guiana.

26. Bignonia Cassinoides. Leaves simple, elliptic, coriaceous; raceme terminating; corolla large, smooth, two inches in diameter .- Native of Rio Janeiro.

27. Bignonia Bijuga. Leaves abruptly pinnate, bijugous; leaflets elliptic, quite entire ; branches alternately compressed above, covered with an ash-coloured bark, and smooth; raceme terminating .--- Native of Madagascar.

Biscutella ; a genus of the class Tetradynamia, order Siliculosa .- GENERIC CHARACTER. Calix : perianth four-15.

16. Bignonia Grandiflora. Leaves pinnate; leaflets ovate, | leaved; leaflets ovate, acuminate, gibbous at the base, coloured, decidnous. Corolla: four-petalled, crueiform; petals oblong, obtuse, spreading. Stamina : filamenta six, the length of the tube of the corolla, two opposite shorter. Antheræ simple. Pistil : germen compressed, orbieulate, emarginate ; style simple, permanent ; stigma obtuse. Pericarp : silicle erect, compressed, flat, semibifid, with roundish lobes, two-eclled ; partition laneeolate, ending in a rigid style; eells two-valved, affixed to the partition, on its straight margin. Seeds : solitary, roundish, compressed, in the middle of the cell. ESSENTIAL CHARACTER. Siliele compressed, flat. rounded above and below, two-lobed. Calix: leaflets gibbous at the base .- They are all annual plants except the last, which perish soon after they have perfected their seeds. These should be sown either in spring or autumn, upon a border of light earth, in an open situation, where they are to remain. Those which are sown in autumn will come up in about three weeks, and the plants will live through the winter without any protection, and flower earlier the following spinmer, whereby good seeds may be always obtained ; whereas those which are sown in the spring, in bad seasons decay before their seeds are ripe. The autumnal plants flower in June, and the spring plants in July, and their seeds ripen about six weeks after; if these are permitted to scatter, there will be plenty of young plants produced without any care. They require no further culture, but to keep them clean from weeds, and thin the plants where they are too close, leaving them eight or nine inches asunder .---- The species are,

1. Biscutella Auriculata ; Ear-podded Buckler Mustard. Calices gibbous on each side with the nectary; silicles running into the style .- Native of the south of France, and Italy.

2. Biscutella Apula; Spear-leaved Buckler Mustard. Silicles scabrous; leaves lanceolate, sessile, serrate,-It flowers in June and July. Native of Italy. 3. Biscutella Lyrata, Silicles scabrous; leaves lyrate,-

Native of Spain and Sicily.

4. Biscutella Coronopifolia. Silicles smooth ; leaves toothed, rough with hairs .- It is found in dry barren places in Spain, Italy, and Germany.

5. Biscutella Lævigata ; Smooth Buckler Mustard, Silicles smooth; leaves lanceolate serrate .-- Flowers in June and July. Native of Italy and Austria.

6. Biscutella Sempervirens ; Shrubby Buckler Mustard. Silicles somewhat scabrous ; leaves lanceolate, tomentose .----This is a very distinct species. Native of Spain.

Biserrula ; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix: perianth one-leafed. tubular, erect, semiquinquefid; teeth subulate, equal, the two upper ones more remote. Corolla papilionaceous; banner larger, reflected on the sides, ascending, roundish; wings ovate-oblong, free, shorter than the banner ; keel the length of the wings, obtuse, ascending. Stamina : filamenta diadelphous, (simple and nine-cleft,) ascending at their tips, inclosed within the keel. Antheræ small. Pistil: germen oblong, compressed ; style subulate, ascending ; stigma simple, Pericarp : legume large, linear, flat, two-celled ; partition contrary to the valves. Seeds: very many, kidney-form, com-pressed. ESSENTIAL CHARACTER. Legume two-celled, flat; partition contrary .---- The only known species is,

1. Biserrula Pelecinus ; Bastard Hatchet Vetch .- This is an annual plant, which grows naturally in Italy, Sicily, Spain, and the south of France. It sends out many angular stalks, which trail on the ground, subdivided into many branches, with long winged leaves, composed of many pairs of leaflets terminated by an odd one; these are heart-shaped ; towards 2 Y

towards the upper part of the branches come out the peduneles, which sustain several small purplish flowers. It is propagated by seeds, which in this country should be sown in the autumn, on a bed of light earth, where the plants will come up in about three weeks, and will live in the open air very well. These should be sown where they are designed to remain, or transplanted very young; for when they are large they will not bear removing. When the plants are come up, they will require no other care but to keep them clean from weeds; and where they are too near they should be thinned to about a foot distance from each other. They flower in June, and the seeds ripen in September.

Bishop's Weed. See Ammi.

Bitter Vetch. See Orobus. Bitter Wort. See Gentiana.

Bixa ; a genus of the class Polvandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth five-toothed, very small, obtuse, flat, permanent. Corolla : double, outer with petals, five, oblong, equal, large, more rude; inner with five petals like the outer, but thinner. Stamina : filamenta numerous, setaceous, shorter by half than the corolla. Antheræ erect. Pistil: germen ovate; style filiform, the length of the stamina ; stigma parallelly bifid, compressed. Pericarp: capsule ovate cordate, compressed, fenced with bristles, bivalve, gaping at the angles, one-celled, with an inner bivalve membrane. Seeds : numerous, turbinate, with a truncated navel, berried. Receptacle : linear, longitudinal, fastened to the middle of the valves. ESSENTIAL CHARAC-TER. Corolla: ten-petalled. Calix: five-toothed. Capsule : hispid, bivalve .---- The only species known is,

1. Bixa Orellana ; Arnotto or Anotta .- This shrub rises with an upright stem to the height of eight or ten feet, sending out many branches at the top, forming a regular head. The name of this plant is variously spelt in England, as, arnotto, arnotta, anotta, anato, anoto, annotto. The drug called terra orellana, or orieuna, roncou, or arnotto, is thus prepared from the red pulp which covers the seeds. The contents of the fruit are taken out and thrown into a wooden vessel, where as much bot water is poured upon them as is necessary to suspend the red powder or pulp; and this is gradually washed off with the assistance of the hand, or of a spatula or spoon. When the seeds appear quite naked, they are taken out, and the wash is left to settle; after which the water is gently poured away, and the sediment put into shallow vessels, to be dried by degrees in the shade. After acquiring a due consistence, it is made into balls or cakes, and set to dry in an airy place, until it is perfectly firm. Some persons first pound the contents of the fruit with wooden pestles, then covering them with water, leave them to steep six days : this liquor being passed through a coarse sieve, and afterwards through three finer ones, is again put into the vat or wooden vessel, and left to ferment a week. It is then boiled until it is pretty thick, and when cool it is spread out to dry, and then made up into balls, which are usually wrapped up in leaves. Arnotto, of a good quality, is of the colour of fire, bright within, soft to the touch, and dissolves entirely in water. It is reputed to be cooling and cordial, and is much used by the Spaniards in their chocolate and soups, both to heighten the flavour, and to give them an agreeable colour. It is esteemed good in bloody fluxes, and disorders of the kidneys : mixed with lemon-juice and a gum, it makes the crimson paint with which the Indians adorn their persons. It was formerly used by dyers to form the colour called aurora; but at present it is not held in such estimation as a dye, though it still maintains its ground with painters. Arnotto is well known to be the drug which Pistil: germen four-connered, short; style setaceous, much

is used for dveing cheese in Gloucestershire, under the name of cheese-colouring. It is used in Holland for colouring butter. The bark makes good ropes for the common plantation uses in the West Indies; and pieces of the wood are used by the Indians to procure fire by friction. It is propagated by seeds, and may be cultivated with great ease. It is planted in many parts of Jamaica, Barbadoes, Cavenne, &c. in rich soils and shady situations, shooting luxuriantly near rivulets. The seed should be sown in a small pot, filled with light rich earth, and plunged into a hot-bed of tanner's bark, where, if the bed be of a proper temperature of heat, the plants will appear in about a month after : when these are about an inch high, they should be taken out of the not. and carefully separated, so as not to tear off their tender roots, and each replanted in a small pot filled with some rich light earth, and plunged into a fresh hot-bed of tanner's bark, observing to shade them every day until they have taken new root, after which they must be treated as other tender plants from the same country.

Blackburnia ; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth very short, four-toothed, inferior; teeth short, acute, horizontal. Corolla : petals four, elliptic. Stamina : filamenta four, subulate, rather shorter than the petals. Antheræ heart-shaped, erect. Pistil: germen conic; style filiform, erect, length of the stamina; stigma simple. Pericarp: berry. Seed: ESSENTIAL CHARACTER. Calix: four-toothed. single. Petals : four, elliptic. Antheræ : heart-shaped. Germen : conic. Stigma: simple. Pericarp: berry with a single seed .----- The only species known is,

1. Blackburnia Pinnata. Leaves alternate, abruptly pinnate, with two or three pair of leaflets, which are opposite, oblique, ovate, quite entire, and very smooth; panicles axillary, small .- Native of Norfolk Island.

Bladder Nut. See Staphylea. Bladder Sena. See Colutea.

Bladhia ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, very short, permanent, five-parted; parts ovate, concave, spreading, torn, subserrate. Corolla: one-petalled, wheelshaped, five-parted; parts ovate, obtuse, spreading. Stamina: filamenta five, very short. Antheræ heart shaped, acute, converging into a cone, shorter than the corolla. Pistil: germen superior; style filiform, longer than the corolla; stigma simple, acnte. Pericarp : berry globose, crowned by the permanent style, one-celled. Seed : single, globose, involved in a membrane. ESSENTIAL CHARACTER. Corolla: wheel-shaped, decidnous; berry containing one arilled seed. These plants are all natives of Japan .---- The species are.

1. Bladhia Japonica. Leaves serrate, smooth; corolla white, sweet-smelling,

2. Bladhia Villosa. Leaves serrate, villose; stem filiform, almost erect, tomentose a finger's length.

3. Bladhia Crispa. Leaves oblong, curled, smooth ; stem round, smooth, a span or more in height; berry red, the size of a pea.

Blaria ; a genus of the class Tetrandria, order Monogynia.-GENERIC CHARACTER. Calix : perianth four-part-ed ; leaflets linear, erect, a little shorter than the corolla, permanent. Corolla: monopetalous, eampanulate; tube cylindrie, the length of the calix, pervious; border small, four-cleft; divisions ovate, reflex. Stamina: filamenta four, setaceous, the length of the tube, inserted into the receptaele. Antheræ oblong, compressed, crect, obtuse, emarginate.

174

longer than the corolla; stigma obtuse. Pericarp: capsule obtuse, quadrangular, four-celled, gping at the angles. Seeds: some roundish. ESSENTIAL CHARACTER. Calix: four-parted. Corola: four-clieft. Stamina: inserted into the receptacle. Copute: four-celled, may-seeded.—These are all shrubs, inhabitants of the Cape of Good Hope; requiring the same shelter and treatment with other Cape plants, in the dry stove; and may be increased by cuttings, like the encas or healths, which they much resemble.—These perices are,

1. Blæria Ericoides; Heath-leaved Blæria. Antheræ awnless, standing out; calices four-leaved; bractes the length of the calix; leaves in fours, oblong, acerose, hairy, imbricate. at is about the height of common heath.

2. Blæria Ciliaris; *Ciliated Blæria*. Flowers in a head; calices ciliate, by the whiteness of which the plant is also readily known.

3. Blæria Articulata; *Jointed leaved Blæria*. Stamina protruded, two-parted; corollas cylindric.—This is a distorted shrub, about the stature of common heath.

4. Blæria Purpurea; Purple-flowered Blæria. Stamina included, two-parted; corollas oblong, straight; flowers terminating, aggregate; peduucles ercct.

5. Blæria Pusilla; Dwarf Blæria. Flowers scattered, corollas funnel form: this must be cautiously distinguished from the heaths.

6. Blæria Muscosa; Moss-leaved Blæria. Antheræ awnless, almost stauding out; calices one-leafed, hajry; corollas bell-shaped, hajry in the upper part; flowers axillary; stigmas peltate. It flowers from June till August.

Blakes; a genus of the class Dodecandria, order Monogyma.-GENERIC CHARACTER. Caliz perianth of the fruit inferior, six-leaved; leaflets ovate, concave, expanding, the size of the flower. Perianth of the flower superior; margin quite entire, hexangular, membranaccous. Corolla: petals six, ovate, expanding, equal. Näemina: filmanent twelve, subulate, erect. Anthere triangular, depressed, concatenated into a ting. Pisiti; germen inferior, obovate, crowned with the margin of the calix; style subulate, the length of the flower; signa acute. Pericapr: caspuel ebovate, six-celled. Seeds: very many. ESSENTAL CHARACTER. Calix: inferior six-leaved; superior entire. Petals: six. Capsule; six celled, many-seeded. These trees have not been cultivated in Europe.---The species are,

1. Bakea Trinervia. "Two-calicled; leaves nereless, very fuely striated across. Flowers opposite, solitary. It grows generally to the height of ten or fourteen feet; but rises always higher when it remains a climber, in which state it continues sometimes. It is certainly one of the most beautiful productions of America. It supports itself for a time by the help of some neighbouring shrub or tree, but it grows gradually more robust, and at length acquires a pretty moderate stem, which divides into a thonsand weakly decliming branches, well supplied on all sides with beautiful rosy blossons. It thrives best in the West Indies, on the sides of ponds or rivules; and appearance, it ought to be supported while it is young and weakly.— Native of cool moist places, in Jamaica.

2. Blakea Triplinervia. Uncalided ; feaves triple nerved. This tree grows to the height of sixteen feaves triple nerved, petioled, six or seven inches long, ribbed underneath, and having a nerve running along the edge; peduades three flowered, seeds minute. The fruit is of a yellow colour, and sapid, --H is a native of Surigam, and also of Guiana, where it flowers and fruits in May.

Blasia; a genus of the class Cryptogamia, order Algæ, or Flags.---- The only species yet brought to light is, Blasia Pusilla; Dwarf Blasia, which grows on the sides of ditches and brooks, and in moist shady places, in a sandy soil, in many parts of Europe.—It is found with us on Hounslow Heath, near Mauchester, and Halifax.

BLI

Blechnum; a genus of the class Cryptogamia, order Flices, or Ferns.—GENERTC CUARACTER. Furctifications disposed in two lines, upproaching to the rib of the frond, and parallel.—These ferns are natives of warm or hot countries, They are increased by parting the roots.——The species are,

 Blechnum Occidentale; South American Blechnum. Fronds pinnate; pinnas lanceolate, opposite, emarginate at the base.—Native of the West India islands, and the continent of South America.

2. Blechnum Orientale; Chinese Blechnum. Fronds pinnate; pinnas linear, alternate.—Found in China, and also in the Society Isles.

3. Blechnum Australe; *Cape Blechnum*. Fronds pinnate; pinnas subsessile, cordate-lance date, quite entire, the lowest opposite.—Native of the Cape of Good Hope.

4. Blechnum Virginicum; Virginian Blechnum. Fronds pinnate; pinnas multifid.-Native of Virginia and Carolina.

5. Blechnum Japonicum ; Japanese Blechaum. Frond bipinnatifid; pinnules ovate, obtuse, serrated.-Native of Japan.

6. Blechnum Radicans; Rooted-leaved Blechnum.-Native of Virginia and Madeira.

Blights. There is nothing so destructive to a fruit-garden as blights; nor is there any thing in the business of gardening which requires more of our serious attention, than the endeavouring to prevent or guard against this great enemy of gardens. 1. Blights are often caused by a continued dry easterly wind for several days together, without the intervention of showers or any morning dew, by which the perspiration in the tender blossoms is stopped, so that in a short time their colour is changed, and they wither and decay; and if it so happen that there is a long continuance of the same weather, it equally affects the tender leaves ; for their perspiring matter is hereby thickened and rendered glutinous, closely adhering to the surface of the leaves, and becomes a proper nutriment to those small insects, which are always found preving upon the leaves and tender branches of fruit trees whenever this blight happens : but it is not these insects which are the first cause of blights, as has been imagined by some ; though it must be allowed that whenever these insects meet with such a proper food, they multiply exceedingly, and are instrumental in promoting the distemper; so that many times, when the season proves favourable to them, and no proper care has been taken to prevent their mischief, it is surprising to think how whole walls of trees have suffered by this infection. The best remedy yet known for this distemper, is gently to wash and sprinkle over the trees from time to time with common water, that is, such water as has not had any thing steeped in it : and the sooner this is done after danger is apprehended, the better ; and if the young and tender shoots seem to be much infected, wash them with a woollen cloth so as to clear them, if possible, from all this glutinous matter. that their respiration and perspiration may not be obstructed ; and if some broad flat pans or tubs of water be placed near the trees, that the vapours exhaled from the water may be received by the trees, it will keep their tender parts in a ductile state, and greatly help them : but whenever this operation of washing the trees is performed, it should be early in the day, that the moisture may be exhaled before the cold of the night comes on, especially if the nights be frosty : nor should it be done when the sun shines very hot upon the wall, which

would be subject to scorch up the tender blossoms. 2. Another cause of blights in the spring is, sharp hoary frosts, which are often succeeded by hot sunshine in the day-time: this is the most sudden and certain destroyer of fruits that is known; for the cold of the night starves the tender parts of the blossoms, and the sun rising hot upon the walls before the moisture is dried from the blossoms, (which being in small globules, collects the rays of the snn,) a scalding heat is thereby acquired, which scorches the tender flowers, and other parts of plants. The method to prevent this mischief is, to cover the walls carefully with mats, canvass, or reeds, fastened so as not to be disturbed by the wind, and suffered to remain on during the night, but taken off every day when the weather permits. Although this method is thought by some to be of little service, (and may be really prejudicial, if the trees be too long covered, or incautiously exposed,) yet when this covering is conducted properly, it frequently proves a great protection to fruit-trees; and if the covering be fixed near the upper part of a wall, and be fastened to pulleys, so as to be drawn up or let down occasionally, the operation will be easy, and the success will sufficiently repay the trouble. 3. But there is another sort of blight that sometimes happens later in the spring, namely, in April or May, which is often very destructive to orchards and open plantations; against which we know not any remedy. This is called a fire-blast, which in a few hours has not only destroyed the fruit and leaves, but many times parts of trees, and sometimes entire trees, have been killed by it. This is supposed to be effected by volumes of transparent flying vapours, which, among the many forms they revolve into, may sometimes approach so near to an hemisphere or hemicylinder, either in the upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays. Against this enemy there is no guard, nor any remedy to cure it : but as this more frequently happens in close plantations, where the stagnating vapours from the earth, and the plentiful perspirations from the trees, are pent in for want of a free air to dissipate and dispel them, (which are often observed in still weather to ascend in so plentiful a manner as to be seen with the naked eye, but especially with reflecting telescopes, so as to make a clear and distinct object become dim and tremulous,) than in those which are planted at a greater distance, or are not surrounded with hills or woods; this directs us in the first planting of kitchengardens and orchards, that we should allow a greater distance between the trees, and make choice of clear healthy situations, that the air may freely pass between the trees, to dissipate those vapours before they are formed into such volumes; whereby the circumambient air will be clear, and less subject to injuries, as also the fruits which are produced in this cleaver air will be much better tasted than those that are surrounded with a thick rancid air ; for as fruits are often in a respiring state, they consequently, by imbibing a part of these vapours, are rendered crude and ill-tasted, which is often the case with a great part of our fruits in England. 4. But that blights are frequently no more than an inward weakness or distemper in trees, will evidently appear, if we consider how often it happens, that trees against the same wall, exposed to the same aspect, and equally enjoying the advantages of sun and air, with every other circumstance which might render them equally healthy, yet very often are observed to differ greatly in their strength and vigour; and indeed we generally find the weak trees to be blighted, when the vigorous ones in the same situation shall escape very

to their healthy constitution. This weakness, therefore, in trees, must proceed either from the want of a sufficient supply of nonrishment to maintain them in perfect vigour, or from some ill qualities in the soil where they grow; or perhaps from some bad qualities in the stock, or inbred distemper of the buds or evons, which they had imbibed from their mother-tree, or from mismanagement in the pruning, &c. all which are productive of distempers in trees, and of which they are with difficulty cured. Now if this is occasioned by a weakness in the tree, we should endeavour to trace out the true cause : first, whether it has been occasioned by ill management in the pruning, which is too often the case ; for how common is it to observe peach-trees trained up to the full length of their branches every year, so as to be carried to the top of the wall in a few years after planting, when at the same time the shoots for bearing have been so weak, as scarcely to have strength to produce their flowers; but this being the utmost of their vigour, the blossoms fall off, and many times the branches decay, either the greatest part of their length, or quite down to the place where they were produced? and this, whenever it happens to be the case, is ascribed to a blight. Others there are, who suffer their trees to grow just as they are naturally disposed, during the summer season, without stopping shoots, or disburdening their trees of luxuriant branches; by which means two, three, or four shoots shall exhanst the greatest part of the nonrishment of the trees all the summer; which shoots, at the winter pruning, are entirely cut out; so that the strength of the tree was employed only in nourishing useless branches, while the fruit-branches are thereby rendered so weak as not to be able to preserve themselves. (See Amugdalus.) But should the weakness of the tree proceed from an inbred distemper, it is the better way to remove the tree at first, and, after renewing the earth, plant a new one in its place. Or if your soil be a hot burning gravel or sand, in which your peachtrees are planted, you will generally find this to be the case, after their roots have got beyond the earth of your borders ; for which reason it is much more advisable to dig them np and plaut grapes, figs, apricots, or any other sort of fruit which may do well in such a soil, rather than to be annually disappointed of your hopes; for, by a variety of experiments, it has been found that apricots attract and imbibe moisture with a much greater force than peaches and nectarines, and consequently are better able to extract the nutritive particles from the earth, than the others which require to be planted in a generons soil, capable of affording them a sufficiency of nourishment without much difficulty : and it is in such places we often see peaches do wonders, especially if assisted by art ; but as for the vine and fig-tree, they perspire very slowly, and are very often in an imbibing state, so that a great part of that fine racy flavour, with which their fruits abound when planted in a dry soil, is probably owing to those refined aerial principles, which are collected when in a state of respiration; and therefore as these trees delight not in drawing much watery nourishment from the earth, so they will better succeed in such a soil, than in one that is more generous ; we should therefore always endeavour to suit the particular sorts of fruits to the nature of our soil, and not

if we consider how often it happens, that trees against the pretend to have all sorts of good fruit in the same ground. Same wall, exposed to the same aspect, and equally exploying the advantages of sun and air, with every other circumstance which might render them equally healthy, yet very often are observed to differ greatly in their strength and vigour; and digner that the other. Corlla: none. Stamina: filmental indeed we generally find the weak trees to be blighted, when the vigourson sones in the same situation shall escape very crect; anthere true. The fill germen ovate, acuminate; styles well ; which must therefore, in a great measure, be ascribed in the length of the stamen; stigmas simple. 16 Pericarp : capsule very thin (rather the crust of the seed) ovate, a little compressed, contained within the calix, now become a berry. Seed : single, globular, compressed the size of the capsule. ESSENTIAL CHARACTER. Calix: trifid. Petals; none. Seed ; one, with a berried calix. This genus consists of annual plants, which will drop their seeds if permitted, and the plants will come up in plenty the following spring : or if the seeds of either of the sorts are sown in March or April upon a bed of common earth, in an onen situation, the plants will come up in a month or five weeks after; and if they are to remain in the place where they are to be sown, will require no other care but to keep them clear from weeds, and to thin them out, so as to leave them six or eight inches apart ; and in July the plants will begin to shew their berries, when they will make a pretty appearance. But many people transplant them into the borders of the flower garden, and others plant them in pots, to have them ready for removing to court-yards, or to place upon low walls, among other annual flowers, to adorn those places. When plants are designed to be removed, they should be transplanted before they shoot up their flower-stems, for they will not bear transplanting well afterward : and if they are planted in pots, they will require to be duly watered in dry weather, otherwise the plants will stink, and will not grow to any size; and as the flower-stems advance they should be supported by sticks; for if they are not, the branches will fall to the ground when the berries are grown rather large and weighty .---- The species are.

BOC

1. Blitum Capitatum; Berry-headed Strawberry Blite. Heads spiked, terminal. This is commonly called strawberry blite, strawberry spinach, or bloody spinach; and by some berry-bearing orach .- Native of Switzerland, the Grisons, Austria, the Tyrol, Spain, and Portugal.

2. Blitum Virgatum; Slender-branched Strawberry Blite. Heads scattered, lateral .--- It seldom exceeds a foot high. Native of the south of France, Spain, Italy, and Tartary.

3. Blitum Tataricum. Leaves triangular, sharply toothed ; heads simple, lateral.

4. Blitum Chenopodioides. Heads in whorls, juiceless .--Native of Tartary, now in Sweden.

Blood Flower. See Hamanthus.

Bloodwort, or Bloody Dock. See Rumer.

Blue-Bottle, See Centaurea.

Bocconia : a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth twoleaved, ovate, obtuse, concave, caducous. Corolla: uone. Stamina: filamenta twelve, very short. Antheræ liuear, very large, the length of the calix. Pistil : germen roundish, contracted both ways, large, pedicelled; style one, bifid; stigmas simple, reflex. Pericarp : subovate, attenuated to each end, compressed, one-celled, two-valved; valves coriaceous, gaping from the base, the annular suture continuing ; crowned with the style. Seed : one, globular, the base involved in a pulp, fixed to the bottom of the capsule. ESSEN-TIAL CHARACTER. Calix: two-leaved. Corolla: none, Style : bifid. Berry : dry, one-seeded .---- The only known species is,

1. Bocconia Frutescens; Shrubby Bocconia, Tree Celandine, or Parrot-weed .- It is a shrub rising to the height of ten or twelve feet, with a straight trunk, as large as a man's arm, covered with a white smooth bark, and branched towards the top. The trunk is hollow, filled with a pith like the elder, abounding in a thick yellow juice, like celandine. It is propagated by seeds, which should be sown in a pot filled with light fresh earth, early in the spring, and plunged into a hot-bed of tanner's bark, observing to wa-15.

ter it now and then gently, otherwise the seeds will not grow, When the seeds are come up, they should he each transplanted into separate small pots, filled with light sandy earth. and plunged into the hot-bed again, observing to shade the glasses in the heat of the day, until the plants have taken root. They must be also gently watered, but it should be done sparingly while they are young; for the stems being very tender, and full of juice, will rot, if they receive too much moisture; but after their stems arc become woody, they will require it often, especially in hot weather, when also they should have a large share of air, by raising the glasses of the hot-bed. In two months after this transplantation, they will have filled these small pots with their roots; therefore they should be taken out of them and planted into pots one size larger, filled with light fresh earth, and plunged into the bark-stove, where they should have a good sharc of fresh air in warm weather. The singular beauty of this plant renders it worthy of a place in every curious collection. The juice is acrid, and is employed in the West Indies to take off tetters and warts. Native of Mexico, and the West India islands.

Boehmeria ; a genus of the class Monœcia, order Tetrandria .- GENERIC CHARACTER. Male, Flowers : in the same plant with the females, either distinct or mixed. Calix : perianth one-leafed, four-parted to the base : parts lanceolate, acute, somewhat erect, coloured. Corolla ; none. Nectary : noue. Stamina : filamenta four, longer than the calix, subulate, upright. Antheræ roundish, ovate. Pistil: a rudiment, or none. Female, Flowers. Calix : none ; but numerous, crowded, ovate, acuminate scales, Corolla : none. Pistil: germen ovate, between each scale, compressed ; style filiform, erect, permanent ; stigma simple, pubescent. Pericarp : none. Seed : roundish, compressed, mar-ESSENTIAL CHARACTER. Male, Calix : fourgined. parted, Corolla : none. Female, Calix : none, but crowded scales ; between each germen, obovate ; style single ; seed single, compressed .- The species arc,

1. Boehmeria Caudata. Leaves opposite, ovate, acute serrate; racemes very long, pendulous; flowers diæcous; stem suffruticose, --- Native of Jamaica.

2. Boehmeria Littoralis. Leaves opposite, ohovate, lanceolate serrate; flowers conglomerate, axillary, monocous, mixed; stem herbaceous, four cornered .- Native of Hispaniola.

3. Boehmeria Cylindrica. Leaves opposite, ovate, acuminate, serrate; racemes spiked, axillary, crect, simple .- Native of North America, and Jamaica.

4. Boehmeria Ramiflora. Leaves alternate, broad lauccolate, acuminate, serrate, wrinkled; flowers aggregate, axillary, and lateral monœcous, distinct; males three-stamined, - Native of the West India islands.

Boehmeria Hirta. Leaves alternate, ovate, acute, serrate hirsute; flowers monœcous, heaped, axillary, mixed .- Native of Jamaica.

Boerhavia ; a genus of the class Monandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oblong. tubular, and angular, placed beneath the corolla, with a contracted entire mouth, permanent, Corolla ; one-petalled, bell-shaped, upright, bluntly five-cleft, plaited, seated on the calix; nectary fleshy, subcylindric, with a toothletted mouth, surrounding the base of the germen. Stamina filamenta one, two, or three, inserted into the edge of the nectary, between the toothets, capillary at bottom, within the calix, more slender, upright, about the length of the corolla, Antheræ twin, globular. Pistil: germen roundish, pedicelled; the pedicel surrounded by the nectary; style filiform. twisted, the height of the stamina; stigma capitate, Peri-2Z

carp: none. Calix: enlarged, closed, incrusts the seed. Seed : one, oblong, obtuse-angular. ESSENTIAL CHARAC-TER. Calix : none. Corolla : one-petalled, bell-shaped, plaited. Seed : one, naked, inferior. Stamina : one, two, -The species are, or tree.-

BOM

1. Boerhavia Erecta; Upright Hogweed. Stem erect, smooth ; flowers two-stamined .- This was discovered at Vera Cruz, and in the Society Isles ; it is an annual plant.

2. Boerhavia Diffusa ; Spreading Hogweed. Stem smooth and even, diffused ; leaves ovate .- The flowers are purple, have only one stamen, and a twin anthera. Native of both Indies.

3. Boerhavia Hirsuta. Stem diffused, pubescent ; leaves ovate, repand .- Native of Jamaica.

4. Boerhavia Scandens; Climbing Hogweed. Stem erect; flowers two-stamined; leaves cordate, acute .- Native of Jamaica, especially about Spanish Town.

5. Bocrhavia Repens. Stem creeping .- Native of Nubia.

6 Boerhavia Angustifolia. Leaves linear, acute .-- Native place unknown.

7. Boerhavia Tetrandria. Stem creeping; flowers fourstamined .- Native of the Society Isles.

Bog-Rush. See Schanus.

Boletus, is characterized by Linnens as a horizontal fungus, porous, or punched with lobes underneath. In the Sus tema Nature, 14th Edition, only twenty-one species are recited; eleven of which are parasitical and stemless, the rest are stipitated. Mr. Hudson has thirteen species, five of which are not in Linneus, but chiefly from Schæffer, who has a vast many others not noticed by Linneus. From the Boletus Igniarius is prepared the Amadon, commonly used on the continent for tinder, to receive the spark struck from the steel by the flint; and the agaric, for stopping hæmorrhages in amputation.

Boltonia : a genus of the class Syngenesia, order Polygamia Superflua.-GENERIC CHARACTER. Calix: common, flattish, imbricate, with somewhat equal, linear, sharp scales. Corolla : compound, radiate; corollets, hermaphrodite, tubular, numerous in the hemispheric disk. Females, several in the ray. Proper of the hermaphrodite, funnel-form, five-cleft. Female : lincar, entire. Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil, in the hermaphrodites : germen oblong ; style filiform, length nearly of the hermaphrodite; stigmas two, revolute. Pericarp: none. Calix : unchanged. Seed, in the hermaphrodites : solitary, compressed, crowned, with a five-toothed margin: in the females extremely similar. Receptacle : naked, hemispheric. ESSENTIAL CHARACTER. Calix : common subimbricate, with linear scales. Corolla : radiate. Germina : compressed, vertical. Down : obscurely toothed, two-horned. Receptacle : honey-combed .---- The species are,

1. Boltonia Asteriodes ; Starwort-flowered Boltonia. Leaves quite entire .- Native of America.

2. Bombax Glastifolia; Glaucous-leaved Boltonia. Lower leaves serrate .- Native of America.

Bombax ; a genus of the class Monodelphia, order Polyandria. GENERIC CHARACTER. Calix : perianth one-leafed, tubular, campanulate, permanent ; mouth three or five-cleft, obtuse, erect. Corolla: five-parted, spreading; segments oblong, concave. Stamina: filamenta five or many, subulate, the length of the corolla, connate at the base. Antherae shot to their top. oblong, bent in, incumbent. Pistil : germen roundish. Style : filiform, the length of the stamina ; stigma capitate, five-toothed. Pericarp: capsule large, turbinate, oblong, before it branches, and is eighteen feet in thickn five-celled, five-valved; valves woody. Seeds: very many, abounds in Malabar, and is also a native of America.

round, woolly. Receptacle columnar, five-corneted, forming the partitions. ESSENTIAL CHARACTER. Calix: five-cleft. Stamina : five or more. Capsule : woody, five-eclled, fivevalved. Seeds : woolly. Receptacle : five-cornered .- The plants of this genus are all tender, and will not thrive in the open air in England; they are propagated by seeds, which must be sown on a hot-bed in the spring; and when the plants are fit to be removed, they should be each planted in a small pot. and plunged into the hot-bed, and treated as other tender exotic plants. Bombax, or silk-cotton, is propagated by seeds, which must be sown on a hot-bed in the spring ; if the seeds are good, the plants will appear in a month, and will be strong enough to transplant in a month after, when they should be each plauted in a small pot, filled with fresh loamy earth, and plunged into a moderate hot-bed of tanner's bark. being careful to shade them from the sun till they have taken fresh root; after which they should have a large share of fresh air admitted to them when the weather is warm, to prevent them from being drawn up weak; they must also be frequently refreshed with water, which must not be given in large quantities. In this bed they remain till autumn, provided there be room for the plants under the glasses, but if the heat of the bed decline, the tan should be stirred up, and fresh added to it; and if the plants have filled the pots with their roots, they should be shifted into pots a little larger; but there must be care taken not to overpot them, for nothing is more injurious to these plants than to be put into large pots. in which they will never thrive. In the autumn they must be removed into the bark-stove, where they must constantly remain, being too tender to thrive in this country in any other situation. In winter they must have but little wet, especially if they cast their leaves; but in the summer they should be frequently refreshed with water, and in warm weather must have plenty of fresh air admitted to them. With this management the plants will make great progress, and in a few years will reach the glasses on the top of the stove. They form an agreeable variety in a large stove, where they have room to grow, their leaves having a different appearance from most other plants; but as they are several years old before they flower in the countries where they grow naturally, there is little hopes of their producing any in Eugland .----The species are,

1. Bombax Pentandrum. Flowers five-stamined; leaves in sevens .- Native country unknown.

2. Bombax Ceiba. Flowers many-stamined; leaves quinate. -The canoes now made in the West Indies from this tree frequently carry from fifteen to twenty hogsheads of sugar, from six to twelve hundred weight each ; the average about twenty-five tons burden. When sawn into boards, and then well saturated with lime-water, the wood bears exposure to the weather many years; it is also formed into laths for roofs, curing-pots, and hogshead-heading. When the tree decays, it becomes a nest for the Macaca beetle, the caterpillar of which, gutted and fried, is esteemed by many persons one of the greatest delicacies. The down which is enclosed in the seed-vessels is seldom used, except by the poorer inhabitants to stuff pillows or chairs; and it is generally thought unwholesome to lie upon. It is a native of both Indies; and some modern writers have affirmed, that there are trees of the silkcotton now growing in the West Indies, so large as not to be fathomed by sixteen men, and so tall that an arrow cannot be

3. Bombax Heptaphyllum. Flowers many-stamined ; leaves seven fold .- This tree grows to the height of fifty feet before it branches, and is eighteen feet in thickness. It tomentose underneath .- Native of the Spanish West Indies, where the inhabitants spin the down enclosed in the pods, which is of a fine purple colour, and work it into garments, which they wear without dyeing.

Bonnetia : a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, five-parted; parts concave, acute, two larger. Corolla : petals five, ovate, somewhat obtuse, concave, longer than the calix, of which the three smaller are upright; the two larger declinate, gaping. Stamina : filamenta very many, inserted into the receptacle, shorter than the corolla, dilated at the tip. Antheræ oblong, tetragonal. Pistil: germen oblong, superior; style length of the germen, incurved; stigma three-lobed. Pericarp: capsule oblong, three-celled, three-valved ; valves sharp pointed. Seeds: very many, very small, oblong, involved in a coloured membrane, affixed to the three-sided receptacle. ESSENTIAL CHARACTER. Ca. lix : five-parted, two parts larger. Corolla : five-petalled, three smaller upright, two larger declinate. Capsule : oblong, three-celled, three-valved, many-seeded .---- The only known species, is,

1. Bonnetia Mahuria, which grows in marshy places in Cayenne and Guiana .- It is a tree of about fifteen feet high, branching chiefly towards the top ; the branches are upright in their growth; the leaves are alternate, smooth, ovate, and entire : the flowers are borne on terminal spikes, and are of a purple colour. In its native climate it flowers in August, and ripens its seeds in October.

Bentia ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth one-leafed, five parted ; leaflets blunt, upright, permanent. Corolla onepetalled, ringent; tube long, cylindric; border gaping; upper lip upright emarginate ; lower revolute, semitrifid, the size of the upper. Stamina : filamenta four, subulate, bending to the upper lip, the length of the corolla, two higher. Antheræ simple. Pistil : germen ovate ; style simple, situation and length of the stamina ; stigma bifid, blunt. Pericarp : drupe ovate, with the top oblique. Seed : nut-oval, one celled, germinating. ESSENTIAL CHARACTER. Calix: five-parted. Corolla: two-lipped, lower lip three-parted, revolute. Drupe: ovate, onc-seeded, with the end oblique. ---- The only known species is,

1. Bontia Daphnoides; Barbadoes Wild Olive. Leaves alternate; peduncles one flowered .- Birds grow fat upon the fruit, but unless the entrails are taken out as soon as the bird is killed, it becomes too bitter to be eaten. This plant is greatly cultivated in the gardens at Barbadoes, for making hedges, than which there is not any thing more proper for those hot countries, it being an evergreen and of quick growth. From cuttings planted in the rainy season, when they have immediately taken root, there has been a complete hedge, four or five feet high, in eighteen months : and as this will very well bear cutting, it is formed into a very close thick hedge, which makes a beautiful appearance. In Europe, it may be raised from seeds, which should be sown on a hot-bed early in the spring, that the plauts may acquire sufficient strength before winter. When they are come up, they must be transplanted out, each into a separate halfpenny pot, filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, observing to water and shade them until they have taken root; after which they must have a large share of air in warm weather, and be often refreshed with water. In winter they must be placed in the stove, where they should have a moderate degree of warmth, and but little water during that season. In summer they

4. Bombax Gossipinum. Leaves five-lobed, acuminate, | must have a great share of air, but will not do well if exposed abroad, especially in cold summers, so that they should remain in the stove among plants which require a great share of air, which may be admitted by opening the glasses in very hot weather. They may also be propagated by cuttings, which should be planted in summer.

Bonus Henricus. See Chenovodium.

Borage and Boraginoides. See Borago.

Borago ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calin: perianth five-parted, permanent. Corolla: monopetalous, rotate, length of the calix ; border five-parted, rotate, flat ; throat crowned with five emarginate obtuse prominences. Stamina: filamenta five, subulate, converging. Antheræ oblong, fixed to the inside of the filamenta in the middle, converging. Pistil: germen four; style filiform, longer than the stamina; stigma simple. Pericarp: none. Calix: larger, inflated. Seeds: four, roundish, wrinkled, keeled outwards at the top, globular at the base, inserted longitudinally into a hollow receptacle. ESSENTIAL CHARACTER. Corolla: rotated, throat closed with rays .---- The species are,

1. Borago Officinalis: Common Borage. All the leaves alternate; calices spreading .- The whole plant of common borage is rough, with white, stiff, prickly hairs; it is a biennial plant, flowering from May till August. It came originally from Aleppo, but is now naturalized in most parts of Europe; in England we frequently find it on dunghills and heaps of rubbish. It was formerly in great request, being reckoned one of the four cordial flowers. Very light, surely, (says an ingenious author,) were those sorrows which could be so driven away. The whole herb is succulent, and very mucilaginous, having a peculiarly faint smell when bruised : the juice affords a true nitre : the plant is now seldom taken inwardly, except as an ingredient in cool tankards: the young tender leaves may be used in salads, or as a potherb. A water distilled from the flowers of this plant was formerly in great esteem as a cordial and strengthener, but is very little regarded at present. It is, however, of a remarkably cooling nature, and consequently may be used with success, in inflammations of the eyes externally, and inwardly in burning fevers. The juice is good in obstinate coughs, catarrhs, hoarseness, and defluxions on the lungs: the flowers made into a conserve, are said to be good in putrid malignant fevers, and hypochondriacal complaints; likewise to remove obstructions, and cure the jaundice. This is an annual plant, which, if permitted to scatter its seeds, the plants will come up in plenty without care; the seeds may also be sown either in spring or autumn, but the latter season is preferable, on a spot of open ground where the plants are designed to remain; when the plants have obtained a little strength, the ground should be hoed to destroy the weeds, and the plants must be cut up where they are too near each other, leaving them eight or ten inches asunder: after this they require no farther care, unless the weeds should come up again; then the ground should be a second time hoed over to destroy them, which, if well performed, and in dry weather, will clear the ground from weeds, so that it will require no more clearing till the borage is decayed. The plants which are raised in the autumn, will flower in May; but those which arc raised in the spring, will not flower till June : so that where a continuation of the flowers is required, there should be a second sowing in the spring, about a month after the first ; this must be done upon a shady border, and in dry seasons the ground should be often watered

2. Borago Indica ; Indian Borage. Leaves of the ramifications opposite, stem-clasping ; peduncles one-flowered .- NaBOR

tive of the East Indies. The seeds of this, and the third and fourth species, should be sown upon a hot-bed in March. and when the plants are strong enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a new hot-bed to bring them forward, otherwise they will not perfect their seeds in this country : but in hot weather they must have a great share of air, otherwise they will draw up weak, and fail before the seeds are ripe.

3. Borago Africana ; African Borage. Leaves opposite, petiolate, ovate ; peduncles many-flowered ; corolla a dirty white .- Native of the Cape of Good Hope. See the second species.

4. Borago Zeylanica; Ceylon Borage. Branch-leaves alternate, sessile; peduncles one-flowered; calices carless .--Native of the East Indies. See the second species.

5. Borago Orientalis; Oriental Borage. Caliccs shorter than the tube of the corolla; leaves cordate .- Native of the country about Constantinople. It is easily propagated by the root, which may be parted in the autumn; it should have a dry soil and a warm situation, for as the flower-stalks appear early in the spring, when they are much exposed, they are often killed by the frost : if it be planted in dry rubbish, it will not grow too luxuriant, nor be in danger of suffering by the frost.

Borassus ; a genus of Palms (see the Appendix, Palmæ, of Linncus.)-GENERIC CHARACTER. Male Ampana. Calix: spathe universal, compound; spadix amentaceous, imbricate. Corolla: perianth proper three-leaved; leaflets ovate, concave, Stamina; filamenta six, thickish, Antheræ thicker, striated. Female Carimpana: on a different plant. Calix : spathe and spadix as in the male. Corolla : perianth proper three-leaved, permanent; leaflets roundish, obtuse; petals three, roundish, small, acute, permanent. Pistil: germen roundish; styles three, small; stigmas simple. Pericarp: berry (drupe) roundish, obtuse, rigid, one-celled. Seeds three, subovate, compressed, distinct, filamentose. Es-Corolla: three-parted. Male, SENTIAL CHARACTER. Stamina : six. Female Styles : three. Drupe : three-seeded .----- The only known species is,

1. Borassus Flabelliformis. Fronds palmate, plaited, cowled ; stipes serrate .- This tree is twenty five or thirty feet in height, two feet thick at bottom, and one at top. 'The fruit is the size of a child's head : a wine and sugar are made from the sap of this palm. It is a native of Ceylon, the coast of Coromandel, and Java.

Borbonia; a genus of the class Diadelphia, order Decan- cordate, many-nerved, quite entire. dria .- GENERIC CHARACTER. Calix: perianth one-leafed, semiquinquefid, turbinate, half the length of the corolla ; cordate, many-nerved, toothletted. divisions lanceolate, acuminate, rigid, pungent, subequal, the lowest longer than the rest. Corolla pentapetalous, papilionaceous, hirsute on the outside ; banner reflected, obtuse, claw the length of the calix; wings semicordate, a little shorter than the banner. Keel : two-petalled, lunulate, obtuse. Stamina : filamenta nine, united into a cylinder, gaping longitudinally above, rising at the ends. Antheræ small. Pistil: germen subulate; style very short, ascending; stigma obtuse, emarginate. Pericarp: legume roundish, acuminate, one-celled, mucronate, with a spine. Seed : kidneyform. ESSENTIAL CHARACTER. Calix: acuminate, spiny, Stigma : emarginate. Legume: mucronate .- The only method of propagating these plants in the country, has been that of laying down their shoots; but these are commonly two years before they put out roots fit to be separated from the old plant. In laying these down, the joint which is laid plants must be housed in winter. in the ground should be slit upward, as is practised in laying

carnations, and the bark of the tongue at bottom taken off. The best time is the beginning of September : and the shoots most proper for this purpose, are those which come out immediately from, or very near the root, and are of the same year's growth; not only from their situation being near the ground. and thereby better adapted for laying, but these are also more apt to put out roots than any of the upper branches. But where good seeds can be procured, that is the more eligible method of propagating the plants, for those raised from the secds make the straightest plants, and are quicker of growth. They should be sown in pots filled with light loamy carth, as soon as they are received; if it happens in the autumn, the pots should be plunged into an old bed of tanner's bark, under a frame, where they may remain all the winter, being careful that they are secured from frost, and have not much wet. In the spring the pots, should be plunged into a hot-bed, which will bring up the plants in five or six weeks. When these are fit to remove, they should be each planted into a small separate pot, filled with the like loamy earth, and plunged into a moderate hot-bed, observing to shade them until they have taken fresh root, as also to refresh them with water as they may require it. After this they must by degrees be inured to the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy the air and sun. During the winter season, these plants must be sparingly watered; but in summer, when they are placed abroad, they will require to be frequently refreshed, but must not have too much water given them at each time. These plants make a pretty variety in the greenhouse in winter, and as they do not require any artificial heat to preserve them, they are worthy of a place in every garden where there is a conveniency for keeping them. They are all natives of the Cape of Good Hope,----The species are,

1. Borbonia Ericifolia. Leaves sublinear, acute, villose: heads terminal.

2. Borbonia Lævigata. Leaves lanceolate, nerveless, smooth; involucres and calices rough with hairs.

3. Borbonia Trinervia. Leaves lanceolate, three-nerved, quite entire.

4. Borbonia Lanceolata; Spear-leaved Borbonia. Leaves lanceolate, many-nerved, quite entire. It flowers in August and September.

5. Borbonia Cordata ; Heart-leaved Borbonia. Leaves

G. Borbonia Crenata ; Notch-leaved Borbonia. Leaves

Borrago. See Borago.

Bosea ; a genus of the class Pentrandria, order Digynia .--GENERIC CHARACTER. Calix : perianth five-leaved, equal : leaflets roundish, concave, erect, thinner at the edge. Stamina : filamenta five, subulate, louger than the calix. Antheræ simple. Pistil: germen ovate, oblog, cuspidate; style none; stigma two. Pericarp: berry-globular. Seed: one, round, acuminate. ESSENTIAL CHARACTER. Calix: fiveleaved. Corolla : none. Berry : one-seeded .- The only species is.

1. Bosea Yervamora; Golden rod Tree .- This is a pretty strong woody shrub, with a stem as large as a middling person's leg. It is a native of the Canary Islands ; and has also been since found in some of the British West India Islauds. It may be propagated by cuttings in the spring; and the

Box-Thorn. See Lycium.

Box-Tree. See Buxus. Brabeium ; a genus of the class Polygamia, order Moucecia .- GENERIC CHARACTER. Calix : ament with ovate, obtuse, three-flowered, pubescent scales. Corolla : onepetalled, funnel-form, four-parted, deciduous, divisions linear, obtuse, rolled back at the top, deciduous. Stamina : filamenta four, capillary, inserted into the base of the segments of the corolla, and scarcely so long as that. Antheræ small, gaping on the sides. Pistil: germen very small, villose; style filiform, the length of the stamina, somewhat thicker at the top; stigma simple. Pericarp: drupe very dry, roundish, villose. Seed: nut-globular. Male in the same tree. Calix : ament as in the hermaphrodites. Corolla : one-petalled, funnel-form, four or five-cleft; clefts oblong, revolute, Stamina: filamenta four or five, inserted into the throat, of a middling length; antheræ oblong, fastened to the inside of the filamenta, except at the tip. Pistil: germen none; style filiform, of a middling length; stigmas two, erect. ESSENTIAL CHARACTER. Hermaphrodite : scales of the ameut. Corolla : four-parted, revolute above. Stamina : four. Pistil : one. Drupe : roundish. Seed : globular. Male: scales of the ament. Corolla: four or five-parted. Stamina : four inserted into the throat; style

bifid, abortive .- The only known species is, 1. Brabeium Stellulifolium ; African Almond .- Native of the Cape of Good Hope, where it becomes a tree of middling growth; but in Europe it seldom exceeds nine feet high. It is difficult to propagate this tree by lavers, which are often two years before they make roots strong enough to be taken from the old plants : when the branches are laid down, it will be a good method to slit them at a joint, as is practised in laying carnations; which will promote their taking root. They must have but little water, especially in winter, for as the young shoots are chiefly pith within, they are very apt to rot with much moisture. The best time to make the layers is in April, just as the plants are beginning to shoot; and they must always be of the former year's growth. The plants must have a good green-house in winter; but in summer they should be set abroad in a growth. sheltered situation, where they will thrive, and annually produce flowers in the spring, making a pretty variety among exotic plants.

Bradleja ; a genus of the class Monœcia, order Monadelphia .- GENERIC CHARACTER, Calix: none, Corolla: petals six, ovate, concave, spreading, nearly equal. Stamina: filamenta three, extremely minute. Antheræ cylindric, erect, formed of three united twin antheræ, tipped at the point with a cusp or spearlet. Female Flowers, Calix: none. Corolla : one-petalled, six-parted, inferior, three of the parts interior. Pistil: germen globose, six-furrowed, superior ; style none ; stigmas six to eight, very small, converging. Pericarp : capsule depressed, round, twelvestreaked, six-celled, six-valved, gaping. Seed : solitary, somewhat globose. ESSENTIAL CHARACTER. Male. Calix : none. Corolla : petals six, nearly equal ; filamenta three, with three twin antheræ. Female, Calix : none. Corolla: six-parted, there parts interior; germen superior, with six to eight stigmas. Capsule : six-celled, six-valved; seed solitary .---- The species are,

1. Bradleja Sinica; Chinese Bradleja. A shrub with leaves resembling the annona, but not of a lucid surface.

2. Bradleja Zeylanica. A Ceylonese shrub.

3. Bradleja Glochidium. A shrub which grows in the islands of the Southern or Pacific Ocean.

Brassica; a genus of the class Tetradynamia, order 16

leaved, erect; leaflets lanceolate, linear, concave channelled, gibbous at the base, erect, parallel, deciduous. Corolla: tetrapetalous, crnciform. Petals subovate, flat, expanding, entire, gradually lessening into claws nearly the length of the calix. Nectareous glands four, ovate ; of which one on each side between the shorter stamen and the pistil, and one on each side between the longer stamina and the calix. Stamina : filamenta six, subulate, erect; of these, two opposite ones are of the length of the calix, and four longer. Antheræ erect, acuminate. Pistil: germen columnar, the length of the stamina; style short, the thickness of the germen; stigma capitate, entire. Pericarp ; silique long, somewhat like the shaft of a column, but flatted on both sides ; partition with a prominent columnar top, two-celled, two-valved; valves shorter than the partition. Seeds : many, globular. EssEN-TIAL CHARACTER. Calix: erect, converging. Seeds: globular. A gland between the shorter stamina and the pistil, and between the longer and the calix,----The species are.

* Style bluntish.

1. Brassica Orientalis; Perfoliate Cabbage. Leaves cordate, stem-clasping, smooth; root-leaves scabrous, quite entire; siliques four-cornered .-- Native of corn-fields and cliffs in the Levant, about Montpellier ; in Germany, Switzerland, Austria, Carniola, Piedmont, &c. In England it is found near Harwich; Bardsey, near Orford, Suffolk; Godstone, and Maresfield, Sussex. Annual, flowering in June. This, with the second, third, fourth, and fifth species, may be propagated by sowing their seeds on a bed of light earth, early in the spring, in the place where they are designed to remain, for they do not bear transplanting well. When the plants are come up pretty strong, they should be so thinned as to leave them four or five inches apart, and they must be constantly kept clear from weeds. They will flower in June, and ripen seed in the beginning of August. If these be permitted to fall, the plants will come up, and maintain themselves without any further care. They are cultivated merely for curiosity.

2. Brassica Austriaca; Austrian Cabbage, Leaves cordate, stcm-clasping, smooth, all quite entire; siliques fourcornered, striated, erect .- Native of Austria. It is a biennial plant. For its culture and propagation, see the preceding.

3. Brassica Campestris; Yellow Field Cabbage. Root and stem slender; stem-leaves uniform, cordate, sessile. Root annual; corolla yellow, never white. For its culture and propagation, see the first species.

4. Brassica Arvensis; Purple Field Cabbage. Leaves stem-clasping, spatulate, repand; the upper cordate, quite entire -- Native of moist fields in the south of Europe. For its culture and propagation, see the first species.

5. Brassica Alpina; Alpine Cabbage. Stem-leaves cordate, sagittate, stem clasping ; radical leaves ovate ; petals erect. For its culture and propagation, see the first species .- Native of Germany and Sweden.

6. Brassica Napus; Wild Cabbage, Rape, or Navew. Root caulescent, fusiform .- The roots when cultivated may be eaten, but have a stronger taste than the turnip. It is much cultivated in the Isle of Ely, and some parts of England, under the title of Rape or Coleseed ; and in some parts of England for its seed, from which the rapeoil is drawn; and for feeding cattle. The residue, after the oil is expressed, is called oil-cake or rape-cake. It is a very efficacious manure, and is sold at from four to six pounds per ton. It is not this, but the lint-cake, or residuum of flax-seed, used in making linseed oil, that is used in fatting beasts. It grows among Siliquosa. - GENERIC CHARACTER. Caliz: perianth four- corn, and on ditch-banks. When it is cultivated for feeding 3 A

cattle, it should be sown about the middle of June. The ground should be prepared in the same manner as for turnips: the quantity of seeds for an acre of land is from six to eight pounds, and as the price of the seeds is not great, it is better to allow eight pounds ; for if the plants are too close in any part, they may be easily thinned when the ground is hoed. When the plants have put out six leaves they will be fit to hoe, which must be performed in the same manner as is practised for turnips, with this difference only, of leaving these much nearer together ; for as they have fibrous roots and slender stalks, they do not require near so much room. They should be hoed a second time, five or six weeks after the first, which if well performed in dry weather, will entirely destroy the weeds, and they will require no farther cul-By the middle of November these will be grown large ture. enough for feeding, when, if there is a scarcity of fodder, this may be either cut or fed down; but where there is not an immediate want of food, it had better be kept as a reserve for hard weather, or spring feed, when there may be a scarcity of other green food. If the heads are cut off, and the stalks left in the ground, they will shoot again early in the spring, and produce a good second crop in April, which may be either fed off, or permitted to run to seed, as is the practice where this is cultivated for the seeds : but if the first is fed down, there should be care taken that the cattle do not destroy their stems, or pull them out of the ground. As this plant is so hardy as not to be destroyed by frost, it is of great service in hard winters for feeding ewes; for when the ground is so hard frozen that turnips cannot be taken up, these plants may be cut off for a constant supply. In several places an acre of land, sown with this seed, has produced as much food as almost two acres of turnips; and this will afford late food, after the turnips are run to seed : one acre will produce as much as, at a moderate computation, will sell for five pounds, clear of charges. Partridges, pheasants, turkeys, and most other fowls, are very fond of this plant; so that wherever it is cultivated, if there are any birds in the neighbourhood, they will constantly lie among these The seeds are sown in gardens for winter and spring plants. salads, as it is one of the small salad herbs. Cole or rape is sometimes sown on fallow like turnips, sometimes on the stubble of an arable crop; it requires good land; very stiff clay does not suit it, and poor land is wholly unfit; but on the sward of old grazing grounds, on fen and marsh lands, it generally turns out the most profitable crop for seed, either immediately, or after flax. On old pastures the turf is pared aud burnt, and the ashes are spread generally with a mixture of lime. The seed is sown in July, early enough to get a strong leaf, and late enough to prevent its running up to stem the first autumn; the quantity of one gallon to an acre, generally on one ploughing, and brushed in with a thorn-harrow. The crop is seldom hoed or weeded. The vacant patches are filled up in October with plants from those parts which are over-stocked; this work is done by women : the plants seldom fail, but they ripen later than the others. When a large piece fails, the plough is sometimes used in transplanting ; the expense, four shillings an acre; namely, eight women at sixpence a day: would it not therefore be better to transplant the whole crop ? In the common method of culture, the whole tribe of biennial weeds have time to establish themselves before winter; and the crop not being reaped until July or August following, they have time to mature and shed their seed. The grasses and strong-rooted weeds of every kind, gain possession of the soil; which also gets out of tilth, by lying so long without ploughing. One ploughing the crop should be hoed, as above directed, and the vacant

grasses and strong-rooted weeds, and preserve the soil in tillage. Draw from the first land sufficient plants for the last land, and bury the roots in a vacant place until wanted. Plough the first land, burying the weeds and the refuse rape, and stock it at the same time with plants drawn from the second land. The first land being finished, supply the second with plants from the third, and so on, furnishing the last land with the plants in reserve. Thus the entire piece would have prime plants. equal in strength and regular in distance; the soil would be evenly occupied, and the crop would ripen equally; the hoe, and even the horse-hoe, might be used between the rows; and the foulest crop which farmers have to deal with, might, at a small expense, be rendered a fallow crop of the first estimation. In this management, the first or seed ploughing ought to be very shallow across the ridges; and the second or transplanting ploughing should be across the first; gathering up the ridges dry against winter. A manured fallow, a rich wheat stubble, or other land sufficiently clean and in heart, might be planted in a similar manner; raising plants for this purpose in a detached seed-bed. Rape is generally ripe in July, and is considered as fit for cutting when the forwardest of the seed has begun to turn black. It is cut with sickles, and laid in broad thin heaps upon the tops of the stubble, which is generally cut about a foot high, or as high as the lower branches will allow. It lies until the sap is pretty well dried out of the greenest pods, and the ripest are ready to open, and is commonly threshed in the field upon a cloth. It would be far better however to bind, shock, and carry it into the barn, threshing When rape it when markets and conveniency require. succeeds flax, the ground is cleared of weeds as soon as convenient; it is then ploughed four or five inches deep, and from half a peck to a peck of seed, according to the richness of the soil, is sown from a week before to a week after Michaelmas; it is usually well harrowed in, and if it grows into rough leaf before winter, i. ; considered as better than growing more, which would place it in danger of being destroyed by frost; no weeding takes place, and the crop will be ready about the middle of July. It is reaped, and laid on the ground in single haudfuls, and when dry, it is carried to the threshing-floor, on sledges covered with sailcloth. The crop is from three to seven quarters on an acre. The seed lost in reaping and getting in, produces a crop of green food for sheep, which is fed off early enough to prepare the ground for a second crop of flax. The straw is sold at two shillings an acre, to persons who burn it on the spot for the ashes. For immediate profit, and on old pastures broken up, rape or cole may be thus cultivated for seed; but on stubbles or fallows it answers better to feed it off with sheep, (the fat ones going over it first, and afterwards the lean or store sheep following,) in the autumn, but particularly in the spring, when there is frequently a scarcity of green food: this is an excellent preparation for either wheat or barley. It succeeds best on a deep soil, with good manure, and deep ploughing, and does best after beans, barley, oats, or wheat; it is sometimes sown after turnips or cabbages, which cannot be a right practice. When sown on a fallow, the land should be ploughed up soon after Christmas, and lie till the end of March : it should then be ploughed a second time, harrowed down, and a coat of manure laid on, as for turnips : when this is spread, the land should be crop-ploughed, and got into fine tilth by the end of June. The first rain after this, the seed should be sown, from two to four quarts an acre, according to circumstances, in the same manner with turnips, and the land should be lightly harrowed and rolled: in autumn would extirpate the biennial weeds, check the places filled up in October : many persons omit the hoeing

entirely, when it is intended only for feeding. Coleseed being | sometimes the contrary. The first earth or ploughing for an exhauster of land, should not be repeated oftener than every seventh year, and not so often when cultivated for the seed.

7. Brassica Rapa : Turnip. Root caulescent, orbicular, depressed, fleshy .- The variations of turnip are chiefly in the root, and arise from the different soils, situations, and modes of cultivation. The general use of this root, for the table and feeding of cattle, is well known; and it has been a considerable improvement of light lands, particularly in the county of Norfolk, whence other counties have derived the culture. Skilful farmers prefer the large green-topped turnip, because the roots grow to a large size, and continue much longer good; it also grows above ground more than any of the others, which renders it preferable for feeding cattle ; and being the softest and sweetest, even when very large, it is most esteemed for the kitchen. In very severe winters, however, this is in greater danger of suffering by frost, than those whose roots lie deeper, especially if the ground be not covered with snow; for when the roots are alternately frozen and thawed, they rot sooner than those which are more covered and less tender. Roots of this sort have been boiled when more than a foot in diameter, and ate as sweet and tender as any of the smallest that could be found. The next in goodness to the green-topped, is the red or purple-topped turnip, which will also grow large, and be extremely good for some time; but the roots will become stringy much sooner than the others. The long-rooted, the yellow, and the black rooted turnips, are now rarely cultivated for the sake of variety, none of them being so good for the table, or for seed, as the red and green-topped sorts. The early Dutch turnip is chiefly sown in the spring, to supply the table before the others can be procured; and when drawn off young, this sort is tolerably good, but if the roots be left to grow large, they become stringy, rank, and unfit for use. The French turnip is not much cultivated in England, but in France and Holland it is in great esteem, especially for soups, in which, being small, the roots are boiled whole : they must be used whilst they are young, otherwise they are rank and stringy. Turnip roots are reputed to relax the bowels, and to sweeten the blood ; to be hurtful to pregnant and hysteric women, and to all who are subject to flatulencies. The juice, well fermented, affords by distillation an ardent spirit: the riud is acrimonious. The tender tops boiled, are frequently eaten in the spring as greens with meat. Although the practice of sowing turnips for feeding cattle was evidently known to the ancients, it has only been of late adopted in Europe. The turnip delights in a light, sandy, loamy soil; in a rich soil the roots grow rank and are sticky, but if it be moist, they will thrive better in summer, especially in fresh land, where they are always sweeter than upon an old worn-out or rich soil. In field culture, a deep sand, such as has adhesion enough to make it of the value of from 5s. to 10s. au acre, is the best. If the land be wet or stiff, such as yields good wheat crops, the culture may not be advantageous, especially if used, as it should be, as a preparation for barley; on such soil it would shorten the crop at least two or three coombs an acre. Even blowing sands of 8s. 6d. or 2s. 6d. an acre, are to be preferred; for these, when folded, if the season should happen to be wet, yield profitable crops; indeed such lands are to be farmed no other way; for if no turnips are gained, no corn can be had, and a mere sheep-walk is then the only use that can be made of them. Where a farmer has no proper soil for turnips, it s more prudent to give up the winter-feeding of more cattle turnip, a small, hard, sweet root, which stands the winter with than his hay and straw will do for, unless he can depend on buying turnips, which may sometimes be advantageous, and signalar hardihood. In a common season, sow two pounds

6

land is foul, in which case it should be ploughed very shallow, in two-furrow ridges, and the second time to the full depth, but it should never be ploughed in wet weather. This second earth, for which frequently the farmer has not leisure, should be given before the spring seed-time, and will be very useful; for if there should be any spire or spear grass (quick, quich, or couch) in the land, that permicious weed is too apt to get a hold before barley sowing is over. Immediately after the barley is in the ground, the third earth should be given, this will be in May; the fourth, about the second week in June; and the fifth, or seed-earth, about the latter end of the same month : unless the soil be subject to the mildew. in which case Old Midsummer, the first week in July, will be full soon enough : and let it be observed, that harrowing with every earth is very necessary, for the surface should always be kept in fine friable order, that the seed-weeds may grow; whereas, if this be omitted till the seed-earth, they will then be grown so powerful as to smother many of the young plants. On a light dry soil, the turnip root is in a degree necessary; but where land will remain in grass, and where other arable crops are more certain and productive, it is less essential to good husbandry : in particular situations, however, under proper management, it may frequently be useful, and may be occasionally practised, on a small scale, in almost every situation. It may be very acceptable, therefore, to give the proper tillage of the turnip crop on rich retentive soils. If the land be foul, or if early sowing be proposed, break up in autumn, by a rice-balk or half-ploughing across the lands, gathering a bont in each interfurrow, and opening the cross trenches in order to lay the soil as dry as possible during the winter : but if the land be tolerably clean, and early sowing be not wanted, break up in the spring, in order that the roots and stems of grasses, &c. may remain in an undigested state, and assist in rendering a closely-textured soil loose, and fit to receive the weakly fibres of the seedling turnips : cross, and give the first stirring (the third ploughing) without previous harrowing; and if the root-weeds be not yet subdued, give a fourth ploughing before the harrows be suffered to come upon the land. Spread dung which is in a middle state on the rough plit; if too loug and strawy, it is pulled up by the harrows, and if wholly digested, it loses the valuable quality of rendering this retentive soil loose and open. As the dung is spread, harrow and roll, until the surface be perfectly reduced, and in this state let it lie until the seed-weeds have vegetated. Turn under the weeds, and manure, by a mean depth, or somewhat shallow ploughing; if not, harrow aud roll, letting another crop of seed-weeds spend themselves ; remembering that the stronger the seed-weeds are before they are ploughed under, the fitter the soil will be for the reception of the seedling turnips, especially if it be of a tenacious quality. Harrow immediately the plit of the seed-ploughing with rough harrows, in order to give a uniform looseness to the surface, as well as that the seed may be buried at an uniform depth. Sow, and immediately cover with one full tine of a pair of light harrows, and, if possible, with the horses trotting. For a crop to be eaten off in autumn, sow, in June, the tankard or pudding turnip, which has a rapid growth, but standing high above the ground, cannot bear the winter. For winter and spring feed, sow the common white loaf in July ; if these miscarry, or if stubble turnips be attempted, sow in August the stone

BRA

turnips should be given before Christmas, or certainly not

later, and should be of a common staple depth; unless the

BRA

the nearer the plants come up, the less danger there is of their being wholly cut off by insects ; but if these are known to be in force, or if any doubt arise, either as to the quality of the seed or the season, sow at least three pounds of seed to an acre; if the soil lie in broad rough lands, plough one, two, or even three bonts in each interfurrow, according to the width, height, and wetness of the lands, as soon as the seed-weeds have done vegetating; and if any root-weeds appear to be alive on the surface, or being dead, if any are likely to impede the hoe, pick them off, and cast them upon the intervals. If the first sowing miscarry, and the failure be fully ascertained, before the weeds have got too strong to be got out with rough harrows, harrow only before resowing ; but if the weeds have got fast hold of the soil, or if the season be too moist to obtain the intention by harrowing alone, plough a mean depth, and harrow, sow, and cover as before. On such soils the turnips cannot be fed off the lands without injury, even by sheep; nor can they well be carted off, except in light broad-wheeled carts, or on sledges: they may, however, be useful in stall-feeding bullocks, or given to sheep on a sound piece of pasture. Another method has been practised lately in cultivating turnips; which is, by sowing the seed in rows, with the drilled plough. In some places the rows have been sown three feet asunder, in others four, in some five, and some six. The latter has been commended by skilful persons as the most proper distance, for although the intervals are so large, yet the crop produced on an acre has been much greater than upon the same quantity of land where the rows have been but half this distance ; and upon all the fields which have been cultivated for turnips, the crops have greatly exceeded those which have been hand-hoed. In a trial which was made of these two methods of husbandry, the same field was divided into different lands, which were alternately sown in broadcast; the latter were hoed by hand in the common method, and the other cultivated by the hoeing plough; and when the roots were fully grown, an equal quantity of land, which had been sown in different methods, was measured, and their roots drawn up and weighed; and those roots which had been cultivated by the plough, were so much larger than the other, that the crop of one acre weighed a ton and a half more than that of an acre in the other husbandry. When the turnips are sown in drills, they will require to be hoed by hand, to separate and cut out the plants when they are too near together in the rows, as also to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus stirring the ground, and prepare it much better for the crop of barley, or whatever else is sown the following spring. This method of culture may be supposed to be more expensive than that commonly practised by those unacquainted with it; but those who have made trial of both, find the horse-hoeing to be much the cheapest, and by far the best, for the labourers who are employed in hand-hoeing turnips, are very apt to hurry over their work, so that half the weeds are left growing, and the plants are seldom singled out so well as they should be; nor are they curious enough to distinguish the charlock (which is one of the most common weeds in arable land) from the turnips ; so that about the middle of September, it is very common to see the fields of turnips full of the yellow flowers of the charlock. Now, in the horse-hoeing, all the weeds in the intervals will be entirely destroyed, or if a few plants of charlock in the rows should be overlooked, they may be easily drawn out afterwards, and by this method the land will be sooner tainty, on this soil than on any other. The sowing engine,

of seed on an acre, all upon the same surface; for perhaps and better cleared from weeds. The above advantages of drilling turnips have been confirmed from subsequent observations and experiments: the spaces between the rows will be hoed in half the time that would be required if sown in the common way; and when they come to be set out at proper distances in the rows, the superfluous plants may be cut out in one-third of the time usually required, and that by women and children, which is a considerable advantage. when the hoeing is to be done in the busy time of harvest, It is not the practice, nor does it seem to be any advantage, to set out the rows at a greater distance than from seven to eight, or ten to twelve inches. The difference in weight, on a given quantity of land, appears also to be considerably to the advantage of the drill culture, to the amount of one ton, three, four, or twelve hundreds ; two tons, five hundred ; and even three tons. But the principal advantage seems to consist in depositing the seed at a proper depth in the soil, namely, about two inches, where there is moisture, even in a dry season, to send the plants up in a few days; whereas, when they are sown broadcast in a time of drought, the seed may remain for several weeks waiting for raiu to make them vegetate, and the seed being all deposited at the same depth, will vegetate at the same time, and by getting into the rough leaf sooner, will stand a better chance of escaping the fly. No turnips, and consequently no barley after them, can be had without dung, and the crop in a great measure depends upon the quantity of it. The dependence for manure is chiefly on the fold or farm-yard, usually both. Of farm-yard dung, or else muck, that is, dung mixed with mould, marl, &c. not less than twelve loads should be spread on an acre. such as was made the precediug winter, and once turned over. The dung should neither be long nor quite rotten; the best condition is, when it is in such a state, that the labourers say it will neither spit nor fork. When the dung is rather long, and ploughed in with the seed-earth, the seed should be only rolled in. It is the custom with some farmers, to turn in the dung very shallow at the last ploughing but one, harrowing well to mix it with the soil, and they think it will ferment by the time the seed-earth is given to the land. It seems, however, to be the better method, to turn in the dung by the last ploughing or seed-earth, because it is then turned down, not by a shallow furrow, but covered as soon as possible from the sun, and deposited where the roots will be sure to find it, and where the immediate action of the sun and wind is excluded; whereas, in mixing the manure with the soil by the harrow, much of it is pulled out and exposed or the surface. Rough dung is in general preferred before such as is rotten ; a better crop, however, has been obtained by mixing dung with earth or other manure in the winter, and getting it rotten enough to lay at top, and harrow it ir with the seed, than by ploughing in long dung. Rape-cake in a pulverized state, is also recommended for turnip manure being reduced to powder by two mills, it is put into the drills. The quantity used to an acre, is a quarter of a ton, which has never exceeded 25s. in price. Others use malt-coombs, soot, soaper's ashes, lime, crag, &c. but none of these manures are very general, or so effectual as farm yard dung. The quantity of seed to be sown depends much on the soil; upon a naturally good turnip sand, a pint a acre, evenly delivered by a good hand or sowing engine, wil be enough; but in general two pints are allowed. No soi requires so much seed as chalky lands, when the chalk come quite to the surface : upon such soil a quarter of a peck wil seldom be too much for an acre, because the fly is sure t attack the plants more voraciously, and with greater cer

stopped by two seeds sticking in them, so that if the sower is not very attentive, he may go some distance without a regular delivery. The common season for sowing turnips, is any time from the beginning of June till the middle of August, or a little later, though it is not advisable to sow them much after, because if the antumn should not prove very mild, they will not have time to apple of a proper size hefore winter, nor will the roots of those which are sown after the end of July grow very large, unless the frost keeps off very long in autumn. But notwithstanding this is the general season in which the greatest part of the turnips are sown in the country, yet about London they are sown successively from March till August, by those who propagate them to supply the markets with their roots; but there is a great hazard of losing those which are sown early in the year, if the season should prove dry, by the fly, which will devour whole fields of this plant while young, so that where a small quantity for the supply of a family is wanted, it will be absolutely necessary to water them in dry weather: and where a person sows those seeds in April or May, it should always be upon a moist soil, otherwise they seldom come to good, the heat of the weather being too great for them at that season upon a dry soil; but those which are intended for the general crop, are sown towards the end of June, when they commonly receive some refreshing showers to bring them forward, without which it is very common to have them all destroyed. The season for field-sowing extends from a week before Midsummer, to the middle or end of July: this variation is necessary for two reasons; first, because the land cannot be all manured to sow early; and secondly, because the late-sown will last much longer than the early ones, which are subject to the blight or mildew, and consequently are more likely to be rotted by hard frosts afterwards, for which reason all farmers should take care to have some latesown. Sometimes a crop sown the first week in August, has proved the most profitable, this having escaped, whilst the rest has been killed by the frost. An active farmer, therefore, will, in cases where it is necessary, as soon as he has set up or shocked his wheat, plough up the intervals, and sow them immediately with turnips, for the chance of a late crop, which will furnish spring-feed, although they should fail of appling well. Where a farmer has many turnips, it does not seem a bad plan to sow a fourth part at the end of June, or the beginning of July, to come up early; half in the middle of July, for the main crop, and the remainder at the end of the same month to come late: this, however, must depend upon his business, the weather, and other contingencies. At any rate, the main crop should not be sown too soon, nor allowed too much room, because large roots will not stand the frost near so well as smaller ones. What is ploughed for the last earth should always be sown the same day, else, unless rain fall, the ground will be too dry for the seed to vegetate : the seed must be harrowed in as soon as it is sown with a short-tined harrow, and the ground rolled with a wooden roller to break the clods, and make the surface even : the plants will come up in ten days or a fortnight after sowing; but this will vary very much with the weather; and there will be a difference of three days between the germinating of new and old seed. When the plants have got four or five leaves, they should be hord. to destroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about six inches asunder each way, which will be room enough for the plants to stand for the first hoeing ; and the sooner this is performed when the plants have four leaves, the better they will thrive ; 16.

though with care a good tool, yet is liable to have the holes | but in the second hocing, which must be performed about a month after the first, they should be cut up so that the remaining plants may stand fourteen or sixteen inches distance or more, especially if they are designed for feeding cattle, for where the plants are allowed a good distance, the roots will be proportionably large, provided the ground is good, so that what is lost in number, will be overgained by their bulk : but in places where they are sown for the use of the kitchen, they need not be left at a greater distance than a foot, because large roots are not so generally esteemed for the table. The time for the first hoeing of field turnips is very uncertain, depending on the soil and the season, and varying from three to eight and nine weeks from the time of sowing : the size of the plants is the only guide, and the best rule is, to begin hoeing as soon as they are about the size of the palm of the hand, or spread upon the ground from three to four inches; if the hoe be put in too soon, the plants which are set out are liable to be buried, and their roots disturbed in setting out others which are near them ; and if the turnips be suffered to grow too large, it is difficult to set out the plants, and they are liable to be drawn up by weeds: if these be numerous or luxuriant, it will be necessary to begin hoeing somewhat earlier, in order to check them in time : some persons remove the ground with a light harrow once in a place, as soon as the plants are stout enough, to assist the hoeing; and if any of the fields after the hoeing begin to get too forward, which in a wet season is often the case, they give them a second harrowing the contrary way. Nothing but practice can teach the method of hoeing turnips; to be performed well, it requires a quickness of eye and a dexterity of hand which does not fall to the lot of very many. The hoe is generally drawn round the plant with a long sweeping stroke; and when the plants are small, then only that stroke ought to be used ; but when the plants are out of danger of being buried, a short straight stroke is more expeditious, and in some hands makes tolerably good work. The general effect of hoeing ought to be, that the whole ground should be stirred, all the weeds effectually cut up, and the plants set out singly at proper distances : the common practice is, to set out the plants at fourteen or fifteen, and sometimes at eighteen inches' distance ; this, however, is not always necessary, and is frequently injurious. The proper distance depends upon the soil, and the time of sowing; the richest soil will admit of the greatest distance, because the plants in that will be more luxuriant than in a soil of inferior quality; and early-sown turnips will come to a greater size than such as are sown late, and therefore should be allowed more room to spread themselves : the best general rule in this case is, to give the plants room to keep themselves in a state of vigour and full growth, without leaving any space unoccupied by, or even thinly filled with leaves. Since turnips, therefore, commonly run from four to eight inches in diameter, twelve inches may be taken as a proper medium distance, except in land of an extraordinary goodness. The main purpose of the second hoeing is to loosen the mould, and to draw it in some measure to the roots of the plants; to reduce the weeds effectually; and to single such plants as have been left double by the first hoeing, as well as to remove such as have been missed, or having been buried in the loose mould in moist weather, have struck root again in improper places. With respect to the time of the second hoeing, it ought to be given before the leaves become too large to prevent the plants from being properly singled and set out, or the weeds from being effectually cleared away; but the longer they stand before the last hoeing, the more effectually will the weeds be overcome. If when the 3 B

shew themselves, women and children should be sent in to pull them by hand. The second hoeing is sometimes omitted, but seldom without great detriment to the crop and the land; and, strange to tell, there are yet some parts of the kingdom wherein, it is said, hoeing of turnips is altogether omitted. Upon the whole, the object of the first hoeing should be, not so much that of setting out the plants at exact and wide distanees, as of checking the weeds, and thinning the plants, to prevent their crowding each other; the regulation of distances should be left in a great measure to the second hoeing: in the first, by reason of many accidents young turnip plants are liable to, it is a work of hazard and uncertainty; in the second, not only proper distances, but proper plants, may be chosen with a degree of safety and certainty. The Norfolk hoes are from nine to eleven inches wide. It is the interest of the hoer to work with a wide hoe, because he performs his work sooner, and has fewer plants to set out; his interest, therefore, is, in this case, in direct opposition to that of his employer. The width of the hoe ought to be in proportion to the medium distance between the plants, and that, it has already been observed, should be in proportion to their expected size : for twelve inches, a seven-inch hoe is sufficient. By sowing at different seasons, six men will hoe a hundred acres twiee over; such as do not vary the season, must of course proportionably increase the number. The price in Norfolk, is 6s. an acre for the two hoeings, when let jointly, as they commonly are; if let separately, the first is from 3s. 6d. to 4s.; the second, from 2s. to 2s. 6d. In other counties, 8s., 10s., and even 12s. an acre, are given for the two hoeings; but the Norfolk men are more expert in the business, and the soil of that county is more friable, and free from obstructions. In crops of drilled turnips, the work of hoeing may certainly be done cheaper, namely, from four to five shillings the acre; and cheaper still with the horse-hoe, when handhoeing will be required only in the rows. When turnips are sown in drills, it will be the best way to hoe between every other row first, and some time after to hoe the alternate intervals, by which method the plants will receive more benefit from the often stirring the ground, than they would do if all the intervals were hoed at one time, and the plants will be in less danger of suffering from the earth being thrown up too high on some rows, while others may be left too bare of earth; but when the earth has been thrown up on one side of the drill, it may be turned down again when the next interval is hoed, and this alternate moving of the earth will prepare the ground very well for the succeeding erop, as well as greatly improve the turnips; but as this plough cannot be well drawn nearer to the drills than two or three inches, the remaining ground should be forked to loosen the parts, and make way for the fibres of the roots to strike out into the intervals; otherwise, if the land be strong, it will become so hard in those places which are not stirred, as to stint the growth of the turnips, and this may be prevented at a small expense : a good hand will perform a great deal of this work in a day; and whoever will make the trial, will find their account in practising it, especially on all strong land, where the turnips are much more liable to suffer from the binding of the ground, than on a loose soil; but yet in all sorts of ground it will be of great service to practise this, When the ground is thus stirred in every part, one ploughing will be sufficient, after the turnips are eaten off the ground to prepare it for the sowing of barley or any other crop, so that there will be an advantage in this when the turnips are kept late on the ground, as will often be the case, especially when they are cultivated for the feeding of ewes, because it

turnips are so closed as to exclude all hoeing, any weeds still is often the middle of April before the ground will be cleared : for late feed in the spring, before the grass comes up, is the most wanted, where numbers of sheep and ewes may be maintained, and one acre of turnips will afford more feed than thirty acres of the best pasture at that season. The chief consumption of field turnips is for feeding either neat cattle or sheep ; the first is most common in Norfolk, and the second in most other counties. In feeding neat or black cattle, the most common practice is, to draw and cart off the whole crop; the time of drawing begins about Michaelmas, and continues until the plants are in blow. They are drawn by hand until the frost is in the ground, or has cut off the tops; they are then pulled by two-tined hooks, which in Norfolk they call crooms. When the roots are buried in a deep snow, it is removed by an implement called the snowsledge : the head-lands and side-lands are first cleared, and then they begin on one side, and clear the ground progressively for the plough : some leave the small roots to increase in size, and to throw out tops for feed in the spring; but this can be done only on land that will bring barley with one ploughing. The most common method of giving turnips to cattle, is by throwing them abroad on stubbles, grass-land, and fallows : the general practice is, to begin with the wheatstubbles, until they are broken up for fallow for barley. The next throwing ground is frequently the barley stubbles, until they in their turn are broken up for turnip-fallow. From about Christmas till the beginning of April the clover lays are thrown open ; and after these are shut up, the turnipfallows sometimes become the throwing place. In throwing turnips, the carts begin on one side of the land, and work regularly to the other, giving every part an equal share, and never throwing twice in the same place, until the whole is gone over. At the beginning of the season, whilst grass is still in plenty for the lean stock, the fatting cattle are kept constantly in the same piece, having a fresh supply of turnips every day, or every two days at farthest : but when the clover stubbles are cleared, and the store-beasts begin to want assistance from turnips, the fatting cattle are followed by rearing cattle, lean bullocks, cows, or store-sheep, to pick up their leavings. In this case it is convenient to have three shifts or pieces of throwing ground, one for the head beasts, one for the followers, and the third empty, to throw in : two pieces or divisions are indispensably necessary. The turnips should be thrown evenly and thinly, about a yard asunder, not in heaps or parcels; for whilst a bullock is breaking one turnip, he should not have it in his power to tread or dung upon another. The bullocks, sometimes, when the distance is not too great, are driven into the straw-yard at night, otherwise they have a little clean straw given them under the hedge, merely to clean their mouths from the dirt of the turnips: not one in ten of the highly-finished bullocks, that are annually sent to Smithfield market out of Norfolk, taste one handful of hay, or any other food beside turnips and barley straw, except such as are finished with ray-grass in the spring; and a few, that have a little hay and turnips towards spring, when the turnins are going off, before the ray-grass lays are ready to receive them; which is an excellent practice, bullocks being otherwise liable to receive a check between turnips and grass. It is evident that this method of throwing turnins cannot be practised except on dry land, and not even on that in a wet season ; in such cases, nothing but a sound old lay will answer the purpose; and, where it can be done, a farmer should contrive to have two such pieces in the neighbourhood of his turnips. Another method of fatting cattle is, to keep them loose in a straw-yard, giving them the turnips in close bins, or small cow-cribs, with boards or bars

BRA

187

nearly close at the bottom; the turnips are usually put in whole, being first tailed, that is, having their taproot cut off in the field, and also topped, unless the tops be fresh and palatable ; these, if eatable, being given to store-cattle. This method is somewhat more troublesome than that of throwing the turnips abroad ; which, if the soil be dry enough to bear stock, and so light as to be benefited by treading, is, upon the whole, the most eligible management. But in deep land, and in a wet or severe season, the yard, if it be kept dry and well littered, is the most comfortable place, especially if it he provided with open sheds for the cattle to take shelter under in inclement seasons. By this method the dung is lost abroad, which is highly serviceable to light land, but then a great quantity of manure is made in a yard well littered. A third method of fatting beasts on turnips is, to keep them tied up in hovels, or under open sheds, with troughs or mangers to receive the turnips, which are frequently chopped into slices, or else quartered, which is not so eligible. The top, with the crown of the root, is thrown aside for the storecattle, and the taproot with the bottom rind is suffered to drop on one side of the basket, so that the fatting cattle have only the prime part of the bulb. This accounts for the quick progress which shedding-bullocks sometimes make, especially in cold weather : but on account of the extraordinary attendance they require, not only in cutting the turnips, but in littering and cleaning out the stalls, besides the check they are liable to receive in close weather, this practice is seldom followed by large farmers, unless to push forward a particular beast : much depending on care and management in this method, little farmers, who have leisure and inclination to tend their own sheds, may find their account in it. The cattle have a little barley straw given them from time to time, to clean their mouths, and dry up the superfluous juice of the turnips. If the turnips could be boiled or baked at a moderate expense, a much smaller quantity would suffice to fatten the bullocks. In some places good hay is given with the turnips; and in others, pollard or barley meal. The second great application of turnips, is to feeding sheep. On the best turnip land, that is sufficiently dry, there is no better preparation for barley than feeding sheep with turnips upon the land. Those however which are eaten early in the winter will not give barley so good as those which are eaten later, provided they do not run to flower; for then they are supposed to exhaust the land, and injure the succeeding crop. Carting off from such land, besides the expense, is not advisable, the crop of barley depending on the manure and treading of the sheep. When the turnips are fed off the ground, the sheep should not be suffered to run over too much of it at one time; for if they are not confined by hurdles to as much as is sufficient for them one day, the sheep will spoil three times the quantity of turnips they can eat, so that it is very bad husbandry to give them too much room; therefore the hurdles should be once or twice every day removed forward; and if the turnips be drawn out of the ground before the sheep are turned into the new inclosure, there will be less waste made, for they will then eat up the whole roots ; whereas if they are turned upon the turnips growing, they will scoop the roots and leave the rinds, which being hollow, the urine of the sheep will lodge in them; so that when they are forked out of the ground, the sheep will not eat any of those roots which are thus tainted. When a flock of sheep are turned into a piece of standing turnips, the first thing they do is to run over the whole, and then to eat such of the tops as they have not trampled down. Whilst they are doing this, they stand upon the roots, which being firm in the ground, and flat in the top, are not incon-

venient to stand upon; and if one of their feet happen to fall near the edge of the turnip, it frequently barks and fouls the root. Whereas, if sheep be put upon drawn turnips, their tops may be injured, but their roots cannot; for being round, and lying loose on the ground, they afford no foothold, but become stumbling-blocks to the sheep, which therefore carefully avoid them, and stand upon the ground. But the better to avoid waste, it is frequently the practice, instead of hurdling the sheep upon the crop, to keep them back upon the cleared ground, and to throw the turnips upon it. But in this case the turnips must either be thrown in part over the ground already fouled by the sheep, or must be confined to the space from which they are drawn, by which means the principal intention of drawing is frustrated. Some farmers therefore, who fat large quantities both of neat cattle and sheep, pursue the following method in the consumption of their crop. The head-lands and side-lands being cleared, the area is drawn, and carried in alternate stripes about ten paces wide. The first drawing is expended on the bullocks in one or other of the ways already described; whilst the remaining stripes are drawn, and scattered over the whole ground for the shcep. The principal intention of drawing, (which is, to distribute the turnips evenly and thinly, so that whilst one is eaten another may not be soiled,) is thus obtained. It is a common error, that has generally prevailed among most persons, who are ill informed upon the subject, that the mutton fattened upon turnips is rank and ill-tasted ; whereas it is a known fact, that the best mutton this country affords is all fattened on turnips; and that rank mutton, the fat of which is yellow, is what the low marshy lands of Lincoln-shire, and other rank pastures, produce. Turnips are sometimes used for feeding milch cows, but this is a bad practice when the milk is used for making butter, which acquires a disagreeable taste from this root ; but it answers very well in suckling, as it keeps the cow in heart, and furnishes abundance of milk. Field turnips are sometimes sold, but it is not the general practice to raise turnips for this purpose; nevertheless every year some are sold. Little farmers who want conveniency or skill, and larger ones who want money to lay in a proper stock, or who from the comparative prices of stock and turnips judge it more eligible to sell them to feed, sell their turnips to those who have judgment, money, and spirit to buy stocks. Sale turnips are usually consumed on the premises. Sometimes the buyer and sometimes the seller draws the crop and tends the cattle, for which sometimes the one and sometimes the other finds straw. The medium price of a middling crop of turnips, is about fifty shillings' an acre; but the price is subject to great and sudden fluctuations. Raising of seed, is the third purpose to which turnips are applied. In order to sow good turnip-seed, transplant some of the fairest roots in February, place them at least two feet asunder each way, observing to keep the ground clear from weeds, until the turnips have spread so as to cover the ground, when they will prevent the weeds from growing; and when the seedpods are formed, you should carefully guard them against birds, otherwise they will devour them, especially when they are nearly ripe. When the seed is ripe, it should be cut up, and spread to dry in the sun; after which it may be threshed out, and preserved for use. It is generally understood that no turnip-seed is fit to be sown that has not been raised from transplanted roots; but in Norfolk it is thought that if the turnips be gathered from untransplanted roots, the turuips will become coarse-necked and foul-rooted, and the flesh of the root rigid and unpalatable; and that if they be gathered year after year from transplanted roots,

the necks will become too fine, and the fibres too few, the plants acquiring a weak delicate habit, and the produce, though sweet, being small : sweetness therefore, and not size. being the quality requisite for the table, it is a good rule for the gardener to raise his seed generally from transplanted roots. But it is the farmer's interest to avoid the two extremes of coarseness and delicacy, which can be accomplished only by sometimes transplanting his seed plants, and sometimes letting them run up in the seed-bed: and it is found by experience, that transplanting two, three, or four years, and letting the plants run up in the third, fourth, or fifth, will keep the stock in the desired state. The time of transplanting is from Old Christmas to Old Candlemas. The cleanest plants are the best, without much respect to size: a piece of good ground near a habitation is most proper for the purpose, because the plants can there be most easily defended from the depredations of the birds. It is of great consequence to secure seed of a good sort and quality, which cannot always be obtained from dealers; without care it will degenerate, and a mixed seed is too frequently sold : such persons therefore as are curious, should either raise it themselves, or have it raised by a neighbouring labourer, or at least procured from those on whom they can depend. The large green-topped turnip is the most productive, the sweetest, and most juicy; but the red or purple-topped is the hardiest. Admirably as the turnip is calculated for cleaning land, and feeding cattle and sheep. it is to be lamented that it is so liable to accidents and failures as not to be absolutely depended upon for these purposes. It has the fly, and many other enemies of the insect tribe, to contend with, in the early stage of its growth ; second and third sowings, which are frequent, seldom produce much more than the good spring-feed for sheep; alternate frosts and thaws rot the turnips before the season of greatest necessity arrives, or if they are not absolutely rotted, beasts fatten but ill on frozen turnins : if, on the contrary, the winter be mild, the turnips run to flower, and then the root has little substance in it. The turnip crop is precarious, principally because the farmer is obliged to depart from the common course of nature in accommodating it to his wants. Instead of putting the seed into the ground in the spring months, when there would be as great a certainty of a crop as of any other vegetable, he is obliged to defer sowing till the hottest season of the year comes on, when, unless he is so fortunate as to have a few rainy days, or cloudy weather with frequent showers, he can have little hope of success. The first enemy of the turnip is the fly, as it is commonly called ; or, as others name it, the flea; or, as it is provincially termed, the black dolphin. It is in fact a small insect of the coleopterous or beetle tribe, and is named by naturalists Chrusomela saltatoria. In hot summers it abounds to an amazing degree, and may be heard in a field or garden among the leaves of turnips, or any of the cabbage kind, making a pattering like rain from its continual skipping. This mischievous insect is not more than from one-twelith to one-tenth of an inch in length; it attacks the plant as soon as it appears above ground, whilst in the seedfeaf : and as soon as the rough leaves are put out strong, the plant is supposed to be safe from this enemy, which is calculated to destroy an entire crop once in five or six years, besides the partial damage which it does in most years. It has however a rival in mischief, the turnip bug, which becomes a small fly, about one-twentieth of an inch long, and not Harger than a grain of turnip seed. It is the same with the black bug, collier, or negro, with which beans are frequently infested, in some places termed smother fly. The bugs, or

fly in a larva state, frequently cover the under sides of the seed-leaves, and are of different colours, yellow, green, and black. When the seedling plants are infested with them, they make no progress, nor any visible effort to get into rough leaf; fifty of these vermin have been counted under one pair of seed-leaves, sucking the juices through their long probosces. The smallest of the flies, or aphides, are of a cream colour, the next green, the next to these reddish green, and the largest black. The destruction, however, which is imputed to the fly, or (to speak more properly) to the turnip beetle, sometimes seems to originate in the season. When the soil is fully and permanently moistened by a steeping rain, the seed will vegetate, the plants will push into rough leaf, and rise without a check, though the beetle and their other insect enemies be in full force : but if the turnips have only showers to depend upon in hot dry weather, the seed will vegetate, but by the time the seed-leaves are formed, the moisture is wholly drawn off by the intervening days of drought; and the plants, deprived of nourishment, pass away, parched up as in an oven. The injury however which is done by the fly being confessedly great, many remedies have been proposed for it, although it is much to be feared that they are by no means effectual. Some good, it is said, may be done by running a light roller over the crop, with a bundle of blackthorn fastened behind it. Branches of elder are recommended to be drawn over the turnips in the same manner; and the seed is directed to be soaked in the juice of the bruised leaves. But these are palliatives at best, and have been found to be utterly ineffectual. Some recommend the land to be fumigated, by burning heaps of quick, and other weeds, to windward, when it is ready for sowing, and after the seed is come up; whilst others prescribe a steep for the seed, of train or other oil, in which it is to be immersed twenty-four hours or more; when the seed is drained from the oil, it is to be mixed with good earth finely sifted, and sown immediately; when the plants begin to appear, the ground is to be sown with soot, from eight to sixteen bushels the acre. Soot is very generally recommended as a specific against the fly; so also is tobacco dust, but this can be applied only in small crops, such as are grown in gardens. We are told to shake the seed in a bottle with flower of brimstone, and to sow them together; or to steep it in water strongly impregnated with brimstone or horsealoes. A much more likely way than any of these to secure a good plant of turnips, is, after having made the land clean and fine, as soon as the weather will permit, to sow two, three, and even four pints of seed upon an acre, in suspicious seasons: thus having a sufficient quantity of plants for the fly and the crop. In case the fly does not take them, it may be said that the plants will be so thick that they cannot easily be hoed ; they may however be made fit for the hoe by harrowing them first; and, at any rate, it is a less evil to have too much work for the hoe, than little or no crop. Another method of securing a crop, is sowing seed that will germinate at different times. This may be done by mixing new and old seed together, and by soaking half of each in water, or the drainings of a dunghill, for half an hour, and then spreading it on a floor until it is dry enough for sowing. Thus there will be four chances for a crop, as the seed thus mixed and prepared will come up at four different times. Or, sow immediately after the plough without harrowing, and then the seed, lying at different depths, will come up at several times, and consequently have several chances of escaping the fly or turnip beetle. It is very sensibly remarked by Mr. Miller, that whatever will add vigour to the young plants will prevent their being destroyed by the fly, for these never

attack them until they are stinted in their growth. Good tillage therefore, and having the land in heart, is of more consequence to prevent the ravages of the fly, than all the nostrums that have been published. The provident farmer will, as far as he can, watch for favourable opportunities to sow his seed ; and he had better defer sowing, than do it when the weather is hot and dry. He will have his land in proper order ; he will be at the pains of procuring good seed new, if he can get it; and he will sow a sufficient quantity : but above all, he will lay in a proper quantity of manure, to promote the growth of the young plants, and to push them forward as fast as possible. It is this purpose which is answered by dressings of ashes, soot, composts of lime and dung, &c. in sufficient quantities; either sown with the seed, or rather immediately before, well harrowed in, and completely incorporated with the soil. There is some doubt, however, respecting the expediency of dunging largely for turnips. One says, the only available precaution against the fly, consists in ploughing the land till it is very fine, and filling it with muck ; whilst others are of opinion that the flies are increased by the dung, which certainly is a nest for a great variety of insects. Folding may perhaps be better than the dunging, the treading of the sheep both destroying the insects, and rendering light land more firm. In seasons wherein apprehensions of the fly are entertained. it is recommended to plough for sowing, as soon as it is light in the morning, only so much land as can be sown and harrowed by six o'clock ; and about six in the evening again to plough as much as can be sown and harrowed before dark. The seed being thus sown while there is some moisture in the newly-ploughed ground, will vegetate sooner, and come up more regularly, than it would do if the ground were dry. If the season should prove dry, the ground should be well looked over; and when the young plants begin to be attacked by the fly, the land should be strewed all over with vegetable ashes, and the night following it should be rolled. If rain come on in a day or two after, the turnips will soon be out of danger, by the rain washing the salts of the ashes to their roots : if not, in a week's time a fresh dressing of ashes, with rolling, should again be applied. Where wood or peat ashes are not to be had in plenty, the farmer ought to raise a quantity for the purpose, from burning quick and other weeds, or turf, litter, furze, heath, fern, &c. Or if he has only a small quantity of ashes, he may have recourse to a compost of these with soaper's ashes, coal-ashes, quick-lime, and soot, mixed well by turning them two or three times, and passing them through a sieve : it is scarcely necessary to add, that the ashes should be kept in a dry place. When large patches are irrecoverably gone, it is best to plow immediately, and sow again, har-rowing in the seed. The early stone turnip is recommended for this purpose, because it comes to maturity sooner than the common sort, and may be sown twenty days after the first sowing. The bug fly, or aphis, is by no means so tremendous an enemy as the beetle : being extremely soft and tender, and therefore easily crushed, a light roller, especially if it were muffled in some soft elastic covering, so as to press in between the clods, might perhaps be effectual in destroying these insects, without injuring the plants. Another danger of the crops being destroyed is from the caterpillars, which very often attack them when they are grown so large as to have six or eight leaves on a plant ; the surest method of destroying these insects, is to turn a large parcel of poultry into the field, which should be kent hungry, and turned in early in the morning; these fowls will soon devour the insects, and clear the turnips. The 16.

turnips sown in drills are not so much exposed to this evil, for as the ground between the rows will be kept stirred, the plants will be kept growing, and will not be in danger of suffering from these insects; for the parent insects never deposit their eggs upon any plants which are in health, but as soon as they become stinty, they are immediately covered with their eggs; so that it is the disease which occasions the vermin, and not the vermin the disease, as is commonly imagined : therefore as the plants will always be in greater health when the ground is well stirred about them, there will be less danger of their suffering from these enemies when they are cultivated by the horse-shoe, than by the common way. These caterpillars are provincially called black cankers; they are not so universal as the fly or turnip beetle, but their ravages, though partial, are in some seasons very great, especially near the sea-coast. Many remedies have been proposed against this destructive insect; as, drawing a rope over the ridges, two persons holding the ends; this will brush the caterpillars off, and perhaps may save a few acres, where it can be frequently repeated, and the insects are not very numerous. It is an improvement upon this expedient to fasten twigs upon the rope, for which purpose elder twigs have been preferred, but certainly without sufficient reason. Stiff crooked boughs will injure and tear the plants. Others draw a brush made of furze over the turnips ; the branches are fixed to a long pole or axle-tree, with a wheel at each end, of such a height that the furze will brush the plants without pulling them up by the roots. This mischief might be prevented, if the inhabitants of the sea-coast would burn the flies on their arrival, when they are spent with their flight, and frequently may be taken up by shovels-full. Another enemy to turnips, and to the garden in general, as well as to flax, wheat, &c. is the naked snail, or *slug*. This, however, is a triffing evil in comparison with the others. Slugs abound most in wet seasons, when the fly is least prevalent, and chiefly on fresh ground and bad fallows. The only remedy prescribed, is night-rolling, when the dew is upon the ground. The wire or red worm, is also complained of as injurious to turnips, as well as to the gardens in general, particularly by those who pursue the drill culture. The grub is perhaps in itself not fatal, did not the rooks, in order to come at it, pull up not only the plants which are attacked, but those also which are free from it, and thus clear them as they go. There is a disease to which turnips are subject, called the anbury or hanbery. It is a large excrescence, which forms itself below the bulb or apple, grows to the size of both the hands, and when brought to maturity becomes putrid, and smells very offensively: it is irregular in its form, with excrescences, like races of ginger, hanging to it. The tops of those turnips which are much affected, turn yellow, and flag with the heat of the sun. It is a common notion that this disease is caused by the soil's being tired of turnips; that is, by their being sown too often on the same land. Now this is erroneous, for the anbury appears on land which has never borne turnips before. It is more probable that it is caused by some grub or insect, that diverts the course of the sap by wounding the vessels of the taproot. In Norfolk, marle is esteemed a certain preventive of the anbury. The last enemy to be mentioned, is severe frost, which usually destroys the sown turnips, and much injures the late ones. The only method of counteracting this evil is to preserve or store up a certain quantity of turnips, in case of frost or a deep snow, This may be done by drawing them in dry weather, when they have attained their full growth; topping and tailing them ; and carting the roots into an adjoining new-made dry 3 C

ditch, first covering them with straw, and then with hurdles or faggots from the cattle; or still better by stacking them in the field with lavers of straw between, covered and thatched with straw; either on the ground, or, if the land will bear it, in beds or pits dug one or two feet deep, or more, three yards wide, and of what length you want them. If straw be scarce, old haulin or stubble will answer the purpose. Or else, to carry them home, and pile them in small stacks in a clean home pasture, or near the vard; or, to house them where there is room, always screening them with straw, and putting some between the layers to absorb the moisture. This practice not only preserves some turnips from the rot, and furnishes cattle and sheep with feed, in time of the greatest distress; but prevents the crop from exhausting and impoverishing the land, and gives time for preparing it for the succeeding crop of barley. After all, the provident farmer will not absolutely depend upon his turnip crop, for feed late in the spring; but have in reserve some cabbages, coleworts, rye, or winter tares, according to his convenience and the nature of his land; not only to guard against failures in his turnip-crop from frost, &c. but to have some provision for the couples, by the time the lambs begin to feed, which will put them on much faster than the best turnips. A square perch of turnips, which is sixteen fect and a half, drilled in rows three feet apart, has been found to contain eighty-four roots, weighing seven hundred two quarters ; which is sixty tous to a statute acre: eighty-four turnips picked within fifteen yards of the above perch, weighed eighteen hundred three quarters seventeen pounds ; which is one hundred and twenty-six tons nine hundred and twenty pounds to an acre.

8. Brassica Oleracea; Common Cabbage. Root caules-cent, columnar, fleshy .- The cabbage, as it is found wild on the shores of Britain, has the stem-leaves very much waved, and variously indented, the colour sea-green, frequently with a mixture of purple; the lower leaves somewhat ovate and sessile, the upper almost linear; the flowers are large. Early in the spring, the sea-cabbage is preferable to the cultivated sorts; but when it is gathered on the coast, it must be boiled in two waters, to take away the saltness. When old, it is said to occasion giddiness. The roots may also be eaten, but they are not so tender as those of the turnip aud navew. The varieties, which all originate from this, may be reduced to three general divisions : the first comprehending those which grow in the natural way, without forming the leaves or stalks into a head. This division, besides the sea-cabbage, or wild colewort, would comprehend the green colewort, the borecoles, and turnip-cabbage. Secondly, those which form the leaves into a head, as the white cabbage, the red, the savoy, &c. Thirdly, those which form their stalks into a head, as the cauliflower, and the different varieties of broccoli. The first division might be subdivided into the wild. with broad leaves and an even stem : the turnip cabbage, with broad leaves and a protuberant stem; and the borecoles, with fine cut leaves and an even stem. The second division contains the cabbages commonly so called : as, the red, the numerous varieties of the white, such as the sugar-loaf, the early, the foreign musk, the small Russia, the large-sided, the flattopped, the Yorkshire, Scotch, American, &c. &c. and those with wrinkled leaves, as the common savoy, the green savoy, &c. Of the borccoles in the first, and the broccoli in the third section, there is also a variation in colour; the purple, and the white. The common colewort, or Dorsetshire kale, is now almost lost near London, where the markets are usually supplied with cabbage plants, which are more tender and delicate, instead of them. The common colewort is 10

indeed better able to resist the cold in severe winters ; but it is not good till it has been pinched by frost, and our winters being generally temperate, cabbage plants are now constantly brought to market; which, if they be of the sugar-loaf kind, are the sweetest greens from December to April, yet known. Indeed, where farmers sow coleworts to feed their milch cattle in the spring, in case of a scarcity of herbage, the common colewort is to be preferred, because no frost will destroy it. The curled colewort, or borecoles, are more generally esteemed than the common one, being, like that, so hardy as never to be injured by cold, and at the same time much more tender and delicate; these, however, are always sweeter in severe winters than in mild seasons. Of the heading cabbage, the red is chiefly cultivated for pickling; the common white, flat, long-sided, and savoy, for winter use. The musk cabbage is almost lost, although for eating it is one of the best we have ; but being tenderer than many other sorts, it is not so profitable for market gardeners; such, however, as cultivate for their own tables, should make choice of this rather than any of the common cabbages, for it is always looser, the leaves are more crisp and tender, and it has a most agreeable musky scent when cut. The early and sugar loaf cabbages are generally sown for summer use, and are commonly called Michaelmas cabbages. The Russian cabbage was formerly in much greater csteem than at present, it being now only to be found in particular gentlemen's gardens, and rarely brought to market. The other varicties are chiefly cultivated for feeding cattle, but they are undoubtedly a very exhausting crop. The Germans cut cabbages in pieces, and, with some aromatic herbs and salt, press them close in a tub, where they soon ferment, and are then eaten under the name of sour crout. In this state they are much recommended against the sea-scurvy; indeed cabbages in general are esteemed a salubrious aliment in the putrid scurvy; they are laxative, aud produce flatulencies, but the laxative matter is extracted by long boiling. The white cabbage is the most putrescible, aud the red most emollient. The canliflower was first brought to England from the island of Cyprus, since which it has been greatly improved. Purple and white broccoli are only varieties of the cauliflower. The following are the methods of propagating and cultivating the different kinds of cabbages. Colewort seeds should be sown in July, in an open spot of ground, and transplanted, as soon as the leaves are two or three inches broad, into rows a foot asunder, and six inches distant in the rows; the rows may be drawn alternately for coleworts, and the remainder left to cabbage. To continue them for spring drawing, they should be sown again at the beginning of August. In the field culture of coleworts, the best method is to sow the seeds, nine pounds to an acre, about the beginning of July, choosing a moist season, which will bring up the plants in about ten days or a fortnight: when they have got five or six leaves they should be hoed, as is practised for turnips, cutting down all the weeds from among the plants, and thinning them where they are too thick; but they should be kept thicker than turnips, because they are more in danger of being destroyed by the fiy : this work should be performed in dry weather, that the weeds may be killed, for if it should prove moist soon after, the weeds will take root again, and render the work of little use. About six weeks after, the plants should have a second hoeing, which, if carefully performed in dry weather, will entirely destroy the weeds, and make the ground clean, so that they will require no further culture. In the spring, they may either be drawn up and carried out to feed the cattle, or the cattle may be
101

turned in to feed upon them as they stand; but the former | they should be pricked out into shady borders, about three method is to be preferred, because there will be little waste; whereas, when the cattle are turned in amongst the plants, they will tread down and destroy more than they eat, especially if they are not fenced off by hurdles. The perennial colewort is also little cultivated in the gardens near London at present : this is very hardy, and may be cultivated in the same manner as the former sort ; this will continue two years before it runs up to seed, and will afterwards produce many side-shoots, and in poor land will continue three or four years. but in rich soils it will not last so long. This may be used as the former sort, to feed cattle, for it is not so good for the table (unless in very severe frost) as the plants which are now cultivated for that purpose. The early and sugar-loaf cabbages, are commonly sown for summer use, and are called by the gardeners about London, Michaelmas cabbages; the season for sowing these is about the end of July, or beginning of August, in an open spot of ground; and when the plants have got eight leaves, you must prick them into beds at about three inches' distance every way, that they may grow strong, and short-shanked ; and in the middle of October, you should plant them out for good ; the distance that these require, is three feet from row to row, and two feet and a half asunder in the rows: the gardeners near London commonly plant these cabbages upon the same spot of ground where their winter spinach is sown, so that when the spinach is cleared off in the spring, the ground will have a crop of cabbages upon it ; you must therefore clear off the spinach just round each plant early in the spring, that with a hoe you may draw the earth up to the stem, and when all your spinach is cleared off, which is commonly in the beginning of April, you must hoe down all the weeds, and draw up the earth again about your cabbage plants. In May, if your plants were of the early kind, they will turn in their leaves for cabbaging, at which time the gardeners near London, in order to obtain them a little sooner, tie in their leaves close, with a slender osier twig, to blanch their middle; by which means they have them at least a fortnight sooner than they could have if they were left untied. Fewest of the early kind should be planted, for they will not supply the kitchen long, generally cabbaging apace when they begin, and soon grow hard and burst open ; but the sugar loaf kind is longer before it comes, and is as slow in its cabbaging, and being of a hollow kind, will continue good for a long time. It has been known, that a large quarter of ground, which was planted with this sort of cabbage for market use, has afforded a supply for nearly three months together. It may be planted out in February, and will succeed as well if planted earlier, with this difference only, that the plants will be later before they cabbage. Some plants of the early sort should also be reserved in some well-sheltered spot, as a supply in case of failure, for in mild winters many of the plants run to seed, cspecially when sown too early, and in severe winters they are often destroyed. The Russian cabbage must be sown late in the spring, and managed as above directed, with this difference only, that it must be finally planted out sooner, must have an open clear spot of ground, and requires much less room, being a very small hard cabbage; it will be fit for use in July or August, but will not continue long before it breaks and runs up to seed ; the way to have this sort good, is to procure fresh seeds every year from abroad, for it soon degenerates in England. The common white, red, flat, and long-sided cabbages, are chiefly cultivated for winter use ; the seeds of these sorts must be sown at the end of March or beginning of April, in beds of good fresh earth; and in May, when the young plants will have about eight leaves,

inches square, that they may acquire strength, and to prevent their growing long-shanked : about the beginning of June, you must transplant them out where they are altogether to remain, which, in the kitchen-gardens near London, is commonly between cauliflowers or artichokes, at about two fect and a half distance in the rows ; but if they are planted for a full crop in a clear spot of ground, the distance from row to row should be three fect and a hair, and in the rows two feet and a half asunder; if the season should prove dry when they are transplanted out, they must be watered every other evening, until they have taken fresh root ; and afterwards, as the plants advance in height, the carth should be drawn about their stems with a hoe, which will keep the earth moist about their roots, and greatly strengthen the plants. Weeds, if suffered to grow among them, will draw them up tall, and often spoil them. Some of these cabbages will be fit for use soon after Michaelmas, and will continue until the end of February, if they are not destroyed by bad weather; to prevent which, the gardeners near London pull up their cabbages in November, and trench their ground up in ridges, laying their cabbages as closely as possible against one side of their ridges, burying their stems in the ground : in this manner they let them remain till after Christmas, when they cut them for the market; and, although the outer part of the cabbage be decayed, (as is often the case in very wet or hard winters,) yet, if the cabbages were large and hard when laid, the inside will remain sound. The savoy cabbage is also cultivated for winter use. being best when pinched by frost : it must be sown about the middle of April, and treated as the common white cabbage, except that it may be planted closer, two feet and a half square being sufficient. This sort should have an open situation, clear of trees and hedges; for in close places it is very subject to be eaten by caterpillars and other vermin. especially if the autumn prove dry. If early savoys are desired, some seed must be sown sooner, as in March, February, or autumn. The autumn-raised plants will be very large. and in order for the table from the end of August, through September and October. The musk cabbage may be cultivated in the same manner as the common cabbage, and the plants set out at the same distance; it is in use from the beginning of October until Christmas, and is apt to suffer in very severe winters. With respect to the field culture of cabbages, the sorts most commonly cultivated for feeding cattle, are, the Scotch, the drum-head, and the American. The first, if it be the true flat-topped firm sort, is never affected by frost, a few of the outside leaves excepted. The true drum-head is said to be hardy, and the heaviest of any for the size; it may be planted closer than the large American : it is called the tallow-loaf in some places, and being too tender to bear very sharp frost, a mixed stock has been procured, by planting this and the common red cabbage together, and when the seed-pods were formed, cutting down the red, and leaving the other for seed : this mongrel is of a deep-green colour, with purple veius, retains the size of the drum-head, and has acquired the hardness of the red cabbage. The American comes to a great size, and lasts good very late in the spring : there are many varieties, as, the flat, Dutch, Yorkshire, &c. and the same variety is known under several names in different parts of the country. The cabbage culture is best adapted to strong land, and comes peculiarly in aid to the farmer, who cannot to much purpose avail himself of turnips. It succeeds admirably on a rich, moist, friable loam. The tillage for cabbages differs very little from that which is given for turnips; they are commonly, 192

planted on stubbles, after wheat, barley, oats, or beans : the land is ploughed up at Michaelmas, hes till spring, is then ploughed again three or four times; is manured with from fifteen to twenty-three loads of dung, or else with from twenty to thirty loads of compost, to an acre, before the last ploughing, which lays the land in three-feet ridges, towards the end of May or the beginning of June, in which state it must be left for rain, to enable the farmer to plant. Some persons spread the dung upon the stubble, and bury it with the first ploughing; because, if the weather should set in dry at the time of planting, the dung opens the soil too much, lets in the drought, and thus destroys, or at least stunts the plants. The best method of raising, is to sow the seeds as early in the spring as the weather will permit, (the end of February, or beginning of March,) upon good land, well sheltered, digged, and dunged, on beds from four to five feet wide, for the conveniency of cleaning them, and destroying the fly. Plants may be thus obtained, of sufficient strength to plant out by the third or fourth week in May, at the latest; and these plants will be in perfection by the third week in October, and will continue to the end of March, or the middle of April. The best seed, sown upon a poor soil without dung, will produce many runaway plants: these are also frequently spoiled by being sown too thick : an ounce and half of seed on a bed fourteen yards long, and five feet wide, will, allowing for all accidents, produce two thousand good plants : half a pound of seed is fully sufficient to produce plants for an acre; or a pound of seed, sown on ten rods of land, may do for three acres, according to the goodness of the land, and the season : seven thousand plants are fully sufficient for an acre. Though spring plants are most commonly reputed the best for general use, not so much on account of their size as their duration : (because the slugs are apt to destroy much of the autumn sowing, in winter; and because, by good management, as large and heavy a cabbage may be produced from spring sowing ;) yet some persons are attached to sowing in autumn, about the middle of August; and pricking the plants out into a warm place, where they may be sheltered from very severe frost : they may be thus planted out in May, whereas the spring-sown ones can hardly ever be planted out till near Midsummer, perhaps in a dry time, when they will be scorched up, and are scarcely ever so large : it is to be considered, however, that the great use of cabbages is for feed late in the spring, when the early-sown will be run up to seed. Some persons prick out the young springsown plants from the seed-bed, which is certainly an advantage to them, but is attended with too much expense and trouble to those who cultivate this crop on a large scale. As to planting, that operation depends upon the weather, and may be performed as soon after the middle of May as that will admit; but it is vain to attempt it until there has been a ground rain, and then it must be done as quickly as possible : the plants are commonly set in one row on each ridge, at the distance of two or three feet, or, according to some, of four; most persons plant them two feet and a half asunder in the rows ; some are for small distances, as two feet, or eighteen inches; others are for larger, as three feet; the distance ought, however, to be regulated by the size of the cabbage, and the strength of the soil : they should be planted wide enough to admit of being cleared with the plough, and yet so near as to afford a full crop. It must be a great advantage, on land that will admit of it, to plant them at equal distances every way, so that the plough may pass crosswise as well as longwise, between the rows, in cleaning

rolled on the plants, in ploughing between the rows, are removed. About three weeks after planting, taking the opportunity of rain, replant whatever vacancies may have arisen from failures. Cabbages are applied to feeding milch cows, to fattening bullocks, sheep, and swine; we have not heard of their being given to horses; and yet it is probable, that either alone, or mixed with chaff, or cut-meat, they might he a valuable horse-feed. They are very generally and successfully applied to feeding milch-cows, in the great dairy farms of High Suffolk ; where they have eight or ten acres of the great Scotch and American cabbage, to forty cows; and in some parts they are of opinion, that one good acre of cabbages will do for seven or eight cows, yielding as much food as three acres of turnips, and making the cows give more and better butter. A more common proportion, however, is, four cows to an acre, without hay or straw, and six or seven with straw and some hay : one acre and one rood, producing forty-five tons of cabbages, fed nine cows and a bull thirteen weeks and two days. The report concerning the effect of cabbages upon milk, is different; some asserting that the butter is as bad as from turnips; others, that they yield not only more milk, but better butter. Cabbages are also reputed excellent for weanling calves; turnips being apt to give them the garget, which cabbages never do. In fattening beasts, three-quarters of an acre of a middling crop, will do for two beasts of fifty stone each, that have had the summer grass, A middling bullock will eat two hundred pounds of cabbages in twenty-four hours, and therefore a score may be kept on an acre for nearly a month, if the crop be tolerably good. Fifteen fatting oxen, nine hundred weight each when fat, were kept from the fifth of November to the thirty-first of December, that is, eight weeks, on two acres of antumpsown cabbages, with the addition of four tons of hay: upon the whole, an acre of eabbages is supposed to fatten one beast in four more than turnips, and all in two-thirds of the time. Another circumstance of consequence to the grazier, is, that they are said to have a remarkable effect in laying on the fat on the grazier's points. With respect to sheep, one of twenty pounds a quarter, will eat fifteen pounds of cabbage in twenty-four hours ; one acre, therefore, will nearly maintain two hundred sheep a month, if it be a good crop. Thirteen fat wethers, who had nothing else to eat, except what they picked up, in open weather, on a bare grass-field, consumed one load in a week, that is, in the proportion of an acre to twenty-six sheep, for one hundred and twenty days, or more than sixteen weeks. When the autumn-sown plants run up to seed in April, sheep will eat every morsel of them clean up, when they will not touch a turnip. When the plants are suffered to run up, that part of the land should have a light dressing of pidgeon-dung, soot, or malt-dust, to make it amends for supporting the cabbage-stalks so much longer. Hogs do very well on cabbages, and prefer them to turnips; for when they get into a field containing both, they constantly take to the former, and will scarcely touch the latter : by sowing early in the spring, or by sowing some in autumn, a succession of cabbages may be obtained, from the third week in October, or a month after Michaelmas, to the end of March; or, if desired, even to the middle or end of April: they ought, however, in the general opinion, to be off by the middle of March, because they then shoot, and exhaust the land. How valuable, therefore, must this crop be, thus adapted as it is to feeding milch kine, bullocks, sheep, &c. and which is in perfection during the months of February, March, and part of April; when the anxiety of them. In the common practice, the rows are kept clean by farmers, particularly of those who keep large flocks for a hand-hoeing; and at the same time, any clods that may have supply of food, is at the height! On moist soils, turnips,

however valuable they may be, are so much affected by the

193

vicissitudes of the season, as to be a very uncertain provision; for how often does it happen, that after a year's fallow, an ample and expensive manuring, great care to prevent the ravages of the fly, slug, caterpillar, &c. unremitting attention to the hoers, and altogether an expense of from three to five pounds an acre, one sharp frost succeeding a wet season, in the months of January or February, destroys all the farmer's hopes, and leaves his flocks or bullocks destitute of food when they want it most; or reduces him to the necessity of feeding them on hay, which perhaps is so dear as to devour all his profits. Now, cabbages are by no means so liable to these accidents, for unless a long-continued drought succeed the planting out, they are in a manner a certain crop, neither frost nor snow will materially injure it; and, as a farther recommendation, it is more grateful to the consumers. The dung of the cattle fed upon cabbages is better, and more in quantity, than when they are fed on turnips. They are an excellent preparation for barley and oats, as well as turnips; or if they be, as some think, in a small degree inferior in that respect, it ought to be considered, that the crop in itself is more valuable, being worth from four to seven pounds an acre. The accidents to which cabbages are liable, are, first, to be destroyed in the seed-bed by the beetle or fly, as well as turnips: but in this situation, these insects are easily destroyed, by sowing wood ashes, soot, &c. the moment they appear; and at the same time the plants are invigorated by the dressing. They are, secondly, attacked both in the seed-bed and by the caterpillar of the papilio brassicæ, or cabbage butterfly; this insect, though destructive to the plants in general, is of little consequence in field culture, because it comes too late to injure the seed-bed; and if the plants prosper after they are set out, they become so strong and numerous as to set it at defiance. Au easy method of arresting their progress, is to turn up the leaves, wherever the white butterflies are observed to be busy about the plants, and rub off the eggs, which they deposit along the ribs of them, with the back of the knife, which operation is performed in a very short time, whereas this picking of the caterpillars, after they are hatched and dispersed, is very tedious. The slug, that common enemy to all crops, attacks the cabbage, but is by no means so injurious to it as to the turnip, because it stands up above his reach. From frost cabbages sustain little or no damage, if they be of a hardy sort, a few of the outside leaves excepted. There is a disease to which cabbages are subject, which is, the roots becoming swollen or knobbed, and the plant at the same time smaller. It is occasioned by grubs, which are the large of flies, and is incident chiefly to such cabbages as are sown or planted for several years together on the same land. It does not, therefore, affect the field-culture, unless the seedbed should be continued on the same piece: the two principal objections to the field-culture of cabbages are, the impoverishment of the land, and the difficulty of carting them off. That it is an exhausting crop, is generally allowed, and that it is much more so than turnips ; a gentleman, however, who has given it repeated trials for twelve years, on a wet clayey loam, declares himself fully assured, that it does not impoverish the soil, but, on the contrary, meliorates and cleans the land to which it is adapted, better than turnips, One acre of his cabbages is often worth three, and sometimes four, acres of adjoining turnips, on land five shillings an acre better than his. The average crop of cabbage is twentysix tons; of barley after it, thirty-seven bushels; of wheat, thirty bushels; of oats, sixty bushels; of clover, when mown,

remarking. The cabbages being disposed of, by carrying the best to the cows and other cattle in the straw-yard, and folding ewes and lambs upon the remainder in March and April: the land is sown with barley and clover: the autumn following, the clover is broken up, and set with wheat; the year after, oats are sown upon the wheat stubble; and at Michaelmas following, from twelve to fourteen loads of compost being ploughed in the May or June after, cabbages are again planted. Another great advantage of cabbages is: by their being planted on four-furrow work, the land lies drier, and works better for barley or oats, than turnip-land ; there is always mould to sow in spring, after feeding off with sheep, which is by no means the case in the same sort of land with turnips : if the season be wet when they are feeding, and sets in dry in seed-time, it is not possible to get the seed in properly. Many are inclined to attribute the exhausting of land by cabbages, to the practice of leaving the stalks in the ground, which throw out sprouts, and thus draw the land, when the effect of the crops ought entirely to have ceased ; but if we should allow, (what, however, some dispute,) that barley after turnips is better, by eight bushels an acre, than after cabbages ; yet, if one acre of cabbages be more valuable, as is commonly thought, than two acres of turnips, there will be a gain upon the whole; it is found, however, that to ensure a good crop of barley, the cabbages should not be taken off too late. As the crop cannot be fed upon the land by heavy cattle, this occasions an expense to cart it off, which also damages the land, by cutting it up and poaching it in a dreadful manner. The turnips, however, are most damaged, because they are on straches nearly flat; whereas the cabbages being on three-feet ridges, the poaching is chiefly in the furrows, and no part of the crop which is left for the sheep is injured; the carting also is done at half the expense. and the food is cleaner for the stock. If broad arched ridges were used, all the carting being in the furrows alone, the productive part of the field would be secure from injury, in the case both of cabbages and turnips. The manner of cultivating the turnip-cabbage, and the turnip-rooted cabbage, is, to sow the seeds in April, on a bed of light fresh earth. and when the plants are an inch high, they should be transplanted into a shady border, at two inches' distance every way, kept clean from weeds, and watered till they have taken root : if the season should prove extremely dry, they should be watered afterwards, every four or five days, to prevent the mildew. In the beginning of June, they should be transplanted where they are to remain, at two feet distance every way, and watered till they have taken root. As their stems advance, draw the earth up to them with a hoe, but not too high, so as to cover the globular part which is eaten. To cultivate these plants in the field, sow a pound of seed early in March, for every three acres intended to be planted ; prepare the land by three or four earths, the first given at Michaelmas; before the last earth, manure as for turnips: finish the whole ready for planting by the first week in June, The first ground rain after that, set all hands to planting, the rows two feet asunder, and the plants twelve inches apart in good land, and eighteen in poorer soils; plough the intervals three times, and keep the rows perfectly clear by hand-hoeing. When the plants are to be taken up, plough the rows without a coulter, and a round share with a blunt edge. Every farmer should cultivate so much of this root. as will ensure him provision for his cattle and sheep three or four weeks in the latter end of the spring, unless he be otherwise provided. The Swedish turnip, or roota baga, is of the same nature with those, and equally hardy; the twice three tons from an acre : this course of crops is worth root is sweet and firm, being nearly twice as heavy as one of 3 D

our turnips of the same size : when dressed for the table, it is preferred to ours, and is particularly grateful to all sorts of cattle ; hares and pheasants will take it, and leave cabbages and common turnips untouched; and the culture and application of it are the same as that of the latter,-The Borecole, or Fringed Cabbage : of this sort the varieties are ; 1. Green-curled. 2. Red-curled. 3. Thick-leaved curled. 4. Finely fringed. 5. Siberian or Scotch kale. All these plants bear our severest winter, are a useful reserve for the table in such seasons, and then eat very sweet and tender, for before they are frost-bitten they are tough and bitter. They may be cultivated in the same manner as winter cabbages, but they need not be planted above one foot asunder in the rows, and these need not be more than at two feet distance. The seeds of the Siberian borecole may be sown in the beginning of July; and when the plants are strong enough, they should be set in rows eighteen inches asunder. and ten inches distant in the rows ; this work must be done in a moist time; they will be fit for use after Christmas, and continue good till April. Green borecole is also a very useful green food for sheep, because it is not only hardy, but growing three feet high, it may at all times be got at by the animals in deep snows, which frequently cause them to suffer much for want of food : it may be cultivated exactly as above directed for the turnip-cabbage .- Cauliflower. This kind of cabbage is continued for several months together, but the most common season for the crop is in May, June, and July. Having procured a parcel of good seed of an early kind, you must sow it about the middle of August, upon an old cucumber or melon bed, sifting a little earth over the seeds, about a quarter of an inch thick ; and, if the weather should prove extremely hot and dry, you should shade the bed with mats, to prevent them from drying too fast, which would endanger the spoiling of your seed ; and give it gentle waterings, as you may see occasion. In about a week's time, your plants will appear above ground, when you must take off your coverings by degrees, but do not expose them too much to the open sun at first : in about a month's time after sowing, your plants will be fit to prick out, you should therefore put some fresh earth upon your old cucumber or melon beds; or where these are not to be had, some beds should be made with a little new dung, which should be trodden down close, to prevent the worms from getting through it; but it should not be hot dung, which would be hurtful to the plants at this season, especially if it prove very hot : into this bed you should prick your young plants at about two inches square, observing to shade and water them at first planting; but do not water them too much after they are growing, nor suffer them to receive too much rain if the season should prove wet, which would be apt to make them black-shanked, as the gardeners term it, which is no less than a fatal rottenness in their stems. In this bed they should continue till the end of October, when they must be removed into the places where they are to remain during the winter season; you should also be provided with another more late kind, which should be sown four or five days after the other, and managed in the same way .- Broccoli. The seeds of the broccoli, of which there are several kinds, viz. the Roman or purple, the Neapolitan or white, and the black broccoli, with some others, of which the Roman is chiefly preferred, should. be sown about the latter end of May or beginning of June, in a moist soil ; and when the plants are grown to have eight leaves, transplant them into beds, as was directed for the common cabbage, and towards the middle of July they will be fit to plant out finally, which should be in some wellsheltered spot of ground, but not under the drip of trees : gynia.-GENERIC CHARACTER. Calix : perianth five-

8

the distance these require, is about a foot and a half in the rows, and two feet row from row : the soil in which they should be planted, ought to be rather light than heavy, such as that of the kitchen-gardens near London; if the plants succeed well, as they generally do unless the winter be extreinely severe, they will begin to show their small heads, which are somewhat like a cauliflower, but of a purple colour, about the end of December, and will continue eatable till the middle of April. In order to have broccoli produce well, transplant it into the alleys of your onion, carrot, &c. beds, the beginning of July; preserving it from snails, and hilling it up, it will produce more noble heads in January and February, and will furnish the table until it is quite over. By sowing very early in the spring, the most forward will succeed the autumnal-sown crops, and keep up by that means a constant succession.

9. Brassica Chinensis; Chinese Cabbage, Leaves oval. almost quite entire, the floral ones stem-clasping, lanceolate: calices longer than the claw of the petals .- Native of China : flowers yellow, like those of the common cabbage; even when it has been frozen, it was much worse than the common colewort, and is therefore not worth propagating.

10. Brassica Violacea. Leaves lanceolate-ovate, smooth, undivided, toothed .- Native of China.

11. Brassica Polymorpha. Inferior ; leaves linear, lanceolate, pinnatifid, toothed, upper subulate, entire .- Annual ; a native of Siberia.

** Erucas with an ensiform Style to the Siliques.

12. Brassica Erucastrum; Wild Rocket. Leaves runcinate; stem hispid; siliques smooth and even; root annual, fusiform .- Native of the southern countries of Europe, in sandy fields, by way-sides, and on walls; flowering from June till August.

13. Brassica Eruca ; Garden Rocket. Leaves lyrate ; stem hirsute ; siliques smooth ; root annual .- Native of Switzerland, Austria, and Piedmont. It was formerly much cultivated in the gardens as a salad herb, but at present is little known, having been long rejected on account of its strong ungrateful smell; it is esteemed as a strong dinretic. When this is propagated for salads, the seeds should be sown in drills, in the same manner as is practised for other small salad herbs, but if it be not eaten young, it will be too strong for most palates. When sown in summer, the plants soon run up to seed, and are too rank ; when cultivated for the seed, which is sometimes used in medicine, it should be sown in March, on an open spot of ground ; and when the plants have put out four leaves, they should be hoed to three or four inches' distance, and have a second hoeing in five or six weeks afterwards. When the seeds are ripe, the plants should be drawn up; they require no other culture but to thin them, and keep them clear from weeds.

14. Brassica Vesicaria. Leaves runcinate ; siliques hispid, covered with a swelling calix : root annual, spindleshaped .- Native of Spain and Aleppo.

15. Brassica Muralis; Wall Rocket. Leaves lanceolate, sinuate, serrate, smoothish; stem erect, smooth .- It grows on old buildings and walls, in many parts of England; as, at Yarmouth, Chester, Taunton Castle, Litchfield Close, Bristol, Exeter, Berwick, and plentifully in and about London: it flowers during the greatest part of the summer.

16. Brassica Richerii. Root caulescent ; leaves petiolate, subserrate, upper linear-lanceolate, entire ; siliques four-cornered .-- Native of the south of France, and the mountains of Piedmont.

Brathys; a genus of the class Polyandria, order Penta-

Jegyed ; leaffets hanceohate, acute, permanent. Corolla: per tals fice, lanceohate, quite as long as the calix. Attamina: filamenta many, more than twenty, capillary, the length of the calix. Antherae twin. Pistil: germen superior, ovate; tayles five, patalous, filiform; stigmas capitate. Pericary: capsale ovate, with five little swellings, one-celled. Seeds: very many, roundish. EssENTIAL CRARCTER. Calix: five-leaved. Petals: five. Nectary: none. Capital: onecelled, many-seeded.—The only known species is,

 Brathys Juniperium.—This shrub is of a habit between heath and juniper, very branching and upright, the branches covered with leaves; leaves opposite, very much crowled, accrose, an inch long, acute, unarmed, evergreen; flowers terminating, the branches several together, sessile.—Found by Mutis in New Granada.

Bread-fruit Tree. See Artocarpus.

Bread-nut Tree. See Brosimum.

Breynia ; a genus of the class Polygamia, order Diæcia. -GENERIC CHARACTER. Hermaphrodite flowers, Calix: perianth one-leafed, turbinate, minute, six-parted ; parts concave, blunt, closely converging, depressed, flat at the end, so that it is pervious only by a small hole. Corolla: none. Stamina: filamenta none. Antheræ five, linear, upright, fastened longitudinally to the style, approximating. Pistil: germen very small; style cylindric, the length of the calix; stigma blunt. Pericarp ; berry dry, globular, three-celled, propped in the perianth, now become three times its former size, and spreading very much ; the segments orbiculate, and nearly equal. Seeds: two, convex at the back, flat on the sides. Male Flowers, Calix: perianth one-leafed, five-parted ; leaflets roundish, concave, almost equal. Corolla: none. Nectary five glands, subpedicelled, alternate with the stamina. Stamina : filamenta five, very short. Antheræ roundish, the length of the calix. Female Flowers, Calix and Corolla: as in the male. Pistil: germen globose; style none; stigmas five, obcordate, resembling petals. Pericarp: capsule five-celled. Seeds : solitary, subtriquetrous. ESSEN-TIAL CHARACTER. Calix: one-leafed. Corolla: none. Hermaphrodite. Calix: six-parted. Antheræ five, linear, fastened to the style ; berry three celled ; seeds two. Male, Calix : five-parted ; filamenta five ; antheræ roundish. Female : stigmas five, obcordate, petaloid, without any style. Capsule five-celled ; seed solitary .---- The only known species, is,

1. Breynia Disticha.—Native of New Caledonia, and the isle of Tanna in the South Seas.

Briony. See Bryonia.

Britannica. See Rumex.

Briza; a genus of the class Triandria, order Digynia .--GENERIC CHARACTER. Calix: glume many-flowered, bivalve, spreading, collecting the flowers into a heart-shaped distich spike ; valves heart-shaped, concave, equal, obtuse. Corolla: bivalve; lower valve the size and figure of the calix; upper very small, flat, roundish, inclosing the body of the other. Nectary two leaved ; leaflets linear, crenulate, Stamina : filamenta three, capillary. Antheræ oblong. Pistil: germen roundish; styles two, capillary, recurved; stigmas plumose. Pericarp; none. Corolla: unchanged, contains the seed, gapes, and drops it. Seed : one, roundish, compressed, very small. ESSENTIAL CHARACTER. Colix: bivalve, many-flowered; spikelet distich, with heart-shaped obtuse valves, the lower of which is minute. If the seeds of this genus be sown in the autumn, or be suffered to scatter themselves, the plauts will come up much stronger, and flower much earlier, than when they are sown in the spring .---- The species are,

 Briza Minor; Small Quaking Grass. Spikelets triangular; caits longer than the seven floscules,—"This is annual. Native of Germany, Switzerland, the south of France, Italy, and Britain; flowers from June till August.

BRO

2. Briza Virens; Green Quaking Grass. Spikelets ovate; calix equal to the seven floscules.—It is an annual; native of the Levant, Spain, and the county of Nice, flowering in July.

3. Briza Miedia; Aliddle, or Common Quaking Grass, Cairguakes, Shakers, Ladics' Hair, Bird's Egret. Spikelets orate; caix shorter than the seven flocales. — This beautiful grass is very common in pastures, especially dry ones, in most parts of Europe, and is easily distinguished by the continual shaking of the spikelets, from which it derives most of its comnon English manes. It flowers from May to July. Cattle eat it has no peculiar excellence that we are acquainted with, nor has it ever been cultivated separately; indeed it furnishes very little faod, and generally occasions a poverty of soil.

4. Briza Maxima; Greatest Quaking Grass. Spikelets heart-shaped; floscules seventeen.-Native of the south of Europe.

5. Briza Eragrosiis; Branched Quaking Grass, or Lore Grass. Spikelets lancoduct; flocules trenty.—This grass varies much, being commonly small and decumbent, but sometimes rising to the height of seven feet; at others of a middling size, with longer and more contracted spikelets. Native of the south of Europe: it flowers in July and August.

6. Briza Monspessulana. Spike nodding, simple; spikelets alternate, peduncled, subsolitary, ovate; calix five-flowered.

Broccoli. See Brassica.

Brome Grass. See Bromus.

Bronelia ; a genus of the class Hexandria, order Mongynia—GRNERIC CHARACTER. Calix: perianth threecornered, small, superior, permanent ; divisions three, ovate. Corolla ; petals three, narrow, lanceolate, erect, longer than the calix. Nectary fastened to each petal above the base, Suminar ; flammenta six, subulate, shorter than the corolla, inserted into the receptacle. Antherw erect, sagittate. *Pixili*: germen inferior; style simple, fillorm, the length of the stamina; stigma obluse, trifid. *Pericary*; berry roundish, umbilicate, one or three-celled. *Seds*: numerous, incumbent, somewhat oblong, obtuse. ESENTIAL, CHARACTER. Calix: trifid, superior. *Petals*: three, and a nectareous scale at the base of each. *Berry*: three-celled. ——The sneecies are.

1. Bromelia Ananas; Ananas, or Pine-apple. Leaves ciliate, spiny-mucronate; spike comose .-- The fruit now so well known in Europe by the name of ananas, or pine apple, and so much esteemed for the richness of its flavour, is produced from an herbaceous plant, which has leaves somewhat resembling those of the aloe, and for the most part servate on their edges, but much thinner, and not so succulent as those of the aloe. The fruit, resembling in shape the cone of some species of the pine-tree, derives its vulgar name of pine apple from that resemblance. It is difficult to determine of what country this plant is a native, but it is probably indigenous in Africa, where it grows plentifully in uncultivated places. There are many varieties of this fruit, and if the seeds were sown frequently in their native country, the varieties might be as numerous as those of apples or pears in Europe. The queen pine is the most common variety in Europe, but the sugarloaf is much preferable to it, being larger and much better flavoured; the juice also is not so astringent as that of the former, so that it may be eaten in greater quantities with less danger. The sngar-loaf pine is easily distinguished from all 196

BRO

the others, by its leaves having purple stripes on their inside | the whole length : the fruit is of a paler colour when ripe, inclining to a straw-colour. This was brought from Brazil to Jamaica, where it is esteemed far beyond the others. The next in goodness to this, is what the inhabitants of the islands in America call the Montserrat pine; the seeds have been imported from the island of St. Thomas, where this fruit is in greater perfection than in any of the British islands. The king pine has been raised from seed taken out of a rotten fruit which came from the West Indies, and produced large fruit. The smooth pine is preserved by some curious persons for the sake of variety, but the fruit is not worth any thing. The green pine is at present the most rare in Europe; this has been esteemed the best sort known, by some of the most curious persons in America, many of whom have thrown out all the others from their gardens to cultivate this only. The fruit, if suffered to ripen well, is of an olive colonr ; to have it green, it must be cut before it is ripe, when it is unfit to be eaten : plants of this sort may be procured from Barbadoes and Montserrat. The other varieties, most known among the growers of pines, are the following : the black Antigua or ripley, Granada pine, with marbled leaves, and very large fruit; bog-warf pine, with broad green leaves; smooth, long, narrow-leaved pine, Montserrat, and Surinam pine, with silver, and also with gold-striped leaves : but it is unnecessary to go beyond naming such varieties, because they are not permauent; new ones may be produced every day; and after all, the oval whitish fleshed or queen pine, and particularly the pyramidal yellow-fleshed or sugar-loaf pine, are confessedly superior in flavour to all the rest. They are propagated by planting the crowns which grow on the fruit, or the suckers which are produced from the sides of the plants, or under the fruit, both of which have been found to be equally good ; although some persons think the crown preferable to the suckers, supposing it will produce fruit sooner than them, which is certainly a mistake; for by constant experience, we find the suckers, if equally strong, will fruit as soon and produce as large fruit, as the crowns. The suckers and crowns must be laid to dry, in a warm place, for four or tive days or more, according to the moisture of the part which adhered to the old fruit, for if immediately planted they will rot, especially the crowns. The certain rule of judging when they are fit to plant, is by observing if the bottom be healed over and become hard, for if the suckers be drawn off carefully from the old plants, they will have a hard skin over the lower part, and need not lie so long as the crowns, or those whose bottoms are moist ; but whenever a crown is taken from the fruit, or the suckers from old plants, they should be immediately deprived of their bottom leaves, so as to allow depth for their planting; so that they may be thoroughly dry and healed in every part. If they are taken off late in the autumn, or during the winter, or early in the spring, they should be laid in a dry place in the stove, for a fortnight or three weeks; but in the summer season they will be fit for planting in a few days. As to the earth in which these should be planted, if you have a rich good kitchen-garden mould, not too heavy, so as to detain the moisture too long, nor over light and sandy, it will be very proper for them without any mixture; but where this is wanting, you should procure some fresh earth from a good pasture, which should be mixed with about a third part of rotten neat's dung, or the dung of an old melon or cucumber bed, which is well consumed. These should be mixed six or eight mouths at least before they are used, but if it be a year, it will be the better, and should be often turned, that their parts may be the better united, and the clods well

broken : this earth should not be sieved very fine, but only cleared of the great stones. Always avoid mixing any sand with the earth, unless it be extremely stiff, and then it will be necessary to have it mixed six months or a year before it be used, during which time it must be frequently turned. that the sand may be incorporated in the earth, so as to divide its parts; but you should not put more than a sixth part of saud, for too much is very injurious to these plants. In the summer season, when the weather is warm, the plants must be frequently watered, but not with large quantities at a time; care must be taken to see that the moisture be not detained in the pots, by the holes being stopped, for that will soon destroy the plants. In very warm weather they should be watered twice or three times a week; but in a cool season once a week will be often enough ; during the summer season their leaves also should be washed gently all over. which will remove the filth from off them, and greatly promote the growth of the plants. Some persons shift these plants from pot to pot, but this is by no means to be practised by those who propose to have large well-flavonred fruit; for unless the pots be filled with the roots, by the time the plants begin to show their fruit, they commonly produce small fruit, which generally have large crowns on them; therefore the plants will not require to be potted oftener than twice in a season: the first time should be about the end of April, when the suckers and crowns of the former year's fruit (which remained all the winter in those pots in which they were first planted) should be shifted into larger pots, according to the size of the plants, nothing being more injurious than over-potting them. The second time for shifting them is in the beginning of August, when those plants which are of a proper size for fruiting in the following spring, should be removed into two penny pots, which are full large enough for any of these plants. At each of these shifting times the bark-bed should be stirred up, and some new bark added, to raise the bed to the height it was at first made; and when the pots are again plunged into the barkbed, the plants should be watered gently all over their leaves, to wash off the filth, and to settle the earth to the roots of the plants. If the bark-bcd be well stirred, and a quantity of good fresh bark added to it at this latter shifting, it will be of great service to the plants, and they may remain in the same tau until the beginning of November, or sometimes later, according to the mildness of the season, and will require but little fire before that time. They will not require watering more than once a week during winter, and then it must be sparingly given, as it is much better to give them a little water often, than to run the risk of over-watering them at that season. You must observe never to shift those plants, which show their fruit, into other pots; for if they be removed after the fruit appears, it will stop their growth, and retard its ripening, so that many times it will be October or November before the fruit is ripe; therefore you should be very careful to keep the plants in a vigorous growing state, from the first appearance of the fruit, because upon this its goodness and size depends, for the fruit is generally small and ill-tasted, if it receive a check after this. When the fruit is cut off from the plants which you desire to propagate, trim the leaves, and plunge the pots into a moderate hot-bcd, observing to refresh them frequently with water, which will cause them to put out suckers in plenty; so that a person may soon be supplied with plants enough of any of the kinds, who will but observe to keep the plants in health. The plants are often attacked by small white insects, which appear at first like a white mildew, but soon after have the appearance of lice, which attack both root and leaves at the

whole stove, and entirely stop the growth of the plants. The best method of destroying them is to wash the leaves, branches, and stems of the plant attacked, frequently with water, in which there has been a strong infusion of tobacco stalks; which has been found to kill the insects, without prejudiciug the plants. Care must be taken to examine between the leaves, or the evil will be but partially removed. Those plants which shew their fruit early in February, will ripen about June; some sorts are at least a month or five weeks longer in ripening their fruit than others, from the time of the appearance of the fruit; but the season in which the fruit is in the greatest perfection, is from the beginning of July to the end of September; though in March, April, and October, they are sometimes found in tolerable perfection. The method of judging when the fruit is ripe, is by the smell, and from observation; for as the several sorts differ from each other in the colour of their fruit, that will not be any direction when to cut thein ; nor should they remain so long as to become soft to the touch, before they are cut, for then they become flat and dead, as they do also when they are cut long before they are eaten; therefore the surest way to have this fruit in perfection, is, to cut it on the same day that it is to be eaten; but it must be cut early in the morning, before the sun has heated it, observing to cut the stalk as long as possible, and lay the fruit in a cool but dry place, preserving the stalk and crown unto it until it is eaten. 2. Bromelia Pinguin; Pinguin, or Broad-leaved Wild Ananas. Leaves ciliate, spiny, mucronate ; raceme terminal. -The fruits of this plant are separate, each nearly of the size of a walnut; the pulp has an agreeable sweetness, but joined with such a sharpness, that if it be suffered to lie any time in the mouth, it will corrode the palate and gums, so as to make the blood issue from those tender parts. It resembles the pine-apple, by its tuft of leaves growing above the fruits, but on a closer inspection, the difference is easily discerned, the fruits not being coadunate as in that, but produced separately in clusters; it is now very common in Jamaica, growing wild in some of the savannas, and on the rocky hills. It is commonly used there, and in the other islands of the West Indies, for fencing pasture lands, its heaves being very formidable to eattle, the edges being very prickly, and the prickles are hed backwards. These, stripped of their pulp, soaked in water, and beaten with a wooden mallet, yield a strong thread, which is twisted into ropes and whips, and by the Spaniards is manufactured into hammocks; it has also been worked into good linen cloth. A small quantity of the juice of the fruit in water, makes an admirable cooling draught in fevers; a tea-spoonful, corrected with sugar, destroys worms in children, cleanses and heals the thrush, and other ulcerations in the mouth and throat, and is extremely diuretic ; it also makes a very fine vinegar. Dampier says, the penguin fruit is of two sorts, the yellow and the red ; the yellow grows on a green stem, as big as a man's arm, above a foot high, the leaves are half a foot long, and an inch broad, the edges full of sharp prickles. The fruit grows at the head of the stalk, in two or three great clusters. sixteen or twenty in a cluster; it is as big as a pullet's egg, round and yellow, the rind is thick, and the inside full of small black seeds. It is a sharp and pleasant fruit, which, as well as the karatas, is propagated by seed, for though there are often suckers sent forth from the old plants, yet they come out from between the leaves, and are so long, slender, and ill-shapen, that if they be planted, they seldom make regular plants. These seeds should be sown early in the spring, in small pots, filled with rich light earth, and

same time, and if not destroyed will soon spread over a plunged into a hot-bed of tanner's bark. When the plants are strong enough to transplant, they should be carefully taken up, and each planted into a separate pot, filled with light rich earth, and plunged into the hot-bed, again observing to refresh them frequently with water, until they have taken new root, after which time they should have air and water in proportion to the warmth of the season. In this bed the plants may remain till Michaelmas, at which time they should be removed into the stove, and plunged into the bark-bed, where they should be treated in the same manner as the ananas. They will not produce their fruit in England, until they are three or four years old, therefore they should be shifted into larger pots, as the plants advauce in their growth, for if their roots are too much confined, they will make but little progress. They should also be placed at a considerable distance from each other, for their leaves will be three or four feet long, which turning downward, occupy a large space. The leaves are strongly armed with crooked spines, which render it very troublesome to shift or handle the plants, for being some bent one way and others the reverse, they catch both ways, and tear the skin or clothes of the persons who handle them, where there is not the greatest care taken.

BRO

197

3. Bromelia Karatas; Karatas, or Upright-leared IFild Annans. Leaves erect; howers stemless, sessile, aggregate. --This is an elegant plant, generally found growing at the root of some shady tree, in hilly and woody places, in America, and the Caribbee islands. The fruits, when ripe, are far from unpleasant; bat when unripe, they set the teell on edge, and excortate the mouth. The ecoupy of this plant, in preserving its fruit to maturity, is wonderful; being so protected by the spines of the surrounding leaves, as to be secured from all injuries. It propagates itself by mucus produced among the leaves, which become procument after the fruit is ripened. For its culture and propagation in England, see the preceding species.

4. Bromelia Lingulata; Tongue-leaved Bromelia. Leaves serrate, spiny, obtuse; spikes alternate .-- The bromelias, properly so called, are propagated by seeds procured from their native country, for they do not produce any in England. These must be sown in small pots, filled with light kitchengarden earth, and plunged into a moderate hot-bed of tanner's bark ; the earth in these pots should be sprinkled over with water two or three times a week, according to the heat of the weather, but must not have too much moisture. If the seeds be good, the plants will appear in about five or six weeks, and in about a month after will be fit to transplant, when they should be carefully shaken out of the pots, and each placed in a separate small pot filled with the same earth as before; they must then be plunged again into a moderate hot-bed, observing frequently to sprinkle them over with water, but be cautious of giving them too much, lest it should rot the roots. During the summer season they should have a moderate share of air, in proportion to the heat of the weather ; and in autumn, they must be removed into the bark-stove, and treated in the same manner as the ananas or pine-apple, with which management they will make good progress; but after the first winter, they may be placed upon stands in the dry-stove, though they will thrive much better if they be kept constantly in the tan-bed, and treated like the ananas, and will flower in three or four years, whereas those in the dry-stove will not flower in twice that time, The other part of their culture, is only to shift them into fresh earth when they require it, but they should by no means be put into large pots, for they will not thrive if they are over-potted; nor must they have much wet, especially 3 E

17.

in winter. These plants making a pretty variety in the hothouse, those who have room may allow a plant or two of each sort to have a place in their collection of exotic plants.

BRO

 Bromelia Nudicaulis ; Naked-stalked Bromelia. Radical leaves tooth-spiny ; stem-leaves quite entire.—Native of the West Indies ; for its culture and propagation, see the preceding species.

 Bromelia Humilis; Dwarf Bromelia. Almost stemless; flowers aggregate, sessile; axillas stoloniferous; flowers blue, about thirty in number.—For its propagation and culture, see the fourth species.

7. Bromelia Acanga. Panicle diffused ; leaves eiliate, spiny, mucronate, recurved.—Native of Brazil : for its propagution and culture, see the fourth species.

B. Browelia Bracteata. Leaves serrate, spiny; bractes ovate-lanceolate; scape elongatcd; raceme compound; racemules subdivided; flowers sessile.—For its propagation and culture, see the fourth species.

 Bromelia Paniculigera. Leaves serrate, spiny; bractes lanceolate; raccme compound; racemules subdivided; flowers peduncled.—For its propagation and culture, -sec the fourth species.

Bromus ; a genus of the class Triandria, order Digynia .-GENERIC CHARACTER. , Cally: glume many-flowered, bivalve, spreading, collecting the floscules into a spike ; valve ovate obloug, acuminate, awnless ; the lowest smallest. Corolla : bivalve, lower valve larger, the size and form of the calix, concave, obtuse, bifid, putting out a straight awn below the top ; upper valve lanceolate, small, awnless. Nectary: two-leaved; lcaflets ovate, acute, gibbons at the base. Stamina : filamenta three, capillary, shorter than the corolla. Antheræ oblong. Pistil: germen turbinate; styles two, short, reflex, villose; stigmas simple. Pericarp: corolla very straightly closed, adhering, not gaping. Seed : one, oblong, covered, convex on one side, furrowed on the other. ESSENTIAL CHARACTER. Calix: two-valved; spikelet oblong, columnar, distich; awn below the top. For the culture and propagation of this genus, see Grass .---- The species are.

1. Bromus Secalinus; Field Brome Grass. Panicle expanding ; syiklects ovate; awas straight; seeds distinct.— It has an annual root, and is chiefly a native of barren pastures: it abounds among corn, particularly ryc. When ground among flour, it is said to render the rye-bread bitter and aupleasant, and to have the same narcotic quality with folium temuleatum, or annual ray-grass, or darnel. It has been a popular notion in England, that the several species of corn degenerates into grasses, which bear some resemblance to them, and that they were only these grasses improved by cultivation.

2. Bromus Japonicus; Japan Brome Grass. Panicle spreading, branching; spikelets oblong, smooth; awns divaricate.--Native of Japan.

3. Bromus Mollis; Soft Brome Grigas. Panicle rather rect: spik-tels ovate, publecard: joins straight; leaves very softly villose—h. corn-fields the root is annual, in nuclivated places biennial. There are many varieties of this grass, both in degrees of publescence, from universal heariness, to almost perfect smoothness; and in size, from three, and even four feet in height to that of a few inches, not to mention other concomitant and less striking circumstances. It is a native of most parts of Europe, by way-sides, on banks, in uncultivated places, on walls, in com-fields, particularly amog balley, in meadows and pastures, especially in a dry sandy soil, flowering in May and June. With us it forms a principal part of many moving grounds, and abonds in most

of our best meadows. It springs early, and ripens its seeds about the time of hay-making. The seed is large, each panicle containing as much as a common oat, and although cattle are not fond of the leaves and green panicle, it perhaps contributes to render the hay more nutritive; it has, however, a bad property, for the panicle is so heavy, that it is very apt to be laid by rain; it is also so much earlier than many other grasses, that by the ordinary time of mowing, it is in a manner withered away, and what seeds have not fallen are lost in the making and carting; finally, the seeds are said to bring on a temporary giddiness in the human species and in quadrupeds, and even to be fatal to positry; if this be in any degree true, it is an objection to the cultivation of this grass, which in other respects docs not rank among the best kinds. It is recommended for subdning or consolidating shifting sands; but surely a perennial grass, with crceping roots, would answer this purpose much better.

4. Bronus Squarrosus; Open-enterd Brown Grass, Panicle nodding; spiklelis ovate; awns diveriate.—This is a robust annual grass, flowering in July. Native of England, Prance, Germang, Switzeland, and Siberia; with us in cornfields near Glastonbury in Somersetshire, and Maresfield in Sussex.

5. Bromus Purgans; Purging Brome Grass. Panicle nodding, curled; leaves naked on both sides; sheaths hairy; glumes villose.—Native place uncertain.

6. Bromus Inernis; Awnless Brome Grass. Panicle erect; spicules subcolumnar, subulate, naked, almost awnless.-Native of Germany, and Switzerland.

7. Bromus Bifidus; *Bifid Brome Grass.* Panicle erect, branching; spicules ovate, subtriflorons; glumes bifid, setaceous; awn divaricated.—Native of Japan.

8. Bromus Asper; Rough Brome Grass. Paniele branched, nodding, scabrous; spikelets linear, roundish, ten-flowered, hairy, awned ; culm and heaves rough with linits.—II grows in hedges and woods, in Britain, Germany, Switzerland, &ce, and flowers with us from June till August : it appears to be too coarse a grass to be cultivated for catile.

 Bromus Ciliatus; Ciliate Brome Grass. Panicle nodding; leaves on both sides, and shcaths somewhat hairy; glumes ciliate; flowers eight, awned under the tip; calices naked; glumes of the corolla lanccolate.—Native of Canada.

 Bromus Sterilis; Barren Brome Grass. Panicle spreading; spikelets oblong, distich; glumes subulate, awncd; root annual.—Found by way-sides, and on the borders of corn-fields, flowering in July.

11. Browns Arvensis; Corn Brome Grass. Panicle nodding; spikelets ovate, oblong; root annual.—Found by waysides, and on the borders of corn fields, flowering in July.

12. Bromus Geniculatus; *Kneed Brome Grass*. Panicle erect; floscules distant; peduncles angular; culm with a procumbent knee.—Native of Portugal.

13. Bromus Tectorum; Wall Brome Grass. Paniele nodding; spikelest linear; root annual, or at most biennial.— Native of most parts of Europe, on walls, buildings, and in dry pastures, but not of England: it flowers from May to July, and when approaching to a state of maturity, may be useful in dyeing, where it can be obtained in sufficient quantities.

14. Bromus Giganteus; Tall Broam Grass. Fanicle nodding; spiklets four-flowered; awas shorter; root preremial. —Native of most parts of Europe, in woods, and under moist hedges, flowering from July till September. It is a productive grass, and cattle are said to be foud of it, but there is not much probability of its being good for meadows or pastures.

15. Bromus Rubens ; Red or Spanish Brome Grass. Pa-

BRO

nicle fascicled, ovate; spikelets subsessile, villose, sevenflowered; awns erect; root annual.—Native of the neighbourhood of Madrid, on the borders of corn-fields, flowering in May.

16. Bromus Scoparius. Panicle fascicled; spikelets subsessile, smooth; awns spreading.—The awns in the same plant are sometimes upright, sometimes spreading; the corollas are smooth, especially the outer glume; the colour is sometimes green, often blood-red, but more frequently valer.

17. Bromus Rigens; Sliff Brome Grass. Paincle spiket; spikelets subsessile, erect, pubescent, subquadrifiorons; culms sis or seven inclues high, clothed with leaves, which are nerved, and sightly haired on the upper surface, the sheaths covering the whole culm. Native of Portugal.

18. Bromus Racemosus; Racemed Brome Grass. Raceme entirely simple; peduacles one-flowered; spikelets sixflowered, even-awned.—It is found in calcareous pastures in the neighbourhood of Oxford, flowering in Jane and July.

 Bromus Triflorus; Three-flowered Brome Grass. Panicle spreading; spikelets subtriflorons; stem five feet high. – Native of Germany and of Denmark, in woods; flowering in June and July.

20. Bromus Madritensis; Madrid Brome Grass. Panicle thinner, expanding, erect; spicules linear; the intermediate ones in pairs; pedicles thicker apwards.—Native of Spain, Italy, and England, on old walls about London, Oxford, and Sevenstoke in Worcestershire: very common in dry meadows, flowering in May.

21. Bromas Ramosus; Branched Brome Grass. Culm much branching; spicules sessile; leaves iuvolute, subulate; root perennial.—Found in the Levant, and observed also in Dauphiny.

22. Bromus Pinnatus; Pinnated or Spiked Browne Grass, Colum andivided; spikelets alternate, subsessile, columnar, subawned; root perennial; leaves flat; the flat side of the spikelets is turned to the culm; awas terminating—Whilst if flowers, the spikelets separate horizontally from the culm; before and after flowering, they are pressed to it. The meadow spiked brome-grass, according to Mr. Hudson, is smooth, of a yellowish green, the lower leaves sometimes a little hairy, the awn shorter than the floxedes.

23. Bromus Cristatus; Crested Brome Grass. Spikelets imbricate, in a double row, sessile, depressed.—Native of Siberia and Tartary.

24. Bromus Distachyos; Two-spiked Brome Grass. Spikes two, erect, alternate.—Native of the south of Europe and the Levant; it is an annual plant.

25. Bromus Stipoides. Paulcle somewhat erect; peduncles ensiform .--- Native of Majorca.

Broom. See Gonista and Spartium.

Broom, African. See Aspalathus.

Brosimum; a genus of the class Diœcia, order Monandria. -GENERIC CHARACTER. Male, Calix : ament common, globular, covered on all sides with imbricate, orbicular, peltate, membranaceous, deciduous scales; three larger surrounding the base of the ament; and others smaller, of an irregular shape, between each of which the stamina break out. Corolla : none. Stamina : filamenta solitary, very short, cylindric. Antheræ bilamellate; lamellas orbicular, peltate; lower gaping from the upper, dispersing a globular pollen. Pistil : germen at top included in a spongy ament, very small, ovate, abortive ; style single, upright, bifid at the tip ; stigmas reflex, simple. Female on a different tree. Calix : ament like the male, Corolla : none. Pistil : germen globular, (the scaly body of the ament itself;) style springing from the middle of the germen at top, long, bifid ; stigmas

simple, sharp, a little reflex. *Pericarp*: berry pedicelled, corticose, spherical, onc-celled. *Secds*: solitary, with a twolobed kernel surroanded by a thin membrane, and bipartic. *ESENNTIAL CHARACTER, Mole. Amett:* globular, covered all round with orbiculate peltate scales. *Corolla*: none. *Filamenta*: solitary, betwen 'the scales. *Female*. *Ament* as in the male. *Corolla*: none. *Slyle*: bifd. *Berry*; one-seeded.—The species are,

1. Brosimum Alicasirum. Leaves ovate, lanceolate, perenial; a menus globular, pedicelled, solitary, axillary; fruit corricose.—This tree is frequent in the parishes of 8t, Elizabeth and 8t, James; in the island of Jamaica; and in both is computed to make up a third part of the woods. The timber is not despicable; but the leaves and younger branches are more useful, and a hearty fattening fodder tor all sorts of cattle. The fruit, boiled will salt fish, pork, becf, or pickle, has been frequently the support of the negroes and poorer sort of white people, in times of searcity; and younger shoots are full of gun, which renders them disagreeable to most cattle a first, but they soon grow very fond of them.

2. Brosimum Spurium. Leaves lanceolate, orate, acuminate; aments pedicelled, ovate, axillary in pairs; fruits soft,—This is pretty common in St. Mary's parsin, Jamaica, where it is called *milk*-toodd. It rises to a considerable height in the woods, is reckoned among the timber trees, and is sometimes used, though not generally valued.

Brossea ; a genus of the class Pentandria, order Mongynia.--GENERIE CHARACTER. Callt: perianth oneleafed, five-parted; divisions ending in erect points, the length of the corolla. Corolla: nuonopetalous, conic, truncated at the end, entire. Stamina: five. Pistil: germen pentacoccous; style subulate, shorter than the corolla; stigma simple. Pericarp: capsule roundish, divided with five furrows, five-celled, covered with a large, converging, fleshy, succulent calls, barsting at the sides. Seeds: very many, settemely minate. ESSENTIAL CHARACTER. Calis ; fleshy, Corolla; truncate. Capsule ; five-celled, manyseeded.----The only known species is,

 Brossea Coccinea. Branches alternate; leaves alternate, ovate, serrate, petiolate; flowers few, terminating the branches, alternate.—An obscure plant, and the character doubtful. Native of South America.

Browallia ; a genns of the class Didynamia, order Angiospermia.-GENERIC CHARACTER. Calix : one leafed, tubular, short, five-toothed, permanent; toothlets a little unequal. Corolla : monopetalous, funnel-form ; tube cylindric, twice as long as the calix; border flat, equal, five-cleft; divisions rounded, emarginate; the upper somewhat large, constituting the upper lip; the four others equal. Stamina: filamenta four, in the throat of the corolla; the two upper shortest; the lower broader, higher coloured, reflex, closing the throat of the corolla. Antheræ simple, bent in, converging; the inner ones twin, the outer opening at the top with a little hole, and closing the throat of the corolla. Pistil: germen ovate, retuse; style filiform, the length of the tube of the corolla; stigma thick, four-lobed. Pericarp : capsule ovate, obtuse, one-celled, covered, bursting into four parts at the top. Partition thin, parallel : seeds numerous, small. Receptacle nearly columnar, compressed. ESSENTIAL CHARACTER. Calix : five-toothed. Corolla : border five-cleft, equal, spreading, with the navel closed. Antheræ : two larger, Capsule : one-celled,-These plants being annual, their seeds must be sown every

year upon a hot-bed in the spring; and the plants must be germina four, superior, ovate, compressed on the inner side : brought forward on another, to perfect seeds in England. Some of them may be transplanted, in June, into the borders of the flower-garden; where, if the season prove warm, they will flower, and perfect seeds; but lest these should fail, there should be two or three plants kept in the stove for that purpose .---- The species are,

1. Browallia Demissa; Spreading Browallia. Peduncles one-flowered .- This usually grows about two feet high, and spreads out into lateral branches. Native of South America, flowering from July till September.

2 Browallia Elata ; Upright Browallia. Peduncles oneflowered and many-flowered .- This also rises about two feet in height. It is a native of Peru, and flowers from July till September.

Brownea; a genus of the class Monodelphia, order Decandria.—GENERIC CHARACTER. Calix: perianth one-leafed, furbinate, inequally bifid, acute. Corolla: outer monopetalous, funnel-form; border five-cleft; divisions oblong, concave, obtuse, crect; inner five-petalled. Petals obovate, flat, obtuse, patulous, sitting on the tube of the outer corolla; claws long. Stamina : filamenta ten or eleven, subulate, alternately shorter; fastened to the tubes of the outer corolla, united into a cylinder, divided above. Antheræ oblong, incumbent. Pistil: germen oblong, acute, sitting on a pedicle fastened to the wall of the outer corolla ; styles subulate, erect, longer than the corolla; stigma obtuse. Pericarp: legume oblong, compressed, narrowed about the partition, two-celled: partition membranaceous. Seed : solitary, ovate, compressed, somewhat wrinkled, involved in fungose fibres. ESSENTIAL CHARACTER. Calix: unequally bilid. Corolla: double; outer five-cleft, inner five-petalled; legume two-celled .---- The species are.

1. Brownea Coccinea. Flowers disjoined, umbelled .-This is a shrub, or small tree, growing to the height of about eighteen feet. The wood is covered by an ash-coloured bark: when in flower, it has a beautiful appearance. The leaves are oval, entire, smooth, opposite, with short footstalks; they grow two or three pairs on a spray. The flowers grow about ten together, and are pendulous. The calix is ferraginous, the corollas scarlet, and the stamina yellowish. Native of hills and woods in America.

2. Brownea Rosa. Flowers aggregate, in heads, sessile ; staining very long .- This is also an American shrub, or small tree, with an ash-coloured bark, and opposite leaves, which are entire, and smooth on both sides. The flowers are borne in a kind of aggregate manner, so as to form heads or bunches of the size of one's fist. They are red, and make a very beautiful appearance. The stamina are extremely long. It grows principally in hilly situations.

Brucea ; (so named in honour of the celebrated traveller into Abyssinia, James Bruce, Esq.) a genus of the class Dicecia, order Tetrandria .- GENERIC CHARACTER. Male. Calix : perianth four-parted, flat, villose ; parts lanceolate, acute, spreading. Corolla: petals four, lauceolate, acute, ciliate, spreading, scarcely larger than the calix. Nectary: a body placed on the receptacle, flat, four-lobed; lobes obscurely emarginate, opposite to the petals. Stamina: filamenta four, upright, short, opposite to the calix, inserted into the receptacle between the lobes of the nectary. Antheræ: roundish. Female, Calix and Corolla as in the male. Nectary : the inner margin of the receptacle thickened, four-lobed ; lobes emarginate. Stamina : filamenta four, inserted into the receptacle on the outside of the division of the nectary, filiform, but thicker towards the tip, sharpish, a little shorter than the petals, without any antherw. Pistil. fresh light earth, and plunged into the hot-bed again, observ-

styles subulate, reflex, lying on the germina; stigmas acute. Pericarps: four, one-seeded. Seeds: solitary. ESSENTIAL CHARACTER. Calix: four-leaved. Corolla: four-petalled; Female. Pericarps: four, one-seeded .---- The only known species is,

1. Brucea Ferruginea .- Mr. Bruce thus imperfectly describes it. Leaf pinnate; leaflets oblong, pointed, smooth, and without collateral ribs that are visible; the upper side of a dcep green, the reverse very little lighter, opposite, with a single one at the end. The flowers come chiefly from the point of the stalk, on each side of a long branch. According to Mons. L'Heritier, who has described it more com-pletely, it is a shrub of the middling size; stem upright, the bark ash-coloured, becoming yellowish; branches few, alternate, patulous, round, thick, with broad scars from the fallen leaves continuing long on them; shoots angular, with the petioles tomentose, rufous; leaves alternate, spreading, unequally pinnate, consisting of six pairs of opposite lobes. one foot in length; petiole round, thickened at the hase; tomentose, rufous; leaflets on short petioles, oblong, ovate, entire, acuminate, veined, villose, somewhat fetid when rubbed; the two lower ones smaller, the upper one on a longer petiolule, three inches long, and one inch broad ; the midrib raised on both sides, especially beneath; the veins concentrically retuse towards the edges; spikes of the male flowers solitary, axillary, upright at first, then spreading, finally nodding; peduncles almost simple, or scarcely compounded of many flowered very short spikelets, remote at bottom, but gradually approximating towards the top, tomentose, rufous, from six to eight inches in length; the flowers are crowded together, either sessile or on very short pedicels, of an herbaceous colour, tinged with red or russet. The male plant began to flower in the stove of the Paris botanic garden, when it was between two and three feet high, in May and June, 1780 or 1781. The female plant has flowered in the royal garden, at Kew, in April and May .-- It is a native of Abyssinia, where it is known by the name of wooginoos. The root is a specific in the dysentery. It is a plain simple bitter, without an aromatic or resinous taste, leaving in the throat and palate something of roughness resembling ipecacuanha.

Brunella. See Prunella.

Brunfelsia ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth one-leafed, bell-shaped, five-toothed, obtuse, very small, permanent. Corolla : one-petalled, funuel-form ; tube very long, slightly curved inwards; border flat, five-cleft, blunt. Stamina: filamenta four, very short. Autheræ oblong, upright; two a little higher than the others, prominent from the mouth of the tube. Pistil: germen roundish, small; style filiform, the length of the tube; stigma thickish. Pericarp: capsule berried on the outside, globular, one-celled, two-valved. Seeds : very many, compressed, convex on one side, angular on the other, rugged with dots. Receptacle: fastened to the bottom of the capsule, chaffy; chaffs coadunate, subulate at the tip, separating the seeds. ESSENTIAL CHA-RACTER. Calix : five-toothed, narrow. Corolla : with a very long tube. Capsule : one-celled, many-seeded, with a very large fleshy conceptacle .- The plants of this genus may be propagated from seeds, which should be sown early in the spring, in pots of light earth, and plunged into a hot-bed of tanner's bark, observing to water the earth as often as you find it necessary. When the plants are come up, they should be transplanted each into a separate small por, filled with

200

ing to water and shade them until they have taken root;] after which they must have air admitted to them every day, in proportion to the warmth of the season. When the plants have risen too high to be continued in the frames, they should be removed to the bark-stove, where, during the summer months, they should have a large share of free air ; but in winter they must be kept very close; with this management the plants will be very strong, and produce their flowers every season. They may also be increased by planting cuttings in the spring, before they begin to make new shoots, in pots filled with fresh light earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root; after which they must be managed as has been directed for other tender exotic plants from the same countries .----- The species are,

1. Brunfelsia Americana. Leaves elliptic, acuminate, on longer petioles ; tube of the corolla erect ; border entire .-This is a tree growing from ten to fifteen feet in height, native of Jamaica, and most of the sugar islands in the West Indies, where they call it trumpet-flower.

2. Branfelsia Undulata, Leaves lanceolate-ovate, drawn to a point at both ends; petioles very short; tube of the corolla curved; border waved .- Native of Jamaica, where it flowers in the spring.

Brunia; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth common, roundish, imbricate, many-flowered; leaflets ovate, oblong. Proper five-leaved, inferior; leaflets oblong, villose. Corolla; petals five, claws slender; borders roundish, spreading. Stamina: filamenta five, capillary, inserted into the claws of the petals. Antheræ ovate oblong. Pistil: germen verv small, superior; style simple, cylindric; stigma obtuse. Pericarp and Seed: not ascertained. Receptacle: common, hairy. ESSENTIAL CHARACTER. Flowers : aggregate. Filamenta: inserted into the claws of the petals. Stigma: bifid. Seeds: solitary, two-celled .---- The species are,

1. Brunia Lanuginosa; Heath-leaved Brunia. Leaves linear, spreading, callous at the end; flowers white, borne in heads .- Native of the Cape of Good Hope.

2. Brunia Ciliata : Ciliate-leared Brunia, Leaves ovate. acuminate, ciliate; the germen is superior, and the style bifid .- Native of the Cape of Good Hope.

3. Brunia Verticillata: Whorled Brunia, Leaves threecornered ; branchlets in whorls, fastigiate ; heads terminating, smooth; heads small, not globular .- Found at the Cape of Good Hope, by Thunberg.

Bruonia : a genus of the class Monœcia, order Syngenesia. -GENERIC CHARACTER. Male Flowers. Calix: peri-anth one-leafed, bell-shaped, five-toothed; toothlets subulate. Corolla : five-parted, bell-shaped, fastened to the calix : divisions ovate. Stamiua: filamenta three, very short. Antheræ five, two connate, on each of two filamenta, and a single one on the third. Female Flowers. Calix : perianth as in the males, superior, deciduous. Corolla : as in the males. Pistil: germen inferior; style trifid, the length of the corolla, expanded ; stigmas emarginate, patulous. Pericarp : berry subglobular, smooth, and even. Seeds : a few, fastened to the coat, subovate. ESSENTIAL CHARACTER. Calix: five-toothed. Corolla: five-parted. Male: filamenta three. Female Style: quadrind; berry subglobular, many-seeded. -The species are,

1. Bryonia Alba; Black-berried White Bryony. Leaves palmate, callous, scabrous on both sides; flowers monocous; light fresh earth, and must have as much air as possible, and said to be one of the best diurctics known in medicine : it is son, but in winter they must all be sheltered, and then they 17.

an excellent remedy in the gravel, and all other obstructions of nrine, and in disorders of the urinary passages in females. For propagation and culture, see the next species.

BRY

2. Bryonia Dioica ; Red berried White Bryony. Leaves palmate, callous, scabrous on both sides; flowers diocous; berries red .- It is easily distinguished by its prodigious root, its stems climbing by tendrils; leaves resembling those of the vine in shape, not smooth, however, as they are, but harsh and rugged, and of a paler colour; and by its bunches of small berries, which are red when ripe, and produced on a different plant on the male flowers. It is called in English, bryony, white bryony, white wild vine, wild hops, wild nep. and tetterberry ; in German, zaunrube, stickwurz ; in Dutch, witte bryone, wilde wyngaard ; in Swedish, hundrosva ; in Danish, ralkrove, galdebær, hundebær; in French, bryone, couleuvrée ; in Italian, brionia, rite bianca ; in Spanish, nueza alba. It is common in the hedges of these countries, and flowers in May with us: goats aloue are said to cat this plant. The roots of bryony grow to a vast size, and have been formerly, by impostors, brought into a human shape, carried about the country, and shown for mandrakes to the common people. The method which these knaves practised, was, to open the earth round a young thriving bryony plant, being careful not to disturb the lower fibres of the root; to fix a mould, such as is used by those who make plaster figures, close to the root, fastening it with wire to keep it in its proper situation; and then to fill in the earth about the root, leaving it to grow to the shape of the mould, which is effected in one summer : see Atropa Mandragora. Bryony is a famous hydragogue, highly purgative and acrid ; a drachm of it in substance, or half an ounce infused in wine, is a full dose; others give two drachms in dropsical cases, and have used half an ounce of the fresh root, or three drachms of it dry, in decoction, without purging; some it purges moderately, others violently, and it frequently becomes diaretic and diaphoretic. A cold infusion in water is used externally in sciatic pains : a cataplasm of it is a most powerful discutient : a decoction, made with one pound of the fresh root, is the best purge for borned cattle. The active virtues of this plant seem to give it a claim to more attention than is now bestowed upon it. Small doses of the juice, given with white wine, promote the menses, and hasten delivery; and in larger doses, it is an excellent medicine in the jaundice, dropsy, and other complaints of a like nature. Made into syrup with honey, and a small quantity of vinegar, it is beneficial in asthmatic complaints; it likewise kills worms in the stomach and intestines, and is good in hysteric cases, but for this purpose it must be given in very small quantities, and the use of it continued for some time. This and the first species, or common European bryony, may be cultivated in a garden for use, by sowing the berries in the spring, on a dry poor soil : in two years' time, the roots will grow to a large size, if the plants be not placed too close together. It may, however, be in general easily procured on dry banks and in hedges, in most parts of England.

3. Bryonia Palmata; Palmated Bryony. Leaves palmate, smooth, and even, five-parted ; divisions lanceolate, repand, serrate .- Native of Ceylon, This, and the fourth, fifth, sixth, and seventh species, require the protection of the barkstove, according to the climate they come from. They are also propagated by seeds sown upon a hot-bed; when they are fit to transplant, they should be put into pots filled with berries black.-Native of Sweden, Denmark, Carniola, Eng- may be frequently refreshed with water in dry weather; land, and other parts of Europe, in hedges. The root is several of them will endure the open air in the summer sea-3 F

BUB

should have very little water: they mostly flower in July, and in favourable summers will perfect their seeds.

 Bryonia Grandis; Great-flowered Bryony. Leaves cordate, angular, smoothish, glandular at the base underneath; tendrils simple.—Native of India, and Cochin-china. See the preceding species.

5. Bryonia Corditolia; *Heart-leaved Bryony*. Leaves cordate, oblong, five-lobed, toothed, scabrous; petioles twotoothed.—Native of Ceylon. See the third species.

6. Bryonia Laciniosa; Laciniated Bryony. Leaves palmate; divisions lanceolate, serrate; petioles muricate.—Native of Ceylon. See the third species.

 Bryonia Africana; African Bryony. Leaves palmate, five-parted, smooth, and even on both sides; divisions pinnatifid.—Native of the Cape of Good Hope. See the third species.

8. Bryonia Crctica; Cretan Bryony. Leaves palmate, callous, dotted on the upper surface .- Native of Crete or Candia, as its name imports. This, and the tenth, fifteenth, and sixteenth species, must be raised on a hot-bed early in the spring, and when the plants are about three inches high, they should be each transplanted into a small pot filled with fresh light earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root. When the plants are grown so large as to ramble about on the surface of the bed, and begin to entangle with other plants, they should be shifted into larger pots, or placed in the bark-stove, where their branches may be trained to the wall, or against an espalier, that they may have sun and air, which is absolutely necessary for their producing fruit. When they are full of fruit, they make a pretty variety in the stove among other exotic plants.

 Bryonia Scobra; Kough or Globe-fruited Bryony. Leaves cordate, angled, villose underneath, callous-scabrous on the upper surface; tendrils simple; berries globular; seeds smooth.—Native of the Cape of Good Hope, and flowers in September and October.

10. Bryonia Scabrella; Roughish or Bristly Bryony, Leaves cordate, angular, and lobed, callous, hispid; tendrils simple; berries globular; seeds muricate; corollas small, yellow.—For its propagation, see the eighth species. Native of the East Indies.

 Bryonia Japonica; Japan Bryony. Leaves cordate, undivided, and angular, toolhed, unarmed, hispid.—Native of Japan. For its culture and propagation, see the eighth species.

12. Bryonia Latebrosa; Hairy Bryony, Leaves subtrilobate, hairy, drawn to a point at the base.—This is easily distinguished from the rest, by the leaves not being in the least cordate at the base, but subdecurrent along the petioles. It is a native of the Camary Islands.

13. Bryonia Verrucosa; Warted Bryony. Leaves cordate angled; the upper surface, and the veins underneath, callous-scabrous, the callosities remote; tendrils simple; berries globular,—It is a native of the Canary Islands.

 Bryonia Racemosa. Lcaves cordate, three-lobed, the upper ones ovate, and somewhat rugged; flowers in racemes; berries nodding, oval.—Native of Jamaica.

15. Bryonia Variegata. Leaves palmate, with lanceolate segments, spotted on the upper, but smooth on the under side; fruit ovate, scattered.—For the propagation and culture of this plant, see the eighth species.

16. Bryonia Bonariensis. Leaves palmate, five-parted, hairy, with obtuse segments.—Root and stems like those of the common bryony, the latter the thickness of a quill at bottom and angular, towards the top deeply streaked dark green.

Native of Buenos Ayres. For the propagation and culture, see the eighth species.

17. Bryonia Hastata. Leaves hastate, toothletted, smooth; peduncles many-flowered; stem herbaceons, slender, scandent, cirrhose; flowers androgynous, white, axillary.--Native of China about Canton.

18. Bryonia Triloba. Leaves three-lobed, five-nerved; stipules roundish, concave; peduncles one-flowered; stem shrubby, grooved, climbing by trilid tendrils.—Native of Cochin-china.

 Bryonia Cochin-chinensis. Leaves five-cornered, rough, berries three-celled, ten-cornered.—It differs from the other bryonies, but cannot be so well placed in any other genus. Native of Cochin-china, in hedges.

Bryum ; a genus of moss, distinguished by a capsule covered with a lid, and over that a smooth veil ; but these characters it has in common with the Mnium and Hypnum, two other genera much resembling this. The peculiar note of the bryum is, that the thread, or little stem supporting the fructification, grows from a tubercle at the ends of the stem and branches. The character of this genus, as given by Hedwig and Schreber, is as follows :- Capsule : ovate, oblong. Peristomium: double, outer with sixteen broadish sharp teeth; inner membranaceous, plaited and keeled, jagged; jags broadish, capillary, alternate. Males: capitate or discoid, or gemmaceous, on the same or a different plant. Linneus has thirty-seven species ; Hudson has forty-five, besides many varieties ; Lightfoot has twenty-nine, described particularly, with many good observations; Withering has sixtyfive, besides many varieties well distinguished; Allioni has twenty-eight species; and Haller enumerates thirty-three. Many of the figures of these mosses have been given by Cnrtis, Dillenius, Vaillant, in Flora Danica; also by Dickson, Hedwig, &c.

Bubon ; a genus of the class Pentandria, order Digynia .--GENERIC CHARACTER. Calix : umbel universal, of about ten rays, the middle ones shorter: partial of fifteen to twenty rays; involucre universal, five-leaved; leaflets lanceolate, acuminate, patulous, equal, much shorter than the umbel, permanent. Partial with rather more leaflets of the same shape, the length of the umbellule; perianth proper fivetoothed, very small, permanent. Corolla: universal, uniform, all the floscules fertile; proper of five, lanceolate, inflex petals. Stamina: filamenta five, simple, the length of the corollule. Antheræ simple. Pistil: germen ovate, inferior; styles two, setaceous, permanent, hardly the length of the corollule, spreading, and reflex ; stigmas obtuse. Pericarp: none ; fruit ovate, striated, villose, bipartile, crowned. Seeds : two, ovate, flat on one side, and convex on the other, striated, villose. ESSENTIAL CHARACTER. Fruit ovate, striated, villose .---- The species are,

1. Bubon Maccdonicum; Maccdonian Parsley. Leaflets fromb-oate, gash-toothed; teeth acuminate; umbels very numerous; seeds rough with hairs.—Native of Greece and Barbary, and probably of the East Indies; if flowers with us in July, or from June to Angust. In warm countries it is biennial, but in England the plants seldon flower till the third or fourth year from seed, but whenever they flower they always die. In some parts of the East, this plantisus of userd, is easily in the seader programs. The plant, but especially the seed, is estemed to be directie, camenagoute, and carminative; the seeds are an ingredient in theriaca. It is proparated by earth, either early in the autumn, or in April; and if the season prove warm and dry, the ground should be laded

202

in the heat of the day, and frequently refreshed with water, which is a sure method to bring up the plants; but where this is not practised, the seeds often fail, or remain long in the ground. When the plants come up, they will require no other care but to be kept clean from weeds, till the beginning of October, when they should be carefully taken up, and planted in a warm border of dry ground, and a few of them should be put into pots, that they may be sheltered under a frame in winter; for in severe frosts, those which are exposed to the open air are frequently killed, though in moderate winters they will live abroad without covering.

2. Bubon Galbanum; Lovage-leaved Bubon. Leaflets ovate, wedge-form, acute, finely serrated ; umbels few ; seeds smooth; stem shrubby, glaucous .- It rises with an upright stalk to the height of eight or ten feet. It flowers in August, but has not produced seed in England. When any part of the plant is broken, there issues out a little thin milk of a cream colour, which has a strong scent of galbanum, which is obtained from this root partly by spontaneous exudation from the stem, but more commonly by incision in the stalk a little above the root, from which it immediately flows, and soon becomes sufficiently concreted for gathering. This gum resin, immediately considered, may be said to hold a middle place between assafectida and amnioniacum, but is far less disagreeable than the former. It has the credit of being highly-useful in hysterical cases, and of promoting and correcting various secretions and uterine evacuations. Externally, it has been applied to expedite the suppuration of indolent tumors, and especially as a warm stimulating plaster. It is a native of the Cape of Good Hope; and to propagate it, the seeds should be sown in pots, filled with light loamy earth, as soon as they arrive ; if it happen towards autumn, they should be plunged into a bed of tanner's bark, where the heat is gone, and screened from frost in winter. In the spring the plants will come up, and by the middle of April be fit to remove, when they should be gently shaken out of the pots, taking care not to tear off their roots, and replanted each into a separate small pot, filled with the same earth as before; then plunge the pots into the tan again, and water them to settle the earth to the roots of the plants, and shade them from the sun in the day-time, until they have taken new root; after this they must be inured gradually to bear the open air; into which they should be removed in June, and placed with other exotic plants in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy as much of the sun and air as possible, but defended from frost. They should have but little water given them in winter, for much wet is very injurious to them: in summer, when they are exposed to the open air, they must be often watered in dry weather; but too much watering must be guarded against, as that will rot their roots. These plants make a pretty variety in the green-house in winter, and when they are placed abroad in the summer, with other green-house plants, they have a good effect, especially when they are grown to a large size. They generally flower the third year from seeds, but their flowers are produced so late in summer, that the seeds have seldom time to form before the cold comes on in the autumn.

3. Bubon Gummiferum ; Gum-bearing Bubon. Leaflets gashed, acuminate, the lower ones broader; seeds smooth; stem shrubby. It rises with a woody stalk about two feet high, with leaves at each joint, branching out like those of the preceding species, but the leaflets are narrow, and indented like those of bastard hemlock. The stalk is termi-

of the Cape of Good, and must be propagated in the same manner as the preceding species; which see. In hot summers it will perfect its seeds, if it stand in a warm sheltered situation.

BUB

4. Bubon Rigidus; Stiff leaved Bubon. Leaflets linear .---This is a low perennial plant, having low stiff leaves, which are very narrow. Native of Sicily. It is propagated by seeds, which should have a dry soil and warm situation, where the plants will continue several years.

5. Bubon Lævigatum ; Smooth Bubon. Leaflets lanceolate, very obtusely and obscurely crenated ; seeds smooth; stem shrubby .- Native of the Cape of Good Hope : it flowers from December to February.

Bubroma ; a genus of the class Polyadelphia, order Dodecandria .- GENERIC CHARACTER. Calix : perianth threeleaved ; leaflets ovate, concave, acute, spreading, deciduous, two a little larger than the rest. Corolla : petals five ; claws large, narrow at the base, vaulted, helmet-coucave, inflex at the tip, beaked, emarginate, converging, inserted into the nectary at the base ; borders semibifid, with linear spreading segments; nectary, a bell-shaped pitcher, divided into five, equal, lanceolate sharp, minute, upright segments, spreading a little at the tip. Stamina : filamenta five, filiform, upright, bent outwards at the tip, outwardly fastened to the nectary, alternate with its segments and a little shorter, trifid at the tip; the divisions very short. Antheræ on each filament three, two at the tip, on each side the third a little lower, each placed on one of the divisions of the filamenta; the cells marginate. Pistil : germen superior, roundish, hisped ; style filiform, almost the length of the stamina; stigma simple. Pericarp : capsule subglobular, woody, muricated all round with club-shaped tubercles, terminated by a five-rayed leafy star, punched with a tenfold row of little transverse dots, five celled, valveless, not opening ; partitions woody, fibrous; cells covered on the inside with a thin membrane. Seeds very many, angular, fixed in a double row to a central subglobular receptacle. ESSENTIAL CHARACTER. Calix: threeleaved. Petals: five, arched, semibifid. Antheræ on each filament three. Stigma : simple. Capsule : muricate, ending in a five-rayed star, punched with holes, five-celled, valveless, not opening .---- The only known species is,

1. Bubroma Guazuma; Elm-leaved Bubroma, or Theobroma, or Bastard Cedar. This tree rises to the height of forty or fifty feet in the West Indies; having a trunk as large as a middling-sized man's body, covered with a dark brown furrowed bark, sending out many branches towards the top, which spread out wide every way. According to Linneus, this tree sleeps with the leaves hanging quite down, whilst the petioles remain entirely stiff and straight. From its similitude to the elm, the French call it orme d'Amerique, and bois d'orme. In Jamaica it is known by the name of bastard cedar, and is peculiar to the low lands there, forming a very agreeable shade for the cattle, and supplying them with food in dry seasons, when all the herbage is burned up, or exhausted. The seeds are very mucilaginous, but otherwise agreeable to the palate. The wood is light, and so easily wrought, that it is generally used by coach-makers in Ja-maica in all the side-pieces. It is also frequently cut into staves for casks. A decoction of the inner bark is very glutinous, and very like that of the elm; it is said to be excellent in the elephantiasis, a disorder to which the poor negroes are greatly subject. It flowers here in August and September. To propagate this tree, sow the seed on a good hot-bed in the spring, and when the plants are fit to remove, plant them each in a separate small pot, and plunge them into a hot-bed of tanner's bark, observing to shade them from the nated by a large umbel of small white flowers .-- It is a native sun till they have taken new root; they then should be treated in the same way as the coffee-tree, keeping them cordate, erect. *Pistil*: germen inferior, ovate; style filiform the length of the stamina; stigma obtuse. *Pericarp*: berry

Buchnera ; a genus of the class Didynamia, order Angiospermia.--GRNERIC CHARCTER. Calls: ; perianth oneleafed, obscurely five-toothed, scabrous, pernanent. Carolla: monopetalous; tube very long, filform, howed; border flat, short, five-cleft, equal; the two upper divisions very short, reflex; the three lower cordate, nearly equal. Stamina: filamenta four, very short in the throat of the corolla; the two upper ones prominent, outward, short. Antherae oblong, obluse. Pistil: germen orate, oblong; style filform, the length of the tube; sigma obluse. Pericarp: capsule, acuminate, covered, two-celled, gaping at the top into two parts. Partition contrary. Seeds: numerous, angular. Receptacle: isstened to the middle of the partition. EssExp. Tata CLarAnzTER. Calls: obscurely five-toothed. Corolla: border five-cleft, equal; lobes cordate. Capsule: two-celled. ----The species are,

1. Buchnera Americana; North American Buchnera. Leaves toothed, lanceolate, three-nerved.—This herb grows black in dying. It is hardy, and a native of Virginia and Canada.

2. Buchnera Cernua; Drooping Buchnera. Leaves wedged, five-toothed, smooth; flowers spiked; stem shrubby. --Native of the Cape of Good Hope, requiring the protection of the dry-stove, conservatory, or glass-case.

 Buchnera Cuneifolia; Wedge-leared Buchnera. Leaves wedge-form, smooth, seven-toothed at the end.—Native of the Cape of Good Hope; to be propagated in the same way as the Cape plants.

4. Buchnera Cordifolia; *Heart-leaved Buchnera*. Stem four-cornered; leaves opposite, cordate, three-nerved, serrate; racemes terminal, subspiked.—Native of the East Indies.

5. Buchnera Grandifolia; Great-flowered Buchnera. Scabrous; leaves opposite, sessile, oblong, entire; peduncles axillary, one-flowered, two-leaved; calix finnel-form.—This is a very beautiful plant, with an upright, smooth, and very simple stem. It was found in South America by Mutis.

6. Buchnera Æthiopica. Leaves three-toothed; flowers peduneled; stem shrubby; calix somewhat hispid. Corolla yellow.—Native of the Cape of Good Hope.

7. Buchnera Capensis. Leaves toothed, linear; calices pubescent.-Native of the Cape of Good Hope.

8. Buchnera Asiatica; Eastern Buchnera. Leaves quite entire, linear; calices seabrous.—The corolla has a bifd purple border; one of the segments almost npright, and trifid; the other, spreading and widely cordate. Native of Ceylon and China.

9. Buchnera Pinnatifida; *Pinnatifid-leared Buchnera*. Leaves pinnatifid, smooth.—Found at the Cape of Good Hope by Thunberg.

10. Buchnera Viscosa; Clammy Buchnera. Leaves linear, lanceolate, loosely toothed, somewhat glutinous; flowers pedancled; stem shrubby.—The flowers are purple, with a yellow eye. It does not boast much heativ, but nevertheless occupies little room, and flowers during most of the summer. Found at the Cape of Good Hope.

13. Buchnera Elongata. Leaves entire, opposite; calices somewhat hairy, longer than the fruit.—Native of South America and Januaica. It must be kept in the bark-stove, if cultivated in England.

Bucida; a genus of the class Decandria, order Monogynia. will have filled these small pots with their roots by the mid-GENERIC CHARACTER. Calix: perianth one-leafed, bell-form, obscurely five-toolhed, superior, permanent. Corolla: none. Stamiaa: filamenta ten, capillary, inserted into the base of the calix, and longer than it. Anthera When these are potted, the tan should be turned over the

cordate, erect. *Pisitli germen inferior*, ovate; style filform the length of the stamina; stigma obluse. *Pericarp*: berry dry, ovate, one-celled, crowned with the calis. *Seed*: one, ovate. *EsseNTAL CHARACTER*. *Collis*: five-toothed, superior. *Corolla*: none. *Berry*: one-seeded.—The only species known is,

1. Éncida Buccas; Olice Bark Tree. Brown obserces, that this tree is remarkable for its sleader crooked branches, and the tufted disposition of the leaves, that it grows to a considerable size, is reckoned an excellent timber tree, and that the bark is greatly esteemed by the tanners. It is a native of the West Indies, in low swampy clayey hands near the coast, flowering in spring; in Janabara it is called black olice; in Antigua, French oak; and in the Freuch islands, grigmon.

Buckbean. See Menyanthes.

Buckler Mustard. See Biscutella and Clypeola. Buck's Horn. See Plantago.

Buckthorn. See Rhamnus.

Buckwheat. See Polygonum.

Budding. See Inoculating.

Baddlea; a genus of the class Tetrandria, order Monogynia.—GENERIE CHARACTER. Caliz: periault very small, four-cleft, acute, ereet, permanent. Corolla: monopetalons, bell-form, four-cleft half way, erect, three times greater than the calis; divisions ovate, straight, acute. Staunina: fihamenta four, very short, placed at the divisions of the corolla. Anthera very short, placed at the divisions of the corolla. Anthera very short, placed at the divisions of the corolla Seeds: numerous, extremely minute, adhering to a fungous receptacle. ESENTIAL CHARACTER. Caliz: four-cleft. Corolla: four-cleft. Stamina: from the divisions. Capsule: two-furrowed, two-celled, many-seeded.—The species are,

1. Buddlea Americana; Long-spiked Buddlea. Leaves ovate .- This is a shrub about the height of a man. Brown informs us, that it is used in emollient baths and fomentations, and is thought to have all the properties of mullein. It is propagated by seeds, (as it does not produce them in England,) which should be brought over in their capsules or pods; for those which are taken out before they are sent, seldom grow. They should be sown in small pots filled with light rich earth, and very lightly covered with the same; for as these seeds are very small, if they are buried deep in the ground, they perish. The pots should be plunged into a mo-derate hot-bed, and every third or fourth day must be gently watered, being very careful not to wash the seeds out of the ground by too hastily watering them. If the seeds be fresh and good, the plants will come up in about six weeks, provided they are sown in the spring; and if they grow kindly, will be large enough to transplant in four months after; they then should be carefully separated, and each planted into a small pot filled with light rich earth, and plunged into the hot-bed again, observing to shade them from the sun until they have taken new root, as also to refresh them with water when they require it. After the plants have again struck root in these pots, there should be fresh air admitted to them every day, in proportion to the warmth of the season; they must also be frequently but moderately refreshed with water. If the plants thrive well, they will have filled these small pots with their roots by the mid-

renew the heat, and if it is wanted, some fresh tan must be added to the bed, to encourage the roots of the plants. In this bed they may remain till autumn, when they must be removed into the stove, and plunged into the tan-bed, where they must constantly remain, for they are too tender to thrive in this country if they are not so treated. During the winter they must have but little water, and should be kept warm; but in summer they should have fresh air admitted to them constantly when the weather is warm, and frequently sprinkle all over with water : with this management the plants will flower the fourth year from seeds, and continue to do so every year after, and will make a good appearance in the stove.

2. Buddlea Occidentalis; Spear-leaved Buddlea. Leaves lanceolate .- This sort rises much taller than the first, and divides into a great number of branches; it grows naturally in gullies, or other low sheltered spots, in the West Indies, the branches being too tender to resist the force of strong winds, are rarely seen in open situations. For its culture and propagation, see the first species.

3. Buddlea Virgata. Leaves linear, oblong, obtuse, entire; racemes terminal; branches wand-like, erect .- This has the habit of hyssop. Native of the Cape of Good Hope.

4. Buddlea Incompta. Leaves fascicled, ovate, hoary; brauches flexuose, rigid ; racemes terminal .- Native of the Cape of Good Hope.

5. Buddlea Globosa ; Round-headed Buddlea. Leaves lanceolate; heads solitary.—It is a native of Chili, and flowers in May and June. This and the sixth species may be propagated by cuttings, on an old hot-bed, in July, covered with a bell or hand-glass, and shaded from the sun; in a month they will have taken root, and may then be planted in pots, placed in the shade till they have taken fresh root, when they should be removed to a sheltered situation till the winter; and then they must be preserved in the conservatory or dry-stove. The fifth will flower well, and live through a mild winter in an open border, provided it be in a warm sheltered situation.

6. Buddlea Salvifolia; Sage-leaved Buddlea. Leaves lanceolate, ovate, cordate, wrinkled .- Native of the Cane of Good Hope; flowers in August and September. For its propagation and culture, see the fifth species.

7. Buddlea Asiatica. Leaves lanceolate-linear wrinkled smooth, spikes full ; stem suffruticose, three feet high .-- Native of Cochin-china.

8. Buddlea Ternata. Leaves ternate, acuminate; peduncles one-flowered ; stem suffruticose, two feet high, upright, round, branched .--- Native of Cochin-china.

Buffonia ; a genus of the class Tetrandria, order Digynia. -GENERIC CHARACTER. Calix: perianth four-leaved, erect, permanent; leaflets subulate, keeled, with membranaceous edges. Corolla : petals four, oval, emarginate, erect, equal, shorter than the calix. Stamina : filamenta four, equal, the length of the germen. Antheræ twin. Pistil: germen ovate, compressed; styles two, the length of the stamina; stigmas simple. Pericarp: capsule oval, compressed, one-celled, two-valved. Seeds : two, oval, compressed, with a swelling convex on one side. ESSENTIAL CHARACTER. Calix: four-leaved. Corolla: four-petalled. Capsule one-celled, two-seeded .---- The only known species is,

1. Buffonia Tenuifolia; Small Buffonia, or Bastard Chickweed. Root annual, long, slender, firmly fixed, but having few, almost naked, filiform fibres ; stem half a foot to a foot in height, upright, round, commonly branched at the base; branches diffused, procumbent; there are also smaller branches higher up, which are straight, contracted, subdi have the morning sun, but screened from the south. In very 18.

vided; the swelling joints are more frequent at bottom, and become very distant towards the top; the internodes are round, where there are no branches, but somewhat angular about the origin of the branches, which are ancipital at the base; they are smooth, and slightly streaked .- Ray first noticed this little plant in England : he also found it near Montpellier. It is found wild in France, Italy, and Spain, and was observed by Mr. Ray on the sea-coast of Lincolushire, about Boston, and by Mr. Doody on Hounslow Heath. It flowers in May and June.

Bugle. See Ajuga.

Bugloss, Buglossa, and Buglossum. See Anchusa, Asperugo, Borago, Lythospermum, Lycopsis.

Bugloss, Viper's. See Echium.

Bulbocodium; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla: hexapetalous, funnel-form; claws very long, linear; throat connecting the petals; border erect; petals lanceolate, concave. Stamina; filamenta six, subulate, inserted into the claws of the petals. Antheræ incumbent. Pistil: germen ovate, subulate, obtusely three cornered, superior; style filiform, the length of the stamina ; stigmas three, oblong, erect. channelled. Pericarp : capsule triangular, acuminate, angles obscure, three-celled. Seeds: numerous. ESSENTIAL CHA-RACTER. Corolla: funnel-form, hexapetalous, with narrow claws bearing the stamina; capsule inferior .---- The only known species is,

1. Bulbocodium Vernum ; Spring-flowering Bulbocodium. Leaves lanceolate. The bulb or hybernacle, commonly called the root, resembles that of the common colchicum in shape, but is much smaller ; it is covered with a dark brown skin. Some time in January, or not later than the middle of February, according to the season, the flower springs up, inclosed within three brownish green leaves, which, opening themselves almost as soon as they are out of the ground, show their buds for flowers within them very white oftentimes, before they open far, and also purplish at first appearing. There is frequently only one flower, but never more than two flowers on a root : they never rise above the leaves, nor the leaves much higher than they, whilst they last; they are smaller than the flowers of colchicum, and are at first of a pale red or deep blue colour, but afterwards change to a bright purple, and continue long in beauty, if the weather be not severe. After the flowers are past, the leaves grow to the length of a man's longest finger, and in the middle of them rises up the secd-vessel, which is smaller, shorter, and harder than that of colchicum, and contains many small round brown seeds. It is a native of Spain, and also of mountainous situations in Russia. At present it is a rare plant among us, the bulbs not admitting of much increase, and being liable to damage from frost. It is propagated by offsets, like other bulbonsrooted flowers. The time to remove them, is soon after the leaves decay, but the roots may be kept out of the ground two months without prejudice at that season: they should not be removed oftener than every third year, for the roots do not multiply very fast ; by suffering them, therefore, to remain, they will flower much stronger, and make a greater increase, than if they are often taken up. It should have a warm situation, and may be planted in a south border, in a fresh loamy soil, but not dunged. "It may also be propagated by seeds, which should be sown in pots filled with fresh loamy earth, in September, and the latter end of October ; the pots should be placed under a frame, to protect them from severe frost; in the spring the plants will appear, when they may be removed out of the frame, and placed where they may

3 G

dry weather, they should be refreshed now and then with a little water, while their leaves continue green; but when these decay, the pots should be removed to a shady situation, where they may remain till autumn, observing to keep them clean from weeds. In October, there should be a little fresh earth haid on the surface of the other, and the pots placed in shelter again till the following spring, when they must be treated in the same manner as in the former year until their leaves decay, then the roots should be carefully taken up, and transplanted into the borders of the flower-garden, treating them as the old roots, and in the spring following they will produce their flowers.

Bubush. See Scirpus.

Bunalda: a genue of the class Pentandria, order Digynia. —GENERIC CHARACTER. Calk: perianth on-leafed, five-parted almost to the base; divisions ovate, obtuse, concave, a little shorter than the corolla. Carolla: five-petalled; petals linear, obovate, inserted into the germen. Stamina; there inserted, into the claws of the petals, filform, erect, rough with hairs, almost the length of the corolla. Anthere inserted into the back, ovate, twin. Pisitl; germen superior, conic, villose; styles two, erect, villose, the length of the filamenta; sigmas simple, headed, trueate. Pericarp: seems to be a two-celled cusule. Seeds: not ascertande. ESENTIAL CHARCTER. Corollar invegentalled. Styles: villose: capsule two-celled, two-beaked.—The only known species is,

I. Bumalda Trifolia. Stem shrubby; branches close, in all parts smooth; branches obscurely angular, jointed, purple; divisions opposite, filiforn, much spreading, leafy; leaves opposite, petioled, ternate; leaflets ovate, acuminate, finely serate, pale underneath, on very short capillary petioles, spreading very much, or reflex; flowers terminating, the branches in racemes, on capillary peducles.—Native of Japan.

Bumelia; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fiveleaved; leaflets roundish, ovate, incumbent, concave, Corolla: one-petalled, five-cleft or five-parted; tube very short, round; border five-parted; parts ovate, entire, spreading, concave, with two little scales at the base of each. Nectary five-leaved; segments smaller than the corolla at the base of the filamenta, surrounding the germen, acute. Stamina: filamenta five, inserted into the corolla, at the bottom of the tube, between the lower segments, the length of the tube. Antheræ ovate. Pistil : germen superior, ovate ; style thick, erect, shorter than the stamina ; stigma obtuse. Pericarp : drupe oval. Seed : kernel single, oblong, smooth, with a lateral scar. ESSENTIAL CHARACTER. Corolla: fivecleft, with a five-leaved nectary ; drupe one-seeded .---- The species are,

1. Bumelia Nigra; *Black Bumelia*. Branches wand-like, spreading; leaves terminating, oblong, lanceolate, smooth, waved about the edge; branchlets flower-bearing.—Native of Jamaica.

2. Bumelia Pallida; Pale Bumelia. Branches upright; leaves terminating, elliptic, obtuse; flowers crowded, lateral. —Native of Jamaica.

3. Bumelia Retusa; *Retuse-leaved Bumelia*. Leaves opposite, wedge-ovate, retuse, rigid; flowers crowded, axillary. --Native of the West Indies.

4. Bumelia Montana; *Mountain Bumelia*. Leaves scattered, alternate, oblong, obtuse; flowers axillary, peduncled. --Native of Jamaica.

5. Bumelia Salicifolia; Willow-leaved Bumelia. Leaves lanceolate, ovate, acuminate; flowers crowded, axillary, and lateral. See Achras Salicifolia.

6. Bumelia Rotundifolia; *Round-leaved Bumelia*. Leaves suborbiculate, margined, veined, coriaceous, smooth on both sides.—Native of the West Indies.

7. Bumelia Pentagona; Pentagona-fruited Bumelia. Leaves lanceolate, acuminate, shining; flowers axillary; drupes five-cornered.—Native of the islands of St. Vincent.

Bunias ; a genus of the class Tetradynamia Siliquosa .-GENERIC CHARACTER. Calix: perianth four-leaved; leaflets ovate-oblong, spreading, deciduous. Corolla: tetrapetalous, cruciform; petals obovate, twice as long as the calix; claws attenuated, erect. Stamina: filamenta six, the length of the calix; of which two opposite a little shorter. Antheræ erect, bifid at the base. *Pistil*: germen oblong: style none; stigma obtuse. Pericarp: silicle irregular, ovateoblong, four-sided, the angles with an acumen or two, not bursting, deciduous. Seeds : few, one under each acumen of the silicle, roundish. ESSENTIAL CHARACTER. Silicle: deciduous, four-sided, muricated with unequal acuminate angles. These plants are all propagated by seed, to be sown where they are designed to remain, either in April or in autumn. When the plants come up they should be thinned to the distance of one foot from each other; and after that they will require no other care, but to keep them clean from weeds. They are all hardy enough to flower in the open air. but some of them scarcely perfect their seeds uuless they be sown in the autumn.----The species are,

 Buuias Cornuts; Horned Evanies. Sliteles divaricate, two-horned, spinyat the base.—This is a very singular plant; thas a silicle transversely oval, finishing on each side in a horn, or very long and strong spine, so that the silicle resembles a pair of horns ; in the middle of the silicle are four small spines directed different ways. Native of the Levant and Siberia.

 Bunias Spinosa; Thorny Bunias. Raceme spinescent. —This is an annual plant. Stems a foot high, upright, branching, subdivided, round, and rushy, very smooth and even, green. Native of the Levant.

3. Bunias Erucago: Prickly-podded Bunias. Silicles four-cornered; angles two-rested.—This is also an annual plant, sending out many branches, which spread, and incline towards the ground. The leaves are glancous, and deeply divided into many segments, almost like those of swine's cress. The flowers are produced singly from the axils of the leaves towards the extremity of the branches, they are small, and of a pale yellowish colour. Native of the south of France, Switzerland, Austria, and Italy.

4. Bunias Orientalis; *Oriental Bunias*. Silicles ovate, gibbose, warted; root perennial, with an annual stalk.--It grows naturally in the Levant, and flowers from May to July.

5. Bunias Cochlearoides; Scurvy-grass Bunias. Silicles cordate, ovate, even, inflected,—It is about two feet high; the root slender, and fibrose at the sides. The corolla is white and veiny. Found in low meadows near the river Jaik.

6. Bunias Cakile; Sea Rocket. Silicles ovate, even, ancipital.—It is a smooth, annual, glaucous plant, with a saltish taste; root slender, woody, running deep into the sand. It is a native of the sea-coast, in many parts of Europe, and North America: with us, on the coast of Norfolk, Suffolk, Scotland, and Ireland, in deep sand, frequently near highwater mark: Nowering in June and July.

7. Bunias Mysgrödes; Myagrum-Tike Dunias. Sliteles two-jointed, ancipital, torulose above; leaves pinnate, with reflected sinuses; root annual; stem straight, two feet high, even; panicle branched; lower leaves pinnate, or bipinnate; border not fleshy, deep green, even; divisions or pinnas oblong-toothed, the upper ones very like these, but narrow

pinnas ; racemes terminal, long, straight ; flowers subsessile ; calix closed ; petals quite entire, pale purple ; style ensiform. -Native of Siberia.

8. Bunias Ægyptiaca ; Egyptian Bunias. Silicles fourcornered, wart-muricate on every side ; leaves runcinate ; root annual; stem a foot high, hispid at bottom, smooth at the top; flowers pedicelled; calix yellowish.-Native of Egypt. Flowering in August.

9. Bunias Balearica ; Minorca Bunias. Silicles hispid ; leaves pinnate ; leaflets slightly toothed ; root annual ; stem a foot high, very much branched, spreading, angular, even ;

Bunium ; a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix : umbel universal, manifold, with rays fewer than twenty ; partial, very short, crowded ; involucre universal, many-leaved, linear, short ; partial setaceous, the length of the umbellule; perianth proper, scarcely apparent. Corolla : universal uniform ; floscules all fertile ; proper of five, inflex, cordate, equal petals. Stamina: filamenta five, shorter than the corolla, simple; antheræ simple, Pistil : germen oblong, inferior ; styles two, reflex ; stigmas obtuse. Pericarp : none; fruit ovate, bipartile ; seeds two, ovate, convex on one side, flat on the other. ESSEN-TIAL CHARACTER. Corolla: uniform; umbel crowded; fruits ovate. ---- The only known species is,

1. Bunium Bulbocastanum; Earth Nut, or Pig Nut. Root perennial, tuberous on the outside, of a chesnut colour, within white, solid, putting forth slender fibres from the sides and bottom of an agreeable sweetish taste, lying deep in the ground; stem from one to two feet high, upright, round, stiffish, the thickness of a crow quill, slightly striated, smooth throughont, of a green colour, and branched ; radical leaves on long petioles; stem-leaves sessile, all very finely divided, deep green, the folioles edged with prickly hairs visible only by a glass; sheath short, grooved, smoeth, the edge membranous and whitish; umbels several; universal rays from seven to twelve; partial about twelve; universal and partial involucre, often wanting; filamenta longer than the corolla, deciduous; styles white, nearly upright; seeds oblong, ovate, smooth, and somewhat aromatic .- This plant has several other names in English besides the two given above : as, kipper-nut, hawk-nut, jur-nut or yer-nut, earthchesnut, and ground-nut. In German, it is called erdnuss; in Dutch, aardnoot ; in Swedish, jordnot ; in Danish, jordolden ; in French, suron, terre noix ; in Italian, castagna di terra; in Spanish, castano di tierra; in Portuguese, castanha di terra. In England it grows on heaths in pastures, woods, and among bushes, in a gravelly or sandy soil. Forcign authors, as Haller, Pollich, &c. say that it grows among corn. It flowers in May and June. The roots are frequently dng up, and are eaten raw by the poorer sort of people. Swine are very fond of them, and will soon become fat by feeding upon them. When boiled, they are very plcasant and delicious, and are supposed to afford great nonrishment. They are said to be prepared and eaten in Holland, in the Alps, and in some parts of Eugland, in soup or broth. Roasted, they are little inferior to chesnuts, and might be no disagreeble addition to our winter deserts. The knobbed root, and finely divided leaves, so distinguish this plant from all the poisonous species of the umbellate tribe, that it can hardly be mistaken, especially if the place of growth be attended to. Oenanthe fistulosa, indeed, when thrown out on ditch-banks, or cultivated in a garden, has roots so much resembling those of Bunium, that it may deceive even good judges; the

linear: all have sinuses reflected down at the egress of the | root-leaves also are finely divided ; but this is a water plant. and it ought to be remembered that all aquatics of this tribe are of a suspicious character.

Buphthalmum; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix: common various in the different species, imbricate. Corolla: compound radiated ; corollules hermaphrodite, numerous, forming a flat disk ; females more than ten in the ray ; proper of the hermaphrodite funnel-form, with a five-cleft patulous border : of the female, ligulate, longer, spreading, three-Stamina : of the hermaphrodite, filamenta five, toothed. capillary, very short. Antheræ tubular, cylindric, Pistil ; of the hermaphrodite; germen ovate, compressed; style filiform, the length of the stamina; stigma thickish, simple of the female. Germen : ancipital ; style filiform, of the same length as in the hermaphrodite ; stigmas two, oblong. Pericarp : none : calix unchanged. Seeds : of the hermaphrodite solitary, oblong, crowned with a gashed manifold edge; of the females, solitary, compressed, with each edge cutting, crowned like the others. Receptacle : chaffy, convex. ESSENTIAL CHARACTER. Stigma of the hermaphrodite, floscules undivided. Seeds : have the sides, especially in the ray, edged. Down: an obscure edge; receptacle chaffy. -The species are,

+ Asterisci of Tournefort.

1. Buphthalmum Frutescens; Shrubby Oxeye, Leaves opposite, lanceolate; petioles two-toothed, stem shrubby .---It rises with several woody stems from the root, and grows to the height of eight or ten feet, furnished with leaves very unequal in size, some of which arc narrow and long, others are broad and obtuse; these are intermixed, sometimes coming out at the same joint, and often at the intermediate one, they arc soft, hoary, and placed opposite. The footstalks of the larger leaves have on their upper side, near their base, two sharp teeth, standing upwards, and a little higher; there are generally two or three more, growing on the edge of the leaves. The flowers are produced at the end of the branches, single; these are of a pale yellow colour, and have scaly calices. It grows naturally in America, and is also a native of Jamaica, where it grows only near the sea side, in a bushy tufted form, seldom rising above two or three feet in height. Neither this nor the second species will perfect their seeds in this country, they are therefore propagated by cuttings. They should be planted in July, when the plants have been for some time exposed to the open air, whereby their shoots will be hardened, and better prepared to keep root than when they first come abroad. The cuttings should be planted in small pots filled with light loamy earth, and plunged into a very gentle warmth, observing to shade them from the sun in the heat of the day, and gently refresh them with water; but it must be given to them sparingly, for much wet will rot them. In about six weeks these will have taken root, when they must be gradually inured to bear the open air; and soon after they should be each planted in a separate small pot, filled with light loanty earth, and placed in the shade until they have taken fresh root ; after which they may be removed to a sheltered situation, where they may remain until the middle of October, when they must be removed into the green-house. The first species being harder than the other. may be placed in a common green-house, but the other will thrive better in a warm glass-case, where it will receive more sun, and have a drycr air. During the winter they should have but little moisture, and in very mild weather they should have fresh air admitted to them. In the summer they must be placed abroad in a sheltered situation, and treated in the same manner as other exotic plants.

2. Buphthalmum Arborescens; Tree Oxege. Leaves opposite, lanceolate, tomentose on both sides, toothless, quite entire; stem shrubby.—This seldom grows more than three feet high, sending out many succulent stalks from the root. The flowers are larger than those of the first species, and of a bright yellow colour. They appear in July, August, and September, but often continue till the end of October.—Native of the Bermudas. For its propagation and culture, see the first species.

BUP

3. Bmphthähnum Sericeum; Silkg Ozege. Leaves scattered, wedge-slapped, acute, quite eutire, villos-silky; branches thick, woody, covered with sears left by the falling leaves; fowers terminating, large and yellow.—Found in Fuertaventara, one of the Canary Islands. It flowers from May to July.

4. Buphthalmum Spinosum; Prickly Oxeye. Calices acutely leafy; leaves alternate, lanceolate, stem-clasping, quite entire .- This is an annual plant ; the ray of the corolla is manifold, and very slender. It is of a bright vellow colour; the disk is of a gold colour. The flowers appear from June to August, and the seeds ripen in September. It is a native of the south of France, Spain, and Italy, on the borders of fields, and on ditch-banks. The leaves were formerly used in medicine. In Arragon it is called cevadilla, from its quality of exciting sneezing. The seeds of this, and of the fifth species, should be sown in the beginning of April, on open borders, where they are to remain, and will require no other care but to keep them clear of weeds, and thin them to the distance of a foot and a half, that their branches may have room to spread. If the seeds be sown in the autumn, or be permitted to scatter when ripe, the plants will come up soon after, and these will more certainly ripen than spring plants.

5. Explifialmum Aquaticum: Sweet-scented Oxyge. Calics obtusely leafy, sexile, axillary: leaves alternate, oblong, obtuse; stem herbaccous.—This is also an annual; seldom growing more than a foot high in gardens, and, where it is wild, not so high; it sends out many alternate spreading branches near the root; the leaves are hairy and sessile; the flowers, which are sessile in the forks of the stem, have an agreeable dodur. Native of the south of Europe. It flowers in July and August. For the mode of propagating it, see the fourth species.

6. Buphthalmum Maritimum; Sea Oxeye, Calices obtusely leafy, peduncled; leaves alternate, spatulate; stem herbaceous .- This is a low perennial plant, with a shrubby stalk, rarely rising a foot high, with many spreading branches; leaves hairy, narrow at the base, but broad and roundish at the extremity. Native of Sicily, flowering from July to September. This plant seldom produces seed in England, but is easily propagated by slips during the summer season ; if the cuttings are planted in a bed of fresh loany earth, and covered with a hand-glass, observing to shade them from the sun in the heat of the day, and frequently refresh them with water, they will take root in about six weeks, when they should be carefully taken up, and each planted with a separate small pot filled with fresh undunged earth, and placed in a shady situation, till they have taken fresh root; after which they may be removed to a sheltered situation until the end of October, when they must be placed under a frame for the winter season; but as they only require protection from hard frost, they will thrive better when they have a great share of air in mild weather, than if confined in the green-house; therefore the best method is to place them in a common frame, where they may be fully exposed in mild weather, but screened from the frost,

7. Buphthalmum Durum. Leaves alternate, lauceolate, quite entire; stem undershrnbby.—This shrub is a native of the Cape of Good Hope.

† Asteroidea of Tournefort.

8. Buphthalmum Salicifolium ; Willow-leaved Oxeye. Leaves alternate, lanceolate, subserrate, villose; calices naked; stem herbaceous .- The root is perennial; the stem upright, round, a foot or eighteen inches in height, with upright one-flowered branches. It is thought to be the yellow aster of the Italians, the juice of which, when applied to the wounds which a dog had received from the bites of a viper, enabled him to bear them without injury. Native of Italy, the south of France, Switzerland, Austria, and Carniola. It flowers from June to October. This, as well as the ninth and eleventh species, may be propagated by parting the roots towards the end of October, when the stalks begin to decay. Those of the eleventh should be removed every other year, to prevent their spreading too far. It is hardy, and will thrive in any situation, but as the roots are apt to extend, it is not proper for the borders of small flowergardens ; but in large borders, on the sides of rural walks, or in spaces between shrubs, it will be ornamental during the season of flowering.

9. Buphthalmum Grandiflorum; Great-flowered Ocepe-Leaves alternate, hancolate, stem-clasping, orate, naked, serrate, subclinate; stem one-flowered.—This is also peramial, with an annual stalk; it grows near two feet high, with sender branching, and shall and sender branching. And are of a bright yellow colour. It flowers in June and July, and the seeds ripen in automn. It is a native of Italy, Austria, and the south of France. There are two or three varieties, differing in the breadult of their leaves, and the size of their flowers, for the space is not seeds. For its propagation and culture, see the eighth species.

10. Buphthalnum Speciosissimum. Leaves alternate, stemclasping, ovate, naked, sertate, subcilate; stem one-flowered; root fusiform, resembling a tuberous one.—H grows wild im the mountains about Brixen in the Tyrol, and is perennial. The leaves of this, and those of the minth species, have a task somewhat like those of the a, and may be used instead of them,

11. Buphthalmum Helianthoidés; Sunfhueer-leared 02: egre. This is a perennial plant, a fathon in height; root branched, whitish, fragrant—It is a native of North America, and is said to be found wild very where between the tropics. It flowers from July till October. For its propagation, see the eighth species.

12. Buphthalmum Oleraceum. Calicine leaflets acute, connected laterally; leaves opposite, lanceolate, curved back; stem herbaccous, two feet high, upright, round, whitish, smooth, branched; leaves lincar, lanceolate, unequally toothed, smooth, juicy, thick, ash-coloured; flower large, oslitary; calits hemispherical, with sharp heaflets, connected by a lateral membrane; disk of the corolla flat with yellow florets; ray wide, spreading, with many white trifd florets; receptacle flattish, with very small chafts; crown of the seeds margind; the sitgmain the hermaphrodite flowers is simple.—It is an odorous plant, cultivated as a potherb in the gardens of China and Cochin-china.

Bupleurum; a genus of the class Pentandria, order Digynia.-GENERIC CHARACTER. Calix: unbel universal, with fewer than ten rays; partial with scarcely ten rays, erect, expanding; involver universal, unary-leaved; partial five-leaved; larger leaflets expanding, ovate, acute. Periauth proper obscure. Corolle: universal uniform; floxedles all BUP

ferific; proper of five, involuted, entire, very short petals. Staminar if memta five, simple. Anthere roundish. *Pistil:* gemen inferior; styles two, reflected, small; stigmas very small. *Pericarp*: none; fruit roundish, compressed, striated, splitting in two. *Scedis*: two, ovate, oblong, convex, and striated on one side, fat on the other. EssENTIAL CHA-RACTER. *Involucers* of the unabellule larger, five leaved, *Petals*: involuted. *Fruit*: roundish, compressed, striated. -The buplenums in general are cultivated only in botanic gardens. The seeds should be sown in autumn, wherever they are designed to remain, for they do not bear transplanting well. To keep them clean from weeds, is all the culture they require. —The species are,

1. Bupleurum Rotundifolium ; Common Thorough-wax. Universal involucres, none ; leaves, or rather stem, perfoliate. -Our common or round-leaved hare's-ear, is known in Englaud by the name of Thorough-wax, from the singular circumstance of the stalk waxing or growing through the leaf; which alone may serve to distinguish this plant, it being the only one, among our indigenous herbs, which has a simple leaf perforated by the stem. Every part of the plant is remarkably hard and rigid, and has a slightly aromatic smell. It had the reputation formerly of being a vulnerary herb; but this is a quality which no medicine can have, any otherwise than as a tonic, strengthening the constitution; nor can any external application be specifically healing or consolidating, or be useful in any other way, except as a defence from the air. Country people make use of the leaves externally, against wounds and bruises; and the seeds inwardly, to prevent the bad effect of inward hurts. Culpeper says, the decoction of the herb, or powder of the dried herb, taken inwardly, and the same or the leaves bruised, and applied outwardly, is singularly good for all ruptures and burstings, especially in children before they be too old. Native of most parts of Europe, from Britain southward, as a weed among corn. With us, however, it is not very common. It has been found near Lewisham, and between Queenhithe and Stone in Kent, and Harefield in Middlesex, which are the nearest places to the Metropolis in which it has been discovered. It appears in tolerable plenty in several parts of Cambridgeshire, and was observed near Feversham by Mr. Ray, nearly a century and half ago. Since that time, it has been remarked on the lower road to Gogmagog-hills, by Linton, and near Kingston wood. Mr. Crow has found it near Marham in Norfolk ; Mr. Woodward at Carlby, between Stamford and Bourn in Lincolnshire. It is plentiful in many parts of Kent; and between Farningham and Ainsford. it grows in great quantity in the corn-fields. Dr. John Sibthorp marks it as growing about Southheigh and Middleton Stoney in Oxfordshire. It grows near Epsom, Sutton, and Leatherhead in Surry; and doubtless in many other places in the southern counties. In the northern counties, and in Scotland, we have no account of it. A dry calcareous soil snits it best ; and it has never been observed among wheat, It flowers in June and July.

2. Bupleurum Stellatum; Starry Hare's Ear. Involucels united; universal involucer three-leaved; root perennial; stema foot or eighteen niches high.—Native of the Alpa Switzerland, and Dauphiny. Its season for flowering is from May to July.

3. Bupleurum Petræum; Rock Hare's Ear. Involucels united; universal involucre five-leaved; root perennial; rootleaves very numerous, long, narrow, and tender, like those of the most delicate grasses, spreading on the ground.—It is a native of Switzerland, Monte Baldo, and the south of France; and flowers from May to July.

4. Bupleurum Angulosum; Angular-learch Hare's Ear. Involuced Sive-leared, orbiculate; universal involucer threeleaved, ovate; leaves stem-chaping, cordate, lancolate,— This sort is large, being eighteen inches high, and is easily known by its awned involucres. It is a native of Switzerland, and ñovers from May to July.

BUP

5. Bupleurum Longifolium ; Long-leaved Hare's Ear. Involucels five-leaved, ovate; universal involucre, with about five leaflets; leaves stem clasping .- This closely resembles the first species: but the root is perennial, and the rootleaves are permanent, and more lengthened out. Native of Germany, Flanders, Switzerland, Dauphiny, and Savoy ; flowering from May to July. The fresh-gathered leaves are a good application to green wounds, which they speedily heal without any other assistance; the method of using them is as follows : take three or four of the leaves, and after closing the lips of the wound, lay them one over the other, and secure them with a linen baudage for the space of three or four days; at the end of which time, in most cases, the cure will be effected, and nothing but a scar will be found remaining. It is likewise supposed to possess considerable efficacy in scrofulous complaints, but is not altogether to be depended on for the cure of a disorder which frequently sets the most powerful medicines at defiance. This herb has always been included among the vulnerary plants.

6. Bupleurum Falcatum; Twisted städked Harés - Ear, Involucefs five-leaved, acute; universal involucer, with about five leaflets; leaves hanceolate; stem flexuose; root perennic]; flowers small, deep yellow.—Native of Germany, Switzerland, Austria, the south of France, and Italy. It flowers in our gardens from May to September.

 Bupleurum Odonities; Narrow-leared Harés Ear., Involucels five-leaved, acute; universal involucre three-leaved; the central floscules ligher; branches divaricated; root annual.—Native of the south of France, Switzerland, Carniola, Spain, and Italy. It flowers from June till August.

8. Buyleurum Semicompositum; Dreaf Har's Ear, Umbels compound, simple, scarcely a span high; branches divaricate; leaves lanceolate; compound umbels, with five rays, and a five leaved involucer, the leagth of the umbel; the petals are purplish.—Native of Spain, Montpellier, Villa France. Annual; flowering in July and August.

9. Bupleurum Rannacülaides. Involucels five-leaved, lanceolate, longer; universal involucer three-leaved; stem-leaves lanceolate.—This is commonly a very small plant, not more than a few inches in height; in some situations it is scarcely more than one inch high; in others, it rises to a foot. The root is perennial; the stem simple; the leaves grass-like and stiff; unbel unequal; universal involucer ovate, acute, Notive of the south of France. Switzerland, and the Pvernees.

 Buplearum Rigidum; Stiff-leaved Have's Ear. Stem dichotomous, almost naked; involucres very small, acute; root perennial.—It grows naturally about Montpellier, and Frankfort on the Maine.

11. Bupleurum Gerardi. Stem erect, panicled; leaves lanceolate, linear; involucres and involucels five-leaved; root annual, simple, naked.—Native of Provence and Austria.

12. Bupleurum Tenuissimum; Least Harés Ear. Unbels simple, alternate, five-laverd, with about three flowers.— This is an annual plant, with the stem a foot high, and much branching; the branches alternate, long, and many-dowered. – Native of Germany, Austria, Switzerland, France, Italy, and England, near Huntingdon, Ellesley, Cambridge, Lynn, Holkham, Malden, Hastings, Petti n the isle of Thannet, and

3 H

18.

BUR

BUP

probably in many more places, where it has been overlooked, being a plant of little appearance or colour, and in a manner lost in the grass among which it grows: it flowers in July and August.

13. Bopleurum Junceum; Linear-leared Har's Ear, Stem erect, panicled; leaves linear; involuces three-leaved; involucels five leaved; root annual; stem six feet high, rashy, of an even surface, with alternate opright branches; the seeds are almost of the size and colour of parsley. It is a mitive of France, Italy, Switzerland, and Germany: it flowers in July and August, and was cultivated in the botanic garden at Chelsea.

* Shrubby.

14. Bupleurum Fruticosum; Common Shrubby Hare's Ear, or Shrubby Ethiopian Hartwort. Leaves obovate, quite eutire .--- It is an evergreen shrub, rising to the height of five or six feet, and dividing into many branches, so as to form a large regular bush ; the stem is covered with a purplish bark; the branches are well furnished with oblong, smooth, shining, stiff leaves, of a sea-green colour, placed alternately four inches long and one broad in the middle; at the ends of these the flowers are produced in umbels; they are yellow at first, but fade away to a brown; they appear iu July or August, but seldom perfect seeds in England. It is a native of Spaiu, and flowers in August and September. This is commonly known among gardeners by the name of shrubby Ethiopian hartwort, and is now propagated in the nursery gardens for sale: being hardy, it will thrive in the open air, and may be intermixed with other evergreen shrubs of the same growth in the front of taller trees, where their stems are designed to be excluded from sight. It is propagated by cuttings, which should be planted in pots filled with fresh loamy earth, and in winter sheltered under a hotbed frame; in the spring the cuttings will put out roots, but they will not be fit to transplant till the autumn following: so the pots should be placed in a shady situation in summer, and in dry weather they must be refreshed with water: the young plants may be placed in a nursery-bed at two feet distance, for a year or two, to get strength, and then transplanted where they are to remain.

15. Bupleurum Fruitcescens; Grass-teard Skrubby Hare's Ear. Leaves linear; involucer universal and partial.—The leaves of this are sharp and rather fleshy. It is a native of Spain, and flowers in August and September. This may be cultivated in the same manner as the preceding species, but it is not so hardy.

16. Bupleurum Difforme ; Varions-leaved Hare's Ear. Vernal leaves decompound, flat, gashed; summer filiform, angular, trifid .- This rises with a shrubby stalk to the height of five or six feet, sending out some side-branches, which in the spring have on their lower parts leaves composed of so many small flat leaflets, finely cut, like those of coriander, and of a sea-green colour; these leaves soon fall off, and the upper part of the branches is closely covered with long rushlike leaves, having four angles coming out in clusters from each joint. It is a native of the Cape of Good Hope, and flowers from June till August. This is also propagated by cuttings, which readily take root, if they are planted in April, in pots filled with light earth, and plunged into a moderate hot bed ; when they have taken root, they should be inured to the open air by degrees, and after they have obtained strength, may be planted each into a separate pot filled with light loamy earth, placing them in the shade till they have taken fresh root, when they may be placed with other exotic plants in a sheltered situation, where they may remain till the autumn, and then they must he removed into the green-house of dryxtove. If this plant he propagated by seeds, they should be sown in autumn, soon after they are ripe, in pots filed with light earth, which must be sheltered under a frame in winter, and in the spring removed to a very gentle hot-bed; it he plants must be inured to the open air by degrees, and then treated in the same manner as those raised from cuttings.

17. Bupleurum Spinošum. Branches of the panicle, when old, naked and spinoscent | teaves linear; root perennial; stem low, shrubby, unequal, streaked, rigid, with very frequent joints; branches divaricate and hent back; root-leaves linear, lanceotate, three-nerved, acute; stem-leaves very like them; those on the branches sharper and very short.— Native of Spain. This, as well as the eighteenth and nineteenth species, may be propagated by outlings, and treated as the spittenth; or by seeds, when they can be obtained. They will probably bear the open air in mild seasons, but are not yet sufficiently common to run that hazard.

10. Bupleurum Nudum; Nakad-stalkdel Hare's Ear. Stem branched, leafless; root-leaves decompound, fiat, gashed; involucers and involucels lanceolate, obloug.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the seventeenth species.

19. Bupleurum Coriaceum; Thick-leaved Shrubby Hare's Ear. Frutescent; leaves lanceolate, coriaceous, oblique; stems upright, sparingly branched, round, dark-coloured, annulated with the scars left by the falling leaves, from three to four feet in height; branches alternate, upright, marked with lines, fistulose, green; leaves alternate, approximating, half stem-clasping, quite entire, cultrate about the edges, with a sharp reflex point, attenuate at the base, having one whitish nerve, glaucous, permanent, five inches long, and nearly an inch broad; when held up to the light, appearing very finely netted ; scape or common peduncle, in which the branches terminate, furnished in the lower part with remote leaflets, branched at top into lateral umbels marked with lines a foot and half in length, more slender by half than the branch from which it springs. Native of Gibraltar. For its propagation and culture, see the seventeenth species.

Buriardia; a genus of the class Pentandria, order Pentagynia.--GENREIC CHARACEE. Colir: periodi fiveleaved; leaficts ovate, externally villose, acute, decidous; Corolla: p teals five, roundish, obtuse, spreading, almost the length of the calix. Stamina: filamenta five, capillary. Anthera ovate. Pisifi: germen three-cornered; styles five or sit, long; stigmas flat, broadish, fleshy, with five prominent streaks. Pericarp: capaule three-sided, one-celled, threevalved. Receptacle linear, fastened longitudinally to the middle of acit valve. Seeds: seven or eight, subvate, adhering to each receptacle. ESENTIAL CHARACTER. Calix: five-leaved. Corolla: five-petalled. Capsule: angular, no-celled, three-valved, seven or eight-seeded.----The only known species is, 1. Burcardia Villosa,--This is an annual plant, with a

I. Burcardia Villosa,—This is an annual plant, with a branched stem, two feet high, hirsute, with reddish brown hairs; leaves alternate, subsessile, ovate-oblong, wrinkled, toothed, covered with hairs of the same colour with those on the stem; flowers at the end of the stem and branches, sailary, solitary, on long hairy peduncles; the whole plant, indeed, is covered with stiff hairs. It is found on the sandy coasts of Cayenne and Guiana.

Burdock. See Arctium aud Xanthium.

Burmannia; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. Calix: perianth long, one-leafed, prismatic, coloured, with three longitudinal mem-

210

branous angles; the mouth trifid, small. Corolla ; petals three, ovate, oblong, very small, placed in the mouth of the calix, extremely minute. Stamina : filamenta six, very short. Antheræ in the mouth of the calix, very short, two always together, separated by a reflected point. Pistil: germen cylindric, shorter by half than the calix ; style filiform, the length of the corolla ; stigmas three, obtuse, concave. Pericarp : capsule covered by the calix, cylindric, three-cornered, three-celled, three-valved, gaping at the angles. Seeds ; numerous, very small. ESSENTIAL CHARACTER. Calix: prismatic, coloured, trifid; angles membranous. Petals: three. Capsule : three-celled, straight. Seeds : minute .-These plants are very difficult to preserve in gardens, for as they naturally grow in marshy places, which are covered with water great part of the year, they will not thrive when planted in dry ground, and being too tender to live abroad, in England they must be planted in pots, plunged in troughs of water, so as to cover the surface of the mould about three inches .---- The species are,

1. Burmannia Disticha. Spike double; root composed wholly of capillary fibres, and very small .- The plant has the appearance or habit of an anthericum ; root-leaves six, eight, or nine, grass-like or ensiform, two inches long, quite entire: stem upright, straight, quite simple, a span or a span and a half in height, having six or seven very small, alternate, scale-like leaves, sheathing the base, an inch long, scarcely separating from the stem, but in a manner embracing it ; two equal, simple, divaricating spikes, each composed of about nine flowers, terminate the stem. The flowers are sessile, in a single row, pointing upwards; they are blue, very elegant, and do not fall off. Native of Ceylon, in open watery places; called in that country, jawal, jawul, or dya-jawul, that is, water jawul. The troughs in which this sort is planted should be placed in a warm stove, where the plants should constantly remain, being careful to supply the water as it diminishes.

2. Burmannia Biflora. Flowers two together ; root strong and fibroas, with several obloag oval leaves arising from it, which are smooth and entire, four or five incluse long; among these springs the flowers growing two together in each sheath: it grows maturally in watery places, in Virginia and Carolina. The tronghs in which it is planted should be placed in a green-house in winter, to protect the plants from frost, but in summer they may be able to plant and the plant for the plant is showed to the system.

Burnet. See Potesium, and Sangnisorba.

Burnet Saxifrage. See Pimpinella.

Bur-reed. See Spargianum.

Bursera ; a genus of the class Polygamia, order Diæcia. -GENERIC CHARACTER. Calix : perianth onc-leafed, minute, three-parted ; parts ovate, acute. Corolla : petals three, ovate, acute, spreading, entire, deciduous. Stamina : filamenta six, subulate, erect, fixed round the base of the germen. Antheræ ovate, erect. Pistil: germen ovate; style short, thick, trifid at the tip; stigmas very short, simple. Pericarp : capsule fleshy, obovate, three-cornered, threecelled, three-valved. Seeds : berried, solitary, commonly only oue, compressed. Male on a separate tree. Calix: perianth five-toothed, minute. Corolla: petals five, lanceolate, acuminate, reflex, shrivelling. Stamina: filamenta five, eight, ten, placed round a slightly convex surface, scarcely shorter than the petals, subulate. Autheræ oblong, two-celled. Pistil: a rudiment ; germen none ; style trifid, caducous, or none. ESSENTIAL CHARACTER, Hermaphrodite, Calix : three-leaved. Corolla : three-petalled ; capsule fleshy, three-valved, one-seeded. Male, Calix : five- wild in Britain.

toothed. Corolla: five-petalled. Stamina: ten,----The only known species is,

1. Bursera Gummifera ; Jamaica Birch tree .-- This is a very lofty tree, with an upright, round, smooth trunk, covered with a livid shining bark, peeling off in round pieces, like the European birch ; branches terminating, smooth, horizontal ; twigs ferruginous and villose ; leaves pinnate ; petioles round, villose; petiolules compressed, channelled, villose beneath; flowers small and white; capsule red, resembling a drupe, On the male trees the flowers are more copious and crowded in the racemes, but are scarcely larger. According to Sir Hans Sloane, the roots run very superficially; the trunk is as thick as a hogshead or pipe; there are four or eight pairs of leaflets, an inch and half long, and half as long near the round base where broadest; the petals are five in number, thick, yellowish, and short; the berries three-sided, the size of a small pea, with a reddish brown skin, very gummy, and smelling like turpentine, under which lies a white, very hard, triangular stone, containing a kernel. The tree having stood naked some time, has first its flowers come out, and its leaves begin to bud a little after. This tree is common in all the sugar islands of the West Indies; the bark is very thick, and exudes a clear transparent resin, which soon hardens in the air, and looks like the mastic of the shops ; but by iucision, it yields a considerable quantity of a more fluid substance. which has much of the smell and appearance of turpentine, and may be used for the same purposes. The bark of the root is thought to be the sima rouba of the shops, which is an effectual remedy in bloody fluxes; it is administered in decoctions, and one or two drachms is sufficient for a quart of water, for if it be strong it purges or vomits. In the French islands it is called gommier blanc; and an infusion of the buds and young leaves is recommended there in disorders of the breast ; it flowers from May to July,

Batcher's Broom. See Rusais.

Butomus; a genus of the class Enneandria, order Hexagynia-GENERIC CUARACTER. Calitz: involucer simple, three-leaved, short. Corolla: petals six, roundish, concave, withering; three outer, alternate, smaller, more acute. Stamina: filamenta nine, subulate. Anthera bilamellate. Pissimple. Pericarp: capsules six, oblong, gradually attenuated, erect, one-valved, gaping on the inside. Steels: very many, oblong, cylindric, obtuse at both ends, fixed to the wall of the capsules. ESENTAL CHARACTER. Calitz: none, Petals: six. Capsule: six, many-seeded. This plant may be propagated in boggy places; or by planting it in cisters kept filled with water, and having about a foot thickness of the easeles own as soon as they are ripe; or on the sides of ponds, or slow.flowing streams, where it will have a good effect in diversifying the scene.—The only species hitherto discovered is.

1. Butomus Umbellatus ; Flowering Rush, or Water Gladiole. Root perennial ; leaves ensilorm, long, triangalar, smooth, quite entire, spongy, at bottom sheathing, at top flat and twisied; scape upright, round, smooth, from one to three or five and six feet high; corolla handsome, nearly an inch in breadth, commonly of a bright or pale flesh-colour; purple, or rose-colour; it is found in and by the sides of watery ditches, moats, lakes, ponds, and brooks, in most parts of Europe, from Lapland to thay. It flowers with us from Jaly to September ; the corolla varies in different shades of red or purple, mised with white, and is sometimes entirely white. This is the only plant of the Enneandria class, which grows wild in Britan. Butterbur. See Tussilago.

Butterwort. See Pinguicula.

Buttneria ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, five-cleft, decidnous; divisions ovate, acute, spreading very much. Corolla: petals five, oblong, short, converging; above broadish, concave, ending in a long subulate bristle, incumbent on the nectary at the base, then erect expanding, longer than the calix, and in two other, small, lateral, short reflex bristles. Nectary five-leaved, ventricose, campanulate, shorter than the calix; leaflets obovate, obtuse, flat, erect, semiconnate by the filamenta. Stamina: filamenta five, subulate, on the outside of the nectary, each springing from two adjoining leaflets of it. Antheræ twin, distinct, bifid, roundish. Pistil: germen roundish, quinquangular; style subulate, short ; stigma obtuse, obscurely quinquefid. Pericarp : capsule roundish, depressed, five-grained, five-valved, muricate ; seeds solitary, ovate, compressed. ESSENTIAL CHA-RACTER. Corolla: five-petalled. Filamenta: at the top, connate with the petals. Capsule : five-grained, muricate. -The species are,

 Büttheria Scabra. Leaves lanceolate; rib and petioles prickly.—This is a perennial plant, shrubby at botton, from three to five feet high, with alternate long angular branches, armed with short, reflex, carillaginous prickles.—Fouud by Aublet between Cayenne and Couron, in June.

2. Büttneria Carthagiuensis. Leaves ovate; rib and petioles prickly; stems perennial, rather woody, five-cornered; the throws and angles obtuse, armed with crooked reflex prickles; the tender branches round, prickly, alternate; flowers without smell, small, white, very numerous.—Native of Carthagen and St. Domingo, flowering in September and October.

3. Büttneria Microphylla. Branches flexuose, even; leaves unarmed; spines of the stem solitary, by the side of the leaves horizontal; leaves alternate or in pairs, remote, oval, very blunt, subsessile, spreading.—Found in the island of St. Domingo.

Button-tree. See Conocarpus.

Button-weed. See Spermacoce.

Button-wood. See Cephalanthus.

Buxbaumia; a kind of moss, of which there are only two species, both of which are to be found in the Dissertation of the younger Linneus on mosses.

Buxus ; a genus of the class Monœcia, order Tetrandria.-GENERIC CHARACTER.. Male flowers prominent from the buds of the plant. Calix: perianth three-leaved ; leaflets roundish, obtuse, concave, spreading. Corolla: petals two, roundish, concave, very like the calix, but larger, Stamina : filamenta four, subulate, erect, expanding, rather larger than the calix. Antheræ erect, twin. Pistil : rudiment of a germen without style or stigma. Females in the same bud with males. Calix: perianth four-leaved; leaflets roundish, obtuse, concave, spreading, Corolla : petals three. roundish, concave, very like the calix, but larger. Pistil: germen superior, roundish, obtusely three-cornered, ending in three very short permanent styles; stigmas obtuse, hispid. Pericarp ; capsule coriaceous, roundish, three-beaked, threecelled, bursting elastically into three points. Seeds : twin, oblong, rounded on one side, flat on the other. ESSENTIAL CHARACTER. Male, Calix : three-leaved. Petals two. The rudiment of a germen. Female, Calix : fonr-leaved. Petals three; styles three; capsules three-beaked, threecelled ; seeds two .---- The only known distinct species, of which there are several varieties, is,

Buxus Sempervirens. Box is well known in its dwarf state, and is a shrub about three feet in height; it becomes, comb, and pipe or flute maker; the roots are also employed

however, when left to itself, a tree, twelve or fifteen feet high, with a trunk equalling the human thigh in thickness, covered with a rugged greyish bark, the colour of the bark of the branches being yellowish. The wood is of a yellow colour, of an even close grain, very hard and ponderous, and is the only kind of European timber which will not swim in water, It is ranked with the ebony for closeness of grain. The leaves are ovate or oval in the common sort, hard, smooth, glossy, evergreen, very dark green above, pale green underneath, something resembling those of myrtle, but blunt, and commonly emarginate at the end; the edges are revolute, they are commonly set on very short petioles, and on the twigs they come out regularly in pairs, so close as almost to conceal them. Mr. Miller insists that the common box-tree, the narrow-leaved, and the dwarf or Dutch box, are three certainly distinct species. The two sorts of box-tree have been frequently raised from seeds, and constantly produced plants of the same kind as those the seeds were taken from ; and the dwarf-box will never rise to any considerable height with any culture, nor have I seen this sort flower, where the plants have been encouraged to grow many years in the greatest luxuriancy. There are two or three varieties of the first, which are propagated in the gardens : one with yellow. and another with white striped leaves; the other has the tops of the leaves only marked with yellow, which is called tipped box. The box-tree is a native of most parts of Europe, from Britain southwards. I have seen whole mountains covered with it, between Lyons and Geneva, but none of any size. It is also very common in many parts of Burgundy, Dauphiny, and Provence. It abounds in many countries of Asia, as about Mount Cancasus, in Persia, China, Cochin-china, &c.; also in America. In Eugland it was formerly much more common than it is at present. Gerarde says, "it groweth upon sundry waste and barren hills in England;" and Parkinson, "that it is found with us in many woods, and wood grounds; that it is also planted in divers orchards, or house back-sides, where it never groweth high, but serveth as a bush to dry linen on," &c. Many of these bushes, however, have grown up to trees of a reasonable size, about old mansions, and farm-houses, but are now for the most part destroyed. " These trees rise naturally," says Evelyn, " in Kent at Boxley, and in Surry, giving name to Boxhill. He that in winter should behold some of our highest hills in Surry clad with whole woods of them, for divers miles in circuit, as in those delicious groves of them belonging to the late Sir Adam Brown, of Bechworth-castle, might easily fancy himself transported into some new or enchanted country." The enchantment, alas! has been long broken. In 1759, Mr. Miller lamented that the trees on Boxhill had been then pretty much destroyed, though many of a considerable size still remained : but the destruction since that time has been much greater. It has been conjectured, that Boxhill was planted with these trees by the Earl of Arundel; but there is the most authentic proof that they were there before his time; and the ground on which they grow was not his property. Not only this hill near Darking in Surry, and Boxley in Kent, but Boxwel in Coteswold, Gloucestershire, was named from this tree. Mr. Woodward remarks it "as plentiful on the chalk hills near Dunstable. It is fond of open dry situations, and a calcareous soil. In temperate climates and seasons, it flowers in February and March. The wood of the box sells at a high price, by weight. Being very hard and smooth, and not apt to warp, it is well adapted to a variety of nicer works." "It is of special use," says Evelyn, "for the turner, engraver, carver, mathematical-instrument maker,

BYS

by the inlayer and cabinet maker. Of box are made wheels | from the Greek and Latin, in the European languages; and shivers, pins, pegs for musical instruments, nut-crackers, button-moulds, weavers' shuttles, hollar-sticks, bump-sticks, and dressers for shoemakers, rulers, rolling-pins, pestles, mall-balls, beetles, tops, tables, chess-men, screws, bobbins for bone lace, spoons, knife-handles, nay the stoutest axle-trees, and especially combs, which was the custom of the ancients. who also made of it musical instruments to be played upon by the mouth, according to Pliny and Martial. The Romans likewise clipped it into the shape of various animals, for which purpose it was second to the yew with us in former times, but the dwarf-box stood unrivalled for bordering up a knot, and was esteemed a marvellous fine ornament to the flower-garden." The branches were in request among our ancestors, for decking up houses; they are still seen among other evergreens in churches at Christmas, and in some countries they are borne by attendants at funerals. In our plantations, the box still keeps its place deservedly among ornamental evergreens. It will flourish under the deepest shade, and thrive in any soil and exposure. Dr. Stokes affirms, that it is fit to cut down in about thirty years. Box has been much celebrated as a medicine in the venereal disease, colics, intermittent fevers, &c. But our shrewd old Gerarde sensibly remarks, "that it is more fit for dagger-hafts, than to make medicines ; though foolish emperies and women-leeches do minister it against the apoplexy, and such diseases." He adds, "that the turners and cutlers call this wood dudgeon, because they make dudgeon-hafted daggers with it," Parkinson, in his first work, says, "it has no physical use among the most and best physicians, although some have reported it to stay fluxes. and to be as good as guaiacum for the French disease,' Yet in his second work he sets it down as a medicine for the bite of a mad dog; as a cure for the bots in horses; and the leaves and saw-dust, boiled in lye, to change the hair to aborne, auburn, or abraham colour. According to Dr. Withering, "an empyreumatic oil, distilled from the shavings, is often used as a topical application for the piles, and seldom fails to procure ease; it will frequently relieve the tooth-ache, and has been given internally in epilepsies : the leaves powdered, destroy worms." Decoctions of the wood and bark are wholly disused, on account of their being very nauseous and disagreeable to the stomach. Meyrick observes, that box-root is said to possess the same virtues with guaiacum wood, but in a much greater degree; consequently is a good medicine in a foul state of the blood and juices. A decoction of it is the best preparation; but the use of it must be continued for a long time, as it is one of those medicines which operate but slowly, though effectually. An oil dis tilled from the wood is frequently used to anoint the piles with, and seldom fails of giving ease; it likewise frequently relieves the tooth-ache, cleanses foul ulcers, and disposes them to heal, and is good to rub on such parts as are affected with old aches and pains. Hill assures us, "the wood of the box tree, and particularly the root, is an excellent medicine in all foulnesses of the blood ; it has the same virtues with the guaiacum, but in a greater degree. It is to be given in a moderately strong decoction, and continued a long time. There have been instances of what were called leprosies

cured entirely by this medicine. There is an oil made from it by distillation, which is good for the tooth-ache; it is to

be dropped upon cotton, and put into the tooth. Pliny

affirms, that no animal will touch the seed of box. Gmelin

states, that the branches are fatal to the camels that eat them.

Not one of our animals will touch this tree. Corsican honey

was supposed, by the ancients, to owe its infamy to the bees feeding on the box. The name of this tree varies little

18

being bucks or bucksbaum in German; buxbom, in Swedish and Danish , buis or bouis, in French ; busso or bosso, in Italian ; box, in Spanish ; bucho or buxo, in Portuguese ; the Russians have adopted samschit from the Tartars; the Persians call it schimschat; in Turkey it is named tschemtschir; the Japanese call it xo tsuge ; the Chinese huynh duong ; the Cochin-chinese hoam tuon .- Propagation and culture of the common box ; All the varieties of this tree may be propagated by cuttings, planted in autumn in a shady border, observing to keep them watered until they have taken root, when they may be transplanted into the nursery until they are fit for the purpose intended. These cuttings may be planted as early as August, but the best time is during the fall of the autumnal rains. They should be a foot in length, and rather more than half should be planted in the ground, at the distance of four inches from each other. A slip of the last year's wood, stripped from an older branch, is an excellent set, and there is little fear of its growing. The cuttings or slips may stand three years, and then be transplanted into the nursery any time between August and April, choosing moist weather for the purpose, if this work be performed early or late. In the nursery, the rows may be two feet asunder, and the plants a foot from each other in the rows. The narrow-leaved box-tree may be propagated by laying down the branches. This may be done between Michaelmas and March; and it is the natural way by which box frequently propagates itself; for when it breaks down by its own weight, or by a fall of snow, soon after it comes into contact with the ground it sends forth fibres. Box may be propagated by seeds sown soon after they are ripe, in a shady border, and duly watered in dry weather. This is the best method. to raise large trees. The best soil for the seeds is a light loam or sand, and they should be sown half an inch deep. They will come up in the spring, though probably many will lie in the ground till a second season. They should stand two or three years in the seed-bed ; and when they are strong enough to plant out, they may be removed into the nursery, and placed at the same distance as was prescribed for the cuttings. The best season for removing this tree is October, though it may be transplauted almost at any time, except in summer, if it be taken up with a good ball of earth. Dwarf-box is increased by parting the roots or planting the slips; but as it makes so great an increase of itself, and so easily parts, it is hardly worth while to plant the slips that have no roots. It is so common, that it may be purchased from the nurseries at a cheap ree. The manner of planting it in edgings is well understood by every working gardener.

Byssus ; a genus of the Cryptogamia Algæ, and the last in the scale of vegetation in that class. According to Linneus there are fourteen species, but many more are certainly known. They appear in form of threads, or a kind of meal, on rotten wood, the bark of trees, rocks, damp banks, and walls, especially of damp cellars. Hudson and Withering enumerate nineteen British species, and Lightfoot fourteen. One sort is common on wine-casks : at first it is like flakes of snow, but turns yellow, and at last like a mouse's skin; in this state it has black grains at the base like gunpowder, rots the casks, and is excellent to staunch blood. The green paper byssus is a farina concreting on the surface of the water, where it forms a wide thin film. Weis denies it to be a vegetable, but Withering believed it to be a conferva.

Bystropogon; a genus of the class Didynamia Gymnospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, divided into five awl-shaped segments, closed by a beard at the opening. Corolla : monopetalous, ringent; 3 I

upper lip bifid, lower trifid, the outmost segment most pro- | nerves and viscera, where such warm medicines are reduced. Stamina : filamenta four, didynamous, distant. Antheræ incumbent. Pistil: germen superior, four parted; style subulate; stigma bifid. Pericarp : noue; calix closed with a beard, and cherishing the seeds. Seeds: four. ESSEN-TIAL CHARACTER. Calix: five-subulate, bearded at the opening. Corolla: upper bifid, lower trifid. Stamina: distant .-- As to the culture and propagation of the plants of this genus, the three first sorts must be preserved in the bark-stove, the four last in the dry-stove or conservatory. They may be all propagated by cuttings during the summer -The species are, months .---

BYS

1. Bystropogon Pectinatum; Balm leared Bystropogon. Panicles compact ; flowers directed one way ; leaves ovate .-Native of Jamaica, in all the low lands and dry savannas about Kingston and Spanish Town. It has also been found in Peru, by Dombey. It flowers in December and January.

2. Bystropogon Sidafolium; Sida-leaved Bystropogon. Panicles very loose; peduncles in whorls, filiform; leaves cordate .--- Native of Peru,

3. Bystropogon Suaveolens : Sweet-scented Bustronogon. Peduncles axil'ary, solitary; calices truncate, awned; leaves cordate .- This is an annual plant, the whole of which has a very strong smell, like all the rest of this genus. On this account the Portuguese call it, erva cidreira, or citron herb : and in Jamaica, where it is common about Kingston and Old-harbour, they call it spikenard, on account of its strong and pleasant smell. It is one of the most grateful cephalics and alexipharmics; and may be used in disorders of the

CAB

CABBAGE. See Brassica.

Cabbage-tree. See Areca and Cacalia Kleinia.

Cacalia ; a genus of the class Syngenesia, order Polygamia Equalis .- GENERIC CHARACTER. Calix : common simple, oblong, at the base only subcalicled, cylindric; scales five to ten, equal, lanceolate-linear, forming a tube; a few very short, incumbent on the base. Corolla: compound tubular; corollules hermaphrodite, in number the same as the longer leaves of the calix, uniform. Proper funnel-torm, gradually lessening to the tube; border four or five cleft, erect. Stamina : filamenta five, capillary, very short. Anther cylindric, tubular. Pistil: germen oblong ; style the length of the stamina ; stigmas two, oblong, filiform, revolute. Pericarp none; calix unchanged. Seeds : solitary, oblong, ovate, narrow. Down capillary, very long. Receptacle naked, flat, dotted. ESSENTIAL CHARACTER. Calix: cylindric, oblong, at the base only subcalicled. Down capillary. Receptacle naked .- The plants of this genus, all the sorts of which are natives of the Cape of Good Hope, should be propagated by cuttings during the summer months: these should be cut from the plants, and laid to dry a fortnight, that the wound may be healed over before they are planted. Most people plunge the pots, in which these are planted, into a moderate hot-bed, to forward their putting out roots; but if they are planted in June and July, they will root as well in the open air. Branches broken off by accident, which have fallen on the ground, have frequently put out roots without any care. These branches may be kept six months out of the ground, and will then take root if planted. They should have a light sandy earth, and in winter be placed in an airy glass-case, where they may enjoy the sun and air in mild weather, but must be protected from frost.

quired .- It is a native of the continent of South America, as well as the islands of the West Indies.

4. Bystropogon Plumosum; Woolly-flowered Bystropogon. Panicles dichotomous; calices feathered; leaves ovate, subserrate, tomentose beneath .--- It flowers in June and July, and is a native of the Canary Islands.

5. Bystropogon Origanifolium; Marjoram-leaved Bystro-Panicles dichotomous, calices feathered ; leaves nogon. ovate, quite entire, very white beneath .- This is very nearly allied to the foregoing sort, but the leaves are quite entire and snow-white underneath.

6. Bystropogon Canariense; Canary Bystropogon. Peduncles dichotomous; flowers in heads; leaves ovate, crenate, very villose beneath; stem woody, three or four feet high, dividing into many branches ; leaves on long peduncles, hairy, and ash-coloured on their under side .- The flowers are produced from the side of the branches, on pretty long peduncles, each sustaining four roundish heads, dividing by pairs, and spreading from each other. They come out in June and July, but do not produce ripe seeds in England, The corolla is white; and the leaves, when bruised, emit an agreeable odour. The gardeners have given it the title of Madame Maintenon. It flowers from June to August, and grows naturally in the Canary Islands.

7. Bystropogon Punctatum; Cluster-flowered Bystropogon. Panicles dichotomous; flowers in heads; leaves ovate, Flowers from July till toothed, smooth, finely dotted. September, and is a native of Madeira.

CAC

water; and in summer, when they are placed in the open air. it should not be given them too often, nor in great quantity, but they must be treated like the ficoides, and other succulent plants from the same country.---- The species are,

* Shrubby.

1. Cacalia Papillaris; Rough-stalked Cacalia. Stem shrubby, fortified with truncated petiolary spines .- It has not yet produced any flowers in England. Native of the Cape of Good Hope. This, as well as the second species, requires a sandy poor soil, and to be kept very dry both summer and winter : hard rains often cause them to rot ; but they require the open air in summer.

2. Cacalia Anteuphorbium : Oval-leaved Cacalia, Stem shrubby; leaves ovate, oblong, flat, petioles having a triple line at the base .- This plant is generally known by the name of anteuphorbium, being supposed to have qualities contrary to cuphorbium. Native of the Cape of Good Hope; see the first species.

3. Cacalia Cuneifolia ; Wedge leared Cacalia. Stem shubby; leaves wedge-form, fleshy .- Native of the Cape of Good Hope.

4. Cacalia Kleinia; Oleander-leaved Cacalia, or Cabbagetree. Stem shrubby, compound; leaves lanceolate, flat; scars of the petioles obsolete .- This rises with a thick fleshy stem, divided at certain distances, as it were into so many joints; each of these divisions swells much larger in the middle. The stalks divide into many irregular branches of the same form, which towards their extremities have long narrow leaves, of a glaucous colour, standing all round without order; as these fall off, they leave a scar at the place, which always remains on the branches. The flowers are During the winter season, the plants must have but little produced in large clusters, at the extremities; they are of a 15

faint carnation-colour. It grows naturally in the Canary islands, and lowers in August. September, and the greater part of October, but does not produce seed in this country : it is called cabbage-tree by the gardeners, from the resemblance which the stalks have to those of cabbage; others have named it carnation-tree, from the shape of the leaves and colour of the flowers. In some parts of England, fossils have been dug np, upon which Dr. Woodward supposed that he discovered impressions of this plant. It requires a warm dry glass-case in winter, and very little water: in summer, it must be placed in the open ari, in a warm shellered situation. With this management, the plants will flower annually, and grow to the height of rejeth or ten feet.

5. Cacalia Ficoides; Flai-lared Cacalia. Stem shrubby; leaves compressed, fleshy.—This rises with strong round stalks to the height of seven or eight feet; they are woody irregular branches. These, for more than half their length, have thick taper succulent uywards, sending out many isdes, ending in points covered with a wholist meat; when broken, they emit a strong ofour of turpentine, and are full of a viscid juice: at the extremities of the branches the flowers are produced in small unbels; they are while, and cut into five parts at top; the stigma is of a dark purple colour, and stands erect above the tube; the seeds do not ripen in England. In France, the leaves are sometimes pickled with the white meal preserved on them. It flowers from June to November, and grows naturally at the Cape of Good Hope.

6. Cacalia Repens; Glavcous-leared Cacalia. Stem shrubby; leaves depressed, feshsy.—This plant very much resembles the fifth species in stature; it is also covered with a glaucous meal; but the leaves have their upper surface concare, and are not compressed on the sides. It flowers in June, and is a native of the Cape of Good Hope.

7. Cacalia Suffuticosa; Flas-barcel Cacalia. Stem undershrubby, branching; leaves linear, flat, scattered.—This is an undershrub, a palm in height, variously branched, and filiform; leaves quite entire, by no means fleshy; down with hispid hairs. Native of Brazil.

6. Gacalia Laurifolia; Bay-Leared Cacalia. Shrubby, smooth; leaves petioled, ovate, triple-nerved, obtuse, quire entire, very smooth shrub, resembling the laurustina; smooth—A yevy smooth shrub, resembling the laurustina; border of the corolla larger than the tube, four-toothed. Native of Mexico.

9. Gaadia Cordibila; Henrt-leaved Catelia. Shrubby, hirsute; leaves petioled, cordate, ovate, nerved, acute, scabrous; calix four-leaved, four-flowered, pubescent.—This and the preceding species agree so exactly in the flower, and the number of the floxcles, that they might very well make a separate genues. Observed by Mutsi in South America.

10. Cacaina Asclepiadea; Asciepian-like Cacalia. Shrubby, Tomeutose; leaves petioled, ovate-lanceolate, quite entire, very smooth above, tomentose beneath, the edges rolled back; paniels terminal; stems round, hoary, with a soft map, straight.—This herb has the appearance of an asclepias. Found by Muisi in South America.

 Ciscalia Appendiculata; Ear-leared Cacalia. Shrubby, tomentose; leaves cordate, ovate, acute, acuter, tomentose beneath; petioles with leafy appendicles; stem angular, tomentose, hoary; flowers yellow.—Found by Francis Masson, in watery places of the island of Tenerifle.

12. Cacalia Tomentosa; Woolly-leaved Cacalia. Shrubby, tomentose; leaves lanceolate, toothed, tomentose beneath, sessile,-Found at the Cape of Good Hope.

Herbaceous.

13. Cacalia Porophyllum; Perforated Cacalia. Stem lerbaceous, undivided; leaves elliptic, subcremate; stem from eight inches to a foot in height, round, slender.—It Bowers from June till Octoher, is an annuau plant, and a native of America: This and the thirrieth species differ from the genus in their habit, and in having a subturbinate calix, but have no other generic distinctions separating them from the rest of the genus.

14. Cacalia Sonchifolia; Sowthistle-leaved Cacalia. Stem herbaceous; leaves lyrate, stem-clasping, toothed; root annual .- This plant is much used both in the medicine and economy of the Indians; as it is esteemed to be detergent, and the young leaves are eaten raw as salads. It flowers in July, and the seeds ripen in September, and is a native of the East Indies, Ceylon, Amboyna, China, Cochin-china; and, according to Mr. Miller, seeds of it have been received from the Spanish West Indies. This species is propagated by seeds, which, if sown in the autumn, soon after they are ripe, in a pot, and plunged into the tan-bed in a stove, will more certainly succeed than those sown in the spring ; but where there is not such a convenience, the seeds should be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be planted on another hot-bed to bring them forward, shading them till they have taken new root, after which air should be daily admitted to them in proportion to the warmth of the season. When the plants have acquired strength, they should be planted in pots, and either plunged into a moderate hot-bed under a deep frame, or placed in a glass-case, where they will flower and perfect their seeds.

15. Cacalia Incana; *Hoary Cacalia*. Stem herbaceous; leaves lanceolate, toothed.—Native of the East Indies.

16. Cacalia Saracenica; Creeping-rooted Cacalia. Stem herbaceous; leaves lanceolate, serrate, decurrent; the bractes are bristle-shaped.—Native of the south of France; it flowers from August to October.

17. Cacalia Hastata; Spear-leaved Cacalia. Stem herbacous; leaves three-lobed, acuminate, serrate; flowers nodding; root perennial; stem covered with a glaucous meal; flowers composed of about five white florets, without the bristle-shaped bractes, especially at the subdivisions,—Observed by Gmelin and Pallas in Siberia.

18. Cacaha Suaveolens; Sweet-scentred Cacalia. Stem herbaccous, purjeit; leaves hastate, sagittate, coubletted; petioles dilated at top.—This has a perennial creeping root, sending out many stalks; it smells very sweet when dry. Native of Virginia and Canada, flowering in Angust, and ripening its seeds in October. The roots of it which have been cast out of the Chelsea garden, having been caried by the tide to a great distance, have lodged on the banks of the river, and fastened themelves to the ground, where they have increased so much, that in a few years this plant may appear to be a nuitve of this country. Both this and the inucteenth species multiply greatly by their spreading roots, and also by the exects, which are waffed to a great distance by the wind. The roots should be transplanted in autumn; it requires a moist soil and an open situation.

10. Cacatia Atriplicifolia; Orach-leaved Cacalia. Stem herbaccous; leaves subcordate, tooth-innuate; calices fiveflowered; root perennial, composed of many fleshy spreading tubers, sending out several strong stalks in the spring, four or five feet high; flowers in August, and is a native of Virginia. See the eighteenth species.

20. Cacalia Alpina; Alpine Cacalia. Leaves reniform, cordate, acute, toothletted; root perennial; stem a foot and

half high and more, leafy, and branching at intervals .- Haller, I besides the two principal varieties of this species, the smooth and the tomentose, mentions, that it is found with white florets, and with leaves deeply cut. Mr. Miller makes two species of it; the first, or rough sort, he calls alpina; the second, or smooth sort, glabra. Monsieur Villars has three species, besides varieties; but Allioni considers them all as one species : smooth, in subalpine moistish situations, among bushes; hirsute, or very hairy, in loftier, cold, rocky, alpine situations; tomentose or cottony, among the stoues in open situations on the higher Alps. He adds, that he has observed the tomentose variety to become hirsute, when cultivated in a garden. Native of Switzerland, Mount Jura, Dauphiny, Piedmont, Austria, and Carniola. It is propagated by parting the roots, for it seldom produces good seeds in England; the best time to do this is in autumn : it requires a loamy soil and a shady situation.

CAC

21. Cacalia Échinata. Herbaceous; leaves reniform, cordate, angular, toothed, tomentose beneath; leaflets of the calix tubercled.—Observed by Masson in the island of Teneriffe, on precipices near the coast.

22. Cacalia Albitrons; White-leaved Cacalia. Herbaccous; leaves cordate, biscrate, acute, tomentose beneath; stipules oblong, rounded.—This is a singular plant, and very distinct from the others, in having two leaves at the base of the petioles, resembling stipules; they are sessile, oblong, slightly toothletted, and tomentose beneath.—Native of Austria.

23. Cacalia Bipinnata; Bipinnate-leared Cacalia. Herbaceous; leaves bipiunate, linear; stem upright, streaked, even.—Native of the Cape of Good Hope.

24. Cacalia Acaulis; Stemless Cacalia. Stemless; leaves semicolumnar; scapes one-flowered.—Found by Thunberg at the Cape of Good Hope.

25. Cacalia Radicans; *Rooting Cacalia*. Herbaceous, creeping, rooting; leaves columnar, ovate, fleshy.—Found by Thunberg at the Cape of Good Hope.

26. Cacalia Articulata; Joint-stalked Cacalia. Fleshy; stem decumbent, jointed; lower leaves hastate, upper lyrate. —This is an elegant plant, smooth and glaucous, of an unpleasant balsamic flavour; it flowers in November, and was found by Masson at the Cape of Good Hope.

27. Cacalia Lutea; Yellow Cacalia. Stem herbaceous; leaves five-parted, acute, glaucous beneath; flowers terminal, on very long peduncles.—This species grows naturally at St. Helena; the roots spread and increase under the surface; the leaves arise immediately from the root, having very short footstalks. The flower-stalk arises between the leaves, immediately from the roots; this is naked about eight inches high, terminated by six or eight yellow compound flowers, standing on long foot-stalks, almost in an umbel; the flowers are succeeded by oblong seeds, which arrety ripen in England.

28. Cacalia Carnosa: Narrow-leaved Cacalia. Stem shrubby; leaves roundish, fleshy, bent in; peduncles terminating, one-flowered, naked; it flowers in June.—Native of the Cape of Good Hope. It increases fast by roots, which may be parted either in the beginning of September or the end of March, and should be planted in pots filled with light earth, and plunged into the tan-bed in the stove, where it should be constantly kept, being too tender to thrive clsewhere in this climate.

29. Cacalia Scandens; Climbing Cacalia. Stem herbaceous, climbing leaves sagittate, toothed; petioles simple.—It flowers in April, and is a native of the Cape of Good Hope.

30. Cacalia Ruderalis. Stem herbaceous, branched; leaves decompound, with filiform leaflets; seeds rou lanceolate, entire, glaucous.—This is an annual plant, upright, grooved, wrinkled.—Native of Spain and Sicily.

not more than three feet high, very smooth, panicled; flowers void of scent, with a green calix, and a corolla green and yellow mixed. Native of St. Domingo and Martinico. See the thirteenth species.

31. Cacalia Procumbens. Stem suffruticose, procumbent; leaves ovate, lanceolate, subserrate, fleshy; racemes elongated, iuterrupted; stems perennial, nine feet high, procumbent, round, equal, smooth, succulent, branched, — Native of Chima and Cochim-chima, where it is used as a potherb.

32. Cacalia Bulbosa. Leaves radical, lyrate; stem almost maked; paulice few-flowered; root a roundish, knotled, per-emial bulb.—Native of China and Cochin-china. This plant is emollient, refringent, and resolvent, used chiefly externally in resolving tumors; and in the erysieplea, sa a cataplasm; the juice of the leaves in inflammation of the fauces.

33. Cacalia Pinnatifida. Leaves pinnatifid ; segments lanceolate, serrate ; stem herbaceous, twisted, two feet high, upright, thick. Native of China : found among the rice near Canton.

Cachrys; a genus of the class Pentandria, order Digynia. GENERIC CHARACTER. Calix : umbel universal, mauifold ; partial similar ; involucre universal, many-leaved, linear-lanceolate; partial similar; perianth proper scarcely observable. Corolla : universal, uniform ; floscules all uniform; proper of five, lanceolate, almost upright, equal flattish petals. Stamina: filamenta five, simple, the length of the corolla. Antheræ simple. Pistil: germen turbinate, inferior ; styles two, simple, the length of the corolla ; stigma headed. Pericarp: fruit subovate, angular, obtuse, very large, suberous-cortical, splitting in two. Seeds: two, very large, very convex on one side, flat on the other; fungous, with solitary ovate-oblong nuclei. ESSENTIAL CHARAC-TER. Fruit subovate, angular, suberous-cortical. All the plants of this genus are propagated by seeds, which should be sown soon after they are ripe, for if they are kept out of the ground till the following spring, they often miscarry, and when they succeed, they never come up until the spring after; so that by sowing them in autumn, a whole year is saved, and the seeds seldom miscarry. These seeds should be sown on a shady border, where the plants are to remain, for as they have long taproots, they will not bear transplanting so well as many other kinds; the distance three feet apart, so that if each kind is sown in a drill, when the plants are come up they may be thinned, leaving two of the most promising plants of each kind to remain. These plants will begin to appear early in April, when they must be carefully cleared from weeds; and in dry weather, if they are gently watered while young, it will greatly promote their growth; after which time they will require no farther care but to keep them clean from weeds, and every spring to dig the ground carefully between them, so as not to injure the roots. These plants decay to the ground every autumn, and come up again in the spring; they commonly flower in the beginning of June, and their seeds are ripe in September. Their roots sometimes run down three or four feet deep in the earth, provided the soil be light, and are often as large as parsneps: they will continue many years, and if the soil be moist and rich, they will annually produce good seeds; but when they grow on a dry soil, the flowers commonly fall away without -The species are, seeds .---

1. Cachrys Libanotis; Smooth-seeded Cachrys. Leaves superdecompound; leaflets spreading, acuminate; seeds ovate, furrowcd, unarmed.—Native of Sicily.

2. Cachrys Sicula; Hairy-seeded Cachrys. Leaves superdecompound, with filiform leaflets; sceds roundish, ovate, grooved, wrinkled.—Native of Spain and Sicily. .

 Cachrys Tenuifolia; Fine-leaved Cachrys. Leaves superdecompound, smooth, with very numerous filiform leaflets; seeds oval.—Flowers in May. Native of the country about Montpellier.

CAC

4. Cachry's Odontalgica. Leaves superdecompound, rough with hairs; the end leaftets digitate, multifid, bluntish; seeds oborate, truncate, even.—The root is very long, and being of a very sharp aromatic flavour, is used in the tooth-ache. Found abundantly between the Volga and the Jaick.

5. Cachrys Panacifolia. Leaves pinnate and ternate, with oblong crenate leaflets; seeds hirsute; stem three feet high, streaked, hoary, round, full.—Natives of New Spain and Barbary.

Cactus ; a genus of the class Icosandria, order Monogynia. -GENERIC CHARACTER. Culix: perianth one-leafed, imbricate, hollow, tubular, with scaly leaflets scattered over it, superior, deciduous. Corolla : petals numerous, rather obtuse, broad; the outer ones shorter, the inner larger, converging. Stamina: filamenta numerous, subulate, inserted into the calix. Antheræ oblong, erect. Pistil: germen inferior; style the length of the stamina, cylindric; stigma headed, multifid. Pericarp : berry rather oblong, one-celled, umbilicate, roughened as the calix is. Seeds : numerous, roundish, small, nestling. ESSENTIAL CHARACTER. Ca-lix: one-leafed, superior, imbricate. Corolla: manifold; berry one-celled, many-seeded. This genus consists of succulent plants, permanent in duration, singular and various in structure; generally without leaves, and having the stem or branches jointed, for the most part armed with spines in bundles, with which, in many species, bristles are intermixed. These bundles of spines are placed on the top of the tubercles in the first species, or smaller melon thistle, which is tubercled all over, and produces its flowers between the tubercles. In the second species, or great melon thistle, the spines are ranged in a single row on the ridge of the ribs ; these are of an ovate or globular form. From the third to the eleventh species, or the torch thistle, they are slender, rise up high, are jointed and branched; many of them are almost cylindrical, with from five to ten shallow ribs; some, however, are square or three-cornered. The structure of the creeping cereuses is the same with these, except that the stems are weak, and cannot support themselves; they therefore seek support from trees, and throw out roots from the stem like ivy. In the Indian figs, the branches are jointed, and flatted like the sole of a shoe; the bundles of spines, or bristles, are scattered over the surface; and the flowers are produced from the edge of the extreme branches. In the twenty-third species, the branches are thinner, and may fairly be denominated *leaved*; they are indented along the edge, and the flowers come out singly from the indentures; it seldom has any spines. Pereskia has a round stalk with leafy branches; the leaves alternate, flat, and thick; the prickles arc large and stiff, and come out in bundles on the stalk and branches, chiefly at the axils; the flowers are produced several together, from the axils also. In this and the Indian-fig, the flowers are pitcher-shaped; in the other species they are subcylindrical and longer; in phyllanthus very long; the fruit in some of the sorts is small, like currants, but in most it is larger, and shaped like a fig, whence the name of Indian fig. These singular plants are all natives of the continent of South America, and the West Indian islands. -The species are,

* Echinomelocacti of a roundish form.

1. Cactus Mammillaris ; *Smaller Melon Thistle*. Roundish, covered with ovate bearded tubercles.—This differs from the second species, in being smaller and covered with tuber-19.

cles, between which the flowers and fruit come out, round the middle of the plant; the flowers appear in July and August; the fruit is of a fine scarlet colour, and continuing fresh upon the plants through the winter, are very beautiful at that season. The childing variety is but little larger than the other, growing nearly in the same form, but produces a great number of young plants from the sides by which it is increased : it produces quantities of fruit annually; and as the seeds grow very readily, it is now very common in those gardens where there are stoves to keep them, for if the fruit be permitted to drop upon the earth of the pots, and that is not disturbed, there will plenty of plants come up without any further trouble; and these seedling plants may be taken up as soon as they are of a proper size to remove, and planted six or seven of them into a small halfpenny-pot, where they may stand one year, by which time they will each be large enough for a separate pot, and afterwards they will make great progress, especially if they are plunged into a hot-bed of tanner's bark in summer, for although this sort is much more hardy than the large kind, and may be preserved in a moderate stove, yet the plants will not make near the progress of those which are kept in a greater degree of heat. This sort will continue many years with proper care, and the plant will grow to be a foot high or more; but when they are so tall, the lower part of them is not so sightly, their green being decayed, and the spines changed to a dark dirty colour, they appear as if dead, so that the upper part of these old plants only seem to have life, whereas the plants of the middling size appear healthy from top to bottom. In the spring, when the fruit shrivels and becomes dry, the seeds will be ripe, and may then be rubbed out, and sown upon the surface of the earth in small pots, which should be plunged into a hot-bed of tanner's bark, to bring up the plants. In the childing variety, the young offsets may be taken off, and after laying them up to dry for two or three days, may be planted, and will succeed very well,

CAC

2. Cactus Melocactus: Great Melon Thistle, or Turk's Cap. Fifteen-angled; angles spirally twisted; spines erect, roundish, fourteen or fifteen-angled .- This appears like a large fleshy green melon, with deep ribs set all over with strong sharp thorns; when it is cut through the middle, the inside is found to be a soft, green, fleshy substance, very full of moisture : the flowers and fruit are produced in circles round the upper part of the cap; some of these, which have been brought to England, have been more than a yard in circumference, and two feet and a half high, including the cap : but in the West Indies there are plants nearly twice as large, There are several varieties of this species; indeed Mr. Miller has made four species of the great melon thistle, and thinks, if the islands in the West Indies were examined, many more sorts would be found. These strange plants commonly grow upon the steep sides of rocks in the hottest parts of America, where they seem to be thrust out of the apertures, having little or no earth to support them, their roots shooting down into the fissures of the rock to a considerable depth, so that it is troublesome to get the plants up. As they delight in such rocky places, they seldom live long when transplanted into a better soil. In times of great drought, the cattle repair to the barren rocks where these plants grow, rip them up with their horns, tear off the outside skin, and greedily devour all the fleshy moist part. The fruit is frequently eatcu by the inhabitants of the West Indies. It is about three quarters of an inch in length, of a taper form, drawing to a point at the bottom, but blunt at the top; the taste is an agreeable acid. The great sort may be propagated by seeds; but as the plants which are raised from seeds in Eng-3 K

land will be some years in arriving to any considerable size, it will be much the best way to procure some plants from the West Indies; and if the plants arrive here in any of the summer months, so as that there may be time for them to get new roots before the cold comes on in autumn, the plants will more certainly succeed. When the plants come over, it will be proper to take them out of the earth as soon as possible, and lay them in the stove upon the shelves to dry, for a fortnight or three weeks; and when they are planted, they should be plunged into a good warm bed of tanner's bark, to promote their making new roots; in this bed they may remain till the beginning of October, when they must be removed into the stove, and treated in the manner before directed. The plants require a very good stove to preserve them through the winter in England, nor should they be exposed to the open air in summer, for although they may continuc fair to outward appearance, when they have been some time exposed abroad, yet they will imbibe moisture, which will cause them to rot soon after they are removed into the stove; and this is frequently the case of those plants which are brought from abroad, which have a fair healthy appearance many times at their first arrival, but soon after suddenly decay. Scarcely any appearance of disorder will be seen, till the whole plant is killed, which in a few hours' time has often been the fate of those plants, when they have been placed in the stove.

** Cereuses erect, supporting themselves.

3. Cactus Pitajaya. Erect, triangular .- This has the habit of the sixteenth species, but is upright, and eight or ten feet high; when it grows higher it wants support, but does not put out any roots from the stem; the flower is whitish and very handsome, but has hardly any smell; it is half a foot in diameter, and blows in the night. The fruit is of the form and size of a hen's egg, of a shining scarlet colour on the outside; the pulp is white, fleshy, sweet, eatable, full of small, black, shining seeds. Native of Carthagena, and the isle of Mango. These plants are all propagated by cuttings, so that if you intend to increase the number of them, you must cut off the stems of the upright sorts at what length you please; these should be laid in a dry place to heal the part cut, at least a fortnight or three weeks before they are planted; but if they lie a month it is much the better, and they will be in less danger of rotting, especially those sorts which are the most succulent. These cuttings should be planted in pots filled with the mixture of earth before directed, laying some stones in the bottom of the pots to drain off the moistare; then place the pots into a gentle hot-bed of tanner's bark, to facilitate their rooting, giving them once a week a gentle watering. The best season for this work is in June, or the beginning of July, that they may have time to root before winter, but they should not be wholly exposed to the open air or sun; and at the end of September they must be removed into the stove or green-house, where they are to abide the winter, during which season you must be very careful not to let them have much water, and always observe to place the young plants, for the first winter, in a little warmer situation than the old plants, as being somewhat more tender. They should always have a dry situation in winter, for as they derive the greatest part of their nourishment from the surrounding air, so if this be too moist it will cause them to rot. They should not be exposed abroad, not even in the midst of summer, unless they are under shelter, for the great rains which often occur at that season are very injurious to them; the upright sorts should be therefore placed so as to enjoy a free air in the summer, but at the same time screened from outside is a pale yellow, the inside very white, full of pulp,

to set them in an open glass-stove, where the windows may be opened in fair weather, and shut in cold or wet. The creeping sorts must not be much exposed to the open air, even in the hottest season, especially if you design to have them flower, and in winter they should be kept very warm, and have no water given them. These plants being succulent, will bear to be a long time out of the ground, therefore whoever wishes to procure them from the West Indies, need only request their friends there to cut them off, and let them lie two or three days to dry, then put them up in a box with dry hay or straw, to keep them from wounding each other with their spines : and if they are two or three months on their passage, they will keep very well, provided no wet get to them.

4. Cactus Heptagonus; Seven-angled Upright Torch Thistle, Erect, oblong, seven angled,-The angular upright cactuses are commonly called torch-thistles, and in the West Indies torch-wood, because when they grow old they will burn, and the Indians use them as flambeaux. Native of the British islands in the West Indies. See the preceding species.

5. Cactus Tetragonus; Four-angled Upright Torch Thistle. Erect, quadrangular, long angles compressed .- The angles of this species are compressed, and far asunder. It is very subject to put out many shoots from the sides, which stop its upright growth, so that the plants rarely rise more than four or five feet high; it flowers in July. See the third species.

6. Cactus Hexagonus; Six-angled Upright Torch Thistle. Erect, six-angled, long; angles distant.—The angles of this species are armed with sharp spines, coming out in clusters at certain distances, and spreading from a centre every way; the outer substance of the plant is soft, herbaceous, and full of juice, but in the middle there is a strong fibrous circle running the whole length, which secures the stems from being broken by winds. They will rise to the height of thirty or forty feet, if their tops are not injured, and they have room to grow; but whenever the stems are cut or injured, they put out shoots from the angles, immediately under the wounded part, and frequently one or two lower down ; these, if they are not cut off, form distinct stems, and grow upright, but they are seldom so large as the principal stem, especially if more than one be left on a plant. The flowers come out from the angles on the sides of the stem; they have a thick, fleshy, scaly, round, channelled, hairy peduncle, supporting a swelling germen, upon the top of which sits the scaly prickly calix, closely surrounding the corolla, till a little time before it expands; the flower is then as large as that of a hollyhock; the inner petals arc white, and crenated at their extremity ; the calix is green, with some purple stripes. It is not succeeded by fruit in this country, nor do the plants often produce flowers, but when they do, there are generally several. Native of Surinam. For the culture and propagation, see the third species.

7. Cactus Pentagonus ; Fire-angled Upright Torch Thistle. Erect, long, jointed, with about five angles; stem jointed, the internodes about a foot long; sometimes, but rarely, the stem has six angles; it never puts out any roots, and though slender and weak, grows upright. See the third species.

8. Cactus Repandus ; Slender Upright Torch Thistle. Erect, long, eight-angled; angles compressed, waved; spines longer than the wool .- The flowers are produced from the angles in the same manner as those of the sixth species, but they are smaller, and the calix is of a light green, without any mixture of colour. The fruit is about the size and shape of a bergamot pear, having many soft spines on the skin; the rains and great dews; it will therefore be the best method having a number of small black seeds lodged in it. This

CAC

sort frequently flowers in July, and in warm seasous will perfect its fruit, which has very little flavour in this country, but is frequently served up at table in the West India islands. See the third species.

9. Cactus Lunuginosus; Woolly Upright Torch Thistle. Erect, long, with about nine angles; angles obsolet; spines, shorter than the wool.—This is very spiny; the spines, especially the younger ones, have a brownish wool upon them; the fruit is of the size and form of a hen's egg, red on the ontside, and without spines. A native of America. See the third species.

10. Cactus Peruvianus; Peruvian Upright Torch Thistle. Erect, Iong, with about ten bluntish angles.—The stem is a fathom or more in height, almost simple, two or three inches in diameter, bluut at the end, having ten deep angles set with thorns, crowded eight or ten together, about an inch in length, spreading, the inner ones shorter, tomenoles at the base.— Native of dry situations on the coasts of Peru and Jamaica.

11. Cactus Royena; Royen's Upright or Nine-angled Torch Thistle. Erect, jointed, nine-angled; joints subovate; spines equal in length to the wool.—See the third species.

*** Cereuses creeping, with roots from the sides.

12. Caetus Grandiflorus; Great Night-flowering Creeping Cereus. Creeping, with about five angles .--- These plants are remarkable for the beauty and sweetness of their flowers. This species, when arrived to a sufficient strength, will produee many exceedingly large, beautiful, sweet-scented flowers; like most of this kind, of very short duration, scareely continuing six hours full blown; nor do the flowers ever open again when once closed. They begin to open between seven and eight o'clock of the evening, are fully blown by eleven, and by three or four in the moruing they fade, and hang down quite decayed; but during their short continuance, there is scarcely any flower of greater beauty, or that makes a more magnificent appearance, for the calix of the flower, when open, is near a foot in diameter, the inside of which being of a splendid yellow colour, appears like the rays of a bright star; the outside is of a dark brown; the petals being of a pure white, add to the lustre; the vast number of recurved stamiua surrounding the style in the centre of the flower, make a fine appearance; add to all this, the fine scent of the flower, which perfumes the air to a considerable distance. There is scarcely any plant which deserves a place in the hothouse so much as this, especially as it may be trained against the wall, where it will not take up any room. The usual season of its flowering is in July; and when the plants are large, many flowers will open the same night, and there will be a succession of them for several nights together. Sometimes six, eight, or ten flowers open at the same time on one plant, making a most magnificent appearance by candle-light; but none of them are succeeded here by any appearance of fruit. Native of Jamaica and Vera Cruz. See the third species,

13. Cactus Flagellionnis; Pink-flowering Creeping Correst. Creeping tennaged—This produces a greater number of flowers than the preceding sort; they come out in May, and sometimes earlier when the season is warn; the peths are of a fine pink colour both within and without; they are not so numerus, and the tube of the flower is longer than that of the other: these flowers keep open three or four days, provided the weather, or the place where the plants stand, be not too warn; and during their continuance they make a fine appearance. This sort has very slender trailing branches, which require a support; they are not jointed, nor do they extend so far as those of the other sort, so that they may be easily trained to a little trellis of sticks.

and the plant may be conveyed into the house whilst in flower, to adorn any of the rooms. The flowers are so beautiful, and are produced in such, great plenty, that this may be placed in the first class of exotic plants. Native of Peru, See the third species.

CAC

See the third species. 14. Cactus Parasiticus; *Parasitical Creeping Cereus*,— This is probably the root of some species of epideudrum. See the third species.

15. Cactus Pendulous; Stender Cereus. Pendulous; branches in whorks, round, smooth, without prickles; stem roundish, green, woody, striated, as big as a goose-quill; divided into several slender, round, striated branches, and they into twigs, at distances of one, two, and three inches; at which divisions are set little twigs an inch and a half long, in whorls.—It grows chiefly on the largest trees in Jamaica, hanging commonly to the length of three or four feet. See the third species.

16. Cactus Triangularis; Triangular Cercus, or Strauberry Pear. Creeping, triangular.—This tree climbs to a consideable height, supporting itself by throwing out roots; it also covers shady rocks; the fruit is the best havoured of any of the sorts, being slightly acid, with a mixture of sweetness, and also pleasant and cooling. It has no leaves, but is somewhat irregular with scars. In Martinico, where the fruit is selemend by the inhabitants, they call i proirier de chardon, or thistle pear. Native of the West Indies: see the third species. There is a variety of this species, native of the island of St. Eustatin, the fruit of which is much larger, of a shiring scarlet-cloour, and clothed with leaves which are almost entire; the pulp is white, sweetish, eatable, but has very little flavour; the seeds are black and glossy.

**** Opuntias, compressed with proliferous joints.

17. Cactus Moniliformis; Neck-lace Indian Fig. Proliferous jointed ; joints globular, thorny, glomerate .- This is a very singular plant, and the least known of any in this genus. Native of South America. All the opuntias, except the following or eighteenth species, are too tender to thrive in the open air in England; nor can many of them be preserved through the winter here, unless they have artificial heat, for when they are placed in a green-house they turn to a pale yellow colour, their branches shrink, and frequently rot on the first approach of warm weather in the spring. They may all of them be propagated by cutting off their branches at the joints, during any of the summer months : these should be laid in a warm dry place for a fortnight, that the wounded part may be healed over, otherwise they will rot with the moisture they imbibed at that part, as is the case with most other succulent plants. The soil in which these plants must be plauted, should be composed after the following manner, viz. one third of light fresh earth from a pasture, another third part sea-sand, and the remainder equal parts of rotten tan and lime rubbish; these should be well mixed, and laid in a heap three or four months before it is used, observing to turn it over at least once a month, that the several parts may be well united; then you should pass it through a rough screen, in order to separate the largest stones and clods, but by no means sift it too fine, which is a very common fault; then you should reserve some of the smaller stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off; which is what must be observed for all succulent plants, for if the moisture be detained in the pots it will rot the roots and destroy the plants. When any branches of these plants, except those of the eighteenth sort, are planted, you should plunge the pots into a moderate hot-bed, which will greatly facilitate their taking root ;

you should also refresh them now and then with a little water; but be very careful not to let them have too much, or be too often watered, especially before they are rooted. When the plants begin to shoot, you must give them a large share of air. by raising the glasses, otherwise the shoots will draw up so weak as not to be able to support themselves; and after they have taken strong root, you should inure them to the air by degrees, and then remove them into the stove, where they should remain, placing them near the glasses, which should always be opened in warm weather, so that they may have the advantage of a free air, and yet be protected from wet and cold; they often require water in summer, and thrive best when the heat is at the temperate point, as marked upon the botanical thermometers, for if they are kept too warm in winter, it causes their shoots to be very tender, weak, and unsightly. Those sorts which are inclinable to grow upright, should have their branches supported with stakes, otherwise their weight is so great it will break them down. These plants are by most people exposed to the open air in the summer season, but they thrive much better if they are continued in the stoves, provided the glasses be kept open, so that they may have free air; for when they are set abroad, the great rains which generally fall in summer, together with the unsettled temperature of the air in our climate, greatly diminish their beauty, by retarding their growth ; and sometimes in wet summers they are so replete with moisture, as to rot the succeeding winter ; nor will those tender plants which are set abroad produce their flowers and fruit in such plenty, as those which are constantly preserved in the house.

18. Cactus Opuntia; Common Indian Fig, or Prickly Pear. Proliferous-jointed, loose; joints ovate, setaceous .- The joints or branches of the common opuntia, or Indian-fig, are ovate, compressed, and have very small leaves coming out in knots on their surface, as also on their upper edges, which fall off in a short time; and at the same knots there are three or four bristly spines, which do not appear unless they are closely viewed; but on being handled they enter the skin, are troublesome, and very difficult to get out again. The branches spread near the ground, and frequently trail upon it, putting out new roots, and thus extending to a considerable distance, but never rising in height; they are fleshy and herbaceous whilst young, but as they grow old become drycr, of a tough contexture, and have woody fibres. The flowers come out on the upper edges of the branches generally, though sometimes they are produced ou their sides; the skin or cover of the fruit is set with small spines in clusters, and the inside is fleshy, of a purple or red colour. It flowers here in July and August; but unless the season is very warm, the fruit will not ripen in England. This sort is found growing wild on the sides of the roads about Naples, and other parts of Italy, in Sicily, Spain, Portugal, the Valais, the south of France, Minorca, &c. For the propagation and culture, see the preceding species.

10. Cactus Ficus Indica; Obing Indian Fig. Proliferousjointed; joints ovate, oblong; spines setacous.—The flowers come out from the upper edges of the leaves, like those of the preceding species; but they are larger, and of brighter yellow colour. The fruit is also larger, and of a deeper purple colour; the outer skin is also armed with longer pines. This is the most common sort in Janaica, and upon the fruit of this, the wild sort of cochineal insect feeds, which is called silvester. Dr. Houston, who was writing a history of these insects, sent some of the plants from Jamaica with the insects alive upon them, and they lived three or four months after their arrival. If the fruit of this plant be eaten, it will dy the urine of a bloody colour.

This seems to be a native not only of South America, but also of the East Indies, Cochin-china, Japan, and Madeira: see the seventeenth species.

20. Cactus Tuna; Great Indian Fig, or Upright Prickly Pear. Proliferous-jointed; joints ovate, oblong; spines subulate .- This species has stronger branches than the foregoing sort, and they are armed with larger thorns, which are awl-shaped, whitish, and in clusters ; the flowers are large, of a bright vellow colour ; and the fruit is shaped like that of the foregoing species. Professor Martyn enumerates two varieties; the first of which grows taller, with larger and thicker branches, and of a deeper green, and are armed with strong black spines coming out in clusters which are far asunder: the flowers are smaller, and of a purplish colour, as are also the stamina; the fruit is of the same form with that of the common sort, and does not ripen here; the second variety is the largest of all the sorts yet known ; the joints are more than a foot long, and eight inches broad ; they are very thick, of a deep green colour, and are armed with a few short spines : the older branches of this often become almost taper, and are very strong; it has not flowered, though many of the plants were more than ten feet high. It makes very strong fences, the prickles so sharp that the cattle are afraid of coming near them; and it spreads very much, both by the joints and the seed. When the island of St. Christopher was to be divided between the English and the French, three rows of the tuna were planted by common consent between the boundaries. Dr. Smith, in his very ingenious paper upon the irritability of vegetables, informs us, that the long and slender stamina of the flower are very irritable ; and that if a quill or feather be drawn through them, in the space of two or three seconds they begin to lie down gently on one side, and in a short time become recumbent at the bottom of the flower. It is a native of South America and Jamaica: see the seventeenth species.

21. Cactus Cochinillifer; Cochineal Indian Fig. Proliferous-jointed ; joints ovatc, oblong, almost unarmed .- This, which is supposed to be the plant upon which the cochineal insect feeds, has oblong, smooth, upright branches, rising to the height of eight or ten feet, having scarcely any spines on them, and the few which there are, so soft as not to be trou-blesome when handled. The flowers are small, and of a purple colour; they do not spread open, appear late in autumn with us, and the fruit drops off in winter without coming to perfection. The cochineal insect feeds on many succulent plants, but most commonly on the Cactus genus. For this reason the Indians propagate large quantities of the most harmless species, to breed the insects upon; Dampier's account of which is as follows, "The plant on which the cochineal insect feeds is like the prickly pear, about five feet high, and as prickly, only the leaves are not quite so large, although the fruit is larger: on the top of the fruit there grows a red flower ; this, when the fruit is ripe, falls down on the top of it, and covers it so that no rain or dew can wet the inside. A day or two after, the flowers being scorched up by the heat of the sun, the fruit opens wide, and the inside appears The Indians, when they perceive full of small red insects. the fruit open, spread a large linen cloth, and then with sticks shake the plant, to disturb the insects, so that they take wing to begone, but keep hovering over the plant, till by the heat they fall down dead on the cloth, where they let them remain two or three days to dry. The cochineal plants are called *toona* by the Spaniards. They are planted in the country about Guatimala, Cheapo, and Guaxaca, in the kingdom of Mexico. The difference in point of goodness, observable in the cochineal, is entirely owing to the

plant it feeds upon. The prickly pear, or cactus tuna, so abundant in Jamaica, is covered with the insects, but not having their proper food, they are in general diminutive, and have very little red tincture in their bodies; these plants bear a succulent fruit at their extremities, filled with a delicate red-coloured juice ; this is the natural food of the insect ; the exuvize and animal salts of the insect are, from the minuteness of its parts, inseparable from the essential principles of the dye, and must diminish the brilliancy of the colour : and this has put some persons upon inspissating the juice of the fruit itself. The fruit, when ripe, is said to check fluxes by its mild restringency; it is also a powerful diuretic, and sometimes imparts a tinge to the urine. For the propagation and culture, see the seventeenth species.

22. Cactus Curassavicus ; Curassao, or Least Indian Fig. or Pinpillow. Proliferous-jointed; joints cylindric, ventricose, compressed .- This has thicker and more swelling joints than the other sorts, closely armed with slender white spines. The branches spread out on every side, and where they have no support fall to the ground, very often separating at the joints, and, as they lie upon the ground, putting out roots and forming new plants. It very rarely produces flowers in England. In the West Indies it is called pinpillow, from the appearance which the branches have to a pincushion stuck full of pins. It is said to grow naturally at Curassao: see the seventeenth species.

23. Cactus Phyllanthus; Spleenwort-leaved Indian Fig. Proliferous, ensiform, compressed, serrate, repand .-- It has very thin branches, which are indented regularly on their edges like spleenwort; they are of a light green, shaped like a broadsword, and without spines; the flowers come out from the side and at the end of the branches, and are of a pale yellow colour; the fruit rarely ripens in England. Native of Brazil: see the seventeenth species.

24. Cactus Alatus. Proliferous, ensiform, compressed, serrate, repand ; the stem round, ash coloured, flexile ; the fruit small and compressed. Native of Jamaica: see the seventeenth species.

25. Cactus Spinosissimus; Cluster-spined Indian Fig. Stem upright, compressed; branches opposite, bifarious, compressed ; spines bristle-shaped .- The branches of this species have the joints much longer, narrower, and more compressed, than any of the others; the spines are very long, slender, and of a vellowish brown colour, coming out in clusters all over the surface of the branches, crossing each other, so as to render the plant dangerous to handle; for upon being touched, the spines quit the branches, adhere to the hand, and penetrate the skin, so as to be very troublesome; its growth is more upright and lofty than the other opuntias; the trunk below the branches is so absolutely covered with spines as to be invisible, and to seem nothing but a congeries of these. Hence the gardeners whimsically call this plant Robinson Crusoe's coat. Upon the whole, this species is very different from the rest, and has more of an air of neatness and elegance than any of these strange plants, notwithstanding its roughness. Native of Jamaica: see the seventcenth species.

26. Cactus Pereskia; Barbadoes Gooseberry. Stem arboreous, round ; prickles double, recurved ; leaves lanceolate, ovate, -This has many slender branches, which trail on whatever plant grows near them; the fruit is about the size of a walnut, having tufts of small leaves on it, and within a whitish mucilaginous pulp. It grows in some parts of the Spanish West Indies, whence it was brought to the English settlements in America, where it is called Barbadoes gooseberry. The 19.

cuttings planted during any of the summer months, in pots filled with fresh light earth, and plunged into a moderate hot-bed of tanner's bark, observing to shade them from the sun in the heat of the day, and to refresh them every third or fourth day with water; in about two months the cuttings will have made good roots, when they should be carefully taken out of the pots, and each planted into a separate pot filled with fresh earth, and then plunged into the hot-bed again, where they may remain during the summer season ; but at Michaelmas, when the nights begin to be cold, they should be removed into the stove, and plunged into the bark-bed. During the winter season the plants must be kept warm, and watered twice a week, but not in large quantities. In summer they demand a greater share of air and more water, but they should remain constantly in the stove; for though they will bear the open air in summer in a warm situation, yet they will make no progress if they be placed abroad; nor do they thrive so well in the dry-stove, as when they are plunged in the tan; so that the best way is to set them next a trellis, at the back of the tan-bed, to which their branches may be fastened, to prevent their trailing on other plants.

2. Cactus Portulacifolius; Purslain leaved Indian Fig. Stem round, arboreous, thorny ; leaves wedge-form, retuse ; stem leafless, but armed with bundles of bristle-shaped spines.

Cadia ; a genus of the class Decandria, order Monogynia. -GENERIC CHARACTER. Calix : perianth one-leafed, five-cornered, five-cleft. Corolla : petals five, equal, obcordate. Stamina : filamenta ten, filiform, equal, the length of the petals or nearly so, protuberant at the base. Autheræ oblong, rather sharp at the top, placed obliquely at the ends of the filamenta. Pistil : germen linear; style bowed ; stigma acute. Pericarp : legume linear, compressed, bent at the end, membranaceous, many-seeded. Seeds : oblong, smooth. ESSENTIAL CHARACTER. Calix: five-cleft; petals five, equal, obcordate ; legume many-seeded .----- The only known species is,

1. Cadia Purpurea ; Purple-flowered Cadia .- This is a shrub rising to the height of nearly three feet ; the branches and petioles are pubescent. Forskal observes, that the flowers hang down; that the corolla has sometimes six or seven petals, and that in such cases there are more stamina, frequently twelve or fourteen; and that there is no gland to the antheræ. Native of Arabia; it has not flowered in England,

Canopteris; a genus of the class Cryptogamia, order Filices .- GENERIC CHARACTER. Fructifications: in submarginal lateral lines, covered with a membrane, gaping on the outside .- The only species is,

1. Cænopteris Rhizophylla. Frond bipinnate, rooting at the tip; pinnules obovate, somewhat sickle-shaped, petioled : primordial leaves lobed ; stipe round, brown ; fructifications in short solitary lateral lines, beginning at the nerve towards the base of the pinnules, and covered with an entire scariose brown membrane, opening always on the outside, at length turned back and permanent .- Native of the Island of Dominica.

Casalpinia ; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, five-parted; tube short; segments oblong, deciduous, the lowest longer than the rest, slightly arched. Corolla: petals five, inserted into the throat of the calycine tube, unequal; lamina roundish. Stamina : filamenta ten, inserted into the throat of the calix, filiform, woolly at the base, declining. Antheræ oblong, decumbent. Pistil: germen su-Dutch have named it blad-apple. It may be propagated by perior, linear, oblong, compressed, attenuated at the base ; 2 L

CAL

style filiform, the length of the stamina, blunt. Pericarp: legume oblong, compressed, one-celled. Seeds : few, subovate, compressed flat. Calix : five-parted, the lowest segment longer, and slightly arched. Stamina : woolly at the base; petals five; legume compressed .- The plants of this genus are propagated by seeds, which should be sown in small pots filled with light rich earth early in the spring, and plunged into a hot-bed of tanner's bark, observing to shade them from the sun, and to water the earth as often as it appears dry; if the nights should prove cold, the glasses must be covered with mats, to keep the bed in a moderate warmth; in about six weeks the plants will begin to appear, when they must be carefully cleaned from weeds, and frequently refreshed with water; in warm weather the glasses should be raised in the middle of the day to admit fresh air, which will greatly strengthen the plants; otherwise they are apt to draw up weak. When the plants are about three inches high, they should be carefully taken out of the pots, and each transplanted into a separate small pot filled with fresh light earth, and plunged into the hot-bed again, observing to water them, and screen them from the heat of the sun, until they have taken new root; after which time the glasses should be raised every day in proportion to the warmth of the weather. In this hot-bed the plants are to remain till autumn, when they should be removed to the stove and plunged into the bark-bed, where they may have room to grow; here they should remain; and being placed among tender exotics of the same climate, will afford an agreeable variety .----- The species are,

1. Cæsalpina Elata. Unarmed; leaflets linear, blunt with a point; corymbs compound; calices coriaceous, tomentose; petals fringed; stamina very long; flowers large, yellow; filamenta very dark purple.--Native of India.

2. Cæsalpina Pulcherrima ; Barbadoes Flower Fence. Prickly; leaflets oblong, oval, emarginate, they and the calices smooth; corymbs simple; petals fringed; stamina very long .- It rises with a straight stalk ten or twelve feet high ; it is covered with a smooth gray bark, and is sometimes as thick as the small of a man's leg; it divides into several spreading branches at the top, armed at each joint with two short strong crooked spines. This beautiful plant is a native of both Indies; it is planted in hedges, to divide the lands in Barbadoes, where it has the name of flower-fence ; it is also called Spanish carnations in some of our islands in the West Indies. Dr. Houstoun has found varieties in the colour of the corolla. some having a red and others a yellow flower in the Spanish West Indics. All parts of this plant are thought to be very powerful emmenagogues, and are frequently used for that purpose among the negroes. In addition to what has been observed under the generic description, concerning the propagation and culture of this genus of plants, it is necessary to state, that the flower-fence, if care be taken to water and shift the plants as often as it is necessary, will grow three feet high the first season. When they are grown large, care must be taken, when they are shifted into larger pots, not to suffer the ball of earth to fall from the roots; for when this happens, the plants seldom survive it; they are very impatient of moisture in winter, and if damp seizes their top, it very often kills them, or at least occasions the loss of their heads : with proper management they will grow much tailer here than they usually do at Barbadoes, but their stems will not be larger than a man's finger, which is occasioned by their being drawn up by the glasses of the stove. The beautiful flowers of this shrub appear in December here ; but in the West Indies it flowers twice a year.

Calabash. See Cucurbita.

Calabash-tree. See Crescentia. Calamint. See Melissa.

Calamus; a genus of the class Hexandria, order Monogynia.-GENEBEIC CHARACTER. Caliz: perianth six-leaved, permanent; the three outer leaflets shorter, broader; the three inner longer, narrower, acuminate. Corollar none, except the calis be so called. Slaminar, filamenta six, capallary, longer than the calix. Authere round. Pistil; gene noundish, superior; sylve trifd, columnar, spiral, filform; stigmas simple. Pericarp: nembranous, globular, covered with scales, imbricated backwards, and obtuse; it is one-colled, at first pulpy, but afferwards juiceless. Seed: one, globular, flesby. ESENTIAL CHARACTER. Codis: six-leaved. Corollar none; berry dried, one-seeded, imbricate backwards.

1. Calamus Rotang, or Rattan .- All the sorts or varieties of the calamus rotang, or rattan, have a stem which is perennial. quite simple or unbranched, long, round, unarmed or without prickles, solid, jointed, procumbent when unsupported. scandent when near trees, but without any tendrils. The rattan seems to form the connecting link between the palms and the gramineous plants, having the flower of the former. but the habit of the latter. Loureiro has discriminated six species of rattan, viz. 1. The stone rattan, with a stem as thick as the human arm, and a hundred feet long, used for large spears and halberts. 2. The cable rattan: stem more than five hundred feet long and about an inch thick, very tough, used for ships' cables, for ropes to draw great weights, and to tame and fasten wild elephants. 3. The walking-cane rattan, with very long, subulate, glossy internodes. It grows abundantly on both sides of the straits of Malacca, whence it is exported into China and Europe. 4. The genuine rattan: stem a hundred feet long, yellowish, brown, equal, very flexile. In India the largest cables are made of the stem cut into thongs; besides all sorts of ropes for fastening the planks of the country vessels and the boarding of houses, in which no nails are used ; and also for tying a variety of utensils, both domestic and rural. 5. The bitter rattan; spines crowded; short leaflets linear; spadices remote ; spathes partial. It is used for the same purposes as the genuine rattan, but is harder and more durable. 6. The diacous rattan ; stem the thickness of a goose-quill, twenty feet long, very regular and flexile. It is used for weaving, and fastening smaller and nicer utensils. All these are specifically different, for they grow wild in places very remote from each other, where they regularly preserve their peculiar habits and differences. Many others grow in Cochin-china, the straits of Malacca, and other places, which, on an accurate examination, may be found to be different both from these and each other. They grow abundantly in the East Indies by the sides of rivers. Their extreme toughness and pliability render them very useful to the natives, for withs, and almost all the purposes to which we apply ropes, than which the rattans are said to be more durable in salt water ; they also wattle their houses with them, and make baskets and all kinds of wicker work. The rattan is imported into Europe, and used for a variety of minor purposes, such as bottoming chairs, for riding and walking canes, hoops for the petticoats of fools, &c. &c. The zalaced or salach is cultivated for the fruit, which is about the size of a walnut. and covered with scales like those of a lizard; below the scales, are two or three yellow kernels, in flavour somewhat resembling a strawberry. The last variety is supposed to produce the dragon's-blood.

Calathian Violet. See Gentiana Pneumonanthe.

Calceolaria ; a genus of the class Diandria, order Mono-

gynia.—GENERIC CHARACTER. Caliz: perinath oneleafed, four-parted, spreading, equal; divisions ovate, permanent. Corolar: monopetalous, bilabiate; lower lip resupine; upper very small, contracted, gloiular, bifd anteriorly, lower twy large, slipper-form, inflated, gaping anteriorly. Stamina: filamenta two, very short, within the upper lip. Anthere incumbent, club form, with the handle prominent through the chink. Pistil: germen roundish; style very short; stigma blumish. Periarp: capsule subconic, acuminate, two-furrowed, two celled, two-valved. Seeds: numerous, ovate. ESSENTIAL CLARACTER. Corollaringent, inflated; capsule two-celled, two-valved. Caliz: four-parted, equal.—The species are,

1. Calcolaria Pinnata; Pinnata: Sippervort. Leaves pinnate; root annual; stem erect, two feet high, round, brachite, brittle, with a very thick down, and from fifteen to twenty joints.—It flowers from July to October, and is a native of moist places in Peru. This species may easily be raised from seed, sown on a gentle hot-bed in the spring; the seedlings, when of a proper size, are to be transplanted into the horders of the flower-garden, where they will flower, ripen, and scatter their seedl; sub their ga sund idelicate plant, the beauties of which require a close inspection, it appears tomost davantage in a tan-stove, where, as it will grow from cutings, it may be had in flower all the year through, by planting them in succession.

 Calceolaria Integrifolia; Whole-leaved Slipperwort. Leaves lanceolate, wrinkled, serrate; flowers panicled, tcrminating.—It was observed in Chili by Feuillée.

3. Calceolaria Perfoliata; Perfoliate Slippernort. Leaves perfoliate, sagittate, villose on both sides.—This is a very singular and handsome plant, the whole of which is villose, except the corolla; stem round, from a foot to two feet high, leavy, terminated by a many-flowered leafy corymb; flowers in bundles at the topos of the branches; corolla yellow, large; antherae two-lobed, large; the lobes bent down. Found in New Granada, by Mutis.

4. Calceolaria Nama; Dwarf Slipperwort. Scapes oneflowered; leaves ovate, quite entire; stem none; flowers large, specions, yellow, spotted with red; calix pubescent, with equal divisions bent in at the edge.—Found by Commerson in the Straits of Magellan.

 Calcolaria Plantaginea; Plantain-lawed Slipperword, Scapes few-flowered; leaves ovate, rhombed, serrate; root perennial, fibrous; stem none; leaves many, nervous, smooth, the edges hairy; corolla yellow.—Found in the Straits of Magellan.

6. Calceolaria Ovata. Stem branching: leaves ovate, create; not annual, fibrous; stem arcet, round, hairy; leaves opposite, on short petioles, with white pellucid hairs, and underneath paler; corolla like that of the first species, small and yellow; divisions of the calix thinner, rhombed, veined, hairy—from by Dombey in Pero.

7. Calecolaria Fothergilli; Spatula leaved Slippervort. Laves spatulate, quite eutre; peducles escape-form, oneflowered; stem scarcely an inch bigh, subdivided near the root. Anthere roundish, large; style thick, the length of the stamina; stigma thick-need, flat, biennial: flowering from May to August-Naviev of the Falkland Isles.

Calas; a genus of the class Syngenesia, order Polygamia Equalis.-GENERICCHARACTER. Calis: common, imbricate; scales oblong; somewhat loose. Carolla; compound, umform; corollules hermaphrodite, very many, equal; proper fomel-form, with a five-clef border. Stamina: filamenta five, capillary, very short. Antherae cylindric, tabular. Fitidl; germen somewhat oblong; style filiforon, the length of the corollule; stigmas two, recurved, acute. Pericarp: none; calix unchanged. Seeds: solitary, oblong; down hairy, the length of the calix. Receptacle chaffy ; chaffs a little longer than the calix, eminent between the floscules. ESSENTIAL CHARACTER. Calix: imbricate. Down: hairy, or none., Receptacle : chaffy. These plants may be propagated by seeds, sown upon a hot-bed in the beginning of April; when they come up, they should be tenderly treated whilst young; admitting, however, fresh air to them daily, in proportion to the warmth of the season, giving them water frequently, but sparingly. When they have strength enough to be removed, they must be each transplanted into a separate small pot, filled with light sandy earth, and plunged into a hot-bed, observing to shade them until they have taken new root, giving them air, and watering them frequently, but gently, as before. When the plants are grown strong, they must be removed into larger pots, and placed in the stove or glass-case, giving them plenty of fresh air in warm wcather; with which management they will sometimes ripen their seeds in favourable seasons .---- The species are,

 Calea Jamaicensis. Flowers subtern, peduncled; leaves ovate-oblong; subserrate, petioled; height is or seven feet or more; stems shrubby, narrow, round, obscurely tomentose; leaves hairy, rugged, three-nerved; howers terminating, frequently three together; the pedicles of the same length with the flowers; calix coloured; the pappus or down is rugged, and as long as the flower.—Native of the woods and inland parts of the island of Jamaica.

2. Calea Oppositiolia. Corymbs heaped; peduncles very long; leaves lanceolate; stem herbaceous, two feet high, branched, upright, round, pubescent; the corollules are very small; seeds oblong, compressed, with three or four very minute awms; chaffs lanceolate, the inner ones longer than the outer.—Native of hedges on the mountains of Jamaica.

3. Calca Anellus. Flowers subpanield; calices short; seeds naked; leaves orate-lancedate, petiodel.—This species has woody branches, which spread over the neighbouring plants, and rise eight or tan feet high; the leaves are thick and opposite; there are many side-branches on which are smaller leaves opposite, ikk the others, and terminated by panieles of yellow flowers; calix only half the length of the flower; seeds four-cornered, without down. Native of Jamaica.

4. Calca Lobata. Corymbs heaped; leaves alternate, the upper ones ovate-hanceolate, the lower ones touth-hastate, sinuate, serrate.—This plant generally rises to the height of four or five feet, according to Brown, who calls it halber weed, from the slape of the leaves: he affirms, that it is an excellent bitter, and much used in America, where a spirituous infusion of the tops is generally kept in most plantations, and is often administered as an active warm stomachie. Native of Jannaica.

5. Calca Scoparia. Stem suffruitcose; branches almost opposite, angular.—This is a strub or small tree; is tem the height of a man or more, branched towards the top, even, streaked, wrinkled, with an ash-coloured bark. It is a native of Jamaica, and there found only in the coldest parts of the monitains; it resembles our European broom, and is therefore called mountain broom-tree; it is the only tree of the same appearance in that country.

6. Calea Leptophylla. Flowers terminating in threes and fives, heaped; leaves oblong, imbricate, quite entire, sessile; stem shrubby.---Native of New Zealand.

five, capillary, very short. Antheræ cylindric, tubular. *Pistil:* germen somewhat oblong; style filiform, the length linear, accrose; stem shrubby.—Native of New Zealand. 224

gamia Necessaria .- GENERIC CHARACTER. Calix: common simple, many-leaved, almost upright; segments linearlanceolate, (fourteen to twenty,) nearly equal. Corolla: compound, radiate; corollules hermaphrodite, very many in the disk; females the number of rays in the calix, very long in the ray ; proper of the hermaphrodite tubular, semiquinquefid, the length of the calix; of the female ligulate, very long, three-toothed, villose at the base, nerveless. Stamina: (hermaphrodite) filamenta five, capillary, very short. Antheræ cylindric, tubular, the length of the corollule. Pistil: hermaphrodite; germen oblong; style filiform, scarcely the length of the stamina; stigma obtuse, bifid, straight. Females; germen oblong, three-cornered ; style filiform, the length of the stamina; stigmas two, oblong, acuminate, reflex. Pericarp : none ; calix converging, roundish, depressed. Seeds : hermaphrodite, central of the disk none, of the circumference seldom solitary, membranous, obcordate, compressed; females solitary, larger, oblong, incurved, triangular, with membranous angles, marked on the outside longitudinally, with the figure of a vegetable. Down: none. Receptacle: naked, flat. The flowers are commonly solitary and terminating.— The species are, 1. Calendula Arvensis; *Field Marigold*. Seeds boat-

form, muricated, bent in; the outmost erect, protended; root annual; stalk slender, branching, spreading near the ground; leaves narrow, spear-shaped, hairy, half surrounding the stalk at their base; flowers produced at the extremity of the branches, upon long naked peduncles, they are very small, and of a pale vellow colour ; the florets of the ray are very narrow, as are also the leaves of the calix .- It flowers most part of the summer, and is a native of Sweden, Germany, Switzerland, France, Carniola, Italy, and Spain. If the seeds of the field marigold be permitted to scatter, there will be a fresh supply of young plants, so that from May, when the flowers first appear, till the frost puts a stop to them, there will be a succession of plants in flower.

2. Calendula Sancta; Palestine Marigold. Seeds pitcherform, obovate, even; calices submuricated .- This is very like the foregoing species, but the calix is muricated on the outside. Mr. Miller informs us, that the leaves are much larger than those of the former sort, but yet not so large as those of the garden marigold; and that the flowers are of a middle size between the two others, and of a very pale vellow colour.

3. Calendula Officinalis; Garden Marigold. Seeds all boat-form, muricated, bent in .- This differs from the field marigold not only in the seeds, but in having a loftier stem, more divaricated, pubescent, and pale green, as are also the leaves; these are longer, less sinuated, the lower and middle leaves ovate and blunt, the upper ones lanceolate. Native of France in the vineyards, of Italy in the corn-fields, of Silesia in orchards, gardens, and fields; flowering most part of the summer. The golden splendour of this flower, says Bauhin, the flaventia lumina calthæ, as Columella expresses it, ennobled this plant before it was known to be of any use. It has however been cultivated time out of mind in kitchen-gardens for the flowers, which were dried in order to be boiled in broth ; from a fancy that they are comforters of the heart and spirits. Linneus accordingly says, that they may be used in a double dose, as a succedaneum to saffron ; but modern practice has little confidence in these supposed cordials. The common, or officinal marigold, is a plant which is now much out of use in the materia medica, and has probably been commended beyond its merit as an aperient and detergent in visceral obstructions, jaundice, and men- but most of these differences continue, if the seeds be pro-

Calendula; a genus of the class Syngenesia, order Poly- strual suppressions. It has also been considered as useful in the scrofula of children, eaten in the manner of a salad. There is a certain acrimony in the plant, insomuch that it has even been recommended as a certain extirpator of warts : formerly, the flowers were very much esteemed as preservatives against pestilential disorders, either chewed, or infused in vinegar; or the juice itself, drank to the quantity of some ounces. It has been highly recommended in the plague itself, by some writers, and is esteemed a powerful sudorific ; the leaves are supposed to be more efficacious than the flowers. It has been asserted, that a marigold flower, rubbed on the affected part, is an admirable remedy for the pain and swelling caused by the sting of a wasp or bee. According to Hill, an infusion of the fresh-gathered flower is good in fevers; it gently promotes perspiration, and throws out any thing which ought to appear on the skin. Meyrick says, a water distilled from them is good for inflamed and sore eyes: a decoction of the flowers, in posset drink, is much used among country people, as an expulsive in the small-pox and measles. The leaves of the plant, when chewed, at first communicate a viscid sweetness, which is followed by a sharp penetrating taste, very durable in the mouth, but not of the hot or aromatic kind, but rather of a saline nature. The expressed juice, which contains the greatest part of this pungent matter, has been given in doses of two or three ounces, in cases of costiveness, in which it is very efficacious; and it likewise promotes the other secretions of the body in general. Snuffed up the nose, it excites sneezing, and a discharge of mucus from the head. Linneus observes, that the flowers of this plant are open from nine in the morning till three in the afternoon. This regular expansion and closing of the flowers attracted early notice, and hence this plant acquired the names of solsequia and solis sponsa. There is an allusion to this property in the poems ascribed to Rowley:

" The marybudde that shootethe (shutteth) with the light,"

But more fully thus by Shakspeare.

" The marigold, that goes to bed wi' th' sun,

" And with him rises weeping."

Of the garden marigold, there are the following varieties :-1. The single. 2. The common double-flowering. 3. The largest very double-flowering. 4. The double lemon-coloured. 5. The greater and smaller childing marigold. There are other triffing varieties not worth observation : this plant, in German, is called gewohnlicke ringelblume, goldblume, dotterblume, gilken-butterblume, gemeine sonnenwendes. haussonnenwirbel, weckbroselchen, todtenblume ; in Dutch, tamme goudbloem ; in Swedish, ringblomma ; in Danish, almindelige koeblomme, solsikke, soelsik; in English, common or garden marigold or marygold; by old authors, golds or ruddes. Golds, or gouldes, is a name among the country people, not only for this but for chrysanthemum segetum, any sort of hawkweed, and, in short, for most yellow flowers of the Syngenesia class. The fondness of the British for tacking Christian names to animals and plants, is well known; the Virgin Mary, in particular, has sanctified many of the latter. The French term the garden marigold souci du jardin ; the Italians, calendula ortense, fiorrancio, fiore d'ognimese, which latter name countenances the derivation of calendula from the calends; the Spaniards and Portuguese also call it calendula ortense, and the latter sometimes term it maravilha bas-tarda; in Russian, its name is nogotki. The seeds of the single garden marigold will come up of themselves, if they are permitted to scatter: the varieties are supposed to have been originally obtained from the seeds of the single sort,

CAL

perly saved ; but the two childing marigolds, and the largest double, are subject to degenerate, where care is not taken in saving their seeds : the best way to preserve the varieties, is to pull up all those plants, whose flowers are less double, as soon as they appear, and to save the seeds from the largest and most double flowers ; the childing sort should be sown by itself in a separate part of the garden, and the seeds saved from the large centre flowers, only not from the smaller ones which come from the calix of the other, for the seeds of those are apt to change. The seeds may be sown in March or April where the plants are to remain, and will require no other culture but to keep them clean from weeds, and to thin the plants where they are too close, leaving them ten inches asunder, that their branches may have room to spread. These plants will begin to flower in June, and continue in flower until the frost kills them. The seeds ripen in August and September, which if permitted to scatter, will furnish a supply of young plants in the spring ; but as these will be a mixture of bad and good, the best method is to save the best seeds, and sow each of the varieties distinct, which is the sure way to have them in perfection.

4. Calendula Pluvialis; Small Cape Marigold. Leaves lanceolate, sinuate-toothletted; stem leafy; pedancles filiform; root annual; lower leaves deeply indented on their edges, fleshy, and of a pale green colour; stems declining from six to eight inches long, leafy to within two inches of the top; stem-leaves much narrower and more indented than those of the root; upper part of the stem very slender, upon which stands one flower shaped like those of the common marigold. having a purple bottom, with the ray of a violet colour on the outside, and of a pure white within; it opens when the sun shines, but shuts up in the evening, and remains so in cloudy weather; when the flower decays, it hangs down during the growth of the seeds, but when they are full ripe the peduncle is raised again, so that the heads of the seeds stand upright .- It is a native of the Cape of Good Hope, and flowers from June to August. The seeds of these plants should be sown in the spring, in the borders of the garden where the plants are designed to remain, for they do not bear transplanting well; therefore they may be treated in the same manner, and sown at the same time, with candy-tuff. Venus looking-glass, and other hardy annual plants, putting four or five seeds in each patch; if they all grow, there should not be more than two plants left in each patch; after this they require no farther care but to keep them clean from weeds. If the seeds of these plants be permitted to scatter, the plants will come up the following spring without care, and these will flower earlier than those which are sown in the spring.

5. Calendula Hybrida, Hybridas or Great Cope Marigold. Leaves Inacolate, toolted; stem leaves much longer than in the foregoing, and broader at the end; those near the root are regularly indented, but the stem-leaves have only a few shallow indentures.—Native of the Cape of Good Hope. For the culture and propagation of it, see the preceding species.

6. Calendula Nuficientiis; Nakci-statked Cape Marigold, Leaves lanceolate, sineauti-toothed; stem almost naked.—This is also an annual plant, and has nuch the appearance of the fourth, but the leaves are more deeply indented on their edges. It flowers from June to August, and is a native of the Cape of Good Hope. For the propagation and culture of this plant, refer to the fourth species.

7. Calendula Graminifolia; Grass-leaved Marigold. Leaves linear, almost entire; stems almost naked, one-flowered; seeds obcordate, orbiculate, even.—This is a perennial plant, 19.

which divides near the root into several tufted heads, closely, covered with long grassy leaves coming out on every side without order; some of these have one or two indentures on their edges, but the most part are entire. From between the leaves arise naked peduncles, about nine inches long, sustaining one flower at the top, which is about the size of the common marigold, having a purple bottom; the rays are also purple without, but of a pure white within; these expand when the sun shines, but always close in the evening and in cloudy weather. The general season of their beauty is in April and May, when they have the greatest number of flowers upon them; but there is commonly a succession of flowers late in the autumn, though not in so great plenty. The seeds are heart-shaped, like those of the foregoing. Though this plant has been long in the English gardens, it has not been so often seen there as it deserves, there being few which continue so long in flower; it does not often produce good seeds in Europe, but is easily propagated by slips taken off from the heads, in the same manner as is practised for thrift; they may be planted any time in summer, in pots filled with light fresh earth, which may be plunged into a very moderate hot bed, to forward their putting out roots ; or otherwise the pots may be sunk in the ground up to their rims, and covered with a melon-glass, which, in the middle of summer, will answer full as well, but in the spring or autumn the former method is to be preferred : when these are planted, the glasses must be shaded in the heat of the day, and the slips must be frequently refreshed with water, but it must not be given them too liberally, for much wet will rot them; after they have got strong roots, they should be each planted into several small pots, filled with fresh light earth, and placed in a sheltered situation, where they may remain till autumn, and then should be placed in a dry airy glass-case, for the winter season, or under a common hot-bed frame; for these plants do not thrive in an artificial heat, they only require protection from frost and wet, and should enjoy the air at all times when the weather is mild.

8. Calendula Fruticosa; Shrubby Marigold. Leaves.obovate, a little toothed : stem shrubby, decumbent .- This has a slender shrubby stalk rising to the height of seven or eight feet, but requiring support ; it sends out a great number of weak branches from the bottom to the top, hanging downwards ; the leaves are on short foot-stalks ; most of them are slightly indented towards the top, but some are entire; they are of a shining green colour on their upper surface, but paler underneath ; the flowers come out at the ends of the branches on short naked peduncles .- Native of the Cape of Good Hope. It is easily propagated by cuttings, which may be planted any time in summer in a shady border, or otherwise shaded with mats in the heat of the day; in five or six weeks these will have taken root, when they should be carefully taken up, and each put into a separate pot filled with light sandy earth, but not dunged and placed in the shade till they have taken fresh root; then they may be placed with other hardy exotic plants in a sheltered situation, where they may remain till the frost begins, when they must be removed into the green-house, placing them near the windows, that they may enjoy the free air, for they only require protection from frost. The earth in which they are planted should be light, but very poor, for in rich earth they grow too luxuriantly, and seldom flower.

Calf's Snout. See Antirrhinum.

Calla; a genus of of the glass Gymandria, order Polyandria.—GENERIC CHARACTER. Calix: spathe one-leafed, ovate, cordate, acuminate, coloured at top, very large, spreading, permånent; spadix finger-shaped, quite simple, erect, 3 M covered with fructifications. Corolla: none Stamina: filamenta some, internist with the germina, the length of the pistils permanent, compressed, truncate, Autherse simple, truncate, sessile. Pistil: to each a roundhis lobuse german: style simple, very short; stigma acute. Pericarp: berries as many as there are pistils, four-cornered, globular, pulpy, one-celled; seeds many, (six to twelve), oblong, cylindric, obtuse at both ends. ESENTIAL CHARCTER. Spathe: flat. Spadia: covered with floscules. Caliz and Petals: none. Berries many seeded.—The species are,

CAL

1. Calla Æthiopica; Æthiopian Calla. Leaves sagittate, cordate; spathe cowled; spadix, male at top .-- This plant has thick fleshy tuberous roots, which are covered with a thin brown skin and strike down many strong fleshy fibres into the ground ; the leaves rise in clusters, having foot-stalks more than a foot long, which are green and succulent; the leaves are eight or nine inches in length, and of a shining green, ending in a sharp point, which turns backward; between the leaves comes out the scape, which is thick, smooth, of the same colour as the leaves, rises above them, and is terminated by a single flower, shaped like those of the arum; the hood or spathe is twisted at the bottom, but spreads open at the top, and is of a pure white colour ; in the centre of this is situated the spadix or club, which is of an herbaceous yellow colour, upon which the small herbaceous flowers are placed, so closely joined as that the stamina and pistils are very difficult to distinguish, without the assistance of glasses; it is only about half the length of the spathe. It grows naturally at the Cape of Good Hope, and has long been an inhabitant of the English gardens. It propagates very fast by offsets which should be taken off at the latter end of August, at which time the old leaves decay; but this plant is never destitute of leaves, for before the old ones decay there are young leaves produced, which advance in height all the winter ; but at this season the roots are in their most inactive state; these roots have generally a great number of offsets about them, so that unless there is a want of them, the largest of them only should be chosen ; which should be separated from all the smaller, and each planted in a separate pot, filled with kitchen-garden earth, and placed with other hardy exotic plants in the open air till autumn, when they must be removed into shelter for the winter season, during which time they must not have too much wet, for that will rot the roots. This plant is so hardy as to live in the open air in mild winters without any cover, if it be planted in a warm border, and have a dry soil ; but with a little shelter in hard frost, it may be preserved in the full ground very well. It flowers in May, and the seeds ripen in August; but as the roots increase so plentifully, few persons care to sow the seeds, because the young plants will not flower in less than three years.

2. Calla Palustiis; Marih Calla. Leaves cordate; spathe fai; spadik hermaphrodic all over; leaves creet, acuminate, streaked, bright or yellowish green, smooth, four or five inches long; and three of four broad, alternately embracing the stem, with thick smooth succulent petioles five or six inches long; scape round, thick, succulent, smooth, bright green; the toois creep in the mad, so as sometimes to cover whole marshes; they have a hot biting taste, and yet bread is sometimes made of them. It flowers from Jane to August, and is a native of Laphaud, Sweden, Denmark, Russia, Ger many, and Holend. It is rarely admitted into gardens, and must be planted in an artificial log, or at least in the mud of a pond, or is a pot or tub set in water.

3. Calla Orientalis; Oriental Calla. Leaves ovatc.-This has also a thick tuberous root, from which spring up several

orate leaves, standing on pretty long foot-stalks; the scape rises between the leaves, about six or eight inches high, supporting one white flower at the top.—Native of the mountains near Aleppo. The roots of this sort should be planted in pots filled with light earth, and in summer they may be placed, with other exotic plants, in the open air; but in winter they should be placed under a common hot-bed frame, to screen them from frost, which would be fatal to the roots,

4. Calla Occulta. Leaves cordate, ovate; spathe spiral; spadix male at top; plant one foot high, perennial, with scarcely any stalks.—Native of Cochiu-china in moist places.

Callicarja ; a genus of the class Tetrandria, order Monogynia--GENREIC CHARACTER. Calit : periauth oneleafed, bell-form ; mouth four-cleft, erect. Caralla: menopetalous, tubular; horder four-cleft, obtuse, spreading: Stamina: filamenta four, filiform, twice the length of the corolla. Antheræ ovate, incumbent. *PistII*: germen roundsis; style filiform, thicker at the top; signa thickish, obtuse, *Pericarp*: berry globular, smooth. Szeds: four, oblong, shaped like a meniscus, compressed, calitons. ESERTIAL CHARACTER. Calit ; four-cleft; corolla four-cleft; berry four-seded...—The species are,

1. Callicarpa Americana; American Callicarpa. Leaves serrate, tomentose beneath .- A shrub, from three or four to six feet in height; branches rather compressed; the nerves of the upper surface of the leaves, and the whole under surface, tomentose; the flowers in axillary, dichotomous, tomentose panicles, scarcely the length of the leaves ; with minute subulate bractes, opposite at each fork ; corolla funnel-form, deep purple. Native of Cochin-china as well as of North America, which shews the impropriety of the trivial name ; it is the only plant of its genus which has been yet cultivated in England, and rises easily from seeds on a moderate hotbed; it is best to sow the seeds in pots, and to plunge them into a tan-bed of a moderate warmth; when the plants come up, and have attained some strength, they should be gradually inured to the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn; during this time they must be kept clean from weeds, and gently refreshed with water in dry weather ; but as these young plants are tender, they should be placed under a frame before the early frost comes on, for autumnal frosts will kill the tender part of their shoots, which often causes their stalks to decay most part of their length before the spring. During the winter season they should be screened from frost, but in mild weather they must enjoy the free air, otherwise their shoots will turn mouldy and decay. The following spring, just before the plants shoot, they should be carefully turned out of their pots, so as not to break their roots, and part of them may be planted in small pots filled with light earth, and the others in a nursery bed in a warm situation, at about four or five inches asunder; those in the pots should be plunged into a moderate hot-bed, which will forward their taking root; but afterwards they must be hardened to bear the open air as before; these should be sheltered under a frame in winter for three or four years, till they have obtained strength; then they may be turned out of the pots, and planted in a warm situation, where they will live in the open air through common winters ; but in severe frost they are in danger of being killed, if they be not sheltered; therefore the surface of the ground about their roots should be covered with old tan to keep out the frost, and their tops protected with straw, pease haulm, or fern.

2. Callicarpa Tomentosa. Leaves quite entire, woolly.--This is a singular tree, which has no parallel; a thick nap invests the branches; peduncles, petioles, like woollen croth; Jeaves ovate, the size of the hand, opposite, acaminate, coicosa, winkled, naked, petiolded; pednucles axillary, solitary, dichotomons, the length of the petioles, divariented; corolla four-petalled; finament investment in the receptacle; berry the size of the pepper corn, black, terminated by the sligma, which is pale-coloured, within the calix, which is which with down, orbicular, scarcely toolhed, or very obscurely fourtoothed, spreading very wide; the berry is one-celled, and contains four bony seeds, convex on one side, on the other concave, with an obscurely elevated ridge.—The Indians chew the bark of this tree when they have not the leaves of the betel. Native of the East Indies.

3. Callicarpa Japonica. Leaves broad, hanceolate, serrate, somewhat rugged underneath y cymes terniniting and axilary; stem shrubby, erect, smooth; branches opposite, round, smooth, purple, divaricated; leaves opposite, ou short petioles, oblong, acuminate, entire at the base and point, green above, pale beneath, nerved, two inches long; flowers above, axilary, panieled, very small.—Native of Japan.

4. Callicarpa Ferruginea. Leaves broad, lanceolate, serrate, somewhat rugged underneath; cymes terminating and axillary.—Native of Jamaica.

5. Calicarpa Reticulata. Leaves elliptic, lanccolate, subserrate, wrinkled, tomentose hoary underneath.-Native of Jamaica.

6. Calicarpa Umbellata. Leaves turbinate, ovate, smooth, alternate, undels sessile.—This is a middle-sized tree, with ascending branches; leaves quite entire, reflex at the edge; flowers herbaceous, small, in five coloured umbels, almost at the ends of the branches; calix bluntly four-cleft; corola bell-sbaped, with a short tube; stamina and stigua assise; berry floshy, roundish, small, containing four seeds.—Native of Cachin china, in woods.

7. Callicarpa Triloba. Stem scandent ; leaves three-lobed; peduncles dichotomous. A long branching shrub, elimbing by bifd tendrils; leaves cordate, serrate, smooth, on long petioles; flowers axillary, pale; berry roundish, four-seeded. –Native both of China and Cochin-china.

Calligonum ; a genus of the class Dodecandria, order Tetragynia.-GENERIC CHARACTER. Calix: perianth oneleafed, turbinate at the base, with a five parted border; parts nearly equal, roundish, spreading, finally obscurely turned back, permanent, the two outer a little smaller than the rest. Corolla; none, unless the calix be taken for it, Stamina: filamenta about sixteen, diverging, capillary, at bottom thickened a little and pubescent, surrounding the germen like a nectary, with their slightly coalescent base, withering. Antheræ roundish, two-celled, peltate. Pistil: germen superior, ovate, four-sided, acuminate; styles three or more, frequently four, filiform, spreading, subcoalescent at the base, or ending in an acumen of the germen, scarcely shorter than the filamenta; stigmas capitate. Pericarp: none, except the crust or shell of the nut. Seed : nut with a juiceless inseparable crust or rind, oblong, four-sided, fourwinged, one-celled, valveless; the wings cither membranaceous, longitudinally two-parted, tooth-curled, or bristly; the bristles branched, rigid, but soft; nucleus or kernel of the same form. ESSENTIAL CHARACTER. Calix: five-parted. Corolla: none; filamenta about sixteen, slightly united at the base. Germen ; superior, four-sided ; nut onc-celled. with a crust that has several wings, or many bristles,----- The species are,

1. Calligonum Polygonoides. Fruit latticed: bristles female: petals small, winte, hick, fait, rescent-form; when branched; rigid—A shrob three or four feet in height, very imagnified, they appear to be a collection of air-vessels, to bushy, and extending on every side; the flowers are in the entitle the flower to float.—It is an annual plant, very comfour of basins, cat that of the parts to the middle, where they i on an dicthes and standing waters, flowering from Apil to a standard of the standard from Apil to the standard of the st

are pale green, the rest is white; from the bottom of the basin rises an arguard pisht a line and haff in heregth, surrounded with shine filamenta, which have puryle anthere; each flower is supported by a very slender and short needunch; it the fruit is auton thaff an inch long, and four lines thick, of a c-nical figure, deeply channelled longitudinally; it the channels are sometimes straight, sometimes spiral; the angles are teminated by wings cut into very fine fringes; the poly part is white and angular; the flowers smell like those of the linetree, are long in willering, and continue at the base of the fruit. Found in Armenia, at the foot of mount Ararat, by Tournefort.

2. Calligonum Comosum. Fruits latticed; bristles branched, soft --- Found in Egypt.

8. Calligenum Tallasia. Fruits winged; wings membranecous, curled.—A shrub three or four feet high, with many alternate, round, rechning, flexnose, jointed, somewhat knotty, leafless branches; the shoots at each joint are numerous, (six to ten,) much crowded in bundles, rushy, some simple, others branched; few of these become branches, but most of them perish; they are subulate, jointed, bright green, or somewhat Igacous; flowers lateral or axillary, usually three together at each joint, pedaneled, white, with the disk of the calveice segments greenish, fragmant; with us it flowers in Angast. It was found by Pallas in the sandy deserts of Siberia, between the Volga and the Daick.

Califisia; a genus of the class Timadria, order Monogynia. -GENERIC CHARACTER. Caliz: perianth three-leaved; leaftets linear-hanceohic, keeled, ereet, permanent. Carolla: petals three, hanceohiet, accuminate, ereet, spreading at the top, the length of the calix. Stamina: filamenta three, eaprindry, longer than the corolla, dilated at the top into a roundrish lamina. Anthere double, globular, fixed to the inside of the hamina. Pristi?: germen spacerior, oblong, compressed; style capillary, the length of the stamina; stigman three, spreading, penel-form. Periorgr: capsule ovate, compressed, acute, two-celled, two-valved, the valves contary; seeds two, roundish. ESENTAL CHARACTER. Caliz: three-leaved. P-tals: three. Anthere: double. Capsule: two-celled.—The only known species is,

i. Callisia Repens; Creeping Callisia. Herbaceous, tender, creeping from the joints, father erect at top, a little branching at the base, smooth; leaves ovate, accumitate, subcordate at the base, quite entire, thickish, shinning fat, sheathing, the edge purple, atternate; flowers small, tender, sessile, greenish, generally litree together from each sheath of the lower leaves,—h England, it flowers in June and July, but is a native of the West Indies, in low moist shady places.

Califiriche ; a genus of the class Monandia, order Digyna-GENERIC CHARACTER. Calix: noue. Corolla: petals two, incurved, acuminate, chanuelled, opposite. Stamina: filamenta one, long, recurved. Authera simple, Pisfoli genuen roundish; styles two, capillary, recurved; stigmas acute. Pericarp: capsule roundish, quadrangular, compressed, two-celled; seeds solitary, ollong. ESSEN-TIAL CHARACTER. Calix: none; petals two. Capsule : two celled, four-seded.—...The species are,

1. Calibriche Verma; Vernal Starword, or Star-headed Water Chickwerd. Upper leaves oval; fowers androgynous; stem long, round, brauching, rooting; leaves in pairs, the upper ones radiating, and floating on the surface of the water; fowers sessile in the axis; the upper ones male, the lower female; petals small, white, thick, flat, crescent-form; when magnified, they appear to be a collection of air-vessels, to enable the flower to float.— It is an annual plant, very comon in ditches and standing waters, flowering from April to June. is probably owing to its situation, in places where water has stood in the winter, or in ditches and marshes dried up.

CAL

2. Callitriche Autumnalis; Autumnal Starwort. All the leaves linear, bifid at the end; flowers hermaphrodite .- This differs from the first species in having all the leaves linear, and cleft at the end; to which Withering adds, that the corolla is yellowish white; and Linneus, that it flowers in September. It is sometimes so thickly matted together on deep marshes, that a person may walk upon it without sinking.

Calodendrum: a genus of the class Pentandria, order Monogynia .-- GENERIC CHARACTER. Calix: perianth oneleafed, permanent, five-parted; parts ovate, acute, thickish, villose, muricate on the outside, with the edges slightly revolute. Corolla: petals five, lanceolate, blunt, spreading, channelled, keeled, waved, villose, three times the length of the calix. Necturies five, shaped like the petals, inserted into the receptacle within them, linear-lanceolate, subulate at the tip, terminated by a gland, smooth, silvery, glandular, narrower than the corolla, but of the same length. Stamina : filamenta five, equal, the length of the corolla, four of which have antheræ, one being usually barren. Antheræ ovate cordate, grooved, inserted into the back. Pistil : germen pedicelled, capitate, muricate, superior; style inserted into one side of the germen, filiform, the length of the stamina; stigma simple, blant. Pericarp : capsule peduncled, ovate, blantly five-cornered, five-grooved, muricate, five-celled, five-valved. Seeds : in pairs, triangular, convex at the back, smooth. ESSENTIAL CHARACTER. Calix: spreading, five-petalled, Nectary: five-leaved. Capsule: five-celled .--—The only species hitherto known is,

1. Calodendrum Capense. A tree with branches opposite, or three together; leaves entire, evergreen; flowers in terminating panicles, on opposite one-flowered pedancles .--Native of the Cape of Good Hope.

Calophullum : a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fourleaved ; leaflets ovate, concave, coloured, deciduous ; the two outer ones shorter. Corolla: petals four, oblong, concave, spreading. Stamina : filamenta many, filiform, short. Antheræ erect, oblong. Pistil : germen roundish ; style filiform, the length of the stamina ; stigma headed, obtuse. Pericarp: drupe globular. Seed: nut-globular, subacuminate, very large. ESSENTIAL CHARACTER. Calix: four-leaved. coloured. Corolla : four-petailed. Drupe : globular .-The species are,

1. Calophyllum Inophyllum. Leaves oval; calix the size of the petals; flowers more racemed, and the leaves twelve times larger, than in the following species; leaves a span long, and a hand broad, marked with transverse distant streaks; the root exudes a whitish clear gum, without scent; flowers eight-petalled, snow-white, sweet-smelling, growing in racemes; fruit the size of a walnut, under a fleshy bark, and a woody shell, having a very oily nut, which is bitter, and yields a vellow resinous juice .- It is a tree of great size, ninety feet in height, and twelve in thickness; bark of the branches smooth, at first green, afterwards reddish; of the trank thick, scaly, blackish, and purple within, which, when wounded, exudes a yellowish viscid juice, frequently hardening to a gum ; leaves like those of the water-lily ; fruit smooth, shining, green, when ripe reddish : the nut is at first sweet, but afterwards very bitter. It is common in Malabar, in sandy soils, bearing fruit twice a year, in March and September, frequently to the age of three hundred years. An oil is expressed from the nuts to burn in lamps, to assuage pains, and to make ointments; the bark and gum is also used for medi-

There is a variety of this species, but the difference cinal purposes. The inhabitants of Java plant this tree about their houses, for the elegance of the shade, and the sweetness of the flowers.

2. Calophyllum Calaba. Leaves ovate, obtuse .- This is also a lofty tree, putting out branches from very near the ground, so that it is well adapted for hedges and walks; the vonnger branches are quadrangular; leaves ovate, obovate, or oblong, blunt, emarginate, entire, shining, coriaceous, firm, with parallel transverse streaks, on short petioles, opposite, four inches long; flowers on axillary, simple, loose racemes, usually seven together, white, and smelling sweet ; fruit green, with a little pulp, and that hardish, involving a smooth yellowish ash-coloured nut, in which is a white solid kernel; it is not eaten, but the Caribbees express an oil from it for domestic uses. Brown informs us, that this tree is pretty good timber, but does not bear the weather well, although it is frequently used for staves and heading.

Caltha ; a genus of the class Polvandria, order Polvgamia, GENERIC CHARACTER. Calix : none. Corolla : petals five, ovate, flat, spreading, deciduous, large. Stamina : filamenta numerous, filiform, shorter than the corolla. Antherae compressed, obtuse, erect. Pistil: germen superior, five to ten, oblong, compressed, erect; styles none; stigmas simple. Pericarp : capsules as many, short, acuminate, spreading, one celled, two-keeled, gaping in the superior suture. Seeds: very many, (fifteen,) ovate, or ovate-oblong, smooth, affixed to the superior suture in a double row. ESSENTIAL CHARAC-TER. Calix: none. Petals: five. Nectary: none. Capsule: several; many-seeded, ---- The only species discovered is,

1. Caltha Palustris ; Marsh Marigold, (Souci de Marais.) Root perennial; stems several, almost upright, about a foot high, hollow, nearly round, smooth, branched, purple at bottom; radical leaves on long petioles, cordate, reniform, smooth, shining, and notched or crenated, sometimes scalloped, sometimes entire; stem-leaves nearly sessile, more pointed at top, and sharply crenated; stipules brown, membranous, and withering; branches dichotomous; peduncles one-flowered, upright, grooved ; corolla of five petals, somewhat concave, large, without any gloss on the upper side; antheræ oblong, flat, bending inward, yellow; the inner row of filamenta with broad antheræ, the outer twice as loug, club-shaped, with compressed antheræ; seeds beautiful, at the bottom of an olive, and at top of a reddish colour .-- It is found in wet meadows, and by the sides of rivers, making a noble appearance in March and April, and sometimes so early as February. The flowers, gathered before they expand, are said to be a good substitute for capers. The juice of the petals, boiled with alum, stains paper yellow: cows will not eat it, unless compelled by extreme hunger; it is a valgar notion, therefore, and wholly unfounded, that the yellowness of butter in the spring is caused by this plant: where a high colour is not given by art, it is the effect of abundance of rich pasture. Boerhaave says, that when cows eat this plant, it occasions such an inflammation that they generally die. On May-day, the country people strew the flowers before their doors ; the garlands are also ornamented with it on that day. The leaves seldom appear to be eaten; but the flowers are often de-stroyed by a species of chrysomela. This is the first flower that announces the spring in Lapland, where it begins to blow towards the end of May. Miller insists that the greater and smaller marsh-marigolds never vary, either in their natural places of growth, or when cultivated in a garden. The variety with many double flowers is preserved in many gardens for its beauty. This is propagated by parting the roots in autumn; it should be planted in a moist soil and shady

situation, and may be allowed room where few other plants one-celled; seed single, slightly angular. will thrive: during the season of flowering, it will afford an agreeable variety. The marsh-marigold with double flowers does not appear so early in the spring as the single, but continues much longer in beauty. It flowers from May to the middle of June.

Calycanthus; a genus of the class leosandria, order Polygynia .- GENERIC CHARACTER. Calix : perianth oneleaved, pitcher-shaped, squarrose; leaflets eoloured, lanceolate, the superior ones gradually larger, resembling petals. Corolla: none, except the calyeine folioles, representing petals. Stamina : filamenta numerous, subulate, inserted into the neek of the calix. Antheræ oblong, furrowed, growing to the top of the filamenta. Pistil: germen a great many, ending in subulate compressed styles of the length of the stamina; stigmas glandulous. Pericarp: none; the calix being thickened, obovate, and berried. Seeds : very many, tailed. ESSENTIAL CHARACTER. Calix : one-leafed, pitcher-form, squarrose, with coloured leaflets. Corolla : calvcine : styles very many, with a glandulous stigma. Seeds : very many, tailed, within a succulent calix .---- The species are,

1. Calycanthus Floridus; Carolina Allspice. Inner petals longer than the outer .- This shrub arrives at the height of eight or ten feet where it grows naturally, but it seldom rises more than four feet high in this country, dividing into many slender branches near the ground, covered with a brown aromatic bark, with two entire leaves placed opposite at every joint ou short foot-stalks; the flowers grow single, on short peduncles at the extremity of the branches; they have two series of narrow thick petals, which spread open, and turn inward at the top, like those of the starry anemone, or the virgin's bower ; these are of a dusky purple colour, and have a disagreeable scent; they appear in May. The bark of this shrub is brown, and has a very strong aromatic odour, and hence the juliabitants of Carolina call it allspice. There are two varieties of it : the long-leaved Carolina allspice, and the round-leaved Carolina allspice. It will thrive in the open air in England, if it be planted in a warm situation and dry soil; it is propagated by laying down the young brauches, which will take root in one year, and may then be taken from the mother-plant, and set where they are designed to remain, for they do not bear transplanting well after they are grown to any size. When the layers are transplanted, the surface of the ground should be covered with mulch, to prevent the drying winds from penetrating the ground to the roots ; and if the season prove dry, they must be watered once a week, but should not have too much wet, for that will rot their tender fibres : the best time for laving down the branches is in autumn, but they should not be transplanted till the spring, twelve months after; for the spring is the safest time to remove these plants. After the branches are laid down, there should be some old tanuer's bark laid upon the surface to keep out the frost, which should also be done every winter whilst the plants are young.

Culuptranthes; a genus of the class Ieosandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, bell-shaped, truncate, toothless or very obscurely four-toothed, superior, permanent, covered with an orbicular concave deciduous lid. Corolla : none. Stamina filamenta very many, eapillary, inserted into the inside of the calix at the rim. Antheræ roundish, twin, small. Pistil : germen roundish, fastened to the bottom of the calix, two celled, with a few seeds fixed to the partition ; style simple, filiform, bent in the length of the stamina; stigma blunt. Pericarp: berry globular or oblong, crowned with the calix, 20.

ESSENTIAL CHARACTER. Calix: superior. truncate, covered with a veil-shaped deciduous lid. Corolla: none. Berry ; onecelled, one to four-seeded .---- The species are,

CAM

1. Calvotranthes Chyraculia. Arboreous; peduncles terminating, panicled, trichotomous, tomentose; leaves ovate, attenuated at the tip .- The leaves of this tree are smooth and opposite; the lid is fastened to the calix laterally, but afterwards turns back, and then the filamenta issue forth, which had been before twisted and concealed : it is reckoned an excellent timber tree, but it seldom exceeds fourteen or fifteen inches in diameter. Native of Jamaica.

2. Calyptrauthes Zuzygium. Arborescent ; peduncles axillary, trichotomous, patulous; leaves ovate, blunt; branches dichotomous .- This shrub seldom rises above ten or twelve feet in height; the whole is bushy, and bears black berries, crowned with the margin of the cup; these contain four smooth slightly angular seeds, one or two only usually arrive at maturity; the style is longer than the stamina, and the stigma is acute. Native of Jamaica.

3. Calyptrauthes Rigida. Arborescent; peduncles solitary, axillary, three-flowered, or thereabouts; leaves ovate, acute, convex, veinless, rigid .- Native of Jamaica.

4. Calyptranthes Jambolifera. Leaves ovate, emarginate; corymb terminating .- This is a tree above the middle size, with spreading branches, the smaller oues brachiate. Native of the East Indies and China.

5. Calyptranthes Odorata. Leaves ovate, obliquely trupcate at the base; corymbs terminating, distich .- This is a small tree, about five feet high, with a very straight single stem, and brachiate branches; the young leaves are put into salads, and are not unpleasant. Loureiro observed it in the gardeus of Cochin-china.

6. Calyptranthes Resinosa. Leaves oblong; peduncles lateral. This is a middle-sized tree, with spreading branches, and a very tough resinous bark ; leaves quite cutire ; flowers white, on many flowered axillary peduncles; calix fourtoothed ; corolla four-petalled, bell-shaped ; berry roundish, small, black, four-celled ; stamina eight .-- Native of Cochinchina, where the fishermen dye their nets in a strong decoction of the root, to prevent them from rotting.

Camax; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oue-leafed, five-parted; parts roundish. Corolla: one-petalled, wheelshaped ; tube very short ; border five-parted ; parts roundish, villose above. Stamina : filamenta five, inserted into the corolla between the segments, villose. Pistil : germen roundish, villose, superior; style capillary; stigmas three or four, sharp. *Pericarp*: berry ovate, villose, four-celled; seeds very many, nestling in a viseid pulp. ESSENTIAL CHARACTER. Corolla: wheel-shaped; filamenta inserted between the segments of the corolla; berry four-celled, manyseeded, all villose .---- The only species known is,

1. Camax Guianensis .- This is a shrub growing to the height of twelve or fifteen feet, with a simple, knotty, cylindric stem; leaves many, in whorls at the joints, declining unequally, pinnate, with six alternate leaflets, which are sessile, oval, acuminate, the largest of them ten inches long and three broad, and a little above each of them is a small spine issuing from the midrib, which is three or four feet in length: the flowers are sessile, in great numbers at the base of the leaves, and in the intervals between them. It is called bois gaulete by the Creoles, and arowpouron by the Coussaris, one of the nations of Guiana, where it is a native, and flower's in January: the inhabitants and negroes use the branches of this shrub for wattling their huts. 3 N

Cambogia; a genus of the class Polyaudria, order Monoprina.--GENRIC CHARACTER. Calis: perianth fourleaved; leaflets roundish, concave, deciduous. Corolla: petals four, roundish, oblong, concave, with oblong claws. Stamina: flaanenta very many, short. Antheræ roundish. Pistil: germen roundish, striated; style none; stiguna fourceft, obtuse, permauent. Pericarp: pome roundish, eightangled, eight-celled. Szeds: solitary, reniform, oblong, slightly compresed. EsseNTAL CHARACTER. Corolla: four-petulled. Calix: four-leaved. Pome: eight-celled. Szeds: solitary.---The only species kown is,

CAM

1. Cambogia Gutta. Which is a tall tree, with a trunk sometimes as thick as two men can compass, with spreading opposite branches. According to the Hortus Malabaricus, the fruit is first green, then yellowish, and when ripe whitish. Native of the East Indies, and of the woods in China and Cochin-china, very abundant in Siam and Cambodia, where incisions are made in the bark, and a great quantity of gummi guttæ, or gamboge, is extracted, and exported into foreign This concrete is a gum-resin, in part inflammable, countries. compact, dry, yellow, inclining to orange colour, without smell, and almost without taste ; producing, however, a slight sensation of acrimony in the throat. A greater quantity of it is dissolved in spirits of wine than in water, to which it imparts a lemon-colour ; it is used medicinally in the East Indies, as a purgative, hydragogue, and emetic, particularly in dropsies and worm cases; it is said to lose the latter quality, when macerated in vinegar. The principal use, how-ever, of gamboge, is in painting in miniature and watercolours. The fruit is eaten at meals in the East Indies; and being much esteemed for provoking the appetite, is a frequent ingredient in their sauces.

Cancilia; a genus of the class Monadelphia, order Polyadria.-GESERIC CHARACTER. Cali:: perianth manyleaved, roundish, imbricate; the scales roundish, very blunt, he inner ones gradually larger, concave, cleicluous. Corolla: petals five, obovate, coalescing at the base. Stamina : filamenta numerous, erect, coalescing below into a crown, larger than the style; above unconnected, shorter than the corolla. Antheras simple. PisiAl: germen roundish; style subulate, length of the stamina; stigma acute, reflex. Pericarp: capule turbinate, woody, marked with some furrows. Seeds: kernels equal in number to the streaks of the capsule, roundtish, often filed with smaller seeds. ESENTIAL CHARAC-TER. Calix: imbricate, many-leaved; the inner leaffets larger.--The species are,

1. Camellia Japonica; Japan Rose. Leaves acutely serrate, acuminate; bark ash coloured; branches round and smooth; leaves alternate, ovate, shining on both sides, thick and stiff, paler green beneath, on short petioles ; peduncles terminating, very short, commonly solitary, with the branches lengthened out beyond them .--- It is a vast and lofty tree, in high esteem with the Japanese, for the elegance of its large flowers, which exhibit a great variety of colours, but have no scent, and for its evergreen leaves: it is very common every where in their groves and gardens, flowering from October to April; it varies with single and double flowers, white, red, and purple. It is a native also of China, and occurs very frequently in Chinese paintings. Having been hitherto scarce, and kept up to a high price, it has been generally treated as a stove plant, though it has been sometimes placed in the green house. When it shall hereafter become more common among us, it may perhaps be treated in the same manner as the magnelia : it is propagated by layers ; it may also be propagated by cuttings, in the same manner as directed for gardenia.

Leaves obtusely serrate, emargi-2. Camellia Sasangua. nate .- A tree of a middling size, differing from the first species, in having thinner narrow leaves, obscurely serrate ; flowers many times smaller, with oblong emarginate petals, and a much smaller and more sleuder stem : the flowers are borne singly at the end of the branches; the calix is five-leaved. sometimes six-leaved; the petals are five in number, sometimes six or seven, snow-white, deciduous; the leaves, dried in the shade, have a sweet smell; a decoction of them is used by the women to wash their hair with, and they are mixed with tea, to give it a grateful odour; indeed this so resembles the tea-plant, that it is distinguished by little else besides the coalescing stamina; and this is scarcely a sufficient mark of distinction, since the stamina coalesce only at the base, and even sometimes scem to be distinct. Native of Japan ; flowering in November.

3. Camelhia Drupifera. Leaves ovate-oblong, slightly create; flowers two or three together, terminating; drupes four-celled.—This is a middle sized tree, with sprcading branches; leaves acuminate, smooth, hard, snahl, alternate, petioled; flowers white, terminating on two or three peduncels together, one on each; petals eight, oblong, emarginate; style quadrifid, equal to the stamina; drupe roundish, with a grooved four-celled nut, and roundish kernels; the frait is quadrified, equal to size to the walnut, and not much unlike it, it is not, however, esculent. It is both wild and cultivated in Cochiachian. The oil expressed from the nut is used by the natives to anoint their hair, and for various medical purpose; it has a pleasant doour, and does not easily become rancid.

Camel's Hay. See Andropogon.

Cameraria; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fivecleft, acute, converging, very small. Corolla : monopetalous, funnel-form ; tube cylindric, long, bellied ont at the base and tip; border five-parted, flat; divisions lanceolate, oblique. Stamina: filamenta five, very small from the middle of the tube. Antheræ converging. Pistil: germen two, with lateral appendages; styles hardly any; stigmas obscure. Pericarp: follicles two, horizontally reflected, oblong, obtuse at both ends, and sending forth a lobe each way near the sides of the base, one-celled, one-valved. Seeds: numerous, ovate, inserted on the larger ovate membrane at the base. ESSENTIAL CHARACTER. Contorted. Follicles: two, horizontal. Seeds: inserted into their proper membrane. These plants are propagated by seeds, which must be procured from the places of their growth; they may also be increased by cuttings, planted in a hot-bed during the summer months: they must have a bark-stove, for they are very tender, but in warm weather they must have plenty of air .---- The species are,

 Cameraria Latifolia; Bastard Mangeneel. Leaves orate, acute at both ends, transverse, striated.—This is a tall elegant tree, about thirty feet in height, the whole abounding with an acrid milky juice. Native of Cuba, Jamaica, and St. Domingo: the flowers appear in August, but never produce any seed in England.

2. Cameraria Angustifolia. Leaves linear; stem irregularly branching, shrubby; leaves opposite, quite entire, the middle nerve decurrent; flower and fruit much smaller than in the foregoing species, as is the whole plant.—It grows about eight feet high; the leaves have two ribs running longitudinally; the dhowers are produced scatteringly at the ends of the branches: like the other species, it abounds with an aerid milky usice, and grows naturally in Jamaica.

Cammock. See Ononis.

Camomile. See Anthemis.

Campanula : a genus of the class Pentandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth five-parted, acute, erect, expanding, superior. Corolla: monopetalous, bell-form, impervious at the base, half five-cleft, marescent; divisions broad, acute, spreading. Nectary in the bottom of the corolla, composed of five valves, acute, converging, covering the receptacle. Stamina: filamenta five, capillary, very short, inserted on the tips of the valves of the nectary; antheræ longer than the filamenta, compressed. Pistil: germen angular, inferior; style filiform, longer than the stamina; stigma three-parted, oblong, thickish; divisions revolute. Pericarp: capsule roundish, angular, three or five-celled, emitting the seeds at so many lateral openings. Seeds: numerous, small; receptacle, columnar, adunate. Es-SENTIAL CHARACTER. Corolla: bell-form, the bottom closed with staminiferous valves. Stigma: three-cleft; cansule inferior, gaping, with lateral pores. The directions for propagating and cultivating, which will be found subjoined to various species of this genus, may serve for all the other hardy annuals, biennials, and perennials, of which it consists. Those species which come from the Cape of Good Hope, must be kept in the dry-stove, and otherwise treated like the plants from that country; they may in general be increased from cuttings .---- The species are,

* Leaves more glossy and narrow.

1. Campanula Cenisia; Ciliade Bell flower. Stems oncfowered; leaves ovate, smooth, quite entire, subciliate; root perennial, cereping, often a foot long, dividing into several branches at top; corolla blue, divided to the middle into five segments, which are frequently bent back, twice as long as the caix; capsule three-celled.—Native of the higher rocks of the Alps, about the Glacieres; on the highest pike of Mont Cenis, called Ronche; by the head of the river Durance, and on other neighbouring eminences; also in Dauphiny: if fowers in June and July.

2. Campanula Unifora. Stem one-flowered; calix equaling the corollar; root fibrous, annual; stem absolutely simple, the length of a finger, obliquely erect, round, entire; stem-leaves air or seven, alternate, the lowest vertically ovate, the middle ones lanceolate, the uppermost linear, the last of these is immediately under the flower; a single flower terminates the base, and blue; fruit turbinate, orear, or pearshaped, very large in proportion to the plant, slightly inclined, opening with three holes near where the capsule units with the crowning calix.—Native of the montains of Lapland, where it is very rare, and flowers in the beginning of Jaly.

3. Campanula Pulla; Russet Ball-flower. Stemlets one-flowerel; stem-leaves ovate, crenate; caliese drooping; root filform, creeping; stem a short span in length, erect, flexu-ose, filform, souetimes having a branch or two bearing a single flower; root and stem-leaves ovate, obtuse, with a single flower drooping, the same size as in the next sort, with a smooth calix; the variety has several flowers at the top of the stalk; the corolla is of a very deep blue.—Native of the montanis of Austria, Carniola, and Arragon.

4. Campanha Rotundifolia; Roind-Icared Bell-Joner, Radical leaves kidney-form; stem-leaves linear; root perennial, creeping, sweetish; stems several, a foot or more in beight, varying from two inches to a yard, rather upright, but weak and crooked, round, smooth, solid, milky, and branched; radical leaves heart or kidney-form, petioled, foothed (frequently quite entire;) stem-leaves near the base anceolate and toothed, near the summit linear and entire;

flower-branches spreading, simple or subdivided, almost naked : flowers nodding a little : corolla blue, sometimes white : calix permanent, segments linear, smooth, grooved, considerably expanded when out of blossom; nectary at the bottom of the corolla, formed of five pointed valves, closing and covering the receptacle, fringed, white ; capsule three-celled, The radical leaves, whence this plant has its name, are usually hid in the herbage, and therefore seldom observed; they also dry away and drop off, when it is advancing to maturity. It grows plentifully on heaths and other waste grounds, in dry hilly situations, flowering from June to September. A green pigment is obtained from the flowers; the inice stains blue, but with the addition of alum, green; the stalks and branches, when broken, give out a milky juice, which has a disagreeable smell. There are two varieties of this species, but not worth noticing.

CAM

5. Campanula Patula; Spreading or Field Bell-flower. Leaves stiff, the radical ones lanceolate, oval; panicle spreadjug; root-leaves many together, spreading, small, roundish or oval, soon turning yellowish; those on the stems lanceolate, straight, and even. The herb, though bitter, being frequently eaten down by cattle, side-branches spring up, and flower till the winter frost destroys the root; corolla of an elegant form, tapering at the base, but spreading in the rim. Native of Sweden, Denmark, Germany, Switzerland, Carniola, Piedmont ; in corn fields, woods, hedges, and by roadsides; flowering in July and August: in England it is not common. Lyttleton, Browne, and Merrett, found it at Adferton near Wigmore in Herefordshire; Dilleuius, in a wood called Elberry Hill, about a mile from Worcester, and near Bishop's Castle in Shropshire; Dr. Pulteney, by Buddon wood near Loughborough, and between Litchfield and Meriden ; Mr. Nash, near Malvern ; Mr. Woodward, near the bath at Litchfield, and on the road to Coleshill; Dr. Smith, in the park of the late Lord Ligonier, at Colsham in Surry, See the thirteenth species.

6. Campanula Rapunculus; Rampion. Leaves waved. the radical ones lanceolate, oval; panicle contracted,-The whole plant is full of a milky juice; root biennial, spindleshaped, sometimes branching; stein upright, angular, two feet high, hairy towards the base, smooth above; branches alternate, short, upright ; leaves towards the base of the stem hairy, above or on both sides blunt; the upper ones smooth, and becoming gradually more pointed; obscurely notched, teeth glandular, whitish, not projecting beyond the edge of the leaf; an awl-shaped bracte at the base of each pedancle; segments of the calix awl-shaped or setaceous, twice as long as the germen, with a small tooth on each side of the base ; flowers upright; corolla bluish purple, sometimes very pale purplish, or whitish; each segment marked with three lines; nectary fringed. It grows wild in France, Flanders, Switzerland, Germany, Carniola, Piedmont; by hedges and road-sides, and woods, in fallow-fields and dry pastures; flowering in June, July, and August. In England it has been found growing near Croydon and Esher in Surry; old Buckenham Castle in Norfolk; and about Hindlip and Envilla in Worcestershire : the fleshy roots are eatable, and are much cultivated in France for salads; some years past it was cultivated in the English gardens for the same purpose, but it is now generally neglected. Haller says that it is in great request among the Swiss, in the spring; and that it increases milk; the roots are caten, not only raw in salads, but boiled like asparagus; they were boiled tender and eaten cold with vinegar and pepper, in the time of Parkinson. This plant is propagated by seeds, which should be sown in a shady border the latter end of May, and when the plants are about an inch high, the ground should be heed, as is practised for oaions, to cut up the weeds, and thin the plants to the distance of three or four inches; and when the weeds come up again they must be hoed over to destroy them; this, if well performed in dry weather, will make the ground clean for a considerable time, so that if thrice repeated it will keep the plants clean till winter, which is the season for eating the roots, when they may be taken up for use as they are wanted. These will continue good till April, at which time they will send out their stalks, when they will become hard and unft for use, as do also those roots which have flowered; the young roots only are fit for the table: when the seeds are sown too early, the plants frequently run up to flower the same year, and the roots are spoiled.

7. Campanula Persicifolia ; Peach-leaved Bell-flower, Radical leaves obovate ; stem-leaves lanceolate, linear, subserrate, sessile, remote; root like that of navew, and eatable; stem very straight, eighteen inches high and more, (in gardens two feet and a half) unbranched, angular, smooth, as is the whole plant (except the germen and capsule;) flowers in a thin spike, one or two together, on very long peduncles, which have two stipules at the base : corolla large, broad, bell-form, deep blue, the segments short, and moderately acuminate .- This a perennial plant, native of most parts of the continent of Europe, from Sweden to Spain, but not of Britain. The varieties are, the single blue, and white; and double flowers of both colours; the latter have not been more than fifty years in England, but have been propagated in such plenty, as to have almost banished those with single flowers from the gardens. This species, as well as all the other hardy perennial sorts, which are very numerous in this genus, are easily propagated by parting their roots in autumn, at which time every head that is slipped off will grow; they will thrive in any soil and situation, and are proper furniture for the common borders of the flower-garden and shrubbery.

8. Campanula Pyramidalis; Pyramidal Bell-flower. Leaves smooth and even, serrate, cordate; stem-leaves lanceolate; stems rushy, simple; umbels sessile, lateral,-Scopoli thus describes this plant in its wild state. The root and stem are milky; the latter is four feet high, panicled with short branches from top to bottom; all the leaves are ovate, petioled, and shortly toothed ; the teeth paler, and terminated by a gland; the corolla spreading, five-cleft beyond the middle; the calycine teeth, even whilst the corolla is closed, spreading out horizontally, and twice as long as the germen, which is three-cornered. It is found about Idria, in Strnk; and, according to Allioni, in Savoy. It is thus described by Mr. Miller, as it appears in gardens : it has thick tuberous roots which are milky; these send out three or four strong, smooth, upright stalks, which are nearly four feet high, and are garnished with smooth oblong leaves, whose edges are a little indented; the lower leaves are much broader than those on the stalks, and are regularly set on for more than half their length, forming a sort of pyramid; these are large, open, and shaped like a bell; the most common colour of the flower is a light blue; but there have been some with white flowers, which make a variety when intermixed with the blue, but the latter is most esteemed. This plant is cultivated to adorn halls, and to place before the chimnies in summer when it is in flower, for which purpose there is no plant more proper; for when the roots are strong they will send out four or five stalks, which will rise as many feet high, and are garnished with flowers great part of their length; these upright stalks send out some short sidebranches, which are also adorned with flowers, so that by spreading the upright stalks to a flat frame composed of planted, it will be of great service to them; but as the season

slender laths, as is usually practised, the whole plant is formed into the shape of a fan, and will spread nearly to the width of a common fire-place. When the flowers begin to open, the pots are removed into the rooms, where being shaded from the sun, and kept from the rain, the flowers will continue long in beauty; and if the pots are every night removed into a more airy situation, but not exposed to heavy rains, the flowers will be fairer, and continue much longer in beauty. Those plants which are trained for adorning halls and chimneys, are seldom fit for the purpose the following season ; a supply of young plants therefore should be annually raised: the common method of doing this, is by dividing the roots ; and the best time for doing it is in September, that the offsets may have time to get strong roots before winter. This method of propagating by the offsets is the quickest, therefore generally practised, but the plants which are raised from seeds are always stronger; the stalks will rise higher, and produce a greater number of flowers; and is therefore recommended to the practice of the curious. In order to obtain good seeds, there should be some strong plants, placed in a warm situation, near a pale or wall, in autumn; and if the following winter should prove severe, they should be covered with either hand-glasses or mats, to prevent their being injured by the frost; and in the summer, when the flowers are fully open, if the season should prove very wet, the flowers must be screened from great rains, otherwise there will be no good seed produced: the not observing this had led many to conclude that the plants do not bear seed in England, which is a great mistake, though it has certainly been found that the plants which have been long propagated by offsets, seldom produce seeds, and this is the case with many other plants which are propagated by slips or cuttings, which in a few years become barren. When the seeds are obtained, they must be sown in autumn, in pots or boxes filled with light undunged earth, and placed in the open air till the frost or hard rains come on, when they should be placed under a hot-bed frame, where they may be sheltered from both ; but in mild weather, the glasses should be drawn off every day, that they may enjoy the free air; with this management the plants will come up early in the spring, and then they must be removed out of the frame, placing them first in a warm situation ; but when the season becomes warm, they should be removed where they may have the morning sun only: during the following summer, they must be kept clean from weeds, and in very dry weather now and then refreshed with water, which must be given with great caution, for the roots are very subject to rot with too much moisture. In September, the leaves of the plants will begin to decay, at which time they should be transplanted; therefore there must be one or two beds prepared, in proportion to the number of plants. These beds must be in a warm situation, and the earth light sandy, and without any mixture of dung, which last is an enemy to this plant. If the situation of the place be low, or the soil moist, the beds must be raised five or six inches above the surface of the ground, and the natural soil removed a foot and a half deep, putting limerubbish, eight or nine inches thick, in the bottom of the trench, to drain off the moisture. When the beds are prepared, the plants must be taken out of the pots or cases very carefully, so as not to break or bruise their roots, for they are very tender, and on being broken, the milky juice will flow out plentifully, which will greatly weaken them. These should be planted at four inches' distance each way, with the head or crowns of the root half an inch below the surface; if there happen a gentle shower of rain soon after they are

sometimes proves very dry at this time of the year, in that case it will be proper to give them a gentle watering three or four days after they are planted, and to cover the beds with mats every day, to prevent the sun from drying the earth; but these must be taken off in the evening, that the dew may fall on the ground; towards the end of October the bed should be covered over with some old tanner's bark to keep out the frost, and where there is not a conveniency of covering them with frames, they should be arched over with hoops, that in severe frosts they may be covered with mats; for these plants when young are often destroyed in winter, where this care is wanting. In the spring the covering must be removed, and the plants kept clean from weeds during the following summer; and if the season should prove very dry, they must now and then be refreshed with water ; the following autumn, the surface of the ground should be stirred between the plants, and some fresh earth spread over the beds, and in winter covered as before ; in these beds the plants may remain two years, during which time they must be treated in the manner before directed, by which time the roots will be strong enough to flower : in September they should be carefully taken up, and some of the most promising planted in pots; the others may be planted into warm borders, or in a fresh bed, at a greater distance than before, to allow them room to grow.

9. Campanula Americana: American Bell-flower. Lcaves cordate, and lanceolate serrate; petioles of the lower ciliate; flowers axillary, sessile; corollas five-parted, flat; styles longer than the corolla; root annual; stem and germina smooth; leaves acuminate; flowers three or more from each axil or bracte; corollas small; stylc longer than the co-rolla.-Native of Pennsylvania; flowers in July.

10. Campanula Lilifolia ; Lily-leaved Bell-flower. Leaves lanceolate ; stem-leaves sharply serrate ; flowers panicled nodding .- It is singular in this plant, that the stem, before it produces the panicle, puts out leaves in a kind of rose, which when the panicle comes forth, are dispersed about the stem; it is perennial, and varies much in the colour and size of the flower, quantity of branches, hardness and softness, smoothness and roughness, of the lcaves. It flowers most part of the summer, and was found from the Jaick eastward to the very confines of China, where the roots, both boiled and raw, are eaten by the inhabitants. 11. Campanula Rhomboidea; Germander-leaved Bell-

flower. Leaves rhomboid, servate; spike one-ranked; calices toothed ; root creeping, perennial ; stem erect, smooth, from six, eight, or ten, to eighteen inches in height, unbranched; leaves few, tender, smooth, ending in a point; the upper ones smaller; corollas blue, sometimes white, short, and swelling ; calix capillary .- Native of the mountains of Switzerland, Dauphiny, Carniola, and Italy, on mount Cenis. It flowers in July.

12. Campanula Unidentata; One-toothed Bell-flower. Erect, smooth : leaves lanceolate, acute, one-toothed on each side : panicle divaricated, leafy; stcms extremely simple .- Native of the Cape of Good Hope.

13. Campanula Capillacea ; Fine-leaved Bell-flower. Herbaccous, erect; leaves filiform, smooth; panicle terminal; flowers alternate.--Native of the Cape of Good Hope.

14. Campanula Linearis ; Linear-leaved Bell-flower. Her. baceous, erect; leaves linear, entire, smooth; flowers drooping; capsules hispid .- This differs from the preceding species in having hispid capsules, and the calix the length of the corolla .- Native of the Cape of Good Hope.

20.

toothletted; corollas nearly funnel-form, trifid, and quadrifid. This species, as its name signifies, has the air of a lobelia, the same tenderness, divided in the same manner, and even the the same inflorescence. Perianth three or five-leaved; leaflets ovate, obtuse, permanent; corollas very small, purplish white, twice as long as the calix, funnel-form; tube round, gradually widened; segments erect. It varies with the calix and corolla, three and five-parted, and even with three and five stamina; the capsule also is two-celled; it flowers in July and August. Native of Madeira.

16. Campanula Carpatica; Carpathian or Heart-leaved Leaves smooth, cordate, serrate, petioled; Bell-flower. branches filiform, one-flowered .- This pours out a milky juice when wounded; the root is whitish, and pereunial; stems herhaceous, annual, weak, hardly branching, bearing one or very few flowers. In gardens it becomes branching and many-flowered ; the root-leaves are kidney-form, roundish; the peduncle elongated and smooth; the corolla blue: it flowers the whole summer, and was first observed on the Carpathian Alps. It is yet scarce in our gardens, but deserves to he more generally known and cultivated, its flowers being large and showy in proportion to the plant; and, like many other alpine plants, being well suited to decorate rockwork, or such borders of the flower-garden as are not adapted to large plants: it may be propagated by parting the root; it is a perennial plant.

17. Campanula Grandiflora ; Great-flowered Bell-flower. Leaves tern, oblong, serrate ; stem one-flowered ; flower spreading .- The whole plant is very smooth ; root perennial, white, fusiform, the thickness of a finger, and branched ; stems few, erect, or ascending, simple, round, a foot high, leafy all over, annual, terminated with one handsome flower, but without scent, nodding a little; with sometimes one or two flowers more from the upper axillas ; corolla two inches or more in diameter, very deep blue, with numerous blue veins; elegantly pear-shape, before expanding, and at first green; no holes in the capsule: it flowers in June and the beginning of July, and ripens its seeds in August. Native of Siberia.

18. Campanula Aurea; Golden Bell-flower. Capsules five-celled ; leaves elliptic, serrate, smooth ; flowers subpanicled, five-parted; stem shrubby, fleshy; stems panicled, growing close to the rocks ; leaves lanceolate, smooth ; calix superior, coloured; tube of the corolla distant from the calix; segments linear, reflex; it flowers in August and September.

19. Campanula Tenella. Stems diffused, filiform : leaves ovate, sometimes one-toothed, reflex; flowers solitary, terminal; stem determinately branched and hard; branches simple, and covered with leaflets ; calix glossy, acute ; corolla five-parted .- The leaves are seldom without a lateral tooth. Found at the Cape of Good Hope.

20. Campanula Porosa; Porous-stalked Bell-flower. Leaves lanceolate, glossy; stem crect, porous with dots upwards .- This is a plant difficult to be distinguished, unless by the pores, scarcely distinguishable by the naked eye, which penetrate into the stem, not downward but upwards ; stem round, a foot high, erect; branches numerous, erect, short; the upper leaves linear, even, quite entire; racemes terminal, crect; flowers small, rather erect; calix shorter by half than the corolla, even, with lanceolate segments .- Native of the Cape of Good Hope.

21. Campanula Uudulata. Leaves lanceolate, tooth-waved : flowers subsolitary, peduncled; stem a foot and a half high, 15. Campanula Lobelioides; Lobelia-like Bell-flower. erect, filiform, glossy, somewhat branched at top; leaves Small stems round, stiff, smooth; leaves linear, lanceolate, sessile, reflected at the edgc, subdecurrent, repand, some-30

what glossy; peduncles terminal, long, leafless; flowers the size of the fourth species; calix glossy, with short acuminate teeth.—Native of the Cape of Good Hope.

** Leaves rugged, broader.

22. Campanula Latifolia ; Broad-leaved Bell flower : Giant Throatwort. Leaves ovate, lanccolate; stem very simple, columnar; flowers solitary, peduncled; fruit drooping; stem three feet high and more, angular, smooth, not branching; leaves sharply serrate, on short petioles, hirsute; flowers axillary, one or two together, on peduncles shorter than the leaf; corolla very large, blue, the segments triangular, divided by a line: the fruit compels the peduncle to bend down beneath its weight; the whole plant abounds with a milky liquor; it varies with purple, and with white flowers. It grows naturally in the northern parts of England, in Flintshire, Scotland, Denmark, Sweden, Switzerland, Piedmont, &c. flowering iu July and August; it is perennial, and easily propagated by seeds, which it furnishes in great plenty; if these be suffered to scatter, the plants will come up abundantly the following spring, when they may be removed into the nursery till autumn, at which time they should be transplanted whither they are intended to remain. As this sort delights in shade, the plants may be placed under trees, or in shady borders, where few better things will thrive, and they will there afford an agreeable variety when in flower.

23. Campanula Rapunculoides; Reampion-like Bell flower. Leaves cortaket, lauceolate; stem branching; flowers oneranked, scattered; calices reflex; the throat of the corolla is not very hairy; the root creeps prodigiously, and is said to be esculent.—Native of France, Germany, Austria, Switzerland, and Piedmont. Ray noticed it about Geneva, towards Gex, and on Mont Saleve: it is perennial, affects a dry soil, and flowers in July and August.

24. Campanula Bononiensis ; Bolggna or Panieled Bielforcer. Leaves ovate, lanceolate, rugged beneth, sessile ; stem panieled; leaves istem-clasping, lanceolate, serrate ; flowers in a very long thyrse; peducedse generally threeflowered ; root large, woody, like that of navew ; stem three fet high or more, erect, with uany ascending conjugate branches; leaves stem-clasping, almost cordiate, villose with a white map beneath, but not rough, moderately serrate; the same under the flowers, which come out on almost naked branches, and at the top of the stem, the lower ones on erect short pedunoles, three together, the upper ones sessile, in the axillas solitary or two together, at the top of the stem very numerous but small, forming a spike ; they are of a violet colour.—Native of Bologna, Monte Baldo, Austria, Switzerland, Puednont; it is pereminid.

25. Campanula Graminifolia; Grass-leated Boll-flower, Leaves linear, subulate: head terminal; stems extremely simple, scarcely longer than the leaves; flowers fascicled into a head with ovate bracters, subnikat at top; stigma bifd. —Native of Italy, in the mountains of Abruzzo near Salmone, and Monte Vergine.

26. Campanula Cinerea. Erect, tomentose; leaves subulate, entire, erect, approximating; flowers solitary, terminal. --Native of the Cape of Good Hope.

27. Campanula Hispilduh. Hispild; flowers erect; calices the length of the corolla; stem branching, a hand high, and hispid, more branching at top; leaves alternate, linear, acuminate, ciliate, especially the midrib; calices subsessile terminal, linear, with the keel ciliate; corolla fanuel-form; stigma trifid, annual.—Observed at the Cape of Good Hope, by Sparraman.

28. Campanula Trachelium; Great Bell-flower, Greater to two feet in height, beset with flowers from the top to Nettle-leaved Throatwort, or Canterbury Bells. Stem angubelow the middle, in alternate distinct bunches, with a leaf

lar; leaves petioled; calices ciliate; peduncles trifid; root perenuial; stems from two to three feet in height, upright, stiff, hairy, angular, the angles membranaceous, putting out a few short side-branches ; corolla pale or deep blue, purple or white, spreading very much, hairy within, the segments triangular, divided by a hairy line; when the corolla is double, there are no stamina or nectary.-The whole plant contains a juice of a dirty yellow colour. Native of most parts of Europe, and of Japan, in woods and hedges; flowering in July and August. The double sorts of great Canterbury bells are propagated by parting their roots in autumn, which should be annually performed, otherwise the flowers are apt to degenerate to single; the soil should not be too light or rich in which they are planted, for in either of these they will degenerate ; but in a strong fresh loam their flowers will be in the greatest perfection : these plants being extremely hardy, may be planted in any situation ; those, however, with single flowers. do not deserve a place in gardens.

20. Campanula Glomerita; Small or Clustered Beil flower; Little Canterbury Bielk. Stem angular, simple; flowers sessile; head terminal; root perennial; stem upright, angular, hairy, from six to eighteen inches in height, but varying from two and even three feet in strong soils, down to two inches in lofty dry situations; seldom or ever branched, unless when it is eaten down by cattle; corolla blue, purple, or white, five-cleft to the middle; (sometimes four-cleft,) usally villose on the outside, and sometimes on the inside, with white hairs.—Native of most parts of Europe, in hilly and dry pastures, particularly in acclacreous soil; flowering from June to September. This plant is no contemptible ornament for rock-work or dry flower-borders; a moist or rich soil makes it too luxuriant, and renders the flowers pale and degenerate.

30. Campanula Cervicaria ; Wared-Icared Bell-flower, Hispid ; flowers sessile ; head terminal ; leaves lanceolate, linear, waved ; root biennial.—It is a wood plant, native of Sweden, Denmark, Germany, Switzerland, Piedmont, Siberia; (lowering in July and August; the root is esculent. This, as well as the fifth and thirty-minth species, and several others, may be propagated by seeds sevue in autumn; for such as are sown in spring often fail, or at least lie a year in the ground ; when the plants come up, they should be removed into beds, and kept clean from weeds.

Hispid ; raceme ovate, oblong, terminal ; stem entirely simple ; leaves lanceolate, linear ; root large, woody, biennial ; from which rises a round tuft of rough broad ovate lanceolate leaves; from the centre of these springs a stem eight or ten inches high, unbranched, covered with leaves and flowers, the leaves tongue-shaped, longer than the radical ones, equal to the whole stem ; the flowers hirsute, white, or yellowish white, long and slender, collected iuto one very long, ovate, cylindric, close-terminating spike, leafy at bottom, but naked at top; some times the corolla is cut into four or six parts, aud then there is a proportional number of stamina, and two stigmas. In Switzerland it is common in stony Alpine meadows; on the lower mountains it is more rare. It was observed by Ray to grow plentifully on the highest tops of Jura. It is also a native of Germany, Hungary, Austria, Carniola, Savoy, and Dauphiny, and it flowers in July.

32. Campanula Petrca; Great Stone Throatwort. Stem angular, simple; flowers sessile, headed, glomerate; leaves tomentose beneath; stem upright, rough, lairy, from a foot to two feet in height, beset with flowers from the top to below the middle, in alternate distinct bunches, with a leaf

between each; the lower leaves are petioled, the rest are sessile; they are all bluntish, serrate, rugged on the upper surface, white with nap on the under ; corolla white, divided into five, (sometimes seven,) sharp spreading segments, twirling at the extremity .- It was first observed by Pona on Monte Baldo, flowering in August; and is also a native of Piedmout.

*** Capsules covered with the reflected Sinuses of the Calix. 33. Campanula Dichotoma; Dichotomous Bell-flower. Capsules five celled, covered; stem dichotomous; flowers drooping; leaves oblong, rugged; flowers solitary, from the forks and ends of the branches.

34. Campanula Medium; Coventry or Canterbury Bells. Capsules five-celled, covered; stcm undivided, erect, leafy; flowers erect; root biennial; leaves oblong, rough, hairy, serrate, coming out without order from the root, narrowing into a petiole .- From the centre of these, the second season, arises a stiff, hairy, furrowed stalk, about two feet high, sending out several lateral branches, with long, narrow, hairy, serrate, sessile leaves, placed alternately : from the setting on of these leaves come out the peduncles, those on the lower part of the stem and brauches four or five inches long, diminishing gradually in length upwards, and thus forming a sort of pyramid; the flowers are very large, and make a fine appearance; they are smooth, and the segments turn back at the end; they come out at the beginning of June, and if the season be not very hot, will continue a month in beauty; the seeds ripen in September, and the plants decay soon after. It grows naturally in the woods of Germany, Austria, and Italy, and is cultivated in the English gardens for the beauty of its flowers, of which there are the following varieties; blue, purple, white, striped, and double, but the two last are not very common in England: it is propagated by seeds, sown in the spring, upon an open bed of common earth. When the plants are fit to remove, they are to be transplanted into other beds in the flower-nursery, six inches asunder, observing to water them frequently till they have taken new root, after which they will require no other culture but to keep them clean from weeds till the following autumn, when they may be transplanted into the borders of the flower-garden. As these plants perish the second year, young ones should be raised annually for a succession. According to Hill, the fresh tops of this plant, with the buds of the flowers upon them, contain most virtue, but the dried leaves may be used. An infusion of them, sharpened with a few drops of spirit of vitriol, and sweetened with honey, is an excellent medicine for sore throats, used by way of a gargle. The plant, he says, is so famous for this virtue, that one of its common English names is throatwort; if the medicine be swallowed, there is no harm in it ; but in the use of every thing this way, it is best to spit the liquor out, together with the foulness which it may have washed from the affected parts.

25. Campanula Barbata; Bearded or One-leafed Bellflower. Capsules five-celled, covered ; stem quite simple, with only one or two leaves; leaves lanceolate; corollas bearded ; root perennial, white, large, and woody, fusiform, or rather tuberous, two, three, or more inches in length : the whole of the plant is villose; root-leaves many, oblong, lanceolate or tongue-shaped, bluntish, obscurely crenulate, somewhat rugged, from two to three inches long and upwards, narrowing into flat petioles .- Native of the mountains of Italy, Austria, Switzerland, Dauphiny, and Silesia: it flowers in June and July.

36. Campanula Spicata; Spiked Bell-flower. Hispid;

root biennial, the thickness of a finger, two or three inches long, fusiform ; root-leaves linear, lanceolate, quite entire, rough, hairy; stem-leaves like them, but shorter and narrower; stem a foot high, with white stiff bairs, like all other branches of the plant, and alternate branches terminating in a very long loose spike, of many sessile, alternate, remote flowers ; calix hoary, with white hairs ; corolla subcylindric, blue, small in comparison of the plant. Allioni remarks, that it assumes a variety of appearances, in very dry open situations at the foot of the Alps, where it has very rough linear leaves, with a curled waving edge, and flowers in a very long close continued spike. In the county of Nice it has elliptic leaves, not curled about the edge, which flowers in an uninterrupted spike; but it has more usually linear leaves and flowers, though in a spike, yet interrupted so as to form lateral heads. It is common both in the upper and lower Valais, about Chiavenna, and by the Lago Maggiore, and Como, in the vineyards; between Pignerolles and La Perosa, and in the whole valley of Fenestrelles, very common in dry open rocky situations; in Alsace, between Sultz and Zenne; in Dauphiny, but not very common; and in Silesia; it flowers in July.

CAM

37. Campanula Alpina; Alpine Bell-flower. Stem simple; peduncles one-flowered, axillary, two-leaved; root perennial, fusiform; stem absolutely simple, smooth, a span high, loaded the whole length with axillary solitary flowers ; root-leaves oblong, lanceolate, blunt, growing wider towards the top, hirsute, entire; stem leaves ligulate, smaller, sessile; peduncles upright, very long, with two bractes; valves of the nectary semiovate, blue; germen blue, three-cornered, semiovate, fastened by its base to the bottom of the calix; stigma trifid ; capsule roundish, three-celled ; seeds brownish, with a membranaceous edge .- It is found upon Schneeberg, Scheidegg, and also in Silesia; flowering in July,

38. Campanula Mollis; Soft Bell-flower. Capsules fivecelled, covered, peduncled; stem prostrate; leaves suborbiculate; stems decumbent, with few branches, rather stiff, villose ; leaves small, sessile, nearly entire, tomentose, pubesscent .--- Native of Syria, Sicily, and Spain.

39, Campanula Saxatilis; Rock Bell-flower. Capsules five-keeled, covered; flowers alternate, nodding; leaves obovate, crenate .- The stalks rise a foot high; the flowers are large, blue, nodding, alternate ; they open in July, and are succeeded by five-celled capsules, filled with small seeds. It grows naturally in Crete, upon rocks, where the roots penetrate the fissures, and continue much longer than in gardens. For the culture and propagation of this sort, see the thirtieth species. A few of the plants may be set in pots, to be sheltered in the winter.

40. Campanula Sibirica; Siberian Bell-flower. Capsules three-celled, covered; stem panicled; root biennial; stem a foot high, angular, a little hispid, straight, undivided; panicle thin, loose; leaves linear, half stem-clasping; stem-leaves rugged; flowers oblong, small; peduncles generally threeflowered; calices hispid.-There is a variety with a subdi-vided stem, and broader leaves. Native of Siberia, Austria, and Piedmont: it flowers from July to September.

41. Campanula Tridentata; Three-toothed Bell-flower. Capsule five-celled, covered; stem one-flowered; radical leaves three-toothed; stem twice as long as the leaves, with some linear leaves on it; flowers upright, rather large, solitary .- Found by Tournefort in the Levant.

42. Campanula Laciniata. Capsules covered, peduncled: leaves servate, the radical ones lyrate ; stem-leaves lanceolate ; root biennial; stem two feet high, suffruticose, branched spike loose; flowers alternate; leaves linear, quite entire; from the bottom; lower leaves eight inches long, and two inches and a balf wide; those on the branches two or three inches long and sessile, the uppermost only four or five lines in length, slightly crenated and pointed; flowers large, pale, blue; capsule five-celled, nine or ten lines in diameter.

CAM

43. Campanula Stricta. Capsules covered ; leaves rough with bairs ; stem-leaves lanceolate, scratter ; stem quite simple; flowers sessile; stem eighteen inches high, rough with bairs ; root-leaves cordate or ovate, somewhat oblong, serrate, rough with hairs on both sides, petioled; stem-leaves alternate, remote, sessile, obtuse, serate, toothed, rough with hairs, narrow at the base; flowers axillary, solitary, rest, calices rough with hairs, overing the germen with their sinuses.—Native of Syria and Palestine.

44. Campanula Canariensis; Canary Bell-flower. See Canarina.

45. Campanula Fruticosa; Shrubby Cape Bell-flower. Capsules columnar, five-celled; stem shrubby; leaves linear, subulate; peduncles very long. It flowers in August, and is a native of the Cape of Good Hope.

46. Campanula Speculum; Venus's Looking-glass. Stem very much branched, diffused; leaves oblong, subcrenate; flowers solitary; capsules prismatic .- This is an annual plant, which rises with slender stalks a foot high; the flowers are of a beautiful purple, inclining to a violet colour, (sometimes pale purple, or white) and in the evening fold up into a pentagon figure, whence it is also called viola pentagonia; the calix is composed of five narrow leaves, which spread open, and turn back, and are much longer than the petals; these remain on the top of the prismatic seed-vessel, which is filled with small angular seeds. Native of the most southern countries of Europe, among corn; flowers from May till September: it is commonly sown in patches in the borders of the flower-garden, among other hardy annuals, in the spring; but if it be sown in autumn, it will grow much taller, and flower a month earlier, that is, in May,

47. Campanula Hybrida; Corn Biell-flower; Small Venue's Looking-glass: Codded Corn Violet. Stem a little branching at the base, and stiff; leaves oblong, crenate; calices aggregate, longer than the corolla; capsules prismatic—An annual plant, common in corn-fields in England, France, and Switzerland; folowering in June and July.

49. Campanula Limonifolia. Branches expanding, undividel; radical leaves elliptic, even, quite entire; howers sessile, in threes; root-leaves petioled, but not rigid; stem with very simple wand-like branches, and linear or subulate leaves; flowers remote, axillary, with bractes the length of the germen.—Native of the Levant.

49. Campanula Pentagonia. Stem subdivided, very branching; calycine leaflets linear, acuminate .- This is a small plant, a hand or not more than six inches in height, with a simple white root; the stem is slender, weak, shrubby, with frequent branches; flowers at the ends of the stem and branches, twice as large as those of Venus's looking-glass, and of a paler purple, the bottom or eye white, but less so than in that; a broad blue band surrounds the eye, and the edges are purple; the flowers are more concave and bellshaped than in our common garden sort, and the segments are not so deeply cut; the leaflets of the calix are narrow, oblong, sharp, spreading, but not revolute, and sometimes have little bristles at the edges; the flowers, before they open, are folded up like the other sorts, and have five wings like the feathers of a shaft, and hence the name Pentagonia; the seeds are large, round, and shining. Mr. Ray informs us, that the first seeds of this plant were brought from Thrace. This and the fiftieth, and also the fifty-sixth

species, must be treated like the forty-sixth species, which see; if, however, the seeds be permitted to scatter, they will come up without care.

50. Campanula Perfoliata; Perfoliata Bell-Jouer. Stem simple; Laves cordate, toothed, stem-classing; flowers sessile, aggregate--This is an annual plant, which in good ground will rise a foot and half high, but in poor ground, or where it grows wild among corn, scarcely rises to the height of six inches; the stalk is single, rarely putting out any branches, unless near the root, whence sometimes one or two short lateral branches are produced; the laves are roundish and stem-clasping, sharply serrate at the edge, and from their base comes out a close tuft of flowers surrounded with a leaf as with the calix. Native of North America, and flowering in June. See the preceding species.

51. Campanula Capensis; Cape Bell, flower. Leaves lanceolate, toothed, hispid; peduncles very long; capsules strigose; root annual; stem round.—Native of the Cape of Good Hope; flowers in August and September; ripens its seeds in October, and then dies.

52. Campanula Elatines, Leaves cordate, toothed, puescent, petioled, is stems prostrate: peduncles capillary, many-flowered; root perennial; stems namy, procumbent; round, generally simple, from the fissures of the rocks; flowers purple, half five-cleft; the segments hancoabte, revolute; the whole plant is pubescent, with soft hairs, and is very milky—It is found at the foot of the Alps, in the country of the Valdenses, or Vaudois, in rocky shady situations.

53. Campanula Hederacca; Irg-Jaered Bell-flauer. Leaves cordate, fiv-lobed, petioled, smoth; stem lax; root peremial, fibrous, slender, creeping; stems procumbent, fibram, trailing, matted together, and covering spots of a foot diameter: the whole herb pale, tender, delicate, and smooth, except a very few scattered hairs, occasionally found on some of the leaves, the lower of which are heart or kidney-form, and nearly entire; peduncles long, filform, solitary, cither terminating or axillary; segments of the calls pointed and entire; corolla pale blue, slender, oblong; filamenta longer than the antheræ.-Native of England and Wales, Denmark, France, and Spain, in moist shady places: it flowers from May till August.

54. Campanula Erinoides; see Lobelia Erinus. Stems diffused; leaves lanceolate, subserrate, decurrent, with a scabrous line; flowers peduncled, solitary.

55. Campanula Heterophylla. Leaves subovate, smooth, quite entire; stems diffused; root premnial, white, sweet, and full of milk; lower leaves like those of the daisy, dispoed in a ring, brownish greens, shinning, two inches and a half long, and half an inch wide; stems eight or nine inches anillary, seven or eight lines long, and four or five wide, pale blue; calik five lines in length; and full of white pith; flowers axillary, seven or eight lines long, and four or five wide, pale blue; calik five lines in length; the whole plant is inspid.—Native of the Levant; found by Tournefort in the desert isle of Cheiro.

56. Campanula Erinus; Forked Bell-flower. Stem dichotomous; leaves sessile; the upper ones opposite, three-toothed. —This is a low annual plant, seldom rising six inches high, but dividing into many branches; flowers small, pale blue; they are produced at the ends of the branches, and are shaped like those of Fennis's looking-glues, but their colours are less beautiful, and the leaflets of the calix are broader. Native of Spain, Portugal, Italy, Sciily, and the south off France; it flowers in July and August. See the forty-minth species. CAM

57. Campanula Scssiliflora. Prostrate; leaves linear, subulate, entire; flowers axillary, solitary, sessile.—Native of the Cape of Good Hope.

58. Campanula Fasciculata. Shrubby, erect; leaves ovate, with a tooth or two recurved; flowers glomerate, terminal. --Native of the Cape of Good Hope.

59. Campanula Paniculata. Herbaceous; stem panicled; branches divaricate; leaves lanceolate, entire; flowers terminal, solitary.-Native of the Cape of Good Hope.

60. Campanula Adpressa. Herbaceous, erect; leaves lanceolate, toothed, recurved, ciliate at the basc, oppressed; panicle decompound.—Native of the Cape of Good Hope.

61. Campanulata Verticillata; Whork-leared Belt-flower, Leaves and flowers verticilled; root perennial; stems many, straight; leaves in fives or sixes, lanceolate, serrate; corollas small, pale blue; style double the length of the corolla.— Native of Siberia, flowering in June.

62. Campanula Procumbens. Stem dichotomous, diffused; leaves ovate, crenate, obtuse; flowers solitary, erect.— Found in moist places near the Cape of Good Hope, by Thunberg.

63. Campauulata Triphylla. Leaves tern, linear; flowers by threes in a whorl; root fusiform; stein herbaceous, erect, the whole smooth.—Native of Japan: it flowers in September.

64. Campanula Tetraphylla. Leaves by fours, oblong, serrate; stem obscurely angular, jointed, smooth, simple at bottom, panieled at top, two feet high; corolla whitish; an-there linear; style double the length of the corolla; stigma trifid.—Native of Japan.

65. Campanula Glauca. Leaves sessile, ovate, serrate, glancous beneath; stem angular, panieled; peduncles one-flowered; stem undersbrubby, smooth, erect, two feet high; brancles very angular, flexuose, erect, subfastigizite, smooth; corolla large, blue,—It flowers in July and August, and is cultivated in Japan.

66. Campanula Marginata. Leaves lanceolate, waved, serrate, margined; branches weak; flowers terminal, solitary; stem thick at the base, rather woody, decumbent; branches very many, capillary, rather erect, with a very few subdivisions, striated, smooth, a short span in length,—It grows by orad-sides, howering in May and June. Native of Japan.

67. Campanula Gracilis. Leaves linear lanceolate, obscurely serrate; stem dichotomous; flowers solitary, terminal.-Native of New Zealand, and New Caledonia.

68. Campanula Bellardi. Stem naked, one-flowered; leaves petioled, elliptic, lanceolate, toothed. —This very elegant plant has a few leaves at the bottom rather erect, on petioles the length of the leaves, and grooved within; the leaves are drawn to a point at each end, have on each side two or three sharpish teeth, are of a deep green, roughish, rather firm, and not juic; the little stem is erect; rather firm, and not juic; the little stem is erect; rather firm, and not juic; the little stem is erect; rather firm, and not juic; the little stem is erect; rather firm, and not juic; campatible with the segments lance-olate, linear, not reflected nor expanded, nor appendicled; corolla blue. Native of Piedm-att; prevential.

69. Campanula Vesula. One-flowered; leaves smooth, oval, toothed; stem almost maked; calix smooth; radical leaves very many, petioled, decurrent, acute, shortly toothed, or rather notched, nerved beneath, finely and thinly haired, 50 as to seem almost smooth; stem round, a short span in height; calix livid, inve-cleft beyond the middle; segments lanceolate, not reflex; corolla spreading; perennial.—Native of Piedmont.

70. Campanula Cespitosa. Radical leaves kidney-form, gashed; stem-leaves toothed, upper ones quite entire; many 20. stems and shoots form a tuft; the flowers nod; corolla deep blue, half an inch long, and four lines over; form oval, wider below than at the edge, with three lines on each segment. -It is found in dry rocky mountains, flowering at the beginning of August: it is perennial; and a native of Switzerhard, Dauphiny, Carinola, and Piedmont.

CAM

71. Campanula Valdensis. Hirrsute; leaves lanceolate, sometimes toothletted; flower solitary, nodding; root perennial.—It is small, and throws out one or two stems only three inches high, often bending to one side and arched; stem-leaves oval, oblong, linear; a single flower at the top is deep blue or almost black, more lengthened out than in the species that most resemble it. Native of Piedmont and Dauphiny.

72. Campanula Uricifolia. Stem roundish, simple', upper leaves sessile; spike onc-ranked; p-eduncles one-flowered; calices smooth; root perennial; plant entirely smooth; stem three feet high, simple, streaked, round; cach axil produces a flower on a short peduncle; corolla and calix nearly equal. --Native of Italy, in woods.

73. Campanula Alpestris. Stem quite simple, one-flowered ; leaves hanceohate, quite acute, hisrid; corollabearded; capsules three-celled, covered ; root perennial, creeping; root-leaves, which appear the first year, small, blunt, and almost round, those which come afterwards are longer; the bottom stemleaves are still longer, pointed, and a little waved on the edge; they are all roughish, and ciliate on the edge, with small stift hairs.—It grows on the very high Alps, and on Mount Cenis; varies with a white flower.

74. Campanula Nitida ; Smooth-leaved Bell-flower. Leaves oblong, crenate, glossy, those on the stem lanceolate, almost entire; corollas campanulate, rotate .-- This has many stiff oblong leaves coming out from the root on every side, which form a sort of head like those of houseleek, crenate, having a strong rib, running on their border longitudinally: there is a white and blue flower of this sort in the gardens, but in Holland they have it with a double flower. It is a native of North America, and flowers in July. As it does not produce seeds in England, it is propagated by offsets only, which should be taken off in August, that they may get good root before cold weather comes in; they must be planted in small pots, filled with fresh, light, loamy earth, and placed in the shade until they have taken root, then they may be put along with other hardy exotic plants, and in autumn they must be removed into shelter, for in severe winters plants which are exposed are often destroyed, though in mild winters they will live in the open air.

75. Campanula Prismatocarpus: Long Capsuled Bellflower. Capsules linear, two-celled; leaves lauccolate, loosely serrate, very smooth; stem decumbent; the stems are a little shrubby at the base.—It is an annual, and flowers in September.—Native of the Cape of Good Hope.

76. Campanula Fragilis. Štems procumbent; branches directed ohe way, nanar-Mowered; root-leaves kidney-form, crenate; calices angular.—This is a very beautiful plant, but extremely brittle, abounding in milk, commonly quite smooth, bright green, and lucid, but sometimes hamginous; it has a hardsome head of flowers; the troot is pretennial, and brown. Native of the kingdom of Naples, especially on the coast of the bays of Saleron and Arnahi.

77. Campanila Virgata. Branches wand-like; leaves lanceolate, sharp at both ends, toothed, somewhat rugged; flowers in pairs, sessile; corollas deeply parted; root bienniat; stem unpright, streaked, a foot or more in height, searcely leafy, with spreading branches; leaves radical, periodel; flowers remote, commonly two together, blue, with a bracte under them, the length of the germen; segments of 3. P.

the calix acute; those of the corolla lanceolate, cut almost to the base.-Native of Mount Libanus.

78. Companula Repriss; stern subdivided, creeping; leaves oblong, feshy; flowers solitary is stem herbarcous, procumbent, subdivided, very much branched; the small branches creeping; leaves oblong, ovate, quite entire, small, hairy, opposite; flowers white, sessile, axillary, solitary.—Native of Cochin ehina.

Cumpechewood. See Hæmatoxylum.

Camphire or Camphor Wood. See Laurus.

Camphorosma; a genus of the class Tetrandria, order Monogynia - GENERIC CHARACTER. Calix: perianth pitcher-shaped, half four-cleft, compressed, permanent; segments acute, the opposite ones largish, recurved. Corolla: none. Stamina: filamenta four, filiform, equal. Antheræ oval. Pistil: germen ovate, compressed; style filiform, half two-cleft, longer than the calix; stigmas acute. Pericarp: capsule one celled, gaping above, covered by the cahx. Seed: single, oval, compressed, shining. ESSENTIAL CHA-RACTER. Calix: Pitcher form; two of the teeth opposite, and the alternate ones very small. Corolla: none. Cupsule: one-seeded. These plants are preserved in gardens merely for the sake of variety; they are propagated by seeds, which succeed best when sown in the autumn ; the European sorts require only to be thinned, and kept clean from weeds; and if they are permitted to scatter their seeds, there will be a supply of young plants in the spring .---- The species are,

1. Camphorosna Monspeliaca; Hairy Camphorosna, Leaves birsute—This is an anual plant, with trailing branches, a foot or more in length—Native of the south of France, Spain, and the county of Nice: the whole plant smells of camphor; it abounds in a volatile oily salt, and is warm and stimulating: an infusion of it is of service in the saltma : the dose from half an onnect can o nunce and a half.

2. Camphorosma Acuta ; Sharp-leaved Comphorosma. Leaves subulate, rajed, smooth; root perennial, slender, fusiform, fibrous; stems many, woody, decumbent, round, hairy, roughish, frou a finger's length to a foot in height; bianches altennate. It flowers in Jaly and Angnst, and is a native of very dry sandy fedds in the Palatinate; Italy, and Tartary.

3. Camphorosma Glabra; Smooth Camphorosma. Leaves subtriquetrous, smooth, unarmed.—This is a perennial plant, with trailing branches; the flowers are not more visible than those of the first so.t.

4. Camphorosma Pteranthus. Very branching; peduncles ensiform, dilated; bractes crested; root annual, fibrous. —Native of Arabia, Egypt, and Barbary. It is singular in its manuer of flowering, and in its truit, which resembles stag's horns.

5. Camphorosma Palacea. Shrubby; branches spike-form, chaffy, hairy.--A shrub scarcely a foot high, determinately branched. Found at the Cape of Good Hope.

Campion. See Agrostemma, Cucubalus, and Lychnis.

Condurina; a genüs of the class Hexandria, ofder Monegunia.—GENRRIC OHARACTER. Call: : perianth superior; leadels six, lanceolate, recurved, permaneut. Corolla ; monopetalous, bell-form, six-cleft, nervet, neetury of six valves, equal, distant, covering the receptacle. Mamina: finamenta six, subulate, spreading outwards, originating from the valves. Anthera: pendulous from the tip. Plottil: ger men inferior; six-coronered; style conical, short; stigua longer than the stamina, clavated, six-cleft, Pericarp: capsule six angled, obtuse, six-celled. Seeds: numerous, small. ESENTTAL CHARACTER. Caliz: six-leaved. Corolla; six cleft, bell form; stiguns six. Capsule; inferior, sixcelled, many-seeded.—The species are,

1. Canarina Campanula; Canary Bell-flower. Stem crect; leaves hastate, in threes, or opposite; root perennial, tuberous, fusiform : stem three feet high, erect, solitary, round, even, with swelling joints; corolla larger than the leaves, resembling that of a crown imperial, rufous, brighter within, with a vellow eve; each segment with three purple nerves; style club-form, longer than the stamina .- It flowers from January till March; it is propagated by parting the roots, which must be done with caution, for if they be broken or wounded. the milky juice will flow out plentifully, so that if they be planted before the wounds are skinned over, it occasions their rotting; therefore whenever any of them are broken, they should be laid in the green-house a few days to heal; the root must not be too often parted, for that weakens the plants, and prevents them from flowering well; the best time for doing it is in July, soon after the stalks are decayed; the earth should not be rich, for that will cause the plant to be luxuriant in branches, but poor in flowers ; the soil in which they succeed best, is a light sandy loam, with a fourth part of screened line rubbish; the pots should at first be placed in the shade, and, unless the season be very dry, they should not be watered; about the middle of August the roots will begin to put out fibres, when, if the pots be placed under a hot bed frame, and, as the nights grow cool, be covered with the glasses, (opening them every day,) it will greatly forward their flowering, and increase their strength; when the stalks appear, the plants must now and then be refreshed with water, but it must not be given too often, nor in great quantity; by the middle of September the plants will be grown so tall, that they must be removed into a dry airy glass case, where they may enjoy the free air in fine weather, and yet be screened from cold.

 Canarina Zanguebar. Stem scandent; leaves hastate, alternate; stem shrubby, round, even, branched; leaves cordate-hastate, quite enture, smooth, veined, petioled; flowers solitary, lateral; corolla pale coloured.—Native of Zanguebar, on the coast of Africa.

Canarium ; a genus of the class Disceia.—GENERIC CHARACTER. Male, Caliz ; perimuth two leaved; j leaflet ovate, concave, peruanent. Corollo: petals three, oblong, like the calix. Stamina: filmental five, very short. Antherae oblong, of the length of the petals. Femaile, Caliz: as in the unale; leaflets reflex. Corola: as in the male. Piatil: genmen ovate; style scarcely any: stigma headed, htree-cornered. Pericarp: drupe dry, ovate, scanninate; base surrounded by a crenate membrane. Next nutrate, threecornered, acute. ESSENTIAL CUARACTER. Male, Caliz: two-leaved : corolla three petalled. Female, Caliz: twoleaved : corolla three petalled. Female, Caliz: theaved : corolla three petalled. Female, pinated with a three-cornered nut.——The only species known is.

1. Camaium Commune. Leaves alternate, pinnated with an odd foliole; the commune petiols stricted; folioles mine, petioled, ovate-oblong, acuminate, even; panieles with divaricate rigid branches; flowers sessile; it her furit is a superior, ovate, acuminate, herried drupe, covered with a thin olivecoloured skin, and having within it very little paly, full of capillary fibres.—This rise is a native of the Molucca isles, Banda, and New Guinea; the nuts are eaten both raw and dressed by the inhabitants; an ol ii esepressed from them, which is used at the table when fresh, and for lamps when table; bread is also nuade of them, and cakes, biseuits, & & for the table; eaten fresh, they are apt to bring on diarthæsa and dysanteries, and to occasion an oppression of the breast.

Canary Grass. See Phalaris. Candleberry Tree. See Myrica. Candy Tujt. See Iberis.

Cane. See Arundo.

Canella ; a genus of the class Dodecandria, order Monogymia .- GENERIC CHARACTER. Calix: perianth oneleafed, three-lobed ; lobes roundish, concave. Corolla : petals five, oblong, sessile, longer than the calix; two a little narrower than the rest. Nectary pitcher-shaped, the length of the petals, anther-bearing. Stamina: filamenta none. Antheræ twenty-one, linear, parallel, distinct, fastened on the outside to the nectary. Pistil: germen superior, within the nectary, ovate; style cylindric, the length of the nectary; stigmas two, blunt, convex, wrinkled. Pericarp : berry oblong, three-celled; seeds roundish, kidney-shaped, in pairs, cordate. ESSENTIAL CHARACTER. Calix: three-lobed Corolla ; five-petalled. Antheræ twenty-one, fastened to a pitcher-shaped nectary; berry three-celled; seeds two to four .---- The only species known is,

1. Caneila Alba : Laurel leared Canella .- This is a tree, the stem of which rises from ten to fifty feet in height, very straight and upright, and branched only at the top. It is common in most of the West India islands, and is frequently found near the coast ; then seldom exceeding twelve or fifteen feet ; in the inland woods it attains a more considerable height. The whole tree is very aromatic, and when in blossom perfumes the whole neighbourhood; the flowers dried, and softened again in warm water, have a fragrant odour, nearly approaching to that of musk; the leaves bave a strong smell of laurel; the berries, after having been some time green, turn blue, and become at last of a black colour and glossy, with a faint aromatic taste and smell. When they are ripe, the white bellied and bald-pate pigeons feed greedily upon them, and thence acquire their peculiar flavour. The bark of this plant, and the fruit of capsicum, were formerly common ingredients in the food and drink of the Caraibs; and at present it makes a necessary ingredient in the meager pot of the negroes. The bark is brought to Europe in long quills, which are about three quarters of an inch in diameter, somewhat thicker than cinnamon, and both externally and internally of a whitish or light brown colour, with a yellowish hue, and commonly intermixed with thicker pieces, which are probably obtained from the trunk of the tree. In taste it is moderately warm, aromatic, and bitterish ; its smell is agreeable, and resembles that of cloves ; its virtues are extracted most perfectly by proof spirit. The use of canella alba now supersedes that of the old bark of Winter, on the authority of both the London and Edinburgh pharmacopæias. It has been supposed to possess considerable virtues, and is said to be useful in scorbutic and many other complaints. It is now, however, considered merely in the light of an aromatic, and, like many other spices. is employed for the purpose of correcting disagreeable drugs, This tree is too tender to live in England out of a stove ; the plants require to be plunged in the tan-bed, and in winter should be sparingly watered; in summer they should have it in greater plenty, and they should also have a good share of air admitted to them when the weather is warm ; with this management they may be preserved very well; but as they are difficult to propagate by layers, or by cuttings, the surest method is to procure fresh seeds from the West Indies.

Canna; a genus of the class Monandria, order Monogynia. -GENERIC CHARACTER. Calix : perianth three-leaved ; leaflets lanceolate, crect, small, coloured, permanent. Corolla : monopetalous, six-parted ; divisions lanceolate, conjoined at the base, the three outer ones erect, larger than the calix; the three inner ones larger than the outer, two erect, one reflected, and thus constituting the upper hp; nectary petal-like, two parted, of the length and figure of the petals; the upper divisions ascending, the inferior revolute, imitating as are used in Germany, for neither house nor cellar 16

the upper lip of a corolla. Stamina : filamenta none. Antheræ linear, growing to the upper margin of the division which bears the nectary. Pistil: germen roundish, rugged, inferior; style single, ensiform, growing to the anthera-bearing nectary, lanceolate, of the length and figure of a petal; stigma linear, growing to the margin of the style. Pericarp: capsule roundish, rugged, crowned, three-grooved, threecelled, three-valved. Seeds : few, globular. ESSENTIAL CHARACTER. Corolla: six-parted, erect; lip two-parted, revolute. Style: lanceolate, growing to the corolla, Calix: three-leaved. Every species of this genus is propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted into separate small pots, tilled with rich kitchenearden earth, and plunged into a moderate hot-bed of tanner's back, observing to shade them until they have taken root, after which they should have a large share of free air admitted to them every day in warm weather, and be frequently refreshed with water. As these plants will grow very fast, they must be shifted into larger pots filled with the same sort of earth, and part of them pluaged into the hot-bed again; and the others may be placed abroad in June, with other exotic plauts, in a warm situation. Those which are placed in the hot-bed, will be strong enough to flower well in the stove the following winter : but those in the open air will not flower before the following summer: the latter may remain abroad till the beginning of October, but must then be removed into the stove, and treated in the same manner as the old plants until May, when a gentle hot-bed should be made, covered a foot thick with rich carth, and the plants turned out of the pots, planting them with their balls of earth upon the hot-bed, covering each with a bell-glass, which may be raised on one side every day to admit the air to the plants; and as they advance, they must be gradually inured to bear the open sir. With this management the plants will grow much taller and stronger than those which are kept in pots, and from these good seeds may be expected in autumn. These plants will continue many years with proper management; but as young plants always flower better than the old roots, it is not worth while continuing them after they have borne good seeds .---- The species are,

CAN

1. Canna Indica : Indian Shot. Leaves ovate, acuminate at both ends, nerved. This plant has a thick fleshy tuberous root, which divides into many irregular knobs, spreading wide near the surface of the ground, sending out many large ovate leaves without any order; these, at their first appearance, are twisted like a horn, but afterwards expand, and are near five feet long, and five inches broad in the middle, lessening gradually to both ends, and terminating in points. There are several varieties, not worth enumerating; the stalks are sometimes of a pale red, and sometimes of a beautiful scarlet colour, succeeded by a prickly pericarp, with several black seeds, which will kill small birds. The juice of the root is said to be a counter-poison, and to be good, mixed with the bruised leaves and water lify, as a cataplasm for hard tumors and indurations of the spleen. Gerarde informs us, that in his time it was in the garden at Padua, and that he had planted it in his garden divers times. but it never came to a flowering; and that it must be set or sown in a pot with fine carth, or a bed made of horsedung, in the same manner as cucumbers and musk melons are. Parkinson says, that in some kindly years this beautiful plant has borne its brave flowers, but never any ripe seed ; and that it will not abide the extremities of our winters, unless it meet with a stove or hot-house, such

will preserve it. Clusius saw it flowering by house-sides in Spain and Portugal: and says that the inhabitants there use the seeds for making their rosaries. It is found wild within the tropics on all the continents. As, however, this species is a native of the warmest parts of America, its roots will decay nuless placed in a moderate stove during the winter.

CAN

 Canna Angustifolia : Norrow-leared Indian Reed. Leaves lanceolate, petioled, nerved.—This can har-Ily be distinguished from the first species, but is nevertheless lower and narrower. It is found within the tropies of America, in shady and boggy places.

3. Canna Glauca. Leaves laneeolate, petiolate, nerveless. The roots of this are much larger than the former sorts, and strike down strong fleshy fibres deep in the ground; the stalks rise seven or eight feet high ; the leaves are nearly two feet long, narrow, smooth, and of a sea-green colour; the flowers are produced in short thick spikes at the extremity, are large, and of a pale yellow colour; the segments of the petal are broad, but their shape like those of the other Native of New Spain. The young plants of this spesorts. cies, when raised from seeds, are more certain of flowering than the old ones, for their roots send out many offsets, which when they have room soon spread to a considerable distance, but seldom produce flowers. It is therefore by far the best way to raise a sneeession of plants from seeds, and to throw out the old ones after they have perfected their seeds.

4. Canna Flaceida. Leaves narrow, lanceolate, smooth and even on both sides; inner limb of the corolla five-left; segments flaceid, obovate, the outmost largest; four feet high or more, every much resembling eauna galaxca in the herb, with which it is often confounded in our stoves.—Native of South America.

5. Canna Juneca. Leaves linear, nerved; leaves resembling those of grass with five raised nerves, sheatting at the base, near the root covered with eapillary fibres, a span or a foot in length; scape with several lanceloate sheaths and few flowers; corolla small, of a dusky rufous colour; pericarp muricated. It was discovered by Blädh in China.

Cannadis; a genus of the class Dicecia, order Pentandria. -GERERIC CHARACTER. Male. Calis: perianth fiveparted; leaflets oblong, acuminate, obtuse, concave. Corolla: none. Stamina: filamenta three, capillary, very short. Anthere oblong, four cornered. Female. Calis: perianth oneleafed, oblong, acuminate, gapnig longitudinally on one side, permanent. Corolla: none. Pisil: germen very small; calis: tightly closed. Scd: nut-globose, depressed, bivalve. ESSENTIAL CHARACTER. Male. Calis: fiveparted. Corolla: none. Female. Calis: one-lafed, entire, apping on one side. Corolla: none. Styles: two; nut bivalve within the closed calis.——The only known species of this important genus is,

1. Cannabis Sativa. Stem generally six feet, sometimes eighteen feet high, branched, hairy, as are also the leaves, which are digitate, slender, serrate; the folioles seven, the outer ones smallest. In the female plant the flowers are softiary in the axillas; in the male they are in thin pendulous splikes, at the ends of the stem and branches. Some female flowers are frequently found among the males, and since frequently found among the males, and since produced perfect seed, when there have been no male plants near them. Mr. Miller, however, contradiets this assertion, and declares, that for several years he tride the experiment by

removing all the male plants; when, although the female plants continued strong and flourishing, they did not, nevertheless, produce any good seeds. It is also worthy of remark. that all the old authors, ignorant of the true doctrine of the sexes, and blind followers of the ancients, have fallen into an egregious mistake upon this subject, for they invariably call the male plants female, and the female male. It is extremely difficult to ascertain the original place of the native growth of hemp, but the most probable conjecture is, that it is a native of the East. Its use and great importance are well known. Huckaback of an excellent quality for towels and table-cloths, and the low-priced hempen cloths which husbandmen, servants, and labouring manufacturers generally wear, as well as the better sorts for farmers and tradesmen in the country, are made from it. The finer cloths also, which are seven eighths wide, and from 2s. 6d. to 3s. 6d. per yard, are preferred by some gentlemen for their strength and warmth. One advantage they eertainly possess over the Irish and other linens; which is, that their colour improves by wearing, while that of the others declines. English hemp, properly manufactured, is unrivalled for its strength, and in that respect much superior to the Russian. Considerable quantities of cloth are nevertheless imported from that country for sheeting, merely on account of its strength, which is entirely owing to its being coarser than British linen of the same price, which is in reality more durable from the superior quality of the thread, and at the same time lighter in washing. The hemp raised in England is not of so dry and spongy a nature as the Russian, and requires less tar in proportion, to manufacture it into cordage. But as tar is cheaper than hemp, the rope-makers prefer foreign hemp to ours, because they obtain a greater profit in working it : but eordage must certainly be stronger in proportion as there is more hemp and less tar in it, provided there be a sufficient quantity of tar to unite the fibres. An oil is extracted from the seeds of hemp, and the seeds themselves are reekoned to be a good food for poultry, being supposed to make them lay a greater number of eggs. Small birds in general are very fond of them, but they should be sparingly given to birds confined in eages, and always mixed with other seeds. It is recorded, upon unquestionable authority, that the black and yellow feathers of the bulfineh and goldfinch have been sometimes changed to a total blackness by feeding them with hemp-seed alone, or giving them too large a proportion of it when mixed with other food. Hemp is called hanf or hampf in German; in Dutch, hennip or kennip; in Danish, hamp ; in Swedish, hampa ; in French, chanvre ; in Italian, canapa; in Spanish and Portuguese, canamo; in Russian, konapli, konopel, kanaple ; in Polish, konop ; in Illyrian and Selavonian, konoplija ; in Walaehian, kænepe ; in Hungarian, kender ; in Tartarian, kinder ; in Armenian, kanop ; in Arabian, sjaranck ; in Persian, cannab ; in Chinese ma-fuen, chu-tsuo. These is no doubt that the Greeks took their name from the eastern kanop or cannab, and that the plant originally migrated into Europe from those counties, notwithstanding what Pliny and Dioseorides affirm of its growing wild in Enrope. Hemp is commonly sown upon a deep rich moist soil, such as is found in the tract called Holland in the county of Lincoln, and the fens of the isle of Elv, where it is cultivated to great advantage; as it might in other parts of England where there is the same kind of soil. It will not thrive on elay, nor yet on stiff cold land; but is found to succeed very well after turnips on friable loams, and good sauds, provided it be well manured. Spaldingmoor in Lincolnshire is a barren sand, and yet with proper care and culture it produces as fine hemp as any in England,

241

and in large quantities. In the isle of Axholme in the same county, the culture and management of it is the principal employment of the inhabitants; and in the county of Suffolk, in the district extending from Eye to Beccles, it is cultivated on a sandy loam with great success; for upon such soils the quality is much finer, and better adapted to the fabric of hempen-cloth, though the quantity falls short of that produced in black rich mould. As it destroys weeds by depriving them of their nourishment, it is generally reckoned to be a cleansing crop; but it is at the same time a great impoverisher of the land, and must not be repeated upon the same ground, unless it be annually manured, in which case it is said to have been continued for seventy successive years upon the same spot. The letting it stand for seed, is universally acknowledged to exhaust the land ; but many suppose, that if previously cnt, it is an excellent preparation for wheat. The land in which it is to be sown, must have three earths given to it, with sufficient harrowing to make the soil perfectly fine, and laid flat, with as few furrows as possible; it must be well manured with twenty-five or thirty-three horse-loads of muck, or from sixteen to twenty loads of dung, to an acre, immediately after the wheat-sowing is finished, or, according to others, a fortnight before seed-time, which is from the beginning, or rather middle, to the end of April. If it be sown earlier, the spring frosts will greatly endanger the plants. Sowing is sometimes deferred till the middle of May; but when the weather is fine, early sowing is to be preferred, because it improves the quality of the hemp. Although three bushels of seed is commonly allowed to an acre, two are fully sufficient. In the choice of the seed, the heaviest and brightest-coloured should be preferred; and some of them should be cracked, to see if they have the germen perfect. When sown, the seed should be lightly and gently harrowed in ; and the birds should be kept off till the plants appear. In the fen countries, the plants are hoed out in the same manner as is practised for turnips, leaving them a foot or sixteen inches apart, and cutting down all the weeds : they give them a second hoeing about a month or six weeks after the first. If these hoeings be well performed, the crop will not require any farther care, for the hemp will soon cover the ground, and prevent all growth of weeds. The first season for pulling hemp is usually about the middle of August, when they begin to pull the fimble, femble, or thimble hemp, that is, the male plants ; but it would be much better to defer this a fortnight or three weeks, if the hemp be intended to seed, until these male plants have shed their dust, without which it is well known the seeds will not grow, nor will those persons concerned in the oil mills give any thing for them. The second pulling is a little after Michaelmas, when the seeds are ripe; the female plants are then pulled, and called seed hemp, or karle kemp. It is bound up in bundles about a yard in circumference, which are laid in the sun a few days to dry, and then are stacked up or housed till the seed can be threshed out. An acre of hemp on a rich soil will produce near three quarters of seed, which, together with the unwrought hemp, is worth from six to cight pounds. If the hemp be designed for making thread only, without any regard to the seed, the male and female plants are pulled together, thirteen or fourteen weeks after sowing. When the leaves turn yellow and the stalk white, it is known to be ripe: it bears a dry season better than a wet one, and the wetter the season the longer it stands. As soon as it is all pulled up, it is bound up in bundles small enough to be grasped with both hands, which bundles are tied at both ends, and are called baits. It is then conveyed to the water, to undergo the process of water-retting or rotting, for which operation clay

pits are preferred to running water, though they require cleansing once every seven or eight years. The usual produce of an acrc, about three small waggon-loads, may be laid in one bed ; but the same water is not fit for receiving hemp more than three times in a season, although some persons employ the same water five times. The first water always produces the best colour in the least time : where there are not pits sufficient to hold the whole crop, it is customary to pull as they become ready, it being thought iniurious to the hemp to let it lie upon the land after it is pulled. In the pits, the bundles are placed in rows crossing each other, and are kept under water by blocks and logs of wood laid upon them. The hemp generally soaks four days in warm weather, and rarely exceeds five or six, till the outside coat easily rubs off; when it is taken out of the pits, spread out singly upon grass, and turned, in dry weather twice, and in showery weather three times a week ; which operation is called grassing, and generally occupies five or six weeks' time. Afterwards it is tied up in large bundles of eight or ten baits, and carted home to a barn or house, for breaking by a machine called a brake ; which is either immediately done, or deferred till December or January, by laying up the bundles to dry for that purpose. Thus prepared. the hemp is bound up in bundles, weighing a stone or fourteen pounds and a half each, and then taken to market. Whatever hemp breaks off in the operation is called shorts, and is also bound up by itself, and is about half the value of the long hemp. The offal is called hemp-sheaves, which is sold for fuel at two-pence per stone. The custom of many is to dew-ret or rot their hemp; which is done by spreading it upon meadow-land as soon as it is pulled, and turning it frequently; but it is a very bad method, for as the bark will not come off completely, it demands more violent means to be employed in bleaching the yarn, and consequently diminishes the strength, besides being much more liable to injury in rainy seasons. Hemp, when left for seed, is seldom waterretted, being generally stacked and covered during the winter, and spread upon grass in January or February; and if the season favour it, especially if it be covered with snow, it will acquire a good colour, and make a strong coarse cloth. but is after all greatly inferior to that which is pulled at a proper time, and water-retted. The hemp now passes from the grower to the hatcheller, or heckler, who first bunches or beats it, either by hand, or more frequently by a mill; and then dresses or combs it, by drawing it through hatchels, or heckles. resembling wool-combers' tools, but differing from them in being fixed. It is dressed finer or coarser, to suit the designs of the purchasers : hence the whole is sometimes worked together for one sort, and sometimes it is divided into two or three sorts, called long-strike, short-strike, and pull-tow. The heckler either sells the latter to spinners and weavers, or puts it out to spin, and then disposes of the yarn to the weaver, who delivers it to the whitester, from whom he receives it back again bleached. The bleaching is a difficult operation; the art consisting in procuring the best colour, with the least diminution of strength. The yarn is laid in large tubs, covered with thick cloths, upon which ashes are placed, through which hot water is poured daily, turning the varn frequently until the bark comes off, after which it is spread upon poles in the air. In general, hempen cloth is sold as it comes from the loom, and is bleached by the purchaser ; some, however, is bleached ready for weaving, either by the weaver or a whitester, by boiling it in lye made from ashes, and frequently spreading it upon grass. Although in the process of manufacturing, hemp passes through the hands of the breaker, heckler, spinner, whitester, weaver, and bleacher; 20

21.

yet many of these operations are frequently carried on by the of the season. In the autumn they must be removed into the same person : some weavers bleach their own yarn and cloth, others their cloth only; some heckle their tow, and some put it out to spinning; others buy the tow, and put it out; and some carry on the whole of the trade themselves. When this trade is conducted by different persons, their interests often clash: by under-retting the hemp, the grower increases the weight; by slightly beating it, the heckler increases the quantity of tow, but leaves it fuller of bark; by drawing out the thread beyond the staple, the spinner increases the quantity of yarn, but injures the quality; by forcing the bleaching, the white-ster increases his profit, but diminishes the strength of the yarn; and we generally find, that in manufacturing cloth, strength is sacrificed to fineness and colour. The expense of an acre of hemp may be estimated at eight or nine pounds, and the average produce at forty-five stones, which produces £16, 17s. 6d. at 7s. 6d. per stone: some crops produce fiftyfive stones, and even more, but are counterbalanced by others which fall as low as twenty-five; and the price also varies from 6s. to 9s. and 10s. per stone, according to the quality of the produce. The principal objections to the hemp crops are, that their coming in the middle of harvest is embarrassing, and that the attention they require is very great during every stage of their progress, especially where they are only a secondary consideration: the cultivation of hemp is nevertheless of great consequence to the country, particularly as it affords much employment for the industrious poor. and therefore certainly deserves every encouragement from the legislature.

Canterbury Bells. See Campanula. Cape Jasmin. See Gardenia. Caper. See Caparis.

Caper Bean. See Zugophyllum.

Capparis; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fourleaved, coriaceous; leaflets ovate, concave, gibbous. Corolla : petals four, obtuse, spreading, very large. Stamina : filamenta numerous, filiform, patnlous. Antheræ oblong, versatile, inclined. Pistil: germen pedicelled; style none; stigma obtuse, sessile. Pericarp : berry corticose, one-celled, pedicelled. Seeds : numerous, reniform, nestling. ESSEN-TIAL CHARACTER. Calix: four-leaved, coriaceous. Petals: four. Stamina: long. Berry: corticose, one-celled, pedicelled .- This genus consists of shrubs; the leaves are simple, frequently having, in the berry-bearing sorts, two spines at the base, but in those which bear pods they are commonly uaked or biglandular; the flowers are solitary, axillary, or in a kind of corymb, terminating. Every species, except the first, being a native of hot climates, requires the protection of a stove, to survive the rigour of an English winter: they are propagated by seeds, which must be procured from the countries where they naturally grow, since they do not produce them in England; the seed must be sown in small pots filled with light sandy earth, and plunged into a hot-bed of tanner's bark, which should be now and then moderately refreshed with water; they frequently remain in the ground a whole year without vegetating; and must be screened during the winter, and plunged, in the following spring, into a fresh hot-bed of tanner's bark, which, if the seeds were good, will soon compel the plants to appear. In warm weather they require little water, but much air; and when they are large enough to remove, must be each transplanted into a separate small pot, filled with the same earth, and replaced in the hot bed again, observing to shade them until they have taken fresh root ; after which, fresh air mast be every day admitted to them, in proportion to the warmth

stove, and plunged into the bark-bed, where they should constantly remain, as they require the same treatment as other tender exotic plants from the same countries, with this difference only, that they require little water, especially in winter, for the roots of these plants are very subject to rot with wet. If the seeds be brought over in their capsules, they will keep much better than without them ; but they should be secured from insects, by wrapping them in well-dried tobacco-leaves, for without this precaution they will be destroyed before they arrive. The seeds are said to germinate immediately. and therefore cannot well be sent dry to Europe, which, together with the great difficulty of preserving the plants, account for the present scarcity of them in our stoves .----- The species are,

1. Capparis Spinosa; Prickly Caper Bush. Peduncles one-flowered, solitary; stipules spiny; leaves annual; capsules oval .- The common caper-bush is a low shrub, generally growing out of the joints of old walls, the fissures of rocks, and among rubbish; the stems are woody, and covered with a white bark: it grows wild in the southern countries of Europe, and in the Levant, on rocks, walls, and in dry places: Mr. Ray observed it on the walls of Rome, Sienna, and Florence, wild; and cultivated, in the neighbourhood of Toulon. " It is surprising," says Dr. Smith, " that this beautiful shrub, which in the south of France is as common as the bramble is with us, and which even at Paris grows luxuriantly when trained against a wall in the open air, should be almost unknown in English gardens, where we can scarcely produce a flower, unless by stoving it with every possible precaution ! The flower-buds, which are produced in great plenty on the wild plant, are well known as a pickle; and in Italy, the unripe fruit is prepared in the same manner. Every part of the plant, in a recent state, is highly acrid and burning to the taste; it thrives best in an horizontal position, so that when planted either in pots or the full ground, it seldom thrives, although it may be kept alive for some years. In the warmer parts of Europe, they are propagated by seeds, but the importers of orange-trees bring roots of this plant annually from Italy, some of which, when planted in walls, have lived a few years, but have not lasted long.

2. Capparis Zeylonica. Peduucles one-flowered, solitary; stipules spiny; leaves ovate, sharp at both ends; stem shrubby, six feet high, upright, but weak; branches divaricating; stamina thrice the length of the corolla .- Native of hedges in Ceylon and Cochin-china.

3. Capparis Horrida. Peduncles axillary, by two; stipules prickly; branches flexuose; leaves ovate-lanceolate, mucronate, smooth .- Found by Kænig in Coromandel.

4. Capparis Sepiaria. Peduncles umbelled; stipules spiny; leaves annual, ovate, emarginate; branches round and woody; spines stipular, double-recurved, short, black .- Native of the East Indies.

5. Capparis Frondosa, Peduncles umbelled; leaves every where crowded; height above seven feet, extending as far as twenty; branches very few, and scarcely divided .-- Native of thickets in South America.

6. Capparis Ferruginea. Peduncles umbelled ; leaves permanent, lanceolate, tomentose beneath ; flowers eight-stammed .- This is a small tree or shrub, with striated, rnfous, or ferrugioous-coloured branches; corollas white; flowers in a sort of corymb, terminating on bifid or trifid peduncles, and fragrant: this plant is strongly impregnated with an actid volatile salt, like the mustard tribe ; and hence, in Jamaica, where it grows wild, it has obtained the name of the mustard shrub.

 Capparis Baducca. Peduncies one-flowered : leaves perennial, ovate-oblong, determinately crowded, naked; leaves smooth on both sides, obscurely netted.—It is a native of the Kast Indies, where it is cultivated for the beauty of the flowers, which appear in January.

8. Capparis Cynophallophora. Peduncles many-flowcred, terminal; leaves oval, obtuce, perennia; glancia saillary.— This species varies considerably in its habit or general appearance, according to the soli in which it is found: in sunny hedges it is weak, thin, and, as it were, supported by the neighbouring vegetables; but in fields, and towards the shores, it is a kind of shrnb, or little tree, of twelve feet high, and of a pretry appearance; in the axilla of the leaves there is a roundish solitary gland, which is scarcely ever missing; the flowers are becautiful, very patulous, and extremely fragmant, of a white or greenish white; the stamina often four inches long. Native of the West Indies.

9. Capparis Pulcherrina. Peduncles racemed; leaves oblong, obtuse; finits berricad.—This is an unright shrub, in open situations, only two or three feet high, but in woods rising to twelve feet; flowers beautiful, of a pale yellow coloar, and having a very sweet seent; filamenta at first white, then bright purple; each raceme has only one or two berries, from two to four inches in diameter, variegated green and brown on the outside; the flesh or pulp when unripc, hard, and having fille scent; but when ripe, soft, nauseous, and so feetid that no animal will touch it. Native of Carthagena in New Spain, puon the declivities of the mountains.

10. Capparis Linearis. Peduncles subracemed; leaves linear.—This plant, which grows in great plenty on the woody bills of Carthagena, is an elegant upright brauchy tree, about fifteen feet high; the flowers are white, inodorous, and about half an inch in diameter; the fruits are orange coloured, with a reduess intermixed, and are about an inch in diameter.

11. Capparis Breynia. Pedoncles racemed; leaves permonent, oblong; calices and peduncles tomeutose; flowers eightstamined.—A small tree, with an upright smooth trunk, and flexnose branches, scarred with the fallen leaves; twigs angular and pubscent. It is a native of dry coppices near the sea in Jamaica, and most of the other islands in the West Indies.

12. Capparis Hastata. Peduncles many-flowered : leaves hastate, lanceolate, glittering.—Thus is an upright weak shruh, divided into a few very long branches, often six feet long : the common footstaks of the flowers are clustery, terminal, almost half a foot long, and support tabout eight flowers, which are somewhat odorous, purple, and nearly two inches in diameter. Native of Carthagena, in woody places.

13. Capparis Flexuosa.-See the eighth species, which is the same.

14. Capparis Siliquosa. Peduncles many-flowered, compresed: leaves permaneut, lanceolate, oblong, acuminate, dotted beneath.—The leaves of this species are extremely acuminated; the upper surface is glittering, and the lower powlered with ferruginous dust. According to Mr. Miller, it rises with a shrubby stalk to the height of ceight of ten feet, sending out many woodly branches, covered with a reddilin brown bark; it was sent to him from Tolu in America.

15. Capparis Grandis. Corymbs terminating; leaves ovate, acute, smooth; fruit globular — This is a large hoary tree; flowers whitish yellow. Found by Konig in Ceylon.

16. Capparis Magna. Stem arboreous, unarmed; leaves temate, lanceolate; corymbs terminating.—This is a middling-sized tree, with spreading unarmed branches; flowers

large, white, in spreading corymbs. Native of Cochin china, on the banks of rivers.

CAP

17. Capparis Falcata. Stem arborcous, unarmed; leaves ternate, sickle-shaped; racemes loose, terminating.—This is a large tree, with spreading unarmed branches; corolia white, resembling that of the foregoing sort; stamina eighteen. Native of China, near Canton.

18. Capparis Cautoniensis. Peduncles racemed; stipnles thorny; leaves ovate, acuminate, wrinkled; stem shrubby, upright, branched; flowers white, axillary, and terminating; filamenta long.—Native of China, near Cauton.

19. Capparis Torulosa. Pedancles subbiforous, round, terminating; leaves lanceolate, oval, dotted with white undemeath; pods round, linear, torulose.—It grows into a shrubby tree, and is a native of Jamaica.

20. Čapparis Longifolia. Leaves linear-lanceolate, dotted with meal underneath.-Native of Jamaica.

21. Capparis Arborescens; leaves lanccolatc, ovate, perennial; stem arborescent. Native of Carthagena in New Spain.

22. Capparis Racemosa. Leaves ovate, opposite, perenail; flowers racemed.—It ires with a trunk about twenty feet high, sending out many long slender branches, which are covered with a brown bark, and garnished with leaves like those of the bay-tree, but longer, and deeply ribbed on their under side, standing nop nerty long foot-stalks opposite; the flowers are produced upon long branching peduncles, which tare large and white, and are succeeded by pods two or three filder while are slarge hand white, and are succeeded these long, the thickness of a man's little finger, which are falled with large kidney-shaped seeds; these pods have a thick fields cover.

23. Capparis Fruticosa. Leaves lanceolate, acute, crowded, perennial; stem shrubby.—This species rises with a shrubby stem to the height of twelve or fourteen feet, sending out many strong lateral branches, covered with a dark brown bark; the antheræ are of a purplish colour, but the stamina are white. Sent from Tolu in America.

24. Capparis Conferta. Leaves hanceolate, alternate, on very long petioles; flowers crowded.—It rises with a shrubby stalk to the height of ten or twelve feet, sending out slender horizontal branches, which are covered with a reddish bark. Sent from Tola in America.

25. Capparis Trifora. Leaves haucoolate, nerved, pereunial; pednucles three-flowered.—This has slender slimbly stalks, which rise seven or eight feet high, sending out many woody branches, with very long nerved spear shaped leaves; the flowers come ont at the ends of the branches, three standing upon each pednucle; they are small, white, and are succeeded by oval fruit.

Copraria; a genus of the class Didynamia, order Angiospermia.-GENERIC CHARACTER. Calkis: periath oneleafed, five-parted, oblong; divisions linear, erect, distant, bell-form, five-cleft, nearly equal; divisions oblong, acute; the two apper ones more erect. Stamiar, filamenta four, subulate, inserted into the base of the corolla, shorter by laif than the corolla, the volume or earlier shorter than the others. Antherw cordate. *Pistili*: germen conical; syle fillform, longer than the stamina; sigma cotdate, bi-"alve, equal. *Pericary*: capsule oblong, conical, compressed at the tip, biolocular, biralve, with a contrary partition, which is doubled by the bending in of the edge of the valves. *Capsule* five, billocular, many-sceded. Those pinats of

CAP

this genus which are natives of the Cape of Good Hope, may be increased by cuttings, and are not so tender as the first species.——The species are,

1. Capraria Billora; Shrubby Goatuced, or Sueretued, Leaves alternate; flowers in pairs.—This is a shrub seldom exceeding four feet in height; branches long, sonie-shar wordy, creet, roundish, sometimes slightly histure; dowers without secnt; corolla white; seeds very snall. It is very common in Jamaica, and is one of the plants formerly taken for the tea of the Chinese, and hence, in the French West India islands, called thé adu pays. It is propagated by seeds, which must be sown upon a hol-bed in the spring of the year, and the plants must be sown upon a hol-bed in the spring of the year, and the plants must be brought forward by planting them upon a second hot-bed; about the middle or end of June, where they will perfect their seeds in atume.

 Capraria Durantifolia. Leaves in threes, toothed; peduncles solitary; branches alternate; stem about a foot high, obtusely hexangular.—Native of sloughs in Jamaica, where mud has been worked up by carriages.

3. Capraria Crustacea. Creeping ; leaves opposite, ovate, subpetioled, crenated.—It is a native of Amboyna and China.

 Capraria Lanccolata; Willow-leaved Capraria. Leaves opposite, linear, lanceolate, quite entire; racemesterminating, compound; shrubby.—Found at the Cape of Good Hope.

5. Capraria Undulata; Waved-leared Capraria. Leaves opposite, ovarie coblong, quite entire, waved ; the upper sub-corlate, verticelled; racemes spike-form, shrubby; leaves scattered in a sort of whod, unequally approximating; flowers in an almost simple terminating raceme.—It flowers from March to July. Found at the Cape of Good Hope.

6. Capraria Lucida; Shining Capraria. Leaves opposite, oblong, acute, finely serulate, glossy; petioles winged; pedancles three-dowered, smootk; stems quadrangular; corolla salver-form; tube cylindric, pale purple, a little longer than the calix, gibbous on the outside at the base, above that a little bent, then erect, a little elongited on the outside, so that the border is entirely horizontal; segments ovate, obtuse, equal, reddish purple, with a dark purple spot near the threat, which is hairy—It flowers in April and May, is biennial, and a native of the Cape of Good Hope.

 $\dot{\tau}$. Capraria Humilis; Dwarf Capraria. Pubescent; leaves opposite or in threes, ovate, sertate, petioled; peduncles axillary, shorter than the petiole.—Annual; and a native of the East Indics.

Capsicum; a genus of the class Pentandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth one-leafed, five-cleft, erect, permanent. Corolla: monopetalous, rotated; tube very short; border half five-cleft, spreading, plaited; divisions broad, acute. Stamina: filamenta five, subulate, very small. Antheræ oblong, converging. Pistil: germen, superior, ovate; style filiform, longer than the stamina; stigma obtuse. Pericarp: berry without pulp, approaching to an ovate figure, bilocular, hollow, coloured; receptacles growing to the dissepiment, exsuccous. Seeds : very many, reniform, compressed. ESSENTIAL CHARAC-TER. Corolla: rotated. Berry: exsuccous. Most of the plants of this genus are natives of both the Indies, but they have been principally imported from America into Europe. They abound in all the Caribbee islands, and are greatly water; they will flower at the end of June and in July, and used in sauces, especially by the negroes, whence the firnit is ripen fruit in autumn. The above directions are for the called negro and Guinea pepper. The well-known preparation called Cayenne pepper, made from the pods of the smaller rally planted for ornament .-- Bonnet-pepper, cherry-pepper,

sorts of capsicum, when used in moderation, is by no neaus unwholesome, especially to cold phlegmatic habits. In such temperaments, as well as in paralytic cases, it is used medicically, in small quantities, as one of the highest stimulants. It has also been eshibited, in combination with aloctic medicines and the deobstruent guns, in uterine disorders. A small quantity of the powder of capsicum has sometimes given almost immediate relief in the tooth-ache, when arising from a caries or rotten tooth; it is to be applied to the part affected, by introducing it into the cavity of the carious tooth. —The species are,

1. Capsicum Annuum; Annual Capsicum, or Guinea Pepper. Stem herbaceous; peduncles solitary; leaves ovate lanceolate, quite entire, smooth, dark green; flowers white, lateral, solitary; the fruit is a berry varying much in size and shape, extremely smooth and shining on the outside, scarlet or yellow, inflated or hollow, two-celled, sometimes three-celled; the partitions at top commonly failing towards the axis; receptacle at the bottom of the berry solid, ovate, conical, intimately connected with the partitions, so that some of the seeds are sometimes fixed to the partitions themselves; seeds kidney-shaped or round, beaked, smooth, whitish or pale straw-coloured ; two seems to be the natural number of the cells, for berries which are three-celled become two-celled towards the top. Long informs us, that there are fifteen varieties cultivated in Jamaica : the common long-podded capsicum has been long cultivated in our gardens; it varies, 1. with oblong fruit, growing erect; 2. with a divided fruit; 3. with oblong and short pods growing erect; 4. with a taper fruit a span long. The capsicum with heartshaped pods has also several varieties: 1. with round hanging pods; 2. with larger and rounder pods; 3. with the largest round pods; 4. with upright heart-shaped pods; 5. with upright round pods: these also have both red and yellow fruit. Bonnet-pepper has small wrinkled leaves; the fruit is also furrowed and wrinkled, generally growing upright, and of a beautiful scarlet-colour ; some of them have their tops compressed like a bounet, whence the name ; others are bellshaped. Cherry-pepper was sent from the Spanish West Indies; it does not grow so tall as the others, but spreads near the ground ; the leaves come out in clusters, are of a shining green, and stand on long footstalks; the fruit is round, smooth, of a beautiful red, and the size of a common cherry. Olive-pepper came from Barbadoes: this is like the first in stalk and leaves, but the fruit is oval, and about the size of a French olive. These are all annual with us, their stalk decaying soon after they are ripe, whatever they may be in their native countries: they are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants have six leaves, they should be transplanted on another het-bed, at four or five inches' distance, shading them in the day-time from the sun until they have taken root, after which they must have a large share of air admitted to them in warm weather, to prevent their drawing up weak. Toward the end of May the plants must be hardened by degrees to bear the open air; and in June they should be carefully taken up, preserving as much earth about their roots as possible, and planted into borders of rich earth, observing to water them well, as also to shade them, until they have taken root, after which time they will require no other management, but to keep them clean from weeds, and in very dry seasons to refresh them three or four times a week with

Published by Nuttall, Fisher & Dison, Liverpool, Oct. 1810.

and olive-pepper, being tender, the plants should be put into | -It is cultivated in Martinico, aud used there for culinary pots, and placed in an old hot-bed under a deep frame, where they may have room to grow; or if they are planted in the full ground, the plants should be each covered with a bellglass, to screen them from cold ; these glasses may be set off every day in warm weather, and placed over them in the evening again; and in unfavourable weather, the glasses should be raised on the side opposite to the wind, to admit fresh air. With these precautions the fruit will ripen in England, which seldom arrive to maturity without it; and never, except in very warm seasons. The beauty of these plants lies in their ripe fruit, which being of different forms and colours, intermixed with the green leaves and white flowers, which appear at the same time, make a pretty appearance at the latter part of the summer, when they are properly disposed in the borders of the flower-garden ; or if planted in pots for the decoration of courts, and intermixed with other annual plants, which are in beauty at the same season, they will make a pleasing variety, especially if as many of the different-shaped fruits, of both red and yellow colours, as can be procured, are propagated.

2. Capsicum Baccatum ; Small-fruited Capsicum, or Bird-Penper. Stem shrubby, smooth, and even; peduncles in pairs .- This differs but slightly from the fifth species; the stem is tenderer, more shrubby, and not roughish ; the berries are very small, of an ovate form, and of the size of currants ; the branches are divaricated, not spreading out at a right angle with the stem. According to Loureiro, the stem is three feet high, smooth, and upright, with longish, scattered, slender branches; leaves lanceolate, quite entire, smooth, scattered, small, petioled; berry roundish, very red, the size of a common cherry; the lower leaves opposite, the upper alternate. It is gathered when ripe, dried in the sun, pounded, and mixed with salt; it is then kept stopped in bottles, and is known by the name of Cayenne-pepper. A mixture of sliced cucumbers, eschalots, or onions, cut very small, a little lime juice, and Madeira wine, with a few pods of bird or bonnetpepper, well mashed, and mixed with the liquor, seldom fails to excite the most languid appetite in the West Indies, and is therefore called man-dram; the pods, gathered fresh from the bush, are also liberally used in the West Indies, to assist digestion and correct flatulencies : both this and the common guinea-pepper are given internally to horses and mules, to cure the dry gripes, occasioned by rank and sour grass: they are likewise externally applied in cataplasms. Miller enumerates four sorts with perennial shrubby stalks, and informs us, that they rise four or five feet high, and are not so hardy as the annual sort; hence, when they have been brought forward in the hot-bed, as was directed for the common sorts, they should be each planted in a pot filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance; and in warm weather, they should have a large share of air admitted to them, but must be covered with glasses every night, or in cold weather, and frequently watered. Thus managed, they will produce plenty of fruit in autumn, which ripen in winter, but they must be removed into the stove on the first approach of frost, and placed where they may have a temperate warmth, in which they will thrive better than in a greater heat; and the fruit will continue in beauty most part of the winter, making a pretty appearance in the stove during that season.

3. Capsicum Sinense ; Chinese Capsicum. Stem shrubby ; flowers and fruits peudulous; trunk perennial, woody, with an ash-coloured bark; the whole plant is smooth; fruit shining, ovate, obtuse, obscurely angular, yellow; seeds pale. 21.

purposes.

4. Capsicum Grossum; Heart-shaped Capsicum, or Bellpepper. Stem undershrubby; fruits thickened, various.-This bears a great resemblance to the annual capsicum, and indeed seems to be the connecting link between the herbaceous and shrubby sorts; the stem is perennial, a span in height, and somewhat branching; the fruit is very large in proportion to the plant, being almost as big as an apple, but differing in shape, as it is solitary and erect, from an inch and half to two inches long, swelling and wrinkled, flatted and angular at top. Bell-pepper is the sort most proper for pickling, the skin being fleshy and tender, whereas in the others it is thin and tough; the fruit should be gathered before it arrives at the full size, whilst the rind is tender : it should be slit down on one side, to get out the seeds; after which it should be soaked two or three days in salt and water: when drained from this, it must be covered with boiling vinegar, and closely stopped down for two months. and then boiled in vinegar to make it green; it wants no addition of spice : if the ripe fruit of this or any of the capsicums be thrown into the fire, it will raise strong and noisome vapours, which occasion vehement sneezing and coughing, and often vomiting; the powder taken up the nose will excite violent and dangerous fits of sneezing. These plants. which are propagated for pickling, should be planted in a rich spot of ground, in a warm situation, about a foot and a half asunder, and shaded until they have taken root, and afterward duly watered in dry weather, which will greatly promote their growth, and cause them to be more fruitful, as also enlarge the size of the fruit; thus there may be at least two crops for pickling obtained in the same year, provided the season does not prove too cold, but there should be one plant with large and forward pods, chosen, to save seeds; and the first fruits on this should be suffered to remain, that they may have time to perfect their seeds before the frost comes on in autumn, for the early frost generally destroys these plants: when the fruit is fully ripe, it should be cut off, and hung up in a dry room till the spring, when the seeds are wanted.

5. Capsicum Frutescens; Shrubby Capsicum. Stem shrubby, roughish; peduncles solitary; stem three feet high, and rugged; brauches diffused, frequently scandent; leaves lanceolate, quite entire, waved, small, smooth, petioled, alternate or scattered; flowers axillary, small, white, five or sixcleft; fruit at first green, but when ripe golden or saffroncoloured, crooked, and shaped like a horn, an inch long, usually solitary.

Capura; a genus of the class Hexandria, order Monogynia. GENERIC CHARACTER. Calix: none. Corolla: monopetalous, tubular; tube cylindric; border six-parted; divisions rounded, the exterior alternate ones narrower, Stamina: filamenta hardly any. Antheræ six, oblong, within the tube; the alternate ones superior. Pistil : germen superior, triangularly roundish, truncate; style cylindric, very short; stigma nearly globose; pericarp berry. ESSENTIAL CHARACTER. Calix: none. Corolla: six-cleft. Stamina: within the tube. Germen : superior. Stigma : globular. Pericarp : berry .---- The species are,

1. Capura Purpurata. A tree with brachiate purplish branches; leaves opposite, subpetioled, ovate, quite entire, sharpish, annual; bunches of flowers axillary, shorter than the leaves, purple .-- Native of the East Indies.

Caraway. See Carus.

Cardamine ; a genus of the class Tetradynamia Siliquosa. -GENERIC CHARACTER. Calix: perianth four-leafed :

3 R

small, deciduous. Corolla: four-petalled, cruciform; petals oblong, obovate, spreading much, ending in erect claws of twice the length of the calix. Stamina : filamenta six, subulate; of these the two opposite ones are twice the length of the calix, but the rest only a little longer. Antheræ small, cordate-oblong, erect. Pistil : germen slender, cylindric, length of the stamina; style none; stigma obtuse, headed, entire. Pericarp : silique long, cylindric, compressed, bilocular, bivalve; the valves, ou opening, rolling spirally backwards. Seeds: very many, roundish. ESSENTIAL CHA-RACTER. Silique opening elastically; the valves revolute. Stigma: entire. Calix: rather gaping. Few of the plants of this genus are admitted into gardens; they are mostly low plants, growing in wet or Alpine situations; the perennials may be propagated by parting their roots in the autumn, and require a strong soil with a shady situatiou. All the species may be propagated by seeds sown in the autumn, on a shady border, where they require no care but to be kept clean from weeds, and will flower early in the following season. As they are very prolific in seed, and their pods are provided with a particular mode of dispersing them, by means of the twisting of the valves in opening; they will propagate themselves abundantly when once introduced, but they will thrive best in the shade. All the species of cardamine are mild antiscorbutics, as the taste sufficiently indicates, but they are not received in practice .---- The species are.

* Leaves simple.

1. Cardamine Bellidifolia : Daisy-leaved or Alpine Cress. Leaves simple, ovate, guite entire; petioles long; root simple, white, very long .- The plant has no smell, and flowers in July and August. On the highest Alps, at first it appears with a stem scarcely two inches high, yet with some leaves on it. It is frequent on the mountains of Lapland : on the Alps of Switzerland, Dauphiny, Austria, and Carniola, and upon the highest Alps between Savoy and Piedmont; there is some doubt whether it be a native of Great Britain : it is perennial, and flowers in April and May.

2. Cardamine Asarifolia; Asarabacca leaved Cress. Leaves simple, subcordate; leaves round, a little sinuated; corolla white; siliques long, many, bursting at the least touch when ripe .- This species has all the qualities of scurvy-grass, and is substituted for it where it grows in abundance. It is found at Barga in Tuscany ; iu the Modenese, at the foot of Mount Cenis; in the Vaudois Alps; above Tende, &c.

3. Cardamine Nudicaulis; Naked-stemmed Cress. Leaves simple, lanceolate, sinuate-toothed ; stems naked, abont nine inches high; leaves smooth, firm, about three inches long .-Observed by Steller in Siberia.

4. Cardamine Petræa; Rock Cress, or Alpine Ladies' Smock. Leaves simple, oblong, toothed; roots percunial; stems from three to six inches high, reclining at the base, and increasing by offsets .- Perennial; flowering in May and June: found upon lofty moist rocks in Wales, Scotland, Sweden, Denmark, and Silesia.

** Leaves ternate.

5. Cardamine Resedifolia; Rocket-leaved Cress. Lower leaves undivided, upper three-lobed and pinuate; root biennial .- Native of the south of France, the Swiss Alps, and the Pyrenees, Germany, Austria, Piedmont, on the highest rocks; flowering in July.

6. Cardamine Trifolia; Three leaved Cress. Leaves ternate, obtuse; stem almost naked; root creeping; stem in a great degree; in exposed situations, it seldom exceeds branched, cicatrized with the fallen petioles; radical leaves six or eight inches high, and is generally much more hairy, often continuing to another year, ternate, on long reddish and when it grows singly, also much more branched : the

leaflets ovate-oblong, obtuse, somewhat spreading, gibbous, semicylindric petioles; leaflets rounded above the middle. with repand or subcrenated edges the notches ending in a point; one leaf on the stem .- Native of Lapland, and Westrogothia, Switzerland, Carniola, and Austria.

7. Cardamine Africana; African Cress. Leaves terpate. acuminate; stem very branching; leaflets stiff, large, roundish, with sinuated edges, the terminating one very large; stems a span or more in height, round, somewhat hairy, and striated towards the top; flowers in spikes, purple; siliques long. -Perennial; flowering in May, and a native of Africa.

8. Cardamine Chelidonia; Celandine-leaved Cress, Leaves pinnate; leaflets in fives, gashed; stem herbaceous, eight inches high, with many ascending branches; leaflets seven, lanceolate, smooth; flowers white, in simple terminating spikes.-Native of Italy, Siberia, and China.

9. Cardamine Impatiens; Impatient Ladies' Smock. Leaves pinnate, gashed, stipuled; flowers without petals; root annual; stems from six to twelve or eighteen inches high, angular, hollow, stiff, erect, somewhat flexuose, simple, or but little branched ; radical leaves have five pairs or more, ovate ; pinnas obtusely lobed ; stem-leaves very numerous, growing without order, shortest towards the bottom of the stem, pinnate; pinuas nine pairs or more, oval lanceolate, or lanceolate, deeply and acutely lobed or indented, especially on the lower edge; smallest towards the stem, and gradually larger, odd leaflet usually three-lobed ; flowers in erect spikes ; siliques numerous, almost parallel to the stem, long, stiff, swelling out a little .- It is called impatient, from the elasticity of the siliques, which, if touched when they are ripe, spring open, and cast out their seeds with violence to a considerable distance. It is found upon the Swiss mountains, and in Sweden. Denmark, Germany, the south of France, Austria, Carniola, Piedmont, the Pyrenees: in England, it grows in Derbyshire, Yorkshire, Westmoreland, Worcestershire, and Somersetshire; flowering in May and June.

10. Cardamine Parviflora ; Little-flowered Ladies' Smock. Leaves pinnate, without stipules ; leaflets lanceolate, obtuse; flowers corolled .- An annual plant, and native of most parts of Europe.

11. Cardamine Græca; Greek Cress, or Ladies' Smock. Leaves pinnate; leaflets palmate, equal, petioled; root annual; height less than a span; stems slender, jointed, branched; leaflets nine, small, ovate, semipalmate, obtuse, divided about the edge; flowers few, at the tops of the branches; calix erect; corolla white .- Native of Sicily, Corsica, and the Greek islands.

12. Cardamine Hirsuta; Hairy Ladies' Smock. Leaves pinnate; flowers four-stamined and six-stamined; root annual, fibrous; stem a span high or more, solid, upright, flexuose, grooved or angular, purple near the base, and commouly very hairy, above nearly smooth, branched, sometimes very much so; radical leaves numerous, forming a circle, pinnate; leaflets petioled, round, angular, generally fivelobed, hirsute, roughish, with little prominent points; the lobes unequal, bluut or pointed; stem-leaves narrower, and more deeply indented, with fewer lobes; calix has a few white hairs; corolla almost twice the length of the calix; small, white ; petals entire, obtuse ; silique about an inch in length, upright; seeds twelve, flattened, smooth, yellowish brown .- Early in the spring, when the weather is cold, it has only four stamina, but as the summer advances it has constantly six : in a wet and luxuriant soil, it loses its hairiness

leaflets vary much in shape; the young leaves are a good salad in the spring. It is a native of most parts of Europe, in wet shady places, and flowers in April or May.

13. Cardamine Pratensis; Common Ladies' Smock, or Cuckoo Flower. Leaves pinnate ; the radical leaflets roundish, those on the stem lanceolate; root perennial; stem nine inches or a foot high, upright, at top a little branched, round, scarce perceptibly angular, smooth, stiffish, with a purple tinge at bottom; radical leaves on petioles from an inch to two inches in length, having three or four pairs of leaflets; frequently imperfect, after the stem is advanced; the pinnas roundish, running out into three unequal angles or teeth, the outcrmost largest, and having for the most part five angles; calix yellowish green; corolla, large, pale purple; lamina ovate, emarginate, deeply veined; claws yellowish; nectary of four glands, two surrounding the base of the short filamenta, and two on the outside of the base of the long filamenta .- Most authors speak of the corolla as being purple, it is singular therefore that our poets should allude to the silvery whiteness of it, when it is generally more or less tinged with purple, till it has been bleached by the sun. It is very common in moist meadows, and by the sides of ditches and streams, flowering in April and May. From its early appearance the name of cuckoo flower has been given to it, as well as to other spring plants The young leaves of this species, as well as several others, are gathered in the spring and put into salads, instead of cress, of which they have the flavour and the antiscorbutic quality. Cows seldom touch it : but sheep will eat it, at least when they are first turned into a meadow or marsh. The medical virtues of the flowers, in hysteric and epileptic cases, was first mentioned by Ray and Dale, from Dr Tancred Robinson, and since by Dr. Baker. The dose is from twenty to ninety grains twice a day, of the powder of the dried flowers. Withering asks, if they do not act like the erysimum cheiranthoides in the epilepsies of children, and cure the disease by destroying the worms in the stomach and intestines ? He adds: I have accounts, upon good authority, of their success in young epileptics, but have never been fortunate enough to see them of much use in hysteric cases. From the disuse into which this medicine has fallen, it would seem to have disappointed the expectations of practitioners. Cases have, however, occurred to some very eminent physicians, in which epilepsies and obstinate head-aches, even in old people, after resisting every other remedy, have been cured by this medicine, given in the quantity above prescribed, twice or thrice daily. It usually operates by occasioning a degree of hæmorrhage per anilm, and sometimes from the other emunctories, It seems particularly serviceable in those kinds of epilepsies which are brought on by the recess of the menses, and has also been considered as useful in scorbutic cases, like many other plants of the same natural order. Meyrick prescribes the expressed juice of the leaves, which he says operates powerfully by urine, and is good in the jaundice, and all other complaints arising from obstructions of any of the viscera, and in scorbutic disorders. A wine glass, is a sufficient quantity to be taken at a time. He adds : the flowers, carefully dried, are very efficacious in nervous disorders; such as convulsions, the falling sickness, palsy, and hysteric fits. The dose is from a scruple to half a drachm twice a day. The double varieties of this species, which have white and purple flowers, deserve a place in the shady moist borders of the flower-garden, where they will thrive, and make a pretty appearance during their continuance in flower. They are propagated by parting their roots in autumn; at which time they should be annually transplanted.

14. Cardamine Amara ; Bitter Cress, or Ladies' Smock. Leaves pinnate ; axillas stoloniferons .- According to Withering : leaflets of the stem angular, scssile, large, broad, and very angular, resembling those of water-cress. The young leaves are acrid and bitterish, but do not taste amiss in salads. They are pungent, bitter, and aromatic, in such a degree as to promise very considerable medicinal uses. This plant is a native of Sweden, Switzerland, Germany, France, and Piedmont. It is found near London, at Chelsea, Battersea, Lewisham, Uxbridge, Harefield; Dorking in Surry; Braintree in Essex : Middleton in Warwickshire ; Aston near Birmingham, above Worcester; and Great Comberton in Worcestershire ; near Norwich ; Bungay, Suffolk ; and in Scotland. It grows near rivulets, on the banks of rivers, in boggy places, and moist meadows: flowering in April and May. Perennial.

15. Cardamine Virginica; Virginica Cress. Leaves pinnate; leaflets lanceolate, one-toothed at the base; radical leaves in a circle, pinnate; leaflets numerous, almost imbricate, sublanceolate, with one short toothlet from the hinder side near the base; stem with few leaves, generally linear and entire—Native of Virginia.

16. Cardamine Thalicitoides. Leaves ternate, pinnate, and simple: Leafts obliquely lobed, roundish; petals thrice the length of the calix; stem striated, branching, procumbent, the extreme branches bearing flowers on a short umbel; leaves tender; juicey, not hirsute, pinnate; the radical ones have often two pinnas: biennial.—Native of Mont Cenis, St. Bernard, and the Grand Chartreuse.

17. Cardamine Stolonifera. Stem-leaves oblong, sinuate-toolide; runners from the root and base of the stem; stem six inches high, erect, brauching, moderately hirsute; radical leaves on long petioles, obtuse, repand, with one pinnule beneath, a line in length; leaves of the runners small petioled, sharpish with acuminate angles behind.—Native of Carniola, Austria, and the borders of Bohemia.

16. Cardamine Scurata. Leaves ternate, scutate, encled; stem almost naked; root fibrous; fibres very close, capillary; scapes naked; a finger's length; root-leaves very many, petioled, ternate, ercet, loose; lower stem-leaves often solitary, sometimes oposite in pairs, ovate, subpectioled, very small; the terminating one round, curled, smooth, dotted.—Native of Japan.

Cardamomum. See Amomum.

Cardinal Flower. See Lobelia.

Cardiospermum; a genus of the class Octandria, order Trigynia .- GENERIC CHARACTER. Calix: perianth four leaved; leaflets obtuse, concave, the alternate interior ones the size of the corolla, permanent; corolla petals four, ob-tuse, alternate with the larger leaflets of the calix; nectary four-petalled, coloured, inclosing the germen ; leaflets obtuse, growing upon the petals, two upon the erect lip, callous at the tip, hooked at the side; the rest upon the closed lip with equal sides. Stamina : filamenta eight, subulate, equal with the nectary. Antheræ small. Pistil : germen three-sided ; styles three, short; stigmas simple. Pericarp: capsule roundish, trilobate, inflated, trilocular, gaping at the tip. Seeds : solitary, globular, marked at the base with a cordate scar. ESSENTIAL CHARACTER. Calix: four-leaved. Petals : four. Nectary : four-leaved, unequal. Capsule : three, connate, inflated,-In both Indies, of which these plants are natives, they climb upon whatever shrubs are near them, and rise to the height of eight or ten feet, but in England they are seldom much above half so high; they send out many side-branches, which spread to a considerable distance, and will fasten themselves to the neighbouring

plants by their small tendrils, if permitted. They are annuals, and die soon after they have perfected their seeds: and being natives of hot countries, they will not thrive in England but in a stove. They are propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a pot filled with light sandy earth, not too rich, then plunged into a very moderate hot-bed, where they must be carefully shaded until they have taken fresh root; after which a large share of fresh air must be admitted, to prevent them from being drawn up tall and weak ; and when their roots have filled the pots, they should be carcfully shaken out, preserving all the earth to their roots, and put into pots which are a little larger, filling them up with the same light earth, and placing them either under a deep frame, or behind the plants in the stove, where they may be screened from the sun till they are well settled in the pots; after which they may be removed into the glass-case, where they may have room to grow, escape the cold of the nights, and enjoy the air in warm weather. With this management they will flower in July, and ripen their secds in autumn. - — The species are,

1. Cardiospermum Halicacabum; Smooth-leaved Heart Pea, or, Heartseed. Leaves smooth and even; stem herbaceous twining, striated, unarmed, slender, long, branched; leaves broad-hanceolate, sinaate-gashed, smooth, biternate; flowers vaillary, solitary, small, white, on long pediuncles; calix fiveleaved.—Native of both the East and West Indies, and the Society Isles in the South Seas. It flowers here in July.

2. Čardiospermum Corindum ; Woolly-leaved Heart Pea, or Parsley-leaved Heartseed. Leaves tomentose underneath .- This rises, with a slender channelled climbing stalk, to the height of four or five feet, sending out many sidebranches, with leaves upon very long footstalks, coming out opposite at the lower part of the stalk ; but upward the leaves come out on one side, and the peduncle at the opposite; the petioles are divided into three, each of which sustains small leaves, which are again divided into three parts, that are sharply cut on their edges, and end in sharp points. The peduncles are long, naked, and toward the top divided into three short ones, each sustaining a single flower ; immediately under these divisions, come out tendrils or claspers, like those of the vine, but smaller; these fasten themselves to whatever plants grow near them, and are thereby supported; the flowers are small, white, and composed of four small concave petals, two of which standing opposite, are larger than the others; when these fall away, the germen becomes a large inflated bladder, having three lobes, in each of which is contained one, two, and sometimes three seeds, which are round, hard, and the size of small pcas, each being marked with a black spot, in the shape of a heart. It is a native of Brasil, and, according to Loureiro, of the suburbs of Canton in China. It flowers in July and August.

3. Cardiospermum Grandiflorum; Great-flowered Heartseed. Leaves pubescent; capsules acuminate, very large, smooth, and even.—Native of Jamaica.

Carduus ; a genus of the class Syngenesia, order Polygamia Æqualis-G ENERIC CLARACTER. Calix : common ventricose, imbricate; scales very numerous, lanceolate, acuninate, spiny. Corolla: compound, tubular, uniform ; corollules hermaphrodite, subequal, reflected; the proper oue monopetalous, infundibuilion; tube very slender; border erect, ovate at the base, quinquefid; divisions linear, equal, one more deeply separated than the rest. Stamina : filamenta five; capillary very short. Anthera evlindrical, tubular, length of the corollule, five-loohded at the month. Pis-

111: germen ovate; style filform, longer than the stamina; stigma simple, subulate, naked, emarginate. Pericarp: none; calix converging a little; seeds solitary, obovate, four, cormerd, the two opposite corners obliterated; down assile, very long. Receptacle: hairy, flat. ESSENTIAL CHARACTRE. Calix: ovate, imbirizate with spiny scales; receptacle hairy—It is scarcely necessary to say any thing concerning the propagation of thisley, as they are justly considered as weeds demauding eradication, not as plants fit for cultivation. A small number only of them is admitted in gardens, and merely because they are foreign plants. The greater part of the species are biennial, which must be raised from seeds. The perennial sorts also are easily increased in the same manner, and by the rots.—The species are,

 Carduus Leucographus. Leaves decurrent, toothed, spiny; pedunclear maked, very long, one-flowered; calices spiny, inclined; root annual; stem three feet high; flowers upright; down simple.—Native of the country of Nice and Campania.

2. Carduus Lanceolatus; Spear Thistle. Leaves decurrent, pinnatifid, hispid; divisions divaricate; calices ovate, spiny, villose ; stem hairy; root biennial; stem upright, three or four feet high, angular, downy, frequently purple; corolla purple, sometimes white; down plumose, almost as long as the blossom.-It is sometimes found the height of a man, with heads twice the size of the common ; as also with smaller heads, in all respects a less plant. It is called the burthistle in Yorkshire, and is found on road-sides, hedges, and fallows, flowering in July. Although this plant, in common with most of the thistles, is merely regarded as a noxious weed, yet, as Linnens judiciously remarks, it preserves annual plants, by protecting them with its spines, and giving them opportunity to seed in quiet. If a heap of clay, says Dr. Withering, be thrown up, nothing would grow upon it for several years, did not the seeds of this plant, wafted by the wind, fix and vegetate thereon ; under the shelter of this, other vegetables appear, and the whole soon becomes fertile. The seeds are eaten by birds; and the flowers, like those of the artichoke, have the property of curdling milk. This is the most common species of its genus, and is a large succulent plant, well known upon all strong lands. Mr. Miller says, "I have seen the air perfectly filled with the down of this thistle, for miles together, flying along in windy weather, till it was intercepted by a hedge, bank, or rising ground. The greatest part of it indeed is down without seed; and for this the husbandman is obliged to the goldfinch and other small birds, who nevertheless generally leave enough to stock his ground; and the misfortune is, that let a farmer be ever so neat in himself, if he happen to live near a slovenly neighbour, he will be stocked annually from the other's neglected banks, headlands, and fallows. Nothing is easier than to destroy these thistles; for they are biennial plants, and only require to be mowed down before they perfect their seeds. It is better to do this while the plant is yet tender, for as it advances to maturity the stalk grows very hard; but if the operation have been neglected till the seeds are forming, it will be a proper precaution to rake the plants into heaps, and burn them. The ashes may be afterwards spread ; and as they contain a considerable quantity of salts, will be of some advantage to the soil, which they had previously impoverished.

3. Carduus Arabicus; Arabian Thistle. Leaves decurrent, pinnatifid, lanuginously villose; divisions divaricate; calices oblong, spinulose, sessile, aggregate; root annual, fusiform, white; stem erect, about a foot high, scarcely branched, lanuginous, and hoary; corollules purplish. An-

248

smooth.

4. Carduus Nutans; Musk Thistle. Leaves semidecurrent, spiny; flowers drooping; scales of the calix spreading at top; stems from two to three feet high, overspread, as are also the leaves, peduncles, and calices, with a cottony down ; peduncles one-flowered ; flower hanging down, smelling very sweet, particularly in the evening .- This plant is well known to entomologists, on account of the moths which feed upon it; the dried flowers of this species, as well as the former, are sometimes used to curdle milk. It flourishes in a calcareous soil, upon road-sides, in a sandy or gravelly soil, and is common on most of the fallows about Cambridge ; it is biennial, flowers in June, the earliest of the thistles, and is easily known by its nodding bright purple heads and musky scent; it does not however confine itself to borders, but takes possession of the arable lands in good soils, and does real injury to the farmer.

5. Carduus Acanthoides : Prickliest Thistle. Leaves decurrent, sinuate, spiny about the edge; calices peduncled, solitary, erect, villose; flowers small, pale purple, crowded on the top of the stem ; the colour of the whole plant ash or gray; down simple, nearly as long as the corolla. Gerarde calls it thistle upon thistle; and Parkinson, the most prickly thistle. It flowers from June until September, and is found in most parts of Europe upon ditch-banks, road-sides, waste places, and borders of corn-fields. It is sometimes found with white flowers, and in different situations varies from two to five-feet in height, is more or less hairy, and has its flowers more or less clustered.

6. Carduus Crispus; Curled Thistle. Leaves decurrent. sinuate, spiny about the edge; flowers aggregate, terminal; scales of the calix unarmed, subaristated, expanded. It grows wild in the same soil and situations with the foregoing; flowers about the same time; and, like that, is annual,

7. Carduus Polyanthemus. Leaves decurrent, sinuate, naked beneath; flowers peduncled, heaped; peduncles curled, scarcely cobwebbed; flowers usually three or four at top, subsessile. Corollas in the outside purple, in the disk red. Antheræ violet ; styles white ; stigmas purple .- Biennial : native of Rome.

8. Carduus Palustris ; Marsh Thistle. Leaves decurrent, toothed, pricky at the edge; flowers in racemes, upright; peduncles unarmed; root biennial; stem four, five, or six feet in height, in woods frequently ten or twelve, upright, branched, multangular, hirsute with numerous long white hairs, winged, prickly, variegated longitudinally with green and purple. It is called the red thistle in Yorkshire, and being never found except in wet places, it is not likely to be mistaken for any other thistle; it has generally more purple about it than the other species; and formidable as its stems and leaves are from their numerous prickles, the heads of the flowers and peduncles are perfectly harmless; the tender stalks of this plant, like most of the genus, are esculent when peeled and boiled, and are thus eaten, as Linneus informs us, by the inhabitants of Smoland. It grows wild in most parts of Europe, in marshes, boggy woods, and moist heaths, commons, and meadows, flowering in July; it varies with a white flower, as most of the thistles occasionally do.

9. Carduus Pycnocephalus; Italian Thistle. Leaves decurrent, pinnatifid, sinnate, pubescent, spiny; peduncles naked, tomentose ; calices deciduous .- Native of the southern parts of Europe.

10. Carduus Argentatus, Leaves decurrent, runcinate, spiny; peduncles subtomentose, one-flowered; calices ovate, mucronate, unarmed ; stem a foot high, flexouse, even, 21.

there dark purple; pappus hairy, sessile, brown; seeds branched; corolla very small, purple, mixed with the down, searcely gaping. Antheræ blue ; down ash-coloured. It is an annual plant.

Leaves decurrent, runcinate, 11. Carduus Australis. spiny; ealiees subsessile, terminal; stem-a foot high, round, striated, woolly, villose; corolla consisting of about eight purple flosenles .- Native of southern Europe.

12. Carduus Dissectus ; Meadow Thistle. Leaves decurrent, lanceolate : toothlets unarmed ; calices spiny .-- The leaves are wholly destitute of prickles.

13. Carduus Cyanoides; Bluebottle-leaved Thistle, Leaves decurrent, pinnatifid, linear, quite entire, unarmed, petioled, tomentose beneath .- The leaves have a white cotton underneath.

14. Carduus Canus; Hoary Thistle. Leaves decurrent, lanceolate, erose-toothed, ciliate, prickled, cobwebbed, subvillose on both sides ; roots fusiform, aggregate, fleshy, white like skerrets; stem four feet high, green, angular, cobwebbed; flowers solitary, purple; calices unarmed, with a white line on the outside of the scales .- Perennial; flowering in July : and a native of Austria and Tende.

15. Carduus Pectinatus, Leaves decurrent, lanceolate, pinnatifid, pectinate; peduncles very long; heads, when past flowering, drooping; stem two feet high, erect, even, unarmed, as is the whole plant : leaves uninterrupted, decurrent, with a pale keel beneath, pinnatifid or very deeply toothed; flowers the size of burdock, purple with a long pistil; filamenta white, erect .--- Biennial; sent from Pennsylvania.

16. Carduus Defloratus ; Various-leaved Thistle. Leaves decurrent, lanceolate, serrate, subspinose, ciliate, naked ; peduncles very long, lanuginous, one-flowered; stems many, angular, smooth, leafy, generally simple; peduncles leafless, somewhat woolly, very few; flower solitary, erect. Perennial; native of Montpellier, Switzerland, Carniola, and Gorizia.

17. Carduus Monspessulanus; Montpellier Thistle. Leaves decurrent, lanceolate, subrepand, smooth, unequally ciliate; peduncles alternate ; calices unarmed. Perennial ; found about Montpellier, and in the county of Nice.

18. Carduus Pannonicus. Leaves semidecurrent, naked, undivided, ciliate; flowers subsolitary; unarmed; leaves smooth and even, with soft bristles; corolla pale purple .--Perennial ; and a native of Austria.

19. Carduus Tuberosus ; Tuberous Thistle. Leaves subdecurrent, petioled, subpinnatifid, spiny; stem unarmed; flowers solitary; corolla purple; down simple; perennial; flowering in July and August .- Native of Montpellier, Leipsic, Bohemia, the Palatinate, Austria, Geneva, Switzerland, and the county of Nice.

20. Carduus Chius, Leaves stem-clasping, the lower ones semidecurrent, semipinnatifid, ciliate, spinulose; stcm unarmed; peduncles one-flowered; stem the height of a man. branching from top to bottom, angular, villose, erect .-- Native of Chios.

21. Carduus Parviflorns ; Small-flowered Thistle. Leaves aduate at the base, lanceolate, naked, erose, ciliate, spinulous, unarmed; stem erect; leaves repand, toothed, green on both sides; flowers terminal, peduncled, white with very long styles .- Perennial; native of the southern subalpine mountains.

22. Carduus Linearis. Leaves sessile, linear, ciliate, spiny, smooth ; flowers terminal, solitary ; stem herbaceous, erect, round, striated, smooth, unarmed, a foot high and upwards ; branches alternate, spreading, like the stem, a little tomentose at the end : flowers small : calices subtomentose at the base, smooth at the top.

23. Carduus Casabonæ; Fish Thistle, Leaves sessile, 3 S

lanceolate, quite entire, the edge with terminate spines.— This is a biennial plant, which rises six feet high, with an upright stalk. Native of the south of Europe, The seeds of this species should be sown where they are to remain, upon a warm border in the spring, otherwise they will not survive the winter.

CAR

24. Carduus Stellatus; Starry Thirtle. Leaves sessile, cartire, lanceclate, maraned, tomentose beneath; spines branched, axillary; flowers sessile, lateral; stem a foot bigh, straight, round, cottony; floscules parpled.—Annual, and a native of Sicily and the county of Nice. The seeds of this plant should be sown upon a bed of light earth in the spring; where the plants are to remain, for they do not bear transplanting, unless performed when they are very young; for these be broken, the plant seldom survives. The only care they require is, to keep them clear from weeds, and to thin them where they come too close together.

25. Cardnus Marianus ; Milk Thistle, or Ladies' Thistle. Leaves stem-clasping, hastate, pinnatifid, spiny; calices leaflcss ; spines channelled, doubly spined ; radical leaves spread on the ground, from one to two feet or more in length, with white veins on the upper surface. The beautiful milky veins forming an irregular net-work on the leaves, would form an obvious character to distinguish this species, if they were not sometimes found wholly green; in which case recourse must be had to the strong spines of the calix. It is found upon banks, by road-sides, and in waste places ; flowering from May and June till July and August. It is a biennial, and eaten when young as a salad, and is by some persons blanched and dressed, as a curious dish. The tender leaves, stripped of their spines, are boiled and eaten as greens ; the young stalks are excellent, after their bitterness is extracted by soaking them in water; and the scales of the calix are as good as those of artichokes; the root is good to eat early in the spring; the seeds are large, and contain a portion of oil, whence they have sometimes been used in emulsions, to thin the blood, and to cure stitches and pleurisies, for which purpose they are still prescribed by the German physiciaus, in doses of from one to three grains each. The Italian physicians also give the expressed juice in agues. Grani-vorous small birds, particularly goldfinches, feed much upon the seeds of this and other thistles. In Apulia this plant is grown in preference to grass, on account of its yielding a larger quantity of food for the cattle. . It makes a handsome appearance, and deserves a place in all large gardens.

26. Cardins Syriacus; Syrian Thistle. Leaves stemelasping, angular, spiny; flowers solitary, subsessile, fortified with about five leaflets; flowers white; in the Egyptian variety purple,—It is annual; and a native of Syria, Crete, and Spain.

27. Carduus Eriophorus; Woolly-headed Thistle. Leaves essile, pinnaitid, in two rows; divisions alternate, erect; calices globular, villose; stem four or five feet ligh, angular, striated, woolly, without thorns, much branched; flosules purple, sometimes white; style much longer than the anthere; i down shorter than the corolla, fringed with long hairs; the receptacle is puly and esculeat, like that of the artichoke.—It is biennial; flowers from July till September, and frequents dry pastures, road-sides, and waste places, in Great Britain, France, Switzerland, Germany, Austria, Carniola, Spain, and Portugal. It is the most showy of all the thistles, and ought therefore to be introduced into large gardens, where it will not flower unit the second year; but when once admitted, will sow and maintain itself without requiring any forther care.

28. Carduus Altissinus; Giant Thistle. Leaves sessile, pinnatifid, sinuate, serrate, unarmed; stem very branching; calices villose, subserrate; stature ten or twelve feet; corolla pale purple; down plumose.—Seeds imported from Carolina.

20. Carduus Virginianus; Virginian Thistle. Leaves lanceolate, spinulous, tomentose beneath; stem unarmed, leafy, one flowered; stem slender, a foot or eighteen inches high; corolla purple.—Imported from Virginia.

30. Cardnus Heterophyllus. Leaves stem-clasping, lanceolate, ciliate, entire and lacinate; stem with one or two flowers; calix unarmed; root perennial, creeping; stem erect, quite simple, striated, tomentose; leaves half stem-clasping, serrate, the serratures spiny, the middle nerve white, alternate; the bottom ones perioled; flower one, purple, terminal; calix ovate; scales acute, somewhat spined.—Prennial; flowering in July, and abounding in moist meadows, and marshy places.

31. Cardnus Helenioides: Melancholy Thistle. Leaves stem-clasping, lanceolate, toothed; spinules unequal, clilate; stem unarmed; stem above a foot high when wild, but generally double that height in gardens, where the leaves grow so much larger, that it seems a different plant; leaves shining green on the upper side; the roots creep far muder the surface.—It has been cultivated in the gardens of some quacks, who pretended to cure machines with it, and from that circumstance in all probability obtained the name of melancholy thistle. It is found in mountainous pastures in Yorkshire, Westmoreland, Cumberland, and Wales; at Mulbarton near Norwich; Acton in Gloesershire; in a meadow near Highgate; on Hounslow Heath; near Croydon; and in Scotland.

32. Carduus Serratuloides; Sane-wort Thistle. Leaves rather stem clasping, hanceolate, entrice; seratures spiny, setacous; peduncles one-flowered; stem solitary, from a foot and a half to three feet in height, simple, one-flowered, or divided into few elongated erect peduncles, striated, frequently fexouse, woolly as if, covered with a cob-web, leafy to about half the height, the rest leafless and of a dusky purple; flosueles purple; seeds pale shining; down plumose.— Native of Siberia, Switzerland, Austria, Carniola, Piedmont, and Monthellier.

33. Carduus Tataricus; *Tartarian Thistle*. Leaves stemclasping, lanceolate; serratures spiny, setaceous; flowers threeleaved. *Calix*: cylindric, not globular; floral leaves small, not broad, concave, or pale.—Perennial; native of Siberia.

34. Carduus Ciliatus ; Ciliate Thistle. Leaves half stemclasping, pinnatiful, laciniate, spiny, tomentose beneath ; scales of the calix ciliate; reflex at the base; corolla purple red; seeds scarcely four-cornered, and of a pale purple.— Native of Siberia.

35. Carduus Flavescens. Leaves lanceolate, entire, unarmed, toothed, smooth; flowers leadess, weak, spiny; stem eighteen iuches high, upright, grooved, smooth, sparingly branched; corolla yellowish white; seeds turbinate, fourcornered; down plumose, very abundant.—Found in Spain by Loefling, and in Sileisi by Krocker.

30. Cardius Rivolaris. Leaves at bottom pinnatifd into oblong divisions, at top entire and scrnter, weak, spiny, sessile; stem unarmach; flowers in heads; root perennial; stem unarmach; flowers in heads; root perennial; stem a little vilose, angular at bottom, striated at top, generally quite simple, but sometimes it puts forth short one-flowering branches from soue, seldom from all the axils; corollules purple.—It is found in moist meadows, and begins to flower in the middle of May.

37. Carduus Mollis. Leaves pinnatifid, linear, tomentose

beneath; stem one-flowered, unarmed; stem one, erect, a foot and a half or two feet high, round, a little angular, tomentose, sometimes tinged with red, the size of a pen or rather larger; radical leaves in a tuft; floscules deep purple; calks tomentose.—The whole plant smells strong of musk. It is found about Montpellier, in Germany, Austria, and Carniola; flowering in July and August.

38. Carduus Acaulis; Deerf Carline Thistle. Stenles; calk smooth; leaves lyng close to the ground, with one purple flower in the midst of them; down long, plumose; root-leaves spreading in a circle on footstalks, pinnatific; pinnas irregularly lobed and waved, anguler, with sharp spines at the edge, green on both sides, hairy towards the base.—Linneus justly observes, that this dwarf plant occupies a foot in dimeter, not suffering any plant to grow beneath it, and that it is therefore injurious to pustures; it affects dry open situations, such as heaths and downs, particularly where the soil is calcareous; is a perennial, flowering in July; and found in most parts of Europe. This this lie is only to be destroyed by ploughing: it is, however, common in the very dry light ands, beside being the great pest of the sheer downs.

39. Carduus Inclinans, *Thistle upon Thistle*. Leaves decurrent, thorny at the edge, calicos roundish, lax ; scales of the calix subulate, straight; the innermost unarmed, coloured; corolla parple.—It is an annual plant, growing upon ditchbanks and road-sides, in hedges, among briars, in waste baces, and on the borders of coru-fields; flowering in July,

40. Carduus Pratensis; English Soft or Gentle Thistle, Single headed or Meadow Thistle. Leaves seasile, half stemchasping, lanceolate, somewhat toothed; fringed with small unequal thorns; stem mostly one-flowered; root perennial, florus, creeping; flower terminal, purple; calix ovate, tomentose; the scales imbricate, ovate, acuminate, purplish; seed very short; down nearly as long as the corolla, plamose, with long hairs.—Found in marshy places and swampy meadows.

41. Carduus Carniolicus. Lower leaves pinnatifid, on: short peiloles, upper ones stem-chaying, heads (three or four) terminal, heaped; stem two feet high, striated, simple, not winged, the thickness of the hitle finger; heads of flowers sessile; floscules pale yellow; antheræ ferræginous, putting out two little bristles behind; filamenta brown; down plumose,—Native of Carniola, Austria, and Piedmont.

42. Carduus Carlinoides; Pgrenan Thiatle. Leaves decarrent, decursively pinnate; pinnules palmate, quadrifid, aculate, woolly; steu corymbed, many-flowered; ibowers glomerate; root perenniai; stem a cubit high, sometimes panicle branchecd, woolly; branches axillary, alternate, soiltary, from half a palm to a foot in length; corollas purple.— This is a very handsome species, native of the Pyrenees, and of the mountains about Tende.

43. Cardous Medius. Leaves decurrent, pinnatifid, thorny about the edge; stem on-flowerol; peduncles very long; scales of the calix unarmed, spreading, bristle-shaped; stem a cubit high, very simple, erect; leaves lanceolate, an inch wide, three inches long; flower nolding, purple or deep red, --Perennial; found upon the Pyrenees, aud out the mountains of Piedmont.

44. Carduus Ochroleucus. Leaves pinnate; pinnas ciliate; scales of the calix recurved; height two feet; head not lanuginous; down plunose.—Perennial; native of Switzerland.

45. Carduus Pyrenaiens. Leaves decurrent, oblong, lanceolate, ciliate at the edge, spiny and tomentose on both sides; Bowers subsexile; stem three feet high or more, striated, freeen, smooth; top of the stem almost naked; corolla purple; nectary. These plants are very nearly allied to the grasses,

down plumose.—Perennial; native of Provence, Austria, and Piedmont.

46. Carduus Paniculatus; Panicled Thistle. Leaves semidecurrent, oblong, lanceolate, unequal, ciliate, smooth; the lower lyrate, waved; flowers panicled.—This is a perennial plant, flowering in June and July; native of the south of Europe.

47. Carduus Rigens; Upright Alpine Thistle. Leaves oblong, lancelate, smooth, thorny at the edge, pinnatifid; segments oblique, lobed; calices oblong, bacted; calix oval, with close scales; corollules yellowish white; the whole plant has an ill smell.—It is biennial or perennial, and is a large, thick, strong plant, but very low in proportion to the thickness of the stem, which is selfour more than a foot in height; it flowers in July and August, and is a native of Switzerland and Dauphiny, in moist meadows exposed to the north.

48. Carduus Diacantha. Leaves sessile, lanceolate, tomentose underneath, spines in pairs; flawers corymbed; stem two feet high, straight, single, striated, tomentose; florets of a violet colour.—Native of mount Libanus.

49. Carduns Pinnatifidus. Leaves pinnatifid, tomentose, nerves woolly; stem one-flowered; root short, fibrous, annual; flowers terminating, solitary.--It flowers at the end of May and in June, and is a native of Spain.

50. Carduns Graphaloides. Leaves sessile, in a sort of whorl, lanceolate, quite entire, tomentose beneath; root peremnial, woolly, adhering to the clefts of rocks, whence the plant hangs; flowers terminating, purple, an inch in length; it flowers early in the spring, and continues flowering through the summer to the autum; it the corolla smells sweet; the leaves are dry, and insipid to the taste.—It is a native of the farther Calabrini, where its leaves are only half the width, and much more tomentose; it grows very luxuriantly in gardens.

5). Carduus Tenniforus; Stender Jlowered Thistle. Leaves decurrent, prickly about the edge; branches stiff; calices aggregate, sessile, oblong, conical; scales upright, spreading at top, and prickly at the end; root annual; stem from two to three feet high, upright, branched at the base; branches few, long, upright, perfectly straight, roundish, slightly grooved, cottonv, particularly towards the top, with broad spinous wings; flowers in clusters at the top of the branches, sessile, small, of a pale purple or flesh-colonr.—It is very common in the neighbourhood of London, growing in the very suburbs, and delighting in warm sheltered situations, and is frequeutly found under paling, walls, hedges, and ditch-banks, and near the sea-side; flowering from June till August.

Carex ; a genus of the class Monœcia, order Triandria,-GENERIC CHARACTER. Male flowers disposed in a snike. Calix: ament oblong, imbricate, constant; scales one-flowered, lanceolate, acute, concave, permanent. Corolla : none. Stamina : filamenta three, bristle-shaped, erect, longer than the calix. Antheræ erect, long, linear. Female flowers in the same plant. Calix: ament as in the male. Corolla: petals none; nectary inflated, ovate oblong, bidentated at the tip, contracted upwards, gaping at the mouth, permanent. Pistil : germen three-sided, within the nectary : style very short; stigmas two or three, subulate, incurved, long, acuminate, pubescent. Pericarp ; none ; the nectary grown larger, protects the seed. Seed : single, ovate, acute, three-sided, one angle being generally less than the others. ESSENTIAL CHARACTER. Ament imbricate. Calix: one-leafed. Corolla: none. Female, Nectary: inflated, three-toothed; stigmas three; seed three sided, within the but are of a much harsher texture; the stem, which is frequently three-cornered, is not hollow, but filled with a spongy substance; the difference in the fructification is very consider able, as will appear from a comparison of the generic character. Most of the species grow in wet swampy grounds, in bogs, fens, marshes, or by the sides of ditches and rivers, or in moist woods; some few, however, affect hilly pastures and heaths: they are perennial, and flower in May and June, or from April to July and August. The carices or sedges are classed rather among the noxious plants, than with such as are useful; because they yield a very coarse grass and fodder, to the exclusion of real grass and other profitable plants, which they subdue by their strong creeping roots; but it should be considered that they grow chiefly on poor spongy land, on bogs, to which they give stability, or on the banks of streams, which they enable to resist the current; that they may be destroyed by draining and manuring, and hence, after all, are of considerable use : beside their common use for coarse fodder, they are employed for covering hovels and stacks, for lighting fires and heating ovens, for tying the young hop-plant to the poles; the Italians use them to cover wine flasks, for putting between the staves of casks to make them tight, and for chair bottoms. The Laplander combs and dresses some species of sedge as we do flax, and in winter stuffs his shoes and gloves with it, as a defence against the extreme rigour of his climate. They cannot, upon the whole, be considered as useful plants, except in such situations as will not produce better fodder and herbage; or where they contribute to fill up marshes, and lay a foundation for their becoming hereafter dry land and useful meadows: wherever a meadow is capable of being drained, the sedge may be destroyed, wet being necessary to the existence of those sorts which overrun pasture grounds; they are never cultivated except in botanic gardens, for the determination of the species, and are propagated by the roots ; some few of them require a dry soil and others a shady situation ; but the greater part must be placed with water and bog plants, either by the side of ponds, or in pots or tubs filled with marsh or bog earth, and standing in water; and yet with all these advantages some of them will scarcely flower in a garden .---- The species are,

* With one simple Spike.

1. Carex Dioica: Small Sedge. Spike simple, dimcous: margins of the capsules serrulate; culm slender, upright, smooth, from four to six or even ten inches high, with three sharpish angles .- Found on boggy grounds, flowering in Inne

2. Carex Capitata; Round-headed Sedge. Spike simple. androgynous, ovate; upper part male; capsules imbricate, expanding, with entire margins; very similar to the preceding species.

3. Carex Pulicaris ; Flea Sedge, or Flea Grass. Spike simple, androgynous ; upper part male ; capsules divaricated, bent back, acuminated at both ends; root not creeping, but fibrous .- Frequent in moorish and boggy places.

4. Carex Squarrosa. Spike simple, androgynous; lower part male; capsules imbricated, herizontal; spike oblong, thick, consisting of horizontal imbricate capsules, with a linear tip as long as the capsule itself; the bottom of the spike is covered with dry barren chaffs .- This is one of the largest species, and is a native of Canada.

part male; awns of the female uncinated; males awnless; fertile flowers constituting two-thirds of the spike, below native of bogs and marshes, flowering in June, and is admirathe barren ones; small spicules sometimes hang down by the bly well qualified for planting in loose boggy ground; its 16

side, probably barren .--- It is the handsomest of the genus, and a native of New Zealand.

6. Carex Cyperoides. Head terminal, roundish; flowers very simple, subulated, involucre long; culms a foot high, three-cornered; head consisting of several glomerules in a small umbel; the outer glumes of each barren, the inner fertile ; filamenta white ; pistil longer than the nectary, with a bifid style .- Native of Siberia and Bohemia.

** Spikes androgynous.

7. Carex Baldensis. Spikes tern, heaped, sessile, ovate, three-cornered, androgynous; involucre two-leaved .- Native of Monte Baldo.

8. Carex Arenaria; Sand or Sea Sedge. Spike leafy, oblong, sharpish ; spikelets several, the terminating ones male ; the lower ones female ; culm incurved .- Roots creeping horizontally about four inches under ground, in a moveable sand upon the sea-shores, as at Yarmouth, Lowestoft, and in Scotland, also in the interior of Germany: it rarely flowers in a garden.

9. Carex Aliginosa. Spike compound; spikelets androgynous; the lower ones more remote, furnished with a longer leaflet; culm round .--- Found upon turf-moors in Sweden.

10. Carex Lappina. Spike compound; spikelets ovate, sessile, approximate, alternate, androgynous, naked.

11. Carex Vulpina; Great Sedge. Spike superdecompound, contracted, branched, blunt; spikelets male at top; capsules diverging; angles of the culm very sharp; culm thick, firm .- It flowers in May, and is common on the banks of rivers and ditches.

12. Carex Brizoides; Rough Sedge. Spike compound, distich, naked; spikelets androgynous, oblong, contignous; culm naked; stem slender, three-cornered, eighteen inches high; leaves scarcely a line wide.

13. Carex Muricata; Spiked Sedge. Spike oblong, superdecompound; spikelets distinct; capsules diverging, with a cloven month; root fibrous .- Found in moist woods and meadows; flowering in May and June.

14. Carex Loliacea. Spikelets subovate, sessile, remote, androgynous; capsules ovate, roundish, awnless, divaricate; root creeping; leaves grassy, tender, smooth and even; culm smooth and even, the upper part naked; spikclets four or eight, small, scattered at the top of the culm, whitish .-- Native of Sweden and Saxony.

15. Carex Remota; Remote Sedge. Spikelets axillary, solitary, subsessile, remote; leaflets very long; capsules undivided at the tip; a very elegant plant; stems several, one to two feet high, sleuder, weak, three-cornered, above the lowest floral leaf rough, below smooth; leaves numerous, long, slender, at the lower part of the stem .- This is found in moist woods and by the sides of ditches; flowering in May and June.

16. Carex Elongata. Spikelets oblong, sessile, remote, androgynous; capsules ovate, acute; culms two feet high, rough, three-cornered, almost naked ; glumes brown, sharp.

17. Carex Canescens; Gray Sedge. Spikelets roundish, remote, sessile, obtuse, androgynous; capsules ovate, bluntish. -Native of Lapland, Upland, &c

18. Carex Paniculata; Panicled Sedge. Spike superdecompound, panicled, branched, acute; branches alternate, somewhat remote; capsules spreading; culm three-sided; stems numerous, from one to three and sometimes four feet high, naked in the upper part, three-cornered, with the angles 5. Carex Uncinata. Spike simple, androgynous; upper minutely toothed; the lax branchy disposition of the spike sufficiently discriminates this species from the rest .- It is a
immense tufts affording a firm support for the heaviest bodies.

19. Carex Indica: Indian Scage. Spikes androgynous, cylindric, panieled, pinnate, a few of the lower floceules female; culus subtriangular, smooth and cven, a foot and balf in height, erect; fruit ovate, three-cornered, acute.—Native of the East Indies.

20. Carex Brunnes; Bronen Sedge. Spikes androgmous, peduacled, linear, in the upper part male; leaves linear, attenuated toward the end, entire, smooth, erect, longer than the culm, which is three-cornered, smooth, and a foot in height; spikes crect, acute, hrown, smooth, about twelve in number; glumes ovate, acute.—Observed in Japan by Thumbers.

*** Male and Female Flowers on distinct Spikes: Females sessile.

21. Carex Plava; Vellow Sedge. Sheaths short, nearly equiling the divaricate leaft; nucle spike linear; females roundish; capsules rostrate, acuminate; stems two inches to a foot high, numerous, declining; in the smaller plants leafy up to the spike, but in the larger usually naked upwards, triangular, not rough to the touch; leaves pale yellow; hig reen.—Mr. Ray calls this species marsh hedge hog grass; it is common in bogg and wet meadows, marshes, and the boggy parts of barren heaths: flowering in May and Juue.

22. Carex Pedata. Female spikes sessile, oblong, the lower axillary; leaves sublifibrom; leaves a foot long, very narrow, somewhat exif, smooth and even at bottom; culm very solid, somewhat even, rounded on one side, longer than the leaves; spikes three, sessile; male terminal, oblong, ferruginous; temales two, alternate, ovate-oblong, brown, ferruginous; upper without any leaf under it; lower from the saila the length of the culm; floxules less closely inbricate; capsules obscurely pubcscent.—Native of Lapland.

23. Cares Digitata; Digitatad Sedge. Spikes linear, rect; male shorter; bractes membranaccous, almost leafless, sheathing halved; capsules distant; leaves in a thick tufi; stems obscurely three-cornered, slender, not rough, from six to twelve inches high, entirely naked, except some reddish brown leafs sheaths at the base; male spike land i an inch long, closely imbricate, from the some sheath with the uppermost female spike, and, being shorter, overtopped by it; scales numerous, yellowish brown, membranaceous, and shiring at the ends, and so blumly rounded as to seem truncate. —It flowers in May and June, and is native of many parts of Europe.

24. Carex Montana; Mountain Sedge. Female spikes sessile, subsolitary, ovate, approximating to the male; culm maked; capsules pubescent; culms filiform, naked, a short span bigh; leaves filiform, soft, of a yellower green than the other species; stem-leaves very short; male spike terminal, peduncled, subcylindric, brown; female when ripe hecomes back; scales brown; seeds scarce perceptibly hairy, gibbous, divaricate.—It is found on mountainous pastures and heaths.

25. Carex Tomentosa. Female spikes subpeduncled; capsules subglobular, tomentose; culm three-cornered; leaves narrow; bractes the length of the upper culm.

26. Carex Globularis. Male spike oblong; femalc sessile, ovate; floral leaf shorter, approximating; leaves in a thick tuft, firm, short, not more than half a line broad; culm three inches high, almost naked, three-cornered.

27. Carex Filiformis. Sheaths short, nearly equaling the peduncles; male spikes commonly two; females ovate, remote; cassules downy; leaves slender, upright, ending in a very taper point, roughish on the edges and along the keel, 22.

from one to three feet in length; culm upright, slender, almost equal to the leaves, the angles sharp and hispid.—It flowers in June, is a native of woods in several parts of Europe; and has been observed near Eaton in Shropshire, and at the south end of Λ it Links in Scolland.

26. Carex Piblifera; Round-headed Sedge. Sheaths none; male spike sublinear; females rounded, sessile, crowd-ed; culu weak; leaves in a thick tuft, bright green; the longest scarcely half as long as the stem, which is three-conrect, slender, not rough, somewhat ascending at the base.—It is common in moist pastures and heaths, flowering in April and May.

29, Carex Saxatilis; Rock Sedge. Spikes three, ovate, sessie, alternate; male oblong, terminal; spike male, bay or pale ferruginous; female spikes two, black, and scalv; germina black, three-cornered; styles black, blidd, long; beneath the lowest spike is a setaceous leaf shorter than the spike. -Native of the mountains of Laphaud and Switzerland.

30. Carex Tristachya. Spikes monoecous, three, sessile, linear, nale longer; one leaf or two leaves at most, alternate, linear, smooth, reflected, short; culu three-connered, capilary, stristed, smooth, recet, four inches high; spikes terminal; females lower than the wale, and only half the length.

**** Male and Female Spikes distinct : Females peduncled.

31. Carex Atraia; *Black Sedge*. Spikes all androgynous, terminal, peduncled, when in flower erect, when in fruit pendulous; capsule ovate, sharpish; sheaths scarcely any; stem three-cornered, smooth, with leaves from one inch and half to two inches from the root, naked upwards; the apper often longer than the sitem.—It is singular in this species, that it has for the most part only two stamina, and a few hermaphrodite flowers; it is having no sheaths, or at least very minute ones, and black ovate spikes, are marks sufficient to distinguish it readily from all others with which it can come in any competition. Native of most parts of Europe, on mountains; and found in Wales and Scotland, dowering from May till July.

32. Carex Limosa. Spikes ovatć, pendulous, when in fruit; male longer, more erect; root creeping; styles three; root jointed, creeping—In a garden, where it will rarely flower, it frequently throws up barren leafy stalks, which will readily take root, if planted in pots planuged in water; it is commou in boggy ground, and flowers in June; found in Yorkshire, Lancashire, and Westmoreland.

33. Carex Capillars: Capillary Solge. Spikes pendulous; male erect; females oblong, distich; capsules maked, acuminate; culm, when in flower, shorter than the leaf, scarcely a finger's breadth high, with a single leaf; from the end are produced four crect spikes, one of which is male; in a short time the culm becomes a span in leight, filform, erect, with one sheathing leaf in the middle of it, but shorter than the culm.—Native of the Highland mountains of Scotland.

34. Carex Pallescens; Pale SciQg. Sheaths very much abbreviated; female spikes subcylindric, when fruit-bearing pendulous; capsules oblong, blunt; bractes perunanent; capsules by no means acuminate; stems many, from one to two feet high, three-cornered, roughish, leafy below, naked upward, except that there is generally a kind of false floral larf similar to the stem-leaves, proceeding from a joint one or two inches below the spikes.—Native of woods, meadows, and moist pastures; flowers in May and June.

35. Carex Panicea; *Pink-leaved Sedge*. Spikes peduncled, erect, remote; females linear; capsules bluntish, inflated, somewhat distant; stems bluntly three-cornered, 3 T

CAR

CAR

smooth, twelve to eighteen inches high; leaves smooth, seagreen, shorter than the stem.—It is found in moist meadows, flowering in May and June.

36. Carex Folliculata. Spikes terminal, peduncled, male and female; capsules subulated, the length of the spike; culm three-cornered, two feet high, clothed with very narrow leaves.—Found in Canada by Kalm.

 Carex Pseudo-Cyperus; Bastard Sedge. Sheaths scarcely any: female spikes cylindrical, peduncide, pendulous; capsules awned and beaked, somewhat divaricate; bractes almost sctaceous.—Found flowering in June, upon the sides of dirches and moist woods.

38. Carex Caspitoss; Tarfy Sedge. Styles two; spikes subsesile, subcylindric, obtuse; leaves erect, softish.—It is casily distinguished from the other species by its long marrow leaves, of a pleasant green, in fuller tufts than in any of the rest, by two female spikes, erect and blackish; capsules yel-lowish, sessile, erect, obtuse, outate, inbrincate; culm naked, exactly three-concreted; mder the lowest spike a small leaf longer than the spike; that under the other is shorter; it fills up bogs by its large tufts or hassocks, and will speedily do this, as cattle will will not eat it.

39, Carex Distans; Distant-flowering Stedge, Spikes very remote; bracte sheathing the pedurele; capsules augular, mucronate; capsules acuminate; scales of the calix slarp; stems nine to eighteen inches high, sometimes two feet, or even a yard, leafly, very ob-curely three-correct—It is found in marshes, especially salt marshes, and usually flowers in May and June.

40. Carex Japonica. Spikes monocous, peduncled, erect; females peduncled, ovate; male terminal, linear; culm leafy, three-cornered, erect, weak, smooth, a span high.

***** Spikes Male and Female, distinct; Males several.

41. Carex Acuta; Sharp Sedge, Male spikes many; female subsessive; capsules blunisth, style to tifd, hispid, white, shrivelling; scales ovate, brown, with a longitudinal green line.—It is a very variable plant, an inch high in dry meadows, but in watery situations often rises to the height of three feet.

42. Carex Vesicaria; *Biadder Sedge*. Male spikes linear; female spikes oblong, spreading; caspulse inflated, oblong, acuminate, beaked, spreading; stem three-cornered, leafy, fnely serrate at the cdges; leaves two lines broad, finely serrate, bright green.—It is found in bogs and marshes, and flowers in May.

43. Carex linta; Hairy Sedge. Hairy, all the spikes oblong; females remote, sheathed; capuales hairy; leaves on the outside, and their sheaths white, villose; capsules villose, inflated, two horned at the end; male spikes usually three; female very remote, erect, peducaled; it flowers in May and June, and grows in moist meadows, watery places, and marshes.

44. Carex Pumila; *Dwarf Sedge*. Male spikes two, terminal, sessile; females two, peduncled, oblong, erect; culm very short, indeed scarcely any; leaves linear, attenuated, convolute, smooth.

45. Carex Pauciflors; Tice flowering Sedge. Splike simple, androgynous; female flowers two or three, remotish, spreading; one make flower, sometimes two in the upper part; siem four inches high, obscurely three-cornered, smooth, striated, with two smooth grass-like leaves, the uppermost longest, but generally shorter than the stem.—Native of Sectland, and of the coast of Labradore, in a boggy soil.

46. Carex Hamata; Hooked Sedge. Spike simple, androgynous, linear; male at top; females awned; awns hooked at the tip, and equal.—Native of Jamaica and New Zealand.

47. Carex Rupestris. Spike simple, androgynous, oblong, with male fowers in the upper part; formale glumes awned; Culm scarcely four inches high, naked, three-cornered, twice as high as the leaves; spike an inch high; male glumes subovate, not awned; females broad, ovate, acute, hay-coloured, with a paler edge, and a broadish nerve ending in an awn.

48. Carex Bellardi. Spike one, androgynous, strigose; culm round; leaves capillary.—This species forms little infig. composed of lard round leaves, somewhat yellowish, resembling those of rashes, differing little from the culm, and about the same length, from three to six inches.—Native of the Alps, of Switzerland, Daupliny, and Piedmont.

50. Cares Feitida; Stinking Sedge. Spike conglomerate, brown, stinking.—This plant is fortid, both in a recent and in a dried state; culm maked, three-connered, edges rough; spike one only, blackish, formed of very many small ones, tirrgularly conic, obusely five-cornered, very broad, shorily acuminate.—Native of Świtzerland, Dauphiny, and Piedmont.

51. Carex Psyllophora. Spike simple, and rogynous; male at top; capsules reflex; seeds cylindric.—Native of Sweden, and Germany.

52. Carex Leucoglochin. Spike simple, androgynous, male at top; capsules reflex; seeds three-sided.—Native of Sweden and Germany.

53 Carex Uncinata. Spike simple, androgynous, linear, male at top; awns of the females hooked; males awnless.— This is the handsomest species of the genus; it is a native of New Zealand.

54. Carex Disticha; Soft Sedge. Spike oblong, obtuse; spikelets very many; the lowest and end-one females; the middle ones male; culu upright; style divided absolutely to the base, whereas in the other it is cleft only about one quarter of its length.—It is found in marshes, flowering in June.

50. Carex Divisa. Spike orate, subdecompound, with an upright leaff(1; spikelets rather remote; capsules pressed close; root creeping; leaves narrow, sometimes longer than the culm, which is from eighteen inches to two feet in height, and three-cornered.—It grows in salt marshes, where it flowers in May and June.

56. Carex Incurva. Spike conic; spikelets several, heaped, sessile; involucre none; culm incurved; stems three or four inches high, obscurely three-cornered, smooth, and curved in the arc of a circle.—Found in Scotland in deep loose sand; also native of Demmark and Piedmont.

57. Carex Divulsa. Spike decompound, clongated, somewhat branched at the base; the lower spikeles remote, the upper ones contiguous; capsules somewhat erect; leaves dark green, unarrowish, sharp on the ked, and along the edge, longer than the culm, which is from a foot to eighteen inches in height, weak, somewhat recliming, three-connered, the conners acute and roughish.—Found in moist woods, flowering from May to July.

58. Carex Tripartita. Spike terminal, three-parted; radical leaves shorter than the culm, a line or more in breadth; culm naked in the upper part, three-cornerèd, six inches high; neither that nor the leaves are rough.

60. Carex Bipartita. Spikes two, terminal; the upper compound; culm round, naked; culms straight, twice as high as the leaves, straited; leaves smooth, a little convoluted, straited, acute, and almost pungent.

60. Carex Nigra. Spikes androgynous, erect, sessile, tern, terminal, black; culm three-cornered, leafy; leaves shorter than the culm, which is from a finger's length to a foot in whitish edge.

61. Carex Bicolor. Spikes androgynons, sessile, tern, terminal; eapsules longer than the glumes; calm round, naked. scarcely more than a finger's breadth in height.

62. Carex Stellulata. Spikelets subtern, remote ; eapsules diverging, acute; mouth entire; leaves pale green, narrow, rough at the edges and keel, especially towards the tip.

63. Carex Curta. Spikelets six or more, ovate, remotish, naked; seales ovate, sharpish, shorter than the eapsule; leaves of a pale subglaucous colour, rough along the edges and keel, upright, narrow .- The whiteness and tenderness of the seales are striking circumstances; the root, though it cannot be called directly creeping, has a tendency to increase itself something in that way. It inhabits marshes and watery places, but is not very common, and flowers in June.

64. Carex Ovalis. Spikelets about six, oval, approximating, alternate; seales lanceolate, equalling the capsule; leaves dark green, roughish along the edges and keel, narrow, nearly equalling the stem, which is upright, a foot high, triangular, with the angles sharp and rougish .- It is found in marshes and moist meadows ; flowering in June.

65. Carex Teretiuseula. Spike superdecompound, contracted, branched, sharpish; spikelets glomerate, male at top; capsules spreading; culm roundish; leaves green, upright, stiffish, sheathing near half the culm, at the base convex without, channelled within, rough along the edges and keel, longer than the culm when in flower; the upper leaf longer than the rest .-- Found in marshes near the city of Norwich.

66. Carex Chordohiza. Spike compound; spikelets and rogynous, approximating male at top; capsules compressed; root creeping, filiform .- Native of Sweden.

67. Carex Heleonastes. Spike compound; spikelets androgynous, approximating female at top; eapsules imbrieated, with the sides quite entire .- Native of Sweden,

68 Carex Prostrata. Bractes membranaceous, almost leafless, sheathing; female spikes remote, searcely surpassing the sheath; the calix very large; stem, when old, prostrate; leaves slender, three or four times as long as the culm, channelled at the edges and keel, towards the tip rough .- Observed upon St. Vincent's rocks near Bristol. It flowers in the very beginning of April.

69. Carex Conglobata. Spikes sessile, approximating, few-flowered; capsules ovate, hirsute; leaves in tufts resembling those of pinks, repand, marked with a line, rough about the edge, a line in breadth and more.

70 Carex Mucronata. Spikes sessile, approximating very short; glumes laneeolate, mucronate; leaves rush-like; culms a foot high, naked at the top.

71. Carex Alba. Spikes peduncled, white ; sheaths long, obtuse; filamenta and styles long, white; culm round, slender, with three white leafy sheaths; styles long, trifid.

72. Carex Fusea. Female spikes three, erect; capsules ovate, shortly mucronate, petioled, sitting on the leaf; culm sheathed six inches high ; capsules pale ; leaves long, less than a line wide, nearly the length of the stem, and rough,

73. Carex Trigonia. Male spike peduncled ; females sessile, remote, three-cornered; culm leafy, a foot high and more, three cornered, striated, smooth; leaves linear, striated, dark green, shorter than the culm; male spike one, oblong; glumes bay, obtuse.

74. Carex Foliosa. Female spikes sessile, the lowest peduncled; glumes very narrow; a very distinct species; culm a foot high, three-cornered ; capsules slender, with very long points.

CAR

76. Carex Obœsa. Female spikes sessile, tern; capsules ovate, three-cornered ; leaves short, not above a line in breadth, rough.

77. Carex Ferruginea. Male spike one, acuminate ; female spikes two or three, slender pedicelled ; scales ferruginous ; capsules bifid ; eulm half a foot high, pale green ; the leaves are long and hard, but flexible. It forms large tufts on high mountains exposed to the north,

78. Carex Frigida. Female spikes in threes and fours. distich ; capsules long-pointed ; glumes sharply lanceolate, shining bay, with a green or yellowish nerve.

79. Carex Extensa. Sheaths very short, equalling the pedunele; the leaflet somewhat reflex; spikes crowded; females roundish ; eapsules ovate, acute ; root-leaves narrowish, shorter than the culm, except those which embrace the base of it, which often equal and even surpass it, roughish along the edges and keel towards the top .- This plant does not owe its height to its being drawn up by the surrounding herbage, for it is always found in open places, as in the marshy ground near Harwich, and on the west side of Braunton Burrows in the north of Devonshire. It is not very common; and flowers in June.

80. Carex Fulva. Lowest sheath about half the length of the pedancle, upper one nearly equal to it; female spikes two, oblong, acute ; capsules acuminate, beaked ; leaves upright, narrow, rough along the edges and keel, shorter than the culm, which is upright, slender, about a foot in height, threesided, with the angles acute and rough .- Native of Newfoundland and America; and found at Eaton, near Shrewsbury. It flowers in June and July,

81. Carex Rigida. Rigid-leaved Sedge. Two-styled ; sheaths none; spikes oblong, subsessile; leaves somewhat recurved, rigid; root thick, creeping very much .- Observed on the top of Snowden, and on the summits of the highest mountains in Scotland.

82. Carex Stricta; Stiff-leaved Sedge. Two-styled : sheaths none; spikes subsessile, cylindric, aente; male one or two ; leaves upright, stiff .- The root creeps very much ; it grows in marshes, and flowers in April. Mr Pitchford observed it near Norwich.

83. Carex Præcox; Vernal Sedge. Sheaths short, nearly equalling the peduncles; spikes approximating; males subclavate; females ovate; capsules roundish, pubeseent; leaves dark green, slender, rough along the edges and keel, shorter than the culm, which is upright, from six to twelve inches high, three sided, with the angles bluntish and smooth,-It is a very common plant, growing on most of our heaths, and in meadows; flowering in April and May,

84. Carex Depauperata. Sheaths more than half the length of the peduneles; female spikes remote, few-flowered; capsules ovate, inflated, aenminate, beaked ; stems upright, leafy, three-cornered, from a foot to eighteen inches high, It flowers in May and June, and was discovered by Dr. Goodenough in Charlton-wood ; and by Mr. Dickson in dry woods, near Goldalmin in Surry.

85. Carex Elata. Male spikes two, females sessile : cansules ovate, with a very short undivided point; leaves very long, two or three lines broad, the edges and nerve rough ; culm three-cornered, three feet high.

86, Carex Pendula; Pendulous Sedge. Spikes cylindric, 75. Carex Alpestris. The lowest female spike radical; very long, pendulous; capsules ovate, acute, very much

crowded; sheaths long, nearly equal to the peduncles; leaves half an inch broad, thick, stiff, very dark green, somewhat glaucous underneath .- It is not uncommon in woods and hedges ; flowering in May and June.

CAR

87. Carex Strigosa ; Loose Sedge. Spikes filiform, loose, recurved ; sheaths long, nearly equalling the peduncle ; capsules oblong, subtriquetrous, acute ; leaves broad .- It grows in woods and hedges, as in Witham and Noke woods, Oxfordshire; flowering from April to June.

88. Carex Sylvatica; Wood Sedge, Sheaths shorter than the peduncles; spikes filiform, loosely pendulous; capsules ovate, awned and heaked; root creeping, and throwing out from the joints .- It flowers in May and June.

Spikes crowded, 89. Carex Recurva ; Heath Sedge. peduncled, cylindric, rather pendulous; male terminal; capsules imbricate, rather obtuse; culms erect, three-cornered, with obsolete angles; leaves and stem sea-green .-- Found in meadows, woods, and heaths; flowering in May and June.

90. Carex Juncea. Spikes very remote ; male longer than the females, which are subsessile; capsules bifid, three-cornered, smooth; seed three-cornered; culm a foot high; leaves scarcely two lines broad.

91. Carex Leptostachys. Spike sexually distinct; male single; females peduncled, remote, pendulous, filiform; capsules remote, entire at the end .- Native of Germany.

92. Carex Chinensis. Spikes erect ; male terminating ; females peduncled, four ; capsules acuminate.-This is a span high, and a native of China,

93. Carex Riparia ; Common Sedge. Spikes oblong, acute; scales of the males lanceolate, those of the females acuminate and awned; capsules lanceolate, ovate, with two teeth at the point. This is the largest and most common of all the sedges;' its spikes, cspecially the lowermost of the female ones, frequently become branched; the capsules are large, somewhat inflated, pointed and slightly bifid at the extremity. It flowers in April and May, and is common by the sides of ditches, lakes, and rivers. The glass-makers of Italy use the leaves to bind their wine-flasks, the chairmakers to bottom their chairs, and the coopers in heading their casks, in the same manner as the stalks of the scirpus lacustris is used in England.

94. Carex Paludosa; Sharp Sedge. Spikes oblong, bluntish; scales of the males blunt, of the females lanceolate; capsules ovate, lanceolate, somewhat toothed at the tip .--This plant, which is so very common with us, does not appear to have been noticed by Linneus. It is found in marshes, and by the sides of ditches; flowering in May and June.

95. Carex Gracilis ; Slender-spiked Sedge, Spikes filiform ; flowers two-styled ; mouth of the capsules very entire ; the female flowers are always digynious.

96. Carex Ampullacea; Bottle Sedge. Spikes filiform; males more slender; females round, upright; capsules inflated, globose, awn-beaked, divaricate ; root creeping very much ; leaves glaucous, upright, narrow, longer the culm, rough on a great part of the edges and keel .- It grows in fens, and flowers in May, Near London it is not common, but may be found in abundance at Virginia Water.

Carica ; a genus of the class Diœcia, order Polygamia .---GENERIC CHARACTER. Male. Calix : scarce manifest ; it has, however, five very short sharp teeth. Corolla : monopetalous funnel-form; tube slender, very long, gradually slenderer downwards; border five-parted; divisions lanceolate, linear, obtuse, obliquely and spirally revolute. Stamina: filamenta ten, in the top of the tube of the corolla; the five alternate ones inferior. Autheræ oblong, fixed to Catherine pear; the flowers of the female or rather hermathe filamenta on the inner side. Hermaphrodite. Calix: peri- phrodite papaw, also come out between the leaves, toward

anth very small, five-toothed, permanent ; teeth ovate, acute, spreading. Corolla : five-parted ; parts lanceolate, sharp, erect below the middle, but reflected and twisted above. Calix: perianth very small, five-toothed, permanent; teeth ovate, acute, spreading. Corolla : five-parted ; parts lanceolate, sharp, erect below the middle, but reflected and twisted above. Stamina : filamenta ten ; five alternate shorter subulate, all united by a membrane at the base. Antheræ ovate, erect, two-valved, fertile. Germen : ovate ; style none; stigmas three or five, broad, flat, expanding, multifid; segments very short, blunt. Pericarp : berry very large, angulated with three or five furrows, unilocular, fleshy. Seeds : numerous, ovate, green, very smooth, tunicated, nestling in the middle of the berry. ESSENTIAL CHARACTER. Male. Calix : very small, five-toothed. Corolla : fiveparted, funnel-form; filamenta in the tube of the corolla, alternately shorter. Hermaphrodite. Calix : five-toothed. Corolla : five-parted. Stigmas : five. Berry one-celled, many-seeded .- These plants being natives of hot countries, will not thrive in England, unless they are preserved in a warm stove; where there are such conveniences, of proper height to contain the plants, they deserve a place as well as almost any of the plants which are cultivated for ornament; for when they are grown to a large size, their strong upright stems make a noble appearance, as they are garnished on every side near the top with large shining leaves, spreading out near three feet all round the stems; the flowers of the male sort come out in clusters on every side; and the fruit of the female growing round the stalks between the leaves, being so different from any thing of European production, may entitle them to the care of the curious. They are easily propagated by seeds, which are annually brought in plenty from the West Indies. These should be sown in a hot-bed early in the spring, that the plants may obtain strength before the autumn; when they become nearly two inches high, they should be each transplanted into a separate small pot, filled with a light gentle loamy soil, and plunged into a hotbed of tanner's bark, carefully shading them from the sun till they have taken root; after which they must be treated in the same manner as other tender plants from the same country; but as they have soft herbaceous stalks, and abound with a milky juice, they must not have too much water, for they are frequently killed with moisture: there should also be great care taken, when these plants are shifted from small pots into larger, to preserve the whole ball of earth to their roots, for they rarely survive their being left bare. As they grow they will require larger pots, and when they are too tall to remain under frames, they must be placed in the tan-bed of the bark-stove, where they should constantly remain; they must have but little water during the winter, and in the summer small quantities, but frequently repeated, should be given. In the West Indies these trees are easily propagated by layers as well as by seeds .--The species are,

1. Carica Papaya; Common Papaw Tree. Lobes of the leaves sinuated .- It rises with a thick soft herbaceous stem, to the height of eightcen or twenty feet, naked till within two or three feet of the top, and having marks of the fallen leaves great part of its length. The whole plant abounds with a milky acrid juice, which is esteemed good for the ringworm ; the stem of the plant, and also the footstalks of the leaves, are hollow in the middle; the flowers stand in loose clusters, are of a pure white, and have an agreeable odour: sometimes they are succeeded by small fruit, about the size and shape of a

the upper part of the plant, upon very short peduncles, singly sitting close to the stem; they are large and bellshaped, composed of six petals, which are commonly yellow, but those of the pyramidal sort are purple; when these fall away, the germen swells to a large fleshy fruit, the size of a small melon, but of different forms; some are angular, and compressed at both ends, others are oval and globular, and some pyramidal; the fruit also abounds with the same acrid juice as the plants ; this fruit, when ripe, is eaten like melons, with pepper and sugar, by the inhabitants of the Caribbee Islands; but it is much inferior to our common melon in flavour, even in its native country, and those which have ripened in England were detestable. The best use that can be made of this fruit is, to soak them in salt-water till the milky juice is extracted, and then to pickle them for mangos, for which they have been esteemed a good substitute. Long informs us, that the flowers, buds, and tender footstalks of the hermaphrodite or female trees are preserved as a sweetmeat, and the long mango papaw or fruit as a pickle, which is little inferior to the East Indian mango; the rounder fruit is boiled when ripe, and eaten with any kind of flesh-meat, being looked upon as perfectly wholesome; but when eaten raw, contains an acrid juice, which is very destructive to the intestines. The negroes suppose that papaw trees conduce to the purification of the air, and therefore plant them near their houses. The blossoms are extremely odoriferous, and the trunks so succulent, and so quick of growth, that they probably assist to drain off a large portion of superfluous moisture from the soil where they are planted. Native of both Indies, America, and the Philippine Islands.

2. Carca Posoposa; Dwarf Papuw Tree. Lobes of the leaves entire.—This was found growing in a garden at Lima, by father Feuillee, who remarks, that it was the only plant of its kind that he had seen in his travels. Brown says, that it is frequent in some parts of Jamaica, and that it seldom rises above four or five feet in height. It differs from the first species in having a hairy branching stalk, the lobes or divisions of the leaves being entire, and the fruit shaped like a pear. Fenillee says, that the fruit subscript inches long, and or a sweet flavour, the flower of a rose-colour, and only divided into five fars.

Carissa; a genus of the class Pentandria, order Monogynia--GENERIC CHARACTER. Calk: perianth very small, five-parted, eaute, permanent. Corolla; monopetalous, immel-form; tube cylindrical, bellying at the mouth, longer than the border; border five-parted, flat; divisions oblong. Simmias: finamenta five, very slort, in the top of the tube. Antherw oblong within the mouth. Pistil; germen roundsit; style filtorm, length of the stamias; sigman atther simple. Pericarp: berries two, oblong, bilocular. Seeds: seven or eight, oval, compressed. ESSNTIAL CHARAC-TER. Corolla: contorted; berries two, many-seeded.----The species are,

1. Carissa Carandas. Leaves elliptic, obtuse.—A tree with dichotomous branches; flowers like those of jessamine. Native of the East Indies.

2. Carissa Spinarum. Leaves ovate, acute.--A tree with branches, first trichotomous then dichotomous, horizontal. Native of the East Indies and Japan.

Cortina; a genus of the class Syngenesia, order Polygamia Equalis.- GENERIC CHARACTER. Coliz: common, ventricose, radiated, imbricated ; scales numerous, loose, acute, of which the interior ones are disposed in a circle, very long, expanding, glossy, coloured, radiating the com-22.

pound flower. Corolla ; compound, uniform, tubular; corollets, hermaphrodite, equal; the proper one monopetalous, funnel-form ; tube slender ; border five-cleft. Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil : germen short ; style filiform, length of the stainina ; stigma oblong, bifid or entire. Pericarp : none. Calix; remaining unchanged. Seeds: solitary, somewhat rounded; down plumose, branched, sessile. Receptacle: flat; chaffs ternute, cleft. ESSENTIAL CHARACTER. Calix: radiated with long, coloured, marginal scales .- The plants of this genus may all be propagated by sowing their seeds in the spring, on a bed of fresh undunged earth, where they are to remain : for as they send forth tap-roots, they will not bear transplanting so well as most other plants. When they appear above ground, they should be carefully weeded, and, as they grow in size, thinned where they are too close, leaving them about ten inches or a foot asunder. The greatest part of them will flower in the second year ; but unless the summer prove dry, they rarely produce good seeds in England, and most of them decay soon after they have flowered ; and hence it is rather difficult to preserve a succession of them in this country .---- The species are,

1. Carlina Acaulis ; Low Carline Thistle. Stem oneflowered, shorter than the flower; root an inch thick, black, woody, having an acrid penetrating smell, and a bitter aromatic taste : flower usually one, but sometimes more, three inches in diameter when expanded, for it closes during the night and in rainy weather; rays white, shining; floscules greenish vellow, with purple toothlets - Native of Switzerland, Germany, Carniola, Italy, and south of France. Perennial. The receptacle and upper part of the root are eaten when tender: but the root of the adult plant becomes acrimonious, and is recommended as an alexipliarmic. It contains an acrid resinous principle, by which it stimulates the solids, dissolves the humours, and promotes perspiration. The dose of the dried root is from one to two drachms; when fresh, from two drachms to half an ounce: but it is more frequently given in decoction, than in substance.

2. Garlina Lanata; Woolly Carline Thistle. Stem bifdi ; calices blood-red, terminal, the first axillary, sessile.—When out of flower, it puts off the wool; the juice is blood-red; the true scales of the calix are all terminated by a very simple spine, but in the rest the spines are compound; ray purple on both sides.—Annual; and a native of the south of France, and Italy.

3. Carlina Corymbosa; Corymb Carline Thiste. Stem many-dowerd, subdivided; fowers sessile; ray of the calices yellow; stem purplish at top, scarcely publescent; the leaves even, next the flowers subplinatifid; ray yellow, on the outside and at the base only purplish.—Native of the south of France, and Italy.

4. Carlina Vulgaris; Common Carline Thistle. Stem many-flowered, corymbed; flowers terminal; ray of the calices white or yellowish; root fusiform with a few stiff fibres; stem twelve to fifteen inches high, swelling just above the root, round, ribbed, purple, slightly downy, subumbelled at top : the chaffs of the receptacle are longer than the florets ; the flowers expand in dry, and close in moist weather, which property they retain for a long time. It indicates very barren soil, and is found in dry pastures all over Europe, and is biennial; flowering from June to September. It is serviceable in hysterical and other nervous complaints, and being of a diurctic nature, may be useful in the beginning of dropsies. The powder of the dried root is said to kill worms, remove obstructions of the meuses, and prove serviceable in defluxions on the lungs, or other parts of the body; but 3 U

CAR

though it be not altogether destitute of virtues, more are evidently attributed to it than it really deserves.

5. Carlina Racenosa; Racened Carline Thistle. Flowers sessile, lateral, very few.—The leaves have three nerves: the two side-ones run distinctly from the base to the middle, and then unite with the other; in each, small nerves run parallel across, from the principal to the side-nerves.

6. Carlina Pyrenaica; Pyrenean Carline Thistle. Stem many-flowered; leaves decurrent, runcinated; leaves tomentose on both sides; the pinnas hastate-toothed, with a yellowish spine at each apex.—Native of the Pyrenees towards Spain.

7. Carlina Xeranthemoides. Strubby, branching, tomentose; leaves linear, subulate; serratures spinescent; paniele terminal; ray yellow.—A handsome shmb; steur round, covered with wool, pressed close; leaves scattered, not decurrent, terminating in a spine; upper surface green, smooth, lower while with wool. Observed by Masson in Barancas, about Chasna.

8. Carlina Atractyloides. Stem branching; calices with ciliate spines.—Native of the Cape of Good Hope.

9. Carlina Acanthifolia. Stenless; leaves sinuate, pinnatific, tomentoes; divisions Laft two-lobed, pungent; flower large, sessile, with white-coloured scales; bractes lanceolate, having ternate diverging spines placed in a pinnate order, the middle one longer and stronger before the flower opens; these bractes represent a beautifully netted hemisphere, and when this is open they are reflected. This is the species, the receptacle of which is caten, either as the articloke, or preserved with honey and sugar.

Carnation. See Dianthus.

Carob-tree. See Ceratonia.

Carolinea ; a genus of the class Monadelphia, order Polyandria .-- GENERIC CHARACTER. Calix ; perianth oneleafed, bell-form, truncate, quite entire, very short, deciduous. Corolla: petals five, ensiform, very long, somewhat erect. Stamina : monadelphous ; filamenta very numerous, connate at the base, filiform, very long. Antheræ oblongish, erect. Pistil : germen inferior, oblong, cylindric ; style filiform, the length of the stamina; stigma simple. Pericarp: pome ovate, five-grooved, two-celled ; seeds twin, one above the other, ovate, gibbous, flattish within. ESSENTIAL CHA-RACTER. Monogynous. Calix ; simple, tubular, truncate ; petals ensiform; pome five-grooved, two-celled .- The plants of this genus may be propagated by seeds or by cuttings, in a light loamy soil, plunged in the bark-stove, and watered moderately in summer, but sparingly in winter .---- The species are,

T. Carolinea Princeps. Leadets about five, ovate, lancecolate.—It is a large thornless tree; leaves alternate, petioled, digitate; leadets three or five, broad lanceolate, subpetioled, quite entire; stipules two, short, caducons; flowers obitary, axillary, sessile, very large and beautiful; petals yellow; filamenta red; antheræ purple. The fruit las the appearance of that of the checolate, or of eucumber, torulose and obovate, with seeds like almonds; the cotyledoms paired; these are eatable, but are very flatulent when taken raw in any considerable quantity. Native of Guiana, in salts by the banks of rivers.

2. Carolinea Insignis. Leaflets about seven, obovate, oblong.-Native of Tobago and Vera Cruz.

Carota. See Daucus.

Coroxylon; a genus of the class Pentandria, order Monogynia-GRNERIC CHARACTER. Calk: periant twoleaved, suborbienhate, rude, concave within, keeled on the ogside, very thin at the edge, creet, shorter than the corolla. Corolla: one-petalled, five parted; tube none; border segments 15

obtuse, broad, roundish, concave, curled, membranous, expanding, yellowish or dusky purple; nectary scales five, inserted into the middle of the corolla, somewhat narrower and shorter, and connate with it at bottom; they are placed on the converging fruit, are ovate, sharpish, concave, membranous, yellowish with a greenish base. Stamiae: filamenta five, inserted into the side of the germen, shorter than the corolla, white, capillary. Anthera very small. *Pistit*: germen superior, conic, smooth; style simple, shorter than the corolla, white, capillary. Anthera very small. *Pistit*: germen superior, conic, smooth; style simple, shorter than the corolla, spiral, clothed with a very thin membrane, covered with the permanent filamenta and nectary. Essenxtrate CHARCTER. Corolle: five-petalled. Nectary; five-leaved, converging, inserted into the corolla; seed clothed.——The on't known species is.

 Caroxylon Salsola. Root perennial; stem arborescent, erect, very branching, naked; branches scattered, stiff, flexuose, spreading subdivided.—The Africans make soap with the ashes of this plant and mutton suct.

Carpesium ; a genus of the class Syngenesia, order Polygamia Superfina,-GENERIC CHARACTER. Calix: common, imbricate; the exterior leaflets larger, spreading, reflex, the interior ones equal, close, shorter. Corolla: compound, equal: corollets hermaphrodite in the disk, female in the circumference : the proper one in the hermaphrodites funnelform ; border quinquefid, spreading : in the females tubular, quinquefid, converging. Stamina : in the hermaphrodites five, short. Antheræ cylindric. Pistil: in the hermaphrodites, germen oblong; style simple; stigma bifid; in the females very similar to the hermaphrodites. Pericarp : none. Calix: unchanged, Seeds: in the hermaphrodites obovate. naked; in the females very similar to the hermaphrodites. Pericarp : none. Calix : unchanged. Seeds : in the hermaphrodites obovate, naked ; in the females very similar to the hermaphrodites. Receptacle : naked. ESSENTIAL CHA-RACTER. Calix: imbricate; the outer scales reflex. Down: none; receptacle naked .- The plants of this genus may be propagated by seeds .---- The species are,

1. Carpesium Cernnum; Drooping Carpesium. Flowers terminal; root perminal; scatten leafy, erect, from one to two feet high, round, striated, hirsute, branched at top.—According to Miller, it is a biennial plant; flowering in July, and ripening the seeds in September. Native of the south of France, Italy, Carnola, Austria, Switzerland, and Japan. The seeds must be sown upon a bed of light earth in the spring; and when the plants come up, if they be thinned and kept elean from weeds, they will flower and produce seeds; soon after which the plants care.

2. Carpesium Abrotanoides. Flowers lateral; stems branching, hardish; seeds oblong, naked, smooth, smeared with a kind of balsam.—Native of Chima and Japan. The seed should be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a single pot; and when the weather becomes warm, they may be exposed, but in autumn they must be housed.

Carpinus ; a genus of the class Monocia, order Polyandria.—GENERIC CHARACTER. Male flowers disposed in a cylindric ament. Calix : ament common on all sides, loosely imbricate, consisting of seales, ovate, concave, acute, ciliate, uniforous. Corolla : none. Stamina : filamenta generally ten, very small. Anthere didymous, compressed, villose at the tip, bivalve. Famale flowers disposed in a long ament, upon the same plant. Calix : ament common, loosely imbricate, consisting of lanceolate scales, which are villose, reflected at the tip, uniflorous. Corolla: caliciform, monophyllous, sit-cleft, it wo of the divisions larger than the rest. *Pittil:* germina two, very short, two styles on each, capillary, coloured, long; stigmas simple. *Pericarp:* none; ament becoming very large, concealing the seed at the base of each scale. *Sced:* nut-ovate, angular. *EssENTIAL CHARACTER. Caliz:* con-cleafed, with a ciliate sear. *Corolla:* none. *Male. Stamina:* twenty; female gernina two, with two styles on each, nut-ovate.—*The* species are,

1. Carpinus Betulus: Horn-beam, Hard-beam, Horse-beech, Horn-beech, Wych-hasel. Scales of the strobiles flat; leaves ovate, acuminate, sharply serrate, strongly nerved, bright green, smooth, three inches or more in length, and nearly two in breadth, on round petioles which are slightly pubescent, half an inch in length, and having ovatc red glaudules at their base .- The leaves begin to open about the end of March, and are usually quite out by the middle of April; the flowers are in full blow towards the end of the same month. The hornbeam is very common in many parts of England, but is rarely suffered to grow as a timber tree, being generally reduced to pollards by the country people; yet where the young trees have been properly treated, they have grown to a large size. Mr. Miller says, "I have seen some of them in woods upon a cold stiff clay, which have been nearly twenty feet high, with large noble fine stems, perfectly straight and sound. The Eastern hornbeam, which is a varicty of this species, rarely rises above ten or twelve feet high. As the common hornbeam will thrive upon cold barren exposed hills, and in such situations where few other sorts will grow, the proprietors of such lands may cultivate it to great advantage: it will resist the violence of winds better than most other trees, and is by no means slow of growth. Those which are propagated for timber, should be raised from seeds, upon the very spot where they are designed to be hewn down, and not brought from better soils and warmer situations. as is often the case : they should not be propagated by layers, according to the common method, when they are merely intended for hedges and underwood; which answers well enough for those purposes, but ought not to be preferred in raising timber trees. The seeds should be sown in autumn soon after they are ripe, for if they be kept out of the ground until the spring, the plants will not come up till the following year. When the plants appear, they must be kept very clean from weeds, and treated as other forest trees : they will be fit to transplant in two years' time; for, like all timber trees, if they are at all transplanted, the sooner it is done the larger they will grow, and the more durable and firm will their wood become ; and hence, as above stated, they ought if possible to be planted at first where they are always to remain. If these trees be not intermixed with others, they should be planted pretty close, especially on the outside of the plantations, that they may protect and draw each other up : and if they be kept clean from weeds three or four years, it will greatly promote their growth; after that they will have obtained sufficient strength to keep down the weeds themselves For a wood of hornbean Mr. Hanbury recommends to prepare the ground by a crop of oats, barley, or turnips, to plough very deep when these are off, to harrow well, and just before planting to crossplough and harrow as before. To plant from the seminary at two years old, in four-feet rows, at two feet distance in the rows. When they are too thick, to remove every other tree, and to thin them afterwards as often as their heads touch. When hares and rabbits cannot be kept out, the plants must continue in the nursery, till their leading shoots are out of reach. As the trees advance in growth, they must be thinned with caution, cutting

away the most unpromising plants gradually, so as not to let in too much cold at once, especially on the borders of the plantations. The timber of this tree is very tough and flexible, and might be converted to many useful purposes, if it were suffered to grow to a proper size; but as this is not allowed, the principal uses it is applied to is for turnery ware, for which it is an excellent wood; for mill-cogs, heads of beetles, stocks, and handles of tools, and yokes: it is also excellent for fuel. As the leaves remain till the young buds in the spring thrust them off, so that they afford much shelter for birds in winter; this also renders them very proper to plant round the borders of other plantations in exposed situations, to defend and promote the growth of more tender trees: it also preserves itself well from the bruttings of deer, so that the clumps of this tree are proper in parks both for beauty and shelter. There is a variety with striped leaves, which is propagated by budding on the common sort, but the colours are neither strong nor lively.

Carpadetus; i genus of the class Pentandra, order Mongrain-GENERIC GHARACTER. Cali:: perianth turbinate, fastened to the germen, five-toothed; teeth subalter, decidoons. Corolda: petals five, orate, small, inserted into the margin of the calix. Stamina: filamenta five, subulate, short, inserted into the margin of the calix. A Althere roundlis. Pittil: germen inferior; style filicorn, longer than the stamina; stigma flat-headed. Pericarp: berry dry, globular, surrounded with the margin of the calix, fastened to it like a ring, five-celled. Seeds: a few, slightly angular. Es-SENTIAL CHARACTER. Calis: five-toothed, fastened to the germen; corolla five-petalled; stigma flat-headed; berry globular, five-celled.—The only species known is,

1. Carpodetus Serratus .-- Native of New Zealand.

Carrot. See Daucus.

Carrot Candy. See Athamanta.

Carthamus; a gcnus of the class Syngenesia, order Polygamia Æqualis.-GENERIC CHARACTER. Calitz: common ovate, imbricate; scales numerons, contracted below, increased at the tip by a foliacous appendicle, which is subovate, flat, spreading, obtuse. Corolla: compound, uniform, tubular; corolleis bermaphrodite, equal; the proper one monopetalous, funnel-form; border five-parted, erect, subequal. Stamina: filamenta five, capillary, very short. Antheræ cylindrie, tubular. Pistil: germen very short, Antheræ cylindrie, tubular. Pistil: germen very short; Antheræ cylindrie, converging. Szeda: solitary. Recepcarp none. Caliz: converging. Szeda: solitary. Receptacle: flat, jolse, hairs longer than the sed. ESSENTIAL CHARACTER. Calit: ovate, imbricate, with scales, which at the end are subovate, foliacous.---The species are.

1. Carthamus Tinctorius; Officinal Bastard Saffron, or Safflower. Leaves ovate, entire, servate, aculeate .--- This is an annual plant, which rises with a stiff ligneous stalk, two feet and a half or three feet high, dividing upwards into many branches, with ovate pointed sessile leaves; the lower part of the calix spreads open, but the scales above closely embrace the florets, which stand out nearly an inch above the calix; these are of a fine saffron-colour: when the florets decay, the germina become oblong angular seeds, of a white colour, and having a pretty strong shell or cover to them ; it flowers in July and August, and the seeds ripen in autumn; but if the season prove cold and moist when the plant is in flower, it will produce no good seed, so that there are few seasons wherein the seeds of this plant come to perfection in England; it grows naturally in Egypt, and in some of the warm parts of Asia. Mr. Miller informs us, that he has frequently received the seeds from the British islands in America, but whether they naturally grew there or not, he 260

CAR

was never positively informed. This plant was formerly cultivated in the fields in several parts of England for the dyer's use, and particularly in Gloucestershire, where the common people frequently gathered the florets and dried them, to give a colour to their puddings and cheesecakes; but by employing too great a quantity, they acquired a cathartic quality. It this plant were ever cultivated among us in large quantities, it is surprising how it came to be so totally neglected, that at present there are not the least traces of its cultivation to be met with in any part of England, insomuch that the commodity is scarcely known, except to those who deal in it. The quantity annually consumed in England is so great, as to make it a considerable article of trade, so that it might be well worthy of public attention ; for although the seeds seldom come to perfection in England, yet these might be procured from abroad, and the plants would constantly produce the flower, which is the only part used in dyeing, This plant is cultivated in great plenty in some parts of Germany, where the seeds constantly come to perfection; and a short account of their method of cultivation, by a curious gentleman of that country, is here inserted, for the benefit of those who may be induced to engage in cultivating it. The ground in which they sow has always a double fallow given to it, first to destroy the weeds, and afterwards to make it fine; they make choice of their lightest land, and such as is clear from couchgrass and other troublesome weeds, after the land has been fallowed a summer and winter, in which time they give it four ploughings, and harrow it between each to break the clods and pulverize it : in the latter end of March, they give it the last ploughing, when they lay it in narrow furrows of about five feet or a little more, leaving a space of two feet between each; then they harrow these lands to make them level, and after it is finished they sow the seeds in the following manner : With a small plough, they draw four shallow furrows in each land, at near a foot and half distance, into which they scatter the seed thinly, then with a harrow, the teeth of which are little more than one inch long, they draw the earth into the drills to cover the seeds; after this they draw a roller over the ground, to smooth and settle it : when the plants are come up so as to be distinguished, they hoe the ground, to destroy the weeds; and at this operation, where the plants happen to be close, they cut up the least promising, leaving them all single, at the distance of three or four inches, which they always suppose will be sufficient room for their growth, till the second time of hoeing, which must be performed in about five weeks after the first, in which they are guided by the growth of the weeds; for as this work is performed with a Dutch hoe, so they never suffer the weeds to grow to any size before they cut them; in which they judge right, for when the weeds are small, one man will hoe as much ground in a day, as can be performed by three when they are permitted to grow large, and the words will also be more effectually destroyed ; they give a third hoeing to the plants about five or six weeks after the second, which generally makes the ground so clean, as to require no farther clearing until the carthamus is pulled up. When the plants begin to flower, and have thrust out their florets or thrum to a proper length, they go over the ground once a week, to gather it; and as it is from time to time gathered, it is dried in a kilu for use: there is usually a succession of flowers for six or seven weeks. After the crop is gathered, the stalks are pulled and tied in bandles for fuel; and after they have been set up a few days to dry, they are carried off, and the ground is ploughed for wheat, which they say always succeeds well after this plant. The following is the method pursued in cultivating the carthamus in

British gardens: The seeds are sown in April, upon a bed of light earth, in drills drawn at two feet and a half distance from each other; the seeds are thinly scattered, as the plants must not stand nearer to each other than a foot in the rows; but as some of the seeds will fail, a sufficient quantity to admit of thinning when the ground is hoed, should be sown. If the seed be good, the plants will appear in less than a month ; and in a fortnight or three weeks after they appear, it will be proper to hoe the ground to destroy the weeds, and at the same time thin the plants wherever they may be too close: but at this time they should not be separated to their full distance, lest some of them should afterwards fail; if removed six inches asunder, there will be room enough for the plants to grow till the next time of hoeing, when they must be thinned to the distance they are finally to remain : after this they should have a third hoeing, which, if carefully performed in dry weather, will destroy the weeds and make the ground clean, so that the plants will require no further care, till they come to flower, when, if the safflower is intended for use, the florets should be cut off from the flowers as they come to perfection; but this must be performed when they are perfectly dry, and afterwards they should be dried in a kiln, with a moderate fire, in the same manner as the true saffron, which will prepare them for use. If the plants be intended to seed, the plants should not be gathered; for if the florets be cut off, it will render the seeds abortive, though they may swell and grow to their usual size, for when they are broken they will prove to be a shell without a kernel; this is frequently the case in wet cold seasons; and in very wet ones the germen will rot, and never come so forward as to form a shell. The good quality of the carthamus consists chiefly in the colour, which should be a bright saffron, in which that cultivated in England often fails; for if there happen much rain while the plant is in flower, it will change the florets to a dark or dirty yellow, and also that which is gathered when there is any moisture remaining upon it; great care therefore must be taken not to gather it till the dew is dried off, nor should it be pressed together till it has been dried on the kiln; for which, see the genus Crocus. Great quantities of this plant are annually imported into England for dyeing and painting, from the Levant, where, as well as in many parts of Europe, it is at present cultivated. The Spaniards retain this plant in their gardens, to colour their soups, olios, and other dishes, in the same manner as the marigold in England. The Jews also are very partial to it, and mix it in most of their viands, and probably were the first importers of the seed into America, and taught the inhabitants the use of it, for it is now as commonly used by the English there as in any part of Europe. The plant itself may be admitted to have a place in the borders of large gardens, where it will add to the variety during the time of its continuance in flower, which is commonly two months or ten weeks; for if the seeds be sown in the beginning of April, the first flowers will at least appear by the middle of July, and there will be a succession of flowers on the side-branches till the end of September, and in mild warm seasons till the middle of October, during which time the plants will not be destitute of flowers, which being of a bright saffron colour, make a pretty appearance; and if the plants be supported, to prevent their being broken or blown down by the wind, they will not interfere with the other flowers, because they have a regular upright growth.

 Carthanus Lanatus; Yellow Distaff Thistle, or Woolly Carthaneus. Sten hairs, woolly towards the top; lower leaves pinnatifid, upper stem-clasping, toothed; the florets are first golden, then saffron-coloured, with the edges of the

segments black, and five black lines running down the co- | filled with light sandy earth, which are to be plunged into a rolla .- It grows naturally in the south of France, Spain, and Italy, where the women use the stalks for distaffs, whence it derived the title of distaff thistle; some call it bastard wild saffron : the leaves are sometimes prescribed as a medicine, and are supposed to have the same virtues as carduus benedictus: it flowers in June and July, and ripens seed in autumn; if the seeds be sown in autumn, the plants will flower early the following summer, so that there will be a certainty of good seeds; they may be sown in any situation, and require no other culture but weeding and thinning when too close together. There is a variety of this species, which grows much taller; the heads also are larger, and the leaves are placed closer upon the stalks. It was found by Tournefort in the Levant.

3. Carthamus Creticus; Cretan Carthamus, Stem somewhat glossy; calices a little woolly; floscules about nine; lower leaves lyrate .-- This is an annual plant, growing nearly four feet high; it differs from the foregoing in having a smooth stalk; the leaves are very stiff, deeply indented, smooth, and armed with very strong spines; the heads of flowers are oval, and the florets white. Discovered in Candia by Tournefort. Cultivated in the same manner as the preceding species; which see.

4. Carthamus Tingitanus; Tangier Carthamus. Radical leaves pinnate ; stem-leaves pinnatifid ; stem one-flowered .-This species has a perennial root; the stalks rise about a foot and a half high, seldom putting out any branches; the stalk is terminated by one large scaly head of blue flowers. It is a native of Barbary, and was brought from Tangier : it is increased by parting the roots, the best time for which is in the beginning of March; it should have a dry soil and a warm situation, otherwise it will be liable to be destroyed in severe winters.

5. Carthamus Coruleus; Blue-flowered Carthamus, or Bastard Saffron. Leaves lanceolate, spiny, toothed; stem one or two-flowered .- This rises with a single stalk about two feet high, of a purplish colour, hairy and channelled, closely beset with broad spear-shaped leaves, sharply serrate, and covered with a short hairy down : it flowers in June and July, and the seeds ripen in autumn; it grows naturally in Spain, France, and Italy, on arable land ; it may be increased by parting the roots in autumn when the leaves decay; iu a light soil it will survive the cold of our winters, and last many years: it may also be propagated by seed, which ripen here in dry seasons.

6. Carthamus Nutissimus; Small Carthamus. Leaves unarmed, those next the root toothed, on the stem pinnate; root-leaves some lanceolate, dilated at the end and very smooth, from the middle to the end toothed, the teeth turned upwards, sharp, ending in a small thorn; flower bright blue. -Native of France, about Paris, and Montpellier.

7. Carthamus Carduncellus; Mountain Carthamus. Stemleaves linear, pinnate, the length of the plant; root perennial; stem, in gardens, about six inches high, channelled and hairy; each stalk is terminated by one large head of blue flowers .-Native of the south of France, Spain and Italy: the root is eaten in Africa. It is difficult to propagate this species in England, the roots not putting out offsets, and the seeds ripening only in warm dry seasons; it requires a dry soil and warm situation.

8. Carthamus Arborescens ; Tree Carthamus, Leaves ensiform, sinuate, toothed; the whole plant is pubescent; flowers terminal, sessile, yellow, sweet-smelling; down hairy. -Native of Andalusia; it is increased by the side-shoots slipped from the branches in the spring, and planted in pots 22.

moderate hot-bed, observing to shade them till they have taken root; they then must be gradually hardened, and removed into the open air, and when they have acquired strength, some may be planted in a warm dry border, where they will endure the cold of our ordinary winters; but in severe frosts they are frequently destroyed, and therefore a plant or two should be potted and sheltered in winter.

CAR

9. Carthamus Salicifolius; Willow-leaved Carthamus. Shrubby; petioles spiny; leaves lanceolate, entire, tomentose beneath, pungent at the end; branches one-flowered; branchlets oue-flowered ; florets white .-- Native of Madeira,

10. Carthamus Corymbosus; Corymbed Carthamus. Flowers corymbed, numerous; root perennial; stem single, white, smooth and channelled, never putting out any side branches; leaves long, narrow, pale green, closely armed on their edges with short stiff spines .- Native of Apulia, the Hellespont, Lemnos, and Thrace: it seldom perfects seeds in England, and is increased by parting the roots in the spring; in a light soil and warm situation it will endure common winters in the open air, but in severe frost it is sometimes destroyed.

Carum ; a genus of the class Pentandria, order Digynia .---GENERIC CHARACTER. Calix: umbel universal long; rays ten, frequently unequal; umbel partial, crowded; involucre universal, often monophyllous; partial none; perianth scarcely manifest. Corolla: universal uniform: florets of the disk abortive; proper unequal; petals five, unequal, obtuse, carinated, inflex, emarginate. Stamina : filamenta five, capillary, length of the corolla, caducous. Antheræ roundish, very small. Pistil: germen inferior; styles two, very small; stigmas simple. Pericarp: none; fruit ovate, oblong, striated, bipartile ; seeds two, convex on one side, ovateoblong, striated, flat on the other side. ESSENTIAL CHA-RACTER. Fruit : ovate-oblong, striated. Involucre : oneleafed. Petals: keeled, inflex, emarginate .---- The only known species is,

1. Carum Carui: Common Caraway. It is a biennial plant, has a taper root like a parsnep, but much smaller, running deep into the ground, sending out many small fibres, and having a strong aromatic taste.-It grows naturally in rich meadows, in Lincolnshire, in Yorkshire, near Hull, in Norfolk, near Cambridge, Bury, &c. and is cultivated in some counties, particularly Essex; it flowers in May and June, and the seeds ripen in autumn. Parkinson says, the young roots are better eating than parsneps; the tender leaves in the spring are boiled in soup; the seeds, it is well known, are much used in cakes, and incrusted with sugar for comfits; they are also distilled with spirituous liquors for their flavour: they were formerly recommended by Dioscorides for pale-faced girls; and it is said, that modern ladies have not despised his recommendation ; they are a good remedy in tertian agues, and abound with an essential oil which is antispasmodic and carminative. Lewis says, that about one ounce in thirty of essential oil arises from the seeds in distillation : this oil is of a bright yellow colour, hotter, and more pungent to the taste, than what is obtained from most other warm seeds, and is given from one to five drops as a carminative, and is supposed to be of peculiar efficacy in promoting urine; the herb affords a similar oil, but sixteen pounds of it, stripped from the stalks, scarcely yields an ounce; the seeds are the part commonly employed in medicine; they are of an agreeable aromatic smell, and a warm pungent taste; given in substance from a scruple to half a drachm, they dispel wind from the stomach, and greatly strengthen that organ: the seeds bruised, and made into a 2 X

262

poultice, will remove the marks occasioned by blows, falls, or bruises, and are good in hysteric fits. The best season for sowing the seeds of caraway is in autumn, soon after they are ripe, when they will more certainly grow than those sown in the spring; and the plants which rise in the autumn generally flower the following season, so that a summer's growth is hereby saved : when the plants come up the ground should he hoed to destroy the weeds, and where the plants are too close they must be thinned, in the same manner as is practised for carrots, leaving them three or four inches apart : in the following spring they will require to be twice more hoed, which will keep the ground clean till the seeds are ripe, then the stalks must be pulled up and tied in bundles, setting them upright to dry, when the seeds may be threshed out for use. The method of culture in Essex, where it has long been cultivated, is, about the beginning of March to plough some old pasture land, (if it have been pasture for a century, the better, especially if the soil be a strong clayey loam ;) twelve pounds of caraway seeds are mixed with ten of coriander, and twelve pounds of teasel-seed ; this is sufficient for one acre, and is sown directly after the plough, harrowing the land well: when the plants appear of sufficient strength to bear the hoe, which will not be till about ten weeks after sowing, it must not be omitted ; and in the course of the summer the crop will require three hoeings, besides one at Michaelmas, each costing about eight shillings an acre. The coriander being annual, will be fit to cut about the beginning of July, aud is reaped at four shillings the acre; it is left in the field after cutting, and threshed by day in a cloth, in the same manner as rape-seed : about April following, the caraway and teasel will want a good hocing, done deep and well, and another about the beginning of June, which hoeings are performed at the rate of seven shillings each per acre: the caraway will be fit to cut the beginning of July, and must be threshed in the same manner as the coriander; the teasel will not be ready till the middle of September: some of the plants of caraway and teasel do not perfect their seeds till the third or fourth year, though in general there is a crop the second year, yet enough is left for a crop the third year; and the seeds that are scattered from the crop the second year, often come to perfection in the fourth : and there are several instances of its being continued for seven years: the usual way, however, is to plough directly after the crop is gathered the third year, and to sow wheat, of which commonly a very good crop is obtained, the land being in fine order from the rotting of the turf, and repeated hoeings. The produce of caraway on the very rich old lays, in the hundreds or low lands of Essex, has often been twenty hundred-weight to the acre. There is always a demand for the seed in the London market, where it sometimes sells as low as twelve shillings the hundred-weight, and has been up to fifty shillings, but is mostly on an average at twenty-one shillings. The land can only be filled with plants; and the more one predominates, the less must reasonably be expected of the others. This compound crop is mostly sown on land so strong, as to require a little previous exhaustion to prepare it for corn. Caraway and coriander are oftenest sown without teasel, the latter being a troublesome and uncertain crop, and the produce of caraway much greater without it.

Caryorar; a genus of the class Polyandria, order Tetragraina-Gie RERIC CHARATCER. Calix : quinquepartile, A tincuter of cloves coloured; divisions obluse, concave, deciduous. Corolla: extracted from then petals five, oval, concave, large. Staamiars filamenta numenot often unsophisi rous, filtorun. A utherae oblong. Pisitil: germen globose; a lanost immunerable, alveles four; stigmas obtuse. Porieary: drupe floshy, spile. Caryota; a genus

rical, very large. Seed: nuts one to four, oval, triquetrous, reticulated with furrows, angulated with a suture on one side, ESSENTIAL CHARACTER. Calix: five-parted. Petals: five. Styles: usually four; drupe with four nuts, reticulated with furrows.—The only known species is:

1. Caryocar Nuciferum. A tall tree with ternate leaves; corolla purple; drupe the size of the human head; nuts esculent, having the taste of almonds.—Native of Berbice and Essequibo.

Cargophyllus; a genus of the class Polyandria, order Moongvnia.--GKNERIC GHARCTER. Colik: periath of the fruit superior, quadripartile, acute, small, permanent; perianth of the flower superior, tetraphyllous; leaflets roundish, concave, deciduous. Corolla: petals four, roundish, crenate, smaller than the calix of the flower. Stamina: filamenta numerous, capillary. Anthera simple. Pisitli germen inferior, oblog, large, terminated put calix of the fruit; style simple, inserted into the quadrangular receptacle; stigma simple. Pericarp: oval, unilocular, terminated by the hardened couverging calix of the fruit, umbilicate. Seed: four-petalled. Calix: four-leaved, duplicate. Berry: oneseeded, inferior.---The only known species is,

1. Caryophyllus Aromaticus; Clove Tree. According to Mr. Miller, this tree rises to the height of a common appletree, but the trunk generally divides at about four or five feet from the ground, into three or four large limbs, which grow erect, and are covered with a smooth thin bark, which adheres closely to the wood ; these limbs divide into many small branches, which form a sort of conical figure ; the leaves are like those of the bay-tree, and are placed opposite on the branches; the flowers are produced in loose bunches at the end of the branches; are small, white, and have a great number of stamina, which are much longer than the petals; they are succeeded by oval berries, which are crowned with the calix, divided into four parts, and spreading flat on the top of the fruit, which, when beaten from the trees before it is half grown, is the clove so commonly used all over Europe. The clove-tree is not confined to Banda and Amboyna, but is found in all the Moluccas, in many of the South Sea islands, New Guinea, and the neighbouring isles: it also grows wild in Cochin-china, where it has scarcely any smell or taste. There are no plants of this remarkable tree in either the English or Dutch gardens; indeed the Dutch have ever been particularly jealous lest other nations should share the spice trade with them, and will not suffer them to grow wild any where if they can prevent it. Captain Rofy told Dampier, that he was sent to the uninhabited islands on purpose to cut them down, and that he actually destroyed seven or eight hundred trees at different times. But notwithstanding the unremitting caution and watchfulness of Dutch avarice, the French, at Cayenne and elsewhere, have had this valuable tree for some time in their possession. It has been received into the British botanic garden in the island of St. Vincent, and was sent thence to Barbadoes in 1794 .---The clove is esteemed one of the hottest and most acrid substances of the aromatic class; and is often used, not only internally but externally, as a stimulant; as, for example, in paralytic cases, wherein the oil of cloves has been advautageously administered. It is often used in the tooth-ache, and frequently succeeds in suddenly subduing the pain. A tincture of cloves in rectified spirits, and an essential oil extracted from them, are kept in the shops, but the latter is not often unsophisticated : the culinary uses of cloves are

Caryota; a genus of the class Monœcia, order Polyandria.

CAS

-GENERIC CHARACTER. Male, Flowers. Calix: spathe universal, compound; spadix ramose. Corolla: tripartite; petals hancedate, cancave. Stamina: filamenta very numerous, almost longer than the corolla. Antheras linear. Female Flowers in the same spadix with the males. Calix: common with the males. Corolla: tripartite; petals acominate, very small. Pisiti! geneme roundish; style acuminate; stigma simple. Pericarp: herry roundish; style acuminate; two, large, oblong, roundish on one side, lat on the other. ESENTIAL CHARACTER. Male. Calix: common. Corolla: tripartite. Stamina: very many. Fenale. Calix: as in the male. Corolla: tripartite. Pisiti! one. Berry: dimenmous.— The species are,

1. Caryota Urens. Fronds bipinnate ; leaflets sessile ; berry two-seeded .- This palm becomes a lofty tree; the trunk is frequently so large as scarcely to be embraced by two men : it is covered with a sort of cinereous crust, which is quite smooth; the corolla, which is sometimes bipartite, but commonly tripartite, is at first green, then red or purple, and finally yellow; the fruit is a succulent globular berry, a little flatted, terminated by a triangular twin stigma; at first it is hard and green, next yellow, then red, and when quite ripe dark red, (almost black,) and shining; the rind is thin, and the pulp is soft and red, very sharp and acrid; within are two stones or seeds, (sometimes only one,) hard, roundish or oblong, convex on one side, flat on the other, wrinkled : they are of a dark red or blackish colour on the outside. The Cevionese know this tree by the name of kettule : it yields a sort of liquor, which they call tellogie, sweet and pleasing to the palate, wholesome, and not stronger than water ; it is taken from the tree twice, and sometimes thrice a day, and the quantity obtained is three or four gallons; they boil this liquor, and thus make a kind of brown sugar, called jaggory, of it; but if they manage it skilfully, can make it as white as the second-best sugar. When the tree is come to maturity, there comes out a bud from the top, which, if it be suffered to grow, will bear the fruit, but this is only fit to set for increase; this bud is cut and prepared, by putting salt, pepper, lemons, garlic, leaves, &c. upon it, which keep it from ripening : they then daily cut off a thin slice from the end, and the liquor drops into a vessel which they set to catch it. This tree bears a leaf like that of the betcl-nut tree, which is fastened to a skin as that is, only this skin is hard and stubborn like a piece of board; the skin is all full of strings as strong as wire, and is used for making ropes. While the tree grows, the leaves shed ; but when it is come to its full growth, they remain many years before they fall; as the top bud withers, other buds come out lower and lower every year, till they come to the bottom of the boughs, and then having done bearing, may stand seven or ten years, when it dies. The wood is not above three inches thick, very strong and hard, but apt to split; being very heavy, they make pestles of it to beat their rice with; the colour is black, but it looks as if it were composed of several pieces; the buds of this plant, like those of the cocoa and betel-nut tree, are excellently well tasted, resembling walnuts or almonds.

2. Caryota Nutis. Fronds bipinnate: petioles of the leaf-lest nodding: berries one-seeded.—The trunk of this palm is fifteen feet high, two inches thick, very straight and regular; the berry is round, coriaccous, smooth, black, the size of a musket-builet; containing one globular pale softish seed: it is not eatable, but does not occasion itching, as the other species does. It is a most heautiful palm, and grows in the woods of Cochin-china.

Cassia. See Osyris.

Cassada, or Cassava, See Jatropha,

Cassia ; a genus of the class Decandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth pentaphyllous, lax, concave, coloured, deciduous. Corolla: petals five, roundish, concave; the inferior ones more distant, more spreading, larger. Stamina : filamenta ten, declined ; the three inferior ones longer ; the three superior shorter. Antheræ, the three inferior very large, arcuate, rostrate, gaping at the tip ; the four lateral ones without the rostrum, gaping ; the three superior ones very small, sterile, Pistil: germen subcolumnar, long, peduncled; style very short; stigma obtuse, ascending. Pericarp : legume oblong ; partitions transverse; seeds many, roundish, affixed to the superior suture. ESSENTIAL CHARACTER. Calix : pentaphyllous ; petals five; the three superior antheræ sterile; the three inferior beaked ; legume .- Many of these plants are preserved in curious gardens, though several of them have little beauty to recommend them. The handsomest are the eighth, fourteenth, thirty-first, thirty-ninth, fortieth, and forty-first speeies; these all make a good appearance in the stove when in flower, and as they retain their leaves all the year, form an agreeable variety in winter. All the species contract their leaves every evening as the sun declines, and re-open them when he re-appears; the under surface of the leaflets is turned outward, the upper surfaces being clapped close together. Most plants whose under surface is thus turned outward, grow on dry sandy land, where the roots do not find a sufficient supply of moisture; the lower surface of the leaves being generally covered with a short soft down, detain and imbibe the nightly dews. Those which have the upper surface of the leaves turned outward, do not stand in need of this supply; and accordingly that surface being smooth, the moisture is cast off, and not imbibed. All the species of this genus are propagated by seeds, which, as they mostly come from very hot climates, must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, filled with light earth, and plunged into a moderate hot-bed, where they should be shaded until they have taken fresh root; after which they must have the air admitted to them every day, in proportion to the warmth of the season, and should be frequently watered. When the plants have filled the pots with their roots, they should be shifted into larger, and if they be too tall to remain in the hot-bed, they must be placed either in the stove, or in a glass-case, where they may be defended from cold, and have plenty of fresh air in warm weather: they will flower in July or August, and perfect their seeds in October, and may be preserved through the winter in a stove, where they will continue flowering a long time. In warm summers, they may be placed in the open air, where they will flower very well about the end of June, but will not perfect their seeds, unless they are removed into the stove in autumn .---- The species are,

1. Cassia Diphylla; *Two-leaved Cassia*. Leaves conjugate; stipules cordate-lanceolate.—A shrub with a round stem. Annual; native of the West Indies.

2. Cassia Bacillaris. Leaflets two pairs ovate, oblique, an obtuse gland between the lowest; racenes axillary, peduncled; silique round, long.—A shrub of twelve feet in height, and very smooth. Native of Surinam.

 Čassia Absus; Four-leaved Cassia. Leaflets two pairs obovate; glands two, subulate beneath the lowest.—A hairy plaut, with a slender striated stem. Annual; native of India, Cevion, and Egypt.

4. Cassia Viminea ; Weakly Senna Shrub, or Twiggy Cassia. Leaflets two pairs, ovate, oblong, acuminate, an oblong gland between the lowest ; spines subpetioled, obsolete, three-

CAS

toothed; stem shrubby, climbing to the height of forty or tive, opening the passages without irritating the intestines fifty feet, striated, stiff; branches divaricate, loose, stiffish, round, striated, smooth ; flowers large, on peduneles longer than themselves .- Native of Jamaica, in the woods of the higher mountains in the interior of that island ; it is also called atao or attoo. Half a pint of the decoction of the root, taken three or four times daily, is prescribed as a cure for the dry belly-ache; ground into a paste, and plastered over the body, it cures the head and fevers.

5. Cassia Tagera. Leaflets three pairs; gland petiolar; stipules ciliated, cordate, acuminate.---A small procumbent shrub, with filiform branches. Native of India.

6. Cassia Tora; Oval-leaved Cassia, or Wild Senna. Leaflets three pairs, obovate; the outer ones larger, a subulate gland between the lower : stem erect, less woody, roughish, knotty from the scars of the leaves : flowers pale vellow .-- Native of the East Indies, Japan, and Cochin-china. Annual; the leaves are substituted for senna, in the natural place of its growth.

7. Cassia Bicapsularis ; Six-leaved Cassia. Leaflets three pairs, obovate, smooth, the interior ones rounder and less, a globular gland interposed .- It is perennial, and grows naturally in Jamaica, and the other sugar islands, and also in the island of Madeira.

8. Cassia Emarginata. Leaflets three or four pairs, obovate, almost entire; flowers in racemes, irregular; stem arboreous; height from one to two feet .--- Native of Jamaica. It must be plunged into the tan-bed, and watered very sparingly in winter.

9. Cassia Obtusifolia ; Round-leaved Cassia. Leaflets three pairs, obovate, blunt .-- Native of America.

10. Cassia Falcata; Sickle-leaved Cassia. Leaflets four pairs, ovate-lanceolate, back-sickled; a gland at the base of the petioles; stem crect, roundish, obtusely grooved; branches scarcely pubescent. Perennial; native of America.

11. Cassia Longisiliqua; Long-podded Cassia. Leaflets four pairs, the outmost lanceolate, a subulate gland below the inmost and between the outmost .-- Native of America ; and perennial.

12. Cassia Occidentalis; Occidental Cassia. Leaflets five pairs, ovate-lanceolate, scabrous about the edge, the outer ones larger, a gland at the base of the petioles; stem a foot and a half high; flowers pale yellow without any spot .-- It is very common about Kingston in Jamaica, and is there called *stinking weed*. The tops of it are commonly employed in all resolutive baths; and it is accounted a very powerful ingredient on such occasions. According to Dr. Barham, the whole plant is cooling and cleansing, and the decoction of the root diuretic, and a powerful antidote against poison. An infusion of it in water, with juice of tansy, and a small quantity of garlic, is a good vermifuge.

13. Cassia Planisiliqua. Leaflets five pairs, ovate-lanceolate, smooth; a gland at the base of the petioles .- Native of South America.

14. Cassia Fistula: Alexandrian Purging Cassia, Cassia Stick, or Pudding Pipe-tree. Leaflets five pairs, ovate, acuminate, smooth ; petioles without glands .- This tree rises to the height of forty or fifty feet, with a large trunk, dividing into many branches; the flowers are produced in long spikes at the end of the branches, each standing upon a pretty long peduncle; they are of a deep yellow colour, and are succeeded by cylindric pods, from one to two feet long, having a dark brown woody shell, with a longitudinal seam on one side, divided into many cells by transverse partitions, each containing one or two oval smooth compressed seeds, lodged in a sweetish black pulp; this pulp is an easy gentle laxa-

but it grows rancid when it has been long out of the cells. and then acquires an acrimony that renders it precarious, and even dangerous. Native of both Indies: the seeds may be procured from the druggists, who import the pods for use; these must be sown upon a hot-bed, and treated as above directed.

15. Cassia Atomaria. Leaflets five pairs, ovate, subtomentose; petioles round, without glands; stem the height of a man, woody, ash coloured, very branching .- Observed by Jacquin in America.

16. Cassia Pilosa. Leaflets four or five pairs, with very minute glands; stipules semicordate, acuminate; stem stiff. hairy : stem from one to two feet high .-- Native of Jamaica : flowering toward the end of the year.

17. Cassia Senna ; Egyptian Cassia, or Senna. Leaflets four to six pairs, subovate; petioles without glands .- The plant which produces the leaves commonly known in medicine by the name of senna, is annual, and rises with an upright branching stalk about a foot high; the flowers are yellow. and produced in loose bunches at the top of the stalk; it grows naturally in Persia, Syria, and Arabia, whence the leaves are brought, dried and picked from the stalk, to Alexandria in Egypt, and being thence imported into Europe. acquires the additional title of Alexandrina. Senna is one of the most gentle purgatives in the materia medica; for this purpose it is used in infusion, and is not unfrequently mixed with other substances, as manna, &c. it operates without violence, and is sufficiently efficacious, but is sometimes apt to excite tormina, and has the disadvantage of being nauseous to the taste. But to remedy this inconvenience, compositions of various kinds are prepared in the shops; thus, for example, six drachms of tamarinds, and two of crystals of tartar, are boiled in a pint and half of water till a pint is exhaled, and the strained liquor poured boiling hot upon one, two, or three grains of senna; after maceration for four hours, the strained infusion is sweetened with an ounce of syrup of violets, and flavoured with half an ounce of simple cinnamonwater: or, three drachms of senna are infused in a quarter of a pint of boiling water for four hours, or till the liquor has grown cold, with the addition of a scruple of ginger ; or with half a drachm of lesser cardamom seeds husked, and threefourths of a drachm of crystals of tartar, which last are previously boiled in the water till dissolved; or with two drachms of fresh lemon-peel, and the same quantity by measure of lemon-juice : the latter, which is the infusum sennæ limoniatum, is considered the most agreeable form in which the infusion of senna can be conveyed. Meyrick and Hill observe, that the dried leaves of this plant are imported by our druggists from the East, and that they are a moderately strong and safe purgative; they may be taken wherever catharties are necessary, either in substance reduced to powder, or in a strong infusion, but it will be advisable to add a little of some warm aromatic to the dose, as they are otherwise apt to gripe during the operation. It requires the same treatment as the other sorts ; but being an annual plant, unless it is brought forward in the spring, it will not flower: it must therefore be kept constantly in the hot-bed all the summer. admitting plenty of air to it in warm weather : it rarely perfects its seed in England.

18. Cassia Biflora; Two-flowered Cassia, Leaflets six pairs, rather oblong, smooth ; the lower ones smaller, a subulate glaud between the lowest; pedicels two-flowered; flowers yellow; pods linear, compressed .-- Native of the West Indies.

19. Cassia Ruscifolia. Leaflets six pairs, lanceolate, acute,

smooth, a gland above the base of the rib; flowers racemed. —This is an elegant shrub, the height of a man; gathered upon the rocks of Madeira.

20. Cassia Hirsuta. Leaflets six pairs, broad, ovate, acuminate, woolly.-Native of America.

21. Cassia Multiglandulosa; *Glandulous Cassia*. Leaflets six pairs, villose beneath and about the edges, obtuse; a gland between each pair of leaflets.—Brought from Tenerifle to England, where it flowers most part of the summer.

22. Cassia Tomentosa. Leaflets six or rejett pairs, linear, obliquely rounded at the base, rough with hairs on the upper surface; panicles axillary; legumes villose—This is a tree with round flexonse branches, covered with a thick soft whree pile, which is yellow when they are dry. Found in South America by Mutis.

23. Cassia Serpens. Leaflets seven pairs; flowers pentandrous; stems filiform, prostrate, herbaceous,—This is an annual plant, native of Jamaica, where it is found in dry pastures, creeping among the grass.

24. Cassin Ligustrim, Privet-leaved Cassia. Leaflets seven pairs, hancolate, the outmost smaller; a gland at the base of the petioles; stem six or seven feet high or more, the thickness of the little finger, slightly angular, putting forth many deeply striated branches from top to bottom; flowers many, terminating, yellow; the leaves and flowers have somewhat of a faotid small.—Native of the isle of Providence, and other islands in the West Indies.

25. Cassia Alata; Broad-leared Cassia. Leaflets eight pairs, oral-oblong, the lowest smaller; petioles without glands; stipules spreading; stem subherbaceous, six feet high and more, branched, upright, furrowed, smooth, with simple striated branches, --I lives but a few years, though it puts out the appearance of a shrub in its growth; and when cultivated, rises sometimes to the height of seven or eight feet, but seldom exceeds four in its native soil. Auts are very fond of the flowers: the juice of the leaves or buds is said to cure the ring-worm, whence it is called the ring-worm wild, also call it *lerbe à dartres*. It flowers in the spring; and, according to Mr. Miller, has a strong fortid dour.

26. Cassia Marilandica ; Maryland Cassia. Leaflets eight pairs, oxate-oblong, equal ; a gland at the base of the petioles; root perennial; calix pale or greenish yellow.—Native of North America. It will live io the open ari, if plauted in a warm border and dry soil; the seeds will come up in the full ground, if sown in April, and in autumn the plants may be removed into the borders where they are designed to remain.

27. Cassia Tenuissima. Leaflets nine pairs, oblong, a subulate gland between the lowest.-Native of the Havanna.

28. Cassia Sophera. Leaflets ten pairs, lanceolate; an oblong gland at the base; corolla very pale yellow with brown veins.—Native of the East Indies, China, and the island of Tongataboo in the South Seas.

29. Cassia Bracteata. Leaflets ten pairs, oblong, obtuse, without glands; racemes elongated; bractes ovate, swelling, imbricate; legume quadrangular, compressed; corollas yellow. --Found at Surinam by Dalberg.

30. Cassia Auriculata; Eared Cassia. Leaflets twelve pairs, obtuse, mucronate; several subulate glands; stipules kiduey-form, bearded.—Native of the East Indies.

31. Cassia Javanica; Java Cassia. Leaftets trevler pairs, oblog, obtuse, smooth; no gland,.....This rises to a great magnitude, with a large trunk dividing into many branches; the seeds are surrounded with a black purging pulp; this is called horse-cassia, because it is generally given to horses, 23.

but is seldom used by the human species, on account of its griping quality. Native of the East Indies.

CAS

32. Cassia Grandis. Leaflets twenty pairs, somewhat silky, without glands.—This is a stout tree, and the branches are covered with a purple silky down.—Native of Surinam.

33. Cassia Chamecrista: Ducarf Cassia. Leafter many pairs; a petiodar pedicelled gland; stipules ensiform; stem herbaccous, a foot high or more, diffused, smooth, round, with hirstet branches; corolla small, yellow; legume compressed.—Annual: native of dry pastures in the West Indies. Dr. Wright says, that two quarts of a decoction of this plant, taken daily, is an antidote to the poison of nightshade.

34. Cassia Glandulosa. Leaflets many pairs, with many glands; stipules subulate; stems suffruticose, with almost naked branches.—Native of the West Indies.

35. Cassia Mimosoides. Leaflets many pairs, linear; an obscure gland at the base of the petioles; stipules setaceous. —Native of the island of Ceylon.

36. Cassia Flexuosa. Leaflets many pairs; stipules halfcordate — This is an annual plant, and native of Brazil.

37. Cassia Nictitans. Leaflets many pairs; flowers pentandrous; stem somewhat erect.—Annual; and a native of Virginia.

38. Cassia Procumbens. Leaflets many pairs, without glands; stem procumbent,—An annual plant, and native of both Indies, Cochin-china, Africa, and Virginia.

30. Cassia Fruitcosa. Leafleti two pairs, ovate-lancedate, smooth; flowers terminal; pods long, round; stem shrubby, — This grows upwards of twenty feet high, will several stems covered with brown bark, and dividing into many branches at top; the flowers are produced in loses splices at the extremity of the branches; they are large, of a gold colour, and succeeded by layer brown pods about mine inches long, having many transverse partitions, in which the seeds are lodged in a thin pulpe.—Native of La Vera Cruz.

41. Cassia Villosa. Leaflets three pairs, oblong-ovate, equal, villose; pods jointed; stem erect, arboreous.—This rises with a woody stem to the height of fourteen or sixteen feet, sending out many lateral branches. Native of Campeachy.

42. Cassia Uniflora. Leaflets three pairs, ovate, acuminate, villose; flowers solitary, axillary; pods erect.—Annual; and a native of Campeachy.

43. Cassia Frutescens. Leaflets five pairs, ovate, smooth, the outer ones longer; stems shrubby .-- Native of Jamaica.

44. Cassia Tetraphylla. Leaflets two pairs, ovate; flowers solitary, axillary; siliques hirsute; stems procumbent.—Native of La Vera Cruz.

45. Cassia Minima. Leaflets four pairs, oblong-ovate; stems procumbent; flowers axillary; peduncles two-flowered. ---Native of Jamaica.

46. Cassia Patula; Shining Cassia. Leaflets five pairs, obloug, sharpish, smooth; a gland at the base of the petioles; branches even.—It flowers in August and September. Native of the West Indies.

47. Cassia Stipulacea; Large Stipuled Cassia. Leaflets about eight pairs, ovate-lanceolate; a gland between the lower; stipules ovate, very large.—Native of Chili.

48. Cassia Frondosa; *Smooth-leaved Cassia*. Leaflets nine pairs, oval-oblong, smooth, bluntish, a cylindric gland between the lower; petiole without any gland at the base.—It flowers in March and April. Native of the West Indies.

3 Y

CAS

49. Cassia Sericea. Leaflets about four pairs, ovate, hirsute; a subulate gland between the leaflets; peduncles fourflowered; legumes four-cornered.---Native of Jamaica.

50. Cassia Lineata. Leaflets five pairs, somewhat oblong, pubescent beneath, equal; an obsolete gland beneath the lowest; peduncles one-flowered.—Native of Jamaica.

51. Cassia Virgata. Leaflets ten pairs, ovate-lanceolate, villose, a petiolar pedicelled gland; peduncles one flowered, longer than the leaves.---Native of Jamaica.

Cassine: a genus of the class Pentandria, order Monogynia.--GENERIC CHARACTER. Calit: perianth quinquepartite, inferior, very small, obtuse, permanent. Corolla: quinquepartite, spreading; divisions subovate, obtuse, larger than the calits. Stanina: Alimenta five, subulate, spreading. Anthere simple. Pistil: germen superior, conic; style none; stigmas three, reliex, obtuse. Pericarp: berry roundish, trilocular, umbilicated with the stigmas. Seeds: solitary, subovate. ESSENTIAL CHARACTER. Calit: quinquepartite. Petals: five; berry trispermous.----The species are,

1. Cassine Capensis; Cape Cassine, or Phillpria. Leaves petioled, ovarie-coblong, returne, crenate.—It has a woody stalk, which seldom rises above five or six feet high in this country. Native of the Cape of Good Hope. It is too tender to live abroad in England, but as it requires no artificial heat, may be preserved throughout the winter in a good green-house, where it deserves a place for the beauty of its leaves: it may be propagated by laying down those shoots which are near the root, but they are long in putting out roots; to facilitate this, the shoots should be twisted in the part which is laid; they should be laid in attum, as they will then put out roots sufficient to remove in the following autumn; they may labo propagated by cuttings, but this is a tedioans method, as they are seldom rooted enough to transplant in less than two years.

2. Cassine Pergana. Leaves petioled, serrate, elliptic, somewhat acute; branchlets ancipital.—Native of the Cape of Good Hope. It is propagated by laying down the branches, which afford shoots in plenty for that purpose from the root and lower part of the stem, so as to become very bushy and thick if they are not cut off; there are numbers of those shrubs which produce flowers in England every year, but none of them ripen their seeds; the leaves are frequently pinched by the frost in March, when they appear so soon; it loves a light soil, not too dry, and should have a warm situation; for in exposed places, the young shouts are frequently slitle in the winter, whereby the shrubs are rendered unsightly; but where they are near the shelter of trees or walls, they are very rarely hurt.

3. Cassine Barbara. Leaves sessile, serrate-toothed, cordate, oblong; branchlets quadrangular.-Native of the Cape of Good Hope.

4. Cassine Maurocenia; Great Hottanto Cherry. Leaves sessile, quite entire, obovate, coriaccous.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the first species. It ripens its fruit in the winter, and having remarkably stiff and fine green leaves, makes a good appearance when the leaves and fruit abound. Constructions Sea View.

Cassioberry. See Viburnum.

Cassyla ; a genus of the class Enneandria, order Monogynia. – G SNEBIC C MARACTER. Calitz perianth triphyllous, very small, permanent ; leaflets semi-ovate, acute, concave, erect. Corolla ; petials three, roundish, acute, concave, permanent ; nectury of three glands, oblong, runcate, coloured, length of the germen, standing round it. Stamina: filamenta nine, erect, compressed; two globular glands seated

on the sides of the base of the three interior filamenta. Antheræ adjoined to the filamenta below the tip. Pistil: germen ovate, within the corolla and calix; style thickish, length of the stamina; stigma obscurely trifid, obtuse. Pericarn : receptacle growing out into a depressed globular drupe, crowned with the converging calix and corolla, perforated with a navel. Seed: nut globular, acuminate, with the converging stamina. ESSENTIAL CHARACTER. Corolla: calycine, sexpartite; nectary of three truncate glands, surrounding the receptacle ; interior filamenta glanduliferous; drupe monospermous. These plants are easily propagated by planting cuttings of them during the summer months, but as these cuttings are succulent, it will be proper to cut them off a week before they are planted, laying them in the stove, that the part cut may have time to heal over before they are planted: these cuttings should be planted in small pots, which must be plunged into a moderate hot-bed, where, if they are not over watered, they will take root in six weeks; then they may be parted, planting each into a separate small pot filled with light sandy earth, and may be plunged again into the hot-bed, to forward their taking new root; after which they should be removed into a dry stove, where they should constantly remain, giving but little water in winter, and in summer admitting a large share of air in warm weather, for these plants are too tender to thrive in the open air in this climate. -The species are,

 Cassyta Filiformis. Filiform, lax.—This plant grows naturally in both Indies: Jacquin found it in the island of Tierra Bomba near Carthagena; it also occurs in the Society and Friendly islands.

2. Cassyla Coniculata. Branches woody, spinous.--Native of the monntains of the island of Celebes, among rotten trunks of trees, and of Java.

Castanea. See Fagus.

Castilleia; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: one-leafed, tubular, longitudinally cloven in front beyond the middle. nerved, pubescent, coloured, somewhat swelling at the base, compressed at top; upper lip bifid, obtuse; lower none. Corolla: monopetalous, ringent; upper lip very long, curved inwards, emarginate, pubescent on the back; lower very short, trifid, with acute segments. Nectary two glandular corpuscles, inserted into the throat of the corolla, between the divisions of the upper lip. Stamina : filamenta four, inserted into the base of the corolla, the length of the upper lip, filiform, smooth; the lower pair a little shorter. Antheræ twin, linear, oblique. Pistil : germen superior, oblong, compressed; style filiform, the length of the stamina; stigma simple, obtuse. Pericarp : capsule ovate, acuminate, compressed, even, two-celled, the partition contrary to the valves. Seeds : numerous, small. ESSENTIAL CHARACTER. Calix : tubular, compressed; upper lip bifid; lower none. Corolla: lower lip trifid, with two glands between the segments; capsule two-celled .---- The species are,

1. Castilleia Fissifolia. Leaves pinnate, gashed at the tip; root branched, fibrous.-Found in New Granada by Mutis.

 Castilleia Integrifolia. Leaves linear lanceolate, entire; stem herbaceous, round, upright, branched, leafy, slightly rough with hairs.—Also discovered by Mutis in New Granada.

Casuarina; a genus of the class Monecia, order Monandria — GENERIC CLARACTER. Moles in offljorn ament. Caliz; common ament loosely imbricate, consisting of small one-flowered one-leafed scales. Coroliz scales two-parted, ovate, minute. Slamina: filamenta capillary, longer than the calix. Anthera twin. Franks on the same plant.

bricate scales. Corolla : none. Pistil: germen minute; style filiform, longer than the calix, bifid; stigmas two. Pericarp: strobile of bivalve scales, gaping perpendicularly. Seeds: solitary, conic, with a membranaceous edge. Es-SENTIAL CHARACTER. Male, Calix: of the ament. Corolla : scalelets two-parted. Female, Calix : of the ament. Corolla: none; style bifid. Strobile .---- The species are,

1. Casuarina Equisetifolia; Horse-tail Casuarina. Moncecous; whorls of the stamina approximating .--- A very large, spreading, and lofty tree; the leaves, or rather branchlets, so called, hanging down in bunches from twelve to eighteen inches in length, like a long head of hair, or a horse's tail, all jointed from top to bottom, like the equiseta or horse's tails, is a very remarkable character of this singular tree. It is a native of the East Indies, and the South Sea islands, and flowers in October and November.

2. Casuarina Nodiflora. Monœcous; whorls of the stamina remote; a lofty tree; the branches and branchlets more deeply striated .- Native of the East Indies and New Caledonia.

3. Casuarina Stricta; Upright Casuarina. Diœcous ; branchlets erect; scales of the strobiles unarmed, smoothish; male sheaths multifid, smooth .- A native of New South Wales.

4. Casuarina Torulosa: Cork barked Casuarina. Dicecous; branchlets flaccid; scales of the strobiles villose, roughened with tubercles; male sheaths quadrifid .-- Native of New South Wales.

5. Casuarina Africana. Fronds filiform, swelling at the tip, and floriferous; strobiles roundish, axillary .- This is a tree above the middle size, with few long diffused branches, and leaf-bearing reclining branchlets; the wood is very hard and heavy. Native of the sandy east coast of Africa.

Catananche ; a genus of the class Syngenesia, order Polygamia Equalis .- GENERIC CHARACTER. Calix: common. imbricate, turbinate; leaflets very many, loosely incumbent, acute, scariose; the squamule ovate, acuminate, concave, lax, glossy, permanent, Corolla: compound, generally imbricate, uniform; corollets hermaphrodite, very many, the exterior ones longer. Proper : monopetalous, ligulate, linear, truncate, five-toothed. Stamina: filamenta five, capillary, very short. Antheræ cyfindric, tubular. Pistil : germen oblong; style filiform, length of the stamina; stigma bifid, reflex. Pericarp: none. Calix: unchanged. Seeds: solitary, turbinate, ovate; down from a five-awned calicle. Receptacle : chaffy. ESSENTIAL CHARACTER. Receptacle : chaffy. Calix : imbricate, Down : awned from a fivebristled calicle .---- The species are,

1. Catananche Cœrulea. The lower scales of the calix ovate .-- The stalks rise nearly two feet high, dividing into many small branches upwards; each of the peduncles are terminated with single heads of flowers, having a dry, silvery, scaly calix, in which are included three or four florets, whose petals are broad, flat, and indented at their ends ; these are of a fine blue colour, having a dark spot at bottom; and in each the stamina with their yellow summits, standing a little above the petal, make a pretty appearance .- It is perennial; a native of the south of Europe, and flowers from July till October. It may be propagated by heads taken off the mother plant, either in spring or autumn; but those plants which are raised from seeds are much stronger than those which are raised from slips: they are commonly planted in pots filled with light sandy soil, in order to shelter them in the winter from severe frosts; but if they are planted in warm borders, near walls, pales, or hedges, in a moderately dry the tan should be turned over to the bottom, and, if neces-

Calix : ament ovate, cylindric, with ovate, acute, keeled, im- | soil, they will endure abroad very well ; it may also be propagated by seeds sown in March.

2. Catananche Lutea. The lower scales of the calix lanceolate; "the flowers are small; the leaves green, flexile, and three-nerved ; the latter flowers are sessile at the root, hardly unfolded, but more fertile .- Native of the island of Candia; it flowers in June and July. It is an annual plant, and therefore only propagated by seeds, which ripen very well in England: the time for sowing them is early in March, in beds or borders of light earth, where they are to remain, which will come up in a month or five weeks' time, and require no other care but to keep them clean from weeds, and thin them when they grow too close together.

3. Catananche Græca. Leaves gashed .-- Native of the south of France, Spain, Italy, and Candia, from whence it derived the title of Candia lion's foot.

Catchfly. See Lychnis.

Caterpillar. See Scorpiurus.

Catesbaa; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fourtoothed, superior, very small, acute, permanent. Corolla: monopetalous, funnel-form ; tube extremely long, straight, gradually widening upwards; border semiquadrifid, broad, erect, flat. Stamina: filamenta four, growing within the neck of the tube. Antheræ oblong, erect, almost longer than the corolla. *Pistil*: germen roundish, inferior; style filiform, length of the corolla; stigma simple. *Pericarp*: berry oval, crowned, unilocular. Seeds: many, angulate. ESSENTIAL CHARACTER. Corolla: monopetalous, funnelform, extremely long, superior. Stamina : within the mouth; berry polyspermous. As these plants grow slowly, they will not require to be removed out of the seed-pots the first year : in the autumn the pots should be removed into the stove, and plunged into the tan-bed; they must be watered with great caution during the winter, and should be carefully taken up in spring, and separately planted in a small pot filled with light sandy earth, and plunged into a fresh hot-bed of tanner's bark, where they should be shaded until they have taken fresh root, and gently refreshed with water as they may require it : in warm weather a considerable share of fresh air should be admitted to them, but in autumn they must be removed into the stove, where they should constantly remain, and must be treated afterwards in the same manner as other tender exotic plants .---- The species are,

1. Catesbeea Spinosa; Lily Thorn. Tube of the corolla very long; berries oval .- Discovered near Nassau Town in Providence, one of the Bahama islands. Mr. Catesby says, that the largest of the trees which he saw was about four inches thick, and twelve or fourteen in height; the bark smooth, of a greenish russet colour, and the wood seemingly tough and hard; the leaves, like those of box, but smaller, growing in clusters at intervals of about an inch; from every cluster two sharp pliant spines shooting out; the flowers are about six inches long, in form of a Roman trumpet, except that they are divided at the verge into four deep segments, usually reflex; the fruit is the size of a pullet's egg; the pulp like that of a ripe apple, with an agreeable tartness, and a smooth vellow skin. This shrub is propagated by seeds, which must be procured from the country where it naturally grows; if the entire fruit be brought over in sand, the seeds will be better preserved; and must be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark, and now and then moderately watered; if the seeds be good, the plant will appear in about six weeks after sowing, when, if the heat of the bed declines,

sary, some fresh added to renew the heat, for these plants make but little progress the first year.

2. Catesbea Parviflora. Tube of the corolla four-cornered, abbreviated; berries roundish. Native of Jamaica .- This plant may be propagated by planting cuttings in small pots, filled with light earth, during the months of June and July; the pots should be plunged into a moderate hot-bed of tanner's bark, and the cuttings closely covered with small bellglasses, to exclude the external air. If this be properly performed, the cuttings will put out roots in about two or three months, when they may be carefully separated, planting each into a small pot filled with light earth, and plunged into the hot-bed again, and must afterwards be treated as the seedling plants.

Caturus ; a genus of the class Diœcia, order Triandria. -GENERIC CHARACTER. Male. Calix: none. Corolla: monopetalous, tubular, semitrifid ; divisions ovate, concave, acute, permanent. Stamina: filamenta three, capillary, longer than the corolla. Antheræ roundish. Female, Calix: perianth tripartite ; leaflets ovate, flat, permanent. Corolla: none. Pistil : germen villose; styles three, long, pinnatemultifid ; stigmas acute. Pericarp : capsule roundish, tricoccous, trilocular. Seeds : solitary, round .---- The species are,

1. Caturus Spiciflorus. Spikes axillary, pendulous. This is a tree about twenty feet in height, with many branches diffused all round; the wood is white and close, with a thick, dusky, unctuous, inodorous bark, and a yellow pith within. -Native of the East Indies: where a conserve of the flowers is used in the diarrhea, and all disorders arising from a laxity of the vessels,

2. Caturus Scandens. Spikes axillary, upright; lcaves oblong, subserrate; stem scandent. This is an armed shrub, with a long branching stem, climbing, but without tendrils. Flowers very small, white, in close short spikes, with small subulate bractes. The male flower has three petals, and three filamenta longer than the petals, both diverging elastically .--Native of the woods of Cochin-china.

Caucalis : a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix : umbel universal, unequal, with very few rays; umbel partial, unequal, with more copious rays, of which the five exterior are longer. Involucre universal: with leaflets of the number of the rays, undivided, lanceolate, mcmbranaceous at the edge, ovate, short. Involucre partial : with consimilar leaflets, longer than the rays, often five. Perianth proper five-toothed, protruded. Corolla: universal difform, radiate. Disk-florets abortive ; proper one male, small. Petals five, inflected, cordate, unequal, the exterior one very large, bifid. Stamina : in all the flowers. Filamenta five, capillary; antheræ small. Pistil : germen of the ray oblong, rugged, inferior. . Styles two, subulate : stigmas two, spreading, obtuse. Pericarp : fruit ovate, oblong, with longitudinal streaks, hispid with little rigid bristles. Seeds : two, oblong, convex on one side, armed in the direction of the streaks with subulate points, flat on the other side, ESSENTIAL CHARACTER. Corolla: radiated in the disk. male. Petals: inflex, emarginate. Fruit hispid, with bristles. Involucres entire .- These plants are all annual, or at most biennial, and are seldom cultivated except in botanic gardens. They will rise readily from seeds, where they are permitted to scatter; or if any person be desirous of raising them, the seeds should be sown in autumn, or soon after they are ripe. They will grow in any soil or situation,----The species are,

1. Caucalis Grandiflora; Great-flowered Bastard Parsley. Each involucre five-leaved, one leaflet double the size of the rest; stem very smooth and even, two feet in height. and branched .- Native of the south of Europe.

2. Caucalis Daucoides; Carrot-leaved Bastard Parsley. Umbels trifid, leafless; umbellules three-seeded, three-leaved : stem a foot high, upright, angular-grooved, branched, and even ; the joints white with bristles .-- Native of the south of Europe.

3. Caucalis Latifolia ; Broad-leaved Bastard Parsley. Involucres and involucrets membranaceous; universal umbel with about four rays ; bristles of the seeds clustered and hispid; leaves pinnate, gashed, and hairy. This is the most beautiful of our native umbelliferous plants : stem from a foot to eighteen inches, or sometimes nearly two feet in height, branched, angular, set with short prickles pointing upwards. Corolla purplish; the outer petal large, the rest small .-- Native of Germany, Switzerland, Italy, France, and England. It is one of our rare plants, and has been observed in Cambridgeshire and Hampshire, in corn-fields, flowering from June to August.

4. Caucalis Mauritanica; Barbary Bastard Parsley. Universal involucre one-leafed, partial involucres three-leafed. -Native of Barbary.

5. Caucalis Orientalis; Eastern Bastard Parsley, Umbels spreading, partial; leaflets superdecompound, laciniated; small divisions linear; stem herbaceons, round, straight, streaked, branching, three feet high .- Native of the Levant and China.

6. Caucalis Leptophylla ; Fine-leaved Bastard Parsley. Universal involucre scarcely any; umbel bifid; involucrets fiveleaved; stem low, round, rugged backwards .- Native of the south of Europe, and of England, in corn-fields, and by waysides, in Cambridgeshire, Lincolushire, Norfolk, &c. flowering in June and July.

7. Caucalis Arvensis; Corn Bastard Parsley. Universal involucre scarcely any; seeds ovate; styles reflex; leaves decompound, outmost leaflet linear lanceolate ; stem branching very much; common in England, and growing wild in Switzerland.

8. Caucalis Anthriscus; Hedge Bastard Parsley. Involucres many-leaved ; seeds ovate ; styles reflex ; leaves decompound, outmost leaflet linear lanceolate; stem from four to six feet high, upright, somewhat flexuose, round, purplish, rough, covered with minute white rigid bristles, pressed downwards to the stem, and scarcely visible .- Dr. Withering says, that horses are fond of it. It is common in hedges and bushes, flowering in July and August.

9. Caucalis Nodosa ; Knotted Bastard Parsley. Umbels simple, subsessile; leaves superdecompound; stems two, three, or more, round, striated, rough, branched, commonly prostrate, from a span to a cubit in length .- Native of the south of Europe, and of England, on the borders of cornfields, and on banks ; flowering from May till August.

Cauliflower. See Brassica.

Ceanothus ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, turbinate; border five-parted, acute, close, converging, permanent. Corolla: petals five, equal, roundish, of an arched saccular shape, compressed, very obtuse, spreading, smaller than the calix, seated on claws the length of the petal, growing from the interstices of the calix. Stamina: filamenta five, subulate, erect, opposite to the petals, the length of the corolla. Antheræ roundish. Pistil : germen superior, triangular; style cylindric, semitrifid, the length of the stamina ; stigma obtuse. Pericarp : berry dry, three-grained, three-celled, obtuse, retuse, set with tubercles. Seeds: soli-

CERES SILIQUASTRUM. _ Common Judas Tree.

CHELIDONIUM _ Common ve devas Celandine

CED

tary, ovate. ESSENTIAL CHARACTER. Petals five, saccular, vaulted; berry dry, three-celled, three-seeded .---- The species are,

1. Ceanothus Americanus ; American Ceanothus, or New Jersey Tea. Leaves three-nerved .- In England this shrub seldom rises more than three or four feet high, sending out branches on every side, from the ground upward : at the extremity of each shoot, the flowers are produced in close thick spikes, and are composed of five small petals of a clear white ; they appear in July, and make a pretty appearance during their continuance; for as every shoot is terminated by one of these spikes, the whole shrub is covered over with flowers, the branches commonly growing very close to each other; and when the autumn proves mild, they often flower again in October: it is best propagated by seeds, which should be sown in the antumn in smail pots, and plunged into an old hot-bed, where they may remain during the winter, placing them in the open air during mild weather, but screening them from the cold.

2. Ceanothus Asiaticus ; Asiatic Ceanothus. Leaves ovate, nerveless; branches alternate, flexuose, striated, smooth.-Native of Ceylon and Japan: it may be increased by layers or cuttings, and must have the protection of a bark-stove.

3. Ceanothus Africanus; African Evergreen Ceanothus. Leaves lanceolate, nerveless; stipules roundish .- It rises to the height of ten or twelve feet, with a woody stem, covered with a rough dark-coloured bark, and sends out many weak branches, which hang downward; these while young are green, but afterwards change to a purplish colour : they are garnished with oblong pointed leaves, of a lucid green, smooth and slightly serrate on their edges : the flowers are small, of an herbaceous colour, coming out from the side of the branches : they sometimes appear in July, but are not succeeded by seeds in this country, nor do the plants often produce flowers; so that they are merely preserved for the beauty of their shining evergreen leaves, which make a variety in the green-house during the winter season. They are generally propagated by cuttings, as that is the surest and most expeditions way: they should be planted in spring, in pots filled with good kitchen-garden carth, and plunged into a very moderate hot-bed, observing to shade them in the heat of the day, and now and then to refresh them with water : in two months, or less, they will have taken root, when they must be gradually inneed to the open air, placing them in a sheltered situation till they have obtained strength, when they may be separated, and each planted in a small pot filled with light earth, placing them in the shade until they have taken fresh root; then they may be removed, intermixed with other exotic plants, and treated in the same manner.

4. Ceanothus Reclinatus. Leaves ovate, entire, manynerved ; branches hanging down .- Native of Jamaica.

5. Ceanothus Circumscissus. Leaves obcordate, opposite, in two rows; prickles solitary, recurved, opposite to the leaves; branches simple, opposite, spreading very much, angular, even .- Native of the East Indies, Ceylon, and Mauritius.

6. Ceanothus Capsularis. Leaves ovate, cordate, acuminate, serrate; capsules three-valved, gaping .-- Native of Otalieite.

Cecropia : a genus of the class Directa, order Diandria .--GENERIC CHARACTER. Male. Calix: spathe ovate, bursting, caducous, containing aments very many, fasciculate, columnar, imbricate with scales ; the scales (receptacle) copious, turbinate, compressed, quadrangular, obtase, with a double perforation. Corolla : none, unless the scales be called nectaries. Stamina : filamenta two, capillary, very 23.

short, from the perforations of the scales. Antheræ oblong, quadrangular. Female. Calix : spathe ; aments four, columnar, imbricate, with germina. Corolla : none. Pistil: germina many, imbricate, compressed, quadrangular, obtuse; styles solitary, very short; stigmas somewhat headed, lacerated. Pericarp : herry the form of the germen, one-celled, one-seeded. Seed : oblong, compressed. ESSENTIAL CHA-RACTER. Male: spathe caducous; ament imbricate, with turbinate scales, compressed, quadrangular. Corolla: none : female as in the male. Germina : imbricate. Style: one. Stigma : lacerated ; berry one-seeded .---- The only known species is,

1. Cecropia Peltata. Trumpet-tree, or Snake-wood .- This tree seldom falls short of thirty-five or forty feet high, in the most perfect state ; the fruits rise four, five, or more, from the very top of a common peduncle, and shoot into so many oblong cylindric berries, composed of a row of little acini, something like our raspberry, which they resemble in flayour when ripe, and are on that account agreeable to most European palates. The wood of this tree, when dry, is very apt to take fire by attrition. The native Indians have taken the hint, and always kindle their fires in the woods, by rubbing a piece of it against some harder wood. The bark is strong and fibrons, and is frequently used for all sorts of cordage. The trunk is very light, and for that reason much used for bark logs, and fishing floats. The smaller branches, when cleared of the septums, serve for wind-instruments : both trunk and branches yield a great quantity of fixed salt. which is much used among the French to despumate and granulate their sugars. The fruit is much fed upon by pigeous and other birds; and thus the tree is spread and propagated. Native of Jamaica, and other West India Islands; and also of South America. It may be propagated by seeds, procured from the places of natural growth. They should be brought over in sand; for if they be put up in moist papers, they will be apt to grow mouldy. They should be sown in small pots, filled with light earth, and plunged into a moderate hot-bed of tanner's bark, observing to water the pots duly, and to admit fresh air whenever the weather is favourable. When the plants come up, and are fit to transplant, they should be carefully taken up, and each planted in a separate small pot filled with the like light earth, and plunged into the hot-bed again, being careful to water them, to settle the earth to their roots, and also to screen them from the sun till they have taken new root; after which, they should be constantly kept plunged into the bark-bed in the stove, and treated in the same manner as other plants from the same country,

Cedrela : a genus of the class Pentandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth mono-phyllous, campanulate, very small, five-toothed, withering. Corolla : funnel-form, pentapetalous, the tube bellied below ; petals linear, oblong, obtuse, erect, adjoined to the receptacle at one-third beneath. Stamina: filamenta five, subulate, seated on the receptacle, shorter than the corolla. Antheræ oblong, bent outwards at the tip. Pistil: receptacle proper five-cornered; germen globular; style cylindric, length of the corolla ; stigma headed, depressed. Pericarp ; cap-

260

sule superior, woody, roundish, five-celled, five-valved; valves deciduous. Sceds: numerous, fleshy, imbricate downwards, terminated by a membranaceous wing; receptacle woody, five-angled, firee. ESSENTIAL CHARACTER. Calies: withering. Corolla: five petalled, funcel-form, fastened by the base to the receptacle, to one-third of its length. Capsule: woody, five-celled, five-valved, Sceds: imbricate downwards, with a membranaceous wing.——The only species known is,

1. Cedrela Odorata: Barbadoes Bastard Cedar. Flowers panicled. This tree rises with a straight stem, to the height of seventy or eighty feet; while young, the bark is smooth, and of an ash-colour, but becomes rougher and darker by age; corollas whitish, flesh-coloured, liliaceous, resembling that of the hyacinth. The fruit is oval, about the size of a partridge's egg, smooth, of a very dark colour, aud opens in five parts, having a five-cornered column standing in the middle, between the angles of which the winged seeds are closely placed, lapping over each other like the scales of fish. The trunk is covered with a rough bark, marked with longitudinal fissures, and, as well as the berries and leaves, has a smell like assafætida when fresh ; the wood has, notwithstanding, a pleasant smell .- This tree is commonly known under the name of cedar, in the British West India islands ; the trunk is so long, that the natives hollow it out into canoes and periaguas, for which purpose it is extremely well adapted, the wood being so soft that it may be cut out with great facility, and so light that it will carry a great weight upon the water. There are canoes in the West Indies, which have been formed out of these trunks, forty feet long, and six broad ; the wood is of a brown colour, and has a fragrant odour, whence the title of cedar has been given to it : it is frequently cut into shingles for covering houses, and is found very durable ; but as the worms are apt to eat this wood, it is not proper for building ships, though it is often used for that purpose, as well as for sheathing them : it is often used for wainscoting of rooms, and to make chests, because vermin do not so frequently breed in it, as in many other sorts of wood, owing to its very bitter taste, which is communicated to whatever is put into the chests, especially when the wood is fresh; for which reason it is never made into casks, because spirituous liquors will dissolve part of the resin, and thereby acquire a very bitter taste : it yields a fine essential oil, and a spirit not inferior to that which is drawn from rosemary. It is propagated by seeds, which may be easily procured from the West Indies: they must be sown upon a hot-bed in the spring, and the plants treated in the same manner as the mahogany.

Cederofa; a genus of the class Octandria, order Monogynia.-GENERIC CHARACTER. Calir: perianth one-leafed, six-parted; parts ovate, obtuse, concave. Corolla: none. Stamina: filamenta eight, short. Antheræ roundish. Pistil: gernen superior, roundish, surronnded by a gland; style short; siguna obtuse. ESSENTIAL CHARACTER. Cafix: six-partel. Corolla: none. Germen: superior, surrounded by a gland. Styles: short.---The only known species is,

1. Cedrota Guianensis. A tree forty feet in height, and two feet in diameter, with a thick, unequal, wrinkled bank, full of clefts, and a yellow, heavy, aromatic wood, which however becomes light when dry; flowers very small, loosely racemed, on a long, weak, axillary peduncko.—It grows in the great forests of Guiana, flowering in May; the inhabitants call it *bois de cedre*, and use it for making their *pirogues*; they say that it is also fit for masts.

Celandine. See Chelidonium.

Celastrus ; a genus of the class Pentandria, order Monorynia .- GENERIC CHARACTER. Calix : perianth one-leafed, half five-cleft, flat, small; divisions obtuse, unequal. Corolla : petals five, ovate, spreading, sessile, equal, reflected at the borders. Stamina : filamenta five, subulate, length of the corolla. Antheræ very small. Pistil : germen very small, immersed in a large flat receptacle, which is marked with ten streaks; style subulate, shorter than the stamina : stigma obtuse, trifid. Pericarp : capsule coloured, ovate, obtusely triangular, gibbons, trilocular, trivalvular. Seeds: few, ovate, coloured, smooth, half involved in an unequal coloured arillus, with a four-cleft mouth. ESSENTIAL CHARACTER. Corolla : five-petalled, spreading. Capsule : triangular, trilocular. Seed : calyptrated. This genus consists of shrubs or small trees, with alternate leaves, and the flowers many together, on axillary subdichotomous peduncles. The species are, 1. Celastrus Bullatus. Unarmed; leaves ovate, quite en-

tire .- It rises to the height of eight or ten feet; but in England there are few of these shrubs much more than half that height. This shrub flowers in July, but rarely produces good seeds in England: it grows naturally in Virginia, and many other parts of North America. It is propagated by layers, which will take root in one year; the young branches only are proper for this purpose, so that when there are not any of these near the ground, the main stalks should be drawn down and fastened with pegs to prevent their rising, and the young shoots from them should be laid ; the best time for doing this is in autumn, when they begin to cast their leaves, and by that time twelvemonth they will be sufficiently rooted, and should be cut off from the old plant, and be replanted in a nursery for two or three years to get strength, after which they must be removed to the places where they are to remain : it grows naturally in moist places, and will not thrive in a dry soil, although it be very hardy, and bears the cold of our winters very well. It is also propagated by seeds brought from America, but as these rarely arrive in time to sow before the spring, the plants never come up the first year; therefore the seeds may be sown either in pots or in a bed of loamy earth, keeping them clean from weeds during the summer, and those in the pots in the shade till the autumn, when the pots should either be plunged into the ground in a warm situation, or placed under a common frame, to prevent the frost from penetrating through the side of the pots; and if the surface of those which are plunged into the ground, and also the beds where the seeds are sown, be lightly covered with some old tan from a decayed hot-bed, it will secure the seeds from being hurt by severe frosts. In the spring, when the plants come up, they must be kept clear from weeds, and if the season prove dry, they should have water now and then, which will greatly forward their growth. If the plants make a good progress the first summer, they may be transplanted into a nursery in autumn, otherwise they should remain in the seed-bed till the second year, when they may be treated in the same manner as the layers.

2. Celastrus Scandens; Climbing Staff Tree. Unarmed; stam twining.—Li sends ont several woody stalks, which are flexible, and twist themselves round trees and shrubs, or round each other, to the height of twelve or fonrteen feet or more, girding trees so closely as in a few years to destroy them; it flowers in the beginning of June, and the seeds ripen in autumn; native of North America and Japan. The seeds of this species generally ripen well in England, and this may be propagated from these or by layers, as in the former; it delights in a strong loamy soil, rather moist than

270

dry, and will grow in woods among other trees and shrubs; where, when the fruit is ripe, it makes a pretty appearance, and is remarkably hardy.

3. Celastrus Myrtifolius; Myrtle-leaved Staff Tree. Unarmed; leaves ovate, finely serrate; flowers racemed; stem erect,-Native of North America.

4. Celastrue Procumbens : Procumbent Steff Tree. Unramed, procumbent : leaves ovate, serrate : flowers axillary, subsolitary.—Native of the Cape of Good Hope. This, as well as all the Cape sorts, may be propagated by cuttings, which is more expeditions than raising them from seeds, which arely come up the same year: the cuttings flay be planted any part of the summer, but those which are planted early will have more time to acquire strength before the winter: let them be put into small pots filled with good kitchen-graden earth, four together : plunge them into a moderate hot-bed, shade them from the sun, and often gently refeash them with watter; expose them gradually to the open air when they have taken root, and then place them in a sheltered situation until they become strong.

 Celastrus Filiformis; Filiform-branched Staff Tree. Unarmed; leaves lanceolate, entire; branches filiform; peduncles axillary, one-flowered.—Found at the Cape of Good Hope. For its culture and propagation see the preceding species.

6. Celastrus Acuminatus; Acuminate-leaved Staff Tree. Unarmed; leaves ovate, acuminate, serrate; peduncles axillary, one-flowered; stem erect, lax.—Found at the Cape of Good Hope. For its propagation, &c. see the fourth species.

7. Celastrus Microphyllus. Unarmed; leaves ovate, obtuse, entire; cymes terminal, dichotomous,—Found at the Cape of Good Hope. For its culture and propagation, see the fourth species.

8. Celastrus Articnlatus. Unarmed; leaves rounded, acuminate, serrate; peduncles axillary, subtrifid; stem shrubby, erect.—Observed by Thunberg in Japan.

9. Celastrus Dilatatus. Leaves obovate, cusped, serrate at the tip, and smooth; stem unarmed.—Observed by Thunberg in Japan.

10. Celastrus Striatus. Unarmed; branchlets erect, striated; leaves ovate, acuminate, serrate; peduncles scattered, one-flowered.—Observed by Thunberg in Japan.

11. Celastrus Alatus; Wing-branched Siaff Tree. Unamed; branches winged; stem shrubby, a fathom in height; seeds arilled.—This is a handsome shrub, singular for its winged branches; the Japanese frequently cultivate it in their gardens, and the young men hang bunches of the fowers before the doors of the honses where the young women reside, when they wish to signify their desire to pay their addresses to them.

12 Celastrus Buxifolius; Box-leaved Staff Tree. Spines leafy; branches angular; leaves obtuse.—It flowers in May and June, and is a native of the Cape of Good Hope. For its propagation and culture, see the fourth species.

13. Celastrus Pyracanthus; Pyrecentha-leaved Staff Tree; Spines maked, branches round; leaves acute.—It is a mative of the Cape of Good Hope, whence the seeds were first brought to the gardens in Holland, and thence distributed among most of the curious gardens in Europe, For the propagation and culture, see the fourth species.

14. Celastrus Lucidus; Skining Staff Tree, or Small Hottentor Cherry, Leaves oval, shining, quite enrire, margined. It is an upright shrub, with brown hard branches; flowers in April and September, and is a native of the Cape of Good Hope.

15. Celastrus Linearis; *Linear-leaved Staff Tree*. Spines leafy; leaves linear, entire.—Found by Thunberg at the Cape of Good Hope. See the fourth species, for the propagation and culture of this plant.

[°] 16. Celastus Integrifolius; *Entire-leaved Staff Tree*. Spines leafy; leaves ovate, obtuse, quite entire; cymes lateral.—Found at the Cape of Good Hope. For the propagation and culture, see the fourth species.

17. Celastrus Crenatus; Notch-leaved Staff Tree. Unarmed; leaves ovate, crenulate; cymes axillary.-Native of the Marquesas Islands in the South Seas.

 Celastrus Corniculatus. Leaves oval, quite entire, perennial; capsule three-horned.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the fourth species.

19. Celastrus Cassinoides: Crenated Staff Tree. Unarmed; leaves ovate, acute both ways, loosely toothed; pereminal; flowers axillary.—It flowers in August and September, and is a native of the Canary Islands. 20. Celastrus Phyllacanthus. Thorns leafy; leaves lance-

20. Celastrus Phyllacanthus. Thorns leafy; leaves lanceolate, serrate, perennial; flowers lateral.-Found in Senegal.

21. Celastrus Octogonus; Angular-leared Staff Tree. Unarmed; leaves elliptic, angular, almost nerveless, perennial; capsules bivalve, one-seeded; leaves glaucous,—Found in Pegu by Dombey.

22. Celastrus Undulatus; Ware-leaved Staff Tree. Unarıned; leaves nearly opposite, lanccolate, waved; capsules bivalve, many-seeded.—Found by Commerson in the island of Bourbon, where they call it bois de jolicœur.

Celeri, or Celery. See Apium.

Celosia ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth threeleaved ; leaflets lanceolate, dry, acute, permanent, stiffish, caliciform; nectary a margin surrounding the germen, very small, five-cleft. Stamina : filamenta five, subulate, conjoined at the base to the plaited nectary, length of the corolla. Antheræ versatile. Pistil: germen globular; style subulate, straight, length of the stamina; stigma simple. Pericarp : capsule globular, surrounded by the corolla, onecelled, circumcised. Seeds : few, roundish, emarginate. ESSENTIAL CHARACTER. Calix: three leaved ; leaflets similar to those of the five-petalled corolla. Stamina: conjoined at the base to the plaited nectary. Copsule: gaping horizontally. The celosias are all herbaceous plants, and annuals; the flowers are glomerate, in spikes or panicles, some of which are flatted, and shaped something like the comb of a cock, and hence they have been called cockscombs .---- The species are,

 Cclosia Argentea; Silvery-spiked Celosio. Leaves lanceolate; stipules subfalcated; peduncles angular; spikes scariose.—Native of the East Indies, China, Cochin-china, and Japan; it flowers from June to September.

2. Celosia Margaritacea. Leaves ovate; stipules falcated; peduncles angular; spikes scariose.—Native of America.

3. Celosia Cristati; Creted Ameranth, or Cockscomb. Leaves oblong, ovate; peduncles round, substriated; spikes oblong.—This is a plant, well known by its common appelation of cockscomb, which it especially received from the form of its crested head of flowers, resembling the comb of a cock: there are many varieties, differing in form, size, and colour, from the same seed. It is a native of Asia. Thunberg informs us, that the crests or heads of flowers are frequently a foot in length and breadth in Japan, where they are extremely beautiful, but that they degenerate in other countries. In order to have fine large amaranths, great care should be taken in the choice of seed, for if they be not care.

fally selected, the whole expense and trouble of raising them

will be lost : they must be sown on a hot-bed which has been

prepared a few days before, that the violent heat may abate, about the beginning of March; and if the bed be in good temper, in about a fortnight's time the plants will rise; but as they are tender when they first appear, they require great care for a few days, till they get strength; first in giving them a due proportion of air, to prevent their drawing up weak, and next to keep them from too great moisture, a small quantity of which will cause their tender stems to rot; in sowing the seeds, care must be taken not to put them too close, for when the plants come up in clusters, they frequently spoil each other for want of room to grow; in a fortnight or three weeks' time, they will be fit to remove, when you must prepare another hot-bed, covered with good light rich earth, about four inches thick; which should be made a few days, that it may have a proper temperature of heat; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into the new hot-bed about four inches' distance every way, giving them a gentle watering, to settle the earth to their roots; but in doing this be very cautious not to bear the young plants down to the ground by hasty watering; after the plants are thus replanted, they must be screened from the sun till they have taken fresh root : but as there generally is a great steam arising from the fermentation of the dung. which condenses against the glasses, and dropping upon the plants, very frequently destroys them; the glasses should be frequently turned in the day-time, whenever the weather will permit; but if the weather happen to prove bad, it will greatly assist the plants to wipe off all the moisture two or three times a day with a woollen cloth, to prevent its dropping upon the plants: when your plants are firmly rooted and begin to grow, you must observe to give them more or less air every day, let the weather be cold or hot, to prevent their drawing up too fast, which greatly weakens their stems: in about a month or five weeks these plants will have grown so as to meet; therefore another hot-bed, of a moderate temperature, should be prepared, and covered with the same rich earth, about six inches thick, in which they should be planted (observing to take them up with as much earth about their roots as possible) at seven or eight inches' distance every way, giving them some water to settle the earth about their roots, but taking care not to water them heavily, so as to bear them down; they must be kept shaded in the heat of the day, until they have again taken root, and should be gently refreshed with water in proportion to the heat of the weather, covering the glasses with mats every night, lest the cold chill your beds, and stop the growth of the plants. In the middle of May you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow; upon this hot-bed you must set as many threepenny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams; then with a trowel take up the plants, with as much earth as possible to the roots, and place each plant in the middle of one of the pots, filling the pot up with the earth before described, and settling it close to the root of the plant by the hand ; then water them gently as before, and shade them in the heat of the day from the violence of the sun, by covering the glasses with mats; refresh them often with water, and give them a good quantity of air in the day-time: in about three weeks more these plants will have grown to a considerable size and strength,

so that you must now raise the glasses very much in the daytime; and when the air is soft and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat it as often as the weather will permit, which will harden them by degrees, and prepare them to be removed abroad into the places where they are to remain the whole season: but it is not advisable to set these plants out till some time in July, observing to do it when the air is perfectly soft, and, if possible, in a gentle shower of rain; let them be at first set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun and strong winds, to which they must be inured by degrees: these plants perspire very freely when they have grown to a good stature, and must be refreshed every day with water, if the weather prove hot and dry, otherwise they will stunt, and never produce their plumes so fine as when they are taken care of. - The above is the proper management in order to have fine amaranths, which, if rightly followed and the kinds be good, in a favourable season will produce wonderfully large fine heads, and are the greatest ornament to a good garden for upwards of two months : by this method plants five or six feet high, with crests nearly a foot in breadth. have been raised; and if the kind be good, and there be no want of dung or conveniences, in a kindly season they will grow much larger. By the middle or end of September, the amaranths will have perfected their seeds, so that you must make choice of the largest, most beautiful, and least branching plants of each kind, for seed; which you should remove under shelter, especially if the weather prove wet or the nights frosty, that the seeds may be perfectly ripened. The seeds should not be taken from side-branches or the neck of the plume, but those only which are produced in the middle of the plant, which, though generally few in number, are the only ones that can be depended upon for producing good plants in the succeeding year.

4. Celosia Paniculai, Panicled Celosia. Leaves ovateoblog: stem rising, panicled; spikes alternate, terminal, remote; stem suffraticose, prostrate, round, subdivided, stratel; branches diverging.—Mr. Miller says, that the stems are nearly four feet in length, and that the slender spikes are of a pale yellow, shining with a gloss like silk; that it grows naturally in most of the sugar islands, and that Dr. Houston sent him the seeds from Jamaica.

5. Celosia Coccinea; Scarlet Celosia, or Chinese Cockscomb. Leaves ovate, stiff, earless; stem groovel; spikes manifold, crested; it has a furrowed stalk, four or five feet high, and terminated by several spikes of flowers variausly formed, some being crested; others plumed like feathers, of a bright scarlet colour, and making a good appearance.— Native of China.

6. Celosia Castrensis; Branched Celosia, or Cockscomb. Leaves lanceolate-ovate, marked with lines, very much acuminated; stipules falcated; spikes crested.—Native of the East Indies, enlitivated generally in China and Cochin-china.

 Celosia Trigynia; Oral-Leaved Celosia. Leaves ovateoblong; raceme lax; pistil trifid; stem upright, simple, slightly angular, striated, stiff, a foot and half high; corolla ovate, acute, scariose, permanent.—Native of Senegal.

 Celosia Lanata; Woolly Celosia. Leaves lanceolate, tomentose, obtuse; spikes crowded; stamina woolly.—This rises with a white woolly stalk from two to three feet high. Native of the island of Ceylon.

9. Celosia Guaphaloides. Shrubby, woolly; leaves opposite, ovate, white beneath; head globular, peduncled.-It was found on Monte Video in Brazil.

10. Celosia Nodiflora; Knotted Celosia, Leaves wedge-

form, somewhat acute ; spikes globular, lateral.—There are two varieties ; the one comes from Sumatra, and the other from Malabar. It flowers in July and August.

11. Celosia Procumbens; Procumbent Čelosia. Stems decumbent; peduacles very long, leafless; spikes ovate, approximating; capsules compressed, crested, winged; stems two feet high.—Native of St. Domingo.

12. Celosia Monsoniae; Downy Celosia. Spikes compact, cylindric; branches brachiate; leaves subulate.-Native of the East Indies.

13. Celosia Polygonoides. Leaves cordate; stem hispid; raceme spiked, loose; flowers three-styled; stem almost upright, striated.—Sent by Kœnig from Tranquebar.

14. Celosia Baccata. Flowers three-styled; fruits berried; stem upright; flowers small, on very short peduncles. —Found in the East Indies.

Cabia: a genus of the class Didynamia, order Angiospermia.-GENERE CHARACTER. Caliz: perianth five-parted; divisions lancecolate, obtuse, length of the corolla, permanent. Corolla: monopetalous, rotated; tube estremely short; border flat, half five-cleft, unequal; divisions roundish, of which the two appeories ones are smaller, the inferior one larger. Stamina: filamenta four, capillary, inclined towards the smallest divisions of the corolla, of which the two longer ones are shorter than the corolla, and are outwardly woolly. Anthere roundish, small. *Pisiti*: germen roundish; style filiform, length of the stamina; stigma obtuse. Pericary: capule coundish, compressed at the tip, accuminate, sitting on the calix, bilocular. Seeds: very many, small, angular; receptacles solitary, hemispherical. ESSENTIAL CHARAC-TER. Caliz: five-parted. Corolla: rotated. *Fluameta*: barded; capule two-celled.----The species are;

1. Celsia Orientalis, Oriental Celsia. Leaves bipinnate; ; i flowers in June, and the seeds ripen in September.— Native of the Levant. If the seeds be sown on a warm dry border as soon as they are ripe, the plants will offen come up and live through the winter, if the soil be poor; on rich ground they are apit to grow rank, and then they are generally destroyed by the early frosts, or will rot with much wet; but if the plants should not rise the same autumn, there will be little hazard of their not growing in the following spring : they only require to be weeded, and thinned when too close; for as they do not bear removing well, they should be sowed where they are intended to remain : sometimes when the season proves warm, the plants sown in the spring produce ripe seeds; but they cannot be depended upon.

2. Celsia Arcturus; Scollop-leaved Celsia. Radical leaves lyrate-pinnate; peduncles longer than the flowers; corolla yellow. Biennial; native of Crete.--It requires the protection of the green-house.

3. Celsia Cretica; Great-flowered Celsia. Radical leaves lynte; stem-leaves subcordate, embracing; flowers subsessile; corolla yellow, with two ferruginous spots at the upper part of the tube.—Biennial; and a native of the East India, flowering in July, and requiring the protection of a greenhouse.

4. Celsia Linearis. Leaves tern linear, toothietted. This is an elegant evergreen smooth shrub; the trunk is woody, but weak, the thickness of a quill, striated, pale brown, three feet high, putting out numerous spreading branches its whole length; the younger ones green, grooved, and very leafy; corolla briliant scarlet, with a blood-red throat.—Found in Peru by Domby; it may be propagated both by seeds and cuttings; and though it succeeds best in a moderate stove, will bear to be treated as a green-house plant;

Hermaphrodite flowers : solitary. GENERIC CHARACTER. superior. Calix : perianth one leafed, five-parted ; divisions ovate, patulous, withering. Corolla : none. Stamina : filamenta five, very short, concealed at first by the antheræ, but growing longer after the shedding of the pollen. Antheræ oblong, thickish, quadrangular, four-furrowed. Pistil: germen ovate, acuminate, length of the calix ; styles two, spreading, variously inflected, subulate, pubescent on every side, very long ; stigmas simple. Pericarp : drupe globular, onecelled. Seed ; nut roundish. Male flowers ; on the same plant, inferior. Calix : perianth six-parted ; the rest as in the hermaphrodites. Corolla : none. Stamina : six ; the rest as in the hermaphrodites, ESSENTIAL CHARACTER. Hermaphrodite : calix five-parted. Corolla : none. Stamina : five. Styles: two. Drupe: one-seeded. Male. Caliz: six-parted. Corolla: none. Stamina: six. These trees are all propagated by seeds, which should be sown soon after they are ripe, when they can be procured at that season ; for such frequently come up in the following spring; whereas those which are sown in the spring will not come up till a twelvemonth after : therefore it is the best way to sow them in pots or tubs, that they may be easily removed; for those which are sown in the spring should be placed in a shady situation in summer, and constantly kept clean from weeds, but in autumn they should be placed in a warm situation, plunging the pots into the ground; and if they be covered over with a little tan from a decayed hot bed, it will prevent the frost from penetrating the earth to injure the seeds; and if these pots be placed on a gentle hot-bed in the spring, it will greatly forward the vegetation of the seeds, whereby the plants will have more time to get strength before the winter : but when the plants appear above ground, they must have a large share of air admitted to them, otherwise they will draw up weak ; and as soon as the weather is warm, they must be exposed to the open air, and in summer they must be constantly kept clean from weeds ; if the season prove dry, they will require water two or three times a week. In autumn it will be proper to remove the pots, and place them under a hot-bed frame, to shelter them in winter from severe frost ; or where there is not that convenience, the pots should be plunged into the ground near a wall or hedge; and as the plants when young are full of sap, and tender, the early frosts in autumn frequently kill the upper part of the shoots ; therefore the plants should be either covered with mats, or have a little straw or pease-haulm laid over to protect them. In the following spring the plants should be taken out of the seedpots, and planted in the full ground ; which should be done about the middle or latter end of March, when the danger of the frost is over ; therefore a bed or two should be prepared according to the number of plants raised, in a sheltered situation, and, if possible, in a gentle loamy soil. The ground must be well trenched, and cleared from the roots of bad weeds, and when levelled, should be marked ont in lines at one foot distance ; then the plants should be carefully turned out of the pots and separated, so as not to tear their roots, and planted in the lines at six inches asunder, pressing the earth down close to the roots. If the ground be very dry when they are planted, and there be no appearance of rain soon, it will be proper to water the beds to settle the ground to the roots of the plants ; and after this, if the surface of the ground be covered with some old tan or rotten dung, it will keep it moist, and prevent the drying winds from penetrating to the roots of the plants: the following summer the necessary care must be to keep them constantly clean from weeds; but after the plants are pretty well established in the ground, they will not require any water, especially toward the latter end of 4 Å

CEL

summer, for that will occasion their late growth, whereby they will be in great danger of suffering by the autumnal frosts; for the more any of these young trees are stopped in their growth by drought towards autumn, the firmer will their testure be, and the better able to bear the cold. The plants may remain in these turnsery beds two years, by which time they will have acquired sufficient strength to be transplanted where they are designed to remain, because these plants extend their roots wide every way; so that if they stand long in the nursery their roots will be cut in removing, which will be a great prejudice to their future growth—The species are,

1. Celtis Australis; European Nettle Tree. Leaves oate, lanceolate.—The Buropean mettle-tree or lote-tree rises with an upright stem, to the height of forty or fifty feet; the forti is the size of a pea, and black; if grows naturally in the sonth of Europe, where it is one of the largest trees; the wood is one of the hardest we are acquainted with. Evelyon says that it was anciently used for flutness and other musical instruments, and that hafts for knives and tools were made of the root. Wherever it arrives at any considerable size, its lardness, toughness, and dexibility, must fit it for more important services: its fine regular spreading head, of a cheerful green colour, renders this tree extremely proper for clumps in parks, groves, single trees, or avenues: the branches are converted into hoops for casks, and the herries are eaten by birds and children in the southern countries of Europe.

2. Celtis Occidentalis; American Neille Tree. Leaves obliquely ovarle, serate-acuminate.—This tree rises with a straight stem, which in young trees is smooth aud of a dark colour; but as they advance it becomes rougher, and of a lighter green. The fruit when ripe is of a dark purple colour; it grows naturally in North America, and in a moist rich soil becomes a very large tree; the wood of which being tough and pilable, is esteemed by coach-makers for their carriages.

3. Celtis Orientalis; Oriental Nettle Tree. Leaves objudye) cordate, serrate, villose underneath—It rises with a stem about ten or twelve feet high, dividing into many branches, which spread horizontally on every side, and have a smooth greenish bark. The fruit is oval and yellow, when fully ripe it turns to a darker colour; the wood is sery white; it yields a gum like that of the cherry; and is a native of the Levant, the East Indies, Japan, and the Society Isles.

4. Cellis Americana. Leaves oblong, ovate, obluss, nered, smooth above; golden beneth.—This rises with a straight trunk nearly twenty (red high, covered with a grey bark, and dividing at the top into namy beanches; the finit is round and red. It was first discovered by Father Plumier in the French West India Islands. The seeds arrely come up the first year; so that they may be sown in pots, and plunged into the tan-bed in the stove, where they should remain till the plants come up. They must be constantly kept in the barks sove, and treated in the same manner as other tender exotics.

5. Celtis Micrantha; Jamaica Nettle Tree. Leaves obliquely cordate ovate, lanceolate, servates, somewhat rugged on the upper surface.—This shrubby tree seldom rises above ten or trelve feet, and throws on ta great number of loose branches. It flowers in August and September, and is a native of Jamaica.

6. Celtis Aculeata. Leaves cordate-orate, blunt at the tip, almost entire, very smooth; branches prickly—This inelegant little tree has very long, pliant, scarcely divided, and recliming branches; drupp roundish or ovate, crowned with the withering style, yellow, double the size of a pea, containing a sweet berry, which is eaten by the inhabitants of the Caribbee islands; of which, and also of the neighbouring continent, this tree is a native.

7. Celtis Lima. Leaves ovate, lanceolate, acuminate, obliquely cordate, serrate, very rugged above; height fifteen feet; trunk straight, with a smooth, reddish, or light brown bark.—Native of the West Indies.

Cenchrus ; a genus of the class Polygamia, order Monœcia. -GENERIC CHARACTER. Calix : involucres many, laciniate, echiuate, gathered into a head, each sessile, including three calices, biflorous; perianth a bivalve glume, lanceolate, concave, acuminate, biflorous, shorter than the corolla. Corolla: one male, the other hermaphrodite; proper each bivalve ; valves lanceolate, acuminate, concave, awnless; the interior one smaller. Stamina : to each three filamenta, capillary, length of the corolla; antheræ sagittate. Pistil: germen of the hermaphrodite roundish; style filiform, length of the stamina; stigmas two, oblong, hairy, spreading. Pericarp: none. Seed: roundish. ESSENTIAL CHARACTER. Involucre laciniate, echinate, two-flowered. Calix: glume two-flowered, one male, the other hermaphrodite. Hermaphrodite. Corolla: glume awnless; stamina three; seed one. Male. Corolla: glume awnless. Stamina: three .--- The species are,

1. Cenchrus Racemosus; Branching Cenchrus. Panicle spiked; glumes muricated with ciliary bristles.—Native of the southern parts of Europe, the coast of Egypt, and the East Indies. It flowers in July and August.

2. Ceuchrus Lappaceus; Bur Cenchrus. Branches of the paniele very simple; corollas hispid backward; calices three-valved, two-flowered; culm branching even.—Native of the East Indies.

3. Cenchrus Muricatus. Spike muricated; scales various, mucronated; culm procumbent, a short span in length, branching, leafy.--Native of the East Indies.

4. Cenchrus Capitatus; Oval-spiked Cenchrus. Spike ovate, simple; the culm is only three or four inches high, and has only one joint.—Native of the south of France, and Italy.

5. Cenchrus Echinatus; Rough-spiked Cenchrus. Spike oblong, conglomerate.—Native of Virginia and Jamaica.

6. Cenchrus Tribuloides. Spike glomerate ; female glumes globular, muricate, spiny, hirsute.—Native of Virginia and Jamaica.

 Cenchrus Ciliaris; Ciliated Cenchrus. Spike with setaceous, ciliated, four-flowered involucels; culm ascending, glossy, the thickness of a thread, a short span in length, with inflected joints:—Observed at the Cape of Good Hope.

8. Cenchrus Granularis. Racemes double; fruits globular, wrinkle-netted; fruits minute, scarcely so big as a cabbage seed.—Native of the East Indies.

9. Cenchrus Frutescens. Heads lateral, sessile; leaves mucronated; stem shrubby.-Found by Tournefort in Armenia.

10. Cenchrus Setosus. Spike linear, oblong; involucres bristly; bristles unarmed; the interior ones villose at the base; bairs ciliate; glumes even.—Native of the West Indies.

11. Cenchrus Purpurascens. Raceme spiked, simple; florets surrounded with very long awns; culm erect, two feet high.—Native of Japan.

Contaurea: a genus of the class Syngenesia, order Polygamia Frustranea. -GENERIC CHARACTER. Colir: common imbricate, roundish; scales often variously terminated. Corolla: compound flosculous, difform; corollules hermaphrodite, very many in the disk; females fewer, longer, lax in the ray; proper of the hermaphrodite monopetalous; tube fiftorm; border ventricose, oblong, erect, terminated by five divisions, which are linear, erect. Of the females monopetalous, funuel-form; tube sclender, gradually enlarged, recurved; border oblong, oblique, unequally divided. Stamina, in the hermaphrodites: filamenta five; canillary, very CEN

short. Antheræ cylindric, tubular, length of the corollule. Pistil, in the hermaphrodites: germen small; style filiform; length of the stamina; stigma very obtuse, projecting in a point which in many is bifid. In the females ; germen very small; style scarcely any; stigma none. Pericarp: none; calix unchanged, converging. Seeds : in the hermaphrodites solitary; down or egret, in most plumose or pilose. In the females none. Receptacle: bristly. ESSENTIAL CHARAC-TER. Receptacle : bristly, Down ; simple. Corolla : of the ray funnel-form, longer, irregular .- The numerous species of this genus may be increased without great difficulty : those which are annual, by seeds; and such as are perennial, both that way and by parting the roots. The seeds of the greater part may be sown either in spring or autumn in a bed of light earth, either to remain where they are; and in that case only to be thinned and kept clean from weeds; or to be pricked out when of a proper size, into a bed of fresh earth, about six inches asunder, there to remain till autumn, when they should be planted where they are to continue; most of them are hardy, and none of them very tender, although some require a little protection in this climate .----- The species are,

* Jaceas: Calices even, unarmed.

 Centaurea Crupina; Biack seeded Centany, or Beerded Creeper. Scales lanceolate; leaves pinnate, serrate, subciliate; stem striated, three feet high, almost quite simple.—Native of the south of France, Piedmont, Tuscany, and the Levant. Annual.

2. Centaurea Moschata; Purple Sweet Centaury, or Sweet Sultan. Calices roundish, smooth; scales ovate; leaves lyrate-toothed .- This is annual ; and has long been propagated in the Euglish gardens, under the name of sultan-flower, or sweet-sultan. It was brought from the Levant, where it grows naturally in arable land among the corn. It sends up a round channelled stalk nearly three feet high, which divides into many branches, with jagged leaves, of a pale green, smooth, and close to the branches; from the side of the branches come out long naked peduncles, each sustaining a single head of flowers, which are purple, white, or fleshcoloured, have a very strong odour, which is as offensive to some as it is agreeable to others. The seeds are commonly sown upon a hot-bed in the spring, to bring the plants forward, and in May they are transplanted in the borders of the flower-garden ; but if the seeds be sown in a warm border in autumn, they will live through the winter ; and these plants may be removed in the spring into the flower-garden, and will be stronger and come earlier to flower than those which are raised in the spring. The seeds may also be sown in the spring on a common warm border, where the plants will rise very well, but will be later in flowering than any of the rest. The autumnal plants will begin to flower in the middle of June, and will continue flowering till September. The spring plants will flower a month later, until the frost stops them. The seeds ripen in autumn. The yellow sweet-sultan is much tenderer than the former ; its seeds must be sown upon a hot-bed in the spring ; and when the plants are fit to remove. they should be transplanted into a fresh hot bed to bring them forward; and when they have taken root in this bed, they must have air admitted to them every day, to prevent their drawing up weak, and be sparingly refreshed with water, because they are very apt to rot with much wet.

 Centaurea Crucifolia. Scales lanceolate; leaves lanceolate, somewhat toothed; root annual; corolla bright purple; calices pubescent.

4. Centaurea Lippii; Egyptian Centaury. Scales mucronate; leaves subdecurrent, lyrate-toothed; corollas purple, with a large ray.—Native of Egypt, between Alexandria and Rosetta.

5. Centaurea Alpina; Alpine Centaury. Scales orate obtuse; leaves pinnated, smooth, quite entire, the odd leaflet serrated; root perennial, striking deep into the ground.—It grows naturally upon the Alps and in Italy.

6. Centaurea Centaurium; Creat Centairy, Scales ovate; leaves pinnated; leafets sernated, decurent.—This has a strong perennial root, and grows naturally on the mountains of Italy, Spain, and Tartary. It is supposed to be the tristea centaurea of Lucretius, and the graveolentia centaurea of Virgil, recommended by the latter in disorders of the becs. It may be propagated by parting the roots: as it requires much room, it is not proper for small gardens; but not hard real growing plants, it makes a good figure.

** Cyani ; With Scales of the Calix servate-ciliated.

7. Centaurca Phrygia; Austrian Centaury. Calics recurve, plumose; leaves undivided, oblong, scabrous; stem somewhat shrubby, upright, from eight or ten inches to a cubit in height, often branched, furrowed, hispid, but not tomentose; corolla a fine red.—Native of Germany, Austria, and Switzerland.

 Centaurea Capillata; Feathered Centaury. Calices recurved, plumose; bottom-leaves pinnated, toothed; upper lanceolate; stem four or five feet high, angular, hard, branching.—Native of Spain and Siberia.

⁶. Centaurea Unifora; One flowered Centaury. Calices recurve, plumose; leaves lanceolate, somewhat toothed, to-mentose, a palm or foot in height; corolla purple; leaves very narrow, lanceolate, quite entire, covered with a very white pile.—Native of the south of Europe.

10. Centaurea Limiolia; Flaz-leared Centaury. Calices recurve, plumose; leaves linear, scattered; stem a palm in height, often decumbent, branching from the bottom, forrowed, angular, rough with stiff hairs; corolla purple.—Perennial; and a native of Spain and Italy.

11. Centaurea Pectinata. Calices recurve, plumose; leaves lyrate, toothletted; branch-leaves lanceolate, quite entire; corollets pale purple, or white, all equal.—Native of Spain, south of France, and Silesia.

12. Centaurea Nigra; Black Centaury, or Knappeed, Calicse ciliate, with the little scale orate; citias capillary, erect; leaves lyrate, angular; flowers floscular; stem from two to three feet in height; florets all alike; tube whitish, long, and narrow; border purple.—This plant has many provincial names, as knap-weed, knop-weed, knop-weed, knop-weed, knop-weed, lorse-knops; all from knob or nob, a head; also hard-heads, hard-irons, and matfellor; in Scottand horse-knot; it is found in Germany, Austria, and France; it is a had weed in the English meadows and pastures, being a hards hatbborn plant, seldom touched by cattle either green or in hay, and being very difficult to extirpate.

13. Centaurea Pullata. Calices ciliate, verticil, leafy: leaves lyrate, toothed, obtuse; it is a low plant; corolla purplish, with a large ray.—It flowers in June and July, and the seeds ripen in autumn. Native of the south of France, Spain, and the Levant.

14. Centaure Montana; Mountain Centaury, Perennial Blue Bottle, or Batchelor's Buttons. Callecs serrate; leaves lanceolate, decurrent; stem quite simple; root perennial, unning deep into the ground; corollets in the ray very long, blue, with a white tube, neuter; in the disk short, purple, fertile... It flowers in May and Jone, and is a native of the south of Europe. It is now become a common plant in large gardens, from the facility with which it is increased; the roots indeed creep so much, that it is apt to become troublesome: it will grow in any soil and situation. 276

15. Centaurea Cyanus; Corn Centaury, or Annual Blue Bottle. Calices serrate ; leaves linear, quite entire, the lowest toothed; stem one to two feet high, angular, slightly tomentose, branched at top .- It is a common weed among corn, flowering from June till August; the wild flower is usually blue, but sometimes white or purple: our old English writers, besides blue-bottle, a name it has commonly obtained, call it blue-ball, blue-blow, corn-flower, and hurt-sickle; in the Book of Husbandry, ascribed to Fitzherbert, it seems to be called hadods or haudod: some modern agriculturists speak of it under the name of buddle, which is evidently nothing more than a corruption of bottle ; it is called batchelor's buttons in Yorkshire and Derbyshire, but that name is given to many other flowers: in Scotland, it is called blue bonnets; the Germans, Dutch, Swedes, and Danes, call it korn-blume ; the French, bluet ; the Italians and Portuguese, ciano: and the Spaniards, aciano, and azuleio. The expressed juice of the neutral florets makes a good ink, it also stains linen of a beautiful blue; but the colour is not permanent in any mode hitherto used. Mr. Boyle says, that the juice of the central florets, with the addition of a very small quantity of alum, makes a lasting transparent blue, not inferior to ultramarine. A water distilled from the flowers of this plant is good in inflammations and weakness of the eyes; and the leaves which grow on the stems, fresh gathered and bruised, will stop the bleeding of a wound, even if a large vessel be cut; their use, in such cases, is but little known, but they surpass all other things of the kind, and may often be the instrument of saving life, where a surgeon's assistance is not to be procured in time: it is good for wounds or bruises of the breast, spitting of blood, &c. The juice, dropped into old ulcers, cleanses and disposes them to heal. I have known it, says Meyrick, to be made use of by the country people for the jaundice ; and, infused or boiled in white wine, it is an exceedingly good diuretic.

16. Centaurea Paniculata; Panicled Centaury. Calices ciliate; scales flat; leaflets bipinnate; branch-leaves pinnatifid, linear; stem panicled; stem almost woody, stiff, striated, or angular, whitish, branched, from a foot to eighteen inches and two feet in height; florets flesh-coloured, or pale purple .- Native of the south of Frauce, Switzerland, Germany, Austria, Carniola, Italy, and Spain: annual. There are great varieties of colours in the flowers of the common annual blue-bottle, and some of them are finely variegated; the seeds are sold under the name of bottles of all colours; they will rise in any common border, and require no other care but to be kept clean from weeds, and thinned where they are too close, for they do not thrive well when they are transplanted : if the seeds be sown in autumn, they will succeed better, and the plants will flower stronger, than those which are sown in spring.

17. Centaurea Spinosa; Frickly-branched Centaury. Calices subciliate; branches spinous.—The whole plant is tomentose. Native of the island of Candia.

18. Centaurea Ragusina; Cretan Centaury. Calices ciliate; leaves tomentose, pinantifd; leafles tobluse, ovate, quite entire, the outer ones larger; leaves white, as if were pappous, pinanted, with rounded lobes; flower solitary, peduneled; flowers bright yellow.—As this plant retains its leaves, which are extremely white, all the year; it makes a pretty variety in a garden. Native of the island of Candia, and of several places on the coasts of the Medierranean, both in Europe and Africa. This, and the two following species, may be propagated by slips, or by planting the young branches which do not shoot up to flower, in a shady border, any time during the summer; in the autumn they may be removed into warm

borders, or put into pots to be sheltered in winter. This species will endure the cold of our ordinary winters in the open air, if it be planted in dry lime rubbish. 19. Centaurea Cineraria; White-leaved Mountain Cen-

19. Centaurea Cineraria; While-leaved Montain Caraty, Calices ciliate, terminal, sessile; leaves tomentose, bipinnatifid; lobes acute; stems nearly three feet high, branching from a perennial root; flower purple, with white styles; rays scarcely longer than the rest of the corolla.— They come out in June, and in favourable scasons the seeds are perfected in autumn; it grows naturally in Italy, on the borders of the fields. See the cighteenth species.

20. Centaurea Argentea; Siléry Centaury. Calices serrate; leaves tomentose; root-leaves pinnatifid; leaflets earless; stem next the root very tomentose; flowers yellow; leaves white.—Pereunial; flowering in July: native of Candia, or Crete. See the eighteenth species.

21. Centaures Sibirica; Siberian Centaury. Calices cilitac; leaves tomentose, undivided, and pinnatifid, quite entire; stem declined; stem quite simple, sometimes, but rarely, having one small branch, pubescent, somewhat grooved, usually one flower; corolla purple, sometimes flesh-coloured, with a large barren ray.—Found by Gmethin in Siberia.

22. Centaures Sempervirens; Evergreen Centaury, Calics cilitate; leaves lancedate, serrate, substipuled at the lowest tooth; lower leaves hastate; stem round, pubescent, gray at bottom; flowers flowers flowers in social social server through the year; it flowers in June and July, and in warm seasons the seeds ripen in September. Native of Spain and Portugal. It is propagated by seeds, sown in April, in a bed of light certific terth; it will endure mild winters in a dry soil and open situation, but is frequently destroyed by severe frost.

23. Centaurea Scabiosa; Scabiosa Centaury, or Great Knapuzed. Calices ciliate; leaves pimatifid; pimas lance-olate; stem nearly cylindric, upright, alternately branched, leafy, striated, two feet high; leaves roughish, and slightly hairy; flowers solitary, terminating.—Native of most countries of Europe, except the southermost parts, heing found in meadows, on the borders of corn-fields, and by road-sides; it is perennial, flowering in July and August, and is called the great lorsehooks, in Xorkshire.

25. Centaurea Stache. Calices ciliate, collong; leaves pinnatifid, linear, quite entire; root perennial; stems nearly three feet high, branched, with a single leaf at each joint; flowers solitary, terminating.—They appear in June, and the seeds ripen in August.

26. Cantaurea Acaulis; Stemless Centaury. Calices ciliate; leaves lyrate; stem scarcely any; the flowers yellow; the root sweet and esculent.--It is called Toffo by the Arabs.

*** Rhapontica: with the Scales of the Calix dry and scariose.

27. Centaurea Orientalis; Oriental Centaury. Calices scarose, ciliate; leaves pinnatidi ; pinnas lauceolate; the stems rise nearly five feet high, dividing at top into many smaller branches; flowers solitary, terminating, yellow—They come out from June to August, and the seeds ripen in autumn. Native of Siberia. It may be propagated by seeds, or by parting the roots; as the plants require a large share of room, they should not be placed too near other plants, no'r are they proper furniture for small gardeas.

do not shoot up to flower, in a shady border, any time during 28. Centaurea Beben. Calices scariose; radical leaves the summer; in the autumn they may be removed into warm lyrate; lobes opposite; stem-leaves embracing; leaves large,

16

like those of docks, and sharp and stiff like pear-leaves; flowers oblong, yellow .- Found at the foot of Mount Libanus, in shady watery places.

29. Centaurea Repens; Creeping Centaury. Calices scariose; leaves lanceolate, subpetioled, toothed; peduncles filiform, leafless; stem angular, branched, even .- Perennial : and a native of the Levant.

30. Centaurea Jacea; Common Centaury, or Knapweed. Calices scariose, lacerate; leaves lanceolate; radical leaves sinuate-toothed; branches augular. There are several varieties not worth enumerating .- Perennial; native of the north of Europe, and the south of France.

31. Centaurea Amara; Bitter Centaury, Calices scariose; leaves lanceolate, quite entire; stems decumbent; stem panicled.-Native of Spain and Switzerland.

32. Centaurea Alba; White-flowered Centaury. Calices scariose, entire, mucronated ; leaves pinnate, toothed ; stemleaves linear, toothed at the base .- Native of Spain and Switzerland.

33. Centaurea Splendens; Shining Centaury, Calices scariose, obtuse; radical leaves bipinnatifid; stem-leaves pinnated; teeth lanceolate; stems three feet high, angular, hard, smooth, branched, many-flowered; flowers purple, with a beautiful silvery calix, consisting of dry round scales, ending in a harmless awn .- Biennial; flowering in July; the seeds ripen in September. Found in transalpine Switzerland, Spain, and Siberia.

34. Centaurea Rhapontica; Swiss Centaury. Calices scariose; leaves ovate-oblong, toothletted, entire, petioled, tomentose beneath .- This is a handsome plant ; flowers solitary, large; floscules purple, very numerous, without any neuters: it flowers in July, and is found in Switzerland, and about Verona. The root of this plant, and of several of the species allied to it, are bitter and astringent, and were formerly much given in cases wherein Jesuit's bark is now administered; the plant also will dye yellow. Neither this nor the thirty-seventh species, perfect their seeds in England, they must therefore be procured from their native countries : they are perennial, and hardy; and when once obtained, may be increased by the root.

35. Centaurea Babylonica ; Babylonian Centanry. Calices scariose; leaves subtomentose, decurrent, undivided; radical leaves lyrate; corolla yellow .--- Perennial: native of the Levant.

36. Centaurea Glastifolia; Wood-leared Centaury. Calices scariose; leaves undivided, quite entire, decurrent; root perennial, striking deep into the ground; flowers yellow. -Flowering from July till August : native of the Levant and Siberia. See the sixth species.

37. Centaurea Conifera; Cone Centaury. Calices scariose; leaves tomentose, next the root lanceolate, on the stem pinnatifid; stem simple; root perennial, single; the florets are of a bright purple colour, and appear in June .--Native of the south of Europe. See the thirty-fourth species. **** Steebæ: with the Spines of the Calix palmated.

38. Centaurea Sonchifolia; Sowthistle-leaved Centaury. Calices palmate, spiny; leaves subdecurrent, spinulous, repand, toothed; stem simple, angular .- Found on the coast of the Mediterranean.

39. Centaurea Seridis. Calices palmate, spiny; leaves decurrent, tomentose, oblong, the lowest sinuate-toothed. A tomentose plant, hardly a foot high; ray of the flower purple; disk whitish, with few flowers : perennial .-- Native of Spain.

40. Centaurea Romana. Calices palmate, spiny; leaves decurrent, unarmed; radical leaves pinnatifid, the end-lobe autumn, and soon after decay. 24.

largest; root biennial; stems three feet in height; flowers large, red, appearing in July, and ripcning seed in September .- It is a native of the Campania of Rome.

41. Centaurea Sphærocephala, Calices palmate, spiny; leaves ovate-lanceolate, petioled, toothed; root annual; leaves woolly .--- Native of Spain and Barbary.

42. Centaurea Isnardi. Calices palmate, spiny; leaves lyrate, toothed, hispid, almost stem-clasping; flowers sessile, terminal; root perennial .- Flowers purple, solitary, appearing in June and July.

43. Centaurea Napifolia; Turnip-leaved Centaury. Calices palmate, spiny; leaves decurrent, sinuate, spinulous; radical leaves lyrate; root annual; flowers terminating; corolla radiate, purple .- Native of the Archipelago. This species may be increased and treated in the same manner as the common annual blue-bottle. See the fifteenth species.

44. Centaurea Aspera; Rough Centaury. Calices palmate, three-spined ; leaves lanceolate, toothed .- Found about Montpellier, in Tuscany, and in Portugal.

***** Calcitrapæ: with the Spikes of the Calix compound.

45. Centaurea Benedicta; Blessed Thistle. Calices double. spiny, woolly, involucred ; leaves semidecurrent, toothletted, spiny ; root annual .- Flowers from June to September, and is a native of Spain and the Levant. This plant obtained the appellation benedictus, from its being supposed to possess extraordinary medical powers; for, exclusively of those qualities usually applied to bitters, it was thought to be a powerful alexipharmic, and capable of curing the plague and other malignant febrile disorders; it was also reputed to be good against worms, as well as against all sorts of poison. Simon Paulli declares, that it has no equal in consolidating putrid and stubborn ulcers, and even cancers. He relates the case of a woman, whose breasts were wasted by a cancer to the very ribs, and yet was cured by washing them with the distilled water of this plant, and sprinkling them with the powder of its leaves; and Arnoldus de Villa Nova relates, that he saw the putrid and hollow ulcers of a man, who had all the flesh of his legs consumed to the very bone, and who had tried all other medicines in vain, cured by the following recipe: Take the bruised leaves of this plant, and boil them with some generous wine, then add some melted hog's lard; let them boil a little more, and then put in some wheat flour, stirring it about all the while with a spatula, till it comes to the consistence of an ointment, which is to be laid warm upon the ulcers twice a day. However, notwithstanding all these high commendations, we do not find this plant considered as of any great importance in the modern materia medica. In loss of appetite, where the stomach has been injured by irregularities, it is allowed that the good effects of the infusion of this plant have been often experienced. The decoction of it also in water, or posset-drink, still maintains its popular reputation as a gentle vomit, for which purpose it is to be drank in pretty large quantities. Many persons mistake the milk thistle for this plant. Meyrick says, that the leaves of this species are bitter and stomachic, and that an infusion of them, taken in large quantities, excites vomiting, and is good in smaller doses to excite an appetite, and prevent sickness : when dried and powdered, they are good against worms. The surest method of cultivating this plant, is to sow the seed in autumn, and when the plants come up, to hoe the ground, cut up the weeds, and thin the plants : and in the following spring to hoe it a second time, leaving the plants a foot asunder; they will ripen their seeds in

46. Centaurea Eriophora; *Woolly-headed Centaury*. Calices double-spiny, woolly; leaves semidecurrent, entire, and sinuate; stem proliferous.—Flowering in July. Native of Portugal.

CEN

47. Centaurea Ægyptiaca. Calices doubly spiny, somewhat woolly; leaves sessile, lanceolate, entire, and toothed; stem proliferous; corolls white; antheræ yellow, reddish at the tip.—Annual: native of Egypt.

48. Centaurca Calcitrapa; *Star Thistle*. Calices subdouble, spiny, sessile; leaves pinnatifid, linear, toothed; stem hairy; root annual.—Native of England, Switzerland, and the southern parts of Europe.

49. Centaurea Calcitrapoides; *Phanician Centaury*. Calices subdouble, spiny; leaves stem clasping, lanceolate, undivided, serrate.—Found in France and Palestine.

50. Centaurea Solstitalis; St. Barnaby's Thitle. Calices double, spiny, solitary; branch-leaves decurrent, unarmed, lanceolate; radical leaves lyrate, pimatifid, acuminate; flowers tennial, solitary, bright yellow—Annual; and a native of the south of Europe. Discovered by Mr. Rowe, in a grassy field at Arminghall, two miles from Norwich.

51. Centaurea Melitensis; Cluster-headed Centaury. Calices double-spiny, crowded, terminal; leaves decurrent, lanceolate, sinuous, uuarmed.—Annual; found about Montpellier, and 'n the island of Malta. This plant is what we commonly call the solstituitais.

52. Centaurea Sicula. Calices ciliate, spiny, terminal; leaves decurrent, lyrate, unarmed, hoary.—Perennial: native of Sicily.

53. Centaurea Centauroides. Calices ciliate, spiny; leaves lyrat pinnate, quite entire; the end division largest.—Native of Itacy, Spain, and Montpellier.

54. Centaurea Collina. Calices ciliate, unarmed, spiny; radical leaves bipinuatifid; stem acute-augled; florets yellow. —Perennial: native of Moutpellier, Spain, Carniola, and Italy.

55. Centaurea Rupestris; Rock Centaury. Calices ciliate, spiny; leaves bipinnate, linear.-Perennial; native of Italy.

****** Crocodiloidea: Spines simple.

56. Centaurea Verutum; Dwarf Centaury. Calices mostly simple, spiny; teeth two, opposite; leaves lanceolate, entire, decurrent; root annual; corolla yellow.—Native of Palestine.

57. Centaurea Salmantica; Lyre-leaved Centaury. Calices smooth, with a subspiny setule standing out; leaves lyrate, runcinate, serrate; flowers terminal; corollas white or purple.—Native of the south of Europe.

58. Centaurea Cichoracea; Succory-leaved Centaury. Calices setaceous, spiny; leaves decurrent, undivided, serrate, spiny.—Native of Monte Argentario, in Italy.

59. Centaurea Muricata. Calices very simply spiny; lower leaves pinnatifid, upper lanceolate; peduncles very long; stems tender; florets purple.—Annual; and a native of Spain.

stems tender; florets purple.—Annual; and a native of Spain. 60. Centaurca Peregrina. Calicies setaceous, spiny; leaves lanceolate, petioled, toothed at bottom. The stems rise nearly three feet high, with entire leaves at each joint; they are terminated by large single heads of gold-coloured flowers, inclosed in a prickly calix, appearing in July and August, but never producing seeds in this country.—It grows naturally offsets from the roots of the old plants, taken off in autumn; it is very hardy, but requires a dry soil.

61. Centaurea Radiata; Rayed Centaury. Calices almost unarmed and awned, radiate; leaves pinnatifid.—Native of Siberia.

62. Centaurea Nudicaulis; Naked-stalked Centaury. Calices setaceous, spiny; leaves undivided; the upper ones a little toothed : stem almost naked, one-flowered simple; corollas purplish.—Perennial : native of Provence, Spain, and Italy.

63. Centaurea Crocodilium; Blush Centaury. Calices seariose, very simply spiny; leaves pinnatifid, quite entire, the outmost division larger, toothed.—Annual: native of Syria.

64. Centaurea Pumila; Dwarf Centaury. Calices very simply spiny; leaves tooth-pinnate, villose; stem none.— Found in Egypt, by Hasselquist.

65. Centaurea Tingitana; Tangier Centaury. Calices spiny at the edge; leaves lanceolate, undivided, serrate, subspiny.—Perennial; native of Tangier.

66. Centaurea Galactites; White-veined Centaury. Calices setaceous, spiny: leaves decurrent, sinuate, spiny, tomentose beneath.—Observed by Ray, in Sicily, Malta, Italy, and about Montpellier.

67. Centaurea Triumfetti. Calices serrate, with white cilias; leaves deeply pinnatifid, with two pinnas for the most part, decurrent.—Perennial; found upon Mont Cenis.

68. Centaurea Kartschiana. Calices ciliate, spiny; leaves pinnate; pinnas sessile, lanceolate, decurrent, ending in a point; smooth branching stem, angular; florets reddish.

69. Centaurea Alata; Upright Wing-stalked Centaury. Calices ciliate; scales flat, appressed, ciliate at the end; stem-leaves oblong, decurrent; root perennial.—Native of Tartarv.

70. Centaures Intybacea; Succory-leaved Centaury. Carlies editate; scales flat, obluse, editate at the end; leaves pinnatiful; disk equal to the ray; stem two feet high, up-right, hard; strated, branched; flowers terminating, purple, flesh-coloured, or white.—Perennia1; native of the borders of fields and dry pastures in the south of Europe.

71. Centaurea Dilnta; *Pale-flowered Centaury*. Calices ciliate; scales acumiate, somewhat thorny; leaves oblong, and pinnatifid; floscules of the ray longer than the disk.— Native of the south of Europe.

72. Centaurea Strobilacea. Calices seariose, spiny, serrate-cilated; leaves dotted beneth, pinnated; pinnas hanceolate, falcated; erect; the calix closes during the night; the flowers are of a pale yellow colour; the plant has a bitterish taste, but no smell.—It is perennial, and may be raised from seeds sown in the spring, on a gentle hot-bed; but in autumn the plants must be placed under the shelter of a glass-case: it may also be propagated by parting the roots.

73. Centauréa Hybrida. Calices ciliated, ending in a spine; leaves pinnated; brauch-leaves linear, lanceolate, undivided, decurrent; flower terminal, yellow; the whole plant dark green and roughish.—Found on the hills about Turin: biennial.

74. Centaurea Nicœensis. Calices ciliate, spiny; leaves ovate, rough; radical leaves petioled, toothed; stem-leaves embracing, decurrent; flower terminal, yellow.—Found about Nice; annual.

75. Centaurea Cæspitosa. Calices palmate, spiny; leaves sinuate-toothed; the lower ones petioled, the upper ones half stem-chasping; roots perminal, woody, dry, perpendicular, black on the oatside; the flowers, which are purple, have a strong disagreeable smell.—Native of Italy, forming very thick tufis in the sand upon the sea-shore near Naples.

76. Centaurea Elegans. Stem simple; leaves undivided, linear; axillas one-flowered, and one terminal flower; height eighteen inches; stem round; flower blue.—Anuual: found by Dana in the vineyards of Unelia.

CER

77. Centaurea Aurea; Great Golden Centaury. Calices most simply thorned; thorns spreading; floscules equal; leaves hirt, the lower pinnatifid .- Native of the south of Europe.

Centaury. See Centaurea, Chlora, and Gentiana.

Centunculus ; a genus of the class Tetrandria, order Monogynia .-- GENERIC CHARACTER. Calix : perianth foureleft, spreading, permanent ; divisions acute, lanceolate, longer than the corolla. Corolla : monopetalous, rotated ; tube subglobular; border four-cleft, flat; divisions subovate. Stamina : filamenta four, almost the length of the corolla; antheræ simple. Pistil: germen roundish, within the tube of the corolla; style filiform, length of the corolla, permanent; stigma simple. Pericarp : capsule globular, unilocular, opening horizontally. Seeds: very many, very small. Es-SENTIAL CHARACTER. Calix : four-cleft. Corolla : fourcleft, spreading. Stamina : short. Capsule : one-celled, opening horizontally .---- The only known species is,

1. Centunculus Minimus ; Bastard Pimpernel. Root annual; flowers very minute, solitary, axillary, sessile .-Native of Italy, France, Germany, Britain, Denmark, Scania, in sandy or gravelly places that are a little moist. It is found on Honnslow Heath, on Ashford Common, near Hampton Court, Chislehurst, &c. flowering from June till August.

Cephalanthus ; a genus of the class Tetrandia, order Monogynia .- GENERIC CHARACTER. Calix : perianth common, none, but the receptacle collecting many floscules into a globose head ; perianth proper oue-leafed, funnel-form, angular; border quadrifid. Corolla: universal equal; proper monopetalous, funnel-form, acute, quadrifid. Stamina: filamenta four, inserted into the corolla, shorter than the border, Antheræ globose. Pistil: germen inferior ; style longer than the corolla; stigma globose. Pericarp: none. Seeds : solitary, long, attenuated at the base, pyramidal and lanuginous. Receptacle: common globular, villose. Es-SENTIAL CHARACTER. Calix : common, none. Proper : superior, funnel-form. Receptacle : globular, naked. Seed : one, lanuginous.---- The species are,

1. Cephalanthus Occidentalis; American Button Wood. Leaves in pairs or threes .- This shrub seldom rises higher than six or seven feet in this country; the branches come out by pairs, opposite at each joint : it is propagated chiefly by seeds. Native of China.

2. Cephalanthus Angustifolius. Leaves lanceolate, linear, opposite .- This is a middle-sized tree, with ascending brauches. Native of Cochin-china.

3. Cephalanthus Procumbens. Stem procumbent; leaves ovate, lanceolate, alternate .- This is a thick shrub, with many long funicular branches; flowers violet-coloured; leaves large, quite entire, tomentose, petioled. Native of Cochin-china.

4. Cephalanthus Montanus. Leaves ovate, crenate, alternate; a large tree with hempen bark and spreading branches. -Native of China.

5. Cephalanthus Stellatus. Leaves stellate, lanceolate, linear: a middle-sized tree, with ascending branches .- Native of Cochin-china.

Cerastium ; a genus of the class Decandria, order Pentagynia .- GENERIC CHARACTER. Calix : perianth five-leaved ; leaflets ovate, lanceolate, acute, spreading, permanent. Corolla : pctals five, bifid, obtuse, erect, expanding, length of the calix. Stamina : filamenta ten, filiform, shorter than the corolla; the alternate ones shorter; antheræ roundish. Pistil: germen ovate ; styles five, capillary, erect, length of the stamina; stigmas obtuse. Pericarp : capsule ovate, cylindric, or globular, obtuse, unilocular, gaping with a

CHARACTER. Calix : five-leaved. Petals : bifid. Capsule : unilocular, gaping at the tip .- None of these plants make much appearance, and they are therefore only cultivated in botanic-gardens; some of them are common weeds in most parts of Europe: the smoother sorts are not disagreeable to cattle, and the seeds are useful to small birds .---- The species are.

* With oblong Capsules.

1. Cerastium Perfoliatum ; Perfoliate Mouse-Ear. Leaves connate .- Native of Greecc. If the seeds of this or the other annual sorts be sown in antumn, they will more certainly grow than those which are sown in the spring; or if the seeds be permitted to scatter, the plants will come up and live through the winter, and will require no other care than to keep them clean from weeds.

2. Cerastium Vulgatum ; Common or Narrow-leaved Mouse-Ear. Leaves ovate; petals equal to the calix; stems diffused .- It flowers during the whole summer, from May, on walls, by road-sides, among rubbish, and in meadows. Annual.

3. Cerastium Viscosum: Clammy or Broad-leaved Mouse-Ear. Erect, villose viscous. This plant is annual; stem branched at bottom, covered with hairs, each of which is terminated by a gland exuding a viscid juice .- It is found in meadows, on walls, dry banks, and ant-hills, varying in size from three inches to a foot ; and flowers in April and May.

4. Cerastium Semidecandrium; Least Mouse-Ear. Flowers five-stamined ; petals emarginate ; stems from two to six inches high, purplish, covered with glandulous hairs. It is annual : flowering early, and soon disappearing .- Found upon walls and heaths.

5. Cerastium Pentandrum; Five-stamined Mouse-Ear. Flowers five-stamined; petals entire .- Very small : a native of Spain.

6. Cerastium Arvense ; Corn Mouse-Ear. Leaves linear, lanceolate obtuse, smooth; corollas larger than the calix; root perennial, creeping. The whole plant is often very hairy. -It is found flowering from May and June till September, in corn-fields, dry pastures, heaths, and banks. It has been observed near Croydon in Surry, about Newmarket, Bury, and Norwich, and frequently in Cambridgeshire.

7. Cerastium Dichotomum; Forked Mouse-Ear. Leaves lanceolate; stem dichotomous, very much branched; capsules erect. The whole plant is claimmy .- It grows upon arable land in Spain; is annual; flowering in May, and ripening seeds in July.

8. Cerastium Alpinum ; Alpine Mouse-Ear. Leaves ovate, lanceolate : stcm divided : capsules oblong ; root creeping .-Found upon high mountains in many parts of Europe, Snowden, and other parts of Wales.

** With roundish Capsules.

9. Cerastium Repens: Creeping Mouse-Ear, or Sea Pink. Leaves lanceolate; peduncles branching; capsules roundish. -It grows unturally in France and Italy, and was formerly cultivated in the English gardens, under the name of Sea Pink, as an edging for borders, for which it was very unfit, on account of its creeping. The Neapolitans call it erba lattaria, or milk-herb, because it is supposed to increase the milk of sheep and cows. It propagates too fast by its creeping roots and trailing branches, to be admitted into gardens; but is very proper for planting upon rock-work, where it will spread and thrive without care. This and the other perennial sorts may easily be increased by parting the plants, which put out roots at the joints of the branches, and run so much as to overfive-toothed tip. Seeds: very many, roundish. ESSENTIAL power most other weak vegetables, and ought therefore to be cautiously introduced, unless upon banks and walls, or *Corolla*: none. *Pistil*: germen lying concealed within a among stones and rubbish.

CER

10. Cerastium Strictum. Leaves linear, acuminate, smooth; peduncles one-flowered, subtomentose; capsules globular; stems smooth, procumbent; leaves stiff, very much acuminated; perennial.—Native of the mountains of Switzerland, Austria, the Vaudois, and Mount Cenis.

11. Cerastium Suffruticosum. Stem perennial, procumbent; leaves linear, lanceolate, subhirsute.--It is found in the southern countries of Europe.

12. Cerastium Maximum. Leaves lanceolate, scabrous; petals crenated; capsules globular: annual.—Found in Siberia, near the river Jenisca.

13. Cerastium Aquaticum; Water Mouse-Ear, Leaves cordate, sessile; flowers solitary; fruits pendulous; root pereunial; seeds roundish, reddish brown. Antheræ white, bilocular.—Native of moist places, and banks of ditches and rivers, flowering in July and August.

14. Cerastium Latifolium; Broad-leaved Mouse-Ear. Leaves ovate, subtomentose; branches one-flowered; capsules globular; flowers large.—Fond upon the high monntains of the Valais, next the Glaciers, and on the highest rocks in Wales and Sootland. Perennial; flowering in May and June.

15. Cerastium Tomentosum; Woolly Mouse-Ear. Leaves oblong, tomentose; peduncles branching; capsules globular. The whole plant is white, with a thick down.--Native of Granada, Istria, France, Switzerland, Ripton Wood in Huntingdonshire. Perennial; flowering in May and June.

16. Cerastium Manticum. Smooth: stem striated; leaves lanceolate; peduncles very long; capsules globular; root slender; annual.—Native of the neighbourhood of Verona and the Grisons.

17. Cerastium Refractum. Leaves lanceolate, smooth; petioles brokeu: perennial.—Found upon the higher Alps, Mont St. Bernard, &c.

18. Cerastium Divicum; Spanish Mouse-Ear. Hirt, viscid; leaves lanceolate; flowers diœcous; petals three times larger than the calix: perennial.—Native of Spain.

Ceratocarpus : a genus of the class Monœcia, order Monandria .- GENERIC CHARACTER. Male. Calix: perianth one-leafed, tubular, wider at top, thin, coloured, bifid : the upper segments sharp, the lower emarginate. Corolla; none. Stamina : filamentum single, capillary, scarce longer than the calis, inserted into the receptacle. Antheræ twin, oval, upright. Female. Flowers on the same plant. Calix : perianth one-leafed, obovate, compressed, keeled on both sides, permanent, two-horned; horns straight, subulate, divaricate. Corolla: none. Pistil: germen oblong, superior; styles two, capillary; stigmas simple, standing out between the horns of the calix. Pericarp: none, but the calix grown larger. Seed: oblong, attenuated at bottom, compressed. ESSENTIAL CHARACTER. Male. Calix: one-leafed, bifid : corolla none. Female. Calix: one-leafed, keeled, permanent, two-horned ; styles two. Seeds : single, compressed, inclosed in and covered by the calix.— The only known species is, 1. Ceratocarpus Arenarius. An annual branching plant,

 Ceratocarpus Arenarius. An annual branching plant, with very narrow sharp grassy leaves. Three male flowers sessile in each division of the stem; females solitary, sessile in each axilla of the leaves.—It is a native of the rude deserts of Tartary.

Ceratonia: a genus of the class Polygamia, order Tritecia. --GENERIC CHARACTER. Male. Calix: perianth fiveparted, very large. Corolla: none. Stamina: filamenta five, subulate, very long, spreading. Authera large, twin. Fenale. Calix: perianth one-leafed, divided by five tubercles.

Corolla: nonc. Pitili: germen lying concealed within a fleshy receptacle: style long, filiorn; situma leaded. Pericary: legume very large, obtuse, compressed, coriaccous, with a great many transverse partitions, the interstices filled with puly: seed solitary, roundish, compressed, hard, glossy: hermaphrodite flowers on a distinct tree. ESENTIAL CHA-RACTER. Calix: five-parted; corolla none. Stamina: five Style: filiorn; legume coriaccons, many-seeded; discous; male and female separate.—...The only species hitherto discovered is,

1. Ceratonia Siliqua; The Carob Tree. It sometimes grows to a considerable size; leaves pinnate; leaflets roundish, entire, thick, rigid, nerved, dark green above, paler beneath. three inches in breadth, and somewhat more in length .--Native of Syria, Palestine, Egypt, Cyprus, Candia, Sicily, Apulia, and Spain. Ignorance of Eastern manners and natural history, induced some persons to fancy, that the locusts on which John the Baptist fed, were the tender shoots of plants. and that the wild honey was the pulp in the pod of the carob, whence it had the name of St. John's bread : there is better reason to suppose that the shells of the carob pod might be the husks which the prodigal son desired to partake of with the swine. This tree is propagated by seeds, which, when imported fresh in the pods, will grow very well, if they be sown upon a moderate hot bed in the spring; when the plants come up, they should be carefully transplanted, each into a separate small pot filled with light earth, and plunged into another moderate hot-bed, observing to water and shade them until they have taken root ; after which air must be admitted in proportion to the heat of the weather. In June they must be inured to the open air by degrees, and in July they should be removed off the hot-bed, and placed in a warm situation, where they may remain till the beginning of October, when they should be removed into the green-house, placing them where they may have free air in mild weather; for they are pretty hardy, and only require to be sheltered from hard frosts. When the plants have remained in the pots three or four years, and have gotten strength, some of them may be turned out in the spring, and planted into the full ground, in a warm situation near a south wall, where they will endure the cold of our ordinary winters very well, but must have some shelter in very hard weather. The leaves always continue green, and being differently shaped from those of most other plants, afford an agreeable variety when intermixed with oranges, myrtles, &c. in the green-house.

Ceratophyllum : a genus of the class Monœcia, order Polyandria .- GENERIC CHARACTER. Male. Flower. Calix: perianth many-parted ; divisions subulate, equal. Corolla : none. Stamina : filamenta double the number of divisions of the calix, (sixteen to twenty,) hardly conspicuous. Antheræ oblong, erect, longer than the calix. Female. Flowers on the same plant with the males. Calix : perianth many-parted : divisions subulate, equal. Corolla: none. Pistil: germen ovate, compressed; style none; stigma obtuse, oblique. Pericarp: none. Seed: nut ovate, unilocular, acuminate. ESSENTIAL CHARACTER. Male. Calix: many-parted. Corolla : none. Stamina : sixteen to twenty. Female. Calix : many-parted. Corolla : none. Pistil ; one ; style none. Seed : one, naked .- These plants can be cultivated in gardens no other way than by sowing the seeds, or planting them in ponds, muddy streams, or in pots or boxes with earth at the bottom, and filled with water .---- The species are,

 Ceratophyllum Demersum; Prickly-seeded Hornwort. Leaves two-fold, dichotomous; fruits three-thorned; root perennial, striking deep in the mud; stem much branched; flower few in the bosoms of the leaves.—Found in ditches and slow

1

CER

streams, flowering in August and September; also in Japan: it is common in Jamaica, where they call it morass-weed, and use it to cover fish, when it is to be carried to any considerable distance.

 Ceratophyllum Submersum; Smooth-seeded Hornwort. Leaves three-fold, dichotomous; fruits thornless.—It is found in the ditches on the side of the road, from Chichester to the Isle of Selsen.

Cerbera : a genus of the class Pentandria, order Monogynia. -GENERIC CHARACTER. Calix : perianth five-leaved, acuminate, spreading ; leaflets ovate, lanceolate. Corolla : monopetalous, funnel-form ; tube clavated ; border large, five-parted ; divisions oblique, obtuse, more gibbous on one side than the other; mouth of the tube pentagonal, five-toothed, converging in the form of a star. Stamina: filamenta five, subulate in the middle of the tube. Antheræ erect, converging. Pistil : germen roundish ; style filiform, short ; stigma headed, bilobate. Pericarp: drupe very large, roundish, fleshy, excavated on the side by a longitudinal furrow, and with two specks or points. Seed: nut two-celled, four-valved, retuse. ESSENTIAL CHARACTER. Contorted ; drupe oneseeded .- These plants must be propagated from their nuts, which must be procured from the countries where they naturally grow. They should be put into small pots filled with light earth, and plunged into a hot-bed of tanner's bark in the spring, and treated in the same manner as other tender exotic seeds, giving them now and then a little water to promote their vegetation. When the plants are come up about two inches high, they should be transplanted into a separate pot, filled with light sandy earth, and plunged again into a hotbed of tanner's bark, observing to shade the glasses in the heat of the day, until the plants have taken new root : they must also be frequently refreshed with water, but not in large quantities. As the summer advances, they must have air admitted to them in proportion to the warmth of the season; aud when they have filled these small pots with their roots, they should be turned out, and transplanted into those of a larger size. When by any accident the tops of these plants are injured, they frequently put out shoots from their roots, which, if carefully taken up and potted, will become good plants .---- The species are,

1. Gerbera Alionai; Ocal-leared Cerbera. Leaves ovale. –It grows naturally in the Brazils, and in the Spanish West Indies; and also in the British islands of America. It rises with an irregular stem to the height of eight or ten feet, and very part of it is very full of a milky juice; it flowers in July and August, but never produces seeds in England. The wood of linis tree stinks most insufferably, and the kernels of the nuts are a deadly poison. The Indians are not acquainted with any antidote to it; nor will they use the wood for fuel. They put small stones into the enpty nuts, string them, and fasten them about their legs when they dance.

2. Cerbera Manghas. Leaves hanceolate; nerves transverse. This is a milky tree: corolla white; drupe ovate, the size of a goose's egg, with very minute white dots, compressed on one side, and with an obscure suture, inclosing two seeds resembling two large chestnuts, poisonous and vomting.—Native of the East Indies, some parts of the Spanish West Iudies, and of the Society Islands.

3. Cerbera Cevetia ; Linear-Jeared Cerbera. Leaves linear, very long, crowded. This is an elegant shrub or small tree, about twelve feet in height; the stean is round, maramed, abounding in a poisonous milkly juice; if howers large, specious, nodding, yellow, smelling very sweet.— Native of the West Indies, in woods or copprese near the coast. Mr. Miller in forms us that he received it from our islands there, by the 24.

name of *French physic-nut*, and that it flowers here in July and August, but never produces fruit in England. 4. Cerbera Parviflora. Leaves stellate, ovate.-Native of

the Friendly Islands, and savage islands in the South Seas.

CER

5. Gerbera Salutaris. Leaves and fruits oval. This is a middle-sized tree, with a milky juice and spreading branches; flowers white, inodorous, in small subterminating racemes; drupe oval, large, with a smooth skin, yellow on one side, red on the other, containing a fibrous woody unit, with a single kernel in it, not poisonous.—Native of Cochiu-china, near the coast.

Ceres ; a genus of the class Decandria, order Monogynia. -GENERIC CHARACTER. Calix : perianth one-leafed, very short, bell-shaped, gibbous below, melliferous; mouth five-toothed, erect, obtuse. Corolla: pentapetalous, inserted into the calix, resembling a papilionaceous corolla. Wings : petals two, bent upwards, affixed by long claws. Standard : petal one, roundish, clawed beneath the wings, and shorter than the wings. Keel; petals two, converging into a cordate figure, including the organs of generation, affixed by claws. Nectary: a style-shaped gland, below the germen. Stamina: filamenta ten, distinct, subulate, bent downwards, of which four are louger than the rest, covered. Antheræ oblong, incumbent, rising upwards. Pistil : germen linear-lanceolate, pedicelled; style of the length and situation of the stamina : stigma obtuse, ascending. Pericarp: legume oblong, obliquely acuminate, unilocular. Seeds: somewhat roundish, connected to the superior suture. ESSENTIAL CHARACTER. Calix: five-toothed, gibbous below. Corolla : papilionaceous. Standard : short beneath the wings. These plants may be propagated by sowing their seeds upon a bed of light earth. towards the latter end of March, or the beginning of April ; and if a little hot dung be put under the bed, it will greatly facilitate the growth of the seeds. When they are sown, sift the earth over them about half an inch thick, and cover the bed with mats whenever the season turns out wet; otherwise the great rains will burst the seeds, and cause them to rot. The seeds will often remain till the succeeding spring before they appear, and therefore the ground should not be disturbed, till you are convinced that the plants are all come up : for some few may rise the first year, and a greater number the second. When the plants appear, they should be carefully cleared from weeds, and in very dry weather must be now and then refreshed with water, which will greatly promote their growth. In the following winter, if the weather be very cold, it will be proper to shelter the plants, by covering them with mats or dry straw during hard frosts ; but they should constantly be opened in mild weather, otherwise they will grow mouldy and decay. About the beginning of April you should prepare a spot of good fresh ground, to transplant them out, for the best time to remove them is immediately before they are beginning to shoot, which is done by taking up the plants cautiously, being careful not to break their roots, and replanting them as soon as possible. They are generally planted two feet row from row, and a foot asunder in the rows, which is full room enough for them to grow two or three years, by which time they should be transplanted whither they are intended to remain. The ground between the plants should be carefully kept clean from weeds in summer, and in the spring should be well dug to loosen the earth, in order to allow the roots to extend themselves every way; at that season prune off all strong side-branches, especially if you intend to train them up for standard trees, that their top branches may not be checked by their side-shoots, which often attract the greatest part of the nourishment from the roots ; and should their stems be crooked, you must place a stem to it in several places, so as to bring it straight, which direction it will soon take as it grows longer, and thereby the plants will be rendered beautiful.----The species are.

CER

1. Ceres Siliquastrum ; Common Judas Tree. Leaves cordate, orbicular, smooth. The Portuguese and Spaniards call this, the tree of love : it rises with an upright shrub, to the height of twenty feet : the flowers come out on every side of the branches, and in many instances in large clusters from the stem of the tree, arising from the same point upon short peduncles; they are of a very bright purple colour, and make a fine appearance, especially when the branches are covered pretty thick with them; they come out in the spring with the leaves, and are in full beauty before the leaves have attained half their size. The flower is papilionaceous, and, having an agreeable pungency, is frequently eaten in salads. This tree is usually planted with other flowering trees and shrnbs, for ornaments to pleasure-gardens, and for their singular beauty deserve a place as well as most other sorts; for when they are arrived to a good size, they are productive of flowers, so as that the branches are often closely covered with them; and the singular shape of their leaves affords a very pretty variety in the summer. It flowers in May, when planted in the full air; but when placed against warm walls, a fortnight or three weeks earlier. The wood of this tree is very beautifully veined with black and green, and as it takes a fine polish, might be converted to many uses. The two varieties of this species are not worth noticing, being greatly inferior in beauty .- Native of the Levant, Spain, the south of France, on the Appenines, and near Rome in Italy, and in Japan.

2. Ceres Canadensis; Canada Judas Tree, Red-bud Tree. Leaves cordate, pubescent, (ovate, acute.) It grows naturally in most parts of North America; where it is called red-bud, probably from the red buds appearing in the spring, before the leaves come out ; it grows to a middle stature in that country, but in England it rarely rises with a stem more than twelve feet high, branching out near the root; the flowers are not so beautiful as those of the first species, but the trees are equally hardy, and will thrive in the open air : the flowers of this, as well as those of the first species, are frequently put into salads by the Americans, and the French in Canada pickle them, but they have little flavour .- The young branches of this tree will dye wool of a very fine Nankin colour.

Cerinthe ; a genus of the class Peutandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth five-parted ; divisions oblong, equal, permanent. Corolla : monopetalous, bell-form ; tube short, thick ; border tube-bellied, rather thicker than the tube; mouth five-cleft; throat naked, pervious. Stamina : filamenta five, subulate, very short. Antheræ acute, erect. Pistil: germen four parted ; style filiform, length of the stamina; stigma obtuse. Pericarp: none; calix unchanged. Seeds: two, bony glossy, subovate, outwardly gibbous, bilocular. ESSENTIAL CHARACTER. Border of the corolla tube-bellied. Throat pervious. Seeds: two, bilocular .- These plants are propagated by seeds, which should be sown soon after they are ripe; for if they are kept till spring, the growing quality of them is often lost, or at least they lie some months in the ground before they grow : the plants are hardy, and if the seed be sown in a warm situation, will endure the winter's cold without shelter. The autumnal plants are more certain of producing ripe seeds, than those which are sown in the spring, which are generally late in the season before they flower; and consequently, if the autumn should not prove very warm, their seeds would not be perfected. They form a pretty variety for large borders

strong stake down by the side of each plant, and fasten the in gardens, where, if only suffered to drop their seeds, the plants will propagate themselves without further care .---- The species are,

1. Cerinthe Major: Great Honeywort. Leaves stemclasping; corollas bluntish, spreading; stems rather more than eighteen inches high, round, smooth, branching, and leafy. The tube of the corolla is yellow, but the border purple ; the toothlets very short and revolute. This is one of the most common herbs all over Italy; hence Virgil's expression of cerinthæ ignobile gramen. It is no less common in Sicily, and is found also in the south of France, Switzerland, Germany, and Siberia. There is abundance of honey juice in the tube of the flower, for which reason it is much resorted to by bees, and is therefore peculiarly adapted for planting near apiaries.

2. Cerinthe Minor; Small Honeywort. Leaves stemclasping, entire; corollas acute, closed; root-leaves narrowed into a petiole, and obovate ; corolla vellow, without any spot, The entire plant smooth, and flowering the whole summer .--It is annual when sown in the spring, but biennial when sown in autumn; in the wild state it is therefore biennial .- Native of Italy, Germany, Austria, Syria, and Switzerland.

Ceropegia ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth very small, five-toothed, acute, permanent. Corolla: monopetalous, with a large globose base, which is terminated by a cylindrical oblong tube; border very small, five-toothed, acuminate, with the tip converging, gaping at the side. Stamina : filamenta five, in the base of the corolla, very small, incurved, converging. Antheræ small. Pistil: germen very small ; style scarcely any ; stigmas two. Pericarp : follicles two, cylindric, acuminate, very long, erect, unilocular, univalve. Seeds : numerous, imbricated, oblong, crowned with a pappus. ESSENTIAL CHARACTER. Contorted. Follicles two, erect. Seeds : plumose. Border of the corolla converging.----The species are,

1. Ceropegia Candelabrum. Umbels pendulous : flowers erect; a twining plant; stems slender, round, green or reddish .--- Native of the East Indies.

2. Ceropegia Biflora. Peduncles two-flowered; stem twining: perennial; and a native of the island of Cevlon.

3. Ceropegia Sagittata; Arrow-leaved Ceropegia. Umbels sessile; leaves sagittate; stem twining, filiform, tomentose .--Native of the Cape of Good Hope.

4. Ceropegia Tenuifolia. Leaves linear-lanceolate; stems slender, milky, red, bay or green ; fruit slender, broken at a right augle, smooth .--- Native of Cochin-china.

5. Ceropegia Obtusa. Leaves blunt; stem twining, long, round, branching; perennial; flowers greenish yellow, in large hemispherical axillary umbels, on long peduncles .--Native of Cochin-china, climbing in the hedges.

Cestrum; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, tubular, columnar, obtuse, very short; mouth five-cleft, erect, obscure; corolla monopetalous, funuel-form; tube cylindric, very long, slender; throat rouudish; border flat, filiated, five-cleft; divisions ovate, equal. Stamina : filamenta five, filiform, attached longitudinally to the tube, emitting a toothlet inwards at the middle ; antheræ roundish, quadrangular, within the throat. Pistil: germen cylindric, ovate, length of the calix ; style filiform, length of the stamina; stigma thickish, obtuse, scarcely emarginate. Pericarp : berry ovate, unilocular, oblong ; seeds very many, roundish. ESSENTIAL CHARACTER. Corolla: funnel-form. Stamina: emitting a toothlet from their middle. Berry: unilocular .---- The species are,

1. Cestrum Nocturnum; Night-smelling Cestrum. Fila-

rises with an upright stalk, about six or seven feet high ; the flowers are produced at the wings of the leaves in small clusters, standing upon short peduncles, each sustaining four or five flowers of an herbaceous colour. They appear in August, but are not succeeded by berries in this country; those which come from America are small, and of a dark brown colour. It is a native of the island of Cuba, whence Mr. Miller received the seeds under the name of dama de noche, or lady-of-the-night, probably so called from the flowers sending out a strong odour after sunset. Native of the West Indies, and the continent of South America. It requires to be placed in a dry-stove, with a moderate share of heat in winter, and in the summer to be set in a warm situation in the open air; with this management they will thrive, and produce flowers much better than when they have been under a greater heat. They are propagated by seeds or by cuttings, but principally the latter, although those produced from seeds are always the straightest and most vigorous, because they do not ripen the seed in England, and it is rarely imported. The best time to plant these cuttings is about the end of May, by which time the shoots will have had time to recover their strength, after confinement during the winter season: the shoots which come out from the lowest part of the stalk should always be preferred; these should be cut about four inches long, and five or six of them should be planted in each halfpenny-pot: the earth should be fresh and light, but not full of dung; it must be pressed pretty close to the cuttings, and then they must be gently watered, after which the pots must be plunged into a moderate hot-bed of tanner's bark, and every day shaded from the sun; their waterings should be often repeated in the summer, and if they be sprinkled all over their leaves, it will wash and cleanse them from filth, which will greatly promote their growth.

2. Cestrum 'Vespertinum', Chater-Jlowered Cestrum. Filamenta toothless; tube filform: p-denaces very short. A tree twelve feet in height. Corolla larger than the spike, green; tube filform, bordner expanding, five-parted; divisions sublate, sharp, one-third shorter than the tube, equal, greenish while; I the berries are blue; the bark and fruit fetid.—Native of the West Indies. For the propagation and culture of this plant, see the first species; observing, in addition, that both this and the fifth species must be removed into the bark-stove, and plunged into the tan-bed, in autumn, where they require the same treatment as other tender exotic plants.—Great care must be taken in watering these plants in winter, for they are both very impatient of moisture.

3. Cestrum Diurnum; Day-smelling Cetrum. Filamenta to toolkes; segments of the corolla roundish, reflected; leaves lanceolate.—This rises with an upright stalk to the bright of ten or twelve feet, covered with a smooth, light, green bark; towards the upper parts of the shoots the flowers come out from the wings of the leaves, standing in clusters close to the branches; they are very white, shaped like those of the first sort, and smell sweet in the day-time, from which it drives the name of lady-of-the-day. It flowers in September, October, and November; and is a native of the Havamah, d. Cestrum Tomentosimu. Howers crowded, sessile, ter-

minal; branches, leaves, and calices tomentose.—Found by Mutis in South America.

5. Cestrum Lauriblium ; Laurd-leaved Cestrum. Filamenta toothletted or naked ; leaves elliptic, coriaceous, shining very much ; peduncles shorter than the petiole; stem shubby, erect, round, with an ash-coloured bark; corolla four times longer than the calk; s segments of the rim obtuse,

ments toothed; peduncles subracemed, equal to the leaf—tt; spreading, pale yellow, marked with a gold-coloured streak; inces with an myright stalk, about six or seven feet hig; it to flowers are produced at the wings of the leaves in small clussucceeded by oval berries of a violet colour, full of juice, tres, standing upon short peduncles, each sustaining four on —They are reckoned very poisonous, and are called poison free dowers of an herbaccous colour. They appear in Auberries in Jamaica, of which it is a native: it flowers in Aumet. but are not succeeded by berries in this country; those gust. See the second species.

6. Cestrum Auriculatum; Ear-laced Cestrum. Filamentatoothless; stipules lunate.—This is a very fetid shrub, about two fathoms high: the natives of Lima, in Peru, use it externally to cleanse foul ulcers, and internally in the venerad disease; they look upon it as a pectoral, but it seems to be a plant of suspicious character. Dombey observed it in wet places about Lima.

7. Cestrum Parqui. Filamenta toothletted or. naked, floriferous; stem panicled; stipules linear. This is a fortid shrub, six feet high; flowers odorous in the night.—Native of Chili.

8. Cestrum Hirtum. Flowers subspiked, axillary; leaves subcordate, ovate, acute; underneath with the branches rough with hairs,---Native of the West Indies and Jamaica.

9. Cestrum Nervosum. Leaves lanceolate, opposite, with transverse nerves; peduacles branching; stem shrubby, five or six inches high, covered with a brown bark, aud dividing at top into very small branches; corolla white, and inodorous, --Native of Carthagena, in New Spain.

Ceterach. See Asplenium.

Chaa. See Thea.

Chærophyllum; a genns of the class Pentandria, order Digynia .- GENERIC CHARACTER. Calix: umbel universal, spreading; partial nearly equal, as to the number of rays. Involucre universal: none. Partial: subpentaphyllous ; leaflets lanceolate, concave, reflected, nearly the length of the umbellule. Perianth proper obscure. Corolla: universal, nearly uniform; florets of the disk abortive; proper of five petals, heart-inflected, with the point bent in, flattish, exterior ones rather larger. Stamina: filamenta five, simple, length of the umbeilule. Antheræ roundish. Pistil: germen inferior: styles two, reflected ; stigmas obtuse ; pericarp none ; fruit oblong. acuminate, smooth, bipartile. Seeds: two, oblong, attenuated upwards, convex on one side, flat on the other. ESSEN-TIAL CHARACTER. Involucre: reflected, concave. Petal: heart-inflected. Fruit : oblong, even .-- The first and fourth species of this genus are common weeds, the rest are admitted into botanic gardens only, not being much esteemed either for culinary or medical purposes : if the seeds be permitted to scatter, the plants will come up without further care; or they may be sown, in spring, wherever they are to remain. -The species are,

1. Chærophyllum Sylvestre; Wild Cicely, or Cow-weed; Common Cow Parsley, or Chervil. Stem two feet high and upward, hollow, grooved, generally villose, and purplish, much branched; branches suberect, less hoary than the stem; petals flat, obovate, whitish, at first yellowish-white; seeds columnar, glossy, grooved, blackish, without scent, and almost tasteless : it is very common in pastures, orchards, and under hedges, flowering in May, and in warm situations in April .-Linneus remarks, that this plant indicates a luxuriant soil; and informs us, that the flowers communicate a green and yellow dyc to wool: he also says, that horses, sheep, and goats, are not fond of it. Mons. Villars declares, that horses will not eat it, even in the stable; and, according to Mr. Miller, there are few animals who care to eat it, except the ass. Mr. Ray, on the contrary, asserts, that it has the name of cow-weed, because it is grateful food, before it runs up to stalk, to cows, in the spring; and, in confirmation of this account, Mr. Wainwright says, that the cows like it so well,

that when a pasture is overrun with it, which is often the case about Dodley, they always trun them in to eat it up. Rabbits are well known to be very fond of it; and Mr. Curtis relates, that in time of scarcity the young leaves have been used as a pot-herb. John Barhin, however, mentions in stances of two families having been poisoned by eating a small quantity of the root. Haller says, that the Datch use it in gargenes. Meyrick and Hill both agree in stating, that the leaves operate by urine, and are good in obstructions of that viscera; they should be given in decoction, and in small doese of a wine glass each.

2. Charophyllum Bulbosum; Tuberous Cherril. Stem ven, swelling at the joints, rough with hairs at the base; root like the navew, and biennial; petals white, obcordate, unequal; some florets of the disk bortive.—The roots, taken up early in the spring, are eaten, boiled with salt, oil, and vinegar. Gmelin, however, affirms that both these and the seeds occasion vertigoes; but this is certainly incorrect, at least as far as concerns the fresh root, which many persons have eaten with impunity. It flowers in june and July; and is a native of Gernany, Austria, Switzerland, and Norway, in hedges, and by wood-sides.

3. Chærophyllum Aristatum. Stem even, swelling at the joints; seeds rough with hairs, two-awned; stem round, striated smooth, erect.—Native of Japan.

4. Cherophyllum Tenulum ; Wild Chervil, or Rough Coa Parsley. Stem rugged; joints swelling; stem two feet or more in height, branched, round, solid; petals white; the stem being generally spoited with purple, it is frequently mistaken for hemlock.—It derives the name of *tenulum*, or *tenulum*, from its supposed narcotic or inebriatung quality, which, like the first species, it probably possesses only in a very small degree.

 Charoplyllum Hirsutun; Hairy Cherril. Stem equal; leaflets gashed, acute; fruits two-award; a pubescent plant; it is perennial, four feet high; corolla in some plants red, in others white.—Native of Switzerland, Germany, Austria, and Carniola.

 Chærophyllum Aromaticum; Aromatic Chærophyllum.
Stem equal; leaftets serrate, entire; fruits two-awned; stem and petioles rough with hairs.—It flowers in July and August.
Native of Lusatia, Misnia, Austria, and Silesia.

7. Chærophyllum Coloratum. Stem equal; leaves superdecompound; involucels coloured.—Native of Illyria.

8. Cherophyllum Aureum; Golden Cherophyllum. Stem equal; leaftest gashed; seeds coloured, grooved, awnless; pubescent; stem angular, striated, spotted; rough with lairs at bottom, and not hollow; corollas white, reddish on the outside.—Native of the country about Geneva, of Switzerlaud, Austria, and Germany.

 Chærophyllam Scabrum. Stem equal; leaves gashed, acutc, rough with hairs; peduncles rugged; root fibrous. —Flowering in April and May. Found near Jedo in Abyssynia, and in Japan.

10. Chærophyllum Arborescens. Shrubby.-Native of Virginia.

Chafeweed. See Filago.

Chamæ Moly. See Allium.

Chamarops; a genus of Palms, of the class Polygania, order Diocea, —GENERIC CHARACTER. Hermephrodite Fioner. Calix : spathe universal, compressed, bifd; spadis branching: perianth proper, triparitie, very small. Corolla: triparitie; petals ovate, coriaceous, erect, acute, inflected at the tip. Stamina: filamenta asi, subulate, compressed, scarec cohering at the base. Antherae linear, twin, growing to the interior side of the filamenta. Pisidi : germina three,

roundish: styles as many, distinct, permanent; stigmascute, Pericarp; itropesthree, globose, unilocular. Seeds: soltary, globose. Male Flower: in a distinct plant, flowering in the same manner. Calis and Corolla: as in the hermapinodite. Stamina: a gibbous receptacle, ending in six filamenta, not marked by perforations; in every thing else as the hermaphrodites. ESEENTIAL CHARACTER. Hermaphrodite. Cafix: three-petalled. Stamina: six. Pistil: three; drupes three, one-seeded. Males: diacous, as in the hermaphrodite.—The species are,

1. Chamærops Humilis: Dwarf Fan Palm. Fronds palmated, plaited ; stipes thorny .- This tree never rises with an upright stem, but the footstalks of the leaves rise immediately from the head of the root, and are armed on each side with strong spines; they are flat on their upper surface, and convex on their under side. It grows naturally in Italy, Sicily, and Spain, particularly in Andalusia, where, in the sandy land, the roots spread and propagate so fast, as to cover the ground in the same manner as fern in England; the leaves of these plants are ticd together, to make besoms for sweeping. It is commonly propagated by heads, which sometimes separate from the main root ; if these be carefully taken off with fibres, and planted, they will grow; but the plants so raised are not so good as those which are produced from seeds ; the seeds should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark. where they must now and then be refreshed with water, when they appear; if they be not too close to each other in the pots, they will not require transplanting the first year; they should remain in the tan-bed all the first summer, having plenty of air in warm weather, and being removed into the stove in autumn; if they be plunged into the bark-bed in the first winter, it will greatly promote their growth; they should be carefully turned out of their pots in the following spring, so as to preserve their roots entire, for all the palms have tender roots, and are frequently killed when the roots are broken; they should then be each replanted into a separate small pot, filled with light, sandy, undunged earth, and placed in a fresh hot-bed, to encourage their taking root: they should be gradually hardened in the ensuing summer, and in the following autumn may be placed in a dry-stove, but as they advance and acquire strength, they may be placed in the open air, in a warm situation, in summer, and preserved in a warm green-house in winter, without artificial heat; they require but little water, except in very dry weather, especially during the winter season: they should have larger pots as they advance in growth. There is a variety of this species, not worth describing.

 Chamærops Excelsa. Fronds palmated, nervous, serrate; stipes unarmed.—This is a lofty tree; native of Japan. The variety of this species is a much lower tree.

3. Chamærops Cochin-chinensis. Fronds palnate, plaited; stipes thorny; spatlies partial; corollas monopetalous; trunks eight feet ligh, an inch in diameter, straight, equal.—Native of the woods of Cochin-china. The fronds are fit for covering houses, and making umbrellas.

Champignon. See Agaricus.

Changeable Rose. See Hibiscus Mutabilis.

Chara; a genus of the class Monaecia, order Monandria-GENERIC CHARACTER. Fendle Flower. Colix: perianth four-leaved : leaftes sublate, erect, permanent; the two opposite esterior ones longer than the others. Corolla: none-Fisitil: genenen turbinate; style none; stigma five-cleft, oblong, decidnous. Pericarp: ernst ovate, unilocular, adhering. Secd: single, ovate, spirally striated. Male Flower: at the base of the germen, beyond the calix. Calix: none.

Corolla: none. Stamina: filamenta none. Antheræ globose, before the germen; beyond the calix, beneath. ESSEN-TIAL CHARACTER. Male. Calix and Corolla : none. Antheræ before the germen, underneath. Female. Calix: fourleaved. Corolla : none; stigma five-cleft. Seed : one. These plants possessing no beauty, and growing only in water, are not cultivated in gardens. The species are, 1. Chara Tomentosa; Brittle Chara, or Stonewort.

Prickles on the stein, ovate ; plant always flesh-coloured when alive, but when dry it becomes ash-coloured; stem twisted, brittle, and gritty in the mouth. In summer it abounds in oblong berries, growing yellow when ripe, and having very small black seeds in them .-- It is an annual, flowering from June to October, and is found in salt marshes, ditches, pools, lakes, &c. in many parts of Europe. In England, it has been seen near Evansham Ferry, three miles beyond Oxford ; near Chislehurst in Kent; near Bath; Besorleigh, in the rivulet that runs from Malham Tarn; and is very common in the neat-ditches of Lancashire and Westmoreland.

2. Chara Vulgaris; Common or Stinking Chara, or Stonewort. Stem glossy; leaves toothed on the inside; prickles on the stem capillary, crowded ; the whole plant is a yellowish or reddish green when fresh, and extremely fetid .-- It is an annual, flowering in July and August: found in ditches and pools.

3. Chara Hispida; Prickly Chara, or Starwort. Prickles on the stem capillary, crowded .- The whole plant has a strong scent of garlic; it is found upon the sea-coasts in several parts of Europe, and with us upon Hinton moor, near Cambridge; Ellingham, in Norfolk; near Gayton, Staffordshire: in Yorkshire, Lancashire, and Westmoreland; East Lothian, in Scotland; and in the turf-bogs of Ireland. Annual; flowering from June to October.

4. Chara Flexilis; Smooth Chara, or Stonewort, Joints of the stem unarmed, diaphanous, broader upwards; stems eight or ten inches long .- Native of the sea-coasts in several parts of Europe; in England it is found in lakes, ponds, ditches, and bogs; as, about Henley, near Ipswich, near Knaresborough, near Hornsey, and in Loch Lomond, and several of the Scotch lakes. It is annual, flowering from June to October.

Charlock. See Sinapis Arvensis.

Chaste Tree. See Vitex.

Chate. See Cucumis.

Chaw-stick. See Gouania.

Cheese Renning or Rennet. See Galium.

Cheiranthus; a genus of the class Tetradynamia, order Siliquosa .- GENERIC CHARACTER. Calix: perianth fourleaved, compressed; leaflets lanceolate, concave, erect, parallel, converging, deciduous, the two outer gibbous at the base. Corolla: four-petalled, cruciform ; petals roundish, longer than the calix; claws the length of the calix. Stamina: filamenta six, subulate, parallel, the length of the calix, two of them within the gibbous leaflets of the calix, a little shorter than the other four. Antheræ erect, bifid at the base, acute at the tip, and reflected; a nectareous gland surrounds the base of the shorter stamina on each side. Pistil: germen prismatic, four-cornered, the length of the stamina, marked with a tubercle on each side; style very short, compressed; stigma oblong, two-parted, reflected, thickish, permanent. Pericarp : silique long, compressed, the two opposite angles obliterated, marked with a toothlet, twocelled, two-valved, furnished with the very short style, and the erect bifid stigma. Seeds : many, pendulous, alternate, subovate, compressed with a membranous edge. ESSENTIAL CHARACTER. Germen with a glandulous toothlet on each pagated also by slips; as are likewise all the intermediate 24.

side. Calix : closed, with two leaflets gibbous at the base. Seeds: flat.— The species are, 1. Cheiranthus Erisimoides; Wild Wallflower, or Stock.

Leaves lanceolate, toothed, naked ; stem eject, quite simple ; siliques four-cornered; root perennial; flowers yellow, and in loose spikes or corymbs .- It is a native of Italy, Spain, France, Switzerland, Germany, Austria, Hungary, Sweden, and Eugland, where it is found about Godstow, near Oxford, and East Grinstead, in Sussex. It flowers in June, and ripcus its seed in autumn. If the seeds be allowed to scatter themselves, the plants will come up without care, and will thrive in any soil or situation, and upon walls among rubbish, as the common wallflower.

2. Cheiranthus Helveticus; Swiss Wallflower, or Stock. Lcaves lanceolate, toothed, naked ; stem erect ; siliques fourcornered, acuminated with the style; root perennial; stem erect, somewhat angular, eighteen inches high .-- It flowers in May and June, and the sceds ripen in July. Native of Switzerland.

3. Cheiranthus Alpinus; Alpine or Straw-coloured Wallflower, or Stock. Leaves linear, entire, subtomentose ; stem branching. The whole plant is roughish ; root biennial ; the flowers are pale yellow, or sulphur-coloured, and have little or no smell .--- They appear in June and July, and the seeds are perfected in September. It is found on banks and walls in Austria and Provence, in Switzerland, and on the mountains of Piedmont. This sort, when cultivated, grows as large as the common wallflower, and makes a fine appearance, the racemes being longer, and the flowers growing much closer: but as it has little scent, it has on that account been much neglected.

4. Cheiranthus Strictus. Leaves linear, acute, smooth ; stem shubby, erect .-- Native of the Cape of Good Hope.

5. Cheiranthus Callosus. Leaves lanceolate, entire, callous: stem angular, shrubby .--- Native of the Cape of Good Hope, 6. Cheiranthus Cheiri; Common Wallflower. Leaves lanceolate, acute, smooth, subserrate; stem shrubby, a foot high, ascending; branches angular .- On walls it is seldom more than six or eight inches high, with very tough roots and firm stalks, the leaves short and sharp-pointed, and the flowers small; but in gardens it is two feet high, and branches wide; the leaves are broader, and the flowers much larger: the principal varieties are, 1. Common Dwarf Yellow; 2. Large Yellow; 3, Large Yellow Bloody; 4, True Bloody; 5. Narrow-leaved Straw-coloured; 6. Variegated-leaved Yellow; 7. Winter; 8. White, and these are either single or double. The common wallflower is a native of Switzerland, France, and Spain, and is common on old walls and buildings in many parts of England. It is one of the few flowers which have been cultivated in our gardens from time immemorial, on account of their fragrancy; being of a firm texture. with little sap, it is never affected by cold, so that in severe winters, when the plants are frequently killed in the gardens, those upon the walls receive no injury, though they are much more exposed to wind and frost; the variety of this with very double flowers, is propagated from slips planted in the spring, which readily take root. Another variety, which has variegated leaves, is not so hardy: the large bloody wallflower will frequently rise with double flowers from seeds, if they be carefully saved from such as have five petals; and these double flowers may be increased from slips, but the plants so raised will not produce such large racemes of flowers. as those which are propagated by seeds : the old bloody wallflower, the petals of which are shorter and more numerous. approaching to the common double, but much larger, is pro-4 D

varieties, distinguished by florists from the size and colour of the petals : the wallflowers that are single produce seeds in plenty, but the largest and deepest-coloured flowers should always be selected for seeds ; these should be sown in April, upon poor undunged soil, and when the plants are fit to remove, they should be transplanted into nursery-beds, at about six inches' distance each way, observing to water and shade them until they have taken fresh root, after which they will require no farther care but to keep them clean from weeds all the summer, and at Michaelmas they may be transplanted into the borders of the flower-garden, where they are intended to remain, that the plants may root before the frosts come on .- The above is the common method of treating these flowers, but if the seeds be sown upon poor land, where they are designed to remain, and not transplanted, they will thrive and endure the frost much better than those which are removed ; so that the seeds of these plants may be sown upon ruins or rubbish, where they will thrive, and continue much longer than in good land; and if properly disposed, they will be very ornamental in such places, while their flowers, with their strong odour, will fill the air to a considerable distance with an agreeable perfume. According to Hill, the flowers are used; and an infusion of them when fresh is good against the head-ache, and in all nervous disorders; they are also good to steep in oil, to which they give a cordial warmth, and make it good against pains in the limbs; but they are not much used either way at present.

 Cheiranthus Fruticulosus. Leaves lanceolate, acute, smooth, subserrate; stem shrubby.—This strongly resembles the preceding species; flowers one eighth of the size of the common wallflower, less fragrant, pale yellow. Native of Spain.

8. Cheiranthus Chiuš. Leaves obovate, veinless, emarginate; siloues subulate at the tip.—Native of the isle of Chios, and Russia. The seeds of this and the ninth species are sown in patches at two or three different times; the first in autum, the second at the end of March, and the third at the end of April, or beginning of May, in the borders of the flower-garden, where they will make a variety, when intermixed with other low-growing annual flowers, for three months.

9. Cheiranthus Maritinus; Dwarf Annual Stock Gilf. flower. Leaves elliptic, obtuse, naked, roughish; stem diffused, rough.—It seldom rises more than six inches high; it is an annual plant. For the propagation and culture of it, see the eighth species.

10. Cheiranthus Salinns. Leaves lanceolate, obtuse, quite entire; stem erect; antheræ included; corolla purple, with a yellowish throat; it has the smell of the stock gilliflower. —Native of the salt marshes of Siberia and Tartary.

11. Cheiranthus Incanus; Stock Gilliflower. Leaves lanceolate, quite entire, obtuse, hoary; siliques truncate at the end, and compressed ; stem undershrubby .- The queen's stock gilliflower rises with a strong stalk, which is almost shrubby, a foot high or more; the side-branches are each terminated by a loose spike of flowers; these usually appear in May and June, but the same plants frequently continue flowering most part of the summer; the seeds ripen in antumn, and the plants generally perish soon after; but when any of them grow in dry rubbish, they will last two or three years, and become shrubby, but those with single flowers are not worth preserving after they have perfected their seeds; the flowers of this species vary in their colour, some are of a pale, others of a bright red, and some are curiously variegated, but those of the bright red are generally most esteemed: if the seeds be well chosen, threefourths of the plants will frequently be double; and as they

divide into many branches, they make a fine appearance during their continuance in flower. There are three varieties : 1. The Brompton stock gilliflower, with bright red flowers; 2. The white stock gilliflower, with flowers palecoloured purple, and sometimes purple variegated with white; 3. The white wallflower, with flowers which are of a pure white, and have a great fragrancy, especially in an evening, or in cloudy weather. Native of the sea-coasts of Spain; found also in Italy, Greece, Corsica, and the adjacent isles: these flowers are of very long standing in the English gardens. The old English name of gilliflower, which is now almost lost in the prefix stock, is corrupted from the French giroflier; Chaucer writes it gylofre; Turner, gelover and gelyfloure ; Gerarde and Parkinson, gilloflower. Having been thus far removed from its original orthography, it was easily corrupted by those who knew not whence it was derived, into July flower : pinks and carnations also having the name of gilliflower, from their smelling like the clove, which is called girofle in French, from the Latin caryophyllum ; they were called clove-gilliflowers, and these stock-gilliflowers for distinction. Gerarde says, they were also called garnsey violet, and castle gilliflower. All the varieties of this species flower in May and June, at which time they are the greatest ornaments to the flower-garden, and therefore deserve as much attention as any of the beautiful flowery tribe. In order to raise double flowers, there must be great care taken in choosing plants for seed, without which there can be little hopes of having these flowers in perfection. A very sure way of obtaining many double flowers, is to make choice of those single flowers which grow near many double ones, for those seeds saved from plants growing in beds close to each other, if there happened to be a good many double flowers among them, have been always found to produce a much greater number of plants with double flowers, than those which have been saved from plants of the same kinds which grow single in the borders of the flower-garden. There should be a small bed of each kind planted in the flower-nursery, on purpose to save seeds; or if they be sown there, and the plants properly thinned when they are young, they need not be transplanted, for those plants which spring up from scattered seeds, which have not been transplanted, endure the frost much better than those which have been removed ; because. as these plants send out horizontal roots from the bottom of their stems, which spread near the surface of the ground, so, when they are transplanted, the roots are forced downwards out of their natural direction, and if their stalks were grown tall before removal, they are generally planted low in the ground. whereby they are apt to rot, if the ground be moist and the winter should prove wet; therefore where they can be left unremoved, there will be a better chance of their living through the winter, and as these beds need not be of great extent, so that when the winter proves very severe, it will not be much trouble or expense to arch the beds over with hoops, and cover them with mats in frosty weather, by which method they may be always preserved: the ground where these seeds are sown must not have any dung, for the plauts will grow very vigorous in rich land during summer, but frost, or the heavy rains in autumn, will soon destroy them; for they will thrive upon rock or old wall, when all those which are planted in gardens are destroyed. The best time to sow the seeds is about the beginning of May; and if the season should prove dry, it will be proper to shade the beds with mats every day, to prevent the earth from drying too fast; but the covering must be taken off every evening to admit the dews of night, and they should be gently watered in the evening, twice or thrice a week. When they first appear
with their two seed-leaves, they are often attacked by flies, especially in dry hot seasons; therefore, to prevent them from destroying the plants, the above-mentioned covering should be continued over them during the heat of the day, and the plants ought to be frequently refreshed with water, which will keep them in a growing state, and the flies will not infest them, for they never attack any plant until they have been stinted in their growth : after this they will only require to be kept clean from weeds, and to be thinned to the distance of nine inches or a foot, that they may have sufficient room to grow, and not draw each other up tall and weak. There are some who propagate the double stock gilliflowers by slips and cuttings, which will take root when properly managed ; but the plants so raised are never so strong as those which come from seeds, their spikes of flowers are always very short, and have not half the beauty of those raised from the seed.

12. Cheimanthus Fenestralis; Cluster-teamed Stock Gillifaceor. Leaves crowded in heads, recurved, waved; stem undivided; stem shrubby, from six to eight inches high; corolla petia bolordate, reflected, channelled, notchletted, purple, glittering with gold; it continues three or four years, flowering the second; the third and fourth it puts out branches, which flower the same year.--This plant is proper to stand in windows on account of its smallness, and the very grateful odour it exhales, especially in the evening. It flowers from May to July.

13. Cheiranthus Annuus; Annual Stock Gilliflower, or Ten-week Stock. Leaves lanceolate, somewhat toothed, obtuse, hoary; siliques cylindric, acute at the end; stem herbaceous. It rises with a round smooth stalk, about two feet high, dividing into several branches at top. Of this sort there are the red, purple, white, and striped, with single flowers; and the same colours with double flowers, which are very great ornaments in the borders of the flower-garden, in antumn. If the seeds of this plant be sown at three different times, a succession may be kept up during several months. The first sowing should be about the middle of February, upon a very slender hot-bed, just to bring up the plants, which must be guarded against frost; and when they are fit to remove, they should be transplanted into nurserybeds, at about three or four inches' distance, observing to water and shade them till they have taken root, and afterwards to keep them clean from weeds: in these beds they may remain five or six weeks to acquire strength, and may then be planted in the borders of the flower garden, where they are to remain : if they be transplanted during rain, they will the sooner take root, and afterwards require no farther care. To succeed these, another parcel of seeds should be sown in March, and a third parcel at the end of May. If the last be sown upon a warm border, where they may be covered by placing glasses before them in winter, or covering them with mats, they may be continued in flower till Christmas: and if some of the plants be potted and placed under a hotbed frame in autumn, where they may enjoy the open air in mild weather, and be screened from hard rains and frost. they will keep flowering all the winter, while the weather is not very severe.

14. Cheiranthus Littoreus; Sea Stock Gilliflower, Leaves Janceolate, somewhat toothet, tomentose, and fieshy ; petals emarginate; siliques tomentose; stem a foot high, alternately branching, hoary; leaves alternate, channelled, obtuse: the flowers are smaller than those of the common stock, of a bright red at first, but fading to a purple. The whole plant is very white, and having wooly stalks, has the appearance of a perennial plant, but it generally perishes in automn—It grows naturally near the sec-cost, in the south of France.

Spain, and Italy. The seeds should be sown in autumn on a warm border, where the phants are designed to remain. These will flower early in June, and produce good seeds; such as are sown in the spring, in July and August ; but from these there will be no certainty of having ripe seeds, although they may serve to keep up a succession of flowers.

CHE

15. Cheiranthus Tristis; Dark Joncred Stock Glilfflour; Leaves linear, abbinute; flowers sessible ; petals waved; stem shrabby. This seldom rises above eight or nine inclus in height. The whole plant is roughish, and of a hoary ash colour; it has a grateful odour at night, somewhat resembling that of the geranism triste.—Native of the south of Europe: as this is not so hardy as the others, it requires some protection in the winter.

16. Cheiranthns Trilobus. Leaves toothed. obtuse; calices even; siliques knotted, mucronate, filiform, even; root annual. —Native of Italy, on the sea-shore, near Terraeina.

17. Cheiranthus Trienspidatus : Trifd Steek Gillflower, Leaves lyrate ; silones three-toothed at the tip: an annual plant ; corollas purple.—Native of Barbary. If the seeds be sown in autumn on a warm border, the plantis will live through the winter, and flower early in June, so that good seeds may be obtained from them : when the seeds are sown in the spring, the plants flowering in July and in favonrable seasons, the seed will ripen.

10. Cheiranthus Sinuatus; Prickl-podded Stock Gilifloer. Leaves tomentose, obtuse, subsinuate; branch-leaves entire; siliques nuricate; stalk crect, and the whole plant covered with a white down; lower leaves broad, lanceclate, obtus, alternately indented; flowers flexb-coloured, succeded by long woolly pods, brought from the Isle of Rike, near Rochelle.—Found upon the rocks at Aberdovy in Merionethshire, on the sandy coast of Anglesca, about Abermeny Ferry, at Aberdaren in Germarvonshire, and on the coast of Cornwall. It is biennial, and may be increased by seeds in the same manner as the other sorts; and if they be among rubbish, they will survive the winter better than in rich earth.

10. Cheiranthus Farsetia. Siliques oval, compressed ; leaves linear, lanceolate; stem shrubby, creect; stem a foot high, hoary, stiff, straight, and branching: the flowers are of a dull colour, smelling sweet only in the night. – Nuite of Egypt and Arabia, and observed by Forskael in the kingdom of Tunis.

20. Cheiranthus Tenuifolius ; Narrow-leaved Shrubby Stock Gillflower. Leaves filtform, quite entire, somewhat silky; stem frutescent, branched.—This is a shrub a foot and a half in height, the branches becoming bald at bottom: it flowers in May and June, and is a native of Madeira. Both this and the twenty-first species are quick of growth, and may be propagated by enttings put into the ground, as soon as the phants have done flowering. These cuttings will produce handsome plants to place in the green-house upon the approach of winter, to decoute it in the ensuing spring; they will survive a mild winter under a wall in sheltered gardens, and appear to be almost as hardy as the common stock.

21. Cheiranthus Mutabilis; Broad-leard Skrubby Stock Gillflorer. Leaves harcolate, acuminate, sharply serrate; stem futescent; siliques preduncted.—This is a shrub growing to the height of two or three feet: it flowers from March till May: its chief merit consists in its early flowering. The showy blossoms on first opening are white, sometimes inclined to yellow; in a few days they become purple; and hence its trivial name mutabilis or changeable. For the propagation and culture, see the preceding species.

22. Cheiranthus Quadrangulus. Leaves linear, entire;

CHE

siliques sessile, oblong, quadrangular. This grows a cubit in height, with an herbaccous stem. Flowers in terminating, very long, proliferous, subdecumbent spikes, alternate, sessile, sulphir-coloured, odorous: siliques short; seeds not margined.—Native of the desets of Sheria. It is propagated from seeds, and flourishes in the open air, but will not continue many years.

Chelidonium ; a genns of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calia : perianth twoleaved, roundish; leaflets subovate, concave, obtuse, caducous; corolla petals four, roundish, flat, spreading, large, narrower at the base. Stamina : filamenta very many (thirty) flat, broader at top, shorter than the corolla. Antheræ oblong, compressed, obtuse, erect, twin. Pistil: germen cylindric, the length of the stamina; style none; stigma headed. bifid. Pericarp: silique cylindric, subbivalve. Seeds: very many, ovate, increased, shining; receptacle linear, between the valves, of a kind of circumambient suture, not gaping. ESSENTIAL CHARACTER. Corolla: four-petalled. Calix: two-leaved. Silique: one-celled, linear. If the seeds of the four first species be permitted to scatter, the ground will be plentifully stored with plants; and if a few of them be thrown among rock-work, they will come up without trouble, and produce a good effect. Seeds sown in the autumn will grow with more certainty than in the spring, and come earlier to flower : they should be sown where they are intended to remain, and will then require no care but to thin them where they are too close, and to keep them clean from weeds,---The species are,

1. Chelidonium Maius: Common or Great Celandine. Peduncles umbelled; stem erect, from a foot to eighteen inches in height, cylindric, a little hairy .- It is common in hedges and other shady places, in uncultivated grounds, upon walls, and among rubbish; flowering from May to July, during which time it is in the greatest perfection for use. The juice of every part of this plant is very acrimonious : it cures tetters and ringworms : diluted with milk, it consumes white opaque spots on the eyes: it destroys warts, and cures the itch. There is no doubt but a medicine of such activity will one day be converted to more important purposes. Hill observes, that it is an admirable medicine in obstructions of the viscera. The root, beat into a conserve with sugar, operates both by stool and nrine, and is good in the jaundice. An infusion of the sliced roots is a cordial, and greatly promotes perspiration ; and the juice, both taken inwardly and applied externally, is said to be singularly useful in disorders of the eyes. The root, dried and reduced to powder, is sometimes given to the quantity of balf a drachm for a dose, in the bloody flux and other hæmorrhages. Meyric says, that both the roots and leaves of the celandine have a very acrid and somewhat bitterish taste, which is however much the strongest in the roots. The plant is often used in obstinate janndices, dropsies, suppression of the menses, and other disorders; but the utmost caution should be employed in administering a medicine so highly acrimonious and irritating. It has been observed growing in great plenty, among the ruins of the Duke of Leeds' seat at Wimbledon. There is a variety of this species with double flowers, which generally rises the same from seeds, and may also be preserved by parting the roots.

2. Chehdonium Glaucium; See Celendine, or Yelou-horned Poppy. Peduncleo ne flowered; leaves stem-clasping, sinuated; stem smooth. The whole plant is glaucous; stem strong, nearly two feet high, much branched; petals large, ovate, yellow. The large and numerous flowers, which, although of short duration, succeed one another in great abundance

during most part of summer, make a fine contrast with the sea-green dew-bespangled leaves, and are a greet ornament to air sandy shores. The whole plant abounds in a yellow juice, is feit, and of a poisonous quality, being reputed to occasion madness.—Native of sandy soils, in Switzerland, France, Italy, Austria, Carniola, Denmark, Virginia; and on the coasts of Britain, frequently within reach of the spray of the sea, as in Norfolk, Sufolk, about Duawich, in Lancashire, the Isle of Wight, Kent, Essex, Wales, and Scotland, It flowers from June to August.

3. Chelidonium Corniculatum ; Red Celandine, or Horned Poppy. Pednucles one-flowered ; leaves essile, punnatifid ; stem hispid ; plant glaucous ; root spindle-shaped ; petals oral, deep orage veined, with an elliptic purplish spot at the base of each, soon falling off.— Native of Hungary, Bohemia, Moravia, Austria, about Montpeller, in Piedmont, and in Spain : annual ; flowering in July and August. Found in the sandy corn-fields of Norfolk.

4. Chelidonium Hybridum; Violet Celondine, or Horned Poppp. Peduncles one-flowered; leaves pinnatifid, linear; stem glossy, slightly hairy; siliques three-valved; stem erect, a foot higi, petals violet, fugacious, seldom lasting above three or four hours. Anthera twin, pale blue,—Naiive of the southern countries of Europe, and of sandy corn-fields, between Swaffham and Burwell in Cambridgshire, and in Norfolk. Annual; flowering in July and August.

 Chelidonium Japonicum. l¹eduncles one-flowered; leaves petioled, pinnated, ovate; stem herbaceous, striated, smooth, weak, erect; corolla a little longer than the calix, and yellow.—Native of Japan.

Chelone ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-parted, very short, permanent; divisions erect, ovate. Corolla: monopetalous, ringent; tube cylindric, very short ; throat inflated, oblong, convex above, flat beneath ; border closed, small; upper lip obtuse, emarginate; lower almost equal to the upper, very slightly trifid. Stamina: filamenta four, hid beneath the back of the corolla, the two side ones a little longer. Antheræ incumbent: the rudiment of a fifth filamentum, like the point of a dagger between the upper part of the stamina. Pistil : germen ovate ; style filiform, situation and length of the stamina ; stigma obtuse, Pericarp: capsule ovate, two-celled, longer than the calix. Seeds : very many, roundish, surrounded with a membranons rim. ESSENTIAL CHARACTER. Calix: five-parted. Rudiment of a fifth filamentum between the upper stamina. Capsule : two celled. The seeds of all the species succeed best, if they be sown in autumn; for when they are sown in the spring, they frequently lie a whole year before the plants come up; for which reason, where the seeds scatter, the plants will come up much better than those which are sown by hand .---- The species are,
