1. Chelone Glabra; White Chelone. This grows naturally in most parts of North America, and is called the humming bird tree by Joscelin, in his New England Rarities; it has a pretty thick jointed root: the flowers grow in a close spike at the end of the stalks; they are white, and have but one petal, which is tubular and narrow at the bottom, but swells toward the top almost like the fox-glove flower. It flowers in August, and when the autumn proves favourable, will sometimes ripen in England; but as the plants propagate so fast by their creeping roots, the seeds are seldom regarded. The best time to transplant the roots is in autumn, that they may be well established in the ground before the spring, otherwise they will not flower so strong, especially if the season prove dry; but when the are removed in the spring, it is pring.

should not be later than the middle of March, by which time | their roots will begin to push out new fibres. They will thrive in almost any soil or situation ; but their roots are apt to creep too far, if they be not confined, and sometimes intermix with those of other plants ; and then their stalks stand so far distant from each other, as to make but little appearance; therefore they should be planted in pots which will confine their roots, so that eight or ten stalks will be growing together in each pot; which makes a good appearance .- This plant being very hardy, is not injured by cold, but it must have plenty of water in hot weather,

2. Chelone Obligua ; Red Chelone. Leaves petioled, lanceolate, serrate, all opposite .- Native of Virginia, from whence the roots were sent to England. Both this and the third species flower in the autumn, when there is a scarcity of other flowers, which makes them the morc valuable, especially this species, the flowers of which make a very pretty appearance when they are strong : and if some of them be placed in a shady situation in the summer, they will flower later. For its culture and propagation, see the first species.

3. Chelone Hirsuta; Hairy Chelone. Stem and leaves hirsute ; flower purely white .- Native of New England : for its culture and propagation, see the first species.

4. Chelone Peutstemon. Leaves stem-clasping ; panicle dichotomous ; stem cylindric, pubescent ; corolla personate ; tube the length of the calix; throat oblong, bellying; gape white .- Native of North America. The seeds should be sown in autumn. When the plants are grown strong enough to remove, they should be transplanted into a shady border, which will prevent their flowering the same year; and in the autumn they may be planted in the borders of the flowergarden: the roots seldom last above two or three years.

5. Chelone Campanulata. Leaves opposite, sessile, ovate, lanceolate, extremely acuminate, deeply servate. The whole plant is smooth, and a native of Mexico.

Chenolea ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, globular, somewhat fleshy, five-parted ; segments bent in. Corolla : none. Stamina : filimenta five, filiform, from upright bent in, inserted at the base of the calix, and of the same length. Antheræ minute. Pistil: germen superior ; style filiform, very short; stigmas two, simple, subulate, acute, from spreading bent back, a little longer than the style. Pericarp: capsule round, slightly depressed, umbilicate, one-celled. Seed : single, roundish, bifid at the tip, smooth. ESSENTIAL CHARACTER. Calix : globular, oneleafed, five-parted; capsule one-celled, containing one smooth seed, bifid at the tip .---- The only known species is,

1. Chenolea Diffusa. Stems several, radical, filiform, herbaceous, diffused, simple, and branched, covered with leaves, purple, smooth at bottom, subtomentose at top, unequal, the ends upright ; branches alternate, scattered, few, very short ; flowers axillary, solitary, or in pairs .- It flowers in August and September. Native of the low coast of the Cape of Good Hope.

Chenopodium ; a genus of the class Pentandria, order Digynia,-OENERIC CHARACTER. Calix : perianth fiveleaved, concave, permanent ; divisions ovate, concave, membranaceous on the margin. Corolla : none. Stamina : filamenta five, subulate, opposite the leaves of the calix, and of the same length. Antheræ roundish, twin. Pistil : germen orbiculate; style two-parted, short; stigmas obtuse. Pericarp : none ; calix closed, five-cornered, five-angled ; (angles compressed, deciduous.) Seed : single, lenticular, superior. ESSENTIAL CHARACTER. Calix: five-leaved. five-cornered. Corolla: none. Seed : one; lenticular, supe | branched, smooth, sometimes purplish ; branches alternate ; 25.

rior .- Most of these plants are to be eradicated as weeds, rather than cultivated ; being very succulent and exhausting, and abounding very much in seeds : they should be carefully destroyed, especially on dunghills .---- The species are.

With angular Leaves.

1. Chenopodium Bonus Henricus; Angular-leaved Goosefoot, English Mercury, or Allgood, Good Henry, Good King Harry, Wild Spinach. Leaves triangular, sagittate, quite entire ; spikes compound ; leaflets axillary ; root perennial, branched ; spike terminal, yellowish, conical, mealy, at bottom branched, at top clustered and cylindrical.-It is gathered while young and tender, to eat as spinach, and is preferred before spinach at Boston in Lincolnshire, where it is generally cultivated. The young shoots, peeled and boiled, may be eaten as asparagus, and are gently laxative : the leaves are often boiled in broth : the roots are given to sheep afflicted with coughs .- As a medicine, this herb is ranked among the emollients, but rarely made use of in practice. The common people apply the leaves to old ulcers, to cleanse and heal them. It grows in waste places, by road-sides, about farmyards, &c. flowering and seeding from May to August. The dried herb is used in decoctions for clysters. To propagate this plant, sow the seed in March, on a deep loamy soil, prepared as for asparagus; let the seedlings continue to grow till autumn : about the middle of September, taking advantage of a wet season, set the plants on a bed similar to that on which they were sown, about a foot apart; keep them clear of weeds, and in the ensning spring and summer they will afford an abundant crop. The young shoots, with their leaves and tops, are to be cut as they spring up ; and being a perennial plant, it will continue thus plentifully to produce for a great number of years. In the winter the bed is to be covered with dung, which should be raked off as the spring advances, when the earth round the roots is carefully to be dug or forked up.

2. Chenopodium Urbicum; Upright Goosefoot, Leaves triangular, somewhat toothed; racemes crowded, very straight, approximating to the stem, and very long .- It grows abundantly on dunghills, and in waste places, flowering from July to September. Annual.

3. Chenopodium Atriplicis; Orach, or Purple Goosefoot. Leaves deltoid, coloured beneath ; stem erect. This has the appearance, erect stature, height, colour, and leaves of red garden orach : annual .- Found in Siberia, by Pallas. Native of China.

4. Chenopodium Rubrum ; Red Goosefoot. Leaves cordate, triangular, bluntish toothed; racemes erect, compound, somewhat leafy, shorter than the stem; stems decumbent, and close to the ground .- According to Dr. Withering, there are no shining spangles on the leaves or calix, so as to give the plant a white appearance; but when held against a strong light, an infinite number of shining particles appear.

5. Chenopodium Murale ; Wall or Nettle-leaved Goosefoot. Leaves ovate, shining, toothed sharp; racemes branched, naked .- The whole plant is sometimes tinged with red. Mr. Curtis observes that this, and most other species of this genus, afford plenty of seeds for the support of small hardhilled hirds.

6. Chencoodium Serotinum; Fig-leaved Goosefoot. Leaves deltoid, sinuate, toothed, wrinkled, smooth, uniform ; racemes terminal.

7. Chenopodium Album; Common or White Goosefoot. Leaves rhomboid, triangular, erose, entire behind, uppermost oblong ; racemes erect ; stem upright, from one to three feet high, slightly crooked, somewhat angular and striated, solid. 4 E

racenes axillary, upright, forming a spike of flowers growing inlittle clusters.—It is whiter than most of the cheenopola, and varies exceedingly both when young and in its seeding state. It is the commonest plant of the genus, occurring in every garden, on every dunghill, and in almost every corn-field. It is mentioned by Lightfort and several other authors, as being boiled and eaten for greens, and is known by the name of fat-hen, or muck-seed. Linneus afirms that swine are extremely fond of it, and yet this and the minth species are said to be fat lot this animal; which is contrary to all probability, since the common goosefoot seems to be mild and gently laxative like spinach.

8. Chenopodiam Viride; Green Gosefoel. Leaves rhomboid, tooth-sinuate; raceness branched, somewhat leafy; stem upright, green, with purplish angles.—The appearance of the whole plant is greener than the preceding species; the bright red colour at the angles of the joints is constant, and the leaf much longer.

9. Chemopodium Hybridum; Bastard Gaorépot. Leaves cordate, angulart, racuminet; racemes branching, naked; stem from one to two feet high, wpright, branched, angular, and perfectly smooth...-This species varies the least of any; the panicle of flowers is peculiarly branched and naked, and has a strong disgreeable smell. Mr. Lightfoot enumerates it among the Scotish plants; it is not common near London, being only observed in Battersea-fields, and about North-fields: it has also been found near Ely and Colchester. If any of the genus be poisonus, this must be the species.

10. Cheriopodium Botrys; Cluster or Cat-tacaed Goacefoot; or Oak of Jerusalem. Leave solbong; simulate; racemes naked, multifid. This sends up several stems from the upner part of the brancles: they appear in July, and the seeds ripen in Seytember: when bruised, the leaves emit at very strong odour, somewhat like that of ambrosia; and for this principally the plant is preserved in gardens, for the flowers have no beauty, —Mative of the south of Europe. A few of this, and of the eleventh species, which will come up of themselves, may be transplanted in the spring into pots filled with kitchengarden card, to be preserved through the winter; and the other with flower and perfect their seeds; but unless the winter be very floworable; the roots will be destroyed.

11. Chenopodium Ambrosioides ; Mexican Goosefoot, or Oak of Cappadocia. Leaves lanceolate, toothed; racemes leafy, simple; stem from twelve to eighteen inches high, sometimes reddish, round, striated, with fine scattered hairs; leaves pale green, oblong, sinuated .- Native of Mexico. The leaves and flowery heads of both this and the tenth species, to which the reader is referred for the propagation and culture of this plant, have a strong and not unpleasant smell, and a moderately aromatic taste, somewhat bitterish; on much handling them, an unctuous juice adheres to the fingers. The proper menstruum of their active matter is rectified spirit ; but boiling water will also extract it. The infusions, which are not unpalatable, are said to be of service in humoral asthmas and coughs, and other disorders of the breast: they are supposed also to be antispasmodic and antihysteric. The seed is reckoned among the anthelminthics, and the dried herb is put among clothes, to keep away moths. The variety of this species has leaves strongly resembling those of the botrys, with the same scent; but it has a shrubby stalk, which rises five or six feet, and divides into many branches. It is a native of the Brazils, and must be housed in the winter: it is easily increased by cuttings, during any of the summer months, planted in a shady border, and duly watered;

then set in pots filled with light earth, and placed in the shade till ukey have taken root, after which they may be placed with other hardy exotic plants in a sheltered situation during autumn; and when the frost comes on, they must be removed into the green-house, having plenty of air in mild weather.

12. Chenopodium Multifidum; Buenos Agres GoseJoot, Leaves multidi; seguents linear; flowers axillary, sessile. This rises with a shrubby stalk three or four feet high; with oblong leaves cut into many linear segments; it grows naturally at Buenos Ayres.—It is perennial; and, retaining its leaves through the year, will add to the variety in a greenhouse, during the winter; but it has little to letr heavy to recommed it. It may be propagated by cuttings, and must be treated in the same maner as the preceding species.

13. Chenopodium Anthelminiticum; Worm-seed Gose/god, Leaves ovate, oblong, toothed; racemes leaftes; stems three cubits high, straight, stiff, grooved, lairy, dividing into a few branches to the middle, but above that more branched, —Native of Buenos Ayres, of Pennsylvania, and New Jersey, where it is called *vorm-seed*, and *Jeruauem oak*. It has a disagreeable scent, and the seeds are given to children against the worms.

14. Chenopodium Glaucum; Oak-leaved Goosefoot. Leaves ovate, oblong, repand; racemes naked, simple, glomerate; stem decumbent, marked with lines, branching, smooth, mealy, as is the whole plant; leaves sessile, alternate, the uppermost wedge-form or lanceolate, succentent, blue green, with the edges reddish; stem from twelve to eighteen inches high, angular, green.—The leaves are blunted, and quite white.

** With simple Leaves.

15. Chenopodium Vulvaria; Stinking Goosefoot. Leaves quite entire, rhomboid, ovate ; flowers conglomerate, axillary ; the whole plant is sprinkled with a white pellucid meal; stems numerous, spreading, round, somewhat striated, and thinly beset with leaves, which are alternate, petioled .- This species is easily known by its decumbency, and its permanently disagreeable odour, both green and dried, resembling that of stale salt fish. It is common on dry banks, and at the foot of walls and pailings. It is reckoned a useful autihysteric : some recommend a conserve of the leaves, others an infusion in water, and others a spirituous tincture of them : on some occasions it may perhaps be preferable to the fetids, which have been more commonly made use of, as not being accompanied by any pungency or irritation, and seeming to act merely by virtue of its odorous principle. It is omitted in the last edition of the London Pharmacopoeia, and, as Alione affirms, is not undeservedly neglected. This herb dyes a good strong greenish lemon-colour.

16. Chenopodium Polysperauur; Round-teared Gaoegdat, Upright Bitte, or Alkeed. Leaves quite entire, ovate; stem decumbent; cymes dichotomous, leafless, axillary. The stalk is generally of a bright red colour, with long extended branches, and reddish seeds, which are numerous and strikingly visible, from being only in part covered with the calix. —Mr. Curtis remarks, that it is a troublesome weed to the gar-dener, but scarely in jurious to the farmer. Woodward and Ray, however, affirm that it is generally found in turnip-fields, and that it grows abundantly in hop grounds, and among corn, where the soil is good. It is a very grateful food to fash in ponds.

 Chenopodium Scoparia; Flax-leaved Goosefoot, Beleidere, or Summer Cypress. Leaves linear, lanceolate, flat, quite entire; stem round; leaves ciliated about the edge, nerved beneath; flowers two, sessile in the uppermost axils;

style bifid and trifid; pericarp five-cornered. It is a beauti- | ful plant, naturally disposed to grow very close and thick, and in as regular a pyramid as if cut by art. The leaves are of a pleasant green, and were it not for that, it so strongly resembles the cypress, that at some distance it might be mistaken for it. According to Scopoli, this plant drives away bugs. It grows wild in Carniola, Greece, China, and Japan. The seeds should be sown in autumn ; and in the spring, when the plants are come up, they may be put into pots of good earth, and kept supplied with water in dry weather ; these pots may be intermixed with other plants, to adorn courtyards, &c. where they will appear very handsome, until their seeds begin to swell and grow heavy, so as to weigh down and displace the branches, when the pots should be removed for the plants to perfect their seeds, which will come up of themselves in the spring, if they be permitted to scatter.

Cherleria ; a genus of the class Decandria, order Digynia, -GENERIC CHARACTER. Calix: perianth five-leaved; leaflets lanceolate, concave, equal. Corolla: petals none, except the calix or nectary be so called ; nectaries five, emarginate, placed in a circle, very small. Stamina : filamenta ten, subulate, of which the alternate ones are affixed to the back of the nectaries. Antheræ simple. Pistil : germen ovate; styles three, spreading; stigmas simple. Pericarp: capsule ovate, three-celled, three-valved. Seeds : two or three, kidney-shaped. ESSENTIAL CHARACTER. Calix: the leaved. Nectary: five, bild, resembling petals. An-there: alternate, barren. Capsule: one-celled, three-valved, three-seeded.—The only known species is,

1. Cherleria Sedoides; Stonecrop Cherleria. Leaves opposite, linear, rugged about the edge, connate at the base into a sheath. When the leaves are fallen, the sheaths remain with the keel of the leaves, investing the lower part of the stem; it forms large green mossy tufts; stem about two inches high, closely matted; flowers from the summits of the branches, single, erect, on very short peduncles, vellowish green; leaflets of the calix streaked on the back with three lines; nectaries much shorter than the calix, fleshy, and connected .- Scopoli informs us, that in the garden the flower sometimes produces ten entire nectaries, and has all the stamina arising from the receptacle. It flowers in July and Angust, and is found on the mountains of Dauphiny, Switzerland, Savoy, the Valais, Austria, Carniola, and the Highlands of Scotland : perennial.

Cherry Laurel. See Prunus and Cordia. Chervil. See Charophyllum, and Scandix. Chestnut. See Fagus. Chestnut, Horse. See Æsculus. Chickpea. See Cicer. Chickpea. See Alsine, and Arenaria. Chickweed, Bastard. See Bufonia. Chickweed, Water, See Callitriche.

Chimarrhis; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth margin entire, crowning the germen, permanent. Corolla: onepetalled, funnel-form ; tube very short ; border five-cleft ; segments lanceolate, concave, blunt, hirsute below, with a longitudinal line running along the middle and spreading. Stamina : filamenta five, subulate, hirsute at the base, below the divisions of the border, the length of the corolla. Antheræ oval, erect. Pistil : germen roundish, inferior; style filiform, the length of the stamina ; stigma bifid, obtuse. Pericarp: capsule subovate, obtuse, crowned, two-celled, twovalved; the valves bifid at the tip. Seeds: solitary. Es-SENTIAL CHARACTER, Corolla: funnel form, with a very

short tube. Capsule : inferior, obtuse, two-celled, two-valved, the valves bifid at the tip. Seed : one in each cell .---- The only authentic species is,

1. Chimarrhis Cymosa. This is a lofty tree, with a handsome head, and the boughs spreading out horizontally; leaves ovate, acuminate at both ends, quite entire, shining, petioled, opposite, a foot long, commonly eight or ten at the end of each twig; flowers numerous, small, with white corollas, and without scent, disposed in cymose racemes, half a foot in diameter; those in the axils opposite and solitary, those at the end usually four together; capsules small .- The wood is white, and serves for beams, rafters, &c. Native of Martinico, where it is commonly called bois de riviere.

China. See Smilax. China Pink. See Dianthus.

China Rose. See Hibiscus.

Chinchina. See Cinchona.

Chinqua Pine. See Fagus.

Chiococca: a genus of the class Pentandria, order Monogynia,-GENERIC CHARACTER. Calix: periaoth fivetoothed, superior, permanent. Corolla : monopetalous, funnel-form; tube long, spreading; border five-parted; divisions equal, acute, reflected. Stamina : filamenta five, filiform, length of the corolla. Antheræ oblong, erect. Pistil: germen inferior, roundish, compressed; style filiform, length of the stamina; stigma simple, obtuse. Pericarp: berry roundish, compressed, crowned with the calix, one-celled. Seeds: two, roundish, compressed, distant. ESSENTIAL CHARACTER. Corolla: funnel-form, equal. Berry: onecelled, two-seeded, inferior .---- The species are,

1. Chiococca Racemosa; Climbing Suowberry Tree, or David's Root. Scandent : lcaves broad lanceolate : flowers lateral; panicle racemed, one stipular tooth; stem a fathom or more in height, with smooth loose branches, spreading out horizontally; berry snow-white; seeds two, oblong, acuminate .- The root of this plant has much the same bitter acrid taste with the seneca or snake-root, and has been long used as a strong resolutive and attenuant: it is administered with great success in obstinate theumatisms, and old venereal taints; nor is it entirely useless in the spina ventosa; it is best given in decoction. There is a larger variety, distinguished by larger and pale-coloured corollas, which are purple at the corners. Native of the West Indies, in woods, and on the lower mountains of Jamaica. It is propagated by seeds procured from the West Indies, which should be sown in pots, plunged in a moderate hot-bed, where they may remain till the autumn, and should then be removed into the stove for the winter, and placed on a fresh hot-bed in the following spring, in order to bring them up, for they rarely appear the first year. When they are fit to remove, plant them each in a separate small pot filled with light earth, and plunge them in a fresh hot-bed, shading them from the sun till they have taken new root, and then treating them as other tender plants from hot countries. As they obtain strength, the plants may be set abroad in a sheltered situation, for two months or ten weeks, in the warmest part of the summer; and in the winter should be placed in a moderately warm dry-stove, where they will thrive, and produce flowers in autumn.

2. Chiococca Barbata. Erect; leaves ovate; peduncles axillary, one-flowered; corollas bearded in the throat .- Native of the Marquesas, Society, and Friendly Islands, in the South Seas.

Chionanthus; a genus of the class Diandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, four-parted, erect, acuminate, permanent. Corolla:

CHI

monopetalous, funnel-form; tube very short, length of the calix, spreading; border of form divisions, which are linear, erect, acute, oblique, most extremely long. Stamina : filamenta two, very short, subulate, inserted into the tube. Antherme cordate, creet. Pisitl's germen ovate; style simple, length of the calix; stigma obluse, trifid. Pericarp: drupe round, one-celled. Sceet : rul striated. ESSENTIAL CHA-RACTER. Corolla: quadrifid, with the divisions extremely long. Drarge: with a striated unit.—The species are.

1. Chionanthus Virginica ; Virginia Fringe Tree, or Snowdrop Tree. Peduncles three-cleft, three-flowered .- It is a common shrub in South Carolina, where it grows by the sides of rivulets, and seldom is more than ten feet high; the leaves are as large as those of the laurel, but of a much thinner substance; the flowers come out in May, hanging in long bunches, and are of a pure white, from whence it received the name of snowdrop-tree, as, from the flowers being cut into narrow segments, it has received the appellation of fringe-tree. The best way to obtain good plants is from the seeds, which must be procured from America, for they never have produced any fruit in this country; the secds should be sown soon after they arrive, in small pots filled with fresh loamy earth, which should be placed under a hot-bed frame till the beginning of May, when they must be removed to a situation exposed to the morning sun, but screened from the sun in the middle of the day: in dry weather the pots must be watered, and kept clean from weeds : for, as the seeds lie in the ground a whole year before the plants will come up, they should not be exposed to the sun the first summer, but removed in the following autumn, and placed under a frame, to protect the seeds from being injured by the frost: and if the pots be plunged into a moderate hot-bed in the beginning of March, it will bring up the plants much sooner than they will otherwise rise; by which means they will acquire more strength the first summer, and be better able to resist the cold of the next winter. They are liable to suffer from severe frosts while young, but when they are grown strong, will endure unhurt the greatest cold of our climate in the open air; they delight in a moist, soft, loamy soil, and may also be propagated by layers; but these seldom take root under two years, and not then, unless well supplied with water in dry weather.

2. Chionauthus Zeylanica; Ceylon Snowdrop Tree. Peduncles panicled, many-flowerred; leaves opposite, obovate, smooth on both sides, quite entire, subpetioled.

3. Chiomanhus Compacta. Panicles trichotomous, the last flowers subcapitate; calicies villose; leaves lanceolateoblong; antheræ acuminate.—This tree is fifteen feet in height, will a dusky ash-coloured bark; prebis snow-white, scurcely any tube, but the segments very long, and of a linear shape. Native of the Caribbee islands.

4. Chionanthus Mayepea. Panicles asillary, trichotomous, all the flowers distinct; anthera obtuse. This is a middle-sized tree, five or six feet high, and five inches in diameter, the wood and bark whitish; petals white, concave, terminated by a thread three lines in length; fruit the size of an olive; rind violet, succulent, two lines thick, bitter: the flowers exhale a sweet and pleasant odour.—Native of the forests of Guiana.

Chironia ; a genus of the class Pentaudria, order Monogynia.--CBNERIC CHARACTER. Calit. periauth oneleafed, five parted, erect, acute, permanent; leaffets oblong. Corolla: monopetatous, equal; tube narrower: border fiveparted, spreading; divisions orate, equal. Stamina: filamenta five, broad, slort, growing from the tip of the tube. Antherw oblong, erect, large, converging, and (after having

shed the pollen) spirally twisted. *Pistil*: genuen ovate; style filliom, a little longer than the stamma, declinate; stigma headed, ascending, '*Pericarp*: ovate, bilocular. *Sceds*: numerous, small. *ESSENTIAL CHARACTER. Co. rolla*: rotated. *Pistil*: declinate; stamina on the tube of the corolla. *Anthera*: finally spiral. *Pericarp*: two-celled. The drooping stigma seems to constitute the essence of this genus.....The species are,

1. Chironia Trinervia. Herbaceous; leaflets of the calix membranaceous, keeled; stem annual, quadrangular, acute; flowers elegant blue.—Native of Ceylon and the Cape of Good Hope.

2. Chironia Jasminoides. Herbaceous; leaves lanceolate; stem four-cornered; stem glossy; leaves opposite.—Native of the Cape of Good Hope.

3 Chironia Lychnoides. Stem simple; leaves linearlanceolate; stem entirely simple, round, stiff, and straight, two feet high; corolla purple.—Native of the Cape of Good Hope.

4. Chironia Campanulata. Herbaceous; leaves sublinear; calices the length of the corolla; stem a foot high, round, with long branches; flowers terminal, solitary, wheel-shaped, purple, on a long peduncle.—Observed in Canada by Kalm.

5. Chironia Angularis. Herbaceous; stem acute-angled; leaves ovate, stem-clasping.—This has the appearance of lesser centaury.—Found by Kalm in Virginia.

6. Chironia Linoides; *Flax-leaved Chironia*. Herbaecous; leaves linear. An underslarub, with fibronn, round, smooth branches; flowers scartet; tube of the corolla ouly half the length of the calis, which is half-cleft and obtuse.—Native of the Cape of Good Hope.

7. Chironia Nudicaulis. Herbaceous; leaves oblong, bluntish; stems subdiphyllous, quite simple, one-flowered; callees with setaceous teeth.—This species is singular for its oblong teeth, frequently rooted into a tuft. Discovered by Thumberg at the Cape of Good Hope.

8. Chironia Tetragona. Shrubby; leaves ovate, threenerved, bluntish; leaflets of the calix bluntish, keeled; corolla yellow, large.—Native of the Cape of Good Hope.

9. Chironia Baccifera; Berry-bearing Chironia. Shrubby, berry-bearing .- This plant grows to the height of a foot and a half or two feet, and becomes very bushy, and is rather more so than is consistent with ornament; it produces both flowers and fruit during most of the summer. Native of Africa. The seeds of this, and of the teath species, should be sown in small pots, filled with light sandy earth, soon after they are ripe, and plunged into a moderate hot-bed, and must be frequently but gently watered : sometimes the seeds will lie a long time in the ground, so that if the plants do not appear the same season, the pots should not be disturbed, but preserved in shelter till the following spring, and then plunged into a fresh hot-bed, which will bring up the plants in a short time, if the seeds be good. When they are fit to remove, they should be transplanted into small pots, four or five in each pot; then plunge the pots into a moderate hotbed, and sprinkle them with water, shading them from the sun till they have taken new root; after which they will require a large share of air in warm weather, to prevent them from being drawn up weak : when they have acquired some streugth, they may be gradually inured to bear the open air, but must be screened from great or long rains: when their roots have filled the pots, they should be parted, and each put into a separate pot filled with light sandy earth, but not rich with dung, which must shaded until they have taken fresh root, and then removed to some warm situation, among

root with proper management, but not very readily.

10. Chironia Frutescens. Shrubby; leaves lanceolate, subtomentose; calices bell-shaped; branches round, tomentose, ash-coloured, mostly alternate, subdividing a little at top .- Native of Africa. For its propagation and culture, see the preceding species.

Chlora; a genus of the class Octandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth eight-leaved; leaflets linear, spreading, permanent. Corolla : monopetalous, salver-shaped; tube shorter than the calix, coating the germen; border eight-parted; divisions lanceolate, longer than the tube. Stamina : filamenta eight, very short, seated on the throat. Antheræ linear, erect, shorter than the divisions. Pistil: germen ovate-oblong; style filiform, length of the tube; stigmas four, oblong, cylindric. Pericarp: capsule ovate-oblong, one-celled, somewhat compressed, furrowed, twovalved ; valves incurvated on the side. Seeds: numerous, minute. ESSENTIAL CHARACTER. Calix : eight-leaved ; corolla one-petalled, eight-cleft; capsule one-celled, twovalved, many-seeded; stigma four-cleft. All these plants may be casily propagated from seeds, and require only common care in the cultivation .---- The species are.

1. Chlora Perfoliata; Perfoliate Yellow Wort, or Yellow Centaury. Leaves perfoliate; the whole plant generally very glaucous ; stem cylindric, smooth, from three inches to three feet high; corolla gold-coloured, with a milky juice; segments sometimes nine, slightly emarginate .- Annual; found on chalky and limestone soils, flowering from June through the autumn. Haller says, that this plant is more bitter than the red, (gentiana centaurium,) and that it seems to possess the same qualities : our common yellow centaury, however, does not thrive well in a garden, and though rather impatient of cold, vet if sheltered it becomes mildewed,

2. Chlora Imperfoliata. Corollas six-cleft; stem herbaceous, quite simple, erect, four-cornered, glossy, a hand in height ; the internodes longer than the leaves .-- Annual ; and native of Italy.

3. Chlora Quadrifolia. Leaves in fours ; produced from gentiana perfoliata, and linum quadrifolium ; stem simple, a span in height, somewhat quadrangular, jointed .- Found by Alstroemer in the south of Europe.

4. Chlora Dodecandria. Leaves opposite; calix twelve-cleft; leaflets linear, erect.-Native of Virginia.

Chloranthus; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix : none, but an ovate, acute, concave scale, on which the germen is placed. Corolla: one or three-lobed convex petal, inserted into the outside of the germen. Stamina : filamenta none. Antheræ four, inserted into the lobes of the petal, on three edges towards the inside, and bivalve. Pistil : germen obovate, prominent in front, and bearing the petal; style unequal, very short, angular; stigmas three, very minute, erect. Pericarp: drupe oblong. Seed: nut oblong, smooth. ESSENTIAL CHARACTER. Calix: none. Corolla: a petal three-lobed by the side of the germen. Antheræ growing to the petal. Drupe: one-seeded.—The only discovered species is, 1. Chloranthus Iuconspicuus, or Chu-lan. This is an her-

baceous plant; stems many, from the root, half a foot high, spreading, suberect, a little branching, round, smooth; branches opposite, spreading, round, striated, smooth .- This plant has been long introduced into the royal garden at Kew, as a native of China, where, we are told, it is cultivated in their gardens, though it seems not to have any qualities either palatable or odoriferous, nor any thing to recommend it in 25.

plants that require little water; the cuttings also will take with their tea, to give it a pleasant smell; but this plant itself has no smell whatever. It is preserved in the stove, and may be readily increased by runners.

Chocolate-nut Tree. See Theobroma.

Chondrilla; a genus of the class Syngenesia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix: common. calicled, cylindric; scales of the cylinder very many, parallel, linear, coual; those of the base few, very short. Corolla: compound, imbricate, uniform ; corollets hermaphrodite, very many, equal, in several rows; proper monopetalous, strapshaped, linear, truncated, four or five-toothed. Stamina: filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: germen subovatc; style filiform, length of the stamina; stigmas two, reflex. Pericarp: none; calix cylindric, oblong; seeds solitary, ovate, compressed, muricated ; pappus hairy ; stipe long, attenuated above. Receptacle: naked. ESSENTIAL CHARACTER. Calix: calicled. Floscules: in many rows. Seeds : muricated ; pappus simple, stipitated .---- The species are,

1. Chondrilla Juncea; Rushy Gum Succory, Radical leaves runcinate; stem-leaves linear, entire; root perennial; stem much branched, from two to three fect high, erect at bottom, strigose, towards the top smooth, bright green; corollas slender, yellow, like those of lettuce. The juice of the whole plant is extremely bitter, although the Spaniards use it as a salad herd .- It flowers in July, and ripens its seed in September. Native of France, Switzerland, Germany, Austria, Italy, and Spain. It is seldom preserved in gardens, because the roots are very apt to spread, and become troublesome weeds ; the downy seeds also are carried by the wind to a considerable distance, and fill the ground with plants; the roots strike deep and spread out with thick fibres on every side ; each of these, when cut or broken, will shoot up, so that when this plant has once got possession of the ground, it is very difficult to root it out.

2. Chondrilla Crepoides. Leaves sagittate, stem-clasping; flowers subsessile, lateral; stem simple, usually absolutely so, a foot and a half high, purple at the base, striated, set with a few white bristles; corolla yellow, purplish underneath, the length of the calix : annual.

3. Chondrilla Nudicaulis. Scape naked ; flowers panicled; radical leaves runcinate, obtuse at the end, glossy; toothlet ciliated; corolla pale yellow, consisting of about twenty-four corollules, all forming the ray, and obtusely fivetoothed .- Native of the East Indies.

Christmas Rose. See Helleborus.

Christmas Flower.

Christophoriana. See Herb Christopher.

Christopher Herb. See Actera.

Christ's Thorn. See Rhamnus Paliurus.

Chrysanthemum ; a genus of the class Syngenesia, order Polygamia Superflua.-GENERIC CHARACTER. Calix ; common, hemispherical, imbricate ; scales, close, incumbent, the interior ones larger by degrees, the innermost terminated by a parched scale. Corolla ; compound, radiated ; corollets hermaphrodite, tubular, numerous in the disk; females more than twelve in the ray; proper of the hermaphrodites funnel-form, five-cleft, patulous, length of the calix; of the females strap shaped, oblong, three-toothed. Stamina, in the hermaphrodites: filamenta five, capillary, very short. Antheræ cylindric, tubular, shorter than the corolla. Pistil, in the hermaphrodites; germen ovate; style filiform, longer than the stamina; stigmas two, revolute. In the females: germen ovate; style filiform, equal with the hermephrodites; stigmas two, obtuse, revolute. Pericarp: none; its appearance. Dr. Lind asserts, that the Chinese mix it calix unchanged. Seed : solitary, oblong, without any 4 F

293

pappus; receptacle naked, dotted, convex. CHARACTER. Calix: hemispherical, imbricated, the marginal scales membranaceous. Pappus: margined. Receptacle : naked .---- The species are.

* With white Corollas.

1. Chrysanthemum Frutescens; Canary Oxeve, Shrubby; leaves fleshy, linear, pinnate-toothed, trifid at the end; stem shrubby, nearly two feet high, dividing into many branches; flowers axillary, greatly resembling those of common chamomile; there is a succession of them during great part of the year, for which this plant is chiefly estcemed .--Native of the Canary islands; it will perfect its seed in England when the seasons are favourable; but as the cuttings take root very easily during any of the summer months, the seeds are rarely sown. It will not endure our winters in the open air, therefore when the cuttings have made good roots, they should be each planted into a separate pot, and placed in the shade until they have taken fresh root. then remove them to a sheltered situation till autumn, and thence into the green-house, giving them free air in mild weather, and frequently refreshing them with gentle waterings in winter; in summer they will require more moisture, and should receive the same treatment as other hardy exotics.

2. Chrysanthenium Serotinum; Creeping-root Chrysanthemum. Leaves lanceolate, servate at top, acuminate at both ends; root perennial; the roots creep far under the surface : the stems are strong, and three or four feet high : the flowers appear in September .- It multiplies very fast by its creeping roots, and will thrive in any soil or situation.

3. Chrysanthemum Atratum; Fleshy-leaved Chrysanthemum. All the leaves wedge-shaped, oblong, gashed, fleshy; stem one-flowered .- It is a perennial ; and frequents the pastures of the Alps in Switzerland, Savoy, and Austria.

4. Chrysanthemum Alpinum; Alpine Oxeye. Leaves wedge-shaped, pinnatifid; 'scgments entire; stems one-flowered; stems stoloniferous .- It is perennial; and found in the south of France, Switzerland, the Valais, Savoy, about Tubingen, on the Pyrenees, and in Arragon.

5. Chrysanthemum Leucanthemum : Common Oxeve, or Moonflower, or Great Daisy. Leaves stem-clasping, oblong, the upper serrate, the lower toothed; root perennial, somewhat creeping; stem from twelve to eighteen inches high, erect, rigid, angular, at bottom often purplish and hairy, above naked, simple, or little branched .- It is very common in dry meadows and pastures, sometimes on walls, and in corn-fields, flowering from May to July, and increasing greatly by seed. The fresh leaves chewed, have a sweetish, but unpleasant and slightly aromatic taste, somewhat like parsley, but not hot or biting; they have been recommended in disorders of the breast, both asthmatical and phthisical, and as diuretics, but are now seldom called for. Allioni, however, commends it; and John Bauhin observes, that the young leaves are eaten for salads at Padua, as well as in other places. According to Linneus, horses, sheep, and goats eat it, but cows and swine refuse it. Mr. Curtis remarks, that it is singular, while so many beautiful varieties of the common daisy are met with in almost every garden, we never see this plant in a similar state; he has, however, been credibly informed, that two double varieties of this species are found near Ayr in Scotland. Haller asserts, that the varieties of this plant are innumerable, and he mentions several ; among others, one in which the florets of the ray are fistulous: it is highly probable, therefore, that culture would produce as many varieties of this as the common daisy has afforded. Parkinson mentions it with double flowers. The country people give a decoction of the fresh herb in ale for the jaun- lique, subdivided, smooth and even; flowers subterminating,

ESSENTIAL | dice, which operates by urine. Old Gerarde calls this plant maudlinwort.

6. Chrysanthemum Montanum : Mountain Oxeve. Bottom leaves spatulate, lauceolate, serrate, upper linear; perennial; stems many, erect, very hirsute at bottom, and somewhat villose at top, simple, and one-flowered, but becoming branched in a state of cultivation; leaves smooth .- Said, by Mr. Miller, to have been imported from Verona, near which it grows in great plenty. Sow the seeds in a shady border; they will come up in about six weeks : transplant them, when fit to remove, into another shady border, where they may remain, and keep them clean from weeds.

7. Chrysanthemum Graminifolium ; Grass-leaved Oxeve. Leaves linear, toothed at the end, or the whole length ; perennial; ray of the corolla white .- This and the twelfth species rarely perfect their seeds in England, but being perennials, may easily be increased by parting the roots; the best time for this is in autumn.

8. Chrysanthemum Monspeliense ; Montpellier Oxeye. Lower leaves palmate ; leaflets linear, pinnatifid .- An elegant plaut without scent ; perennial; very smooth and slightly villose, with erect branching stems. This species ripens seed every year in England, by which the plant is easily propagated, for if they be sown in the spring on a common border, they will come up in six weeks; when these are fit to remove, they may be transplanted into a nursery-bed, at about a foot distance every way, and kept clean from weeds till autumn, when they may be removed to the places where they are designed to remain. As these plants extend their branches pretty far on every side, they should be allowed at least two feet room; therefore they are not very proper furniture for small gardens, where there is not room for these large-growing plants; but in large gardens, they may be admitted for variety's sake: if planted upon poor dry land, or upon lime rubbish, they will not grow so vigorously as in good ground, but will endure the cold better, and continue longer: when very succulent, they are apt to rot in winter; but where they grow from the joints of old walls, they continue in vigour several years.

9. Chrysanthemum Balsamita. Leaves ovate-oblong, serrate, eared ; perennial ; stems many, ercct, roundish, very slightly villose; the ray of the flower is white; disk yellow,---It was found by Tournefort in the Levant.

10. Chrysanthemum Inodorum. Leaves pinnate, multifid; stem branching, diffused; flowers large, terminating .- It is an annual; found in corn-fields and by road-sides, flowering from July to September. Old authors usually rank this plant with the chamomiles.

11. Chrysanthemum Achillaa; Milfoil-leaved Chrysanthemum. Leaves bipinnate; pinnas imbricate; stem stiff and straight, many-flowered; stem erect, somewhat angular, a foot high .- Perennial; native of Italy.

12. Chrysanthemum Corymbosum; Corymbed Chrysanthemum. Leaves pinnate; gash-serrate; stem many-flowered; stem erect, from eighteen inches to two or three feet high or more: florets of the ray about twenty in number, white, threetoothed; disk flat; the whole plant is void of taste and smell. It is a perennial; flowers in July and August, and is a native of the mountainous woods of the south of France, Switzerland, Germany, Anstria, Carniola, Hungary, and Siberia: See the seventh species.

** With yellow Corollas.

13. Chrysanthemum Indicum. Leaves simple, ovate, sinuate, angular, serrate, acute; root perennial; stem herbaceous, annual, four feet high, upright, round; branches ob-

on long peduncles, commonly one-flowered, and solitary; all the florets ligulate; their colours are white, red, purple, violet, vellow, orange. - The flowers are there inches and more in diameter, but are not remarkable for the pleasantness of their odour: the many varieties of this species differ not only in colour, but in size and doubleness. These are cultivated through the whole empire of Japan, as well as in China and Cochin-ehina, for the beauty of their flowers, which display themselves during the summer and autumnal months.

14. Chrysanthemum Pinnatifidum; Cut-leaved Chrysanthemum. Shrubby; leaves smooth, drawn to a point at the base, pinnatifid; segments gashed .- Found by Masson near torrents on the highest rocks in the island of Madeira.

15. Chrysanthemum Arcticum. Leaves simple, wedge-form, subpalmate, multifid, obtuse; stems weak, diffused, herbaceous, branching at bottom .--- Native of Kamptschatka and Siberia.

16. Chrysanthemum Pectinatum. Leaves pinnate, linear, parallel, acute, quite entire; peduneles solitary, one-flowered; stems very short, thickish, prostrate, creeping --- Perenuial : native of Spain and Italy,

17. Chrysanthemum Segetum; Corn Marigold. Leaves stem-clasping, the upper laciniate, the lower tooth-serrate: the whole plant is smooth; stem a foot or more in height, upright, striated, branched .- Besides the names of corn-marigold, and yellow or golden cornflower, it is called yellow bottle, in Kent; buddle, which is a corruption of bottle, in Norfolk ; golds, or, as it is more generally pronounced, goulds or gowls, in the midland counties; goulans or goldins, in the north of England ; and gules, gools, guills, or yellow gowans, in Scotland, from the golden colour of the flowers, which, however they may give a brilliancy to the fields in tillage, and please the eye of the passing traveller, are, as Linneus observes, no very agreeable sight to the farmer, as it is a very troublesome weed in sandy soils. Linneus informs us, that it was imported into Sweden along with corn from Jutland, about the end of the last century, and that there is a law in Denmark obliging the farmers to extirpate it. A large quantity, which grew on arable land, was cut when in flower, dried, and eaten by horses as a substitute for hay. The Germans use it for dyeing yellow; and Linneus observes, that the flowers, which appear from June to October, follow the sun remarkably. The plant is annual. The recipe which Linneus prescribes for destroying this weed, is, to dung the ground in autumu, then to give the land a summer fallow, and to harrow in about five days after sowing.

18. Chrysanthemum Myconis: Tongue-leaved Chrysanthemum. Leaves tongue-shaped, obtuse, servate; scales of the calix equal; calix with scales scariose at the tip; corolla deep yellow; ray short, three-toothed; crown of the seed membranaceous .- It is annual; and a native of Portugal, Spain, and Italy.

19. Chrysanthemum Italicum. Leaves bipinnate, serrate; rays of the flowers the length of the disk ; stem procumbent. -This resembles the next species very much, but the stem is more branched, many-flowered, and more ereet; the ray of the flower is white, the length of the disk. Observed by Arduini in Italy.

20. Chrysanthemum Millefoliatum, Leaves bipinnate, toothed; stem decumbent; rays of the corolla shorter than the disk: it is low and bushy, but the flower-stems rise nearly two feet high .- It begins to flower in June, and continues till September. Tournefort first discovered it in the Levant. Being very hardy, it will endure the open air, and may be easily increased by slips, but does not perfect seeds in England, unless in warm dry seasons.

rate, villose; rays shorter than the disk; peduncles axillary, naked, one-flowered, pubescent, the length of the leaves .--Observed by Gmelin in Siberia.

22. Chrysanthemum Coronarium vel Cretieum; Garden Chrysanthemum, or Cretan Corn Marigold. Leaves pinnate, gashed, broader outwards; stem furrowed, leafy, branching, three feet high: florets of the ray very large, broad, and short, obtusely three-toothed; in the wild plant yellow: of this plant there are single and double flowers, both white and yellow. There is also a variety with fistular florets, called quill-leaved chrysanthemum; but the seeds of this degenerate to the common sort .- These plants are always esteemed as annual, so the seeds are usually sown upon a slender hot-bed in the spring, and the plants treated in the same manner as the African marigold, for the culture of which the reader is referred to the genus Tagetes: but as the plants which are produced from seeds frequently produce single flowers, even the seeds were saved from the best double flowers; on that account, many persons now propagate these plants from cuttings, whereby they continue the double sorts only. The cuttings are taken from the plants in the beginning of September, and planted in pots. They take root readily, and if placed under a hot bed frame to serven them from the frost in winter, admitting free air in mild weather, they will survive the severity of that season, and may be transplanted into the border of the flower-garden in the spring : here they will continue in succession, until the first frosts set in. By the above method all the varieties may be continued without variation; but the plants which are thus propagated by enttings will soon become entirely barren, by ceasing to produce any seed.

23. Chrysanthemum Flosculosum; Bastard Chrysanthemum. All the florets uniform, hermaphrodite ; flowers small, solitary, terminating, of a deep yellow colour.-Native of the Cape of Good Hope. It may be propagated in the same manner as the first species of this genus ; which see.

24. Chrysanthemum Japonicum. Leaves petioled, gashed at the tip, and toothed; stem simple, ereet, striated, villose. 25. Chrysanthemum Ceratophylloides. Stem one-flowered; pinnas deeply cut. The whole plant is extremely smooth ; stem simple, one flowered, leafy, straight, growing to a foot in height; florets of the ray marked with lines, and gashed .- It is perennial, and found upon the mountains Zeude and Briga.

26. Chrysanthemum Arragonense. Stem one-flowered : root-leaves heaped, linear, silky, slightly three-toothed at the tip; upper stem-leaves quite entire, acute. From the end of each of the slender woody branches of the stem, a naked peduncle is produced six inches long, sustaining one flower of a sulphur colour, which appears in June and July, but seldom ripens seed in England .- Found in La Sierra de Villaroya, near Puriyosa in Arragon. It may be propagated in the same way as the first species, but the cuttings do not so readily take root. It must be sheltered under a common frame in winter, for it will not bear the cold of the open air in this climate, except in unusually mild seasons.

27. Chrysanthemum Procumbens. Leaves sinuate, gashed, blunt; stem procumbent; stem perennial, three feet high, frequently creeping, slender, and very much branched; peduncles many-flowered, terminating.-There are many varie-ties, but the flowers of all are small. It is found both wild and cultivated in China and Cochin-china.

Chrysitrix; a genus of the class Polygamia, order Diæcia. -GENERIC CHARACTER. Hermaphrodite Plant. Calix: glumes bivalve, many, imbricate. Valuelets: ovate, oblong, 21. Chrysanthemum Bipinnatum. Leaves bipinnate, ser- close, cartilagiuous, permanent. Corolla : chaffs extremely

numerous, heaped into a fiscicle, settaceous, membranecous, coloured, bright, larger than the calix, permanent. Stamina : filamenta solitary, between the chaffs capillary, the length of the chaffs. Anthere linear parking on each filamentum, except the tip of the filamentum. *Pistil:* common, germen oblog, oblue; style filform, length of the stamina; sigma simple. Male in a distinct individual. Calix, Corolla, and Stamina, as in the hermaphrodite. Essentrat. CHARAC-TER. Hermaphrodite: glume bivalve. Corolla of numerous setaceous chaffs. Stamina: many, solitary, between the chaffs. *Pistil:* one. Male: as in the hermaphrodite. *Pis*til: none.— The only known species is.

CHR

1. Chrysitrix Capensis. Roof prennial; leave ensiform, equitant, even, a palm of role in length. The sever comes forth from the apper edge of the scape, like a fastigiate fascile of golden ensites, straitened by a cartillaginous perianth. Jussien remarks that this herb has grassy-rooted leaves; a compressed ancipital scape havas g the top, cloven on eside at the edge, putting forth a single sessile head, with a one-valved contentions the below it, and that the german is sometimes abortive. The fruit is probably one-seeded.— Naite of the Cape of Good Hop.

Chrysobalanus; a genus of the class lcosandria, order Monogynia.—GENERIC CHARCTER. Calks: perianth oneleated, bell-shaped, five-cleft; divisions expanding, withering. Corolla: pechasis five, oblong, flat, spreading, inserted by their class into the calix. Stamina: very numerous, placed in a circle, erect, inserted into the calix. Anthera small, twin. Pistil: germen ovate; style of the shape and length of the stamina, inserted laterally at the base of the germen; sigma obluse. Pericary: drupe ovate, large, one-celled. Seed : nut ovate, marked with five furrows, wrinkled, fivevalved. ESENTIAC CHARCTER. Calix: five-cleft. Petals: five-slive. Style: lateral. Drupe: with a five-furrowed, five-valved nut.—The only species is.

1. Chrysobalanus Icaco; Cocoa Plum. It is an irregular shrub, from three to ten feet high, covered with a ferruginous bark, with pale spots ; flowers inodorous, small, with white petals, having almost the character of the plum; fruits roundish, about an inch in diameter : the skin is very thin, and the pulp small, white, with very little smell, adhering very firmly to the nut: it is of the consistence of a baked apple; the taste austere, but rather sweet, and not unpleasant. They are sold in the markets in the West Indies, and are eaten both raw and preserved. The nut or stone varies in form, but approaches to the ovate-acuminate, and sometimes has six or seven angles .- It is a native of the Caribbean islands, and the neighbouring continent, near the sea. There is a variety which is a native of Jamaica, and another which is a very common shrub in St. Elizabeth's, in the same island, and thrives best in a moist cool soil, and when planted in a dry sunny exposure, the nut of which is only covered by a thin skin. As these trees are natives of the hot regions of America, they will not thrive in England, unless protected by a warm stove. They are propagated by seeds, which must be imported from their native country, and sown in the spring, in small pots filled with light earth, aud plunged into a hot-bed of tanner's bark, observing to water them frequently in small quantities at each time. In six weeks the plants will come up, and, if properly managed, will be fit to remove in a month after, when they should be carefully separated, and each planted into a small pot filled with light kitchen-garden earth, and then plunged into the hot-bed again, observing to shade them from the sun till they have taken fresh root; after which they must have air every day, in proportion to the warmth of the season, and their waterings should be

frequent, but sparing, during the summer. In autumn remove them into the bark-stove, and plunge them into the tan-bed.

Chrysocoma; a genus of the class Syngenesia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix: common hemispherical, imbricate; scales linear, outwardly convex, acumiuate. Corolla : compound tubular, longer than the calix ; corollets hermaphrodite, tubular, numerous, equal ; proper funnel-form; border five-cleft, revolute. Stamina : filamenta five, filiform, very short ; antheræ cylindric, tubular. Pistil : germen oblong, crowned ; style filiform, scarcely longer than the florets; stigmas two, oblong, depressed, involute. Pericarp: none. Calix : scarcely changed. Seeds: solitary, ovate, oblong, compressed; pappus hairy. Receptacle: naked, flat. ESSENTIAL CHARACTER. Calix: hemispherical, imbricate. Style: scarcely longer than the florets. Pappus : simple; receptacle naked .-- Most of these plants are perennial, and natives of the Cape of Good Hope, They may be increased by cuttings, which, if planted in a common border in any of the summer months, and covered with hand-glasses, will easily take root, provided they be shaded from the sun, and duly watered ; when these have gotten good roots, they should be carefully taken up, and each planted in a separate pot filled with light earth, placing them in the shade till they have taken new root: they may then be exposed with other hardy exotic plants till autumn, when they must be removed into the green-house, during the winter season; and should have a large share of fresh air in mild weather, for they only require a protection from frost, and must not be too tenderly treated .---- The species are,

* Shrubby.

 Chrysocoma Oppositifolia. Opposite-leaved Goldylocks. Shrubby; leaves opposite, obovate; flowers fascicled, peduncled : a shrub with brachiated distorted branches; flowers yellow, terminating.—Native of the Cape of Good Hope.

2. Chrysocoma Conaures: Great Shrubby Goldylocks, Shrubby : leaves linear, straight, smooth, decurrent by the back.—This rises with a ligneous stalk, about a foot high, dividing into many small branches, which are garnished with deep green narrow leaves. The flowers are produced at the end of the branches, an bich are are produced at the dire great practices. This flowers are produced at the great practice is the start of the year; and the sects ripen very well in automn. Eoth it and the first species may be increased by sowing them in spring, on a border of light earth; but the mode of raising them by cuttings is most expeditions, and therefore most common.—Native of Spin.

B. Chrysocoma Sericea. Shrubby, silky white; leaves linear, channelled; small branches panicled at top. This is easily distinguished by its very white silky leaves, branches, and peduncles, and by its yellow flowers. The bark and wood have an acrid pungent taste.—Native of Spain, where it is used as a remedy for the tooth ache.

4. Chrysocoma Moutana. Shrubby; leaves oblong, quite entire; flowers solitary; stem shrubby, with round villose branches; leaves acute, villose; flowers single at the ends of the branches.—Found upon Mont Horeb, in Palestine.

5. Chrysocoma Patula. Undershrubby; leaves linear, smooth; branches divaricate; flowers terminating, solitary, scarcely peduncled.—Native of the Cape of Good Hope. 6. Chrysocoma Cernua; Small Shrubby Goldylocks.

6. Chrysocoma Cernua; Small Shrubby Goldylocks, Shrubby ; Leaves linear, recurved, subscahrous; flowers, during impregnation, dropping, of a brown sulphur colour, aodding on one side before they are blown. It flowers the greater part of the year, and ripens seed very well. See the second species,—Native of the Cape of Good Hope.

7. Chrysocoma Ciliata; Heath-leaved Goldylocks. Un-

dershrubby; leaves linear, straight, ciliate; branches pubescent,-Native of the Cape of Good Hope. its proper four leaved glume, the outward scale being ovate, and wider; the three remaining ones very narrow, closely

CHR

8. Chrysocoma Tomentosa. Undershrubby; leaves and branches tomentose; leaves linear, straight.-Native of the Cape of Good Hope.

9. Chrysocoma Scabra. Undershrubby: leaves lancolate, orate, recurved, toolidt-cerrate; peduncles pubescent; theight nine or twelve inches, dividing into many woody branches covered with a brown bark, and these into smaller green ones, on which are very narrow sublinsute alternate leaves; corollas very small, yellow.—It flowers in August and Soptember, and is a native of the Cape of Good Hope.

* Herbaceous.

10. Chrysocoma Linosyris ; German Goldylocks. Leaves linear, smooth ; calices lax ; root perennial ; stalks two feet and a half high : the upper part of the stalk divides into many slender peduncles, each sustaining a single head of flowers, of a bright yellow, and disposed in the form of an umbel. The plant, when handled, sends forth a fine aromatic smell .- Native of Germany, Switzerland, France, and Italy. The seeds will ripen in September, in favourable seasons; but the seedling plants do not flower till the second or third year, and hence the most general method of increasing it is by parting the roots. The best time for this, and for removing the plants, is soon after the stalks decay in autumn, that they may have time to strike fresh root before winter. It will increase very fast by the roots in a dry loose soil, and in the open air; but the roots often rot upon strong wet lands in winter.

11. Chrysocoma Bifora: Two-flowered Goldylocks. Panicled; leaves lanceolate, three-nerved, dotted, naked; root perennial, creeping, spreading on every side to a considerable distance, sending up many erect statks, with flat spear-shaped leaves, ending up onnor server statks, with flat spear-shaped leaves, ending up onnor server statks, with flat spear-shaped leaves, ending the points: these are rough, and have three longitudinal veins; the upper part of the stalks branch out, and form loose panieles of yellow flowers, which are larger than those of the former sort.—Il propagates too fast by its creeping roots, to be admitted into the flowergorden; but as they will grow in any soil or situation, a few roots may be planted on the side of extensive rural walks, round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

12. Chrysocoma Villosa. Leaves lauceolate, villose; calices close; stem a foot and a half high, upright, round, hoary, branched; flowers yellow.-Native of Siberia.

13. Chrysocoma Purpurea, Leaves elliptic lanceolate, subserrate, pubescent, panicled, terminating, corymbed.— Found in the Isle of Tanna.

Chrysogonum ; a genus of the class Syngenesia, order Polygamia Necessaria, -GENERIC CHARACTER. Calix; common five-leaved, flat, spreading; leaflets lanccolate, nearly the length of the flower. Corolla: compound radiate. Corollets : hermaphrodite very many in the disk ; females five in the ray; proper in the hermaphrodites, funnel-form, fivetoothed, erect. In the females ligulate, oblong, truncate, three-toothed. Stamina : in the hermaphrodites, filamenta five, very small. Antheræ cylindrical, tubular. Pistil: in the hermaphrodites ; germen very small; style setaceous, length of the corollet ; stigma obscure. In the females : germen larger, covered with its proper perianth; style shorter; stigmas two, revolute. Pericarp : none ; calix unchanged ; seeds of the hermaphrodites none; of the females solitary, inverse, heart-shaped, depressed, quadrangular, with the sides widish, crowned with a three-toothed scale, gaping inwards, contracted towards the base : each seed lies concealed within 25.

its proper four-leaved glume, the outward scale being orate, and wider; the three remaining ones very narrow, closely converging, and gaping when the seed is ripe. Receptacle: clustly, flat; chaffs linear, obtuse. ESSENTIAL CHARAC-TER. Caliz: five-leaved; seed involved in a four-leaved calide; pappus one-leaved; three-toothed. Receptacle: chaffy.—The only species is,

CHR

 Chrysogonum Virginianum. Leaves moderately haivy, opposite, on long petioles; ou the top a golden flower; seeds obovate, convex without, concave within, having two obscure grooves on them, and of a pale bay colour.—Native of Virginia.

Chrusophullum ; a genus of the class Pentandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth five-parted, small; leaflets roundish, obtuse, permanent, Corolla : monopetalous, bell-shaped ; border five-cleft ; segments roundish, very much expanded, shorter than the tube. Stamina : filamenta five, subulate, placed on the tube, converging. Antheræ roundish, twin, incumbent. Pistil: germen roundish; style very short; stigma obtuse, subquinquefid. Pericarp: berry globular, ten-celled, large. Seeds: solitary, bony, compressed, marked with a scar, shining. ESSENTIAL CHARACTER. Corolla: bell-shaped, ten-cleft; segments alternate, spreading. Berry: ten-seeded .- These trees being natives of the hottest parts of the world, cannot be preserved in this country, without being kept in the warmest stoves; and should always remain in a hot-bed of tanner's bark, otherwise they will make but little progress. They are propagated by seeds, which must be procured from the places of their growth, for they do not produce them in Europe. These seeds must be frcsh, otherwise they will not grow; and if they be sent over in sand, it will preserve them from drying too much ; when they arrive they must be sown as soon as possible, in small pots filled with light fresh earth. and plunged into a good hot bed of tanner's bark. If the seeds be good, and the bed in a proper temperature of warmth, the plants will appear in five or six weeks, and in two months after will be strong enough to transplant ; in doing which, the plants with all the earth should be shaken out of the pots very carefully, and separated with their roots entire, and each replanted into a small pot filled with light fresh earth, and plunged again into a hot-bed of tanner's bark, watering and shading them until they have taken fresh root. The chief care they require is, to keep them in a proper degree of heat, and never to put them into too large pots. In winter they should be watered twice a week, in small quantities .---- The species are,

1. Chrysophyllum Cainito; Broad-leared Star Apple. Leaves ovate, striated in parallel lines, tomentose, and shining underneath; leaves alternate, petioled, quite entire; peduncles lateral, one-flowered, numerous, very short .--- Brown has two species of chrysophyllum, which he calls, I. Star Apple Tree, and 2. Damson Plum. Both have the leaves ferruginous underneath. The fruit of the first is larger and globular; of the second, smaller and smooth. The last, he says, is found wild in many parts of Jamaica, but seldom grows to any considerable size: the first is cultivated all over the country, and thrives with very little care; it rises commonly to a very considerable size, and spreads much; but its branches, like those of the other sort, are very slender and flexile, and hang down when charged with fruit. The fruit is full of milk, which it retains even in the most perfect state ; but though this juice be rough and astringent in the bark, and even in the unripe fruit; yet when the fruit is in full perfection it becomes sweet and gelatinous, with an agreeable clamminess, and is very much esteemed. The juice of this 4 G

fruit, a little before it is perfectly ripe, when mixed with a small quantity of orange juice, will occasion extreme costiveness, and would undoubtedly prove a very powerful remedy in some disorders. Perhaps the action of the fire might take off much of the native roughness of the juice, if it were to be inspissated by that means. The Americans are fond of this fruit, but it is rarely eaten by the Europeans .- Native of Martinico and Domingo. This, as well as the rest of the plants in this genus, is preserved in several curious gardens for the beauty of the leaves, for which this species is very remarkable : the under sides of its leaves shine like satin ; the upper sides are of a deep green. They continue all the year. and make a very pretty appearance in the stove.

CHR

2. Chrysophyllum Argenteum ; Narrow-leaved Star Apple. Leaves sickle-ovate, shining, and tomentose underneath. The leaves are green, and smooth on the upper surface, without the parallel lines which mark the foregoing species; underneath they are of a silvery-shining green. The fruit is roundish, of a dirty blue purple colour, the size of a middling plum, and eatable; the pulp is soft, blueish, and slightly milky .--- Native of Martinico.

3. Chrysophyllum Glabrum; Smooth-leaved Star Apple. Leaves quite smooth on both sides. This tree grows fifteen feet in height, erect, and branching ; fruit blue, the form and size of a small olive; but seldom eaten, except by slaves and children.

4. Chrysophyllum Monopyrenum. Leaves elliptic, acuminate, golden, tomentose beneath ; fruit ovate, one-seeded .---Native of the West Indies,

5. Chrysophyllum Microcarpum. Leaves ovate, smooth, pnbescent beneath ; berries oblique, oblong, one-seeded.-Native of Hispaniola.

6. Chrysophyllum Negosum. Leaves oblong, acuminate, smooth on both sides ; fruit acuminate, wrinkled .- Native of Jamaica

Chrysosplenium ; a genus of the class Decandria, order Digynia .- GENERIC CHARACTER. Calix: perianth four or five-parted, spreading, coloured, permanent; divisions ovate, the opposite ones narrower. Corolla : none, unless the coloured calix be called so. Stamina : filamenta eight or ten, subulate, erect, very short, placed in an angular receptacle ; antheræ simple. Pistil : germen inferior, ending in two subulate styles, the length of the stamina ; stigma obtuse. Pericarp: capsule two-beaked, two-parted, one-celled, two-valved, surrounded with the green calix. Seeds: very many, very small.-ESSENTIAL CHARACTER. Calix : four or five-cleft, coloured. Corolla: none. Capsule: twobeaked, one-celled, many-seeded .--- If any curious person feel disposed to cultivate the plants of this genus in a garden, they must be planted in very moist shady places, otherwise they will not thrive. They succeed best in pots filled with bog earth, set in a pan of water, and placed under the shelter of a wall or hedge .---- The species are,

1. Chrysosplenium Alternitolium ; Alternate-leaved Golden Saxifrage. Leaves alternate; the root has offsets, but no creeping suckers ; leaves all deeply notched ; root-leaves two or three, kidney-shaped, bluntly notched, on long hairy petioles; stem-leaves two or three, on petioles decreasing in length as they approach the top; the upper smooth; stem three-cornered, with imperfect angles, hairy below, smooth upwards, near the top forked, the forks bare of leaves .- It it found in moist shady places, and by the sides of rivulets, in Lapland, Sweden, Denmark, Germany, Switzerland, Carniola, Italy, Siberia, Japan, and in Great Britain, though less commonly, near Bingley, and about Esholt, eight miles from Leeds in Yorkshire, Portland Heath, near Norwich, in

Worcestershire, and in Scotland. A black boggy soil by hills, in wet woods, is the favourite situation of this plant.

2. Chrysosplenium Oppositifolium ; Opposite-leaved Golden Saxifrage. Leaves opposite; stems creeping at bottom, square, very tender, erect, about four inches in height, beset with a few stiffish hairs, branched and forked at top; flowers yellow, in a sessile fastigiate corymb ; segments of the calix nearly equal; seeds of an orange colour; stem erect, round. -This is found in the same soil and situation as the other, in Denmark, Holland, Switzerland, and Germany. It is more common in England than the first species, and may be found on Hampstead Heath, in the boggy part of Charlton Wood, Polingland Heath, near Norwich, and at Selborne in Hampshire : it flowers in April, or early in May, and ripens seed in May or June. Perennial.

Chu-lan. See Chloranthus.

Chibouls, or Cibouls. See Allium.

Cicca; a genus of the class Monœcia, order Tetrandria .--GENERIC CHARACTER. Male Flowers scattered. Calix: perianth four-leaved; leaflets roundish, concave. Corolla: none. Stamina : filamenta four, setaceous ; antheræ subglobular, the length of the calix. Female Flowers scattered on the same plant. Calix: as in the males. Corolla: none. Pistil: germen roundish; styles four, two-parted, subulate, the length of the germen; stigmas acute, permanent. Pericarp: capsule subglobular, tetracoccous, elastic. Seeds: solitary. ESSENTIAL CHARACTER. Male. Calix: four-leaved. Corolla: none. Female. Calix: three-leaved. Corolla: none; styles four; capsule tetracoccous.---The only species known is,

1. Cicca Disticha. A shrub: leaves alternate, petioled, distich, ovate, acuminate, glossy.-Native of the East Indies. It is frequent in the kingdom of Champava, and is cultivated, but rarely, in the metropolis of Cochin-china. Cicely. See Chærophyllum.

Cicer ; a genus of the class Diadelphia, order Decandria. -GENERIC CHARACTER. Calix: periantly five-parted, length of the corolla ; segments four, incumbent on the banner, the two middle converging longitudinally, the lower underneath the keel. Corolla : papilionaceous ; banner flat, roundish, larger, bent in on the sides; wings obtuse, half the length of the banner ; keel shorter than the wings, sharpish. Stamina : filamenta diadelphous, rising ; antheræ simple. Pistil : germen ovate ; style simple, rising ; stigma obtuse. Pericarp: legume rhomboid, turgid, inflated. Seeds: two, roundish, gibbous, with knots on the sides, crooked and bent in at top. ESSENTIAL CHARACTER. Calix : fiveparted, length of the corolla; the four upper segments incumbent on the banner; legume rhombed, turgid, two-seeded. -The only species at present known is,

1. Cicer Arietinum; Chickpea. Annual: stem from a foot to eighteen inches in height, erect, leafy, branched; corolla purple or white; calix hirsute .- Native of the south of Europe, the Levant, and Africa, where it is frequently eaten both raw and boiled. Gerarde says it is sown in our London gardens, but not commonly, and is in English named common cich, or ciches, red cich, or sheep's cich, or peason. Parkinson adds the names of cicers and rammes ciches. Hill informs us that the seeds are eaten, and are found to be gentle diurctics. The seeds may be sown in spring, in the same manner as peas, making drills with an hoe about an inch and a half deep, in which the seeds should be sown at about two inches asunder, and the earth drawn with a rake into the drill to cover them. The drills should be made at three feet distance from each other, that there may be room for their branches to spread, when the plants are fully grown,

as also to hoe the plants between them, to keep it clean from weeds, which is all the culture these plants require. It flowers in June, and the seeds ripen in August; but unless the season prove warm and dry, the plants decay in this country before the seeds are ripe.

Cichorium; a genus of the class Syngenesia, order Polygamia Zqualis. GENERIC CHARACTER. Calir: common calicled, cylindric; scales cight, marrow, lancedate, equal, forming a cylinder, and the others incumbent and shorter. Corolla: compound, flat, uniform; corollules hermaphrodine, teeply five-toodited. Stamiar filamenta five, capillary, very short. Anthera cylindric, pentagon, tabulous. Piulli: gene oblong: style filform, the length of the stamina; stigmas two, revolute. Pericarp: none. Calis: cylindric, convergng at top. Seeds: solitary, compressed, with sharp angles; pappus obscurely hairy, slightly five-toothed. Receptacle: conventa charge: slightly five-toothed, obscurely hairy; receptacle somewhat chaffy.— The species are,

1. Cichorium Intijbus; Garden and Wild Succory, or Chicory, Flowers twin, sessile ; leaves runcinate ; root perennial, yellow on the outside, tapering, branched, the thickness of the finger, from a span to a foot in length, milky; stem from one to three feet in height, upright, rigid, crooked, angular, roughish to the touch, and generally very much branched ; flowers generally in pairs, sessile in the bosom of the upper leaves; florets of a fine blue, frequently white, and sometimes red; tube white, dilated, and hairy at top; border ribbed on the under side, and villose; antheræ deep blue .--The fine blue colour of the florets is convertible into a brilliant red by the acid of ants; the flowers open at eight, and close at four. It is common in the borders of corn-fields, flowering from July to September, and increasing itself much by seed. This plant has generally been considered as a noxious weed, although for several years past the French have cultivated it as food for cattle. Arthur Young, Esq. introduced it into England for the same purpose in 1778, and has since cultivated it to a considerable extent with great success. In Lombardy it is sown mixed with other herbs of pasture, and cut three or four feet high; it is there reputed to increase both the milk and flesh of cattle, and to be made very nutritious when made into hay: horses eat it greedily, and it is an important object for summer soiling both for them and cattle; sheep also eat it freely. It defies drought, being of early growth, and the first large and spreading leaves covering the ground so as to retain the moisture : the thick stiff stalks will support themselves against winds and the heaviest rains, nor does the severest cold at all injure it. Its quick growth increases its value, because it furnishes abundance of salutary fodder, at the season when green food is scarce. It has been known to grow seven inches in three weeks, whilst sainfoin and burnet grew only four inches; two cuttings may be made of it in the first year, and three or four, according to the season, every year after, in April, June, August, and October, or in May, July, and October, never letting it stand till it becomes hard and sticky; or it may be cut continually, by beginning again when the whole piece is gone over, and thus yield a constant supply of fresh food during seven or eight months. The produce is said to be superior, on the whole, to that of lucerne, in the proportion of three to one. A piece of ground sown with succory, was found to yield by the acre the year of sowing, at two cuttings, July the 24th and October the 17th, nineteen tons four hundredweight ; second year, at three cuttings, May 21st, July 24th, and December 3, thirty-eight tons nine hundred weight ; and

the whole average produce of four years was nearly thirty tons. The quantity of seed produced on an acre has been, the first year a hundred and a half; the second, two hundred weight; and the third, from three hundred and a half, to four hundredweight and a half. After allowing for the partiality which commonly attends novelties, and notwithstanding this succulent plant seldom dries well for hay in our climate, except in very dry seasons, yet, as far as our experience has hitherto gone, it must be conceded that succory seems to be a valuable object of culture, as fresh feed for horses, cows, and sheep : the leaves, when blanched, are caten early in the spring as salads; and the roots, gathered before the stems shoot up, are eatable, and when dried may be made into bread. The Germans dry and pulverize them to mix with their coffee, to two parts of which they add one of succory roots, which is said to increase its strength and salubrity, as well as improve the taste. Hill informs us, that an infusion of the root opens obstructions, and is good against the jaundice. A decoction of the whole plant, fresh gathered, works powerfully by urine, is good for the gravel, and promotes the menses. Succory is an useful detergent, aperient, and attenuating medicine, acting without much irritation, tending rather to cool than heat the body, and at the same time corroborating the tone of the intestines : the juice, taken in large quantities, so as to keep up a diarrhea, and continued for some weeks, has been found rather to produce excellent effects in scorbutic and other chronical disorders. It is the common succory, or rather highly improved variety of it, (for in its ordinary wild state it is dry, hard, and juiceless,) that is now introduced into field culture with great advantage. The proper quantity of seed to be sown upon an acre, either alone or with spring corn, is twelve pounds; but if it be sown with various other seeds. the quantity of succory seed must be less, in proportion to the quantity of such seeds. When sown with barley or oats. with either of which it succeeds very well, it must be sown of course at the usual time of sowing these grains; but it may be put alone into the ground with safety at any time, between March and September. It should not be mixed with clover, unless the latter be expected to fail; chicory does not stool. tiller, or thicken on the ground ; it flourishes best where it has most room and air; it should seem therefore that the drill busbandry would be most suitable to it : thus cultivated, after the first year it may be mown four times a year. If sown for seed only, it should be drilled alone, or at least drilled across corn before it be up; but it is better sown by itself.

2. Cichorium Endivia ; Broad-leaved Succory, or Common Endire. Flowers solitary, peduncled ; leaves entire, crenate ; stem herbaceous, annual, two feet high, upright, round, thick branched; root-leaves many, large, subcuneiform, sinuatetoothed, smooth on both sides; the uppermost lanceolate, small; flowers pale blue, solitary, peduncled .- Biennial; native of China and Japan. The plain broad-leaved endive is not much cultivated in the English gardens, for the curled endive being more tender and loss bitter, is generally preferred, although the Italians still cultivate the former sort; the curled endive is one of the principal iugredients in autumn and winter salads. The first season for sowing the seeds is in May, for those which are sown earlier generally run up to seed before they have arrived to a proper size for blanching, and it frequently happens that the seeds sown in May, in the rich grounds near London, will run to seed the same autumn ; but this seldom happens in colder situations, therefore there should be some seeds sown about the middle or end of the month. The next sowing should be about the middle of June, and the last in the middle of July : these three crops will furnish a supply for the whole season, as there will be 300

that there will be three different crops from the same beds. When the plants appear they must be weeded, and watered in dry weather, to keep them growing until they be fit to transplant, and should then be removed to a rich spot of open ground, well dug, levelled, and very dry; it must be well watered, to prepare it to receive the plants, the largest of which should then be drawn carefully out of the seed-bed, so as not to break their roots, leaving the smaller ones to acquire more strength. As the plants are drawn up, they should be placed with their roots even, all the same way, and every handful as they are drawn should have the tops of their leaves shortened, to make them of equal length; this will make the planting of them much easier than when the plants are promiscuously mixed, heads and tails; then the ground should be marked out in rows at one foot asunder, and the plants set ten inches distant in the rows, closing the earth well to the roots : they should be well watered every other evening, till the plants have taken good root, and afterwards should be kept clean from weeds. When the plants of the seed-bed have been thus thinned, they also should be well cleaned and watered, which will encourage the growth of the remaining plants, so that in ten days or a fortnight after, there may be another thinning made by removing some more plants, which should be transplanted as above described; and at about the same distance of time, the third and last drawing of plants may be transplanted. Those plants which were first transplanted will be fit to blanch by the latter end of July at farthest; and if they be properly managed, in three weeks or a month will be fit for use, which will be as soon as these salads are commonly required; for during the continuance of good cos-lettuce, few persons care for endive in their salads; nor indeed is it so proper for warm weather: if any of the plants should put out flower-stems, they must be immediately pulled up, and carried away as good for nothing. As the quantity of roots necessary for the supply of a middling family is not very great, there should not be too many plants tied up to blanch at the same time; therefore the largest should be first tied, and in a week after those of the next size, so that there may be three different times of blanching the plants, on the same spot of ground ; but as in some large families there is a great consumption of this herb for soups, the quantity of plants should be proportionably greater, at each time of planting and blanching. In order to blanch endive, provide a parcel of small osier twigs or bass-mats, to tie up some of the largest heads, which should be done in a dry afternoon, when there is neither dew nor rain to moisten the leaves in the middle of the plants. which would occasion their rotting soon after their being tied up: the manuer of doing it is as follows : First gather up all the inner leaves of the plant in a regular order into one hand, and then take up those on the outside which are sound, pulling off and throwing away all the rotten and decayed leaves which lie next the ground, observing to place the outside leaves all round the middle ones, as nearly as possible in the natural order of their growth, so as not to cross each other: then having grasped the whole plant close up in your hand, tie it up with the twig, bass, &c. at about two inches below the top, very close, and about a week after go over the plants again, and give them another tie about the middle, to prevent the heart-leaves from bursting out on one side, which they are subject to do as the plants grow, if not thus prevented; in doing this, you need only tie up the largest plants first, and so go over the piece once a week, as the plants increase in their growth, by which means you will continue the crop longer than if they were all tied up at one the strong winds. Observe also to keep them clear from

plants from each sowing very different in their growth, so time; for when they are quite blanched, which will be in about three weeks or a month after tying, they will not hold sound and good above ten days or a fortnight, especially if the season prove wet, and it is on this account that I would advise sowing at three or four different seasons, that you may have a supply as long as the weather will permit; but in order to this, you must transplant all the plants of the last sowing under warm walls, pales, or hedges, to screen the plants from frost; and if the winter should prove very sharp, you should cover them with some pease-haulm, or such other light covering, which should be constantly taken off in mild weather : these borders should also be as dry as possible, for the plants are very subject to rot, if planted in a moist soil in winter. Although it has been before directed that the plants should be tied up in order to blanch them, yet this is only to be understood for the two first sowings ; for after October, when the nights begin to be frosty, those plants which are so far above ground will be liable to be much injured thereby, especially if they remain uncovered in frosty weather: therefore the best method is, to take up your plants of the latter sowings in a very dry day, and with a large flat-pointed dibble plant them into the sides of trenches of earth, which should be laid very upright, planting them sideways on the south side of the trenches, towards the sun, with the tops of the plants only out of the ground, so that the hasty rains may run off, and the plants be kept dry, and secured from frosts. The plants thus planted will be blanched fit for use in a month or five weeks' time, after which they will not keep good more than three weeks before they will decay; you should therefore continue planting some fresh ones into trenches every fortnight or three weeks, that you may have a supply for the table; and those which were last transplanted out of the seed-beds should be preserved till February, before they are planted to blanch, so that from this you may be supplied until the beginning of April or later : for at this last planting into the trenches it will keep longer than in winter; the days growing longer, and the sun advancing with more strength, dries up the moisture much sooner than in winter, which will prevent the rotting of these plants; but if the weather should prove frosty, these latter plantations of endive should be covered with mats and straw to preserve them, otherwise the frost will destroy them, but the coverings must always be taken off when the weather is favourable. When your endive is blanched enough for use, dig it up with a spade, and after having cleared it from all the outside green and decayed leaves, wash it well in two or three different waters, to clean it the better from slugs, and other vermin, which commonly shelter themselves among the leaves. But in order to have a supply of good seeds for the next season, you must look over those borders where the last crop was transplanted, before you put them into the trenches to blanch, and make choice of some of the largest, soundest, and most curled plants, in number according to the quantity of seeds required: a dozen of plants will produce seeds enough for a small family; and for a large one, two dozen or thirty plants will be sufficient. These plants should be taken up, and transplanted under a hedge or pale, at about eighteen inches distance, in one row, about ten inches from the hedge or pale: this should be done in the beginning of March, if the season be mild, otherwise it may be deferred a fortnight longer: when the flower-stems begin to advance, they should be supported by packthread, which should be fastened to nails driven into the pale, or to the stakes of the hedge, and run along before the stems, to draw them upright close to the hedge or pale, otherwise they will be liable to break with

weeds, and about the beginning of July your seeds will begin to ripen; as soon as you find the seeds quite ripe, you must cut off the stalks, and expose them to the sun upon a coarse eloth to dry, and then beat out the seeds, which must be dried and put in bags of paper, and preserved for use iu some dry place: but be cautions not to wait for all the seeds ripening upon the same plant, for if so, all the first-ripe and best of the seeds will scatter and be lost before the others be nearly ripe; so great an inequality is there in the time of ripening the seeds of the same plant.

3. Cichorium Spinosum ; Prickly Succory. Stems diehotomous, spiny; flowers axillary, sessile. This sends out many long leaves from the root, which are indented on their edges, spreading flat on the ground.-In England the plant is bienuial, but is frequently killed by cold winters; it flowers and seeds about the same time as the first sort, and may be treated in the same way as the endive.

Cichory. See Cichorium.

Cicuta ; a genus of the class Pentandria, order Digynia .--GENERIC CHARACTER. Calix : umbel universal, roundish; rays very many, equal; partial roundish, with very many equal setaceous rays. Involucre universal: none; partial many-leaved; leaflets bristly, short; perianth, proper scarcely visible. Corolla : universal, uniform ; floscules all fertile ; proper of five ovate, inflected, nearly equal petals. Stamina: filamenta five, capillary, longer than the corolla. Antheræ simple. Pistil: germen inferior; styles two, filiform, longer than the corolla, permanent; stigmas headed. Pericarp: none; fruit subovate, furrowed, bipartile. Seeds : two, subovate, convex, and striated on one side, flat on the other. ESSENTIAL CHARACTER. Fruit subovate, furrowed .--The species are,

1. Cicuta Virosa; Long-leaved Water Hemlock. Umbels opposite-leaved; petioles margined, obtuse; stem round, hollow; leaves pinnate; leaflets lanceolate, ternate, the serratures white at the tip; antheræ white or reddish purple; styles at first short and very close, after flowering much longer: stigmas white, obtuse,-This plant generally grows near the sides of large stagnant waters, or in shallow slow rivers: towards the end of autumn, the root for the succeeding summer is formed out of the lower part of the stalk; this is divided transversely into many large unequal cells, so that it becomes specifically lighter than water, and in winter, when the rivers or pools swell, is buoyed up; the old root then rots, floats all the winter, and in rivers is frequently carried to great distances. In the spring the old root is washed away, and the new one, on coming near the soil, sends out many slender fibres, by which it is again fixed, grows, and flowers. This plant is one of the rankest of vegetable poisons; numerous instances of the fatal effects of it are recorded in the Philosophical Transactions by Dr. Watson, upon the authority of Wepfer, Haller, and others. Linnens informs us that it is fatal to swine; and Withering observes, that early in the spring cows often eat of it, and are killed by it; but that as summer advances, and its scent becomes stronger, they carefully avoid it: he adds, that horses and sheep are not affected by eating it, and that goats greedily devour it with impunity. Strong emetics are the most approved remedies for counteracting this poison. It will not grow where there is not a considerable depth of water for it to root in.

2. Cicuta Bulbifera, Branches bulbiferous; the leaves are divided into very minute capillary segments; the flowers are white, with the smell of cumin flowers .- Native of watery places in Virginia and Canada. It may be propagated by seeds sown in autumn on a shady border; the plants will 26.

come up in the spring, and require no other care but to keep them clean.

3. Cicuta Maculata. Serratures of the leaves mucronate : petioles membranaceous, two-lobed at the end; stem thick, spotted with purple, three fect high and more ; flowers white ; fruit middle-sized, ovate-globular, thick, gibbous, distantly ribbed ; umbels many .--- Native of watery places, in Virginia, Switzerland, &c. For its propagation and culture, see the second species.

Cimicifuga ; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth fiveleaved ; leaflets roundish, concave, caducous. Corolla : nectaries four, petal-shaped, urceolate, cartilaginous. Stamina : filamenta twenty, filiform. Antheræ twin. Pistil : germina four to seven; styles recurved; stigmas longitudinal on the style. Pericarp: capsules oblong, opening with a lateral suture. Seeds: covered with spreading scales. ESSENTIAL CHARACTER. Calix: four or five-leaved ; nectary four, urceolate; capsules four to seven .---- The only species is,

1. Cimicifuga Foetida, Root perennial, thick, knotty, short, with many thickish fibres creeping transversely; stem sometimes two yards in height, red at the base, thence green, slightly hirsute, scarcely striated; flowers in long terminating racemes, alternate, globular, on very short pedicels; the flowering-spike hangs down at first, but becomes erect as the flowers open .- The whole plant has a strong virose smell. occasioning the head-ache; it flowers in the middle of July, ripens its seed in the middle of August, and is a native of the farther Siberia, from the river Jenisca. For its propagation and culture, see Actaa.

Cinchona; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, superior, short, five-toothed, permanent; teeth sharp, Corolla: monopetalous, funnel-shaped, five-cleft; tube long, obscurely augular; segments lanccolate or linear, equalling the tube. Stamina : filamenta five, in the middle of the tube. Antheræ linear, erect. Pistil: germen inferior, turbinate, obscurely angular; style the length of the stamina; stigma thick, bifid or entire. Pericarp : capsule crowned with the calix, bipartile, opening into two parts inwardly, the partition parallel. Seeds : many, oblong, compressed, surrounded by a membranaceous wing. ESSENTIAL CHARACTER. Capsule: inferior, two-celled, bipartile; the valves parallel to the partitions, opening inwardly .- The einchonas are trees: the branches are round, except at the top, where they are obscurely four-cornered; the flowering branches are alternately compressed ; the leaves are opposite, undivided, and quite entire; their florescence, in most of the species, is a brachiate panicle, with trifid peduneles.----The species are,

* Flower's tomentose, Stamina included.

1. Cinchona Officinalis; Common Jesuit's Bark, or Officinal Cinchona. Leaves ovate-lanceolate, smooth; capsules oblong .--- This is a tall tree, with a trunk rather bigger than a man's thigh; the branches are covered with a purplish brown bark, frequently rugged, with obliquely transverse chinks, and scarred by the fallen leaves; corolla tomentose on the outside; the segments acute, woolly within, shorter than the tube .- It is a native of Peru, growing most abundantly on a long chain of mountains, extending to the north and south of Loxa, between two and five degrees of south latitude, where the trunks frequently exceed a man's body in size: they thrive best in a red clayey or rocky ground. especially on the banks of small rivers or torrents, and the most proper season for cutting the bark is from September to November, which is the only period of considerable inter-4 H

302

plantation in the low lands to the spot where the trees abound, they build huts for the workmen, and a large hut for the bark : each Indian is provided with a large knife, and a bag that will hold about fifty pounds of green bark; he cuts down the bark as high as he can reach from the ground, and then fastens a stick about half a yard long with tough withs to the tree, like the step of a ladder, and having sliced off the bark as high as he can reach with this, he fixes a new step, and thus ascends to the top, while another Indian below gathers up what he cuts down: this process they perform by turns, going from tree to tree, till the bag is filled. Care is taken not to cut the bark wet; and if it should happen to be moist, they immediately carry it to the low country to dry, for otherwise it loses its colour, turns black, and rots; which will also happen if it remain long in the hut without being spread, so that the Indians remove it as soon as the weather permits, and while they are cutting, the mules are employed in carrying the bark to the drying place, where it is spread in the open air, and frequeutly turned. As the trees are said to perish soon after they have been stripped of their bark, a scarcity of them has been apprehended; but Condamine asserts, that the young trees do not die by losing their bark, but send out fresh roots from the base; and as the trees which stand to any considerable age probably increase by seed, the fear that this valuable bark may be exhausted seems to be groundless. The bark of this tree is brought to us in pieces of different sizes, some of which are rolled up in thick short quills, and others are flat: the outside is brownish, and has sometimes a whitish moss on it; the inside is of a yellowish, reddish, or rusty iron colour. Those who affect to be nice in the choice of their drugs, prefer such pieces as are rolled up about the size of a common quill. To the taste it is astringent and bitter, and has an advantage over other bitters, in being aromatic. To enumerate all its virtues, would require the extent of a volume. Morton, the contemporary of Sydenham, was one of the first who made considerable use of the bark. From us it was carried into France, where the dauphin was cured by it. Boerhaave restrains the use of the bark with almost innumerable cautions; while Hoffman and others are boundless in its praise. All the prejudices with which it had at first to contend, are now done away, and its character has long been universally established : it gives out its virtues both to cold and boiling water ; but the decoction is thicker, and more powerfully tinctured with its taste : the bark, however, is generally given in substance, and may be taken in very considerable doses with the most perfect security: sometimes it is found necessary to join it with opiates, to prevent its passing off too suddenly as a purgative. A most excellent tincture of the bark, under the name of Huxham's Tincture, is sold in the shops, in which preparation the bark is rendered still more efficacious by the addition of orangepeel and snake-root. The best sort is bitter, resinous, breaks short and smooth, and is easily reduced to powder. 'The great number of complaints in which this medicine may be advantageously employed, seem to entitle it to the character of an universal one. In-many disorders it is a sovereign specific ; and every practitioner finds by daily experience, that its use may still be carried to a greater extent of cases. Its first and principal operation appears to be the strengthening of the solids ; and however variously its salutary effects may appear, they are undoubtedly the consequences of their general property or power. In all disorders where the bark is found serviceable, other medicines of an astringent or bitter nature may be used, and will be found serviceable, though not so effectual as that, when it is given in substance, which

mission from rain. Having made a road from the nearest | it always should be where the stomach will bear it, as none of its preparations contain all its parts, and none of its parts separately answers so well as the whole. Many are intimidated from the use of this medicine, though convinced of its salutary effects, through fear of its astringency; but there is very little cause to be apprehensive on that account; it is a prejudice for which there is in reality very little foundation, for the truth is, the bark is not of a very astringent nature: it may be given in almost all disorders, when once there is a fair remission of the fever, and the pain which attends it; and in general, while the pulse of a grown person does not exceed seventy strokes in a minute, it is safe and useful. So far from causing obstructions in any part of the body, it in many instances removes such as are already formed, as is frequently experienced in glandular swellings, and scrophulous cases: it has been given to women two days after delivery with success, to the amount of a drachm every three hours, without lessening the lochia; and during the natural flux of the menses, without in the least interrupting them; and even in the confluent small-pox, the use of it does not lessen the spitting: whence it appears, that the astringency of this medicine is too slight to obstruct either any natural or critical discharge; and, therefore, whenever its use is indicated on other accounts, it may be freely administered, without running any risk of doing mischief by its astringency. If ever any injury were sustained by its use in a case to which it is adapted, a too late, and not too early administration, is generally to be blamed. It was first celebrated for its efficacy in fevers, and in this respect it still maintains its reputation : it is indeed the principal thing to be depended on in all kinds of fevers; and if given in the ardent, when they are once brought to intermit, it generally effects a cure. In the low kinds of fevers its effects are equally salutary, but its use should be begun much earlier ; in agues and all other intermitting complaints, it is almost a certain remedy. It is not, however, only in fevers of every kind that the bark is so potent a remedy, but also in numerous other cases, and particularly in mortifications. It has also of late been much used in cases of acute rheumatism, especially after the violence of the disease has been in some degree moderated by the antiphlogistic treatment, or when an evident remission has taken place. In the fluor albus, profluria, and hæmorrhages of every kind, the decoction of the bark is of excellent use; and the tincture taken in water of various parts, as chalybeate, &c. is extremely useful in restoring lost appetite. If any medicine, in short, deserved the title of a panacea. the bark would prefer the fairest claim. Foul ulcers, by a free use of the bark, are soon reduced to a healing state; it resolves glandular tumors, and promotes a laudable suppuration in those of an inflammatory nature .- But it should be noticed, that as the judicious use of this medicine is so extensively beneficial, so an improper one may be productive of as ill consequences; for though it is an excellent febrifuge, its use in ardent fevers is only in the time of their intermitting, for when the fibres are tense its use is not necessary: its primary effect being to increase their firmness, must, in this case, render it highly improper to be administered. Cases sometimes occur in which its free use would be very hurtful, such as where symptoms of congestion or topical inflammation of the head appear, which are known by redness of the eyes, phrenetic delirium, &c. It has also been sometimes accused of producing a difficulty of respiration; and though it is one of the most potent antiseptics, or resisters of putrefaction, yet in mortifications attended with a fulness of the pulse, or such as arise from too large a quantity of blood, its use should not be admitted; but in such morti-

fications as originate in a poverty of that vital fluid, it is truly excellent, and cannot well be used too freely .- Those who cannot take the bark in substance, may infuse an ounce of it reduced to a fine powder in three quarters of a pint of cold spring water for the space of an hour, and then pour it clear off: three or four ounces of this infusion is a moderate dose. We have no well-authenticated account at what time or by what means the medicinal efficacy of the Peruvian bark was first brought to light: most of the tales commonly related have too fabulous an air to be admitted here; but the following statement given by Geoffry seems to be the most probable, and certainly is the best authenticated. A great number of the trees which surrounded a lake near a town in Peru, were torn up by an earthquake, and thrown into the water, which they rendered bitter. An Indian, urged by his thirst, during a fever under which he laboured, drank plentifully of this water, because he could procure no other; and observing that he soon recovered, he related the case to others, who laboured under similar circumstances, and on following his example were likewise cured; on this, inquiry was made, and it was soon discovered that the water derived its virtue from the trees; and presently after, that the medicinal virtues resided in the bark of them only. About the year 1638, a Spanish soldier being quartered in the house of an Indian, was seized with an ague, and he compassionating his case, told him of a remedy, which was no other thau the bark, with which he cured himself, and afterwards many of his comrades. At length the vice-queen, wife of the count de Cinchon, then viceroy of Peru, was by this same soldier cured of an intermitting fever with the same medicine, which, on this occasion, received the name of pulvis comitissæ, cortex china-china, c chinchina, kina-kina, or kinkina, guinaguina, or guinguina. The countess is said to have distri-buted a large quantity of the bark, upon her recovery, among the Jesuits, in whose hands it acquired still greater reputation, and by whom it was first introduced into Europe, acquiring the name of Jesuit's bark, cortex and pulvis Jesuiticus, pulvis paturm, and also cardinal de Lugo's powder, that charitable prelate having bought a large quantity of it at a great expeuse for the use of the poor at Rome, whence it spread into France and England, and at length became general. For a more particular account of the bark and its various properties, read Lewis, Newman, Motherby, and Percival. The other species of cinchona approach in some degree to the virtues of the common officinal bark, but seem less efficacious, and their power less perfectly ascertained in practice. The red bark (see the seventh species) has indeed been often considered as of still higher efficacy than the common, and has been thought to be the bark, which, according to Arrot, the Spaniards call cascarilla colorada, and was probably the kind brought originally to Europe, and which proved so successful in the hands of Sydenham, Morton, and Lister; as it appears, from the testimony of the oldest practitioners, that the bark first employed was of a much higher colour than the common bark.

2. Cinchona Pubescens; Pubescent Cinchona. Leaves ovate, elongated at the base, pubescent underneath; capsules cylindrical. The branches of this species are pubescent towards the end.—Native of Peru.

3. Cinchona Macrocarpa; Long-fruited Cinchona. Leaves oblong, pubescent underneath, ribbed; branches jointed, the size of a swan's quill; flowers subsessile.—Native of Santa Fé.

** Corollas smooth ; Stamina standing out.

4. Cinchona Caribbæa; Caribbean Cinchona. Peduncles axillary, one-flowered. This is an erect branching shrub,

ten feet high, or from fifteen to twenty feet, according to Swartz; corolla smooth, segments of the border linear, the length of the stamina ; stigma thickened, undivided .- Jacquin informs us, that the leaves are from two to three inches long. and reflex at the end; that the flowers are of a very pale flesh-colour, exceedingly sweet-scented; and the capsules, before they become ripe green, are very bitter, and abound in a juice that excites heat and irritation on the lips and nostrils. Dr. Wright informs us, that the Jesuit's bark tree of Jamaica and the Caribbees rises only to twenty feet, with a trunk not thick in proportion, but hard, tough, and of a yellowish white colour in the inside; the leaves, he says, are of a rusty green, and the young buds of a blueish green hue; the flowers of a dusky yellow colour, and the pods black ; when ripe they split in two, and are with their flat brown seeds in every respect similar to the first species ; the bark in general is smooth, and gray on the outside, though in some rough and scabrous; when well dried, the inside is of a dark brown colour : its flavour at first is sweet, with a mixture of the taste of horse-radish, and of the aromatics of the east, but when swallowed, of that great bitterness and astringency which characterises the Pernvian bark. It grows near the sea-shore, and is called sea-side beech in Jamaica. Native of the West Indies.

5. Cinchous Corymbifers; Corymbiferous Cinchona, Leaves oblong, lanceolate; corymba saillary; trunk upright, round, smoothish, a fathom or more in height, the thickness of the human arm; branchers round, spreading, opposite, the upper ones herbaceous, compressed at the joints; leaves acuminate, spreading, smooth and even, a hand in length, deep green, with the midrh purple underneath; petioles round, spreading, louger than the interstices of the leaves, scarcely an inch in length; stignles membramecous, acute; flowers white, red on the outside; before opening they appear of a dusky purple; the bark is extremely hitter and subastringent, very like the common Jesui's bark.—Native of the islands of Tongatabo and Eaoow in the South Seas, where it is antivated on account of the pleasantness of its odour, and the beauty of its flowers.

6. Cinchona Lineata. Pauicle terminating; leaves ovate, acuminate, smooth; capsules five-cornered; branches round at bottom, with an ash-coloured bark, purplish at top; stipules ovate, acute; germen five-cornered.—Native of the island of Dominica.

7. Cinchona Floribunda. Panicle terminating; capsules turbinate, smooth; leaves elliptic, acuminate; the whole of this species is very smooth: the branches are round at bottom, but obscurely four-cornered at top, and purplish ; leaves resembling those of the coffee shrub, frequently short, a span in length, spreading very elliptic, on the upper surface even, shining, with a groove along the middle, ou the under paler, veined, nerved; the nerves oblique, and but little raised; petiole half an inch in length, convex beneath .- This tree is nearly the size of a cherry tree, seldom thicker than the human thigh, and tolerably straight; the wood is light and porous, without any of the bitterness and astringency of the bark ; the flowers, which appear in June, are in small tufts, at first white, but afterwards purplish ; the bark is of a lighter red than that which was sent to St. Lucia under the name of red bark, inclining more to the colour of cinnamon, notwithstanding which they are probably of the same species. This tree grows in a stiff red clay, delights in a shady situation. a north-west aspect, under larger trees, and is generally near the middle of a hill by some running water. Native of St. Lucia, Martinico, and Hispaniola.

8. Cinchona Brachycarpa. Panicle terminating; capsules

obovate, ribbed; leaves elliptic, obtuse; capsule obovate, | with eleven ribs .- Native of Jamaica,

CIN

9. Cinchona Angustifolia. Panicle terminating; capsules oblong, five-cornered; leaves linear-lanceolate, pubescent. This is a small tree from ten to fifteen feet in height, with an upright smooth trunk, covered with a wrinkled ash-coloured bark, which becomes brown and striated near the root; corolla white and odorous; tube an inch long; segments of the border the length of the tube; capsule oblong, roundish .--Native of Hispaniola.

Cineraria ; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix: common, simple, many-leaved ; leaflets equal. Corolla : compound, radiated; corollets hermaphrodite, equal, numerous in the disk; female ligulate, the same number with the leaves of the calix in the ray; proper of the hermaphrodite funnel-shaped, with an erect five-cleft border; female ligulate, lanceolate, toothletted at top. Stamina, in the hermaphrodite : filamenta five, filiform, short. Antheræ cylindric, tubulous, five-cleft at top. Pistil, in the hermaphrodite : germen oblong ; style filiform, the length of the stamina; stigmas two, almost erect. Females: germen oblong; style filiform, short; stigmas two, oblong, bluntish, revolute. Pericarp: none. Calix: unchanged. Seeds: solitary, linear, quadrangular; pappus hairy, copious. Receptacle, naked, flattish. ESSENTIAL CHARACTER. Calix : simple, many-leaved, equal, Pappus : simple, Recentucle : naked. The leaves are commonly entire, but sometimes pinnatifid; most of the species are tomentose. Every species may be propagated by cuttings, planted in a shady border during the summer months, and duly watered; in a month or five weeks they will put out roots, soon after which it will be necessary to transplant them into pots, as their roots are very apt to spread in the full ground. They are generally natives of the Cape of Good Hope, and therefore too tender to bear the open air of our climate in winter; vet if too tenderly nursed, they are liable to be drawn up weak ; therefore the surest way to preserve them, is to make young plants annually from cuttings, and place them in a common hot-bed frame in winter, where they may enjoy the full air in mild weather, but be screened from the frost; in summer they should be placed abroad with the hardier sorts of exotic plants .---- The species are,

1. Cineraria Geifolia; Kidney-leaved Cineraria. Peduncles branching; leaves kidney-shaped, suborbiculate, sublobed, toothed, petioled, herbaceous, round, striated; stalks with white hairs scattered over them; leaves alternate, smoothish above, subhirsute beneath, especially the more tender ones, two inches long; corolla yellow, shaped like that of common ragwort .- Native of the Cape of Good Hone.

2. Cineraria Cymbalarifolia, Leaves lyrate, the end leaf kidney-shaped, toothletted ; upper stem-leaves clasping, lobed, quite entire; root a solid bulb; stem herbaceous, simple, even; flowers peduncled, terminating, many; ray of the corolla purple .- Native of the Cape of Good Hope.

3. Cineraria Sibirica : Siberian Cineraria. Raceme simple; leaves cordate, obtase, toothletted, even; stem entirely simple, one-leafed; root perennial; stem undivided, the height of a man; stem-leaves with petioles dilated at the base, and clasping .- Native of Siberia, the Levant, and probably of the Pyrenees.

4. Cineraria Glauca. Raceme simple; leaves spatulate. cordate, quite entire; stem quite simple; the leaves are of a glaucous hue, rather fleshy; the petioles are edged in a spatulate form .- Perennial; and a native of Siberia.

difform; flowers large and purple .- Native of the Cape of Good Hope.

6. Cineraria Cordifolia; Heart-leaved Cineraria. Panicle few-flowered; stem-leaves petioled, cordate, sharply serrate. smooth; stem angular; root perennial, fibrose, brown; stem from one to two feet high, straight, obscurely angular, a little striated at top, fistulose, simple, almost smooth and green; corollas yellow; florcts of the ray about twenty; pappus toothletted when viewed with a magnifier .- Native of Austria and Switzerland.

7. Cineraria Crispa. Flowers panicled: stem-leaves spatulate, oblong, serrate, obtuse, clasping, dilated and toothed at the base; two feet high .-- Native of Anstria.

8. Cineraria Integrifolia; Mountain Cineraria, or Fleawort. Leaves oblong, obscurely toothed, (or almost entire,) shaggy; flowers in a simple involucred umbel (sometimes single.) According to Linneus, this plant is extremely varible. The several varieties of it may be found on the Alps and Pyrenees, in Switzerland, Austria, about Montpellier, in Siberia, &c. It grows in high pastures, or open chalky downs, in some parts of England, as on Gogmagog hills, Bartlow hills, and Newmarket heath, and near Basingstoke and Andover. It has the radical leaves numerous, spreading on the ground, ovate, obovate, or spatulate; stem three, and sometimes six and nine inches high; flowers yellow; peduncles unequal; calix furrowed, with scariose edges; seeds hirsute. -It is a perennial, and flowers in May and Junc. See the tenth species.

9. Cineraria Longifolia. Leaves obscurely toothletted, all oblong .- Native of Austria.

10. Cineraria Palustris; Marsh Cineraria, Flowers corymbed; leaves broad, lanceolate, tooth-sinuated; stem villose; leaves thick, tomentose, and almost clammy, covering the stem quite up to the flowers; the lower cut, and scarcely semipinnatifid ; root perennial, large, fibrose, running deep in muddy ditches. Meyrick, Hill, and Culpeper, all agree in calling this plant flea-wort, while Mr. Miller, and others, whose botanical authority is at least more respectable, give it to the eighth species, to which the reader is referred. They say that a mucilage made of the seeds, is useful to cool the throat in fevers, that the juice of the leaves is esteemed a good remedy for disorders of the breasts, but that it is very unpalatable, and not absolutely to be depended upon. This plant frequents marshes, in many parts of Europe .- It is found in Lincolnshire, about Marsh and Chatteress in the Isle of Ely, near Norwich, Yarmouth, and Hadiscoe in Norfolk, about Pillin Moss in Laucashire, and Aberavon in Merionethshire. There are several varieties of this species, but none worth enumerating.

11. Cineraria Aurea. Flowers corymbed ; leaves lanceolate, serrate, tomentose underneath; stem villose; flowers yellow, with a large ray .- Perennial, and a native of Siberia.

12. Cineraria Maritima; Sea Cineraria. Flowers panicled; leaves pinnatifid, tomentose : divisions sinuated : stem shrubby; stems many, woody, two or three feet high, divided in many branches, which have a white downy bark ; leaves very woolly, six or eight inches long, deeply sinuated and jagged on their borders. The stems which support the flowers are a foot or more in length, having two or three small leaves on each, shaped like those below, and terminated by many yellow flowers, growing in pauicles, or rather corymbs, shaped like those of common ragwort : they appear from June till August, and ripen seed in the beginning of October. Ray says this plant is very common every where on the coast of the Mediterranean, but that it cannot be found in England, 5. Cineraria Sonchifolia. Leaves stem-clasping, sinuate, nor any of the northern countries of Europe; yet Mr. Miller

afirms that it grows naturally on the coasts of England and Wales. There is a hardy variety, the stems of which are more woody, rise higher, and do not branch so much; the leaves are broader, not so much sinuated, and of a very dark gere on their upper side; the flowers are produced in smaller bunches, and rarely produce seeds in England.—Native of the sea-coast of Dauphiny, Italy, and Sicily. When the cuttings or slips are well rooted, they should be planted in a dry rubbishy soil, where they will resist the cold of our ordinary winters very well, and continue many years, but in summer, as to be killed in winter when there is much frost.

13. Cineraria Canadensis. Flowers panicled; leaves pinnatifid, subvillose; divisions sinuated; stem herbaceous; stem annual, not perennial; the ray of the corolla spreading, but not revolute.—Found in Canada, by Kalm.

14. Cineraria Capillacea. Leaves pinnate; pinnas capillaceous, entire.—Observed by Thunberg at the Cape of Good Hope.

15. Cineraria Linifolia. Peduncles one-flowered; leaves scattered; stem shrubby; stem compound, rough; leaves very much crowded, linear, very narrow; peduncles filiform, longer than the leaves; flowers small, yellow.—Native of the Cape of Good Hope.

16. Cineraria Purpurata. Stem subbiflorous; leaves obovate, subtomentose; ray of the flower purple; pappus plumose.—Native of the Cape of Good Hope.

17. Cineraria Amelloides; Blue-flowered Cineraria, or Cape Aster. Peduncles one-flowered ; leaves opposite, ovate, naked; stem undershrubby; many of the floscules are abortive, but without any order, both in the disk, and in the ray. which is blue; calix hemispherical, with linear leaflets spreading out horizontally when ripe ; stem purplish, rough, dividing into many branches near the root, so as to form a low bushy plant, seldom rising more than two feet high ; but the branches extending more than a foot on every side. The whole plant is a little acrid to the taste, and it is never without flowers throughout the year .- Native of the Cape of Good Hope. This, and some of the others, may also be propagated by seeds, sown on a bed of light earth in the beginning of April; and when the plants are fit to remove, part of them should be planted in pots, to be sheltered in winter under a hot-bed frame; and the remainder under a warm wall in poor ground, where, if the winter prove favourable, they will live.

18. Cineraria Americana, Shrubby; panicles axillary; leaves alternate, petioled, broad-lancealate, serrate, smooth above, and hoary underneath. The entire plant is clothed with an epidermis of very fine wool, which may easily be unbed off, like a thin membrane; the branches, petioles, peduncles, and lower surface of the leaves, are white with it: eisems woody...Observed by Mutis in South America.

19. Cineroria Alata. Stem herbaccons; leaves obovate, decurrent; flowers corymbed; florets about sixteen, some of the marginal ones naked, and female.—Native of the Cape of Good Hope.

20. Cimeraria Elongata. Leaves subcordate, gnawn pedumels very long, subtalte, scaly : stem erect, branched, a foot and a half high, reddish at the ramifications, tomentose. Calis : entirely simple, divided into twelve or fourteen lanceo-late leaves, the length of the flower : corolla yellow, without suy ray-Native of the Cape of Good Hope.

21. Cineraria Cacalioides. Leaves columnar, oblong, fleshy; panicle terminal, elongated, few-flowered; peduncles alternate,--Native of the Cape of Good Hope. 26. 22. Cineraria Denticulata. Leaves lanceolate, smooth, toothetted; folwers panieled; almost all the leaves are radical and long; it has scarcely any stem-leaves, except some small ones at the ranifications.—Native of the Cape of Good Hope.

CIN

23. Cineraria Perfoliata. Leaves ovate, cordate, stemclasping; peduncles one-flowered, elongated. The whole plant is somewhat fleshy and glaucous.—Native of the Cape of Good Hope.

24. Cineraria Lineata. Leaves lanceolate, tomentose underneath, serrated at the end, toothed at the base; stem herbaceous, a foot high and more, erect, striated, hoary; calices small ; ray of the corolla yellow.—Native of the Cape of Good Hope.

25. Cineraria Hastifolia. Lcaves hastate; divisions lateral, bifd, divaricated; stem erect, more than a span high; calix with about ten leaves; flowers yellow.—Discovered by Sparrmann, at the Cape of Good Hope.

26. Cineraria Japonica. Lcaves sword-shaped, toothed, toomentose; flowers terminal; stem round, simple, erect, to-mentose, a span high; leaves alternate, acute, attenuated to both ends, erect; flowers solitary, or ten, yellow.—Native country unknown.

27. Cineraria Rotundifolia. Panicles few flowcred; leaves petioled, ovate, roundish, quite entire, tomentose underneath; stem arboreous.—Native of New Zealand.

28. Cineraria Repanda. Panicles compound, racemed, diffused; leaves pctioled, ovate, repand-sinuate, tomentose underneath; stem arboreous.--Native of New Zealand.

29. Cincraria Lanata; Woolly Cineraria. Peduncles oneflowered ; leaves cordate, roundish, seven-angled, lanuginous underneath. In the beauty of its blossoms, this species of cineraria, lately introduced from Africa, by far eclipses all the others cultivated in our gardens. The interior of the petals is white, and the exterior of a most vivid purple. It flowers early in the spring, and, by proper management, may be made to flower the whole year through ; some persons keep it in the stove, by which means they make it flower earlier: but it succeeds better in a common green-house, with no more heat than is just necessary to keep out the frost : it may indeed be kept in a common hot-bed frame, unless the weather prove severe. The hardiness of this plant renders it a most valuable acquisition to the green-house, and its value is still further enhanced by its readiness to flower, and the facility by which it may be cultivated by cuttings. As however, like many others, it is obliged to be confined, it thereby also becomes liable to be infested with aphides. or, more pulgato, to turn lousy; however, the best way to have handsome, strong-flowering, healthy plants, is to procure a constant succession by cuttings, which strike very readily, if placed in a pot, and plunged into a bed of tan .- It was found in the Canary Islands by Masson.

30. Cineraira Humifusa; 'Trailing Cineraria. Pedoncles one-diowered; leaves kidney-form, somewhat angular; petioles eared, or naked at the end; flowers yellow; and both they and the calices are villose, and somewhat rugged.—Native of the Cape of Good Hope.

31. Cineraria Viscosa; Clammy Cineraria, Pedancles one flowered; leaves pinnatifid, lobed, acuté, viscid, somewhat fleshy.--Native of the Cape of Good Hope.

32. Cincraria Populifolia Popular-General Cincroviz, Flowers corynologia, souther, somewhan angular, tonentose undernenth, petioles having several pairs of approvales at the end, This is a struck, with an angular tomenaries lickay stem; pawieles terminating; pedieles bracted; (covers yellow, --Found in the Canary Islands by Masson.

44

33. Cineraria Aurita; Purple-flowered Cineraria. Flowers corymbed; leaves cordate, somewhat angular, tomentose underneath ; petioles two, eared at the base ; flowers purple ; leaves resembling those of the poplar .- Native of Madeira.

34. Cineraria Malvæfolia; Mallow-leaved Cineraria. Flowers cymed; leaves cordate, angular, somewhat tomentose underneath ; petioles two, eared at the base .- Native of the Canary Islands, and of St. Miguel, one of the Azores.

35. Cineraria Cruenta: Purple-leaved Cineraria. Flowers cymed ; leaves cordate, angular, purple underneath ; petioles eared at the base .- Native of the Canary Islands.

36. Cineraria Lobata ; Lobed Cineraria. Flowers subcorymbed ; leaves roundish, many-lobed, smooth ; petioles eared at the base ; calices subcalicled .- Found by Masson at the Cape of Good Hope.

37. Cineraria Repanda. Panicle diffused ; leaves ovate, lanceolate, serrate-repand, smooth; stem suffruticose, erect, round, smooth, four feet high, branched; leaves alternate; flowers yellow, terminating .- Native of China, near Canton. 38. Cincraria Minuta. Leaves pinnatifid; stem one-

flowered, capillary; root annual; stems often two, capillary, two inches high, at first woolly, but afterwards almost smooth, one-flowered; leaves alternate, sessile, violet-coloured underneath; flowers terminating, solitary; corolla yellow; corollets in the ray ten, trifid at the end; seeds ovate, oblong, very small, with a sessile plumose pappus .- It flowers in May, and is a native of Spain, near Aranjuez.

39. Cineraria Glabra. Flowers corymbed, calices cylindric; leaves oblong, acute, somewhat toothletted, nerveless, smooth on both sides, and a little succulent; stem shrubby, -Native of Jamaica.

40. Cineraria Discolor. Flowers corymbed; leaves oblong, lanceolate, acuminate, somewhat toothletted, smooth : beneath white tomentose ; stem shrubby .- Native of Jamaica.

41. Cineraria Japonica. Leaves ensiform, toothed, tomentose; flowers terminating; stem round, simple, erect, tomentose, a short span in height; flowers solitary, or else three together, yellow: calix tomentose, woolly .- Native of Japan.

Cinna : a genus of the class Monandria, order Digynia .--GENERIC CHARACTER. Calix : glume one-flowered, twovalved, compressed, linear, keeled, acuminate, one valve shorter, mucronated. Corolla: glume bivalve, compressed, linear; outer valve within the smaller valve of the calix, longer with somewhat of an awn below the tip; inner slender. shorter. Stamina: filamenta one, capillary; antheræ oblong, forked at each end. Pistil: germen turbinated; styles two. capillary, very short; stigmas longer, plumose. Pericarp: none; glume involving; Seed: one, cylindric. ESSENTIAL CHARACTER. Calix : glume two-valve, one-flowered. Corolla : glume two-valve. Seed : onc .--- The only known species is,

1. Cinna Arundinacca. A grass the size of oats': root perennial: culms many : leaves broadish, smooth, many-nerved. rugged about the edge; panicle glaucous, oblong, attennated, somewhat compressed, composed of imbricate racemes; keel of the calix rough, one of the valves having an awn-like point; antheræ simple; styles hirsute .- Native of Canada, whence the seeds were sent by Kalm.

Cinnamon. } See Laurus. Cinnamomum.

Cinquefoil. See Potentilla. Cinquefoil, Bastard. See Sibbaldia.

Cinquefoil, Marsh. See Comarum.

Circæa ; a genus of the class Diandria, order Monogynia. GENERIC CHARACTER. Calix: perianth two-leaved; leafiets ovate, concave, deflected, deciduous; corolla, petals other tender exotics, keeping them constantly in the bark-

two, obcordate, generally shorter than the calix, spreading, equal. Stamina: filamenta two, capillary, erect, the length of the calix. Antheræ roundish. Pistil: germen turbinate. inferior; style filiform, the length of the stamina; stigma obtuse, emarginate. Pericarp: capsule turbinate, ovate, hispid, two-celled, two-valved, opening from the base towards the tops. Seeds : solitary, oblong, narrower at bottom. Es-SENTIAL CHARACTER. Corolla: two-petalled. Calix: two-leaved, superior. Seed : one, two-celled .- These plants multiply exceedingly by their creeping roots, and are therefore seldom kept in gardens. If the roots be planted in any sliady moist part of a garden, they will increase fast enough without requiring any care.----The species are,

1. Circæa Lutetiana; Common Enchanter's Nightshade. Stem erect ; racemes many ; leaves ovate ; root perennial. creeping, toothed; the whole plant pubescent; stems from twelve to eighteen inches and more in height, erect, round, villose or smooth, seldom hairy; the joints swelled, and sometimes purplish, branching; flowers in simple racemes on the top of the branches, both terminating and lateral; frequently solitary; sometimes more than forty flowers in a raceme; corolla small, whitish, reddish-white, or flesh-coloured ; petals the length of the calix, and alternate with its leaflets. It is not uncommon in shady lanes and orchards, under moist hedges and walls, and in woods, flowering in July and August. It frequently infests gardens, and is not very easily destroyed, the roots being creeping : sheep are said to eat it; and although it has not been admitted into the dispensatories, yet it is esteemed very detersive, and is recommended by Chomel against the piles, applied outwardly as a cataplasm, and inwardly in an infusion .- The seeds of this plant stick by their little hooks to any thing that passes: and Bocrhaave informs us, that this peculiarity gave occasion to the name ; the fruit laying hold on the clothes of passengers, and drawing them to it, as Circe was fabled to attack by her enchantments.

2. Circæa Alpina; Mountain Enchanter's Nightshade. Stem prostrate; raceme single; leaves cordate; stem prostrate. scarcely a finger's length ; leaves cordate, toothed, shining ; calix coloured, like the corolla ; raceme generally one, sometimes two, or three; leaves of a yellower green, and the plant sometimes six inches high .- It is found in rocky woods, in Lapland, Sweden, Carniola, Piedmont, Silesia, and Denmark. It was gathered, in the month of August, upon Mount Scheidegg in Switzerland; and Mr. Miller found it growing wild in the wood near the Hague. In Great Britain it is found near Leeds and Halifax in Yorkshire, in Lancashire, Westmoreland, Cumberland, and Scotland.

Cissampelos ; a genus of the class Diœcia, order Monodelphia .- GENERIC CHARACTER. Male. Calix : none, unless the corolla be so called. Corolla: petals four, ovate, flat, expanded; nectary the membranaceous disk of the flower, wheel-shaped. Stamina : filamenta four, very small, coalescent; antheræ broad, flat. Female. Calix : none, except the bracte. Corolla: none; nectary, the membranaceous lateral edge of the germen dilated outwards. Pistil: germen roundish; styles three; stigmas three, erect, acute. Pericarp : berry-globular, one-celled. Seed : solitary, wrinkled, somewhat compressed. ESSENTIAL CHARACTER. Male. Calix: four-leaved. Corolla: none. Nectary: wheelshaped. Stamina: four, with connatc filamenta. Female. Calix: one-leafed, ligulate, roundish. Corolla: none; styles three ; berry one-seeded .- These plants are propagated by seeds, which should be sown upon a hot-bed in the spring. and the plants must afterwards be treated in the same way as

CIS

species are.

1. Cissampelos Pareira. Leaves peltate, cordate, emarginate, and entire; stem climbing, and twining, from ten to fifteen feet in height, lax, round, striated, smooth, or hirsute; corolla none; nectary the disk of the flower, smaller than the calix, entire, a little concave, coloured. The fruit is a roundish, compressed, scarlet drupe, containing a single nut, or very hard seed, compressed, triply echinate, wrinkled at the edge, two-celled. In mountainous coppices it is smooth, with cor-date entire leaves, hoary underneath. In champaign calcareous situations it is hirsute, with cordate, roundish, emarginate leaves, which are tomentose .- Native of the West Indies. The leaf, applied whole or bruised to a wound, cures it effectually; it is also a remedy against the bite of poisonous animals: the root is excellent for the stone, and is looked upon as an excellent diuretic, which the negroes constantly use in all obstructions of the urinary passages. The root, which is the part chiefly used, has a pleasant bitterish taste, and answers well in decoctions. It thrives best in a rich shady soil, is a native of Jamaica, where it grows well, both on the high and low lands, and is very easily propagated by seeds.

2. Cissampelos Caapeba. Leaves petioled at the base, entire. This has round or heart-shaped leaves, which are extremely woolly and soft to the touch. The stalks and every part of the plant is covered with a soft woolly down .- Native of Jamaica.

3. Cissampelos Smilacina ; Smilax-leaved Cissampelos. Leaves cordate, acute, angular; the stalks are slender, running up walls, and twining about posts and trees. The leaves resemble those of common ivy; the berries are red, of the size of small peas, and grow in clusters .- Native of Carolina.

4. Cissampelos Fruticosa. Stem erect, shrubby; leaves ovate, petioled, entire .- Found by Thunberg at the Cape of Good Hope.

5. Cissampelos Capensis. Stem twining; leaves ovate, obtuse, petioled, entire .-- Found by Thunberg at the Cape of Good Hope.

Cissus ; a genus of the class Tetrandria, order Monogynia. -GENERIC CHARACTER. Calix: involucre many-leaved, very small; perianth one-leafed, flat, short, obscurely fourcornered. Corolla: petals four, concave; nectary a rim surrounding the germen. Stamina : filamenta four, the length of the corolla, inserted into the nectary; antheræ roundish. Pistil: germen roundish, obtusely four-cornered, retuse; style filiform, the length of the stamina; stigma simple, acute. Pericarp : berry round, shining, umbilicate. Seed : a roundish stone. ESSENTIAL CHARACTER. Berry oneseeded, surrounded by the calix and four parted corolla .--These plants are preserved in some of the European gardens, more for the sake of variety, than for use or beauty, as they rarely produce either fruit or flowers in temperate climates, They are propagated either by laying their flexible branches down in pots of earth, where they will put out roots in four or five months; or by planting cuttings in pots filled with light earth, which should be plunged into a moderate hotbed of tanner's bark, covering the pots closely with hand-glasses, to exclude the outer air: they must be frequently refreshed with small quantities of water. When these, or the layers, are well rooted, they should be carefully taken up, and each planted in a small pot filled with light earth, and plunged into the hot-bed of tan, where they must constantly re-main. They should be shifted into large pots when it is necessary, and their branches must be supported with stakes,

store, otherwise they will not live in this country.---The and in warm weather the plants should have free air admitted to them daily .---- The species are,

1. Cissus Vitiginea ; Vine-leaved Cissus. Leaves cordate, with about five lobes tomentose. Linneus observes, that this species of cissus has the appearance of a vine, but differs in the calix, corolla, number of stamina, and in having a style. The stem is tomentose; the branches villose, hoary at top, and subquadrangular; flowers hoary, most of them deciduous; fruitful pedicels commonly in pairs and divaricating; berries pear-shaped, the size of peas, of a blueish glaucous colour .- Native of the East Indies.

2. Cissus Repanda. Leaves cordate, entire, or sublobed, repand, smooth on both sides. The branches of this are round, flexuose, jointed, tomentose, but become smooth by age; peduucles opposite to the leaves; rays of the umbel three, dichotomously branched. The last pedicels umbelled; scales villose, very short at the base of the pedicels; berries pear-shaped, the size of peas, mucronate with the permanent style .- Native of the East Indies.

3. Cissus Latifolia. Leaves cordate-ovate, villose, acuminate, setaceous, serrate; branches four-cornered; branches jointed, woody, as are also the petioles and peduncles, ferruginous, tomentose, especially at top, becoming smooth at bottom by age; berries pear-shaped, smooth .- Native of the East Indies.

Leaves cordate, quite entire : 4. Cissus Cordifolia. branches simple, knotty; berries large, oblong; tendrils large, bifid, retrograde. - Native of South America.

5. Cissus Rotundifolia. Leaves cordate, roundish, serrate; leaves smooth, setaceous, serrate; umbels racemed, opposite, many-flowered, about four on each common peduncle, and simple; peduncles nearly the length of the leaves. -Native of Arabia.

6. Cissus Sicyoides. Leaves subcordate, naked, bristly, serrate; branchlets round; stem frutescent, herbaceous at top, scandent, subdivided, divaricating, rooting, round, bloody-dotted, smooth; flowers heaped, in form of an umbellule; the branchlets spreading from a centre, equal, dichotomous; the pedicels one-flowered; nectary a yellow fourparted rim, surrounding the germen; filamenta inserted between the divisions of the nectary, and deciduous; antheræ orange ; style subulate ; berry oblong, black .- Native of Jamaica, in waste places, by walls, and on rocks. Jacquin informs us that it is found in all the Caribbee islands, and in the neighbouring continent, differing in habit according to the situation in which it grows. The berries of this, and some of the other sorts, are sometimes eaten by the negroes, but they are chiefly food for birds.

7. Cissus Quadrangularis. Lcaves cordate, fleshy, serratetoothed; stem four-cornered, somewhat swelling; stem very long, climbing, smooth, and even. The root is tuberous .-Native of Arabia, and the East Indies; found also by Loureiro near Mozambique in Africa.

8. Cissus Acida ; Three-leaved Cissus, Leaves ternate, obovate, smooth, fleshy, gashed ; stem scandent, flexuose, round, tinged with purple, succulent, jointed ; branches short; corolla four-parted, the parts reflex and deciduous; germen truncate; berry black, surrounded by the calix. The whole of this plant is acid.—Native of Jamaica, in woods near the coast.

9. Cissus Trifoliata. Leaves ternate, roundish, hirsute, with a few tecth; branches angular and membranaceous; stem suffrutescent, scandent, having five or six angles knottcd, rooting, branched, green; the angles slightly winged; branches herbaceous, lax; flowers umbelled, blood-red; to prevent them from trailing over the neighbouring plants; calix or rim of the germen entire and four-cornered; herry roundish, one-seeded.—Native of the West Indies, climbing high above the branches of the trees, in the hedges upon the mountains.

CIS

10. Cissus Crenata. Leaves ternate; leaflets roundish, crenate; the branches, petioles, younger leaves, and peduncles, villose; tendrils opposite to the leaves, compound; petals arched; filamenta shorter than the corolla.—Native of the East Indies.

11. Cissus Carnosa. Leaves ternate, ovate, obtuse, serrate, smooth; branches and petioles round. The whole plant is smooth; universal umbel of three rays, partial with dichotomous divaricating branches; general peduncle longer than the leaf.—Native of the East Indies.

12. Cissus Obovata. Leaves ternate; leaflets obovate, quie entire, sinocht, stem seandent, smooth; teudrils opposite to the leaves of the same length, and bifd; peduneles avilary, solitary, longer than the leaves, smooth, trichotomous; the branchlets three-flowered; the flowers pedicelled. —Native of America.

13. Cissus Pedata. Leaves pedate: leaftets lanceolate, serrate, tomentose undernearth; branches tomentose, hoary; leaves petioled five, six, or seven; leaftets also petioled, three or four inches long, unequal attenuated, unequally serrate, but with the point quite eatire, on the upper surface slightly villose, hencath villose, tomentose, hoary, nerted; flowers small; calix obscurely four-toothed, runcinate.—Native of the East Indies.

14. Cissus Heptaphylla. Leaves in sevens, serrate, hispid, This is a sarmentose scandeut shrub; branches pubescent; tendrils opposite to the leaves, bifid; panicles fastigiate, brachiate, peduncled, opposite to the leaves; flowers small. --Native of the East Indies.

15. Cissus Umbellata. Leaves ovate, quite entire; flowers umbelled; stem shrubby, twining, long, branched; leaves opposite, smooth; flowers white, in compound terminating umbels; corolla bell-shaped, four-left, woolly within; calix truncate, surrounding the herry.—Native of China, near Canton. -

Cistus ; a genus of the class Polyandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth five-leaved, permanent; leaflets roundish, concave, of which two alternate ones arc lower and smaller. Corolla: petals five, roundish, flat, spreading, very large. Stamina: filamenta numerous, capillary, shorter than the corolla; antheræ roundish, small. Pistil: germen roundish; style simple, the length of the stamina ; stigma flat, orbiculate. Pericaro: capsule roundish, covered with the calix. Seeds: numerous, ESSENTIAL CHARACTER. Corolla : roundish, small. five-petalled ; calix five-leaved, with two of the leaflets smaller. -The history of this genus is extremely obscure, on account of the multitude of varieties which occur in it. Linneus says, that the species may be much elucidated, if botanists will attend to the following circumstances, in their native places of growth: 1. Whether the trunk be shrubby, undershrubby, annual or percunial; 2. whether the stem be erect or decumbent; 3. whether the leaves be opposite or alternate ; 4. whether there be two stipules or none ; 5. whether the peduncles be one-flowered or many-flowered, naked or with a bracte ; 6, what is the form of the petals ; 7, whether the capsules have three or five valves; 8. whether the calix be equal or unequal. The form of the leaves in the greater part is ovate or lanceolate, or some modification of these two forms ; but the principal difference attending these plants is in the capsule, which in some is five or ten celled, with as many valves, in others one-celled, and three-valved : hence this great genus might very commodiously be divided into two, as

Tournefort, Miller, Jussieu, Gærtner, and others, have divided it, at least in the artificial arrangement, for undoubtedly they all constitute one natural genus. They may be distinguished thus: Cistus, or rock-rose, has a five or ten-celled capsule, with as many valves; seeds fixed to the axis; embryo spiral. These are shrubs, or undershrubs; the leaves opposite, and naked : the flowers in umbels, with unequal calicine leaflets : and the corolla either purple or white, commonly large and specious. Helianthemum, or dwarf sunflower, has a oneseeded, three-valved capsule, with the seeds fixed to the valves; embryo uncinate, inflected. These are suffruticose, or herbaceous; the leaves opposite, or sometimes alternate, stipuled, or naked ; the flowers in spikes, or racemes, with two of the calicine leaflets minute; and a corolla commonly yellow, seldom purple or white, smaller than that of the cistus, very decidnous in both .- All the various kinds of cistus are very great ornaments to a garden ; their flowers, though of short duration, are succeeded by fresh ones almost every day, for above two successive months : they are generally about the size of a middling rose, but single, and of different colours; their leaves continue all the year; they are most of them hardy enough to bear the open air in England, unless in very severe winters, which often destroy many of them, so that a plant or two of each sort may be kept in pots, and sheltered in winter to preserve the kinds; the rest may be intermixed with other shrubs, where they will make a pretty diversity : and in such places where they are sheltered by other plants. they will endure cold much better than where they are scattered singly in the borders : many of these plants will reach five or six feet in height, and, if permitted to grow uncut, will have large spreading heads; but if they be trimmed at all, it should be only to prevent their heads from becoming too large for their stems, for whenever this happens they are liable to fall on the ground, which spoils their appearance. They are propagated both from seeds and cuttings, but the latter method is seldom resorted to except for such species as do not produce seeds in England; these are the twelfth and the fifty-fifth; all the others generally produce plenty of seeds, especially those plants which came from seeds, for those which are propagated by cuttings are liable to become barren. The seeds should be sown in the spring, upon a common border of light earth, where the plants will come up in six or seven weeks, and, if they be kept clean from weeds, and thinned where they are too close, they will grow eight or ten inches high the same year; but as these plants are liable to be injured by hard frost when young, they should be transplanted, when they are about an inch high, into some small pots filled with light earth, that they may be removed into shelter in winter, and the others into a warm border, at about six inches' distance each way: those which are potted must be set in a shady situation till they have taken fresh root; and those planted in the border also must be shaded every day till they are rooted, after which the latter will require no other care but to keep them clean from weeds till autumn, when they should have hoops placed over them, that they may be covered in frosty weather; those in the pots may be removed into an open situation as soon as they have taken new root, where they may remain till the end of October, but must be shifted into larger pots, and frequently watered during the summer; at the end of October they should be placed under a hot-bed frame, to screen them from the cold in winter, but at all times when the weather is mild they should be fully exposed to the open air, and only covered in frosts. The above is the method which the gardeners generally practise; but those who desire to have their plants come forward, should sow the seeds on a moderate hot bed in the spring,

CIS

CIS

which will bring up the plants very soon; but these must have plenty of air when they appear, otherwise they will draw up very weak : when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a very moderate hot-bed, observing not to shade them until they have taken fresh root, when they must have plenty of air admitted to them every day in good weather, to prevent them drawing up weak ; and they must be hardened by degrees, so as to bear removing into the open air in the beginning of June, after which they may be treated in the same manner as is before directed for the other seedling plants. By this method of bringing the plants forward in the spring, they will grow to the height of two feet or more the first summer, and have many lateral branches, so that they will be strong enough to endure planting abroad in the succeeding spring, and most of them will flower the same summer; whereas those which are sown in the full ground rately flower till the year after, nor will they be so strong, or able to resist the cold of the second winter, as those which have been thus brought forward. In the spring following these plants may be turned out of the pots, with all the earth preserved to their roots, and planted in the places where they are to remain, (for they are bad plants to remove when grown old,) observing to give them now and then a little water, until they have taken fresh root, after which time they will require no farther care, than to train them upright in the manner you would wish them to grow; but those plants which were at first planted into a border in the open ground, should be arched over with hoops, and covered with mats in frosty weather during the first winter, but may be transplanted abroad in the following spring. In removing these plants, care should be taken to preserve as much earth as possible about their roots; and if the season be hot and dry they must be carefully watered and shaded until they have again struck root, after which they will only require the treatment above directed. If they be propagated by cuttings, they should be planted in May or June, upon a bed of light earth, keeping them shaded with mats, and frequently refreshed with water until they have taken root, which will be in about two months' time; they may then be transplanted into pots filled with good fresh light earth, and should be set in a shady place until they have again taken root, after which they may be exposed to the open air till October, when they should be removed to pass the first winter under shelter, but in the succeeding spring should be brought forth and planted abroad, as has been directed for the seedling plants. Most of the perennial sorts of dwarf cistus, or sunflower, will thrive in the open air in England; they are propagated by seeds, sown where they are intended to remain, and will require no care, except to keep them clear from weeds, and to thin them where they are too close, always observing to leave those sorts at a greater distance, the stalks of which trail on the ground to the greatest length. These plants will continue several years in a poor dry soil; but in rich ground, or in moist situations, they seldom last long; but as the seeds ripen in plenty, they may be easily renewed ; for the annual sorts the seeds may be sown in April, upon a bed of common earth ; the plants will come up in May, and flower in July .---- The species are,

* Without Stipules, shrubby.

1. Cistus Capensis; Cape Cistus. Leaves ovate-lanceolate, petioled, three-nerved, toothletted, naked on both sides, It is shrubby; branches round, purplish, having hairs thinly scattered over them; petioles distinct; leaves three inches long; corolla yellow .- Linneus remarks, that this differs 26.

from the other species in the toothlets of the leaves. Nativeof the Cape of Good Hope.

2. Cistus Villosus; Hairy Rock Rose, or Shrubby Cistus. Leaves ovate, petioled, rough with hairs, shrubby, erect, without stipules; corolla purple. It has a strong woody stem, covered with a rough bark, and three or four feet high, dividing into many branches, so as to form a large bushy head : the petals, which are purple and large, spread open like a rose, but are of short duration, generally falling off on the same day they expand; but there is a succession of fresh flowers every day for a considerable time, in May and June. and again in September and October, if the autumn be favourable, and even in the winter, if the plants be protected from frost .-- Native of Italy and Spain. It requires the protection of a stove

3. Cistus Populifolius; Poplar-leaved Cistus, or Rock Rose. Leaves cordate, even, acuminate, petioled. This has a stiff, slender, woody stem, six or seven feet high, sending out many branches the whole length; corolla white, and soon dropping off. Linneus adds, that the petals are tinged with purple on their edges, that the stamina are vellow, and that the calices appear three-cornered before they unfold .- It flowers in June and July; native of Portugal. This is a very handsome plant.

4. Cistus Laurifolius; Bay-leaved Gum Cistus. Leaves oblong-ovate, petioled, three-nerved, the upper surface smooth; petioles connate at the base. It rises five or six feet high, with a strong woody stem, sending out many erect hairy branches; leaves lanceolate, acute, thick, dark green above, and white beneath, very glutinous in warm weather. Ac cording to Linneus, they are wrinkled, green on both sides, and scarce visibly hairy; the petioles become purple at the base; the flowers, which appear in June and July, are produced at the ends of the branches, upon long naked peduncles, branching on their sides into smaller ones, each sustaining one large white flower with a hairy calix .- It is a beautiful plant : native of Spain.

5. Cistus Ladaniferus; Spanish Gum Cistus. Leaves lanceolate, even on the upper surface; petioles united at the base, and sheathing; stem strong and woody, five or six feet high, sending out many hairy branches; leaves smooth on their upper side, veined on their under, on short footstalks which join at their base, where they form a sort of sheath to their branch ; corolla white, the size of the officinal poppy .----Native of the hills of Spain and Portugal. There is a variety, which Mr. Miller considers a distinct species : it has smooth branches, covered with a reddish brown bark; the leaves are narrow, lanceolate, whitish on their under side, of a dark green above, having three longitudinal veins; the petals are very large, roundish, white, with a large purple spot at their base. The whole plant exudes a sweet glutinous substance in warm weather, which has a very strong balsamic scent, and perfumes the air to a great distance; it flowers from June to August, There is another variety, with white flowers, having no purple spots, which is in every other respect similar to this. They are all remarkable for their great beauty.

6. Cistus Monspelliensis; Montpellier Gum Cistus. Leaves linear lanceolate, sessile, villose on both sides, three-nerved ; stem slender, from three to four feet high, sending out many hairy branches from the bottom upwards; leaves very dark green, in warm weather covered with a glutinous sweet-scented substance; the peduncles, which come out at the branches. are long, naked, and sustain many white flowers, rising above each other; their calices are bordered, and end in sharp points. It flowers from June till August .--- Native of Narbonne, and the kingdom of Valentia. The variety, or olive-4 K

CIS

leaved rock-rose, of Miller, has, according to him, the stem about four feet high, with very hairy, glutimous, creet branches; and long, narrow, hairy leaves, ending in points, deep green on both sides, having a deep furrow made by the midrib on their upper side; the flowers are on long peduncles at the ends of the branches, of a pale sulphur colour, and have an acute bordered calix. Both plants are remarkably handsome.

7. Cistus Salvifolius; Segr-leared Cistus. Leaves ovate, petioled, liviset on both sides; stem slender, smooth, covered with a brown bark, never rising more than three feet high, and sending out many weak branches spreading horizontally; leaves obtuse, without veins, not os oot as in many other species; peduncles lateral, solitary, one-flowered, longer than that of the other rock-roses. It flowers from June to August.-Naive of Italy, Sicily, Xarbonne, Switzerland, and Carniola.

8. Cistus Încanus; Hoary Rock Rore, or Rose Cistus, Leaves spatulate, tomentose, wrinkled, the lower connate at the base and sheathing; branches villose; leaves not all nerved, ending in a point a little flexusce in the disk, ending at the base in coalescent sheathing petioles, or rather in obvidate spatulate; the lower more connate, and in a manner sheathing; caliees hairy, with subcordate leaflets; petals purple, emarginate, or obcordate, quite entire, concave,— Native of Spain and Narbonne. This also is a beautiful plant.

9. Cistus Creticus; Cretan Ladaniferus Cistus, Leaves spatulate, ovate, petioled, nerveless, rugged; calices lanceolate. A foot and half high, sometimes more, branching, diffused; stem and branches round, and somewhat villose; Leaves from broad stem-clasping, petioled, first spatulate, then ovate or lanceolate, somewhat acute, wrinkled, sometimes waved, roughish, thickish, quite entire, viscid, closely set on both sides and round the edge with white hairs of different lengths, some simple, others branched or headed, scarcely visible to the naked eye; peduncles one-flowered, terminating the last leafy twigs, erect, and villose; calix villose, with ovate acuminate leaflets, nearly equal; petals rosepurple, without smell, very obscurely crenate, forming a corolla an inch and half in diameter ; the whole of the stamina are yellow; germen hirsute, green; capsule ovate, obtuse, brown, hirsute, with ash-coloured hairs, five-celled and fivevalved ; seeds smooth, rufous, angular .- It flowers copiously in June and July, and ripens seeds in September. Native of the Levant, and remarkably handsome. It is from this species of cistus that the drug laudanum is procured; it is a kind of resin, which is secreted from the leaves and other parts of the shrub, and is scraped off by means of a kind of rake, which has numerous leather thongs instead of teeth this being drawn backwards and forwards over the plant, collects the resin, which differs in degrees of purity; the best is in dark-coloured masses, of the consistence of a soft plaster, growing still softer on being handled ; it is, however, subject to many sophistications from the more or less careful manner in which it is at first collected, and from the fraudulent practices of those through whose hands it afterwards passes. Its chief use in modern practice is in fumigations, its fragrant smell having always introduced it into such preparations: sometimes it is used in troches, and in the Paris Pharmacopœia there is a pectoral troche in which a considerable quantity of laudanum is united with musk and amber : in the old German shops, a tincture of this drug is reserved for female weaknesses, but it is unknown to us. Laudanum being entirely resinous, is not soluble in water, but readily gives out its active matter to spirit of wine.

10. Cistus Albidus; White-leard Cistus. Leaves ovatelanceolate, tomentose, hoary, sessile, mously three-nerved; calix not rough with hairs, the outer leaflets longer, the sidge reflex; peduceles from the tops of the branches, many, searcely longer than the leaves; petals purple, not emarginate, somewhat crenate, faith...-Native of Narbonne and Spain. This plant is one of the most beautiful belonging to this elegant genus.

11. Cistuš Crispus; Curl-leard Cistus. Leaves lanceolate, pubsecent, three-nerved, waved; branches weak, slender, woody, spreading horizontally; the shrub is seldom more than two or three feet in height; the peduneles and calices are covered with a thin wool; the calices are lanceolate; the corollas purple, but, according to Mr. Miller, white, coming out upon naked peduneles from the wings of the leaves, in June and July, and are succeeded by ripe seeds in August and September—Maxive of Portugal.

12. Cistus Halimifolius; Sea Purslane-leaved Cistus. Leaves lanceolate, hoary; peduncles wand-like. It is an upright shrub, three or four feet high ; branches round, ashcoloured, angular at top, the younger ones dotted with yellow; leaves petioled, opposite, lanceolate, very white, scarcely soft, without veins, obtuse, flat, about an inch in length; peduncle terminating, compound, white; partial peduncles below opposite, above alternate : there is a sessile leaflet narrower than those on the stem, at the base of the peduncles and pedicels; calicles erect, ovate, acute, somewhat rugged, having two outer leaflets minute and linear at the base of the larger ones. Mr. Miller describes it as rising four or five feet high, and branching from the ground so as to form a large bush; the leaves on the lower part of the branches have footstalks, but those at the top coalesce at their base, and surround the stalk ; the peduncles are a foot in length, naked, hairy, and put out two or four shorter peduncles on the side, each supporting three or four flowers, which are large, of a bright yellow colour, but of short duration, appearing in June and July .- Native of Portugal. There are two varieties, one with a slender stem, woody, and three or four feet high, with many slender branches, with loose bunches of a dirty sulphur-coloured flower, upon slender peduncles, and appearing in June and July; another three feet in height; peduncles naked; flowers solitary, on naked opposite pedicels; corolla bright yellow, with a purple spot near its base, appearing in June and July. This is the ten-derest of all the European species, and will hardly survive an English winter in the open air, unless protected by other shrubs planted near it.

13. Cistus Libanotis; Rosemary-leaved Cistus. Leaves linear, revolute; flowers umbelled, yellow. This shrub resembles rosemary; stem naked, purplish; peduneles terminal, longer than the leaves, with a few yellow flowers.—Found in Spain.

** Without Stipules, undershrubby.

14. Cistus Umbellatus; Umbilled Cistus. Procumbent: leaves opposite: flowers umbelled; stems low, trailing, woody, seldom branching, and not more than four or five inches long; leaves narrow and hoary; flowers while, in small clusters at the ends of the stalks. It seldom continues beyond two years.—Native of the south of France and Spain.

15. Cistus Lawipes; Cluster-leved Cistus. Ascending: leaves alternate, fascieled, filtiorm, smooth; peduneles racemed; root woody, creeping very much; stems many, round, becoming woody, when young herbaceous, glaucous, branched, diffused, spreading horizontally or ascending, very few, erect; the flowers are inodorous, in thin villose racemes at the ends of the branches, on long smooth pedicels; petals ovate. yellow, obscurely crenulate at the end, a little longer than the calix; the outer stamina are barren.—Native of the south of France, in the neighbourhod of Montpellier.

16. Cistus Calicinus. Erect; leaves finear; peduncles one-flowered; calicies three-leaved; stem a foot high, erect; branches opposite, reddish; leaves opposite, even, undermeath obtusely keeled; crowded leaflets from the axils; pedundes terminating, solitary, scarcely longer than the leaves; calix three-leaved, even, equal; corolla yellow, with scarcely the edge red; stamina very short, yellow, all fertile; pisili white; style very short; sigma warted.—Native of the south of Europe.

17. Cistus Syriacus; Syrian Cistus. Erect; leaves lanceolate, revolute; flowers racemed; petals yellow.—Native of the Levant.

18. Cistus Fennans ; Heath-leared Cistus. Procumbent ; leaves alternate, linear, regged about he edge; peduncles one-flowered ; stamina about sixteen, fertile, and as many on the outside, without anthera: [leaves smooth, the edge rugged, with a few very minute spines; stems seldom longer than a foot; peduncie near the top of the stem; petals yellow, longer than the calix, and four seeds in each cell; petals suplaur-coloured, small, seldom expanded, closing before ten o'clock; fruit three-celled. In the autumn this species is often covered with thrs of teaves, in shape of roses, so as to resemble a ledum more than a cistus.—Native of Gothland, France, Switzerland, Austria, and Carniolia.

19. Cistus Canus; Myrtle-leared Dwarf Cistus. Procumbent: leaves opposite, obvate, villose, tomentose underneath; flowers subumbelled; peduncles from the upper axils, and those almost naked; petals deep yellow. The Portuguese variety is larger. The leaves oval or obovate, obtuse, pale ash-coloured above, tomentose hoary underneath; umbel terminating, four-flowered.—Native of the south of France, Spain, Portugal, Austria, Carniola, and Piedmont.

20. Cistus Halicus; *Halian Cistus*. Leaves opposite, hispid, lower orate, upper lanceolate; branches spreading; somewhat deflected, rufous; leaves with a few strigose hairs, mostly twin and subciliate, the lower petioled and ovate, the upper subsessile; raceme terminal; calices hispid; corolla pale, with the petals scarcely emarginate...-It inhabits mountains near the sea, and alpine places not much exposed to the sum.

21. Cistus Marifolius; Marum-leaved Cistus. Leaves opposite, oblong, petioled, flat, hoary underneaft; stems wpright, shrubby, a foot and a half high, sending out branches the whole length; leaves small, silvery, opposite, smooth. The flower-stalks branch; and the flowers, which are white, are produced in short spikes at the ends of the branches.—Native of the south of Europe.

22. Cistus Roseus; Rove-flowrerd Cistus. Procumbent : leaves opposite, oblong, rolled back at the edge, somewhat boary on both sides; stem branched, diffused, shrubby at the base, as are also the branches, woody, premnial, round; younger branches racemes; leaves and calices roughish, somewhat villose, and hoary; leaves on short petioles, and quite entire; racemes terminating, many flowered, erect; fuirjedicies: reflex; three leafless of the calics voate, obluse, comeave, the two others shorter, and very narrow; petial fishescolaured, with a yellow base, very entire, and spreading; finament as well as anthera yellow; pisid green; seeds few, brown.—Native of the county of Nice and Lenelia. Mr. Miller informs us that Dr. William Sherard found it growing near Suyrna, and was the first two seat the seeds to England.

23. Cistus Anglicus; English Cistus. Procumbent: leaves opposite, oblong, revolute, hairy; flowers racemed; stem scarcely six inches high, oblique, all rugged ; leaves lanceolate like those of hyssop, roughish, not even, green on both sides; flowers white, nodding, but erect when in bloom; stems many, slender; leaves resembling those of wild thyme, but thicker, more hirsute, and hoary, dark green above, paler underneath, but hoary on both sides, without any younger ones arising from the axils : on the tops of the branches grow three or four, and sometimes more, small yellow flowers .--- This species was first observed by Mr. Newton, on some rocks near Kendal, in Westmoreland: it has since been found at Buck-harrow Bank Sear, between Brigsteer and Conswick, and about Cartmel Wells, in Lancashire, at Betram-Beuke, about a mile west of Kendal, and also in Caernarvonshire and Anglesea. It flowers in May.

24. Cistus Clandicus. Procumbent: leaves opposite, oblong, smooth on both sides; petioles citalite; petals emarginate; racemes terminating; few-flowered, villose, ercet; flowers sweet-scented; leadlets of the calix very hairy, the two outmost linear, the three inner ones ovate; petals yellow, from roundish obovate, entire or slightly creutlate, scaree emarginate; stamina and pisti all yellow; stigma large, subquadrifid, muricate; capsule hirsute, nodding; seeds ovate, minute.

*** Without Stipules, herbaceous.

25. Cistus Tuberaria; Plantain-Laved Cistus, Perennia; root-leaves ovate, three-nerved, tomentose; stem-leaves smooth lanceolate, the upper alternate; root hard, perennial, gradually narrower as it descends; stem a foot high, simple, villose at the bottom; root-leaves spreading on the ground, narrowed towards the base, white underneatil; stem-leaves sessile, distant, opposite, except the uppermost which are alternate; flowers on the top of the stem in a sort of corymb; the two outer leadies of the calits shorter, and lanceolate, the three inner ovate, acuminate, concave; corolla yellow; casuel globular, three-valved—Native of Spain, in Catalonia, and near Benicasi, in Valencia, also of the south of France, and about Piso.

20. Cistus Guttaus; Annual Spotted-flowered Cistus, Leaves opposite, hanceohte, hree-nerved; racennes without bractes; root annual; stem upright, five or six inches high; that, and the rest of the plant, covered with spreading hairs; leaves sessile, three or four pairs; raceane filtform, terminating; peduneles longer, slender, often without bractes; flowers erect, but when just out of bloom pendent; two leaf-lets of the calix spreading; petals yellow, with a very dark uprile spot approaching to black at the base.--Naitve of the south of Europe, in sandy soils. Columna and flay remarked it at the foot of Mount Vesevius, without any spots in the corolla. It was observed by Brever, in sandy pais, tures, on Licchddne, near Holyhead, and in Anglesca, flowering in June; and by Dr. William Shepherd, on the west side of the Isle of Jersey, near Gronsey Casile.

27. Cistus Canadensis; *Canadian Cistus*. All the leaves alternate, lanceolate; stem ascending; perennial.—Found in Canada, by Kalm.

**** With Stipules, herbaceous.

28. Cistus Leditolius; Ledun-leared Cistus. Erect, sonoch; flowers soltary, subsessile, opposite to a ternate leaf; calix longer than the corolla, which is of a pale yellow; seeds angular, of a ferreginous red colour, angular, not mucilaginous.—This plant assumes different appearances, according to the soil and situation. In a good soli, if the plants stand single, and are not injured by weeds, they will rise nearly a foot and a balf high, the leaves will be two inches

CIS

and a half long, and nearly half an inch broad in the middle, but in a poorer soil they do not attain to half that height; the leaves are much narrower, and the seed-vessels not half so large; but when cultivated in a garden, they are not found to differ. It is annual : native of the south of France, and of Italy, and also found near Smyrna by Dr. William Sherard.

CIS

29. Cistus Salicifolius; Willow-leaved Annual Cistus. Spreading, villose; flowers racemed, erect; pedicels horizontal: capsules longer than the calix; petals yellow, smaller than the calix, and extremely fugacious; it varies with apetalous flowers .- Native of Spain and Portugal, Monte Baldo, near Verona, and in the county of Nice. It is also found in sandy pastures, near Bream-downs in Somersetshire. Annual; flowering in June and July.

30. Cistus Niloticus. Erect, subtomentose : flowers racemed, solitary, sessile, opposite-leaved; stem somewhat woody, a foot high, round ; branches next the root ascending, shorter on the stem towards the top, alternate, erect, few; flowers alternate, accompanied with a leaf, and two stipules, like the stem-leaves ; petals yellow .- Annual ; and a native of Egypt.

31. Cistus Ægyptiacus; Egyptian Cistus. Erect; leaves linear, lanceolate, petioled ; calices inflated, larger than the corolla; root annual, putting out one stem only, which is erect, but not able to support the weight of the fruits ; leaves shining, thickish, furrowed on the upper surface, where the nerve is below, sublinear, drawing to a point at each end ; on each side the petiole is a subulate stipule; peduncles so-Miray i flowers drooping, and without scent; petals lanceo-late, yellow, very short, included.—Native of Egypt.
**** With Stipules, undershrubby.
Cistus Squamatus. Leaves covered with orbiculate

scales; branches rather erect, at bottom four-cornered; leaves oval, lanceolate, thickish, petioled, opposite, or else three on each side ; stipules very minute, racemose, marcescent, sessile; peduncles round, crowded. The whole plant is covered with orbiculate scales, depressed in the centre .--Observed by Loefling, in Spain. 33. Cistus Lippii. Erect; leaves alternate and opposite,

lanceolate, rugged; spikes directed one way; stem round, pubescent, whitish; bifid or sparingly branched; branches below the forking of the stem, lateral, simple, white; leaves petioled, bluntish, spreading, hoary underneath; flowers sessile, crowded ; petals obovate, yellow, scarcely larger than the calix ; stamina usually ten, shorter than the petals ; germen pubescent ; fruits obtuse, covered with the calix, sessile, roundish. The wild plant has the branches and leaves hoary on both sides. The younger leaves of the axils are revolute; stipules bristle-shaped ; calices hairy, silky .-- Native of Egypt, near Alexandria.

34. Cistus Surreianus; Small-flowered Cistus. Procumbent: leaves ovate, oblong, somewhat hairy ; petals lanceolate. Mr. Hudson and others consider this as a mere variety of the common sort; the only material difference being in the shape of the petals. Dillenius, on the contrary, who cultivated it at Eltham, and observed it in many other gardens, and Miller, who cultivated it above thirty years, and never found it to vary from seed, do not hesitate to pronounce it a distinct species .- It was first discovered near Croydon, in Surry.

35. Cistus Nummularius. Lower leaves orbiculate, upper ovate ; stems long, trailing, and dividing into many branches ; leaves veined, of a light green on their upper side, but of a grevish colour beneath, with three narrow erect stipules at their base. The flowers are pretty large, white, and grow in clusters at the ends of the branches .- Found by Magnol, on Mount Capouladon, near Montpellier.

36. Cistus Canariensis ; Canary Cistus. Procumbent : leaves subovate, alternate, and opposite; racemes erect; root perennial; stems shrubby, erect, or ascending, round, scabrous, a span high, branched; leaves quite entire, glaucous, thickish, villose, and somewhat scabrous, flat, obtuse, petioled ; stipules linear, lanceolate, erect ; racemes opposite to the leaves, and terminating with many flowers pointing one way ; bractes linear ; stamina entirely yellow ; petals roundish, yellow, obtuse, spreading very much, a little longer than the calix. It flowers from June to August ; the blossoms expand only in the morning .- Native of Fuertaventura, one of the Canary Islands.

37. Cistus Fætidus. Procumbent: stipules lanceolate; leaves oblong, rugged; root perennial; stems somewhat shrubby at bottom, but the branches annual; branches, leaves, racemes, and calices, beset with scabrous villose hairs; petals rounded, white, or sometimes very pale yellow, with a yellow base; stamina yellow .- It has a strong smell like bryony.

38. Cistus Serpvllifolius; Wild Thymo-leaved Cistus. Leaves oblong; calices even; stems shrubby and crooked, covered with a purplish brown bark, like common heath; branches slender; leaves narrow and stiff, like those of thyme, they are opposite, and have no stipule at their base. The flowers, which are of a pale yellow colour, are produced on naked peduncles, terminating the branches in a sort of umbel .- Native of the Alps, and of Austria. It flowers from May to September.

39. Cistus Glutinosus; Clammy Cistus. Leaves linear, opposite, and alternate; pednncles villose, glutinose; root woody, small, creeping much; stems many, a long span in height, straightish, at bottom woody and branched, but at length solitary, more slender, round, green, naked at top, villose, and glutinous, with very short spreading hairs; racemes few-flowered; peduncles longer than the flower, glutinous, villose; corolla yellow, a little longer than the calix .---Native of the south of Europe.

40. Cistus Thymifolius; Thyme-leaved Cistus. Procumbent: leaves oval, linear, opposite, very short, heaped. The leaves much resemble those of thyme, but they are harder, and a little whiter .- Native of the south of France, and of Spain.

41. Cistus Pilosus; Hairy Cistus. Almost upright: leaves linear, with two grooves underneath, hoary; calices even; stems somewhat erect; bractes solitary, at the side of the pedicels. The white colour of the corolla varies exceedingly, and in the garden the same plant will have white, sulphureous, and rose-coloured flowers. It is also not uncommon on the maritime hills of the county of Nice, with rose-coloured flowers .- Native of the south of France, Spain, and Piedmont.

42. Cistus Racemosus. Leaves linear ; calices racemed, pointing one way, nerved, angular, smooth. This is a weak shrub, half a foot in height : the branches remotely muricated from the fallen leaves, tomentose and hoary at top; leaves opposite, on very short petioles, linear, (or narrow lanceolate, revolute, underneath,) most smoothly tomentose; flowers in a terminating, solitary, very long, pendulous raceme, all directed one way; without any bractes .- Native of Spain.

43. Cistus Angustifolius. Diffused : leaves lanceolate ; calices hirsute; root perenuial, branched; stem round, branched from the base, woody; the younger branches, with the leaves, stipules, and racemes, slightly villose and hoary ; stipules four, subulate, sharp ; petals yellow, with an orange coloured base, either quite entire, or crenulate about the edge; capsule hirsute, ovate.

44. Cistus Helianthemum ; Dwarf Cistus, or Little Sun-

CIS

flower. Procumbent: stipules lanceolate ; leaves oblong, revolute; somewhat hairy. According to Linneus, the petals are suborbiculate, quite entire, yellow, generally with a tawny ring surrounding the receptacle. The racemes nod before they flower, and the leaves have a few hairs scattered over them; germen hirsute, ovate. The usual colour of the corolla is a full yellow, but it varies to lemon-colour, white, and even rose-colour : it is also said to be found with a double corolla : it varies likewise something in the leaves .- Found in dry pastures in many parts of Europe, with us generally in calcareous soils. Perennial: flowering from June to August. Though, says Mr. Curtis, our common dwarf cistus cannot vie with those which are the produce of warmer climates, yet it is one of the most ornamental of our native plants, and admirably well calculated to decorate a rock or dry bank, especially if its several varieties, with white rose and lemoncoloured flowers, be intermixed : it is hardy, and easily propagated, either by seeds or cuttings, and continues during the greater part of the summer to put forth daily a multitude of Haller mentions a variety with double new blossoms. flowers, which would be a valuable acquisition to our gardens if it could be obtained.

45. Cistus Blutabilis; Changeable Cistus. Procumbent: stipules lancelate; leaves oblong, smooth, flat; stems several, branching very much, woody at bottom, and the size of a common quilt, procumbent and brown: from these spring annually numerous smooth ascending branches, about a foot in length; petials obovate, sharp at the base, pale yellow, or rose-coloured; stamina entirely yellow; seeds few, brown.— I flowers in May and June, and the seeds ripen in July.

46. Cistus Hirtus; Rosemary-leared Cistus. Leaves ovate; calces hippid stem crect, sending out many side-branches, with the joints pretty close; leaves very narrow, opposite, revolute, the upper surface of a lucid green, and the under hoary; flowers large, white, in sual clusters at the ends of the branches. Allioni observes, that the calix is whitish, that it has nothing rough or hairy about it, and that it is a very distinct species.—Native of the south of France, and near Villafranca in Spain.

47. Cisius Apenninus; Apennine Cistus. Spreading: leaves lanceohier, rough with hairs; a foot in height, hranching and apreading; leaves green, and rough with hairs on the apper surface, on the lower heary. Mr. Miller makes two apecies of this, and describes them as, 1. with stalks much larger, leaves longer and hoary, racemes much longer, the calk hairy and whitish; and the corollas white and larger: 2, the stems more erect, leaves not so long, stipules very small, and the whole plant very heary; the flowers are white, the splice shorter and more compact.—Native of the Apennines, and of Italy.

48. Cistus Polyfolins; Momilia Cistus. Procumbent: leaves oblog, ovite, hoary; calices even; petals servate; branches many, spreading on the ground, hoary towards the end, towards the base brownish, with frequent joints, and maked, most of them a hand in length, but the inner and younger branches much shorter; leaves thickish, somewhat stiff, revolute, having a prominent rib underneath, hoary frequently, with others much shorter; leaves thickish, somewhat stiff, evolute, having a prominent rib underneath, hoary frequently, with others much smaller growing from the axils; flowers few, terminal, of the same form and size with those of the common sort, or dwarf situs, but white; petals slightly create, generally cordate. In a garden, the leaves become larger, lose their hoarines; and turn green and hairy; flowering branches ascending, white; leaves opposite.—First remarkel by Plukenet, on Brent-down in Somerschlüre, near the Severn sea, and found by Dillenius in the same place, on the inded—or the lik. Native also of the south of Europe.

40. Cistus Arabicus; Arabian Cistus. Procumbent: leaves linear, those on the pednacles alternate, those on the branchels crowded. This plant is a foot high, suffruitcose and diffused; leaves lanceolate, flat, smooth, acute, but the younger ones subpubsecant. Native of Spain.

CIS

50. Cistus Medius. Leaves ovate, lanceolate, wrinkled, petioled, toothletted; stems reddish, viscid; leaves green; peduncles solitary, axillary, and terminal; corolla pale yellow; no stipules; shrubby.--Native of the county of Nice.

51. Cistus Grandiforus; Grat.flowered Cistus, Stipuled, suffruitose; Leaves lancedate, villose on both sides, acaminate; stipules longer than the calk; stem villose, about six incles high; Leaves an inch long; flowers in racenes; peduncles and calices villose; the smaller leaflets of the calix linear, the others twice as long; petas yellow, rounded, almost half an inch in length.—Native of Carniola and Piedmont.

52. Cistus Brevioriolius; Short-Leard Cistus. Shrubby, without stipules: leaves oute, hancoalex, connate, hinsute, wrinkled; peduacles longer. This species differs from the second and eighth species, in having shorter and greener leaves, which are joined at the base and hairy. The peduacles are much longer, and the flowers smaller, but of a deeper purple. It flowers and seeds at the same time with them, and the shrubs grow as large as those of the second species. —Native of Portugal.

53. Cistus Lusitanicus. Shrubby, without stipules : leaves ovate, obtuse, villose, nerved, and wrinkled underneath; flowers of a light purple colour, and very large.

54. Cistus Hispaniens. Shrubby, without stipules, villose: leaves lanceolate, green, connate; flowers sessile; calices acute.—The flowers are of a deep purple colour.

55. Cistus Cordifolius. Shrubby, without stipules: leaves oblong, corduct, smooth, perioles longer. It rises with a smooth shrubby stalk four or five feet high, sending ont many slender woody branches, covered with a smooth brown bark, with oblong heart-shaped leaves, which are smooth, and have long footstalks.—The flowers are produced at the ends of the branches, standing upon pretty long peduales; they are white, and appear in June, July, and August, but rarely produce any seed in England.

66. Cistus Fasciculatus, Leaves in bundles ; stem shrubby, about nine inches high ; leaves very narrow and fine, growing in clusters. The flowers come out from the sides and at the ends of the branches, on slender peduneles ; they are of a pale straw-colour, and it is seldom longer than two hours before the petals fall off. This plant seldom continues more than two years.—Native of the Cape of Good Hope.

57. Cistus Vaginatus; Obbog-leared Cistus. Arborescent, without stipules; leaves oblong, hairy underneath, netted, wrinkled; petioles united at the base, sheathing-furrowed. It flowers from April to June, and was found in the island of Tenerific by Masson.

58. Cistus Laxus; Broad Waved-leaved Cistus. Arborescent, without stipules: leaves ovate, ianccolate, waved, toolhletted, smooth, the upper rough with hairs; calicine leaflets roundish, cordate. If dovers in June and July.— Naive of Spain and Portugal.

50. Cistus Scabrosus; Rough Cistus. Undershrubby, without stipules: leave opposite, ovate, hairy, and rugged, three-nerved; calices three-leaved; stems decumbent, round, closely beset with short stellated hairs, and rugged; branches short; leaves subpetioled, an inch in length; flowers terminating, subpanicled. It flowers in June and July.—Native of Italy and Portugal. 4 L

27,

ovate, tomentose, three-nerved, the lower petioled, the upper- obtuse-headed. Pericarp : berry roundish, somewhat commost sessile; peduncles rough with hairs; stem two or three feet high ; branches round, densely tomentose, heary white ; leaves opposite, hoary, very soft, flat, bluntish, about an inch in length; the four uppermost sessile, subcordate at the base, the rest ending in a short petiole; peduncle from the top of the branches solitary, erect, a short span in length, hoary, wholly beset, as are the pedicels also, with long purplish hairs; petals purple, with a vellow spot at the base; filamenta purple; antheræ yellow .- Native of Spain and Portugal.

61. Cistus Hybridus. Arborescent, without stipules: leaves ovate, petioled, hoary; branches scaly; peduncles elongated, rough with hairs. This is a shrub with all the leaves petioled, flat, the younger ones waved, hoary on both sides, appearing very minutely dotted when viewed with a magnifier, nerved, brittle, half an iuch in length. It is distinguished from the sixtieth species, by having all the leaves petioled and whiter, with the branches covered with yellow scales .- Native of Spain.

62. Cistus Elongatus, Arborescent, without stipules : leaves lanceolate, hoary ; peduncle elongated, two-leaved, that and the racemed calices hirsute. An upright and very branching shrub, a foot or more in height; branches short, the younger ones tomentose, hoary, with yellowish scales scattered over them; flowers racemed; peduncle terminating, half a foot long, erect, by no means hoary, hairy, especially at bottom; flowers nodding before they open; petals yellow, with a dusky spot at the base a little longer than the calix .- Native of Spain.

63. Cistus Alternifolius. Suffruticose, without stipules: leaves alternate; peduncles lateral and terminating, solitary, one-flowered. An erect little shrub, with slender villose branches, and a brown bark .- Native of Brazil.

64. Cistus Lavandulifolins ; Lavender-leaved Cistus, Suffruticose, stipuled : leaves lanceolate, lincar, tomentose ; calices racemed, tomentose, pointing one way, pendulous. This shrub is a palm and sometimes a foot in height, brauched at bottom; branches round, upright, tomentose, hoary; leaves opposite, hoary; flowers copious, without bractes; corolla yellow .- Native of Spain, south of France, and Barbary. Clusius observed it in the kingdom of Valentia, and Vahl about Marseilles, and on the dry hills of Tunis.

65. Cistus Lanceolatus. Suffruticose, without stipules: leaves lanceolate, three-nerved, hairy; stem suffruticose, branched at the base ; branches quite simple, a short span in length, ascending, leafy, smooth at bottom, tomentose at top, hoary, as they are also at the base,-Found by Vahl on the heaths near Bigerta in Barbary.

66. Cistus Ocymoides. Shrubby, without stipules : leaves obovate, three-nerved, those of the branchlets hoary on both sides, reflex at the tip; calices racemed, both they and the peduncles quite smooth. A small upright shrub, a span high; branches opposite, purple at bottom, clothed at the base, as are also the branchlets, with long thinly scattered hairs; stipules none; petals white, with a purple spot at the base .- Native of Spain.

Citharexylum; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth oneleafed, bell form, five-toothed, acute, permanent. Corolla : one-petalled; funnel wheel-form; tube twice as long as the perianth, thicker at the top ; border five-parted, two-lipped ; segments above villose, oblong, truncate, flat, very spreading. Stamina: filamenta four, with the rudiment of a fifth from the middle of the tube, filiform, two of them somewhat longer; antheræ oblong, twin, crect. Pistil: germen

60. Cistus Sericens. Arborescent, without stipules: leaves roundish ; style filiform, the length of the stamina ; stigma pressed, one-celled. Seeds : two, ovate, two-celled, convex on one side, concave at the other, emarginate at the end. ESSENTIAL CHARACTER. Calix : five-toothed, bell-form. Corolla : funnel wheel-form ; segments above villose, equal : berry two-seeded ; seeds two-celled .---- The species are,

1. Citharexylum Cinereum; Ash-coloured Fiddlewood. Branches round; calices toothed. This is a tree rising with a round upright trunk, not more than a foot in diameter, to the height of fifteen or twenty feet, with a handsome branching head; flowers small, numerous, odoriferous, on short pedicels; corolla white; berries succulent, shining, soft, roundish, first green, next red, and finally black. Brown says, that it rises above eight or nine feet in height, that the veins of the leaves and all the tender buds are of a brown colour; the bark of the trunk and lower branches of a whitish ash-colour .- It is very common in all the savannas of Jamaica, and is called old woman's butter ; also in the woods of Martinique, where the French have named it bois cotelet.

2. Citharexylum Candatum; Oval-leaved or Long-spiked Fiddlewood. Branches round ; calices truncate ; the leaves are obovate, and, like the racemes, erect. According to Browne, it is a shrub which seldom exceeds ten or twelve feet in height, and bears a great number of small berries, disposed on divided spikes at the extremities of the branches .- It is pretty common about Sixteen-mile Walk in Jamaica.

3. Citharexylum Quadrangulare; Square-stalked Fiddlewood. Branches quadrangular. The bark is ash-coloured, Mr. Miller describes it with an upright trank, fifty or sixty feet high, sending out branches on every side, which have several angles or ribs, running longitudinally, garnished by three oval spear-shaped leaves at every joint, standing in a triangle upon short footstalks. The flowers come out from the sides, and also at the ends of the branches, in loose branches, which are succeeded by small pulpy berries inclosing two seeds in each. The French call it bois cotelet carré. -Native of Jamaica, Martinique, &c. This species has been long preserved in some of the enrious gardens in England, for the sake of variety; the leaves continuing through the year, and being of a fine green colour, make a pretty variety in the stove during the winter season: it may be propagated either by seeds or by cuttings; the latter of which is the usual method in England, where the seeds are not produced ; but when seeds can be obtained from abroad, the plants raised from them should be preferred. They should be sown in small pots early in the spring, and plunged into a fresh hot-bed of tanner's bark, and treated in the same manner as other exotic seeds which are brought from hot countries. If the seeds be fresh, the plants will appear in five or six weeks; and in a month after that, will be ready to transplant : when this is done, care should be taken not to tear or break the roots in separating them. They should each be planted in a small pot filled with light fresh earth, and plunged into the hot-bed again, observing to shade them till they have taken fresh root ; after which they should have a large share of air admitted to them in warm weather, and must be frequently watered. In autumn they should be removed into the bark-stove, where it will be proper to keep them during the first winter until they have obtained strength. They may afterwards be kept in a dry stove in winter, and be exposed in the middle of summer for two or three months to the open air, in a warm situation, which will cause them to flourish better than when they are more tenderly treated. If the cuttings of these plants be planted in small pots during the summer months, and plunged into a moderate hot-bed,

314

they will take root, and may afterwards be treated in the same manner as the seedling plants.

CIT

4. Citharexylum Villosum; Hairy-leaved Fiddlewood. Leaves villose. This is a small tree, about ten feet in height. The trunk and older branches are round and ash-coloured, the younger ones four-cornered and green ; the young shoots are villose; racemes half a foot long, hanging down at the ends of the branchlets ; flowers numerous, on short pedicels, villose all over, and smelling extremely sweet; calix truncate; corolla white .- Native of St. Domingo.

5. Citharexylum Melanocardium; Black-heart Fiddlewood. Branches quadrangular; racemes terminating, compound ; flowers four-stamined .- This tree frequently rises to the height of forty or fifty feet, and is generally looked upon as one of the hardest and best timber-trees; the body grows to a considerable thickness, and is covered with a thick whitish bark, which, like the grain of the wood, winds in a loose spiral form; the leaves are pretty long, rugged, and slightly serrate; the flowers are disposed in bunches at the extremities of the branches; the berries are small and yellow, and are sometimes eaten by the negroes; they contain each two hemispheric shells with two kernels, and the nuts may easily be parted into two lobes or segments. Native of Jamaica, chiefly in the low lands and savannas. Mr. Miller informs us, that the French call this tree fidele, from its faithfulness or durability in building; and that the English have corrupted the name to fiddlewood, as if it were used for making musical instruments, which is a ludicrous mistake.

Citrus : a genus of the class Polyandria, order Icosandria. -GENERIC CHARACTER. Calix : perianth one-leafed, five-cleft, flat at the base, very small, withering. Corolla: petals five, oblong, flat, spreading. Stamina: filamenta usually twenty, subulate, compressed, erect, placed in a ring or cylinder, united generally into fewer or more bunches. Antheræ oblong. Pistil : germen superior, roundish ; style cylindric, the length of the stamina; stigma globular, ninecelled within. Pericarp : berry with a fleshy rind, the pulp bladdery, nine-celled; seeds in couples, subovate, callous, Observe. Orange has a cordate petiole ; citron, lemon, and lime, have a naked and simple petiole. ESSENTIAL CHA-RACTER. Calix: five cleft. Petals: five, oblong. Antheræ twenty ; filamenta united into various bodies ; berry nine-celled .- All the species of citrons are either trees of small growth, or shrubs; leaves evergreen, ovate or ovatelanceolate, entire or servate, pellucid, dotted, the petiole frequently margined : on the natural trees there are often solitary axillary spines; peduncles axillary or terminating, oneflowered or many-flowered. The species seem best distinguished by the petiole, which in the orange and shaddock is winged; in the citron, lemon, and lime, naked : the form of the fruit, although not quite constant, may also serve for a distinction : in the orange and shaddock it is spherical, or rather an oblate spheroid, with a red or orange-coloured rind in the lime spherical, with a pale rind ; in the lemon oblong, with a nipple-like protuberance at the end; in the citron oblong, with a very thick rind. Mr. Miller distinguishes the citron from the orange, because in all the varieties of citron which he has examined, he found but ten stamina in the flowers, whereas those of the orange always have none. It is very difficult to determine what is a variety and what a species in this genus : the trees in the eastern countries, their natural place of growth, vary not only in the size and shape of their frnit, but also in their leaves; many of those which are only esteemed to be varieties in Europe, and are given here as such, preserve their differences in their native woods. ----'The species are,

1. Citrus Medica. Petioles linear in all the varieties .-- In its wild state this tree grows to the height of about eight feet, erect, and prickly, with long reclining branches; leaves ovate-oblong, alternate, subserrate, smooth, pale green; fruit esculent, both raw and preserved. The varieties are, 1. sweet citron; fruit with a thick rough rind : 2. common citron; fruit with a rough knobbed rind. Genoa supplied the English gardens with several varieties of the citron, that country being the great nursery of lemons and oranges; and the gardeners who cultivate them are as proud of introducing a new variety into their collection, as the nursery-men. in England are of obtaining a new pear, apple, or peach. The fruit of the citron is seldom eaten raw, but is generally preserved, and made into sweetmeats, which being kept till winter and spring, when there is a scarcity of fruit to furnish out the dessert, is the more valuable; but unless the season be warm and the trees well managed, the fruit rarely ripens in England. The best fruit will be produced where the trees are trained against a south wall, through which there are flues for warming the air in winter; and glass covers, to protect the plants when the weather begins to be cold. The citron is a native of all the warm regions of Asia; it was introduced into Europe from Media, and had the name of Malus Medica, and seems to have been brought into Italy after the age of Virgil and Pliny, but before that of Palladius. who appears to be the first who cultivated it there with any success. According to Haller, the Median apple described by Theophrastus, and which, Athenaeus asserts, first came from Persia into Greece, is certainly a sort of orange ; and, if Haller be correct, the tristes succi of Virgil, and the acres medullæ of Palladius, must have been much corrected by culture, for the latter, together with Theophrastus and Pliny, agree in describing it as not eatable, though they celebrate its medical qualities far above its desert. Citrus Medica, or citron, has medical virtues similar to those of the orange and lemon; the fruit is more flavoured than the latter, and the rind acts more as an emetic ; the yellow rind is used, and from it the perfume called bergamot is extracted. Citrons are very rarely kept in the shops, though formerly much used in the materia medica. Whether the Median apple were the citron or the orange, it was anciently celebrated as a cure for the asthma, and for expelling poison.

CIT

Media fert tristes succos tardumque saporem Filicis mali, quo non præsentius ullum (Pocula si quando sævæ infecere novercæ Miscueruntque herbas, et non innoxia verba) Auxilium venit, ac membris agit atra venena. Ipsa ingens arbos, faciemque simillima lauro: Et, si non alium latè jactaret odorem, Laurus erat: folia haud ullis labentia ventis: Flos apprime tenax; animas et olentia Medi Ora fovent illo, et senibus medicantur anhelis.

VIRGIL, Georgic. lib. ii. v. 126-125. The Median fields rich citron fruits produce, Tho' harsh the taste, and clammy be the juice; Blest antidote ! which when in evil hour. The step-dame mixes herbs of pois'nous pow'r, And crowns the bowl with many a muttered spell, Will from the yeins the direful draught expel. Large is the trunk, and laurel-like its frame, And 'twere a laurel, were its scent the same : Its lasting leaf each roaring blast defies, Tenacious of the stem its flow'rets rise : Hence a more wholesome breath the Medes receive. And of their sires the lab'ring lungs relieve.

Pitt & Wharton.

316

CIT

For their culture and propagation, see the second species. 3. Common lemon : leaves ovate-lanceolate, acuminate, subserrate. This differs materially from the orange-tree, both in the naked footstalks of the leaves, and in the shape and colour of the fruit; but there is scarcely any distinction between this and the citron, except it be that the rind of the fruit is generally thicker and more knobbed in the citron than in the lemon, and the fruit itself longer and more irregular; to which Mr. Miller adds, that the bark of the citron-tree is smoother, and the wood less knotty. Many varieties of the lemon are preserved in some of the Italian gardens, and in both the Indies there are several which have not yet been introduced to the European gardens; but these may be wultipled without end from seeds. The most remarkable varieties in the English gardens are: 1. The sweet lemon, plain and variegated; 2. the pear-shaped lemon; 3. the iu-perial lemon; 4. the lemon called Adam's apple; 5. the furrowed lemon; 6. the childing lemon; 7. the lemon with double flowers: 8. Browne mentions the St. Helena lemon. as having been then lately introduced to Jamaica, and much cultivated there, on account of its fruit, which frequently yields above half a pint of juice: 9, in China, and other parts of the East, they have a remarkable variety of lemon or citron, which has a solid fruit without any cells or pulp, and divided above the middle into five or more long round parts. a little crooked, and having the appearance of the human hand, with the fingers a little beut, whence the Chinese call it *phat-thu*, or fingered lemon; it is a monstrous fruit, a mere curiosity without any use. The common and sweet lemon are brought to England from Spain and Portugal in great plenty, but the latter is not much esteemed ; the pearshaped lemon is a small fruit with very little juice; the fruit of the imperial lemon is sometimes imported from Italy, but not from Spain or Portugal, probably therefore it is not propagated in either of those countries. The Portuguese had many of the most curious sorts of orange, lemon, and citron trees brought from the Indies formerly, which seemed to thrive almost as well there as in their native soil, and yet they have not been increased. There are a few trees still remaining in some neglected gardens near Lisbon, which are almost unnoticed by the inhabitants. 4. The sour lemon or lime : leaves ovate, entire; branches somewhat thorny; it grows to the height of about eight feet in its native country, with a crooked trunk, and many diffused branches, which have prickles on them; leaves ovate-lanceolate, almost quite entire; the petioles usually linear; flowers few together, on terminating peduncles; corolla oblong, white, with a purplish spot; stamina twenty, in several parcels; berry an inch and half in diameter, almost globular, with a protuberance at the tip, the surface regular, shining, greenish yellow, with a very odorous rind, nine-celled, abounding in a very acid juice, but having very few subovate seeds : it is a native of Asia, but has long been common and much esteemed in the West Indies. Browne says, that it is a bushy shrub in Jamaica, where it is much cultivated for the sake of its fruit, and not unfrequently planted for fences; that when it grows luxuriantly it is seldom under twelve or fourteen feet in height, and spreads gently about the top, but that it is often stunted, and of a smaller stature. They have also a sweet lime, which is generally a more upright tree, and bears a fruit which in size as well as form seems to hold a mean between the lime and the lemon; the juice is very insipid, but the bark and the fibres of the root have much of that bitter so peculiar to the fime. There can be no doubt that any one investigating the subject in the native climates of these fruits, would detect varieties very different in the colour of the peel, and in the taste both connecting all that are here described as species, not only of that and of the juice, as is well known. The varieties of

the citron, with the lemon and lime, which certainly are no more than varieties, but these also with the shaddock and the orange, which are hardly to be considered as specifically distinct. Mr. Miller declares, that he has never known the common lemon vary to the lime when raised from seeds, nor the lime vary to the lemon; but that he has always found them continue their difference in leaf and branch, and therefore supposes them to be specifically distinct. The lime is not often brought to England, nor is it much cultivated in Europe; but in the West Indies the fruit is preferred to the lemon, the juice being more wholesome, and the acid more agreeable to the palate. 5. The clustered lemon : leaves ovate-lanceolate, subserrate; fruits in clusters. The medical virtues of citrus limon or lemon are very considerable: its juice is very generally carried by sailors going on long voyages, as an antiscorbutic ; it has been found to cure the jaundice, when taken to the quantity of four or six ounces per day; Dr. Whytt says, that it allays hysterical palpita-tions of the heart: the rind is a very grateful aromatic bitter, not so hot as orange-peel, and yields, in distillation, less quantity of the oil, which is nevertheless similar in quality to that of the orange, and employed for the same purposes. For the propagation and culture, see the second species.

2. Citrus Aurantium; Orange. Petioles winged; leaves acuminate. The orange is a middle-sized evergreen tree, with a greenish brown bark ; in its native country the branches are prickly; leaves broad lanceolate, almost quite entire. smooth, with the petioles commonly wiuged ; peduucles manyflowered, terminating; corolla white; stamina twenty, connected in several parcels; berry subglobular, flatted (an oblate spheroid) of a golden colour, shining, odorous, three inches in diameter, divided within into about nine cells, filled with a bladdery pulp, having a sweet acid juice in it; rind fleshy, of a middling thickness, covered with a pellicle which is somewhat biting and bitter to the taste. Loureiro, the author of the above description, says, that it agrees particularly with that sort of orange which is most common all over the world, and is known in Europe by the name of Portugal or China orange, because it was brought from China by the Portuguese, and by them dispersed over Europe. It is a native of India and Chiua, where there are innumerable varieties, as well as in other countries of Asia, in South America, in the West Indies, and even in Europe. He describes the most grateful of all the oranges as a distinct species under the title of citrus nobilis : the branches are less spreading than those of the common orange, but are rather ascending, and without prickles; leaves lanceolate, quite entire, dark green, on linear petioles; berry red within and without, twice as large as the common sort, being five inches in diameter; the skin thick, juicy, sweet, eatable, and irregularly tubercled: it abounds in Cochin-china. The most esteemed fruit in China, according to Grosier, is very small, with a smooth soft skin of a reddish yellow colour: they have also the four-season or everlasting orange, so called from its being always in fruit and blossom, this also bears a very small fruit; the large clove or mandarine, and the small clove or mandarine; the soft cushion orange, the gold orange, &c. The Chinese oranges are generally firmer than those of Europe, their skin does not usually peel off, and the pulp will not separate into small divisions; they commonly give them to the sick, softening them a little at the fire, and mixing sugar with them. The Seville orange differs little from that of China in the tree, except that it is more hardy, and that the leaves are longer and handsomer; the fruit, however, is

the orange most known in the English gardens are, in addi- (tion to the Seville and China, already named, 1. The willowleaved or Turkey orange; 2. the yellow and white-striped leaved ; 3. the curled-leaved ; 4. the horned orange ; 5. the double-flowering; 6. the hermaphrodite; 7. the dwarf, or nutmeg orange. The horned orange divides into parts, spreading out in form of horns; this and the distorted orange are preserved merely for variety, not being so beautiful as the common sort; the leaves of the dwarf orange are very small, and grow in clusters : the joints of the branches are very near each other: the flowers grow very close together, and appear like a nosegay, the branches being covered with them; this, when in flower, is proper to be placed for ornament in a room or gallery, which it will perfume with its flowers; but it requires care, and is seldom in health. The first China orange, says Evelyn, that appeared in Europe, was sent for a present to the old Conde Mellor, then prime minister to the king of Portugal; but of that whole case which came to Lisbon, there was but one only plant which escaped the being so spoiled and tainted, that with great care it hardly recovered to be since become the parent of all those flourishing trees of that name cultivated by our gardeners, though not without sensibly degenerating. Receiving this account, adds our famous planter, from the illustrious son of the Conde, I thought fit to record it as an instance of what industry may produce in less than half an age. South America and the West Indies have been furnished from Spain and Portugal with this fruit, so salutary and agreeable to the palates of the people, and so congenial to those hot climates. Mr. Miller informs us, that he sent two small trees of the true Seville orange to Jamaica, where this sort was then unknown, and that from these many other trees were budded, which produced plenty of fruit, some of which was sent to England, and, although they were long on their passage, yet they were greatly superior to any of the fruit imported from Spain and Portugal, affording three times the quantity of juice. The orange-tree has been cultivated in England ever since the year 1629, and the first shifts made to preserve it will not be uninteresting to the reader. "The orange-tree," says Parkinson, " hath abiden with some extraordinary looking and tending of it, when as neither citron or lemon trees would by any mcans be preserved any long time : some keep them in great square boxes, and lift them to and fro by iron hooks on the sides, or cause them to be rolled by trundles, or small wheels under them, to place them in an open house, or close gallery for the winter time; others plant them against a brick wall in the ground, and defend them by a shed of boards, covered over with sear-cloth in the winter, and by the warmth of a stove, or other such thing, give them comfort in the colder times; but no tent or mean provision will preserve them." But notwithstanding what Parkinson here advances, bishop Gibson, in his additions to Camden's Britannia, probably from Aubrey, says, that the orange-trees at Beddington in Surry, introduced from Italy by a knight of the noble family of the Carews, were the first that were brought into England; that they were planted in the open ground, under a moveable covert during the winter months; and that they had been growing there more than a hundred years, that is, before 1595, the first edition of Camden, by bishop Gibson, being printed in 1695. The editors of the Biographica Britannica, article Raleigh, reciting a tradition preserved in that family, tell us, that these orange-trees were raised by sir Francis Carew from the seeds of the first oranges which were imported into England by Sir Walter Raleigh, who had married his nicce, the daughter of Sir Nicholas 27.

raised from these seeds would have required to be inoculated. in order to produce fruit, and it is therefore more likely that they were plants brought from Italy. Professor Bradley reports, that they always bore fruit in great perfection, that they grew on the south side of a wall, not nailed against it, but at full liberty to spread. And by the account of Mr. Henry Day, the gardener, they were fourteen feet high, the girt of the stem twenty-nine inches, and the spreading of the branches one way nine feet, and twelve feet another; these trees were all killed by the great frost of 1739-40. They had been inclosed by a permanent building, after the manner of a green-house, so that it is uncertain whether the dampness of new walls, and the want of so much air and light as the trees had been accustomed to, might not have destroyed them, if the frost had not happened. Citrus aurantium, or orange, has long maintained a very respectable place in the materia medica. The sort principally employed in medicine is the Seville orange, the juice of which is well known to be a grateful acid liquor, which, by allaying heat, quenching thirst, and promoting various excretions, proves of considerable use in febrile and inflammatory disorders : it is also considered as a powerful antiseptic, and of great efficacy in preventing and curing the scurvy : the juice of the China or common orange possesses the same qualities in an inferior degree. The acid of oranges, by uniting with the bile, is said to take off its bitterness; and hence Dr. Cullen thinks it propable, that acid fruits taken in, are often useful in obviating the disorders that might arise from the redundancy of bile, and perhaps from the acrid quality of it; he adds on the other hand, however, "that if the acids be in greater quantity than can be properly corrected by the bile present, they seem, by some union with that fluid, to acquire a purgative quality that gives a diarrheea, and the colic pains that usually accompany the operation of every purgative." Not only the juice, but the rind or peel, of the Seville orange is of considerable medical efficacy; since, besides its use as a stomachic, it has been much celebrated in intermittent fevers; and in testimony of its efficacy in the most obstinate agues, we find several authorities cited by professor Murray: it has also been experienced as a powerful remedy in menorrhagia, and in immoderate uterine evacuations; and for its good effects in these disorders, we have not only the assertions of foreign physicians, but also those of Drs. Whytt and Hamilton. It gives out its taste and flavour readily to water, is useful in all flatulencies in whatever form it be given, and also sits better on the stomach than most other corroborants. The leaves of the orange are not without their virtues, and have, like the flowers, been particularly celebrated in convulsive disorders. and successfully given in the dose of a drachm at a time, in nervous and hysterical cases. Where the trees are to be raised for stock to bud oranges, some citron seeds, duly ripened, should be prepared, because their stocks are preferable to any other, not only for quick growth, but as they will take buds of either orange, lemon, or citron; and next to these are the Seville orange secds. The best seeds are usually procured from rotten fruits, which may be easily obtained in the spring of the year. Prepare a good hot-bed of tanner's bark, which is preferable to horse-dung, and when this bed is in a moderate heat, sow your seeds in pots of good rich carth, and plunge them into the hot-bed, observing to give them water frequently, and raise the glasses in the great heat of the day, to give a sufficiency of air, lest the seeds should be injured by too much heat: the seeds will soon come up, and if the young plants be not stinted either of proper heat or moisture, they will be fit to transplant into Throckmorton; but this is improbable, since the plants single pots in a month's time after their appearance; you 4 M

quantity of small halfpenny pots, which are about five inches over at the top, fill these half full of good fresh earth, mixed with very rotten cow-dung, and then shake out the young plants from the large pots, with all the earth about them, that you may the better separate the plants without tearing their roots: half fill the pots with earth, and put a single plant into cach of the small pots, and fill them up as before directed, plunging the pots into the new hot-bed, giving them a good watering to fix the earth to their roots, observing to repeat the same very often, for this plant requires much water when in a hot-bed, and must be screened from the sun in the heat of the day; by pursuing this method, your plants will be two feet high in July, at which time you must begin to harden them by degrees, raising your glasses very high, and altogether removing them in fine weather. The plants must not, however, be exposed to the mid-day sun, especially while they are young; they must be housed towards the end of September, observing to place them near the windows of the green-house to prevent the damps from moulding their tender shoots: they should be often refreshed with water during the winter season, and should have their heads and stems washed in March or April, to clear them from the filth that may have settled thereon, during their being in the house ; they must also have a moderate hot-bed in the spring, which will greatly forward them. Towards the beginning of June, however, they ought to be hardened, that they may be in right order to bud in August, when you should choose cuttings from trees that are healthy and fruitful, of whatever kinds you please, observing that the shoots are round, their buds being much better and easier to part from the wood, than such as are flat. When you have budded the stocks, you should remove them into a greenhouse, to defend them from wet, turning the buds from the sun ; but let them have as much free air as possible, and often be refreshed with water. It will be evident which have taken, in a month's time after budding ; they must then be untied, that the binding may not pinch the buds, and let them remain in the green-bouse all the winter; then in the spring prepare a moderate hot-bed of tanner's bark, and after having cut off the stocks about three inches above the buds, plunge their pots into the hot-bed, observing to give them air and water as the weather shall require, and screening them from the sun in the heat of the day. If the buds shoot kindly, they will grow to the height of two feet or more by the end of July, at which time you must begin to harden them before the cold weather comes on, that they may the better stand the green-house during the following winter. In the first winter after their shooting they must be kept very warm, for they will be rather tender by forcing them in the bark-bed; but it is very necessary to raise them to their height in one season, that their stems may be straight; for in trees which are two or more years growing to their heading height, the stems are always crooked; in the succeeding years their management will be the same as in full-grown trees, which will be hereafter noticed. We shall now proceed to treat of the management of such trees as are brought over every year in chests from Italy, which is, in fact, by far the most expeditious way of furnishing a green-house with large trees, for those which are raised from seeds in England, will not grow so large in their stems in less than eighteen or twenty years, as these are when brought over; and although their beads be small when we receive them, yet in three years, with good management, they will produce large heads, and bring forth fruit. In the choice of these trees, observe first the differences of their shoots and leaves, if any remain upon them, to distinguish their dif-

must therefore renew your hot-beds, and having prepared a ferent sorts, for the shaddock and citrons always make much stronger shoots than the orange, for which reason the Italian gardeners, who raise these trees for sale, generally propagate. those sorts, so that they bring few of the Seville oranges over. which are well known to be the most valuable both for their flowers and fruit; prefer also those that have two good buds in each stock, for many of them that have but one, which will always produce an irregular head: the straightness of the stem, freshness of the branches, and plumpness of the bark, are necessary observations. When you have procured the trees, prepare a moderate hot-bed of tanner's bark, and let the length and breadth of it be proportioned to the number of trees which you intend to force; then put your trees about half way up their stems upright into a tub of water, leaving out the head and the upper part of the stem, that they may the better imbibe the moisture: after they have remained several days in this situation, take them out, clean their roots from all filth, cutting off all that are broken or bruised, and all the small fibres which are quite dried by being so long out of the earth ; scrub the stems with a hard hair brush, wiping them afterwards with a cloth; then cut off the branches about six inches from the stem, and having prepared a quautity of good fresh earth, mixed with very rotten cow-dung, plant your trees therein, observing never to put them into large pots, for if they be big enough to contain their roots it is sufficient at first planting. Potsherds and large stones must be placed in the bottom of each pot, to enable the water to pass off freely : hay-bands should also be wrapped round their stems from bottom to top, to prevent. the sun from drying their bark ; then plunge these pots into, the bark-bed, watering them well to settle the earth to their roots, frequently repeating the same all over their heads and stems, yet being very careful not to over-water them, especially before they have made good roots; and particularly observing to screen the glasses of the hot-bed from the sun in the heat of the day, If the trees grow kindly, (of which, under the above management, there will be little doubt,) they will have sent out strong shoots, which should be stopped by the beginning of June, in order to obtain lateral branches to furnish their beads; at this time plenty of air must be admitted to begin to harden them, so that by the middle of July they may be removed into the open air in some warm situation. defended from the great heat of the sun, and from winds, that they may be bardened before winter. They should be housed about the end of September, setting them at first in front of the green-house, near the glasses, opening the windows whenever the weather will permit; and about the latter end of October, when the myrtle and other less tender trees are brought in, let the oranges be set in the warmest and best part of the house, placing lower plants or trees in front to hide their stems : water them frequently during the winter, but in small quantities at a time, for now their heads are but small, and therefore incapable of discharging a large quantity of moisture; they must also be particularly guarded from frost. When you thin the green-house, by taking out some of the hardiest sorts of plants in the spring, it will be well to cleanse the stems and leaves of the orange-trees, taking out the upper part of the earth in the pots, filling them up again with good fresh rich earth, laying thereon a little rotten cow-dung round the outside of the pots, but not near the stems of the trees; after this remove them farther apart in the house, that the air may circulate round their heads, giving them air discretionally, as the weather grows warm: they should not be placed out in the open air until the latter end of May, when the weather is settled, for many times, when they are taken out too soon, the cold mornings give them a great check, at

319

extreme weak part of the shoots : during the summer season, let them be as much as possible defended from the sun, by tall trees or hedges, during the heat of the day, and also from strong winds, both of which are exceedingly injurious to them. As the trees advance in the summer, it will be necessary to stop strong shoots wherever they grow irregularly, in order to force out lateral branches to fill the head, but do not pinch off the tops from all the shoots, as is the practice of some, which will fill the tree with small shoots, too weak to support fruit : the best plan is, to aim at forming a regular head, and obtaining strong shoots, taking away weak trifling branches wherever they are too close: they must be frequently watered in dry weather, cspecially if they be large, and on this account it is advisable to have the water as near the trees as possible, in order to save the trouble of carrying it, which will take up too much time where the number of trees is great; the water should be soft, and exposed to the air, but should never have dung of any sort added to it, which although recommended by many, has always been found to operate upon these and upon all other trees, like spirituous liquors upon the human body, seeming at first to communicate vigour, but afterwards leaving it weaker than before. Orange-trees require to be shifted and new-potted every other year, therefore you must prepare a quantity of good earth, at least twelve months beforehand, that it may be well mixed and perfectly rotten; the best season for this is about the end of April, that they may have taken fresh root before they are removed from the green-house; and when this work is performed, it will be necessary to let them remain in the house a fortnight longer than usual, in order to be well settled. In performing this work, after the trees are drawn out of the pots, all the roots round the outside of the ball of earth must be cut off, and the mouldy roots taken away; then with a sharp iron instrument take away as much of the old earth from between the roots as can be removed without breaking or tearing them, then set the root of the tree into a large tub of water for about a quarter of an hour, to soak the under part of the ball of earth; afterwards scrub the stems of the trees with a hard hair brush, cleaning them and the heads with water and a soft woollen cloth: when the pots are prepared, with some potsherds and large stones at the bottom, put some fresh earth into each pot about three or four inches thick, place the trees thereon in the middle of the pots, upright, filling them up with the same rich earth, pressed down hard with your hands; then water the tree all over the head, with a watering-pot that has a rose upon the spont, to let the water fall light and thick, as in a shower of rain, observing to water them in the same manner during the time they remain in the house after shifting; this will greatly refresh their heads, and promote their taking fresh roots. When these trees are first placed abroad after shifting, they should be placed near the shelter of hedges, and have their stems fastened to strong stakes, to sustain them against strong winds. If old orange-trees have been so ill managed that their heads became ragged and decayed, the best means of restoring them is to cut off the greatest part of their heads early in March, and draw them out of the tubs or pots, shaking off the earth from their roots, casting away all those which are mouldy, together with all small fibres. and then soaking and cleaning their roots, stems, and branches, aud afterwards resetting them iuto a hot-bed of tanner's bark, as above directed for such trees as came from abroad, managing them in the same manner; by this method they will produce new heads, and in two years' time become good trees again : but if they be large trees, that have grown

least changing the colour of their leaves, and often kill the | in tubs for several years, the best way will be to prepare a parcel of rough baskets, such as are used for evergreens, when sent to a distant place : let them be somewhat smaller than the tubs into which it is intended to plant the trees; and set the trees in them, plunging them into the hot-bed ; and in the beginning of July, when they have made good shoots remove them into the tubs with their baskets still about them, filling the empty space with the same good earth; which will preserve the tubs from rotting in the bark; and the trees will do equally well as if planted into tubs at first, provided care be taken, in removing the baskets, not to disturb their roots ; and also to let them remain in the green house a fortnight or three weeks after planting, before you set them abroad. Orange trees are new potted or tubbed every other year, in the month of April: in the years wherein they are not shifted, as much old earth as possible must be taken out from the tops of the pots and tubs, and also round the sides, as can be removed without injuring the roots : this must be replaced with fresh earth: you must also wash and clean their stems and leaves from filth, which will greatly strengthen their flowering, and cause them to shoot vigorously in the following summer. In the mangement of orange-trees which are in good health, the chief care should be to supply them with water duly, instead of starving them in winter, as is sometimes practised, whereby their fibres are dried and become mouldy, to the great prejudice of the trees. But they certainly must not have much water, but should often have small quantities. Care must be taken to secure a free passage for the water to drain off, for if it be detained in the tubs or pots it will rot the tender fibres of the trees : even in winter they require a large share of air when the weather is favourable, for nothing can injure these trees more than stifling them: hence they ought not to be placed too near each other in the green-house, but set at such a distance that their branches may be clear of each other, and that the air may circulate freely round their heads. In summer they should be placed where the wind is not violent, and exposed to the morning and evening sun; but if they be too much exposed to him in the middle of the day, they will not thrive. The best situation for them is near some large plantation of trees, which will break the force of the winds, and screen them from the violent heat of the sun. In this situation they may remain until the beginning of October, or later, according as the season proves favourable; for if they be carried into the green-house early, and the autumn should prove warm, it will compel the trees to send forth fresh shoots, which will be weak and tender, and so liable to perish in winter; and sometimes it will occasion their flowering in winter, which greatly weakens them; nor should they remain so long abroad as to be injured by morning frosts. The hest compost for orange-trees is two-thirds of fresh earth from a good pasture, which should not be too light nor over stiff, but rather a hazel loam. It should be taken along with the sward to the depth of ten inches, and mixed with one-third of cow-dung twelve months before, to rot. It should be turned over every month, to mix it well, and to dissolve the sward, which will at the same time break the clods, and produce finer mould. Before this mixture be used, it should pass through a rough screen, to separate the great stones and the roots of the sward from it; but the earth should on no account be too finely sifted, for that is very prejudicial to most plants, particularly to orange-trees. Of late years many of these trees have been planted against walls, where frames of glass have been constructed to protect them in the winter; and some curious individuals have planted them in the full ground, erecting moveable covers, which entirely enclose them in winter, and in the summer are with

drawn; and where these have been well executed, the trees have made great progress in their growth, and have also produced a much larger quantity of fruit, which have ripened so well as to be extremely good for eating. If these be planted either with a design of training the branches to the walls, or in borders at a small distance, so as to train them up as standards, there should be a contrivance of a fire-place or two. in proportion to the length of the wall, through the whole of which flues should be carried to warm the air in very cold weather, otherwise it will be extremely difficult to preserve the trees in very hard winters, for if they do not die, they may be so weakened by the cold as not to recover their strength for bearing in the following summer; so that wherever the trees are intended to be placed against or near old walls, the flues should be built up against the front, allowing four inches' thickness of the brick-work on each side of the flues, observing to fasten this with iron at proper distances, to secure it against separating from the old wall. Where this contrivance is carefully used, there will be no hazard of losing the trees, be the winter ever so severe ; whereas if this be wanting, it will require endless trouble to cover and uncover the glasses every day, when there is any sun : and if the wall be not thicker than walls are usually built, the frost will penetrate it in severe winters; so that covering and sccuring the glasses of the front will not be sufficient to preserve the trees, though done with ever so much care; and hence the first expense of the walls will save great trouble and charge, and be the securest method. If the ground be wet, or a strong clay which detains the moisture, the borders should be raised above the level of the ground, in proportion to the situation of the place, for where the wet lies in winter near the surface, it will greatly prejudice, if not totally destroy the trees; so that lime rubbish should be laid at least two feet thick in the bottom of the border, to drain off the wet, with the earth two and a half or three feet thick thereon, which will be a sufficient depth for the roots of the trees. In these borders a few roots of the Guernsey and Belladonna lilies and hæmanthus may be planted, or indeed any other exotic bulbous-rooted flowers, which do not grow high, or draw too much nourishment from the borders; and these producing their flowers in autumn and winter, will make a good appearance, and thrive much better than if kept in pots. The management of orange-trees in these places is nearly the same as has been directed for those in pots or tubs, excepting that the borders in these places should be dug, and refreshed every year with some very rotten dung. It is com-monly said that the Maltese red oranges are budded on the pomegranate; and that the orange, budded or grafted on mulberry stocks in Sicily, produces fruit with a blood-coloured pulp : but these accounts of travellers are not to be depended upon. The China dwarf orange, shaddock, and those with striped leaves, are all more tender than the Seville orange, and therefore must be treated with more care, and placed in a warmer part of the green-house in winter. The China orange rarely produces good fruit in England, nor are the leaves of the trees near so large or beautiful as those of the Seville orange ; the latter therefore should be preferred, and only a tree or two of the China sort kept for variety. The varieties with striped leaves never produce good fruit, nor do they even produce flowers in so great plenty as the plain varieties.

3. Citrus Decumana; Shaddock. Petioles winged; leaves obtuse, emarginate. Linneus originally regarded this merely as a variety of the orange, to which it certainly makes very near approaches. It is a tree above the middle size, with spreading prickly branches; leaves ovate, subacute, seldom oblong body, of one uniform substance. Withering's botanical

CLA

obtuse, very seldom emarginate, smooth, scattered ; petioles cordate, winged, the wings as broad as the leaves ; flowers white, very sweet-scented, in copious upright terminating bunches; corolla reflex; stamina about twenty, nearly equal to the petals, collected into a many-cleft tube; berry spheroidal, frequently retuse at each end, eight inches in diameter, of an even surface, greenish yellow, divided into twelve or more cells, containing some a red, others a white pulp, the juice in some sweet, in others acid. The rind is very thick, white, fungous, bitter, useless ; seeds ovate, subacute, two or three in each cell. There are many varieties of this tree, one of which is superior to the rest in the smell and flavour of the fruit, and may be distinguished by having a smaller trunk, and subglobular fruit, five inches in diameter, yellow on the outside, white and very sweet within. In China it is called hiam yuen, in Cochin-china huongien, which signifies sweet ball. Thunberg describes the first in Japan as being the size of a child's head; and says, that it may be kept many weeks on ship-board, if it be hung up; that the juice of it is subacid and sweet, and excellent for allaying thirst. It was brought from Batavia to Japan, and is also found in the Friendly Islands. Captain Shaddock, after whom it has been named, first brought it from the East to the West Indies. The Dutch call it pompelmoes. The fruit has degenerated greatly since its importation into the West Indies, owing to raising the trees from seeds, the greatest part of which produce harsh sour fruit, with a pale yellow pulp; whereas, if they would have budded from a good sort, they might have continued it in perfection : but there are few persons there who understand the method of grafting or budding fruit-trees ; and they are so negligent of their fruits as to leave the whole to nature, seldom giving themselves any farther trouble than to put the seeds into the ground, and leave the rest to chance.

4. Citrus Japonica. Petioles winged ; leaves acute ; stem shrubby. This is a small shrub, with fruit no larger than a cherry; it ripens in December and January, and is very sweet and pleasant. It approaches to the citron in having the flowers axillary, but it has winged petioles like the orange, from which, however, it differs in having only one or two axillary flowers, not panicled, as in that which is native of Japan, where the fruit is ripe in December and January.

5. Citrus Trifoliata. Leaves ternate; stem nearly two yards in height; branches alternate, flatted, and angular, flexuose, spreading very much, stiff, very smooth, thorny; thorns alternate, dilated, and compressed at the base, spreading very much, acute, smooth, yellow at the end, an inch in length; corolla white; stamina double the length of the petals .- This shrub forms strong hedges in Japan, with its long, stiff, sharp thorns. It flowers in April, with leafless branches. to May, when the leaves burst forth. Thunberg says, the fruit is bad, and has a glutinous pulp; and Linneus adds, that it is laxative.

Cives. See Allium.

Clary. See Salvia.

Clathrus; a genus of Fungi, the essential characteristic of which, according to Dr. Withering's botanical arrangement, containing eleven species, is, that it grows in clusters; mostly fixed to a membranaceous base; capsules globular or oblong; seeds escaping from its whole surface, through openings made by the separations of the fibres. They are found chiefly on rotten wood.

Clavaria; a genus of Fungi, one of the lowest order in the scale of vegetation, differing sometimes very little in substance from the rotten wood out of which it issues. It is a smooth arrangement contains twenty species, besides many varieties, the essential character of which he thus states :- Fungus oblong, upright, club-shaped; seeds emitted from every part of its surface.

Claytonia ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth bivalve, evate, transverse at the base. Corolla : petals five, obcordate, with claws emarginate. Stamina : filamenta five, subulate, recurve, a little shorter than the corolla, each inserted into the claw of each petal; autheræ oblong, incumbent. Pistil : germen roundish; style simple, the length of the stamina; stigma trifid. Pericarp: capsule roundish, threecelled, three-valved, elastic. Seeds: three, round. ESSEN-TIAL CHARACTER. Calix: two-valved. Corolla: fivepetalled; stigma trifid. Capsule : three-valved, one-celled, three-seeded .---- The species are,

1. Claytonia Virginica. Leaves linear-lanceolate; petals entire. It has a small tuberous root, which sends out slender stalks three inches high in the spring, having each two or three succulent narrow leaves, about two inches long, of a deep green colour. Four or five flowers arc produced at the top of the stalk in a loose bunch; petals spreading, white spotted with red on their inside. The flowers appear in April, and the seeds ripen in June: both this and the next species are propagated by seeds, and also from offsets sent out from the roots : the seeds should be sown upon a shady border of light earth, or in pots filled with the like mould, soon after they are ripe; for if they be kept out of the ground till spring, the plants will not come up till the next year; whereas those which are sown early in the autumn will grow the following spring; so that a whole year is gained: when the plants appear, they will require no other care but to keep them clean from weeds; and in the autumn, if some old tanner's bark be spread over the surface of the ground, it will secure the roots from being injured by frost; but in mild win-ters they will not require protection. The best time to trans-plant the roots is about Michaelmas, when they are inactive; but as they are small, if great care be not taken in opening the earth, the roots may be buried and lost, for being of a dark colour, they are not easily distinguished from the ground. 2. Claytonia Sibirica. Leaves ovate. This is a low plant.

seldom rising more than two or three inches high; flowers red. For its propagation and culture, see the first species.

Cleavers. See Gallium Aparine.

Clematis; a genus of the class Polyandria, order Polygamia .- GENERIC CHARACTER. Calix : none. Corolla : petals four, oblong, lax. Stamina: filamenta very many, subulate, shorter than the corolla; antheræ growing to the side of the filamenta. Pistil: germina very many, roundish, compressed, ending in subulate styles, longer than the stamina; stigmas simple. Pericarp : none; receptacle headed, small; seeds very many, roundish, compressed, furnished with the style in various forms. ESSENTIAL CHARACTER. Calix: none. Petals: four, sometimes five, or even six. Seeds : having a tail. The virgin's bowers are chiefly climbing shrubs, though some of them are erect; leaves opposite, simple, ternate, or unequally pinnate; flowers axillary, but more frequently terminating; solitary, but more frequently in corymbs; in some species diæcous, and in others furnished with a turbinate bifid calicle, removed a little from the petals .---- The species are, * Climbing.

1. Clematis Cirrhosa; Evergreen Virgin's Bower. Leaves simple; stem climbing by opposite tendrils; peduncles oneflowered, lateral. This has a climbing stalk, rising to the height of eight or ten feet, sending out branches from every 27.

joint, whereby it becomes a very thick bushy plant. leaves retain their verdure throughout the year. The flowers are produced from the sides of the branches, are large, and of an herbaceous colour : they appear at the end of December or beginning of January .- Native of Spain. Gerarde calls it traveller's joy of Candia ; Johnson, Spanish traveller's iou ; and Parkinson, Spanish wild climber. It is valuable on account of retaining its leaves all the year, and was formerly preserved in green-houses in the winter, having been supposed too tender to endure the open air in England; but now it is generally planted in the full ground, where the plants thrive much better than in pots, and produce plenty of flowers, which they never bore when tenderly treated. They do not suffer from severe frosts, even when left uncovered. This species does not produce seeds in England, and therefore is propagated by layers and from cuttings : if by the former, they should be planted in the beginning of October, when the shoots of the same year only should be chosen for this purpose ; for the older branches do not put out shoots in less than two years ; whereas, the tender shoots will make good roots iu one year, and must be pegged down: if the shoots have two inches of earth over them, it will be better than a greater depth; but then a little old tanner's bark should be spread over the surface of the ground, to keep out the frost, for the plants generally begin flowering about Christmas, and at the same time are putting out roots, which being but just formed, may be injured by severe frosts. These layers will have strong roots by the following autumn, when they may be taken from the old plant, and transplanted where they are designed to remain :--- if it be propagated by cuttings, they should be planted in March, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, observing to shade them from the sun in the daytime, and to water them gently twice or thrice a week, and in less than two months they will have taken root, and should be gradually inured to the open air. In the following summer they may be placed in any part of the garden till Michaelmas, and then they should be turned out of the pots and planted in the full ground, either where they are designed to remain, or into a nursery-bed, to grow a year longer, to get strength before they are placed out for good.

CLE

2. Clematis Viticella; Purple Virgin's Bower. Leaves compound and decompound ; leaflets ovate, sublobed, quite entire; stems very slender and weak, having many joints, whence come out side-branches, which are again divided into smaller. If these be supported, they will rise to the height of eight or ten feet; the petals are of a dark worn-out purple or blue, or bright purple or red .- It grows naturally in the woods of Spain and Italy. Gerarde calls it blue or redflowering ladies-bower, from its aptness to make bowers or arbours in gardens. There are four varieties cultivated in the nurseries : 1. the single blue; 2. single purple; 3. single red; 4. double purple: they flower in June and July, but the seeds seldom ripen in England : the last continues to the end of August. All the varieties of purple virgin's bower are propagated by laying down their branches; for although the single flowers sometimes produce seeds in England, yet as these seeds when sown, generally remain a whole year in the ground before they vegetate, the other, being the more expeditious method of increasing these plants, is generally preferred: in order to succeed these, layers should be laid down at different seasons from the former sort; for when they are laid in the autumn, their shoots are become tough, so as rarely to put out roots under two years; and after being so long in the ground, not one in three of them will have made good roots ; so that many have supposed that these plants were difficult 4 N

to propagate, but since they have altered the season of performing it, they have found that these layers succeed as well as those of other plants. The best time for laying down the branches is in the beginning of July, soon after they have made their first shoots, for it is these young brauches of the same year which freely take root ; but as they are very tender, great care must be taken not to break them in the operation ; therefore those branches, from which these shoots were produced, should be brought down to the ground, and fastened, to prevent their rising; then the young shoots should be laid into the earth, with their tops raised upright three or four inches above ground; and after the layers are placed down, if the surface of the ground be covered with moss, rotten tanner's bark, or other decayed mulch, it will prevent the ground from drying, so that the layers will not require watering above three or four times, which should not be at less than five or six days' interval; for when the layers have too much wet, the tender shoots frequently rot; or when the young fibres are newly put out, they are so tender as to perish by having much wet : where the method here directed is practised, the layers will be more sure to take root, than by any other way of treating them. Most of these plants have climbing branches, and should therefore always be planted where they may be supported, otherwise the branches will fall to the ground, and appear unsightly; so that unless they be properly disposed, they will cease to be ornamental, and become the reverse : where there are arbours or seats with trellis-work round them, these plants are very proper to train up against it; or where any walls or other fences require to be covered from the sight, these plants are very proper for the purpose; but they are by no means proper for open borders, nor do they answer the expectation, when they are intermixed with shrubs; for unless their branches have room to extend, they will not be productive of many flowers. The sort with double flowers is the most beautiful, and that should be preferred to those with only single flowers, of which a few should be planted for the sake of variety : they are all equally hardy, and are seldom injured by frost, except in very severe winters, when sometimes the very tender shoots are killed ; but if these be cut off in the spring, the stems will put out new shoots.

3. Clematis Viorna; Leathery flowered Virgin's Bourz-Leaves compound and decompound, some of the leaflets trifid; stems many, slender, samentose, round, striated, prostrate, or climbing—Native of Carolina and Virginia. It Bowers from June to September, and if the autumn prove warm the seeds will ripen. This, as well as the fourth and fifth species, is a very hardy plant, and having climbing branches, may be disposed in the same manner as the first and second species: they are also propagated by layers, which will succeed, if performed at the same time, and in the same manner, as is directed for them.

4. Clematis Cripa : Curied Virgin's Bover. Leaves simple and ternate : leaflets entire, and three-lobed. This has weak stalks which rise nearly four feet high, and by their claspers fasten themselves to neighbouring plants: the corolla is purple, the inside curied, and has many longitudinal forrows: the flowers appear in July, and the seeds ripen in September.—Native ofFlorida and Japan. See the third species.

5. Clematis Oriental'i; Oriental Virgie's Bower. Leaves compound; leaffets gashed, angular-lobed, wedge-form; petals villose on the inside. This also has weak climbing stalks itsing to the height of seven or eight feet when supported; lowers drooping; petals bent beck, finally flat, villose within, of a yellowish green colour, with a tinge of russet on the upper part or outside; staming a collected into an oblong

purple head, with oblong purple antheræ, yellow at the edge. —It flowers from July to October, and was discovered by Tournefort in the Levant. See the third species.

6. Clematis Virginiam; *Firginian Virginis Boure*. Leaved ; compond ; leaflets orate, serrate ; pedindes two-leaved ; corolla spreading, six-petalled ; leaves ternate ; leaflets condate-ovate, creante-geshed ; peduncles brenching, trichouous ; flowers yellowish, diaccous.—Native of New Zealand, and of North America, Japan, and Cochine-china.

7. Clematis Hexapetala. Leaves compound; leafies vorte, serrate; peduncles two-leaved; corolla spreading, sixpetalled; stems clinubing very high; leaves ternate; corolla white, spreading; tomentose beneath; petalis ovate, oblang, not tanceolate, spreading; stamina and pistils yellowish white. ---It flowers from June till August.

 Clematis Florida; Large-flowered Virgin's Bower. Leaves decompound; leafiets binate and ternate; petals ovate; stem striated, purple, smooth; corolla large, handsome, spreading; petals acuminate, yellowish; stamina une equal, purplish.—It flowers most part of the year, and is a native of Japan.

 Clematis Japonica; Japan Virgir's Bower. Leaves ternate: leaflets elliptic, ovate, serrate; flowers cylindric; stem filtform, striated, purple, villose; petiole capillary, loose; flowers from the joints, peduncled, solitary, purple. —Native of Japan.

10. Clematis Diœca; Trifoliate Virgin's Bower, or Climber. Leaves ternate, quite entire; flowers diæcous. This shrub climbs as high as twenty feet, by means of the twisted petioles; flowers in axillary racemes, conjugate, leafy, dividing first into three, then into two smaller branches, sweet-scented .- Native of North America. Both this and the seventeenth species, which are natives of the warmest part of America, are unable to endure the open air in this country. unless they are preserved in stoves; but as they are great ramblers, and not remarkable for beauty, they are seldom preserved in Europe, except for the sake of variety in botanic gardens : they may be propagated by layers in the same manner as the other sorts, or may be raised from the seeds imported from the country where they naturally grow, but must receive the same treatment as other exotic plants from that country.

11. Clematis Vitalba; Common Virgin's Bouer, Wild Climber, or Traveller's Joy. Leaves pinnate; leaflets cordate, climbing. There is little beauty in this sort.—Native of North America. Both this and the twelfth species may be propagated either by seeds or by laying down their branches.

12. Clematis Flammula; Sweet-scented Virgin's Bower. Lower leaves pinnate, lacinate, upper simple, quite entire, lanceolate. This is rather creeping than climbing : it flowers from July to October .- Native of the south of France, Italy, and the Grisons. See the eleventh species. There is a variety, which, as well as most of the other species, is acrid, corrosive, and inflames the skin; whence it derives the name flammula. It is recommended by Baron Stoerck in inveterate syphilitic diseases, in ulcers, cancers, and severe head-aches: it acts as a diuretic or diaphoretic, and rests its character wholly upon Baron Stoerck's authority : he used an extract of the leaves ; but he chiefly recommends an infusion of them fresh, two or three drachms to a pint of boiling water, four ounces to be taken three times a day, whilst the powdered leaves are applied as an escharotic to the ulcers. It may also be employed to raise blisters, where cantharides cannot be obtained.

* Erect.

13. Clematis Maritima. Leaves pinnate, linear; stems
simple, hexagonal. Perennial: leaves opposite .-- Found

near Montpellier, Nice, and Venice. 14. Clematis Recta; Upright Virgin's Bower. Leaves pinnate; leaflets ovate, lanceolate, quite entire; stem erect; flowers four and five-petalled. Perennial: stems herbaceous, annual, round, scarcely branched, from three to five feet high, firm, ending in a panicle at top ; petals white, oblong, four in number, obtuse, somewhat villose, a little longer than the stamina. The flowers come out in June, and the seeds ripen in September .- Native of France, Switzerland, Silesia, Austria, Carniola, Hungary, and Tartary. Both this and the fifteenth sorts have perennial roots, which multiply pretty fast, but their stalks die down every autumn, and new ones arise in the spring : they are propagated either by seeds or by parting their roots, but the latter is generally preferred. The best season for parting these roots is in October or February, either just before their branches decay, or before they rise again in the spring : they will grow almost in any soil or situation; but if the soil be very dry, they should always be new planted in the autumn, otherwise their flowers will not he so strong; but if the soil be wet, it is better to defer it until the spring: the roots may be cut through their crowns with a sharp knife, observing to preserve to every offset some good buds or eyes, and then it matters not how small you divide them, for their roots increase very fast; but if they be parted very small, it will be three or four years before they will be fit to be again removed, for their flowers cannot become strong, and their roots multiplied in eyes, in less time. These plants are extremely hardy, enduring the cold of our severest winters in the open air. They are very proper ornaments for large gardens, either to be planted in extensive borders, or intermixed with other hardy flowers in the quarters of flowering shrubs, where, by being placed promiscuously in little open places, they fill up small vacancies agreeably enough. They begin to flower about the beginning of June, and often continue to produce fresh flowers until August, which renders them valuable, especially since they require very little care in the culture, for their roots may be suffered to remain several years undisturbed, unless they are wanted for parting, without the smallest prejudice to them.

15. Clematis Integrifolia ; Entire-leaved Virgin's Bower, or Hungarian Climber. Leaves simple, ovate-lanceolate ; flowers drooping, perennial; stems several, annual, a foot and half high or more, striated, erect, a little fistulose, somewhat pubescent at top, terminated by a nodding flower, and sometimes branched in the upper axils ; pedancles erect, pubescent, sustaining one elegant scentless flower; petals large, lanceolate, blue-nerved, acute, waved, thick, spreading very much; filamenta very pale yellow, villose all over, and twice as long as the petals .- Native of Germany, Austria, Carniola, and Hungary. It flowers in July, or from June till August, and is not uncommon in the nurseries about London. See the preceding species.

Climbing.

16. Clematis Calycina ; Minorca Virgin's Bower. Calycine involucre approximating ; leaves ternate, the intermediate one three-parted : stem smooth, striated .- It flowers in February, and is a native of Minorca

17. Clematis Americana ; South American Virgin's Bower, or Climber. Leaves ternate ; leaflets cordate-acuminate, quite entire; flowers corymbed. It has strong climbing stalks, which fasten themselves by their claspers to the neighbouring trees, whereby they are supported, and rise to the height of twenty feet or more; at each joint are trifoliate leaves, heartshaped, pointed, and entire .- Native of Campeachy. See the tenth species.

18. Clematis Chinensis; Chinese Virgin's Bower. Leaves quinate, pinnate; leaflets lanceolate; stems four-cornered, weak, so as to want support, scarcely climbing; flowers small; petals linear-lanceolate, dark purple, the inner edge painted with a tomentose line; tail of the seeds scarcely shorter than the antheræ .--- Native of China.

CLE

19. Clematis Ochrolcuca ; Yellow-flowered Virgin's Bower. Leaves simple, ovate, pubescent, quite entire ; flowers erect. This is a low unbranched plant; stem pubescent; leaves opposite, sessile, strongly nerved; flower single, terminating, pale yellow .- Native of North America. It flowers in June and July.

20. Clematis Trifolia. Leaves ternate ; leaflets oyate, serrate; serratures mucronate; peduncles three-flowered; branches striated, smooth; seeds purple, villose, with a long plumose tail .- Native of the Isle of Bourbon.

21. Clematis Minon. Leaves quinate; leaflets conical. three-nerved; peduncles very long; stem suffruticose, round, slender, not very long, scandent, branched; flowers white, axillary, several together; petals oblong, striated; stamina about forty, unequal; styles four, hairy, a little longer than the corolla .--- Native of the suburbs of Canton in China.

Cleome ; a genus of the class Tetradynamia, order Siliquosa .- GENERIC CHARACTER. Calix: perianth fourleaved, very small, spreading, the lower leaflet gaping more than the rest, deciduous. Corolla: four-petalled, all the petals ascending, spreading, the intermediate ones smaller than the others; nectareous glands three, roundish, one at each division, except one at the calix. Stamina: filamenta six (sometimes twelve or twenty-four,) subulate, declining. Pistil: style simple; germen oblong, declining, the length of the stamina; stigmas thickish, rising. Pericarp : silique long, cylindric, placed on the style, one-celled, two-valved ; Seeds : very many, roundish. ESSENTIAL CHARACTER. Nectareous glands three, at each sinus of the calix except the lowest; petals all ascending; silique one-celled, twovalved .- Most of these plants are natives of very warm countries, and will not thrive in England without artificial heat. Their seeds must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be planted in separate small pots, filled with fresh light earth, and plunged into a fresh hot-bed, observing to shade them until they have taken fresh root; after which they should have air admitted to them every day, in proportion to the warmth of the season, and their waterings should be frequently repeated, but not given in too great plenty. When the plants have filled the small pots with their roots, they should be put into larger, and plunged again into a hotbed to bring them forward; and in July, when they are too tall to remain longer in the hot-bed, they should be removed into an airy glass-case, where they may enjoy the free air in warm weather, and be screened from cold and wet; they will soon after flower, and perfect their seeds in autumn .----- The species are,

1. Cleome Fruticosa; Shrubby Cleome, Flowers gynandrous, four-stamined ; leaves simple ; stem shrubby, round, frutescent; racemes terminating, simple .- Native of India.

2. Cleome Heptaphylla; Seven-leaved Cleome. Flowers gynandrous; leaves with about seven leaflets; stem prickly, herbaceous, from three to five feet high, branched, upright, angular, angular grooved; branches subdivided, spreading, grooved, hirsute, viscid, prickly; flowers terminating in long loose spikes .- It is an annual, flowering in June and July, growing plentifully in Jamaica, and also supposed to be a native of the East Indies.

3. Cloome Pentaphylla; Five-leaved Cleome. Flowers gy-

nandrous; leaves ternate; stem unarmed. This is an annual, elegant, but fetid plant, upright, either wholly smooth, or with a few hairs at bottom; the stem round and branching; the germen is placed on a long, slender, purple pedicel, round which are six stamina, of the same colour, and equal.—It flowers in June and July, and is a native of both Indies. 4. Cleome Triphylla; *Three-leaved Cleome*. Flowers gy-

CLE

4. Cleome Triphylla; Three-tared Cleome. Flowers gynandrous; leaves ternate; stem unarmed. Au annual plant, rising two feet high, sending out many side-branches, with leaves having one large spear-shaped lobe in the middle, and two very small ones on the side; these sit close to the branches, from which the flowers come out singly upon long peduncles; they have four large fiesh-coloured petals, and sis stamina, which stand out beyond the petals.—Native of Jamaica.

5. Cleome Juncca; Rushy Chome. Leafless; flowers gymandrous, eight-stamined; corrynks lateral; genitals clongated; silique linear, tomentose; stem shrubby; stem from a foot to two feet in height, hardly the thickness of a goosequill; branches rigid, like spines, commonly ending sharply, greenish, round, spreading; smoothish; corolla none, unless the calix be regarded as such.—Native of the Cape of Good Houe.

6. Cleome Polyzama. Upper flowers four-stannined, male; leaves ternate; leaftes sessible, somewhat prickly on the edge; stem erect, somewhat glossy, and a little branched. It seldom rises above twenty or twenty-five inches.—Native of moist bottoms in Jamaica. If the seeds be sown in autumn, the plants will flower in June, and their seeds will ripen in July; so that unless the season n porting do not flower in July; so that unless the season prove favourable, the seeds will not ripen. If the seed be permitted to scatter, they will come up without care, and require only to be thinned and kept clean from weeds, for they will not bear transplanting.

7. Cleome Chelidonii. Flowers many-stamined; leaflets in fives or sevens, wedge-form, rugged; racenes terminating; siliques filiform; leaves on long petioles, digitate; corolla red; stamina yellow; seeds hispid.—Found in the East Indies.

8: Cleome Felina. Flowers many-stamined, asillary, solitary, peduacled; leaves ternate, wedge-form, strigose; sliques linear, compressed. The whole herb, together with the calix, is strigose; leaves subretuse; corolla angular, small, red; siliques slord, smooth.—Found by Konig in Ceylon. The leaves are singular, being hispid; the hars very much diated at the base, very stift, pressed close to the leaves, pointing towards the extremity, so as exactly to resemble a cat's tonque.—Found in Ceylon by Konig.

 Cleome Icosandra. Flowers icosi-tetraudrous; leaves quinate; stem herbaceous, annual, two feet high, erect, round, unarmed, striated, viscid, hairy; branches ascending; petiole long,—Native of the East Indies, and Cochin-china.

10. Cleome Viscosa; Viscid Cleome. Flowers twelvestamined; leaves quinate and terminate; stem erect, a foot high, simple, round, striated, villose, viscid, (often red.) leaves alternate, viscid, villose; petiole an inch long; leaffets unequal, subrhomboid, quite entire, nerved underneath; flowers axillary, peduncled at the top of the plant; petals yellow, lanceolate, ovate, from erect spreading, and sometimes revoulte, equal, two more distant than the others; stamina eight or nine to thirteen, from the receptacle, not from the germen, unequal.—Annual: native of Ccylon.

11. Cleome Dodecandra; Trecle-stamined Cleome. Flowers twelve-stamined; leaves ternate; stem and siliques viscid, pubescent; petals white, emarginate; stamina ten to fourteen; siliques sessile, erect, fusiform, somewhat inflated.— Annual: native of both Indies.

12. Cleome Gigantea; Gigantic Cleome, Flowers sixstamined; Leaves in sevens; stem unarmed; stem two and even four vards in height, round, pubescent, erect, evergreen; branches few, irregular with scars; petioles longer than the leaves; racemest terminating, crect, stiff, two feet in length; pedicels remote, standing out, glutinous, longer than the flower, without bractes. This beautiful plant has a very burning taste and stinking smell.—Native of South America.

13. Cleome Aculeata; Prickly Cleome. Flowers sixstamined; leaves ternale, quite entire; stipules spinescent; stem herbaceous; stipules in pairs, very short, recurved; flowers solitary, peduncled, small.—Observed by Zæga in America.

14. Cleome Spinosa; Thorny Cleome. Flowers sistais mined; leaves in sevens and fives; stem thorny, herbaceous; root anuual; flowers large, while, on solitary one-flowered pedancles, longer than the bractes; leaffets of the calix lanceolate, linear, concave; petals oblong, entire, with elongated claws, and a roundish ghand at the base of each; filamenta six, nanequally inserted into the receptacle, almost of the same length, spreading, filform, three times the length of the corolla, purple; antherea erect, long, two-celled, yellow; germen pedicelled, round, curved; style none; seeds oblong.—Native of the West Indics.

15. Cleome Serrata; Serrate-leared Chome. Flowers six, stamined; leaves ternate; leaftes linear-lanceolate, serrate. An annual upright plant, two feet in height; racemes loose, simple, terminating; corolla white; stamina tetradynamous, --Native of the moist woods of Carthagena in South America.

16. Cleome Ornithopodioides; Bird's-foot Cleome, Flowers six-stamined; leaves ternate; leafles oral, lanceolate; stem round, straight, from a foot to two feet in height, pale green, with slort, stiffish, rough hairs; leaves strong-smelling, on a rough petiole, half an inch in length; leaflets commonly beat back, of a pale glaucous luce on both sides; smooth in appearance, but roughish to the touch, having numerous short hairs along the edge, scarcely perceptible, except in the younger leaves.—Annual; flowering in June and July. Native of the Levant.

17. Cleome Violacea; Violet-coloured Cleome. Flowers six-staminel; leaves ternate and solitary; leaftets lanceolatelinear, quite entire. This is a visici and pubescent plant; the leaftets nearly equal; the floral-leaves simple; the peduncles even; the calix yellow, with purplish tips; the two upper petals dark purple, with yellow dots; the two lateral cordate, unguiculate, cremate, concolor.—Annual; flowers in June and July. Native of Portugal.

18. Cleome Arabica. Flowers six-stamined; leaves ternate, lanceolate, obtuse; siliques fusiform, viscid, scabrous. Viscid and scabrous, two feet high, and annual; floral-leaves simple; petals yellow, with purple tips; seeds hirsute.—Native of Arabia.

 Cieome Monophylla. Flowers six-stamined; leaves ternate, lanceolate, obtuse; siliques fusiform, viscid, scabrous; stalk herbaceous, a foot and half high; corolla yellow; peduncles axillary, solitary, one-flowered.—Annual.

20. Cleome Capensis. Flowers six-stamined; leaves simple, sessile, linear-lanceolate; stem angular, simple, stiff, and upright.—Native of India, and the Cape of Good Hope.

21. Cleome Procumbens. Flowers six-stamined; leaves simple, lanceolate, petioled; stems procumbent, herbaceous, six inches high, suffrutescent, branched, smooth; flowers axillary, peduncled, solitary; peduncles longer than the petioles, on-flowered, purple; corolla yellow, turning to orange or red.-It flowers in November, and is a native of dry sands in Jamaica and Hispanjola.

22. Cleome Tenella. Flowers six-stamined; leaves termate, filiform, linear, a span high, branching, erect; leaflets sessile, the length of the petals; siliques linear; corolla yellow. —Annual: found by Konig, in abundance, in dry sandy soil in the East Indies.

23. Cleone Filifolia. Flowers six-stamined; leaves lower septemate, upper ternate; stem erect, weak, herbaceous, a foot high, branched, striated towards the top, dotted, with raised minute scattered dots; petioles shorter than the leaves.

Georie: a genus of the class Didynamia, order Gymnopermia.-GENERIC CHAACTER. Cali: perimith oueleafed, tubular, angular, two-lipped, upper lip fattish, broad, three-toothed, lower two-parted, short. Carolla: one-petalled, ringent; upper-lip straight, bifd, keeled, lower trifd; the middle segments two-lobed, the side ones spreading. Stamina: filamenta four, forked at the end, the two lower longest. Antheræ sitting on the outer apex of the filamenta, crossed in pairs. Pistiti: germen four-parted. Style: filiform, the length of the stamma; stigmas four, setaceous, equal. Pericarp: none. Calis: closed with hairs; seeds four, nearly columnar, smooth. ESSENTAL CHARACTER. Filamenta: forked, with an anthera at one of the tips; stigma four-cleft.-----The only known species is,

1. Cleonia Lusianica; Sizeet-scaled Cleonia. Stem erect, brachiste, in the lower part hairy; upper lip of the corolla erect, the segments reflected at the end; lower obcordate, complicate, spreading, gibbous on the upper side of the base; all the filamenta thorny; antheræ crested at the back; seeds roundish, turgidly leus-shaped, macroate at the base. They should be sown in the autama, and the plants will come up may be removed to a border, where they will flower and produce seeds. They do not occupy much room, and re quire fittle culture, and when sown in the spring, frequently lie a whole yeagetate.

Clerodendrum; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth one-leafed, five parted, bell-shaped; segments ovate, acute, broader than the tube of the corolla, permanent. Corolla: one-petalled, irregular; tube slender, long; border fiveparted, equal, the upper segments more deeply separated. Stamina : filamenta four, filiform, much longer than the corolla, ascending through the upper fissure of the corolla, two of them shorter. Antheræ simple. Pistil : germen roundish ; style form, length, and situation of the stamina ; stigma simple, bifid. Pericarp: drupe roundish, placed on a large calix. Seed: one, roundish. ESSENTIAL CHARACTER. Calix: five-cleft, bell-shaped. Corolla: with a filiform tube. and a funnel-shaped, five-parted, equal border. Stamina: very long, gaping very much between the segments. Berry : one-seeded .---- The species are,

 Clerodendrum Infortunatum. Leaves cordate, tomentose. This is a tree, or rather shruh, with subtomentose branches; leaves opposite, acute, veined, somewhat scubrous, arge, quite entire; petioles the length of the leaves; border of the corolla short; segments obvate; anthera oblong; sigma bifd. – Loureiro describes it a supright, seven feet high, with quadrangular four-growed branches; flowers in avast terminating racemed corymb; the peduncle, and all the parts of the flower, are of a bright scattet colour. Native of the East Indies, and China.

2. Clerodendrum Fortunatum; Entire-leaved Clerodendrum. Leaves lanceolate, quite entire. This is a hoary shrub; calices spreading.—Native of the East Indies. 28. 3. Clerodendrum Philomidis. Leaves ovate, toothed, and angular; peduncles axillary, subtriflorous.—This is a hoary shrub. Found by Konig in the East Indies.

 Clerodendrum Calamitosum. Leaves oval, somewhat toothed, naked; leaves opposite, petioled; panicle brachiate. —Observed by Baster, in Java.

5. Clerodendrinm Paniculatum. Leaves five-lobed, toothletted, smooth; panicle brachiate; a vils woolly; branches quadrangular, smooth, purple, with a groove along the sides; calix smooth, with lanceolate segments; corolla au inch over; tube filiform; segments of the border oblong.

7. Clerodendrum Squamatum, Leaves cordate, obscurely angular; branches of the panicle dichtomous, smooth; panicle terminating, spreading, smooth; peduncles thrice dichomous; pedicies not racened, but a one-flowered pedicel in each division; leaflets of the calix ovate, acute, coloured, smooth.—Native of the East Indies.

8. Clerodendrum Diversifolium. Leaves entire, and three-lobed, ovate; branches of the panicle dichotomous, villose; pedicels racemed; panicle terminating, half a foot long; partial peduacles opposite, spreading, twice or thrice dichotonous; flowers pediceiled, alternate, distant; tube of the corolla pubescent, an inch long; upper bifd, with erect linear segments, the lower three-lobed, spreading very much; the lobes oblong, the side ones shorter; the lobes of the corolla are scancely equal.—Native of the East Indies.

Clettra; a genus of the class Decandria, order Monogynia, -GENERIC CHARACTER. Calir: perianth one-leafed, fivepetals five, oblong, broader on the outside, from erect spreading; a little longer than the calis, the upper one broadest, Stamina: filamenta ten, subulate, the length of the corolla. Anthere oblong, erect, gapting at the top. *Pisiti*: germen roundish; style filform, erect, permanent, increasing; stigma trifid. *Pericarp*: capsule roundish, involved in the calix, three-celled, three-valved. *Scels*: very many, angular. Es-SNENTAL CHARACTER. Calis: five parted. *Petals*: five, Strgma: trifid. *Capsule*: three-celled, three-valved. — The species are,

1. Clethra Ahuifolia; Alder-kared Chehra. Shrubby: leaves oborate, hanceolate, scratte, smooth; racenes simple, in form of spikes; the roots spread far on every side, and send up many stems, from eight or ten to fourteen feet high, which are covered with a grayish bark, and divide into small round alternate branches; the flowers are on loose spikes, from four or five inches to a span long; the petals are white, ---Native of moist places by rivulets in NORTh America.

2. Clethra Paniculata; *Panicled Clethra*. Shrubby: leaves lanceolate, naked on both sides; flowers panicled.—It flowers from August to October, and is a native of North America.

3. Clethra Arborea; Tree Clethra. A tree: leaves oblong-lanceolate, smooth on both sides; racemes in form of spikes; calices obtuse.--Native of Madeira.

4. Clethra Tenuifolia. A tree : leaves oblong, lanceolate, quite entire, hoary underneath; racemes panicled, spikeshaped, tomentose .- It generally rises to the height of twelve or fourteen feet, with a thick trunk, covered with a smooth clay-coloured bark ; each flower is on a pedicel, with a subulate bracte at the base; fruit smooth, green, roundish, bigger than peas, containing a sweet white mealy pulp, and a hard brownish-black stoue, larger than a pepper-corn, and much like it ; they are sometimes eaten in Jamaica, of which island it is a native. Sloane calls it the bastard locust-tree; it is sufficiently hardy to endure the open air of our climate, and at the season of its flowering is a most beantiful shrub it will commonly flower here by the beginning of July; and if the season be not very hot, there will be part of the spikes in beauty till the beginning of August; and as most of the branches are terminated by these spikes of flowers, they make an elegant appearance when the shrubs are strong. They will thrive much better in moist than in dry ground. and require a sheltered situation, to defend them from strong winds, which frequently break off the branches, where they are too much exposed to their violence. It is propagated by layers, but they are generally two years before they get root, so that it is now rare in England. They may also be propagated by suckers, sent out from their roots; these should be taken off carefully, together with fibres, in the autumn, and planted in a nursery-bed, whence, at the end of two years, they may be transplanted wherever they may be intended to remain. It may also be propagated by seeds imported from its native country, for they are never produced in Great Britain; but as the seeds seldom arrive here till spring, when they are sown in that season, the plants will not come up till the following spring; therefore the seeds should be sown in pots, and placed in a shady situation till autumn. and then under a frame during winter: the plants will come up in the following spring, and may be transplanted to a nursery-bed in autumn, to acquire strength, before they are finally removed to the spot where they are to remain.

Clevers. See Gallium Aparine.

Clibadium ; a genus of the class Monœcia, order Pentandria .- GENERIC CHARACTER. Calix: common, imbricate; scales ovate, acute. Corolla: compound; corollules tubular, funnel-form; border five-cleft, Corollules; of the disk many, pedicelled; hermaphrodite of the ray three or four, sessile, female. Stamina, in the hermaphrodites: germen very small, superior; style filiform; stigma simple; in the females, germen roundish, inferior; style filiform; stigma two-parted. Pericarp: common, none. Calix: ventricose, coloured; proper to the hermaphrodites none; to the females a roundish, succulent, umbilicate drupe. Seed : one, cordate, compressed. ESSENTIAL CHARACTER. Male: common calix imbricate; corolla of the disk five-cleft. Female; common, calix the same. Corolla : of the ray female, three or four. Seed : an umbilicate drupe .---- The only known species is,

 Clibadium Surinamense. Leaves opposite, petioled, ovate, acuminate, acutely crenate, scabrous; peduncles opposite; common calix violet-coloured when ripe; corolla white; drupe green, with a yellow visoid juice.—Native of Surinam.

C(d) portia; a genus of the class Direcia, order Polyandria, -G EXERIC CLABACTER. Malc. Caliz: periant threeand anting that season should have little wate leaved; leakels ovate, acnte, coriaceous, spreading, deciduous. Corolar zone. Stamina: filamenta about littly, capilary, creet, the length of the calix. A uthera: twin, oblong, for the rains of that season might endanger th obluse, etcel, compressed. Female. Caliz: perianth threelawe only the male plants in Europe, and it leaved, equal, erct, superior, permanent; leadels accuted, provpagete. Native of the Cape of Good Hope.

lanceolate. Corolla: none. Pisitl: germen oblong, infetior; styles: two, filiform, long, plumose; stigmas simple, Pericary: capsule oblong, ucarly columnar, two-celled, crowned with the calix; seeds solitary, nearly columnar, linear. Essentrial CHARACTER. Male. Calix: threeleaved, superior. Stamina: about thirty. Fennets. Calix: three-leaved, superior. Corolla: none; styles two; capsules two-celled. Sted : one.—This genus consists of shrubs from the Cape of Good Hope. Leaves simple or ternate, sheathing at the base; flowers axillary, subsessile.——The species are.

*. With simple Leaves.

1. Cliffortia Odorata. Leaves ovate, serrate, ribbed, villose underneath. This is an erect shrub, three feet high, little branching.—Native of the Cape of Good Hope.

2. Cliffortia Ilicifolia ; Ilex-leaved Cliffortia. Leaves subcordate, toothed. This is a shrub with alternate declining branches, clothed with truncated membranes and stipules; leaves alternate, sheathing very shortly at the base; stem weak, four or five feet high; leaves gravish; flowers lateral, axillary, sessile, solitary, green ; filamenta white ; antheræ yellow; the flowers appear in June, July, and August, but the leaves continue in verdure throughout the year. All the plants of this and of the following species, now in European gardens, are males. It is easily propagated by euttings, which may be planted in any of the summer months; if these be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, they will soon take root, provided they be screened from the sun and duly watered : they must be gradually inured to bear the open air when they have taken root, or they will be drawn up weak; they should therefore he placed abroad till they have acquired some strength, and may afterwards be each transplanted into a separate small pot, and placed in the shade until they have taken fresh root, after which they may be planted with other hardy exoties in a sheltered situation till October, when they should be removed into the greenhouse, or placed under a common hot-bed frame, where they may be screened from the hard frost, but enjoy the free air at all times when the weather is mild. The stems and branches will require support as the plants advance in height, or they will trail upon the ground ; they must be placed in the open air, with myrtles and other hardy green house plants; and in winter the plants may be treated in the same manner as those, but must not have much water. It has en-. dured the cold of our ordinary winters, when planted near a south-west wall without covering, but in severe winters it is always destroyed.

3. Cliffortia Ruscifolia; Butcher's-Broom-leaved Cliffortia. Leaves lanceolate, quite entire ; branches alternate, frequent, ascending, below ash-coloured, smooth above, brown, tomentose; branchlets alternate, very frequent, short, covered with lanceolate, acuminate, imbricate scales, in other respects naked, except at the end, where they are leafy; spikes of flowers roundish at the ends of the branchlets, intrenched in leaves; bractes smaller than the leaves, involving each flower, trifid, hirsute on the outside, spiny, with a sharp, membranaceous, hairy leaflet, near the base on each side .-This is not so hardy as the preceding species, which see; it should therefore be planted in a warm green-house in winter, and during that season should have little water; it may be exposed to the open air, in a sheltered situation during summer, but should not remain abroad too late in autumn, for the rains of that season might endanger the plants: we have only the male plants in Europe, and it is difficult to

326

4. Cliffortia Ferruginea. Leaves lanceolate, setaceous, serrate: the stems are like those of knotgrass, filiform, usually prostrate, even-branching; branches short, ferruginous, herbaceous ; flowers axillary, sessile, trifid .--- Found by Sparmann at the Cape of Good Hope.

5. Cliffortia Graminea. Leaves ensiform, serrulate; petioles dilated, terminated by two stipule-shaped awns ; stems many together, two feet high, scarcely branching, striated, covered with leaves which are approximating, erect, convolute, smooth, striated, acute; petioles connected with the leaves by a joint; the edges elongated into subulate erect divisions .- Native of the Cape of Good Hope.

6. Cliffortia Filifolia. Leaves filiform, triquetrous, smooth, quite entire : branches naked, upright, alternate, gray, pubescent, round .- Native of the Cape of Good Hope.

** With compound Leares.

7. Cliffortia Crenata. Leaves binate, orbiculate, crenulate, An erect shrub, rather large; flowers axillary, solitary, trifid. -Native of the Cape of Good Hope.

8. Cliffortia Pulchella. Leaves binate, orbiculate, quite entire; leaves converging, and guarding the flowers in the cavity which they form, beautifully adorned on the outside with radiating nerves .- Native of the Cape of Good Hope.

9. Cliffortia Trifoliata. Leaves ternate, the middle threetoothed; stems slender, woody, procumbent, silky with hairs, and sending out slender branches on every side ; flowers axillary, on very short peduncles, shaped like those of the second species, but smaller : they appear in July and August .-- Native of the Cape of Good Hope. It requires the same management as the second species, and is equally hardy, but must be sparingly watered in winter, as much water will destroy the roots by causing them to rot. As there are only male plants in Europe, it can only be propagated by layers, and these are two years before they take root; the leaves continue green all the year, and being singularly shaped, make a good variety in the green-house during winter.

10. Cliffortia Sarmentosa. Leaves teruate, linear, villose; stem shrubby, samentose, filiform, four feet high, irregular; branches alternate, short, simple, round, pubescent; flowers lateral, axillary, sessile, solitary, white .- Native of the Cape of Good Hope.

11. Cliffortia Strobilifera. Leaves ternate, linear, acute, even. A shrub with round branches, sparingly branched; stipules sheathing, scariose, subovate, having two teeth, smooth, permanent; leaves sessile, carinated or keeled, on a very short sheathing petiole .- It is a native of the Cape of Good Hope.

12. Cliffortia Obcordata. Leaves ternate; leaflets roundish, the middle one obcordate. An erect lowly shrnb, with distich branches; leaves sessile, obovate, nervelcss, very obtuse, quite entire, smooth; flowers in the axils of the leaves sessile, not longer than the leaves, which are often in pairs. -Native of the Cape of Good Hope.

13. Cliffortia Ternata. Leaves ternate ; leaflets entire, bairy .-- A shrub with small, ovate, lanceolate, hairy leaves, very different from the rest of the genus .- Native of the Cape of Good Hope.

14. Cliffortia Juniperina. Leaves ternate, triquetrous, subulate, crowded. A shrub resembling juniper, erect, three feet in height, branching very much; flowers axillary, sessile. -Observed by Sparmann, at the Cape of Good Hope.

15. Cliffortia Falcata, Leaves ternate, linear, falcated, smooth. A shrub a foot in height, erect, branching, strict; leaves often three from each bud ; leaflets sharpish, incurved. -Native of the Cape of Good Hope.

16. Cliffortia Teretifolia, Leaves fascicled, columnar,

subulate, incurved, smooth, entire .- Native of the Cape of Good Hope.

17. Cliffortia Ericæfolia. Leaves fascicled, columnar, furrowed, smooth --- Native of the Cape of Good Hope, Climber. See Clematis.

Clinopodium ; a genus of the class Didynamia, order Gymnospermia .- GENERIC CHARACTER. Calix: involucre many-bristled, length of the perianth, placed beneath the whorl. Perianth: one-leafed, cylindric, very slightly incurved, with a two-lipped mouth, upper lip wider, trifid, acute, reflected; lower lip divided, slender, inflected. Corolla: one-petalled, ringent; tube short, gradually widened into the throat ; upper lip crect, concave, obtuse, emarginate; lower lip trifid, obtuse; middle segments wider, emarginate. Stamina : filamenta four, under the upper lip of which two are shorter than the others. Antheræ roundish. Pistil: germen four-parted; style filiform, the same situation and length with the stamina; stigma simple, acute, compressed. Pericarp: none; calix contracted round the neck, gibbous round the body, containing the seeds. Seeds: four, ovate. ESSENTIAL CHARACTER. Involucre: many-bristled, under the whorl .- These plants may be propagated by seeds, and also by parting their roots; the latter is the mode generally adopted in England, because the foreign sorts do not perfect their seeds here. The best time to transplant and part their roots is in autumn, that they may strike root again before winter : if planted in a dry soil, they are all, except the third species, sufficiently hardy to thrive in the open air in England, and require no other care but to keep them clean from weeds, to fit them for transplanting and parting every other year .---- 'The species are.

1. Clinopodium Vulgare; Wild Basil. Heads roundish, hispid; bractes bristly; root perennial, fibrous, sending up several stiff square stalks a foot and a half high, from which come out a few lateral branches towards the top : the flowers come out in round whorls; one of these terminates the stalk. and there is generally another which surrounds the stalk immediately below it : the whorls grow very close, and each peduncle sustains several flowers, which are usually purple, but sometimes white, appearing in June : it is fond of a calcareous soil : the smell is slightly aromatic, and not unpleasant .- There are three varieties not worth inserting.

2. Clinopodium Iucanum; Hoary Clinopodium, Leaves tomentose underneath; whorls flatted; bractes lanceolate; root perennial ; stems about two feet high, putting out a few short side-branches towards the upper part; leaves oblong, oval, the size of those of water mint, opposite, sessile, soft to the touch, with a strong odour between that of marioram and basil, the upper surface pale green, the under hoary and woolly; the edges are slightly indented; flowers pale purple, the stamina standing out beyond the corolla; the bractes large, lanceolate, indented .- Native of North America, where in some parts it is called snake-weed, being accounted a remedy for the bite of the rattlesnake. It flowers in England in July.

3. Clinopodium Rugosum; Wrinkled Clinopodium, Leaves wrinkled; heads axillary, peduncled, flatted, radiated; root perennial : stems closely covered with brownish hairs, and between two and three feet high; leaves very unequal in size, serrate, rough on their upper side, hairy on the under: peduncles slender, hairy, about three feet long, sustaining small heads of flowers shaped like those of the scabious ; corolla white, smaller than that of the foregoing; bractes radiate : it flowers in September, but never ripens its seeds in England .- Native of Carolina. They must be planted in pots, and sheltered under a frame in winter, where the plants

frost, which they cannot endure in this country.

CLI

4. Clinopodium Capitatum. Leaves flat, smooth; heads axillary, peduncled; stems suffruticose, two or three feet high, from these in the spring arise herbaceous stems, which are quadrangular, roughish, two feet high, branched : leaves opposite, petioled, ovate, but with the base acute, veined, unequally serrate; acute, both sides appearing hairy with a magnifier, deep green; the lower ones wrinkled, the largest seven inches long ; corolla white, with a tinge of flesh-colour ; tube somewhat hairy on the outside, but the back of the helmet more so. The whole plant is inodorous .- Native of the West Indies.

5. Clinopodium Asiaticum. Leaves oblong, nerved, wrinkled, tomentose underneath; spike whorled, terminating; stem suffruticose, two feet and a half high, erect, quadrangular, four-furrowed, simple, villose ; flowers violet-coloured in interrupted whorls, forming an oblong spike, with sharp hirsute involucres .- Native of Cochin-china.

Clitoria; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix: perianth one-leafed, crect, tubular, five-toothed, permanent. Corolla : papilionaceous; standard very large, straight, emarginate, waved at the margin, spreading and overshadowing the other petals; wings oblong, straight, obtuse, shorter than the standard; keel shorter than the wings, falcated somewhat roundly; stamina in two-brotherhoods (simple and nine-cleft.) Antheræ simple. Pistil: germen oblong; style ascending; stigma obtuse. Pericarp: legume very long, linear, compressed, one-celled, two-valved, with the tip subulate. Seeds: many, reniform. ESSENTIAL CHARACTER. Corolla: inverted ; standard very large, spreading, overshadowing the wings .- The seeds of these plants should be sown upon a good hot-bed early in the spring, and when the plants are two inches high, they should be carefully taken up, and each planted in a small pot filled with light fresh earth, and plunged into a hot-bed of tanner's bark, observing to shade them until they have taken fresh root, and refresh them with water as they may require it : after they are well rooted in the pots, they must have air every day in proportion to the warmth of the season, to prevent their drawing up weak; their waterings should be repeated two or three times a week, but they should not have too much at each time : as these plants have climbing stalks, they will soon grow too tall to remain under common frames, therefore they must then be removed into the stove, and plunged into the bark-bed; but if their roots have filled the pots, they should then be removed into larger, and afterwards they must be treated in the same manner as other plants from their native countries,-The species are.

1. Clitoria Ternatea; Winged-leaved Clitoria. Leaves pinnate: it rises with a twining herbaceous stalk, to the height of four or five feet, in the same manner as the kidneybean, and requires the like support, for in the places where it grows naturally, it twists itself about the neighbouring plants ; the leaves are winged, composed of two or three pair of leaflets, terminated by an odd one: these are of a beautiful green colour, and are placed alternate on the stalks; from the appendages of the leaves come out the peduncles, each of which is encompassed by two very fine leaves about the middle, where they are bent, sustaining a very large gaping beautiful flower, the bottom part of which appears as if it grew to the top: the flowers have a green membranaceous calix ; the corolla is blue, and stains paper like Indigo, but the colour is not permanent.-Native of the East Indies and lition of the antheræ, including the germen. ESSENTIAL

may enjoy free air in mild weather, but be defended from another with blue flowers, very double, which is a singularity in the leguminous class of plants.

2. Clitoria Brasiliana; Brasilian Clitoria. Leaves ternate ; calices solitary, bell-form ; it has a twining stem, which rises five or six feet high, having at each joint one ternate leaf on a long petiole: the flowers come out singly from the axils, on long peduncles, encompassed about the middle with two small oval leaves; they are very large, of a fine blue colour, and make an elegant appearance in July .-- Native of Brasil. There is a variety with double flowers, which was imported from India.

3. Clitoria Virginiana; Small-flowered Clitoria. Leaves ternate; calices geminate, bell-form; stem herbaceous, filiform, subdivided, scandent and twining, round, striated, pubescent. Corolla: resupinate; standard blue, with oblique purple streaks, at the back part dusky and tomentose. This species being tender, and flowering with difficulty in our climate, the flowers frequently come out singly in our stoves ; which accounts for the difference between Mr. Miller's description and the Linnean character. Dillenius also observes, that the flowers were very apt to fall off .- Native of Virginia, Jamaica, and generally of the West Indies.

4. Clitoria Mariana; Maryland Clitoria. Leaves ternate; calices cylindric. The seeds of this species were imported from Carolina, where they grow naturally : it rises with a twining weak stalk about five feet high, having trifoliate leaves of a grayish colour on the under side; the flowers come out by pairs, and their calices are cylindric; the flowers are small, and of a pale blue colour within, but of a dirty white on the outside: it flowers in August, but seldom ripens any seed in England.

5. Clitoria Galactea; Milky Clitoria. Leaves ternate; raceme erect; flowers pendulous; perianth four-toothed, the upper and lower segment larger; it is covered with two very small deciduous bractes; racemes with two flowers or more. -Native of Jamaica, found chiefly in the lower hills: it is easily distinguished by its long reddish flowers, milky branches, and smooth leaves: it is a weakly climber, aud raises itself, by the help of the neighbouring bushes, to the height of eight or nine feet.

Clusia ; a genus of the class Polygamia, order Monœcia. GENERIC CHARACTER. Calix : perianth four, five, or six-leaved, imbricate; leaflets concave, permanent, the interior ones gradually smaller. Corolla ; petals four, five, or six, roundish, spreading, concave, large. Stamina : filamenta many, simple, shorter than the corolla; antheræ simple, growing to the side of the tip. *Pistil* : germen ovate, oblong ; style none ; stigma starred, flat, obtuse, permanent. Pericarp: capsule ovate, marked with furrows, celled, the valves bursting in a radiate manner. Seeds: numerous, ovate, covered with pulp, affixed to a columnar angulated receptacle. Observe. The number in the fruit differs from four to twelve, according to the proportion observed in the stigma, valves, cells, &c.: some of the flowers are sterile with respect to the male organs, and others with respect to the female; in the female-flowers a nectary is formed by the coa-Cochin-china. There is a variety with white flowers, and CHARACTER. Male. Calix: four or six-leaved; leaflets

16

CLU

opposite, imbricate. Corolla: four or six-petalled; stamina numerous. Female, Calix and Corolla as in the male. Nectary : formed by the coalition of the antheræ, including the germen; capsule five-celled, five-valved, stuffed with pulp .- This is a genus of trees, abounding in a tenacious glutinous juice; peduncles sometimes axillary, but commonly terminating, sustaining one, two, or three flowers on bracted nedicels. As the seeds seldom succeed in England, and the young plants grow so slowly as not to make any figure for some years, the best way is to procure these plants to be brought over from the West Indies in tubs : they are tender, and must be kept constantly in the stove, otherwise they will not live through the winter in England, in which season they must have very little water : they may be propagated by cuttings, which must be laid to dry for a fortnight or three weeks when they are cut off from the plants, that the wounded part may be healed over, otherwise they will rot. When the cuttings are planted, the pots should be plunged into a hotbed of tanner's bark, and now and then gently refreshed with water : Junc or July is the best time for planting these cuttings, that they may be well rooted before the cold weather comes on in autumn : they must be placed upon stands in the dry-stove in winter, but if in summer they be plunged into the tau-bed, they will make great progress, and their leaves will be large, in which the principal beauty of these plants consists .---- The species are,

1. Clusia Rosea; Rose-coloured Balsam Tree. Leaves veinless; corollas six-petalled; height from twenty to thirty feet; flowers large, rose-coloured, and very handsome, but without smcll ; fruit green, the size of a middling apple, with eight lines running like meridians on a globe, from the stalk to the crown of it : when the fruit becomes ripe, it opens at these lines, and divides into eight parts, disclosing many mucilaginous scarlet seeds, resembling those of a pomegranate ; the mucilage being washed off, the sceds appear white and hard, and contain a kernel; this fruit is found in the hollow furrows of an octagonal cove. The whole tree is exceedingly beautiful, and the structure of the fruit itself is a most exquisite piece of mechanism .- Native of the Bahama Islands, of St. Domingo, and also of other American islands between the tropics. It is found among rocks, and frequently upon the limbs and trunks of trees, occasioned by birds scattering or voiding the seeds, which being glutinons like those of misletoe, take root in the same manner; but the roots not finding sufficient nutriment, sprcad on the surface of the tree till they find a decayed hole or other lodgment, wherein is some small portion of soil: the fertility of this being exhausted, a root is discharged out of the hole till it reaches the ground, though at forty feet distance, where it again fixes itself and becomes a much larger tree. The resin it produces is used to cure sores in horses, and instead of tallow for paying the bottoms of boats, in order to accelerate their motion through the water.

2. Clusia Alba^{*}, White-flowered Balsem Tree. Leaves vehicles; corollas five-petialed; height thirty feet, an elegant tree, parasitical, or growing on other very large trees like the first species: the trunk is frequently a foot in diameter, and supports a spreading head. The whole abounds in a very tensious balsamic juice, of a green colour, but tarning to a brownish red when exposed to the air; leaves oborate, quite entire, obtase, shining, coriaccous, firm, marked with obliquely transverse parallel nerves, without any connecting veins, on short petioles, opposite, placed clicify at the extremities of the smaller brancher; peduncles short, thick, commonly three flowered and terminating: flowers inelegant and without scent, white, all hermaphrodite, but with the 28.

anthere more or less polliniferous; fruits when ripe scarlet; seeds white, involved in a scarlet pulp; the birds are very fond of them, and when the capsules burst open, lang over them upon the wing, and pluck out the seeds with the pulp althering, --Ir is common in the woods of Martinico, where it is called *aralte*. The Carlob used the juice of it for paying their boats.

3. Clusus Flora : Vellow-flowered Balowin Trac. Leaves vehicles : corrollas four-ptellade... — It is pretty common in the British islands of America, where the trees grow to the height of twenty feet, and shoot out many branches on every side, with thick, round, succulent leaves placed opposite: the flowers are produced at the ends of the branches, each having a thick succellat cover; they are of different colours in different plants, some being red, others yellow, some white, and some green. After the flowers are past, they are succeeded by oval fruit, which are also of different colours in different plants. According to Jacquin, wherever the trunk or larger branches are wounded, they throw out a thick resinous gun, which the inhabitants of Jamies assemtimes use as a vulnerary, although it has neither an extraordinary smell nor a purgent taste.

4. Clusia Venosa; Vein-Leaved Balaam Tree. Leaves veined. This tree rises to the height of twenty or thirty feet; it has very large oval spear-shaped leaves, ending in points, placed alternate on the brunches, and having several ribs, which go off from the uid-rib alternately, rising upward to the side of the leaves, and also a great number of small veins running horizontally between these ribs: the borders of the leaves are serrate, and their under surfaces of a brown colour; the branches are covered with a woolly down, and the flowers produced in loose spikes at the end of the shots. Jacquin describes the corolla as white, and an inch and a half in diameter.—Native of the mostare montainous woods of Martinico, where it is called paletawire demontagence.

5. Clusia Pedicillata. Leaves opposite, obovate, and elliptic, quite entire, veined; cymes axillary; flowers fourpetalled.—Native of New Caledonia.

6. Clusia Sessilis. Leaves opposite, obovate, and elliptic, quite entire, veined; flowers axillary, solitary, subsessile, four-petalled.—Native of Tongataboo.

Clutia. See Cluytia.

Chuytia; a genus of the class Diæcia, order Gynandria.-GENERIC CHARACTER. Male. Calix : perianth fiveleaved, size of the corolla; leaflets ovate, obtuse, concave, spreading. Corolla: petals five, spreading very much, cordatc; claws flat, shorter than the calix; nectaries exterior five, three-parted, oblong, spreading, length of the claws of the petals, placed in a circle within the petals; nectaries interior five, glandiform, small, melliferous at the tip. Stamina: filamenta five, placed on the middle of the style, remote from the corolla, spreading horizontally; antheræ roundish, versatile. Pistil: germen none; style cyliudric, truncate, very long, bearing the stamina on its middle. Female. Calix : perianth as in the male, permanent. Corolla: petals as in the male, permanent; nectaries exterior five, twin, roundish, of the same size and situation as in the male ; nectaries interior, none. Pistil: germen roundish; styles three, bifid, reflex, length of the corolla; stigmas obtuse. Pericarp: capsule globular, six-furrowed, rough, threecelled. Seeds : solitary, roundish, even, appendiculated at the tip. ESSENTIAL CHARACTER. Calix: five-leaved. Corolla: five-petalled. Female. Styles: three, Capsule: three-celled. Seed : one .- The species are.

1. Cluytia Alaternoides; Narrow-leaved Cluytia. Leaves subsessile, linear, lanceolate; flowers solitary, erect; stem shrubby, six or eight feet high, putting out many side-4 P

branches which grow erect: leaves of a grayish colour, and credit as an astringent, having employed it in hæmorrhages and entire. The flowers come out from the joints, at the setting on of the leaves, towards the upper part of the branches: they are small and of a greenish white, flourishing from June till August, but not remarkable for their beauty. Both this and the third species are easily propagated by cuttings during any of the summer months : the cuttings, if planted in small pots, and plunged into a very moderate hot-bed, shaded from the heat of the sun in the middle of the day, will soon take root, and should afterwards be inured to the open air, to prevent them from being drawn up weak; afterwards these plants may each be put into a separate pot, and placed in a sheltered situation till the middle of October, or later if the weather continue mild. They should afterwards be removed into the green house, and so placed that they may enjoy the free air in mild weather, for they do not require much warmth, but merely to be protected from frost; and if the green-house be too closely shut up, or the plants too much shaded by others, the tender shoots will grow mouldy. which destroys more of these plants than the cold : they must be placed abroad in summer among other hardy exotics, in a sheltered situation .- As these plants are always green, they look well in the green-house during the winter season; and in summer, when they are placed in the open air, make a pleasing contrast with the other exotics.

2. Cluytia Polygonoides. Leaves lanceolate ; flowers axillary, very many; flowers usually two together, pendulous, small .- Native of the Cape of Good Hope.

3. Cluytia Pulchella; Broad-leaved Chuytia, Leaves ovate, quite entire ; flowers lateral .- This rises about six or eight feet high, but has a stronger stem than the first species. See the first species.

4. Cluytia Hirta. Leaves wedge-shaped, smooth, flowers lateral, glomerate, hirsute. It is a very branching shrub : the flowers come out towards the ends of the branches and branchlets, and are subsessile ; petals oblong, minute, smooth, -Found at the Cape of Good Hope.

5. Cluvtia Tomentosa. Leaves elliptic, tomentose on both sides; a shrub three feet in height, very branching, erect, tubercled with the scars of fallen leaves; branches round, pubescent; flowers lateral, solitary, sessile, longer than the leaves, white; calix five-toothed, tomentose on the outside .-It flowers in May, and is a native of the sandy shores of the Cape of Good Hope.

6. Cluytia Retusa. Leaves oval, retuse: flowers racemed. axillary; leaves on short petioles; leaflets of the calix acute; petals very small, three-toothed ; no nectaries, but a ring surrounding the receptacle .- Native of the East Indies.

7. Cluytia Eluteria; Maritime Cluytia, or Sea-side Balsam. Leaves cordate-lanceolate. This is a tree with round branches. According to Miller, it rises with an upright shrubby stalk, not more than three or four feet high in England; but in places where it grows naturally it reaches more than twenty feet in height, with branches forming a large spreading head. The leaves are shaped like those of the black poplar: on breaking the more tender branches, a large drop of thick balsamic liquor oozes from the wound ; whence it has the appellation of balsam-tree. The leaves and tender tops are said to heal sores, and are frequently used in baths and fomentations. The cortex cascarillæ is supposed to be the produce of this tree. Stiffer recommended it, at the end of the last century, as a powerful diuretic and carminative ; and he used it with success in calculous, asthmatic, phthisical, scorbutic, and arthritic complaints : since that, it has been used in Germany for the Peruvian-bark, in intermittent fevers; and the German physicians have given it much ripen seed with more certainty, if sown in autumn. If the

various alvine fluxes .- Native of both Indies. This plant will live through our winters in an airy glass-case, without artificial heat, but should have very little water. If they be placed when young in a very moderate warmth in winter, it will greatly forward their growth; but they must not be forced with too much heat, and may be treated more hardily when they have acquired strength. This species may be propagated by cuttings during the summer season, but the cuttings should be laid in a dry place for a few days, after they are taken from the old plants, that their wounded parts may dry and be healed over before they are planted. They must be planted in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark : if the season prove very warm, the glasses should be shaded in the heat of the day, and raised up to admit the fresh air, but they must be sparingly watered : when they begin to shoot, they should be gradually inured to the open air; and when their roots have filled the pots, they should be carefully parted, and each planted in a separate pot of the same light sandy earth ; they then should be placed on the back part of the stove, behind the other plants, where they may be screened from the sun till they have taken fresh root, after which they may be brought forward, and exposed gradually to the open air. In the summer they should have free air constantly in warm weather, but must be screened from heavy rain, and placed in winter in an airy glass-case, where they may enjoy the sun, and during that season have very little moisture admitted to them.

8. Cluvtia Stipularis. Leaves oval, tomentose underneath: branches flexuose, tomentose; flowers axillary, subsessile, not longer than the stipules, dark purple; style columnar, scarcely trifid at the end .- Native of the East Indies.

9. Cluvtia Acuminata. Herbaceous : leaves ovate. smooth, obtuse, with a point; flowers axillary, solitary .---Native of the Cape of Good Hope.

10. Cluytia Lanceolata. Leaves elliptic-lanceolate; flowers lateral, tomentose; leaves broad lanceolate, above two inches long, without any dots beneath, very few above, and they only visible with a magnifier; calices villose, tomentose; capsules not dotted .- Native country unknown.

Chupeola ; a genus of the class Tetradynamia, order Siliculosa,-GENERIC CHARACTER. Calix : perianth fourleaved ; leaflets ovate, oblong, permanent. Corolla : fourpetalled, cruciform; petals oblong, entire; claws rather longer than the calix. Stamina: filamenta six, shorter than the corolla, the two opposite ones still shorter ; antheræ simple. Pistil : germen roundish, compressed ; style simple ; stigma obtuse. Pericarp: silicle orbiculate, emarginate, flat, compressed, erect, deciduous, bivalve; valves orbiculate, Seeds: orbiculate in the centre of the pericarp. ESSENTIAL CHARACTER. Silicle emarginate, orbiculate, compressed, flat, deciduous .- This genus consists of low plants of little beauty, which are preserved chiefly in botanic gardens .-The species are,

1. Clypeola Jonthlaspi: Annual Treacle Mustard, or Buckler Mustard, Annual: silicles orbiculate, one-celled, one-seeded. A low annual plant, seldom exceeding four inches high; stems slender; flowers in terminating spikes, and very minute; corolla yellow, the size of the calix; style scarcely visible with a magnifying glass .- Native of the south of France, Spain, and Italy, flowering there from March to May, but in England from May to July. It is propagated by seeds sown on a border of light earth, where they are intended to remain, and will grow larger, flower stronger, and

seeds be permitted to scatter, the plants will thrive without shoots are more luxuriant, they are sometimes injured. further care.

2. Obypeola Tomentosa; Hoary Treacle Mustard. Perennial: silicles orbiculate, two-celded; two-seeded; leavesublomentose; root perennial, woody, branched; stems shrubby, diffused, leafy at the end; leaves hirsntley hoary; the lower oracia-collong, sinuate, three inches long, and half an inch broad; the stem-leaves alternate, sessile, lincarnaceolate, entire or toolitetted; flowers treminating and axillary, at first in a sort of numbel, but afterwards panieled; calix very small, hairy on the causisd; perlas yellow, emarginate, longer than the calix.—First observed by Tournefort in the Leavat.

3. Clypcola Maritima; Sca Treacle Mustard, or Charles Mustard. Stems much branching, diffusca, evergreen; leaves linear-lanceolate, whitish, not stiff; racemes straited; calix deciduous; petals white, obvate, the claws and filamenta dark purple; antheres yellow. It has the appearance of wall-flower, but the branches are weaker, and both they and the leaves much smaller.—Native of the south of France, Spain, and Italy; common on the coast of the Mediterranean. It should be sown upon a warm border in a dry soil, and does not bear transplanting well.

Genorum : a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. Calix: perianth very small, three-toolhed, permanent. Corolla: petals three, oblong, hauceolate-linear, concave, ercel, equal, decidious. Stamina: filamenta three, subhalete, shorter than the corolla. Authers small. Pivitl: germen obtuse, triangular; style ercet, firm, length of the stamina; stigmen trifd, spreading. Periamp: herry dry, globose, three-lobed, three-colled, scel. spreading, round. ESENTIAL CHARACTER. Calix: three toothed. Petals: three, equal; berry tricoccous. —The only species is,

1. Cneorum Tricoccum; Widow-wail, or Spurge Olive. An humble shrub, which seldom rises more than two feet and a half high in this country, but spreads out on every side with many lateral branches, so as to form a thick bush : the stems are ligneous, and almost as hard as those of the boxtree, and the wood is of a pale yellow colour under the bark ; the branches are garnished with thick stiff leaves, of an oblong oval shape, about an inch and a half long, and a quarter of an inch broad, of a dark-green colonr, having a strong vein or rib through the middle; the flowers are produced singly from the wings of the leaves, toward the extremity of the branches; they are of a pale yellow colour; after the flowers arc fallen, the germen becomes a fruit, composed of three seeds joined together, in the same manner as those of emphorbia or spurge; they are green at first, afterwards of a brown colour, and black when ripe : the flowers begin to appear in May, and are succeeded by others during the summer months; and when the autumn proves favourable, they will continue in flower till the end of October. As this is a low evergreen shrub, it may be very ornamental, if placed in the front of plantations or evergreen trees or shrubs : for as the branches grow compactly, and are well garnished with leaves, it will conceal the ground between the smaller shrubs better than most other plants, and being durable, will not want to be removed.-Native of the south of France, Italy, and Spain, in hot, dry, barren, and rocky soils. It was formerly preserved in green-honses, being thought too tender to bear the open air in English winters, which it has since borne very well, being rarely killed, except by extremely hard frosts, which do not even destroy those plants which grow upon dry, rocky, or rubbishy soils, where their shoots are generally short and firm; but in moist rich ground, where the

shoots are more luxuriant, they are sometimes injured. It is propagated by sowing the seed in autumn, soon after they are ripe, which ensures the appearance of the plants in the following spring; whereas those which are not sown till the spring, will remain a year in the ground, and often miscarry. The seeds may be sown in a bed of common earth, covering them half an inch deep, and will require nothing but weeding during the following summer, and may be transplanted in the succeeding autumn wherever they are intended to remain.

Cnicus; a genus of the class Syngenesia, order Polygamia .- GENERIC CHARACTER. Calix: compound, ovate, guarded with bractes, imbricate; scales ovate, close, branched, thorny. Corolla: compound, tubular, uniform; corollets hermaphrodite, equal. Proper : funnel-form, oblong ; border five cleft, erect, nearly equal. Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: germen short; style filiform, length of the stamina; stigma oblong, emarginate. Pericarp : none. Calix : closed. Seed : solitary; down plumose. Receptacle: flat, villose. ESSEN-TIAL CHARACTER. Calix: ovate, imbricate, with branchthorny scales, guarded with bractes; corollets equal. These are perennial plants, and may be propagated by parting the roots; the best time for doing which is in autumn, that the plants may get good root in winter, for those which are transplanted in the spring, do not flower well in the first year, unless they be planted in a a moist soil. As these plants grow very large, they are not proper furniture for small gardens, where they will take up too much room; for if they be nearer to each other, or to other plants, than four feet apart, they will deprive them and each other of their nourishment, for their roots extend to so great a distance, that two or three for variety's sake are sufficient for any garden, where they should be planted at a distance from choicer plants. They are also propagated by seeds, which may be sown in the spring, on a bed of common ground, and will merely require to be thinned, and kept clean from weeds till autumn, when they may be transplanted to wherever they are intended to remain .---- The species are,

1. Cnicus Oleraceus; *Pale-flowced Cnicus*. Leaves pinnatida, keeled, nakcel; bracics concave, entitre, somewhat coloured; calices lateral, sessile, usually two together, with one between on a short pedinnele; a white line runs along the keel of the calycine scales; leaves smooth, stem-chapnig; flowers pale yellow...-H is found near brooks in the woods of Switzerland, and grows to the height of six feet; it is also a native of most countries of Europe, except the southernmost, where it is found in moist woods, meadows, and marshes, flowering in the autinnmal months. The Russians boil the leaves in the spring, and ent them as coleworts, although, according to Ichreber, no cattle will est it.

2. Cnicus Eristitales; Clammy Cnicus, Leaves stemclasping, pinnatifial, awn scratted; predunceles drooping; calices glutinous; peduncles leafless; howers solitary, nodding, yellow; disk convex, rather long; stem three fect high and more, angular, sometimes a little tomentose, not branched, meless at the top, maked far under the flowers.—Native of France, Switzerland, Austria, Carniola, and Silesia. It begins to flower in June, and is perennial.

3. Cnicus Ferox; Prickly Cnicus. Leaves decurrent, ligulate, toot-thomy; stem branching, crect; stem firm, deeply grooved, covered with a cobweb-like pubescence; a large lead of while or purple floscoles terminates the branches, and is guarded with linear strigoe bractes, having small splues about the edge. Biennial; flowering in July and August—Native of the south of France.

4. Cnicus Pigmæus ; Pigmy Cnicus. Leaves sessile, sub-

linear, very much crowded; calix unarmed; ro fore interneily, black; stem upright, bloluw, from two to fore interhes high, thickened at top, very closely cavered with white hairs; leaves may, black is the uprice there, sharp, three leaves may, black is the uprice the stem, sharp, three inches long, some quite entire, others toothletted, unarmed, the sides rolled back; forever solitary, tother stored back shorter leaves; corollet spurple; tube long and sheared, spread out into a wide and then an orate form; segments linear, obsolver; leaves; corollet spurple; tube long and sheared silverad out into a wide and then an orate form; segments linear, obuuse, equal, short; in the outer florets very much curved in, but in the central one straight; anther wided cloured. It work and any straight is the other mountains of Austria,

5. Cnicus Acama; Yillow Cnicus, Leaves decurrent, Ianceolate, undivided; calices pinnate, thorny; stem herbaceous, winged by the leaves running down it, hoary, a foot high, but sometimes much smaller; leaves sessile, scattered, extremely acnet, hoary, keeled, having a few teeth about the edge, with two or three yellow spines in each; calix woolly; corollets purple; flowers terminating, afterwards axillary, sessile; corollas small, purplish.—Native of the south of France and of Spain.

6. Cnicus Spinosissimus. Leaves stem-clasping, simate, torvuy; head simple; flowers essile; stem unbranched, twelve to eighteen inches high; the top entirely covered with leaves, angular, not winged; stem-leaves most fiercely thorned; pinnas angular, mauy-lobed, the nerves continued into strong thorns; the leaves on the top of the stem form a nest for the flower, broader, ovate, lancedate, linade a naive of Switzerland, Astria, aud Carniola.

 Cnicus Centauroides; Artichoke-leared Cnicus. Leaves pinnatifid; calcies seariose; sceles acuminate; stem three feet high, angular, putting forth few branches, and having at the top heads the size of a small artichoke, and of a tawny colour; corollas purple.—It flowers in July and August, and is a native of the Pyrenees.

8. Cnicus Uniforus. Leaves pinnatifid; calix scarolos; vilose; stem tvo fect high, ercet, subangular, the thickness of the little finger, scarcely lanuginose, one-flowerel; flower terminating, scsile; calix large, globular; scales imbricate, loose, ovate, gray; corolla large, violet; floscules six-eleft, with linear acute segments; stamina and style longer than the corolla, the former white, the latter violet; there are no barren floscules...Perennia!; and a native of Siberia.

9. Cnicus Cernuus; Siberian Chiens. Leaves cordate; petioles curled, thorny, stem-clasping; dowers drooping; caliees services; root preemial, large, and rough, sending out the stalks rise six or seven feet high, sending out a few small branches; they are striated, of a brown colour, and at bottom have hert-shaped leaves half stem-clasping; the leaves to wards the topol. The shaft stem clasping is the topol. The points, each branch is terminated by one large head of flowers; calycine scales imbrieate, ending in a sharp spine; forets pale yellow, with an agreeable scent.—It flowers in the second year after the seed has been sown, in July, and the tonder stalks to biled.

Cocroappselum; a genus of the class Tetrandria, order Monogynia – GENERIC CHARCTER. Calix: perianth oneleaded, four-parted, superior; segments acute, erect. Corollar: one-petalled, inunel-form; tube longer than the calix, gradually widening toward the border, which is four-parted, the parts ovate, petct. Stamius: financita for, the length of

the tube, inserted into the base, hilform, erect. Antherg rect. Pititi's germen ovate, inferior; style the length of the stamina, bifd at the tip; stigmas simple. Pericap; berry roundish, inflated, two-celled, crowned. Stedis: nonnerous, miuute. ESENTAL CHARACTER. Coliz: fourparted, superior. Corolla: funnel-form; herry inflated, twocelled, man-vecded.—...The only known species is,

 Coccocypelum Repens. It grows in spreading turks, each stalk creeping eighteen or twenty inches from the root, and shooting out a few lateral branches as it runs; the leaves are opposite; the flowers and fruit rise on short divided peduncles from alternate axis.—Native of Jamaica, frequent in the cooler mountains of Ligamea, and Mount Diable.

Coccoloba ; a genus of the class Octandria, order Trigynia. -GENERIC CHARACTER. Colix : perianth one-leafed, five-parted; divisions oblong, obtuse, concave, spreading most widely, coloured, permanent. Corolla: none. Stamina : filamenta eight, subulate, patulous, shorter than the calix. Antheræ roundish, twin. Pistil : germen ovate, trigonal: styles three, short, filiform, spreading; stigma simple. Pericarp: none. Calix: berried, thickened, converging, involving the seed. Seed : nut-ovate, acute, one-celled. Es-SENTIAL CHARACTER. Calix: five-parted, coloured. Corolla: none. Berry: calycine, one-seeded .-- The plants of this genus are all easily propagated by seeds, whenever they can be obtained fresh from the places where they naturally grow, for none of them have hitherto produced seeds in England. The seeds should be sown in small pots of kitchengarden earth, and plunged into a hot-bed; if they be fresh and good, and the bed be of a proper temperature, the plants will appear in five or six weeks, and will be fit to transplant in about a month after: they should then be shaken out of their pots, carefully separating their roots, and each replanted in a separate small pot of the same kind of earth, plunging them into a hot-bed of tanner's bark, taking care to shade them in the day-time until they have taken new root. after which they should be treated like other tender exotic plants, which require to be constantly kept in the bark-stove. -The species are,

1. Coccoloba Urifera; Round-leaved Sea-side Grape, or Mangrove Grape Tree, Leaves cordate, roundish, shining, This is a lofty, spreading, branched, irregular, inelegantly formed tree, but rendered handsome by its leaves and truits; bark cinereous, thin, in the younger trees smooth, in the older ones full of chinks; timber hard, ponderous, red, but fit for little except as fire-wood, on account of its fibrous texture, unless it should turn out to be serviceable in dveing ; flowers small, whitish, smelling like those of the cherry .--Gærtner calls the fruit a superior drupe, formed of the berried calix, obovate, of a purple colour, with a bloom, becoming black when rive, and wrinkled; pulp soft, drying into a thin crust; the fruit is very astringent, and may be used in emulsions, boluses, or electuaries, but its action is not of long continuance; it has the exact taste of bistort, and the berries possess an agreeable flavour, but the pulp is not considerable. This tree is common in most of the sugar colonies, and is generally found near the sea. It frequently grows to a considerable size, and is then looked upon as a beautiful wood for all sorts of calinet ware, but it seldom rises so straight or regular. The Spaniards call it urero, and the French raisinier du bord de la mer.

2. Coccoloba Pubescens; Great-leaved Sea side Grape. Leaves orbiculate, pubescent. This is an upright tree, sixty or eighty feet high; the head has frequently no more than two or three thick branches, but little divided and irregular; the bole is sometimes forty feet in length, and puts forth a

332

2

сос

branch or two about the middle. The timber is deep red, high, very hard, and also incorruptible, but brittle; when used for posts, the part placed in the ground becomes as hard as a stone.—It is common in the thick mountainous woods of Mattinico, where the French call it *bois a grandes faultes*.

3. Coecoloba Excoriata; Orel-Leared Nesside Grape, or Monntain Grape, Tree. Leaves ovate; branches as it were harked.—This grows to a very large tree, and the leaves, flowers, and fruits, are all large; the leaves are very smooth, and of a fine lucid green colour. Browne informs us, that it grows to a considerable size in Jamaica, and is looked upon there as a fine timber wood.

4. Coccoloba Nivea. Leaves elliptic, acuminate, veined, shining above; racenes almost upright. It grows to the height of twenty feet, is upright, and the boughs form a head; flowers small, yellowish; fuit sweet and pleasant: the French call it raisinier de Conde.—Native of St. Dowingo, Jamaica, and Martinico.

 Coccoloba Leoganensis. Leaves roundish, quite entire, shining, flat; racemes of the fruit erect. This is a small upright branching tree, ten feet high; leaves veined, coriaccous. Native of Port-au-Prince, and Leogane, in St. Domingo.

6. Coccoloba Obtusifolia. Leaves oblong, very obtuse. This is a small, very branching, irregular tree, about twelve feet high, with smooth ash-coloured branches; leaves quite entire, shining; flowers small, while; fruit astringent.—It flowers in August, and is a native of Carthagena.

7. Coccoloba Flavescens. Leaves lanceolate-oblong, blunt, with a point. A small branching tree, tweeker feet high; leaves quite entire, coriaceous, shining, somewhat rigid; raceness simple, terminating, erect; furges roundish, dark purple, the size of a large pea; the pulp sweet and eatable.—Native of St. Domingo at Port-au-Prince.

8. Coecoloba Punctata: Spear-leared Seeside Grope. Leaves lancedate, ovate. A small, upright, branched tree, fifteen feet in height; leaves quite entire, subcoriaceous, veined, shining; flowers white: almost the whole receptacle, with a small part only of the calks, becomes aroundish drupe of a dark red colour, and a sweetish but austere taste.—Native of Carthagena.

9. Coccoloba Emarginata. Leaves coriaceous, roundish, gash-emarginated.---Native of the West Indies.

10. Coccoloba Barbadensis. Leaves cordate-ovate, waved; bark of the branches cinereous; wood red.—Native of Barbadoes.

 Coccoloba Tenuifolia; Small Sea-side Grape. Leaves orate, membranaceous. This is of a humbler growth than any of the preceding species, having also smaller fruits and flowers; flowers scattered and pedicelled.—Native of Jamaica.

12. Coccoloba Australis. Leaves cordate-ovate, acute; flowers polygamous.—Native of New Zealand.

13. Cocciloba Asiatica. Scandent: leaves oblong-orate, veined; racemes terminating; stem suffruitose, branching; leaves subacuminate, quite entire, coriaceous, alternate; fowers white, in loose racemes; fruit a roundish five-lobed berry.—Native of Cochin china, where it is found in bushes and hedges.

14. Coccoloba Cymosa. Scandent : leaves oblong-ovate, veined ; flowers axillary, and terminating in sessile cymes.— Found also in the hedges of Cochin-china.

Cochlearia; a genus of the class Tetradynamia, order Silcubasa. – GENERIC CHARACTER. Calix: periauth fourleaved; leaflets ovate, concave, gaping, deciduous. Corolla: four-petalled, cruciform; petals obovate, spreading, twice 28.

the size of the calks; claws narrow, shorter than the calks, patulons. Stemina: filamenta six, subulate, length of the calks, the opposite ones shorter; antherae obtuse, compressed. *Psidi:* genen heart-shaped; style simple, very short, permanent; stigma obtuse. *Pericarp:* silicle heart-shaped, gibbons, turgid, emarginate, furnished with a style, twocelled, scabrous; valves gibbous, obtuse; seeds about four in each cell. ESENTIAL CURACTER. Silicle: emarginate, turgid, scabrous; valves gibbous, obtuse, ——The species are,

1. Cochlearia Officinalis; Common Scurvy Grass, or Scrooby Grass, Root-leaves cordate, roundish; stem-leaves oblong, a little sinuate; root perennial; stem angular, branching; petals fleshy, clear white, with greenish claws. The common scurvy-grass has been long held in very high cstimation, as an antiscorbutic and purifier of the blood ; it has a somewhat unpleasant smell, and a warm bitter taste. Its active matter is extracted by maceration both in watery and spirituous menstrua, and accompanies the juice obtained by expression. The most considerable part of it is of a very volatile kind, the peculiar penetrating pungency totally exhaling in the drying of the herb, and in the cvaporation of the liquors. Its principal virtue resides in an essential oil. separable in a very small quantity by distillation with water. Scurvy-grass is an antiseptic, attenuant, aperient, and diuretic, and is said to open obstructions of the viscera and remoter glands, without heating or irritating the system : it has long been considered as the most effectual of all the antiscorbutic plants, for which we have the testimony of the most celebrated physicians; and it has been observed to grow naturally in those high latitudes where the scurvy is most prevalent. In rheumatic pains of long continuance, accompanied with fever, this plant, combined with arum and wood-sorrel, is highly recommended by Sydenham and Lewis. A remarkably volatile and pungent spirit, prepared from this herb, and called spiritus antiscorbuticus, was found by Werlhof to be a useful remedy in the palsy, and other disorders requiring an active stimulant; he gave it in the dose of thirty drops several times a day: but no preparation seems so beneficial, by way of an antiscorbutic, as the fresh plant eaten as a salad, or its expressed juice drank. If the green herb be infused in ale or beer, and put into a bottle well cerked, it will communicate to it all its antiscorbutic virtue, or volatile spirit, in three or four days' time. Mr. Ray recommends this ale, from his own experience, to be taken as the ordinary drink of those who are troubled with the scurvy: he says, it is not so good if the scurvy-grass be long infused in it, for the earthy and fixed parts are thereby forced from the herb, and communicated to the ale, while the volatile parts either fly off, or, being jumbled with the more fixed parts, lose a great deal of their virtue. The juice of the scurvy-grass, with the bruised herb, applied to the face or any other part. has been recommended as a cosmetic, which takes off spots. freckles, and sun-burns; but those who have delicate complexions cannot bear the application without injuring them : those whose vanity induces them to try the experiment, are hereby informed, that the best way of obviating the mischief that may follow the application, is, to wash it off with a de-coction of bran. According to Withering, scurvy-grass is a powerful remedy in the moist asthina, and also in what some authors call the scorbutic rheumatism. A distilled water and conserve are preserved from the leaves, and kept in the shops, and its juice is frequently prescribed, when mixed with that of Seville oranges, under the name of antiscorbutic juices .--It is found on the mountains and sea-shores of the north of Europe : in England, it will be met with near Lynn and Yar-4 Q.

mouth; near Hull, Boston, Whapload, Holbeach; in Cornwall, Cumberland, Lancashire, and Wales; and at a great distance from the sea, near Castleton, in Derbyshire; Penigent, Ingleborough, and Stancmore, in Yorkshire, and near Settle; and on the Highlands of Scotland. It is propagated for its medicinal uses, and ought to be found in every garden : the seeds should be sown in July, soon after they are ripe, in a moist shady spot of ground, and when the plants come up they should be thinned, so as to be left at about four inches' distance each way; the plants which may be taken out in thinning, may be transplanted into other shady borders, if there be occasion for them; if not, they may be hoed out in the same manner as onions, carrots, &c. taking care at the same time to hoe down all the weeds together with them, that the remaining plants may have room to grow strong : in the spring the plants will be fit for use, while those which may be suffered to remain, will produce their seeds in May, and ripon them in June; if the plants be sown in the spring, the seeds seldom grow well, therefore the best time to sow them is soon after they become ripe. The plants rarely live after producing seeds, which should therefore be sown every year, to have it for use.

COC

2. Cochlearia Danica; Danish Scurry Grass. Leaves hastae, angu'ar, all delioid; stem not branching; runners procumbent; both root and stem-leaves hastate, or ovate, with an angle on both sides of the base; capsules ovate.— Found upon the sea-coasts of Denmark, Sweden, Great Britan, the islee of Portland, and about Plymouth; also at Wells, in Norfolk, isle of Walney, in Lancashire; near Llambadrick church, in Anglesca; and in Scotland.

3. Cochlearia Anglica; English, or Sea Scurry Grass. Ali the leaves oval, lanceolate, succulent, often reddish. According to Mr. Woodward, the stem-leaves are arrow-shaped at the base, and stem-clasping; silicles roundish, flcshy, much larger than in the first species, and terminated by a longer style: he thinks it undoubtedly to be a distinct specics, and affirms, that at Yarmouth, where it grows abundantly, as well as in other places, it is never known to vary. Hill recommends the leaves of this plant, or the juice of them, to be taken in the same manner as those of the first species, (which see,) as he affirms their virtues to be the same, and even greater, although the taste be less agreeable. If his account be correct, it is very unfortunate that this species, prowing only in salt-marshes, where the sea-water overflows it almost every tide, can with great difficulty be at all brought to grow in a garden, and never lasts longer than a year .- It is found in muddy soils upon the sea-coasts, on the banks of the Thames, near Portsmouth, Bristol, in the salt-marshes, of Kent and Essex, in the isle of Wight, near Kingsweston, and upon the tocks of Inchcolomb.

4. Cochlearia Greenlandice : Greenland Scarry Grass. Leaves kiduey-form, eatire, fleshy; root-leaves very small, underneath very convex and fleshy, veinless, very entire, on long petioles; sten leaves hastate, angular, on short petioles: not above two inches high.—It is found on the sea-coasts of Muscovy, and Davis Straits, on the mountains of Caernarvoashire, about Llanberys, near Settle, on the Highlands of Scoland, and in the Orkneys.

5. Cochlearia Coronopuis, Wild Sourry Grass, or Swine's Cress. Leaves pinnathfol; tent depresed; stem and leaves smooth, lying flat upon the ground, all about the roots; the flowers grow in short axility tufts, are very small, and have white petals. It is acrid, and tastes like garden-cress; the aches were an ingredient in Mrs. Stephens's once celebrated medicine for the stome. The expressed juice of this plant is a sele but powerful diructic, and is good for all inward

obstructions, the jaundice, and scorbutic complaints; the leaves may be eaten as a salad, or dried and given in decoction.— It is an annual, and commonly found on road-sides, dunghills, and among rubbish; flowering from June to August.

6. Cochlearia Armoracia: Horse Radish. Root-leaves lanceolate, crenate; stem-leaves gashed; root perennial, creeping; leaves very large, varying much, sometimes deeply pinnatifid, sometimes entire, and only crenated; floweringstem a foot or eighteen inches high, branching at top, almost naked : flowers white, in loose panicles : silicle nearly ovate. -Sides of ditches produce it, and it also grows among rubbish and in pastures, flowering in May. Horse-radish, the scraped root of which is used for many culinary purposes, possesses a volatile and pungent quality, which evaporates in drying. It impregnates both water and spirit very richly with its active matter, whether it be extracted by infusion or distillation. It is a moderately stimulating aperient and antiseptic medicine, which sensibly promotes perspiration, urine, the expectoration of viscid phlegm, and excites appetite when the stomach is weakened or relaxed: it is principally used in paralytic and rheumatic complaints, in scurvies, and impurities of the humours, in cachectic disorders, and in dropsies, particularly those which often follow intermitting fevers: it provokes vomiting, if taken in considerable quantities. Thomas Bartholin extols the virtues of horse-radish in the stone, from his own experience; he declares, that the juice of horse-radish dissolved a calculous or stony concretion that was taken out of the human body. Those who are duly solicitous concerning that important object, the preservation or improvement of their complexion, should not remain ignorant of the great assistance they may derive from the horse-radish; an infusion of it in cold milk is said to make one of the safest and best cosmetics; which after all would probably be of more real service if taken into the stomach, instead of being daubed about the face. The horse-radish is propagated by cuttings or buds, from the sides of the old roots; the best season for this work is in October or February; the former for dry lands, the latter for moist: the ground should be trenched at least two spits deep or more; if it will allow of it. The manner of planting is as follows : Provide yourself with a good quantity of offsets, which should have a bud upon their crowns, but it matters not how short they are, therefore the upper part of the roots which are taken up for use, may be cut off about two inches long, with the bud to it, which is esteemed the best for planting; then make a trench about ten inches deep, in which place the offsets, at about four or five inches' distance each way, with the bud upward, covering them with the mould that was taken out of the trench; after this proceed to prepare other trenches, and plant them in the same manner, until the whole ground be filled ; after this is done, level the surface of the ground even, observing to keep it clean from weeds, until the plants be so far advanced as to be strong enough to overbear and keep them down. Under this management, the roots of the horse-radish will grow long and straight, and free from small lateral roots, and the second year after planting they will be fit for use. It is true they may be taken up the first year, but then the roots will be but slender ; therefore it is the better way to let them remain until the second year. The ground in which they are planted ought to be very rich, otherwise they will not thrive.

7. Cochlearía Glastifolia; Wood-leared Scurey Grass, Stem-leaves cordate, sagittate, stem-clasping; root perennial, striking deep; stems several, upright, rouud bclow, somewhat angular at top, herbaccous, annual, slightly villose, about a foot in height.—Abundant about Vienna, even in the suburbs;

COC

also in several parts of Italy, Germany, and France. This and the following species may be propagated by seeds, which, if sown in autumn, will more certainly succeed than in the spring.

a. Cochlearia Draba. Leaves hanceolate, stem-clasping, toothed. This is a biennial plant, which usually grows about a foot and a half high, with upright stalks; the flowers are produced in loose spikes at the end of the branches, they are very small and white: it flowers in May, and the seeds ripen in July and August.—Native of Germany and France. See the seventh species.

Cockle. See Agrostemma. Cock's-comb. See Celosia. Cock's-foot Gruss. See Dactylis. Cock's-head. See Hedysarum. Cocoa-nut. See Coros. Cocoa Plum. See Chrysobalamus.

Cocos; a genus of Palms, of the class Monœcia, order Hexandria .- GENERIC CHARACTER. Male Flowers in the same spadix with the females. Calix: spathc universal, univalve; spadix branching; perianth three-parted, very small; divisions subtriquetrous, concave, coloured. Corolla: petals three, ovate, acute, patulous. Stamina : filamenta six, simple, length of the corolla; antheræ sagittate. Pistil: germen scarce manifest; styles three, short; stigma obsolete, Pericarp : abortient, Female Flowers on the same spadix with the males. Calix: spathe common, with the hermaphrodites, as likewise the spadix; perianth threeparted ; divisions roundish, concave, converging, coloured, permanent, Corolla : petals three, permanent like the calis, but rather larger. Pistil: germen ovate; style none; stigma three-lobed. Pericarp: drupe coriaceous, very large, roundish, obscurely triangular. Seed nut: very large, subovate, acuminate, one-celled, valveless, obtusely three-cornered, the base perforated by three holes; kcrnel hollow. -The species are,

1. Cocos Nucifera; Cocoa-nut Tree. Unarmed: fronds pinnate; leaflets folded back, ensiform. The roots are very slender, simple, and flexile; they arise separately from the bottom of the trunk, and spread in all directions, some running to a great depth, while others creep almost parallel to the surface. The trees grow to a great height; their stems are composed of strong fibres like net-work, which lie in several laminæ over each other, out of which come the branches, or rather leaves, which grow twelve or fourteen feet long. The flowers come out round the top of the trunk of the tree, in large clusters; they are inclused in a large spathe or sheath ; and the nuts also are afterwards formed in large clusters, ten or twelve together. The fruit is properly a berried drupe, superior, vcry large, ovate, rounded, threecornered. The shell itself is of a bony substance: the kernel adheres all round the inner wall of the shell, and the cavity is filled with a milky liquor. The kernel in some nuts is nearly an inch thick ; and the hollow contains about a pint of sweet, delicate, wholesome, and refreshing liquor. While the nut is growing, it contains nothing but this liquor; but as it approaches towards maturity, the kernel begins to settle round the inside of the shell, like soft cream, which, as the nut ripens, increases in substance until it becomes hard. The ripe kernel is sweet, but difficult of digestion, and seldom eaten except by strangers; but while it is young and soft, some will eat it, scraping it out with a spoon after they have drank the liquor. While the nuts are young, the liquor is very pleasant ; as they grow old, it becomes more sharp and cooling, and far more agreeable to feverish habits. The kernel is certainly nourishing in a high degree, and is much

used in making soups, curries, &c. and may be substituted for almonds, in emulsions and apozens, wherever it can be procured fresh : a pure sweet oil is extracted from it, which is fit both for medical and culinary uses : the inhabitants of the Society Isles scent this oil with sandal wood, and other perfumes, in order to anoint their hair and skin with it. Beside the liquor contained in the fruit, there is a sort of wine drawn from this tree, which looks like whey, and is called toddy: it is sweet and very pleasant, when fresh; but if not drank within twenty-four hours after it is drawn, will turn sour. From this wine, in its sour state, they who have a great many trees distil a spirit called arack. It is also distilled from rice, but none is so much esteemed for making panch. as this sort made from sour toddy, or the sap of the cocoanut tree; although it requires a dash of brandy to hearten it, because it is not strong enough to make good punch of itself. This sort of liquor is principally used about Goa, and has thereby acquired the name of Goa arack. In order to make arack, the trees must be prevented from bearing fruit : and to accomplish this, the sprout which produces the nut, and which shoots every month, is cut, and jars fastened to it to receive the liquor ; or the body bored, and a plug put into the orifice, which is occasionally taken out when the liquor is wanted : this liquor is permitted to ferment, and is afterwards distilled into the spirit called arack, which is of a far better quality than that of the same name which is drawn from rice. If this liquor be exposed to the sun, it will soon turn to vinegar. The coat or husk of the shell is composed of strong fibres, and is two or three inches thick. With these fibres, after soaking them in water, sail cloth, cables, and cordage, are made for the largest ships; as also oakum, and a variety of yarn used in caulking ships, and for other nautical purposes. The shells answer a variety of purposes as honsehold utensils; and when worn out, are burnt to make lamp black, for painting, &c. The trunk of this tree is formed into gutters, and occasionally employed for enclosing and roofing outhouses; and being nailed close, is so hardy as to resist the weather for many years. The Indians make boats, rafters, and the whole frame of their houses, from the body of this tree: the leaves of which they use for thatching them. and are wrought into mats, baskets, and many other things, for which osiers are used in Europe. The tender shoots at the top afford a pleasant green or cabbage, which is dearly acquired by the destruction of the tree, which seldom survives their being cut off .- This useful plaut is common almost every where within the tropics, and is cultivated in both Indies, but is supposed to be a native of Asia, and is found in a wild state in the Maldives and Ladrones, as well as in the islands of the South Seas. It is propagated by planting the nuts wherever they are intended to remain; for it will not bear transplanting unless the operation be performed while the trees are very young, for their roots shoot deep and wide, so that if they be cut or broken the plants seldom survive it, which is the case with most of the palms. Where any persons desire to have a plant or two of this sort, they should procure some fresh nuts from the nearest place of their growth, which on their arrival should be buried, lying on one side in a warm bed of tanner's bark, that the young shoot which comes out from one of the three holes may not be injured by wet, covering them at the same time six inches deep with the tan. In this situation, if the nuts be good. they will put out shoots in six weeks or two months, when they should be carefully taken up, and each planted in a separate pot filled with kitchen-garden earth, and plunged into the tan bed in the stove, where the plants should always remain, as they are too tender to thrive in any other situa-

tion; but they should be shifted into larger pots as they advance in their growth, taking care not to cut or tear their roots in the removal. Very few of the nuts brought to England are ripe, being commonly gathered in an unripe state. that they may keep during their passage. The best way to bring them for planting is to put some that are fully ripe in dry sand in a tub, where vermin cannot get at them. These will often sprout upon the passage; which is an advantage, because they may be immediately planted into pots of earth, and plunged into the bark-bed. These trees make considerable progress in the West Indies, but they are many years before they attain to any considerable height in Europe: however, as the young leaves are rather large, they make a good appearance among tender exotics in the course of two or three years. The other species of this genus may be propagated by seeds in the same way: and for further information upon the subject, consult the article Phænix.

COC

2. Cocos Butyracea. Unarmed : fronds pinnate ; leaflets simple; universal spathe, and oblong cylinder, drawn to a point at each end, woody, smooth within, marked on the outside with numerous woody parallel ribs uniting towards the end; it opens longitudinally, falls off after the bursting of the spadix, and is from four to six feet long. The male flowers fall off with the least touch, making a great heap under the tree; female flowers crowded, imbricate, supported with a triple bracte, looser than the other, and very flat; kernel cartilaginous, very hard, but having the same taste as in the common cocoa-nut. The pulp of the nut is very mucilaginous, and therefore used for fattening hogs; an oil or butter prepared from it is in constant use among the Indians in South America, both in food and medicine .- For the propagation and culture, see the first species.

3. Cocos Guinensis; Prickly Pole. The whole spiny: spines bristle-shaped; fronds distant; root creeping; root knotty, round, thicker than the trunk, short, horizontally bent in directly below the surface, creeping, and presently putting out another trunk, so as to make a thicket, while it fixes itself firmly in the soil by slender fibrous roots; trunk erect, armed with very numerous prickles; bark brownish: flowers scentless, with a very slight tinge of vellow ; corolla triquetrous, frequently three-parted almost to the base ; fruits dark purple, the size of a common cherry, containing an acid juice, of which the Americans make a sort of wine : the fruit is eatable, but not pleasant, yet they furnish the wild hogs of Jamaica with abundant fare : canes are made of the trunk when stripped of its bark; they are black, shining, jointed, and very light. The French call them oannes de Tobago, and they are sometimes brought to Europe. The outward part is extremely hard and elastic, looking like whalebone, and being very fit for bows and rammers .- Native of Carthagena in South America. See the first species, respecting its propagation and culture.

4. Cocos Aculeata; Great Macaw Tree. Aculeate-spiny; ated .- Native country unknown. trunk fusiform; fronds pinnate; stipes and spathes spiny. The trunk of this tree is about the thickness of the human body, and rises to the height of thirty feet, with an ashcoloured bark. It is very thickly set with sharp black prickles of different lengths, placed usually in rings. The pinnas of the fronds are very long, and the whole set thick with prickles. The fruit is as large as a crab, and of the same shape. It has a thin sweetish astringent pulp, under a green skin; and within that, a nut full of a white sweet eatable kernel. Browne says, that the husks of this and of the small macaw-tree are full of oil, and the nut black and shining. The negroes say, that it yields the true palm-oil. They form the outside of the trunk into laths, bows, and

darts .- Native of the Caribbee islands. For its culture and propagation, see the first species.

5. Cocos Nypa. Unarmed : fronds pinnate ; spadices to the male-flowers round, to the females roundish; drupe grooved. This is a very thick palm, only four feet high, frequently shorter, or even without a stem; fronds fifteen feet long, almost upright, irregularly pinnate, with a subcylindric rachis or mid-rib .- It is very frequent in salt marshes, and at the muddy months of rivers in Cochin-china, Cambodia, the Philippine Islands, the streights of Malacca, &c. For the propagation and culture, see the first species.

Codded Corn Violet. See Campanula.

Codia ; a genus of the class Octandria, order Digynia .---GENERIC CHARACTER. Calix: common, four-leaved; leaves reflected below the head ; proper four-leaved ; leaflets elliptic, erect. Corolla : petals four, linear. Stamina : filamenta eight, filiform, two, each growing to the base of a petal, longer than the corolla; antheræ ovate-angulate, Pistil : germen very small, superior extremely villose; styles two, subulate, the length of the stamina; stigmas simple. Receptacle: common, villose. ESSENTIAL CHARACTER. Calix: four-leaved. Petals: four. Common receptacle involucred .---- The only known species is,

1. Codia Montana. Leaves opposite, petioled, elliptic, very smooth, entire, obtuse; heads globular, terminating, and axillary, very short, peduncled. It is a shrub .- Native of New Caledonia.

Codlin Tree. See Pyrus Malus.

Codlins and Cream. See Epilobium.

Codon ; a genus of the class Dccandria, order Monogynia. -GENERIC CHARACTER. Calix : perianth one-leafed, tenparted; leaflets subnlate, permanent, somewhat erect, alternately shorter. Corolla: one-petalled, bell-shaped, torulose at the base; border ten-parted, equal; nectary ten-celled, consisting of ten scales inserted into the claws of the stamina, converging, covering the receptacle. Stamina: filamenta ten, length of the corolla; antheræ thick. Pistil: germen superior, conic; style simple, length of the stamina; stigmas two, long, setaceous, divergent, Pericarp: two-celled, Seeds : several, roundish, echinate, with soft papillæ, situated in a juiceless coloured pulp. ESSENTIAL CHARAC-TER. Calix; ten-parted, permanent; leaflets alternately shorter. Corolla : bell-shaped, ten-cleft. Nectary : tencelled, composed of ten scales, Pericarp : two-celled, containing several seeds .----- The only known species is,

1. Codon Royeni. Stem herbaceous, firm, eighteen inches in height, round, with rising branches; leaves alternate, petioled, cordate-ovate, subrepand, undivided, acuminate, subcoriaceous, smooth, without veins on the upper surface: flowers supra-axillary, solitary, peduncled, having the appearance of the corolla of atropa-belladonna, whitish, with ten purple streaks on the outside. The whole herb is stri-

Cali Rosa. See Agrostemma.

Coffea; a genus of the class Pentandria, order Monogynia; -GENERIC CHARACTER. Calix : perianth five-toothed, very small, superior. Corolla : one-petalled, salver-shaped; tube cylindric, slender, many times longer than the calix; border flat, five-parted, longer than the tube; divisions lanceshaped; sides rolled back. Stamina: filamenta five, subulate, placed on the tube of the corolla; antheræ linear, incumbent, length of the filamenta. Pistil : germen roundish, inferior; style simple, length of the corolla; stigmas two, reflected, subulate, thickish. Pericarp : roundish, umbilicated by a one or two-celled puncture. Seeds : one or two, solitary, elliptically hemispherical, gibbous on one side, flat

on the other, where it is furrowed longitudinally, involved in { sun for some days, and then casked for the market. If it be an aril. ESSENTIAL CHARACTER. Corolla: salver-shaped. Stamina : upon the tube ; herry inferior, two-seeded ; seeds arilled .---- The species are,

1. Coffea Arabica; Eastern Coffee Tree. Flowers fivecleft ; herries two-seeded. The coffee-tree seldom rises more than sixteen or eighteen feet high in its native country, or more than ten or twelve in Europe. The main stem grows upright, and is covered with a light brown bark; branches horizontally opposite, brachiate at every joint; leaves opposite, four or five inches long when fully grown, an inch and a half broad in the middle, ovate-lanceolate, the borders waved, and the surface of a lucid green, but paler beneath. The flowers are produced in clusters at the base of the leaves, sitting close to the branches; they are of a fine white, with a very grateful odour, but of short duration, and are succeeded by berries, which are at first green, but turn red when fully grown, and are black when ripe. Dr. Patrick Browne, who resided many years in Jamaica, informs us, that the coffeetree thrives best in a rich soil, and cool shaded situation, where it produces so great a quantity of fruit, that the branches can hardly sustain the weight, and even the very trunk itself yields to the load. This fruit is large and succulent, and the berries lax and clammy; they are gathered when only half ripe; and instead of being stripped of their pulp, and carried down to the low lands to be dried, the seeds are left soaking in their clammy juices, to dry slowly in a damp air. . This will sufficiently account for the inferiority of the Jamaica, when compared with the Arabian coffee, which grows in a sandy, dry, hot soil, where the herries acquire but little pulp, and are soon dried by being spread upon mats and exposed to the sun. The same accurate writer, however, consoles us by his opinion, founded upon repeated experiments, that the West India islands might furnish coffee equal in quality to the Turkish, if the following remarks were attended to : 1. New coffee will never parch or mix well, from the natural clamminess of the juices: 2. the smaller the grain, and the less pulp the berry has, the better the coffee, and the sooner it will parch, mix, and acquire a flavour: 3. the drier the soil, and the warmer the situation, the better will be the coffee it produces : 4, the larger and more succulent the grain, the worse the quality will prove : 5. the worst coffee produced in America, will, in a course of years, not exceeding ten or fourteen, be as good as the best we now receive from Turkey, if care be taken to keep it in a dry place, and to preserve it properly. Mr. Miller advises those who cultivate the coffee-tree in the West Indics; first, to prefer a dry before a moist soil ; secondly, to permit the berries to remain upon the trees until the skin shrivels and turns black ; thirdly, to gather, or rather shake them from the trees when they are perfectly dry, spreading them afterwards upon cloths or mats in the sun, and carrying them every evening under cover, until they are wholly dry, as it is done in Arabia Felix: and when they are thus perfectly dried, deprived of their husks, and winnowed, he advises to pack them up carefully in bags, and not to ship them with rum or other goods, from which they may imhibe a disagreeable flavour. In addition to this, Dr. Browne recommends the possessors of large coffee-walks to have a convenient platform to dry the seeds on, and he thinks it would be a useful experiment, to try whether sweating would remove the clamminess of the large herries. They should, however, be pulped and dried as soon as possible, then husked, and cleared from all the outward coverings. This is generally done, in Jamaica, by pounding the dried herries lightly in a large wooden mortar; they are then winnowed, cleared, again exposed to the 29.

Europe, and when that occurs it loses all its flavour. Long, in his history of Jamaica, observes, that the berries never ought to be gathered until the pulp is exhaled, and the coat suffered to become thoroughly dry and shrivelled, so that they may appear ready to drop off, and actually fall upon a slight touch. In confirmation of this, he affirms that he has experienced the best-flavoured coffee to have been collected from under the trees, where it had recently fallen quite dry, black, and shrivelled : he adds, that the trees should he planted at distances proportioned to their growth, which is five feet in the low lands, and ten or more in the mountains, and that the produce of a good tree is from one pound and a half to two pounds weight: he also thinks, that the mountain coffee might be improved by sending the berries to the low lands, where the heat is greater, and the air more dry; and by having a drying house under a roof, with one or more platforms, admitting a free current of air, and excluding the rain and the beams of the sun : he further informs us, that the husk is no longer beaten off in mortars, but hy rollers turned by mules; that wooden rollers are preferable to iron or stone; and that the most approved machine, invented by Mr. Latham, will clean one hundred hogsheads in a day. Dr. Fothergill very reasonably suggests, that the removal of the coffee-tree from the dry sterile sandy soil of Arabia, into the rich deep staple of Batavia, where the quantity of water falling in the rainy season is excessive; its removal from thence into Holland and France; and its subsequent transportation to a climate much more abounding in moisture than that of which it was a native - may so far have altered the quality of the fruit, as to make it difficult to restore it to its original perfection; which he nevertheless thinks may be accomplished by making the plantations in soils as similar as possible to that out of which it was originally taken : he also hints, that the fruit of young trees is in general more insipid, or has a less refined taste, than the old, and that this probably applies to the coffee-tree, the fruit of which he asserts to be smaller in the old than in the young trees. The French cultivate it with great attention in both Indies; and the consequence is, that their coffee is much superior to ours, and by some is even accounted nearly equal to the best Turkey. They are also more careful in not shipping it among goods which destroy its flavour, and communicate an ill taste in its stead, as with rum and coarse sugars, the ill flavour arising from which can hardly be removed, even by roasting it in the fire. It is also probable, adds Dr. Fothergill, that our plantation coffee is used too soon, and that one part of the excellence of the Mocha coffee may arise from the intervention of two or three years between its growth and consumption. In confirmation of this, the doctor found that some raw coffee which was sent him from the West Indies, and was so ill-tasted as to be unfit for use; after being laid in a very dry closet, was tried again the year after, and found to be greatly amended. Mr. Miller however controverts this hypothesis. "It is, (says he,) contrary to all the experience I have had, and the information I have obtained from those who have been eve-witnesses to the whole process of managing coffee in Arabia. Two gentlemen who have lived there some years assure me, that the berries, when first gathered, are much hetter than those which have been kept any time. And a curious observer, who resided two years in Barbadoes, also informs me, that he never drank better coffee in any part of the world, than what he made fresh from the herries he gathered himself, and roasted as he had occasion for them. This account is further and fully confirmed, by trials with

not well dried, the coffee is liable to heat on its way to

flavour than the best Arabian coffee-berries that can be procured in England. However unfortunate this may be for those who can only procure coffee from distant countries, it is no misfortune to the planter that his coffee is not improved by age, for if it were, it would be extremely difficult for him to keep it so long as is proposed ; which would entirely deprive him of all profit whatever. Fuller, however, informs us, that after a multitude of experiments, the Jamaica planters have, by the most laudable exertions, discovered the art of cultivating, picking, and curing the berries, so as to make their coffee equal to the growth of Arabia. Some samples are said to have been produced, which the London dealers pronounced superior to the best brought from the East. Two of them were equal to the best Mocha coffee; and two more, superior to any that could be procured at the grocers' shops in London, unless at the price of picked coffee, which is two shillings per pound more than what they call the best coffee; to which the remainder of the samples were little, if at all, inferior. As the coffee-tree is an evergreen, it makes a beautiful appearance in the stove at every season, but particularly when it is in flower, and also when the berries are red, which is generally in winter; and as they continue a long time in that state, there is scarcely any plant that better deserves a place in the stove. It is propagated by the berries, which must be sown soon after they are gathered from the trees; for if not soon afterwards placed in the ground, they will not grow. They should be planted in small pots filled with light kitchen-garden earth, and plunged into a hot-bed of tanner's bark ; they must be watered gently once or twice a week, but not so as to make the earth too moist, for that would rot the berries. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks' time, and in about two months more will be fit to transplant: for as many of the berries will produce two plants, so the sooner they are parted, the better the roots will be formed; for when they grow double till they have made large roots, they will be so intermixed and entangled, as to render it difficult to separate them without tearing off their fibres, which will greatly prejudice the plants. When they are transplanted, they must be each put into a separate small pot filled with the same earth as before, and plunged into the tan-bed again, which should be stirred up to the bottom, and, if required, have new tan added, to increase or restore the heat. The plants should then be gently watered, and the glasses of the hot-bed must be shaded every day till they have taken fresh root, after which they must have free air daily admitted to them in proportion to the warmth of the season; and during the summer they will require to be refreshed with water, but it must be given sparingly, for if their roots be kept too moist, they are very subject to rot, which will cause the leaves to decay and drop off, leaving the plants naked, after which they are seldom recovered again. The first sign of the disorder of these plants is their leaves sweating out a clammy juice, which attracts the small insects that too frequently infest the plants in stoves; when they are not in health, and these insects cannot be destroyed till the plants are recovered to vigour, for although they be ever so carefully washed and cleaned from them, yet they will soon be attacked again by them if they are not restored to health, for these insects are never seen upon any of the plants while they are in perfect vigour, but spread over all the leaves of disordered plants, and multiply exceedingly; so that upon the first attack, the plants should be shifted into fresh earth, and all possible care taken to recover them. The disorders

berries produced in our English stoves, which make a better (put into pots too large for them, nothing being worse than overpotting them, or from the earth being too stiff, or from their being overhung by other plants, or from being overwatered. If these things be avoided, and the stove be always kept in a proper temperature, the plants will thrive, and produce plenty of fruit. The plants should not be too often transplanted, for that will greatly retard their growth; if they be new-potted twice a year at most, it will be sufficient; though, unless they make great progress, they will not require removing more than once a year, which should take place in summer, that they may have time to acquire good root again before winter. It has been propagated from layers and from cuttings, but these are long before they make roots, and the plants so raised are never so strong and thriving as those which arise from berries, the plants raised from which produce fruit in two years even in our climate, and much sooner in hot countries. In Arabia Felix the coffee-tree is raised from seeds sown in nurseries, and planted out there as is convenient. The plantations are in moist shady situations, on small eminences at the foot of the monntains, whence little rills of water are conducted in small channels to the roots of the trees, to secure the production and ripening of the fruit. When they remove or tran-plant a tree, they make a trench three feet wide, and five feet deep, which they line or cover with stones, that the water may the more readily sink deep into the earth, and be thereby prevented from evaporating. When the fruit is nearly ripe, the water is turned off, lest it should become too succulent. In places that are much exposed to the south, the coffee-trees are planted in regular lines, sheltered by a kind of poplar tree, which affords a thick shade. Without these precantions the Arabians suppose that the blossoms would be so parched by the excessive heat of the sun, as not to be succeeded by any fruit. The liquor which we call coffee, or coffea, prepared from the berry of this tree, has been drank in Ethiopia from time immemorial. The Galla, a wandering nation of Africa, in their incursions on Abyssinia, being obliged to traverse immense deserts, and desirous also of falling upon the Abyssinians unawares; in order that they may be encumbered with as little baggage as possible, carry nothing with them to eat, but coffee roasted till it can be pulverized, and then mixed with butter into balls, and put into a leathern bag. One of these, which is about the size of a billiard-ball, keeps them, according to their account, in better health and spirits during a whole day's fatigue, than a loaf of bread or a meal of meat. The coffee-tree was introduced into Aden in Arabia, from Persia, by Gemaleddin, only about the middle of the fifteenth century. Not long after it reached Mecca, Me-dina, and Grand Cairo, whence it continued its course to Damascus and Aleppo, and in 1554 became known at Constantinople, being introduced there by two persons, one from Damascus, and the other from Aleppo, each of whom opened a public coffee-house in that city. It is not certain at what time the use of coffee passed from Constantinople to the western parts of Europe; but it is probable that the Venetians, on account of the proximity of their dominions, and their great trade to the Levant, were the first acquainted with it; and Petro della Valle, a Venctian, in a letter from Constantinople, written in 1615, tells his friend, that upon his return he should bring with him some coffee, which he believes was a thing unknown in his country. The first European author who has mentioned coffee, is Rauwolf, who was in the Levant in 1573; but the first who has particularly described it, is Prosper Alpinus, in his Medicina Ægyptiorum, 1591, and in his History of Egyptian plants, 1592. The use attending the coffee-trees generally proceed either from being of coffee was known in London soon after the year 1652, for

338

Mr. Daniel Edwards, a Turkey merchant, brought home with him a Ragusan Greek servant, who understood the roasting and making of coffee. This Greek was the first who sold coffee, and kept a house for this purpose in George-yard, Lombard-street ; or, according to Mr. Houghton, who wrote in 1701, in a shed in the church-yard of St. Michael's, Cornhill, which is now, says he, a scrivener's brave house : he adds, that one Rastall, whom he knew, went to Leghorn in 1651, and there found a coffee-house; that he met Mr. Daniel Edwards there, with his Greek servant; and that Mr. Edwards was the first who brought the use of coffee into England, except it were the famous Dr. Harvey, who, some say, did frequently use it. Pasqua, who first sold coffee in London, being no freeman, the ale-sellers petitioned the lordmayor against him; which induced alderman Hodges, whose daughter Mr. Edwards had married, to join his coachman, Bowman, who was free, as Pasqua's partner; and thus Mr. Rastall found them in 1654. For some misdemeanour, Pasqua was forced to leave the country; and Bowman, by his trade, and a contribution of 1000 sixpences, turned the shed to a house. Bowman's apprentices were, first, John Painter, then Humphry, from whose wife Mr. Houghton first obtained the above minute account of the introduction of coffee into Lon-Two English travellers notice this beverage at the don. very beginning of the seventeenth century. Biddulph, in 1603, says, "The Turks have for their most common drink coff a, which is a black kind of drink, made of a kind of pulse like peas, called coava:" and William Finch, in 1607, says, "that the people in the island of Socotora have for their best entertainment a China dish of cobo, a black bitterish drink, made of a berry like a bay-berry, brought from Mecca, supped off hot," Lord Bacon mentions coffee in 1624; and Mr. Thevenot, the French traveller into the East, at his return in 1657, brought with him some coffee to Paris for his own use. It was, however, known at Marseilles in 1644, although Mons. du Tour, who wrote upon coffee in 1685, says, that the French knew nothing of it till 1645. The first mention of coffee in the English statute-books, occurred in 1660. Monsieur la Roque, who published his Journey into Arabia Felix in 1715, contends, that his father, having been with Monsieur de la Have, the French ambassador at Constantinople, did, when he returned to Marseilles in 1644, drink coffee every day; but he allows, notwithstanding, that Thevenot was the first who taught the French to drink it : however, until the year 1660, it was drunk by those only who had been accustomed to it in the Levant; but in that year some bales were imported from Egypt, and in 1671 a coffeehouse was opened at Marseilles; and it was not known at Paris till two years before, except among Mr. Thevenot and his friends, but in that year it was effectually introduced by Solyman Aga, ambassador from sultan Mahomet, and two years after Pascal, an Armenian, sold it publicly in the Foire St. Germain, and afterwards set up a coffee-house on the Quai de l'Ecole : but meeting with little encouragement, he left Paris, and came to London. Not long after this, spacious rooms were fitted up in an elegant manner for selling coffee and other refreshments at Paris, and in a short time the number of coffee-houses was increased to three hundred. In 1688 the celebrated naturalist Mr. Ray affirms, that London might rival Grand Cairo in the number of its coffeehouses, and that they were to be found not only in the capital, but in every town of note in England. Probably the illjudged proclamation of Charles II. against coffee-houses, in 1675, contributed much to establish them. In his history of plants, published also in the year 1688, Mr. Ray, speaking of coffee as a drink very much in use, supposes that the Arabs | the island of Mosambique.

destroyed the vegetable quality of the seeds, in order to confine their commodity to themselves, and adds, that he wondered the neighbouring nations did not contrive to bring away some sound seeds or living plants, in order to share in so lucrative a trade : this was soon done, for Nicholas Witsen, burgomaster of Amsterdam, and governor of the East India company, desired Van Hoorn, governor of Batavia, to procure from Mocha, in Arabia Felix, some berries of the coffeetree, to be sown at Batavia, which was accordingly done about the year 1690; and Van Hoorn having raised many plants from the seeds, sent one over to governor Witsen, who presented it to the garden at Amsterdam, where it bore fruit, which in a short time produced many young plants. From these, the East Indies, and most of the Europea ngardens have been supplied; and even in the year 1696 it had reached Fulham, where it was cultivated by bishop Compton. In 1714 the magistrates of Amsterdam presented Louis XIV. with . a coffee-tree, which was placed in the royal garden at Marli, under the care of the celebrated Jussieu, who had written a memoir, printed in the History of the Academy of Sciences for 1713, describing the characters of the genus, with a figure of it from a smaller tree, which he had received from the burgomaster of Amsterdam, and director of the botanic garden there. In 1718, the Dutch colony of Surinam began first to plant coffee; and in 1722, M. de la Motte Aigron, governor of Cayenne, contrived by an artifice to bring away a plant from Surinam, which in the year 1725 had produced many thousands. Rochon, in his account of Madagascar, asserts, that in 1718 the inhabitants of the Isle of Bourbon sent to Mocha and Aden for some young plants of the coffee-tree. which being carefully cultivated, in a few years became very productive, and soon afforded the French East India company a very important article of trade, until 1727, when perceiving that this acquisition might be of great advantage to their other colonies, they conveyed some of the plants to Martinico, whence it most probably spread to the neighbouring islands; for in the year 1732, it was cultivated in Jamaica, and an act was passed to encourage its growth in that island. The first plaut that appeared in that island was carried thither by Sir Nicholas Laws, and placed in the garden of Townwell, at present called Temple Hall, the property of Mr. Lutterell; but he dying in 1731, did not see the cultivation of it make any considerable progress. In the year 1752, the export of coffee from Jamaica was rated at 60,000 pounds weight, and in 1775, at 440,000: the abbé Raynal says, that 12,550,000 pounds weight is annually exported from Arabia Felix,

2. Coffea Occidentalis; Western Ceffre Trer. Flowers four-cleft, berries on-escedded. It is upricht, branching, and six feet high; leaves lanceolate-ovate, ending in a blunt point, quite entire, shining, petioled, opposite, only on the young twigs, four inches long; corolla white, very sweet-scented; the flowers appear in December-III is found near Cape François in St. Domingo, and is pretty common in the lower works of Jamaica, Where Brown calls it the wild jessa-mine, the flowers having much of the shape and smell of our white iamin.

3. Corlia Racemosa. Very much branched; leaves rugged; racemes terminating. This is a snall tree, only four feet high, with many diffused round branches; leaves ovate lancolate, quite entire, beset with many tubercles, opposite, on short petioles; flowers subterminating, in erect brachiate racemes; the common peduncle long, quadragular; the partial shorter, round, opposite, or stellate; berry roundish, small, red, watery, one-celled, with two hemispherical seeds.—Native of the island of Mosambique.

nerved. This is a small upright tree, six feet high, with thick short spreading branches; flowers white, axillary, several together on short one-flowered peduncles; border six or seven parted; berries red, oblong, ovate .- Native of Africa, on the coast of Zanguebar, and cultivated near Mosambique, with the preceding species.

COL

5. Coffea Guianensis. Fiowers four-cleft; berries small, violet-coloured, two seeded : stem branching, from one to two feet in height; branchlets quadrangular, knotty; flowers axillary, several together, small and white; stamina four; berry spherical, and violet-coloured .--- It flowers and fruits in September, and is a native of the great forests of Oxapu in Guiana.

6. Coffea Paniculata. Branches quadrangular; leaves ovate-oblong, acute; corollas four-cleft; berries two-seeded; trunk seven or eight feet high, and five or six inches in diameter, covered with a gray, wrinkled, cloven bark ; boughs opposite, branched, knotty, quadrangular; flowers terminating, panicled; corolla white, four-parted, very sweetscented; stamina four .- Native of Guiana; flowering and fruiting in April.

7. Coffea Sambucina. Leaves oblong-lanceolate, acute; cymes corymbed, terminating .- Native of the Friendly Islands in the South Seas.

8. Coffea Opulina. Leaves ovate-lanceolate; cymes contracted, globular, terminating .- Native of New Caledonia.

9. Coffea Odorata. Leaves ovate, acute ; cymes corymbed, axillary .- Native of Tanna, and the Friendly Islands.

10. Coffea Triflora. Leaves ovate-lanceolate, acuminate ; peduncles terminating, three together, one-flowered .--- Native of Otaheite.

Coixa; a genus of the class Monœcia, order Triandria .---GENERIC CHARACTER. Male Flowers : disposed in a loose spike. Calix : glume two-flowered, two-valved ; valves oblong-ovate, obtuse, awnless, the outer thicker. Corolla : two-valved; valves ovate-lanceolate, length of the calix, very thin, awnless. Stamina: filamenta three, capillary. Antheræ oblong, four-cornered. Female Flowers : fewer at the base of the male spike, on the same plant. Calix: glume two-flowered, two-valved; valves rounded, thick, shining, hard; the outer larger, shining. Corolla : glume two-valved; outer valve ovate, larger, inner narrower, smaller, both awnless. Pistil: germen ovate, very small; style short, two-parted; stigmas two, horned, longer than the flower, pubes-cent on every side. Pericarp: none; the outward calycine glume grows closely to the seed, it increases, grows shining, falls, does not gape. Seed: solitary, roundish, covered by the ossified calix. ESSENTIAL CHARACTER. Males: in remote spikes. Calix: glume two-flowered, awnless. Corolla: glume awnless. Female Calix : glume two-flowered. Corolla : glume awnless. Style : two-parted. Seed : covered by the calix, ossified .---- The species are,

1. Coix Lachryma; Job's Tears. Seeds ovate; culm six feet high, perennial, subcylindric, solid, jointed, erect, branched; leaves lanceolate, quite entire, long, wrinkled underneath, reflex, clasping; flowers axillary, on a long, slender, suberect, common peduncle, at the top many males, in a subovate spikelet, and at the base a solitary female; the two styles are capillary, and entirely distinct, with long villose stigmas .- Native of the East Indies. Those who wish to cultivate this plant in England, may procure the seeds from Portugal, and should sow them upon a moderate hot-bed in the spring, to bring the plauts forward, and afterwards transplant them on a warm border, allowing each two feet room the ripening of the seeds? As this plant blossoms late in the

4. Coffea Zanguebariæ. Corollas six-cleft; fruit angular, kept clean from weeds: they will flower about midsummer. and in warm seasons ripen seed at Michaelmas. There is a variety of this with much broader leaves, which was imported from Smyrna.

2. Coix Angulata. Seeds angular .- This grows to the height of seven or eight feet; the stems become hard, like the reed, or Indian corn, branching out, and producing several spikes of flowers. Native of America, and a perennial .- This species will not bear the open air in England, but must be plunged into the bark-bed, where it will flourish, and produce ripe seeds the second year, and may be continued longer if desired.

3. Coix Agrestis. Culm entirely simple; leaves smooth and even; seeds roundish; root perennial, creeping; leaves lanceolate-linear, acuminate, quite entire, suberect, alternate, clasping; peduncles long, erect, axillary, many-flowered; males and females from the same axil ; seed roundish, brown, shining, small - Native of Amboyna, Ceylon, and Cochin-china.

Colchicum ; a genus of the class Hexandria, order Trigynia. -GENEBIC CHARACTER. Calix : none, except scattered spathes. Corolla : six-parted ; tube augulated, rooted ; divisions of the border lance-ovate, concave, erect. Stamina: filamenta six, subulate, shorter than the corolla. Antheræ oblong, four-valved, incumbent. Pistil: germen buried within the root; styles three, thread-form, length of the stamina ; stigmas reflex, channelled. Pericarp : capsule threelobed, connected internally by a suture, obtuse, three-celled : sutures gaping inwardly. Seeds: many, nearly globalar, wrinkled. ESSENTIAL CHARACTER. Spathe. Corolla: six-parted, with a rooted tube. Capsule: three, connected. inflated. All the plants of this genus form a very suitable variety for a flower-garden, as they flower in antumn, when few other plants are in beauty. In May the leaves begin to decay, at which time the roots should be transplanted, for if they be suffered to stay in the ground till August, they will send forth fresh fibres, and after that it will be too late to remove them; the roots may be kept above ground till the beginning of August, and if not then planted, will produce their flowers as they lie out of the ground, which will greatly weaken their roots. For the manner of planting these roots, see Tulipa; and for sowing the seeds, see Xiphium. Whoever desires to obtain varieties in the flowers, must propagate them from seeds .---- The species are,

1. Colchicum Autumnale; Common Meadow Saffron. Leaves flat, lanceolate, erect. It has a bulbous root, about the size and shape of the tulip, but not so sharp pointed at the top ; the skin or cover is also of a darker colour : these bulbs are renewed every year, for those which produce the flowers decay, and new roots are formed above. The flowers come out in autumn, and rise with long slender tubes about four inches high from the root; these tubes are shaped like those of the saffron, but larger; and the number of flowers is generally in proportion to the size of the roots, from two to seven or eight; the green leaves appear in March, and are generally four in number to a full-grown root; they are folded over each other below, but spread open above ground. standing crossways; their colour is a deep green, and when fully grown they are five or six inches long, and one and a half broad : the seed-vessel comes out between the leaves in April, and the seeds ripen in May, soon after which the leaves decay; the seeds lie buried all the winter within the bulb; in spring they grow up on a fruitstalk, and are ripe about the time of hay-harvest. May not the very great length of the styles account in some measure for the delay in apart; when they have taken root, they only require to be year, and would not probably have time to ripen its seeds

may ripen at a considerable depth in the earth, out of the reach of the usual effects of frost; and as seeds buried at a certain depth are known not to vegetate, a no less admirable provision is made to raise them above the surface when they are perfected, and to sow them at a proper season .- This plant is a native of most parts of Europe. Mr. Miller observed it in great plenty in the meadows near Castle Bromwich in Warwickshire, in the beginning of September; and says, that the country people call the flowers naked ladies, because they come up without any leaves; a name they also apply to the hepatica, and indiscriminately to any plant which has flowers on naked scapes, appearing at different times from the leaves. It is also found near Derby and Northampton; Bury in Suffolk: in orchards on the borders of Malvern Chase, and the meadows under Malvern Hills, in Worcestershire; near Wallington and Hales-Owen, Shropshire; about Bath, Bristol, Warminster, Shepton Mallet, Southgate, and also near Comb in Oxfordshire, with a double flower, and some varieties of colour; besides some parts of Scotland, where however it is not very common. The following are the varieties most cultivated by the florists: 1. The meadow saffron, with white flowers; 2. meadow saffron with striped flowers; 3. broad-leaved meadow saffron; 4. striped-leaved meadow saffron; 5. many-flowered meadow saffron ; 6. meadow saffron with double purplish flowers ; 7. meadow saffron with double white flowers; 8. meadow saffron with many white flowers. Cattle will not eat it : in a pasture where there were several horses, and which was eaten down rather bare, not a leaf of the meadow saffron was bitten, although the grass was closely cropped even under the leaves. Notwithstanding the concurrent testimony of ages has coudemned this plant as poisonous, Dr. Stoerck of Vienna, has taught us that it is a useful medicine : the roots are very acrimonious, and an infusion of them in vinegar, formed into a syrup with the addition of sugar or honey, is found to be a very useful pectoral and diuretic. It seems to resemble squill very much in its virtues, but is less acrid and nauseous, though more sedative. Allioni, however, relates, that he has found the squill to be more safe and efficacious than the meadow saffron ; while Meyrick also informs us, " that, indiscreetly used, this root is poisonous, two drachms having killed a large dog after twelve hours of excessive torment: it operated violently by vomit, stool, and urine. A single grain only, being swallowed by a person in health, by way of experiment, produced heat in the stomach, and soon after flushings in various parts of the body, with frequent shiverings, which were followed by colic-like pains, after which he felt an itching in the loins and urinary passages, and soon after that a continual inclination to make water, with a tremor and pain in the head, great thirst, a very quick pulse, and other disagreeable symptoms: yet notwithstanding these effects, it is, when properly prepared, a safe but powerful medicine. The best way of preparing it is, to make it into a kind of syrup, by digesting an ounce of the fresh roots, sliced in a pint of white wine vinegar, over a gentle fire, for the space of forty-eight hours, and then mixing two pounds of honey with the strained liquor, and letting it afterwards boil gently until it becomes of a proper consistence : this syrup is agreeably acid, gently vellicates or bites the tongue, is moderately astringent, and excellent for cleansing the tongue from mucus : in an increased dose, it vomits and sometimes purges, but its most common operation is by urine, for which it is a remark ably powerful medicine; the dose at first should be but small, half a tea-spoonful twice or thrice a day is enough to begin with, and the quantity may afterwards be gradually 29.

before winter, Providence has so constructed it that they increased, as the stomach will bear it for the case may require, may ripen at a considerable depth in the earth, out of the increased, as the stomach will bear it for the usual effects of frost; and as seeds buried at a excit of the usual effects of frost; and as seeds buried at a excit of the usual effects of the overathe, a no less adminable pectorant when all other means fail.

COL

2. Colchicum Montanum. Leaves linear, spreading very much. The leaves of this species come up soon after the flowers decay, and continue green all the winter, like the saffron; they are long, narrow, and spread on the ground, decaying in June; the flowers, which appear earlier than the common sort, are of a reddish purple colour, and come forth in August and September.—Native of Spain, Portugal, Italy, the south of France, and Switzerland.

3. Colchicum Variegatum; Variegated Meadow Saffron. Leaves waved, spreading, for the most part three in unmber, and of a pale and fresher green colour than the common sort, broad at the bottom, a little pointed at the end, waved about the edges, and lying close upon the ground; root not so large as that of the common sort; flowers smaller, but very beautiful, whiths, with deep blue or purple spots. It flowers late, frequently not till October or November, and is somewhat tender.—Native of the Greek islands.

Coldenia ; a genus of the class Tetrandria, order Tetragpria.--GENERIC CHARATER. Caliz: perianth fourleaved; leaflets lanceolate, erect, length of the corolla. Corolla: one-petilled, funnel-form, (with the opening pervious;) border patulous, obtuse, (four-lobed.) Stamina; filamenta four, inserted into the tube. Authers roundish. *Pistil*: germina four, ovate; styles as many, capillary, length of the stamina; stigma simple, peramanent. *Pericarp:* none; froit ovate, compressed; scabrous, acuminate, terminated by four beaks. Scade: two, muricate, two-celled. ESENTIAL CHARACTER. Caliz: four-leaved. Corolla: funnel-form. Styles: four, Seeds; two-celled. Style: one, with a bild stigma. Nuts: four, with a fungous rind.--One species only is known,

Î. Coldema Procumbens. An annual plant, the branches of which trail on the ground, extending nearly a foot from the root, and dividing into many smaller branches; corolla cot into foor segments at the top, of a pale blue colour, and very small.—Native of the East Iudies. This plant is propagated by seeds, which must be sown upon a buched in the spring; and when the plants are fit to remove, they should be each put into a separate small pot, plunged into a hot bed of tanner's bark, observing to shade them until they have taken fresh root, after which they should have air admitted to them every day in proportion to the warm tho of the season, and gently watered two or three times a week in warm weather, but they must not have too much moisture: they require always to remain in the hot-bed, where they will flower in June, and ripen seed in September.

Coleworts. Coleseed.

leseed. See Brassica.

Colliflower.

Collimonia ; a genus of the class Diandria, order Monogonia.–GENERIC CHARATCER. Coil:: perianth oneleafed, tubular, two lipped, upper lip three-cleft, reflex, wider, lower lip two-parted, morcerect, subulate, permanent. Corolla: on-opetalled, uncqual; tube funnel-furm, many times longer than the calis; borders five-cleft; upper divisions obluse, very short, the two upper ones reflex; lower lip longer, manycleft, capillar. Stanina; clinemat two, bristle-form, ercet, very long. Anthere sim, le, incumbent, compressed, obluse. Pisill: germen four-cleft, olitue, with a larger glandule 'sing below the germen; style bristle-form, length of the simmin, included to one side; stigma bridi, acate. Pericarp: none; calix cherishes the sceds in its bottom, and is 45 ESSENTIAL CHARACTER. Corolla: unequal. Calix: of lose; seeds nestling. It is said to be subparasitical .-- Nathe fruit one-leafed, toothed, of the flower bifid. Seed: one tive of the Caribbee islands, Martinico, and Guiana, in moist under the calix of the flower .---- The species are,

COL

Leaves ovate, both they and the stems smooth. It has a perennial root, and attains to the height of four or five feet in America, but seldom grows above three feet high in England; the stalks decay in the autumn, and fresh shoots come out in the spring ; they are square, with heart-shaped leaves, opposite, and serrate; the flowers are produced at the extremity of the stalks, in loose spikes, they are of a purplish yellow, and appear in July; the seeds ripen in autumn; one seed only in general attains to maturity, the others being almost always abortive; this is globose, ash-coloured, obscurely reticulated with dusky veins .- Native of North America, in Pennsylvania, in little woods among bushes, in a rich soil in about 43. 15, north latitude, Mr. Barton was the first who discovered and sent it to Europe : it has a peculiar and very strong, but agreeable scent, and is reputed to be an excellent remedy against pains in the limbs, and a cold, if the affected parts be rubbed with it : a decoction of it is also said to have cured the bite of the rattlesnake; the Americans call it horseweed, because the horses eat it in the spring before any other plant comes up. It may easily be propagated by parting the roots in October; they should be planted at three feet distance, for they require much nourishment to make them thrive, which they will do in the open ground, if planted in a sheltered situation : unless, however, it be kept warm and duly watered, it seldom flowers well: therefore many persons keep them in large pots, but these very rarely produce good seeds ; whereas those which stand in the full ground, and are regularly watered, will ripen seeds very well in good seasons.

2. Collinsonia Scabriuscula; Rough-stalked Collinsonia. Leaves ovate, subcordate, somewhat hairy; stem somewhat hairy, scabrous .--- Native of East Florida : perennial.

Columbine. See Aquilegia.

Columnea; a genus of the class Didvnamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-parted, subventricose at the base ; divisions erect, equal, lanceolate, permanent. Corolla: one-petalled, ringent, villose; tube long, gibbous above at the base; border twolipped; upper lip straight, emarginate; lower lip threeparted; lateral divisions lanceolate, the intermediate longer and more deeply separated, lanceolate. Stamina : filamenta four, of which the two longer are hid under the upper lip. Antheræ simple, connected into a little crown. Pistil: germen ovate; style filiform, length of the upper lip; stigma bifid, obtuse. Pericarp : capsule two-celled, ovate ; seeds numerous, small, lying on a very large receptacle. ESSEN-TIAL CHARACTER. Calix : five-parted. Corolla : ringent, upper lip three-parted, the middle part vaulted, emarginate, gibbous above at the base. Antheræ connected; capsule two-celled. Seeds: nestling .- As all these plants are natives of hot countries, and in general of the West Indies, they are too tender to live in England out of a stove. They are pro-pagated by seeds sown in a good hot-bed, and when the plants come up they must be treated in the same way as other tender exotics which are kept in the bark-stove .---The species are,

1. Columnea Scandens; Climbing Columnea. Leaves ovate, acute, entire, subvillose; leaflets of the calix entire; with winged leaves, composed of four or five pairs of oval corollas and calices pubescent, upper lip undivided; stem lobes, placed opposite, terminated by an odd one; these are scandent; root angular, striated, succulent, brittle, somewhat indented at the top in form of a heart, and are of a grayish hirsute; leaves petioled, opposite, small, scarcely nerved; colour. From the wings of the leaves come out slender

ringent, with an irregular mouth. Seed : single, globose. Ifowers peduncled, solitary, axillary, blood-red, somewhat vilparts of woods at the foot of the mountains. The columnea 1. Collinsonia Canadensis ; Nettle-leaved Collinsonia, with a yellowish flower is only a seminal variation.

2. Columnea Longifolia; Long-leaved Columnea. Leaves ovate, acuminate, serrate, roughly hairy on the upper surface; calycine leaflets toothletted, lanceolate; they and the corollas hirsute, the upper lip bifid; stem herbaceous, erect, two feet high, four-cornered; branches axillary, quite simple, opposite .- Native of the East Indies.

3. Columnea Hirsuta; Hairy Columnea. Leaves ovate, acuminate, serrate, roughly hairy on the upper surface, calycine leaflets toothletted, lanceolate; they and the corollas hirsute, the upper lip bifid,-This beautiful vegetable is a native of the cooler mountains of Jamaica; it is very succulent, and grows luxuriantly in every rich and shady soil, throwing its branches frequently to the height of four or five feet, and higher when supported: the stem is moderately thick ; the leaves opposite, and alternately longer ; the flowers are large, beautifully variegated and hairy on the outside, like the other parts of the plant; the divisions of the calix are pinnated, somewhat like those of the garden rose. It has an uncommon appearance, and is highly worthy of cultivation: it flowers in November.

4. Columnea Hispida. Leaves ovate, obtuse, toothletted, hispid-hirsute; leaflets of the calix lanceolate, entire, hairy; stem hairy, rugged .--- Native of Jamaica.

5. Columnea Rutilans. Leaves ovate-lanceolate, villose, toothletted; leaves of the calix jagged; corollas villose, the upper lip two-parted .--- Native of Jamaica.

6. Columnea Stellata. Leaves stellate; flowers solitary; stem creeping, herbaceous, perennial, round, slender, whitish; branches suberect, four inches long, very tender; flowers white, striped with red, hirsute, axillary, peduncled. It is an aquatic plant, of a very pleasing appearance and agreeable smell, and being emollient and cooling, it is used as a wash by the women.-Native of Cochin-china, where it is cultivated in pots and tubs filled with water, having earth at the bottom.

Colutea ; a genus of the class Diadelphia, order Decandria. -GENERIC CHARACTER. Calix: perianth one-leafed, bell-shaped, five-cleft, erect, nearly equal, permanent. Corolla: papilionaceous. Standard, wing, and keel, differ in figure and various proportion; the wings are pressed close together, lanceolate. Stamina : filamenta diadelphous, sin-gle, and nine-cleft, ascending. Antheræ simple. Pistil : germen oblong, compressed, attenuated to each end; style ascending; stigma is a bearded line, extended from the middle of the style to its tip, from the upper part. Pericarp : legume very large, very broad, inflated, transparent, and membranaceous, the upper suture erect, the lower gibbous, one-celled, gaping on the upper suture at the base. Seeds: several, kidney-shaped. ESSENTIAL CHARACTER. Calix: five-cleft; legume inflated, gaping on the upper su-ture at the base. The plants of this genus are, in general, easily distinguished by their membranaceous inflated pod. The species are,

1. Colutea Arborescens; Common Bladder-Senna. Leaflets oval-obcordate; standard gibbous, abbreviated. This species has several woody stems, which attain to the height of twelve or fourteen feet, sending out many woody branches, with winged leaves, composed of four or five pairs of oval

CONVALLARIA POLYGONATA.

COLUTEA_Pococke's Bladder Senna.

yellow flowers, whose standard is reflexed and large, with a dark coloured mark in it. In England it flowers from June to August. It is a native of the south of France, of Italy, and the warmer parts of Switzerland, and of Carniola. Mr. Ray observed it about Montpellier, and in many parts of Italy, especially on Mount Vesuvins, even in the ascent to the crater itself, where there were scarcely any other plants. The leaves are recommended as answering all the purposes of senna; and Allioni has given particular directions for the preparation of them, as a larger dose of them seems to be required, to produce the same effect. The seeds, in the quantity of a drachm or two, occasion vomiting, but the plant itself is said to afford grateful food for cattle. This, and the second and third species, are very hardy shrubs, which thrive extremely well in the open air, and are generally propagated for sale in the nursery gardens. They are all propagated by sowing their seeds any time in the spring, in a bed of common earth, keeping them clear from weeds when they come up, and transplanting them at the Michaelmas following, either into nursery rows, or into the places where they are intended to remain; for if they be suffered to grow too long in the seed-bed, they are very subject to have downright roots, which render them unfit for transplantation ; nor should they be suffered to remain too long in the nursery before they are transplanted, for the same reason. The first sort growing to the height of twelve or fifteen feet, is very proper to intermix with trees of a middling growth in wilderness quarters, or in clumps of flowering trees, where the singularity of their flowers and pods will make a pretty variety, especially as these trees usually begin flowering by the end of May, and are seldom, especially species, destitute of flowers until September. Mr. Curtis has learned by experience, that a very wet soil proves fatal to the common bladder-senna. The earwigs also, finding a commodious retreat within the bladders, are very destructive to the seeds. Mr. Miller therefore recommends the hanging lohster-claws, or bowls of tobaccopipes, on the shrubs, to entice the insects. The third species does not grow so tall as the common, but makes a more regu-lar shrub, and is less liable to split. The flowers of this sort being of a dusky red colour, spotted with yellow, it makes a very pretty variety, and is as hardy as the common sort, and may be propagated by seeds in the same manner. It sends forth many suckers, by which it may also be increased ; but the seeds are much to be preferred.

2. Colutea Cruenta; Oriental Bladder-Senna. Shrubby: Reflets wedge-form, obcordnets; standard gibbous, obtuse, very small. This has a woody stem, which sends out many branches on every side, which does not rise above seven or eight feet high. The leaves are composed of five or six pairs of small heart-shaped leaflets, terminated by an odd one. The dowers proceed from the side of the branches, standing upon peduncles, each sustaining two or three flowers, of a dark-red colour, marked with yellow; which appear in June, and the seeds ripen in autumn.—Discovered by Tournefort in the Levant. See the first species.

3. Coluten Pocockii; Pococki: Bladder-Senna. Shrubby; i elafts ovare; standard gibbous, clongated, ascending. This shrub seldom exceeds six or seven feet high in England. The branchesare very slender, and much more pliant than the common sort. The flowers also appear a month earlier, and are of a brighter yellow; and as there is a succession of them till late in the autumn, and they are not so liable to be detroyed by the strong winds in summer, the value of this species in much increased.—Native of the Levant. Dr. Ruspel, who resided many years at Aleppo, reports, that this

peduncles, ahout two inches long, each sustaining too or three | shrub is very common in the neighbourhood of that city, yellow flowers, whose standard is reflexed and large, with a See the first species.

4. Colutea Frutescens; Scarlet Bladder Senna. Shrubby: leaflets ovate, oblong. This is a hoary shrub, with tomentose leaflets, smooth on the upper surface; standard of the corolla shorter than the keel; wings very minute; height from two to four feet : in favourable seasons, and in a warm situation, plants of three years' standing will be six feet high, with large heads, and all the branches covered with flowers, making a very fine appearance. Those plants, however, which are exposed to the air, seldom last beyond two years, and are generally destroyed in severe winters; but they make much stronger plants while they last, and produce a greater number of flowers than those which are housed. They appear in June, are of a fine scarlet colour, intermixed with silvery leaves, affording an agreeable variety.-Native of the Cape of Good Hope. This is tender, and cannot endure the open air in severe English winters. In moderate weather, if planted in a dry soil and a warm situation, they will survive that season, even in the open air, and in that case will flower much stronger, and make a finer appearance, than those which are preserved in the green-house, which should always be placed as near as possible to the window, to have all the air they can receive. It is propagated by seed sown early in the spring, upon a warm border of light earth. The plants will flower in August, and ripen seeds very well in favourable autumns; but if the seeds be sown upon a hot-bed in the spring, the flowers will appear as early as July, which gives them a fine opportunity for ripening their seed during the hot weather. They must never be transplanted, except while young, for when they are grown large they will not bear removing. In a well-sheltered situation, they will sometimes live in the open air for three or four years, growing to have large heads, which make a very fine appearance when they are in flower, and the flowers of which also continue much longer in beauty than those produced by plants which have been more tenderly treated.

5. Colutea Perénnis; Perennial Bladder-Senna. Herbaccous: leaftes ovato-blong, pubescent: root perennia; stems erect, round, striated, pale green, annual, quite single, or with almost barren branchlets; flowers small, and without scent; corolla flesh-coloured.—It flowers in August, and is a native of Africa.

G. Colutea Herbacea; Annual Bladder-Senna. Herbaceous : leafter linear, smooth, annual; corollas dark blood-red, with a striated standard, the length of the wings and keel; stem a foot and a half high, and alender, dividing at top into three or four branches.—Native of the Cape of Good Hope. It is a low annual plant, which seldom grows more than a foot and a half in leight: the flowers are small, and having but little beauty, are seldom preserved but in botanic gardens. The seeds of this sort must be sown upon a moderate hor-bed in the spring, and the plants put and up flow grows rule so any upon a moderate hor-bed in the spring, and the seeds will soon after the second will rope in Soptember, and the second will soon after decay.

Colutea Fistulosa. Herbaceous: leaflets ovate, complicate, pubescent underneath; stems angular, striated, fistulous, flowering the second year; calix pubescent; corolla small, whitish or red, with blood-red streaks.

8. Colutea Americana. Shrubby: leaflets ovate, emarginate; legunes oblong, compressed, accuminate. It has a shrubby stalk, rising to the height of fourteen feet; the flow, ers are of a bright yellow. It will not bear the open air in England, but is propagated by seeds sown on a hot-bed in the spring; and when the plants are two inches high, they

should be each transplanted into a separate small pot filled with light earth, and plunged into a hot-bed of tanner's bark, observing to shade them till they have taken fresh root, after which they must be treated in the same way as other plants from the same climate, always keeping them in a stove, which should be of a moderate temperature .-- Native of Vera Cruz in New Spain.

9. Colutea Procumbens. Stems trailing; leaflets ovateoblong, tomentose ; flowers axillary, on very long peduncles. This species has many slender woody stems, which trail on the ground, and are divided into many smaller branches. The flowers are very small, of a purple colonr, and stand three or four together, upon very long slender peduncles : they appear in June and July, and ripen seeds in autumn .-Native of the Cane of Good Hone.

Comarum ; a genus of the class Icosandria, order Polygynia .- GENERIC CHARACTER. Calix : perianth oneleafed, ten-cleft, very large, spreading, coloured, alternate; divisions smaller, inferior, permanent, Corolla : petals five, oblong, acuminate, three times smaller than the calix on which they are inserted. Stamina: filamenta twenty, subulate, inserted in the calix, length of the corolla, permanent. Antheræ lunular, deciduous. Pistil: germina numerous, roundish, very small, collected into a head; styles simple, short from the side of the germen; stigmas simple. Pericarp ; none : common receptacle of the seeds ovate, fleshy, very large, permanent. Seeds : numerous, acuminate, covering the receptacle. ESSENTIAL CHARACTER. Calix: tencleft. Petals: five, smaller than the calix. Receptacle: of the seeds ovate, spongy, permanent .---- The only known species is.

1. Comarum Palustre ; Marsh Cinquefoil. This plant has creeping woody roots, which send out many black fibres, penetrating deep into boggy ground; stems many, herbaceous, about two feet high, generally inclining to the ground : at each joint is one leaf, composed of five, six, or seven leaflets. The petals are not more than a third part of the size of the calix .- Native of most parts of Europe, on boggy ground. A few plants grow upon a bog at Hampstead; but the nearest place to London where it grows wild in plenty, is in the meadows near Guilford in Surry. It is found at Selburne in Hampshire, near Bromsgrove Lickey in Worcestershire, Gambingay in Cambridgeshire, in Norfolk, near Colchester in Essex, Giggleswick Tarn near Settle, and also in Scotland, and Ireland. It flowers in June. The roots dye wool of a dirty red colour; and have astringency enough, with other plants of the same order, to tan leather. The Irish rub their milk-pails with it, to make the milk appear thicker and richer. Goats eat it. Cows and sheep are not fond of it. Horses and swine refuse it. There is a variety with thicker and more villose leaves, which grows plentifully in the north of England, and in Ireland; but after one year's growth in a garden, it cannot be distinguished from the common sort. As this plant is a native of bogs, it cannot well be preserved in a garden, except it be planted in a soil resembling that in which it naturally grows. The roots may be removed from the place of their growth in October, and will be in no danger of failing, if they be planted in boggy ground.

Combretum ; a genus of the class Octandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, superior, bell-shaped, four or five-toothed, deciduous. Corolla : petals four or five, ovate, acute, inserted into the calix, and scarcely longer than it. Stamina: filamenta eight or ten, bristle-form, erect, very long; antheræ a little oblong. Pistil: germen inferior, linear; style bristle-form, length of the stamina; stigma acute. Pericarp: none, ex- three, cross-shaped, pedicelled. Every species of this genus

cept the crust of the seed. Seed : single, four or five-angled; angles membranaceous, acuminate. ESSENTIAL CHARACT TER. Caliz: four or five-toothed, bell-shaped, superior Corolla: four or five-petalled, inserted in the calix. Stamina : very long. Seed : one, four or five angled ; the angles membranaceous.-This genus is very imperfectly known, and being a very fine one, deserves the attention of those who cultivate exotic plants .---- The species are,

1. Combretum Laxum. Spikes lax; leaves opposite. It is a shrub with round scandent branches, the younger ones brachiate ; spikes erect, three inches long, axillary, and terminating; flowers small, whitish, on very short pedicels,-Native of the West Indies.

2. Combretum Fecundum. Spikes in one row : leaves onposite. A small tree twelve fect high, supporting itself on other trees by its round and very long branches; flowers very numerous, with scarcely any scent, yellowish green colour, except the antheræ, which are red, all turned upwards and erect, altogether appearing like a crest. The broken branches and the bruised leaves have a fetid and very unpleasant smell .- Native of Carthagena in South America, and also of Guiana.

3. Combretum Purpureum. Leaves ovate-oblong, both they and the calices naked ; spikes simple, directed one way, This is a smooth shrub, with round brachiate branches; flowers copious, scattered; corolla purple; seed roundish, retuse, very smooth, of a shining golden colour .- Native of the East Indies.

4. Combretum Decandrum. Leaves alternate ; flowers ten-stamined. This is a weak branching shrub, climbing to twenty feet in height, with prickles on the older branches; pedicels very short; flowers small and very numerous, coming out usually before the leaves .- Native of Carthagena, flowering in May and June, and fruiting in July and August.

Cometes ; a genus of the class Tetrandria, order Monogynia .-- GENERIC CHARACTER. Calix: involucre threeflowered, (flowers sessile,) four-leaved ; leaflets oblong, equal. spreading, ciliate-hispid; perianth four-leaved; leaflets oblong, equal, length of the involucre ; corolla none. Stamina : filamenta four, capillary, length of the perianth; antheræ roundish. Pistil : germen roundish ; style filiform, length of the flower; stigma three-cleft. Pericarp: capsule tricoc-COUS. Seed: solitary. ESSENTIAL CHARACTER. Involucre four-leaved, three-flowered. Calix : four-leaved. Capsule : tricoccous .---- The only known species is,

1. Cometes Alterniflora. Stems herbaceous, a foot high, round : leaves opposite, sessile, obovate, acuminate, very entire, smooth; peduncles axillary, alternate, solitary, oneflowered, patulous, the length of the leaves .- Native of Surat.

Comfrey. See Symphytum.

Commetina ; a genus of the class Triandria, order Monogynia .- GENERIC CHARACTER. Calix: spathe cordate, converging, compressed, very large, permanent. Corolla: petals six, of which the three exterior are small, ovate, concave, resembling a perianth ; the three inferior alternate, very large, roundish, coloured ; nectaries three, resembling stamina seated on their proper filaments, cruciform, horizontal. Stamina : filamenta three, subulate, reclined, agreeing in figure and circuit with the filamenta of the nectary, but inferior to them ; antheræ ovate. Pistil : germen superior, roundish; style subulate, revolute, length of the stamina; stigma simple. Pericarp : capsule naked, nearly globular, three-furrowed, three-celled. Seeds: two, angulated. Es-SENTIAL CHARACTER. Corolla: six-petalled. Nectary:

** With three Petals larger.

* With two Petals larger.

 Commelina Communis; Common American Commelina, Corollas unequal; leaves ovate-lanceolate, acute; stem creeping, smooth, annual, having several trailing stalks, that put out roots at the joints; flowers axillary, two or three to gether, on short peduncles; corolla composed of two large blue petuls, and four small green ones; leaves resembling those of sopresert. It flowers in June and July, and the seedsripen in autumn,—Native of America, the West Indies, and Africa.

2. Commelina Africana; African Commelina. Corollas unequal; lexces hancolate, smooth; stem prostnet; root fibrous; stalks many, trailing, three feet long, putting out roots at every joint; so that it will cover a large surface, where it has room to spread; flowers of a deep vellow colour, —Native of Africa. It seldom ripens seed in England; but the roots send out offsets, by which it is easly propagated; but it is too tender to live in the full ground in winter, anless placed in a varm sheltered situation : it should therefore be plated in pots, and sheltered under a common frame in winch, and part these roots, is by the end of March: if they phated in pots, and they cared in the bark-stove in autumn, they will seldom fail to succeed. It flowers in July, and ripens seed in autumn.

3. Commelina Benghalensis; East India Commelina. Corollas unequal; leaves ovate, obtuse; stem creeping; root annual; leaves, before they are open rolled in, from an inchto an inch and a half in length, nerved, pubescent, waved ; peduncle within the spathe double, one slender, longer, oneflowered, the other thicker, channelled, bearing from two to four flowers, on jointed, round, inflex pedicels. The two inner petals very large, blue, the four outer pale blue; nectaries vellow .- Native of Bengal and Cochin-china. This, like all the other species of this genus, except the first, second, and sixth, are so tender that they will not grow unless sown upon a moderate hot-bed in the spring, and must be trans-planted to a moderate hot bed when they are two inches high, in order to bring them forward. When they have again taken root, a large share of fresh air should be admitted to them every day in warm weather, to prevent their growing weak. In June they may be taken up carefully, and transplanted into a border of warm light carth, observing to shade them until they have taken fresh root; after which they will require no further care but to keep them clean from weeds. With this management, the plants will flower, and produce good seeds.

4. Commelina Erecta; Upright Virginian Commelina. Corollas unequal; leaves ovate-lenceolate; stem a foot and a half high, lawing a single leaf at each joint, shaped like those of the first sort, and embraning the stem; followers axillary, at the upper part of the stalk, on short peduncles; petals blue. Nature and the stalk, on short peduncles; petals blue.

-- Native country unknown. See the preceding species. 29. 5. Commelina Virginica. Corollas nearly equal; leaves lanceolate, subpetioled, bearded on the edge; stems upright, simple, glossy, two feet high; spathes terminating, subcordate; flowers blue, with the petals cordate, and very entire; the lower one on a short pedicel.—Perennial, and a native of Virginia. See the third species. 6. Commelina Tuberosa; *Tuberons-rooted Commelina*.

Corollas equal; leaves sessile, oval-lanceolate, subciliate. This has a thick fleshy root, composed of several tubers, somewhat like those of ranunculus, several joining together at the top, where they form a head, and diminish gradually downward; thence arise one or two inclining stalks, which put out side-branches from their lower parts. The flowers are axillary towards the upper part of the stalk, on slender peduncles .- It is said to grow in the mountains of Mexico; and the natives apply it externally for discussing tumors, and internally in hot plethoric habits: it was also sent to Mr. Miller, by Dr. Houstoun, from Vera Cruz in New Spain. If the roots of this species be taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the spring, placing them in a hot-bed, to forward their shooting, whereby they will become stronger plants than those which rise from seeds.

7. Commelina Zannonia; Gextian-leared Commelia. Corollas equal; peduncles thickened; leaves lanceolate; sheaths swelling, birsute about the edge; bractes in pairs. This has trailing statks, embraced by narrow grassy leaves. The flowers are produced at the ends of the stalks, upon thick peducles, which generally have three on each. The corolla has thrce, equal, large, sky-blue petals, and three smaller which are grene. It flowers from June to August, but does not perfect seeds in England.—Native of the West Indies. See the third species.

8. Commelina Vaginata. Corollas equal; leaves linear; flowers two-stamined, sheathed with an involuce, annual; stems ascending, numerous, somewhat scabrous; antherae yellow, spotted with black.—Found by Kenig in the East Indies. See the third species.

9. Commelina Nutifiora. Corollas equal; peduncles capillary; leaves linear; involucre none; flowers two-stamined, annual; stem somewhat erect, decumbent at the base, somewhat scalroux, a spax in height; flowers from four to six, pedicelled, (without any involucre,) nodding.—Found by Kenig in dry nastures of the Fast Indice. See the third species.

in dry pastures of the East Indies. See the third'species, 10. Commelina Spirate; Spear-traved Commelina. Corollas equal; teaves hanceolate; flowers panicled, annual; stem creeping, ascending, somewhat seabrons. The style and stigmas arc spirally convolved, and evolved variously.—Observed near brooks, and in moist places in the East Indies, It flowers in July and August. See the third species. 11. Commelina Cucullata. Corola unequal, two-petalled;

 Commelina Cucullata. Corolla unequal, two-petalled; leaves ovate; involucres, cowled, turbinate; stem erect, a span high, creeping at the base, with filiform roots; flowers peduncled, minute.—It is a weed in the gardens of the East Indies, and Cochin-china. See the third species.

12. Commelina Japonica. Leaves ovate-inuccolate, waved; stem creet, angular, hairy; flowers panicled; stem grooved, erect, hairy, panicled at top, a foot high; flowers on the panicled branches in racemes.—Native of Japan. See the third species.

Commersonia : a genus of the class Pentandria, order Pentagvnia.—GENERIC CHARCTER. Cohie: periath oneleared, five-parted, corolliferous; divisions ovate, acute, Corolla : five-petaled: petals linear, dilated at the base on both sides, with an inflected lobe, spreading ; nectary five-4 T parted, within the stamina; divisions lanceolate, erect, shorter than the petals: corpuscles filiform, five, villose, from the divisions of the nectary. Stamina : filamenta five, very short at the bases of the petals; antheræ roundish, twin, Pistil: germen globular, villose, with five swellings; styles five, filiform, approximating, short; stigmas globular. Pericarp : capsule globular, five-celled, echinate, with long hairy bristles : cells two-seeded. Seeds : ovate. ESSEN-TIAL CHARACTER. Calix: one-leafed, bearing the corolla. Petals: five. Nectary : five-parted ; capsule five-celled, echinate .---- The only known species is.

1. Commersonia Echinata. A tree with alternate, obliquely ovate, acuminate, serrate leaves, hoary underneath ; flowers minute, panicled, hoary .- Native of Otaheite, and the other Society Isles.

Comocladia ; a genus of the class Triandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, three-parted, spreading, coloured : divisions roundish. Corolla: petals three, ovate, acute, flat, very spreading. Stamina : filamenta three, subulate, shorter than the corolla : antheræ roundish, incumbent. Pistil : germen ovate ; style none; stigma obtuse, simple. Pericarp: drupe oblong, crooked, marked above with three dots. Seed : nut membranaceons, the figure of the drupe. ESSENTIAL CHARACTER. Calix : three-parted. Corolla : three-parted ; drupe oblong, with a two-lobed nucleus .- These plants are propagated by seeds, which can only be obtained from those countries where they naturally grow, and should be sown in pots, and plunged into a hot-bed; when they are fit to remove, they must be each planted in a small pot, and plunged into a tan-bed, and in the autumn into the bark-bed in the stove, where they must be treated as other tender plants .---- The species are,

1. Comocladia Integrifolia. Leaflets entire. It seldom exceeds twenty feet in height ; trunk erect, dividing into few branches, adorned at the end with pinnated smooth leaves, like a frond ; flowers very numerous, small, sessile, scentless, of a deep-red colour : many of them have the calix and corolla four-parted, with four stamina. The whole tree abounds in a watery and slightly glutinous sap, which grows black in the air, and stains the hands so deeply with black, that it can scarcely be washed out. The fruit is eatable, but not inviting ; and the wood is hard, of a fine grain, and reddish colour .--Native of Domingo and Jamaica, where it flowers in December, January, and February. 2. Comocladia Dentata. Leaflets spiny-toothed; leaflets

from six to ten, oblong, acuminate, spiny-toothed, veined at the back, and subtomentose ; juice milky, glutinous, turning very black, not to be washed out from the skin or cloth. If the tree be ever so slightly wounded, it has a strong smell of dung .- Native of Cuba, where the inhabitants imagine it to be dangerous to sleep under it.

3. Comocladia Ilicifolia. Leaflets angular, spiny ; flowers racemed .- Native of the West Indies.

Composts. See Manures.

Comptonia; a genus of the class Monœcia, order Triandria. -GENERIC CHARACTER. Male Flowers. Calix : ament cylindric, loosely imbricate all round with concave, kidneyform, acuminate, caducous, one flowered scales; perianth two-leaved; leaflets equal, boat-shaped, shorter than the scale of the ament. Corolla: none. Stamina : filamenta three, shorter than the calix, forked ; antheræ six, twovalved. Female Flowers. Calix : ament ovate, closely imbricate all round with one-flowered scales, as in the male ; perianth six-leaved; leaflets opposite, in pairs, filiform, membranaceous at the base, many times longer than the scales of the ament. Corolla ; none. Pistil : germen guished by its large and spotted stalk, by the dark and shin-

roundish; styles two, capillary. Pericarp : none. Seed : nut-oval, one-celled, valveless. ESSENTIAL CHARACTER. Male Ament. Calix: two-leaved. Corolla: none. Antheræ: two-parted. Female Ament. Calix : six-leaved. Corolla ; none. Styles ; two, Nut ; ovate .---- The only known species is,

1. Comptonia Asplenifolia : Fern-leaved Comptonia. It rises with slender shrubby stalks, which are hairy, and divided into several slender branches, nearly to the height of three feet. The aments of male flowers come out on the side of the branches between the leaves; they are oval, and stand erect. It flowers in England from March to May, and is a native of North America, among firs, in the county of Lancaster, and on the banks of Northampton river. When planted in a loose moist soil, it thrives very well, sometimes creeping at the roots, and sending up suckers plentifully, as in its native country. It may be propagated by these suckers. and will endure English winters very well.

Conferva, or River-weed; a genus of the class Cryptogamia, order Algæ .- GENERIC CHARACTER. Simple, uniform, hair-like, thread-shaped fibres, which are either continuous or jointed. ESSENTIAL CHARACTER. Enequal tubercles, in very long capillary filamenta. Linneus specifies twenty-one species in his system of vegetables, and Dr. Withering has forty-nine, which are natives of England, in his third volume of the Botanical Arrangement of British Plants. published in 1792. A singular instance of irritability has been observed by Major Velley in the conferva corollina, upon its being immersed, when quite recent, into fresh water ; after it had been in the water a few minutes, several fibres were observed to move in an horizontal direction, with a quick convulsive twitch, and to stop suddenly: this they continued to do for some length of time; and the same effect may be produced several times, provided the plant be fresh, The experiment does not succeed in salt water.

Conium ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : umbel universal, with many spreading rays; partial similar. Involucre universal: many-leaved, very short, unequal; partial halved, threeleaved ; perianth proper, scarcely observable. Corolla : universal, uniform; proper of five petals, inflex, heart-shaped, unequal. Stamina : filamenta five, simple ; antheræ roundish. Pistil: germen inferior ; styles two, reflex ; stigmas obtuse. Pericarp: none; fruit nearly globose, five-streaked, the streaks notched, bipartile. Seeds: two, convex on one side, almost hemispherical, striated, flat on the other side. ESSENTIAL CHARACTER. Partial involucre : halved, three-leaved. Fruit: nearly globular, five-streaked, notched on each side .- The species are,

1. Conium Maculatum ; Common Hemlock. Seeds striated ; root biennial, resembling that of a small parsnep; stem from four to six feet and upwards in height, hollow, round, shining, smooth, covered with a bluish powder which easily wipes off, spotted and streaked with livid purple, branched and striated towards the top; bottom-leaves very large, two feet in length, of a dark green colour, but paler underneath, shining, superdecompound, or several times pinnate ; pinnules oblong, gashed, and serrate; petiole spotted, smooth, fistulous, succulent, round, being scarcely flatted at top; sheath grooved; rays of the umbel ten to twelve, of the umbellule fifteen or sixteen; calix entire; corolla white: outer petals largest; fruits ovate, gibbous, with compressed ribs, waved before it is ripe, but becoming almost straight; seeds brownish, resembling those of aniseed, with five notched elevated ridges, three on the back and two on the side .- Hemlock is obviously distin-

347

ing green colour of its bottom-leaves, and particularly by their disagreeable smell when bruised : it is common by road and hedge sides, in cultivated ground, among rubbish, and on dunghills. According to Linneus, sheep eat the leaves, while horses, cows, and goats refuse them. Ray informs us, that the thrush will feed upon the seeds, even when corn is to be had; and Mr. Curtis remarks, that scarcely any insects appear to touch it. The dried fistulous stalks of this and several other umbellate plants, are called by the country people kaxes, or kecksies. This plant, which was stigmatized as one of the most noxious of vegetable poisons, has of late years been considered as a highly useful and powerful article of the materia medica; and it has been proved by indisputable experiments, that though highly deleterious when imprudently used, it has been productive of considerable benefit in cases which have resisted the usual methods; it has been particularly celebrated in cancerous cases; the leaves are frequently employed in poultices, fomentations, and plaisters, to discuss and disperse hard tumors: taken internally in any considerable quantity, they occasion disorders of the senses, convulsions, and sometimes death. The dried leaves, put into little bags, and boiled for a few minutes in water or milk, then squeezed from the superfluous moisture, and applied warm to gangrenous sores, check the progress of the mortification, and procure a separation of the unsound parts : the same application being made to gouty members, immediately abates the pain, softens and dissolves the hard concretions which frequently are formed about the joints in this disorder, and occasions the next fit to be milder and of shorter continuance. In hard glandulous swellings, and cancerous ulcers, its effects are likewise very considerable; and though some have made a trial of it without receiving any benefit, there has hitberto no instance occurred of its proving prejudicial to any. The same author (Baron Stoerck) recommends an extract made from the juice of the plant, to be taken internally at the same time, and for the same purposes : and relates a number of cases, wherein the worst kinds of ulcers, glandular swellings, fistulas, and cancers, were effectually cured by it. The manner in which he orders the extract to be taken, is, to begin with giving one pill of two grains twice a day, then three times, and after that gradually increase the number, till six or more of them are taken for a dose. Withering recommends the extract of hemlock, when prepared with attention and accuracy, as a valuable addition to medicine. " Not," says he, " that I have been a witness to any cures performed by its use, either in occult or ulcerated cancers. but I have never given it without mitigating the pain, and producing an alteration for the better in the discharge. Fifteen or twenty grains of the powdered leaves, taken twice or three times a day, have been found of very great efficacy in obstinate rheumatic complaints, and several other disorders, which are usually supposed to arise from an acrimonious state of the fluids." The following is Dr. Withering's method of preparing this powder of the dried leaves : Gather them about the end of June, when the plant is in flower; pick off the little leaves, and throw the stalks away; dry these small leaves in a hot sunshine, or in a tin dripping pan, or other convenient vessel, before the fire ; preserve them in bags of strong brown paper or powder, and keep them in glass phials, and put them away in a drawer, or place where no light can come upon them, for the light not only takes away their fine green colour, but also their virtue. When administered with prudence, it agrees with all ages and constitutions; joined with pectoral medicines, it promotes perspiration, and has been of great utility in the falling sickness and convulsions: taken inwardly, and applied outwardly at the

same time, it abates inflammations of the eyes, takes away pain, and occasions sleep; and though it has all the good properties of opium, it never produces thirst, or occasions the head-ache, which that drug generally does; nor does it bring on costiveness, but generally produces a loose stool or two the day following. It possesses the property of rendering the corrosive ichorous discharge from cancerous ulcers mild, and of a better consistence, and has been given with great advantage to such as are troubled with bloody ulcers, gleets, and other painful and weakening discharges: it powerfully promotes the menses, particularly when they have been suddenly restrained by cold, or any other external accident; it moreover cures the itch, promotes perspiration in some, and a copious flow of urine in others; and though not a cure for cancerous complaints, it is one of the best palliatives in those dreadful disorders, and far superior to opium. The best way of administering hemlock is, to give the powder or extract in very small doses at first, which are to be increased gradually till the full dose is arrived at, which may be known by its producing giddiness in the head, a motion of the eves as if something pushed them outwards, a slight sickness attended with an universal trembling of the body, and a loose stool or two the day after. One or more of these circum-stances are the signs of a full dose, which should be continned for a considerable time, as little advantage can be expected without a perseverance in the use of it. When hendock is imprudently eaten, or taken in too large doses, it occasions giddiness in the head, dimness of sight, a sort of madness, coldness of the extremities, convulsions, and even death. The mode of obtaining relief in such cases, is to empty the stomach as soon as possible, by means of the most active emetics, and then to give frequent doses of sharp vinegar. This useful plant may be easily propagated from seed, which will come up plentifully if permitted to scatter, and will only require to be thinned for medical use.

2. Coninm Rigens; Fine-leaved Hemlock. Seeds somewhat muricated; peduncles grooved; leaflets channelled, obtuse; stem shrubby, short, stiff branches longer, spreading very much, remote .- Native of the coast of the Cape of Good Hope, where it flowers in June. The seeds of this and the following species should be sown in pots in autumn, soon after they are ripe, and placed under a common frame in winter, where they may always be exposed to the open air in mild weather, and only covered in severe seasons; they appear early in the spring, and must then be as much in the open air as the weather will permit, otherwise they will be drawn up weak : they do not bear transplanting well, and should therefore be thinned to four or five in a pot, after which they only require to be kept clean, and to be watered in very dry weather. The second species may also be increased by cuttings.

3. Conium Africanum; Rue-leaved Hemlock. Seeds muricated; petioles and peduncles glossy; leaflets flattish, not channelled, smelling like smallage or celery ; peduncles opposite to the leaves, not furrowed, as in the foregoing; many of the flowers barren ; the central fruit sessile ; seeds longer than in the common sort .- Annual: native of the Cape of Good Hope. See the preceding species.

4. Conium Royeni. Seeds radiate, spiny .- Native of Egypt.

5. Conium Tenuifolium. Root and stem-leaves simple, linear; stem herbaceous, upright, a foot high, scarcely branched, slender, round, smooth, slightly streaked; leaves very narrow, a little wider at the base, and somewhat sheathing, very smooth, the lower ones four inches long or rather more; stem-leaves remote; umbel small, five-rayed, about

eight or ten flowers in the umbellule; seeds oblong, striated, sions subulate. *Corolla*: petals five, converging, or none, small, smooth; styles permanent, divaricating.—Native of *Stamina*: filamenta either five or ten, subulate, erect. An-there globose. *Pisiti*! germen large, compressed, oblues,

CON

Consumers a genus of the class Monadelphia, order Decandria — GENREIC CHARCTER. Calix: perianth oneleafed, five-parted, erect, tomentose, permanent. Corolla: petals five, lanceolate, erect, equal. Stamina: filamenta ten, subulate, erect, connected at the base, alternately of the length of the flower, and alternately very short. A uthere roundish. Pisitil: germen roundish. Style: cylindric; stigma obtuse. Pericarp: capsule oblong, gibbous, one-celled, two-valved. Style: one. Stigma: simple. Capsule: two-valved, onecelled, on-seeded.——The snecies are.

1. Counarus Monocarpus ; Ceulon Sumach. Leaves alternate, trifoliate, on long petioles ; leaflets ovate, smooth, entire, thick, cach on short petiolules, and remaining green the whole year; flowers in large upright racemes, at the ends of the branches, they are small, hairy, and of a greenish yellow colour, and rarely produce seeds in Europe. It rises with a woody stalk, about eight or ten feet high, hard, rigid, covered with a blackish bark, dividing at top into two or three brauches. -Native of Ceylon. It is usually propagated in gardens, by laying down the young branches, which if tongued, in the manner practised for carnations, and duly watered, will put out roots in twelve months, when they may be cut off from the old plants, and each planted in a separate small pot, filled with fresh light earth, plunged into a moderate hot-bed to forward their taking new root, observing to shade them from the sun every day, and to water them as they may require it. They should afterwards be treated in the same manner as other exotics, placing them in the dry-stove in winter, and for about three months in the summer in a warm sheltered situation in the open air : the cuttings will sometimes take root if they be planted in pots, plunged into a moderate hot-bed of tanner's bark, and closely covered with hand-glasses, or small bell-glasses, but seldom succeed unless they be carefully managed. If fresh seeds can be procured from abroad, they should be sown in small pots, plunged into a moderate hot-bed ; and when the plants are fit to remove they should be separated, each being planted into a separate pot, plunged into a moderate hot-bed, and treated in the same manner as the layers.

 Connarus Africanus. Leaves ternate, lanceolate, elliptic; veins protuberant underneath; branches round, smooth; flowers in a terminating spreading panicle.—Native of the mountains of Sierra Leone.

3: Connarus Santaloides. Leaves pinnate; leaflets ovateacuminate; pednucles avillary, aggregate; flowers racemed; branches round, smooth, with a purplish brown bark; calix ovate, the five segments lanceolate, acute, when in fruit bellshaped; petals twice as long as the calix; finamenta unequal, the length of the corolla, scarcely united at the base.—Native of the East Indies.

4. Connarus Minusoides. Leaves pinnate, with about ten pairs of oval oblong emarginate leaflets; racemes axillary; branches round, villose towards the top; leaves towards the ends of the branches petioled, alternate, approximating, unqually pinnate, with from lute to eleven pairs of leaflets, on very short petioles, opposite or alternate, the inner ones smaller, smooth, very finely veined on the upper surface, bluut, deeply emarginate, paler underneath; petioles very alightly villose—Native of the island of Nicobar.

Conocarpus; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. Calix: perianth oneleafed, superior, very small, five-parted, acute, erect, divi-

1. Conocarpus Erecta; Jamaica Button Tree. Erect: leaves lanceolate. This is an upright branching tree, frequently exceeding thirty feet in height; the younger branches are angular : the flowers small, and of a yellowish colour .---Native of the West Indies, and all the coasts of America, hetween the tropics, in great plenty, near the sea and in salt water : it is esteemed the best fuel in those latitudes, and being small, it is of scarcely any other use; the English call it button-tree, and button-wood ; the Spaniards mangle Saragoza. Both this and the second species are preserved in some curious gardens for the sake of variety, but they are plants of no great beauty; and are propagated from seeds which must be obtained from the places where they naturally grow, as the plants never produce them in Europe. If the seeds be fresh, they will come up very soon when sown upon a hot-bed; and if the plants be potted and preserved in the bark-stove, they will thrive rapidly; but they are too tender to bear the open air in this country, and will not live unless constantly kept in the stove, and treated in the same manner as other exotic plants, observing, as they are natives of swamps, to supply them often with water, but giving them only small quantities in winter; they are evergreen, casting off their old leaves when the new come out.

2. Conocarpus Procumbens. Procumbent: leaves obovate. It is a very branching shrub.—Native of Cuba, on rocks near the coast. See the preceding species.

3. Concearpus Bacemosa. Leaves hanceolate-ovate, bluntisi; frnits segregate. This is a lofty and branching tree, sometimes dividing into three or four trunks close to the ground; the younger branches are shining, red, and opposite; leaves quite entire, shining, thickish, greasy to the touch, deep green, opposite (luree inches long, on a red petiole, with two glands at the top of it; the flowers are small and sessife, and have a slight and not umplexant smell; the petals are whitish.—Native of the Caribbee islands, and the neighbouring coulinent, on sandy and muddy shores. The Spaniards call it mangle bobo, or foolish mangle; the English, white magrone: the Caribbee semploy the bark for tanning leather, and this is the only use to which it seems possible to apply these trees.

Contrayerva. Sec Dorstenia.

Conopria : a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. Calk: ; perinuth oneleafed, five-cornered, permanent, five-cleft; segments subvorate, acuminate, erect. Corola: : one petalled, ringent; tube oblong, gradually widening; border two-lipped; upper lip erect, emarginate, lower trifid, the niddle segments larger, concave. Stamha: filamenta four, two larger, fastened at bottom to the tube of the corolla; antheræ sagittate. *Psidl*: germen roundish; tybe filform, haivy; stigma twolobed. *Pericarp*: capsule roundish, one-celled, four-valved, *Corolla*: ringent, two lipped, lower lip trifid. Stigma: twolobed. *Capsate*; one-celled, four-valved, many-seceded.—— The only known species is:

The only known species is, 1. Conopea Aquatica. This is a creeping plant, with

CON

narcels of small fibrons roots at the joints; it spreads over the neighbouring grass, and on the surface of the water, by the side of which it naturally grows; the stems and branches are square, and each angle is bordered its whole length by a very thin sharp leaf or wing; leaves opposite at each joint, clasping, distaut three quarters of an inch from each other, kidney-form, plaited at the nerves, and waving on the edge; flowers either solitary or in pairs, opposite from the axil of the leaves, on a slender peduncte an inch in length; corolla blue .--- Native of Guiana; flowering in June.

Conservatory. See Green-house.

Convallaria: a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla: monopetalous, bell-shaped, smooth; border six-cleft, obtuse, open, reflected. Stamina: filamenta six, subulate, inserted into the petal, shorter than the corolla. Antheræ oblong, erect. Pistil: germen globose. Style : filiform, longer than the stamina : stigma obtuse, three-cornered, Pericary : berry globose, three-celled, spotted before maturity. Seeds : solitary, or in pairs, roundish. ESSENTIAL CHARACTER. Corolla: six-cleft; berry spotted, three-celled .---- The species are.

* Corollas bell shaped.

1. Convallaria Maialis; Sweet scented Lily of the Valley. Flowers on a scape; root perennial, with numerous round fibres, transversely wrinkled, creeping horizontally just below the surface to a considerable distance. The whole plant is smooth; flowers six to eight in a raceme, nodding, white, fragrant ; pedancles bending, one-flowered, round, filiform ; corolla contracted at the mouth; a purple spot at the base of each filamentum. There are several varieties of the lify of the valley, as: One with narrow leaves, mentioned as having been found by Mr. Lawson in Westmoreland, but upon being removed into a garden, it became in all respects like the common sort. A second with broader leaves, from the Alps, which Mr. Miller informs us retained its difference in the garden in the same soil and situation with the common sort. and therefore he has no doubt of its being a distinct species. A third, with a double variegated flower, supposed to be only a variety of the preceding, though the flowers are much larger, and beautifully variegated with purple, but the roots do not increase so much as the common sort. A fourth, with reddish or red flowers, which Mr. Miller affirms remained the same for forty years; the flowers are smaller, the stalks redder, and the leaves a darker green, than in the common sort : both this and the white vary with double flowers. The lily of the valley claims our notice both as an ornamental and a medicinal plant; in the former point of view, few are held in greater estimation, because few can boast such delicacy with so much fragrance. When dried, they have a narcotic scent ; and if reduced to powder, excite sneezing, and relieve the head-ache: an extract prepared from the flowers or the roots, partakes of the bitterness as well as of the purgative quality of aloes; the dose is from twenty to thirty grains: an infusion of the flowers, constantly taken instead of tea, is an excellent remedy for nervous head-aches, trembling of the limbs, and other similar complaints .- The lily of the valley is a native of Europe, from Lapland to Italy; it is found in woods. Since the trees on Hampstead Heath near London have been destroyed, it has been but sparingly found there ; in lord Mansfield's wood, near the Spaniard, between Shuter's Hill and Woolwich : and in Norwood, particularly, it abounds where large patches have been observed, with very few flowers and no berries. It may also be met with on Bushy Heath, and near Cathioberry in Hertfordshire; near Chisel, hurst in Kent, and near Lee in Essex; near Woburn in Bed-30.

fordshire, whence, according to Mr. Miller, the London markets are generally supplied with the flowers; it has been observed in Whichwood forest, in Oxfordshire; in Beechwood, near Stokenchurch; in Whitewood, near Gambugay, Cambridgeshire ; in Norfolk ; in Buddon and Okely woods, in Leicestershire; King's Cliff, in Northamptonshire; Keudal, in Westmoreland; in the county of Durham; upon Ingleborough in Yorkshire; and in Scotland. It flowers in May, and is therefore named May-lily. Gerarde calls it convall lillie, and informs ns, that in some places it is called liriconfancie. It is propagated by parting the roots in autumn, placing the sets a foot asunder: they require a loose sandy soil and a shady situation; they spread and multiply greatly in a rich soil, but are less productive of flowers. The only culture they require, is to keep them clean from weeds, and to transplant and separate the roots every third or fourth ycar; for if this be neglected, the flowers will be small, and few in number. As the lily of the valley forces very well, by that means its elegant flowers may be enjoyed in a succession for two months.

2. Convallaria Japonica; Grass-leaved Lily of the Valley. Scape ancipital; raceme drooping; root-leaves ten or more, linear, drawn to a point at bottom, three-cornered, flat on one side, entire, striated, bent back, two feet long and upwards : scape finely striated, smooth, a short span in height, flowering at the end, four cornered; corolla white; divisions lanceolate, patulous, a line in length; filamenta hardly any; antheræ linear, acute, brown; style the length of the corolla; berry ovate, obtuse, smooth, blue, the size of a pea, one-celled, adorned with the permanent calix .- They are found near Nagasaki in Japan, and are there used, as well as among the Chinese, in some disorders for which the tubers of the roots preserved with sugar are supposed to be a remedy.

3. Convallaria Spicata; Spiked Lily of the Valley. Scape striated ; raceme spiked ; flowers aggregate ; root fibrous ; root-leaves linear, drawn to a point at bottom, bluntish, manystriated, smooth, longer than the scape, which is angular, simple, erect, smooth, from four inches to a foot in height; raceme a finger's length, with the flowers scatteringly aggregate; corolla six-petalled, almost globular, violet; petals ovate; filamenta inserted into the germen, very short, erect; antheræ ovate twin; germen with six streaks; style shorter than the stamina .- Native of Japan, flowering in September,

** Corollas funnel-shaped.

4. Convallaria Verticillata; Narrow-leaved Solomon's Seal. Leaves verticillate; root perennial, toothed; stem simple, angular, striated, erect, eighteen inches high; leaves narrower than the rest, lanceolate, entire, smooth, three or four in a whorl, three or four inches long, and from half an inch to an inch in breadth, bright green, glaucous beneath; peduncles axillary, solitary, branched, pendulous, from two to six-flowered; corollas oblong, greenish white, striated at the ends, and divided into six bluntish segments, bearded within at the tip, three or four lines in length; berries violet or deep red .- It flowers in June, and is a native of the north of Europe, Germany, Switzerland, and Carniola. Ray observed it near Spa, and on mount Saleve, near Geneva, and it was found by Mr. Arthar Bruce in the Den Rechip, four miles N. E. of Dunkeld in Perthshire, in July 1792. All the Solomon's seals are very hardy plants; they prefer a light soil and a shady situation, and are therefore very proper for plantations, where, if they be not crowded by shrubs, they will thrive and multiply exceedingly, making an agreeable variety during the summer season. They have a very singular appearance, and multiply very fast by their creeping roots, in a proper soil and situa-4 U

tion: the best time to transplant and part the roots is in au-lacrimony; their virtues do not appear to be very great, tumn, soon after the stalks decay; but it may be safely done at any time until they begin to shoot in the spring, when the ground should be dug about them, and kept clean from weeds: they should also have room to spread, and must not be removed oftener than every third or fourth year.

5. Convallaria Polygonata; Single flowered Solomon's Seal. Leaves alternate, stem-clasping, acuminate; stem angular; peduncles axillary, generally one flowered; root twisted, and full of knots; on a transverse section of it, characters appear that give it the resemblance of a seal, from which it derives its name of Solomon's seal .- It varies with a double flower, and is a native of the north of Europe, Holland, Germany, Hungary, Switzerland, Carniola, and Piedmont. It is found, in England, in the fissures of rocks near Wherf, Settle, and Skipton ; and in Syke's Wood, near Ingleton, in Yorkshire ; and also in Virginia. The variety above mentioned, which has white leaves like hellebore, and a purplish stalk, was found in woods on the north side of Mendip Hills. Hill says, that the root of this plant is used, and extremely commended for an outward application against bruises ; he recommends it to be taken, when dried and powdered, to assnage violent purgings, with bloody stools; and when fresh, beaten up into a conserve with sugar, as a preventive against the whites. The roots of this, and of the seventh species, have been made into bread by the Turks in times of scarcity.

6. Convallaria Latifolia; Broad-leaved Solomon's Seal. Leaves alternate, stem-clasping, acuminate; stem angular; peduncles axillary, many-flowered. This has at first a sweet and afterwards an acrid taste, and is also glutinous; stem from half a foot to two feet in height, round at bottom, and angular from thence the whole length, the angles being more remarkable below the middle of the back of the leaf: it has a short pile of hairs toward the top .--- Native of Austria. See the fourth species.

7. Convallaria Multiflora ; Many-flowered Solomon's Seal. Leaves alternate, stem clasping; peduncles axillary, manyflowered; stem round, from eighteen inches to two or three feet high, erect, unbranched; leaves usually bent upwards, and to one side, underneath glaucous : flowers several together, (from two or three to seven or eight) axillary, on branched compressed peduncles ; they are seven inches long, and three in diameter, slightly five-cornered; the segments ovate, obtuse, somewhat reflex; filamenta hirsute; berries round, of a blackish blue colour, varying to purple and red, and containing three or four seeds .- It varies with a double flower, and is a native of the north of Europe, Germany, Switzerland, and Carniola: in England it is found at Newberry, and other places ; in Berkshire ; at Bramdean in Hampshire; Roehill, in Kent; High Wycomb, in Bucks; and Gorlestone in Suffolk. The dwarf Solomon's seal is found in the woods of Wiltshire. The root of this plant, according to Meyrick's account, is a good outward application for bruises; dried and powdered, it is good against purgings with bloody stools; and if beaten into a conserve with sugar whilst it is green, it makes an excellent medicine for that weakening female complaint, the whites. It would be unpardonable to omit what old Culpeper says concerning the distilled water of the whole plant, which, when applied to the face, cleanseth it from morphew, freckles, spots, or marks whatsoever, leaving the place fresh, fair, and lovely, for which it is much used by the Italian dames. The roots are also recommended externally as vulneraries, restringents, and discutients; internally, as incrassants and mild corroborants : they have little or no smell, and are rather sweet at first to the taste, which is soon followed by a very slight impression of bitterness and

Haller asserts, that the berries excite vomiting, and even the leaves a nausea. The Turks cat the young shoots in the same manner as we eat asparagus. See the fourth species,

*** Corollas wheel-shaped.

8. Convallaria Racemosa ; Cluster-flowered Solomon's Seal. Leaves sessile; raceme terminating, compound; stems two feet high, unbranched, with many oblong leaves embracing them at the base, resembling the leaves of plantain: the flowers are small and white, produced in single spikes at the top, and are succeeded by small red berries, about the same size as in the first sort, and contain two hard shining seeds. It flowers in the beginning of June, and the berries ripen in autumn .- Native of Virginia and Canada. See the fourth species.

9. Convallaria Stellata; Star-flowered Solomon's Seal. Leaves stem-clasping, very many; stem upright, about two feet high. The flowers come out from the same joints as the leaves, on short pedancles, each of which sustains five or six : they are small, with short tubes of a dirty white, tipped with green, and slightly cut into six parts at top .- Native of Canada. See the fourth species.

10. Convallaria Trifolia. Leaves stem-clasping, in threes; racemes terminating, simple; root creeping, jointed; stemleaves two, three, or four, often ovate oblong, but not seldom lanceolate .- Native of woods in Siberia. See the fourth species.

11. Convallaria Bifolia; Least Solomon's Seal, or One Blade. 'Leaves cordate; flowers four-stamined. This plant seldom exceeds four or five inches high, tising with a single stalk from the root, with one or two heart shaped leaves, which closely embrace it; the top of the stalk is terminated by a loose raceme of white flowers, which have short tubes, and spread open at the top, where they are divided into four obtuse segments; the fruit is a soft berry, including a hard seed .- Native of the north of Europe, Holland, Germany, Switzerland, and Carniola. As it propagates very fast by its creening roots, they will soon spread over a large space, unless confined in pots. It is remarkable, that where these and other creeping plants are allowed to spread, they seldom produce any fruit.

Convolvulus ; a genus of the class Pentandria, order Monogynia .- GENEBIC CHARACTER. Calix : perianth fiveparted, converging, ovate, obtuse, very small, permanent, Corolla : one-petalled, bell-shaped, spreading, large, plaited, obscurely toothed. Stamina : filamenta five, subulate, shorter by half than the corolla. Antheræ ovate, compressed. Pistil: germen superior, roundish; style filiform, length of the stamina; stigmas two-celled, one two or three-valved; seeds in pairs, roundish. ESSENTIAL CHARACTER. Corolla: bell shaped, plaited. Stigmas: two. Capsule : two-celled, with two seeds in each cell. The general description of this genus is, that the stems are herbaceous, milky, in the greater part twining, in a very few shrubby; leaves alternate; peduncles axillary or terminating, one-flowered, with two bractes. or many-flowered.

* With a twining Stem.

1. Convolvulus Arvensis; Small or Field Bindweed. Leaves sagittate, sharp on each side; peduncles generally one-flowered: bractes subulate, at a distance from the flower: root perennial, milky white, the thickness of a crow-quill, creeping so as scarcely to be eradicated; stalks numerous, stender, twisted, procumbent, branched, frequently sufficating plants by twisting round them ; leaves alternate, hastate, smooth, running out into two points behind; corolla elegantly

CON

CON

variegated with red and white, sometimes wholly white; seeds | angular and brown. This plant is the pest of gardens and arable land, and is more destructive than the second species, because that adheres to the hedges for the sake of climbing, whereas this wanders over whole fields, and cannot be rooted out, except by repeated ploughings in dry weather, every atom of which will grow as well as quick grass, its rival in creeping. Mr. Miller says, it is generally a sign of gravel lying under the surface, and that the roots run very deep into the ground, whence some country people call it devil's guts. It is called corn-bind in Yorkshire, in other parts with bind, bind-weed, barebind, and hedge-bells. The blossoms give a deep yellow or orange tincture to water, which is heightened by alum and alkalies. The root of this plant, says Meyrick, is a rough purgative, and, to such constitutions as can bear the operation, will prove serviceable in the jaundice, dropsies, and other disorders, arising from obstructions of the viscera. The best method of administering it is to bruise the roots, and give their expressed juice in strong beer. It is remarkable, that hogs devour the roots of this and the next species in large quantities, without any visible effect. The best way to destroy this and the second species is, according to Mr. Curtis, to plough them up repeatedly in dry weather, and then pick out the roots and burn them. He declares, that the more he cut and hoed them, the more they spread and grew : although Mr. Miller observes, that in an open clear spot of ground, where the plants are carefully hoed down for three or four months, they may be effectually destroyed ; for when the stalks are broken or cut, a milky juice flows out, and the roots, being thereby exhausted, soon decay, 2. Convolvulus Sepium; Great or Hedge Bindweed.

Leaves sagittate, truncate behind ; peduncles four-cornered, one-flowered, with heart-shaped bractes close to the flower : root perennial, white, the thickness of a goose-quill, creeping, and propagating itself exceedingly, so as not to be destroved without great difficulty; corolla large, and white .--- It flowers in hedges, from July to September. The inspissated juice of this plant, taken in doses of twenty and thirty grains, is a powerful drastic purge. Can it then be worth while, says Dr. Withering, to import scammony from Aleppo, when a medicine, with the very same properties, grows spontaneously in many of our hedges? The smallness of the roots. however, in our common bindweed, would prevent its juice from being collected in the same manner with that which flows on incision from the large root of the scammony, and which by hardening forms that purgative substance. The country people in Northamptonshire use the root of this plant, fresh gathered, and boiled in alc, as a purge. It would certainly offend a delicate stomach, but it saves the expense of an apothecary, and answers the purpose better than any other medicine, for persons of a strong constitution. See the first species.

3. Convolvulus Scammonia : Syrian Bindweed, or Scammony. Leaves sagittate, truncate behind ; peduncles round, bearing about three flowers; corolla pale yellow; the roots are three or four feet long, and from nine to twelve inches in circumference, covered with a light gray bark, tapering, branched at bottom, and containing a milky juice .- Scammony is a gum resin, obtained from the milky juice of the root, by clearing away the earth from the upper part of it. and cutting off the tops in an oblique direction, about two inches below where the stalks spring from it; then, under the most depending part of the slope, a shell or other convenient receptacle is fixed, to receive the juice, which gradually becomes hard, and is the genuine scammony. It is brought from Aleppo, and Smyrna, and appears to have been well a native of Japan, where it is cultivated,

known to the Greek and Arabian physicians, who used it for other purposes as well as for a purgative. It is a stimulating cathartic, but somewhat uncertain in its operation, and is frequently, and indeed generally, employed in composition with other ingredients. The dose is generally from three to twelve grains. Meyrick calls it a rough and powerful, but very useful purgative, of great service in rheumatic and other chronical disorders, for it will reach the seat of many disorders that a common purge will not affect. It should however seldom be given alone, and ought never to be administered to those of irritable habits, or in inflammatory complaints, though even then it is no more hurtful or dangerous than other strong cathartics. Hill says, that a great misfortune is, that the compositions made with scammony are never perfectly to be depended upon, because there is so much difference in several parcels of scammony, that they hardly seem the same medicine, some are so very strong, and some so very weak. This plant will bear the open air of our climate, and will thrive well on a dry soil. Sow the seeds in the spring, on a border of light earth ; keep the plants clean from weeds, and thin them to the distance of three feet. The stalks decay in autumn, but the roots will remain many years.

4. Convolvulus Sibiricus; Siberian Bindweed. Leaves cordate, acuminate, even; peduncles one-flowered; root annual; stem six feet high, even, two-angled from the decurrent stipules, but not ancipital; leaves scarcely repand, quite entire, ending in a point, the length of the leaf, paler underneath, and veined ; corolla whitish, or having a shade of flesh-colonr, with a yellowish bottom .- It flowers in July and August, and is a native of Siberia.

5. Convolvulus Farinosus : Mealy-stalked Bindweed. Leaves cordate, acuminate, repand ; peduncles three-flowered; stem mealy; corolla three times the size of the calix, somewhat flesh-coloured, acute, five-cleft: stigmas oblong, Perenuial : flowering in May and June .- Native of Madeira. 6. Convolvulus Medium; Arrow headed Bindweed. Leaves linear-bastate, acuminate; ears toothed; peduncles one-flowered ; calices sagittate ; stem twining, not rooting .--It is annual, flowers in July and August, and is a native of the East Indies. This, and the tenth, thirteenth, fourteenth, seventeenth, eighteenth, nineteenth, twenty-first, second, third, fourth, fifth, and sixth, twenty-eighth, thirtieth, thirtyfirst, fifth, sixth, seventh, eighth, ninth, fortieth, forty-first, fifty-seventh, fifty-eighth, sixtieth, sixty-second, third, fourth, fifth, sixth, seventh, eighth, ninth, seventieth, seventy-first, sixth, seventh, eighth, ninth, eightieth, eighty-first, and from the eighty-fifth to the hundred and ninth species inclusive. being natives of warm climates, chiefly of the East and West Indies, are tender. When raised from the seed, they must be sown on a hot-bed in the spring ; and when the plants are fit to remove, they must be transplanted each into a separate pot filled with light earth, and plunged into a moderate hot bed, observing to shade them from the sun until they have taken fresh root; then they should have a large share of air admitted to them every day, to prevent their drawing up weak, and also moderate waterings every other day. When the plants are become too tall for the hot bed, they must be shifted into larger pots, and placed in the bark-stove, where, if they be allowed room, they will flower; but they rarely produce seeds in England, and they are therefore generally propagated by cuttings.

7. Convolvulus Japonicus. Leaves hastate-lanceolate, the side-leaves one-toothed ; peduncles one-flowered ; stem filiform, simple, smooth .- It flowers from May till July, and is

351

CON

8. Convolvulus Panduratus; Virginian Binduced. Leaves cordate, entire, panduriform; calcies even; root preemial, thick and long, like that of a carrot; stems very long and slender; peduncles long; slender, sustaining from one to three flowers, large and white, with the botton of a fine parjet; seeds hirsute. It flowers from June until September, and will endure the open air of Great Britain,—It is a native of Virginia and Carolina.

9. Convolvulus Carolinus; Carolina Bindiced. Leaves cordate, entire, and three-boled; corollas undivided ; fruits cerect; stems slender, reddish towards the root, and hairy at the joints; leaves somewhat entire and cordate, others like ivy leaves; peduncles near an inch in length, with a few narrow bractes; corollas pale purple.—The seeds were imported among rice, sent from Carolina to England, where it will thrive in the open air.

10. Convolvatus Hederaceus; Iny learch Bindhrech, Leaves cordate, entire, and three lobel; orollas undivided; fruits erect. The flowers are much larger than those of the preceding species; they are solitary, on very short peduncles, of a very elegant blue colour, with a whirish base. It is an annual plant, and was first raised in England from seeds brought by a slave-slap from the river Gambia in Africa.—It is a native of Asia, Africa, and America. See the sixth species.

11. Convolvulus Nil: Blue or Azure Bindweed. Leaves cordate, three-lobed; corollas half five-cleft; peduncles shorter than the petiole. It is an annual plant, rising with a twining stalk, eight or ten feet high. Each peduncle sustains two flowers of a very deep blue colour, whence it receives its name of anil or indigo. It is one of the most beautiful plants of the whole genus : some have supposed it to be a mere variety of the twelfth sort ; but the leaves have three deeplydivided lobes, whereas in the other they are entire. It flowers all the latter part of the summer, and in good seasons the seeds ripen well in the open air .- It is a native of America. and is now rarely met with in our gardens, although Gerarde cultivated before the year 1597; but it appears to have perished before it ripened its seeds. He says, that the Arabians call it nil; the Italians, campana azurea, from its beautiful azure flowers ; and also for di notte, or night-flower, because its beauty appeareth most in the night. See the twelfth species.

12. Convolvulus Purpureus; Purple Bindweed. Leaves cordate, undivided; fruits drooping; pedicels thickened; peduncles erect, but the pedicels of the fruit thickened and drooping; the calix dotted, scabrous, and hairy. It is commonly known in the gardens by the name of convolvulus major. There are three or four lasting varieties of it, which are annual plants; the commonest has a purple flower, but there is one with a white, a second with a red, and a third with a whitish blue flower and white seeds. If properly supported, will rise ten or twelve feet high; they flower in June, July, and August, and will continue till the frost kills them. The seeds ripen in autumn .- Native of America, and able to endure the open air in England. It is propagated by sowing the seeds in the spring, upon a warm border, where the plants are designed to remain. Some tall stakes must be placed by them, for the stalks to twine about, otherwise they will spread on the ground. The more tender varieties, and the eleventh species, must be brought forward on a hot-bed, and planted out on a warm border towards the end of May.

 Convolvulus Angularis. Leaves cordate, five-cornered, quite entire, villose; peduncles many-flowered; stem pubescent; leaves villose, scabrous.—Native of Java. See the sixth species.

14. Convolvulus Obscurus; Hairy Binduced, Leaves cordate, undivided; stem somewhat pubescent; peduncles thickened, one-flowered; calices smooth; root annual; stem round---lt flowers in August, and is a native of Batavia, China, Cochin-china, Ceylon, and Surinam.

15. Convolvulus Batatas; Tuberous-rooted Bindweed, or Spanish Polatoes. Leaves cordate-hastate, five-nerved; stem round, perennial, hispid, prostrate, creeping, putting forth scattered, oblong, acuminate tubers, purple or pale on the outside; leaves angular, on long petioles; flowers purple, lateral. large, three or thereabouts together, on upright peduncles.-Native of both Indies, also of China and Cochin-china. They came first into Spain from the West Indies or the Spanish Main. and the roots are annually imported into England from Spain and Portugal. They were the common potatoes of our old English writers : the roots which are now so generally cultivated among us under that name, being then little known. They are sweet, sapid, and esteemed nourishing, being commonly cultivated in all the tropical climates, where they eat not only the roots, but the young leaves and tender shoots boiled. There are several varieties, if not distinct species of batatas. Loureiro mentions one, the roots of which are in bunches, white within, and of a tougher substance, though not so sweet as the common sort, but yet more esteemed among the natives. Forster mentions a second, which is found, not only in the South-sea islands within the tropics. but also in Easter Island, and in the northern parts of New Zealand. They are cultivated in warm climates by their roots in the same manner as our common potatoe, but require much more room, for the trailing stalks extend every way four or five feet, sending out large tubers, forty or fifty of which are produced from a single root. In England, the roots must be planted on a hot-bed in the spring ; and if the plants be kept covered in bad weather with glasses, they will produce flowers, and many small roots from the joints; but if they be exposed to the open air, they seldom make much progress.

16. Convolvnlus Bidrous. Leaves cordate, pubescent; peduncles in puirs; lobes of the corolla trifid; root annual; stem round, hairy, branched at the base; petioles round, hairy, branched at the base; petioles round, hairy, shorter than the leaf; corollas while, five-field, snall; the lobes three-cleft, the middle cleft smallest; tube shorter than the calix; stamina the length of the tube; pistil white, the length of the tube; pistil white, the length of the tobia.

17. Convolvulus Verticillatus. Leaves cordate, oblong, naked; peduncles umbellate, bifid, many-flowered; corolla beil shaped; flowers bluish and small.—Native of America.

18. Convolvulus Umbellatus; Umbel Bindueed. Leaves cordate; peduncles unbellate; stem herbaceous, twining, filtiorm, stiff, subdivided, pubescent, round; flowers many, terminating on peduncles three inches long or more; corollas yellow, the border plaited obtusely, pentangular. It flowers in June and July.—Native of the West India Islands. See the sixth species.

10. Convolvnlus Malabaricus. Leaves cordate, smooth; stem perennial, villose; stem perennial, twining; round, slender, villose; leaves acuminate, quite entire; peduncles one-flowered; corolla bell-shaped, with a long tube, white, with a dusky purple base.—Native of the East Indies and Cochim-china. See the sisth species.

20. Convolvulus Canariensis; Canary Binduced. Leaves cordate, pubescent; stem perennial, villose; peduncles many-flowered; roots strong, fibrous; stems woody, branched, growing twenty feet high and more when supported; flowers avillary, several on one peduncle, for the most part of a pale

blue, but sometimes white. It flowers in June, July, and August, and sometimes ripens seeds in England .- Native of the Canaries, Cochin-china, &c. It is easily propagated by lavers or cuttings; the seeds are not much regarded. Those plants, however, which are raised from layers or cuttings do not produce seed, whereas those which come from seeds seldom fail. If the young shoots be laid down in the spring, they generally put out roots in three or four months; they may be taken off an old plant at that season, and each put into a separate pot filled with light earth, and shaded until they have taken new root; after which they may be placed with other hardy greeu-house plants till autumn, when they must be removed into the green-house, and treated as myrtles, &c. The tender cuttings planted during any of the summer months in pots filled with light earth, plunged into a moderate hot-bed, and shaded from the sun, will take root, and may be treated as the layers. The leaves continuing green all the year, this plant makes a pretty variety in the green-house during the winter.

21. Convolvulus Muricatus; Rough-stalked Binduced. Leaves cordate; peduncles thickened; they and the calices even; stem nuricate; stalk very smooth, with harmless prickles scattered over it; leaves undivided; peduncles usually two-flowered; corolla purple.—Native of Suratle. It is annual, and flowers in July and August. See the sixth species.

22. Convolvalus Anceps. Leaves cordate; stem keeled on both sides, smooth; leaves three iuches long, smooth, veined, obtuse, quite entire, on petioles nearly the length of the leaf.—Native of Ceylon and Java.

23. Convolvulus Turpethum; Square-stalked Binduced, or Turbith. Leaves cordate, angular; stem membranaceous, quadrangular; peduncles many-flowered; corolla white, scarcely twice as long as the calix, hell-shaped, plaited, five-elfn.—Native of Malabar of the Island of Ceylon, and of the Society and Friendly Isles, and also of the New Hebrides in the South Seas.

24. Convolvulus Grandiflorus. Leaves cordate, ovate, bluutish, quite entire, peduncicel, bearing about two flowers; calices coriaceous; stem and petioles pubescent; stem arboreous, at first erect, luen twining, pubescent; lawes large, with rounded lobes; obtuse, smooth, on pubescent petioles; flowers large.—Native of the East Indies. See the sixth species.

25. Convolvulus Maximus. Leaves cordate, ovate, acuminate, quite entire, very smooth; stem and petioles very smooth; stem woody at bottom, then twining and mounting to a great height. The whole plant very smooth,—Native of Ceylon. See the sixth species.

20: Convolvulus Speciosus; Broad-leared Binduced. Leaves cordate, tomentose, silky on the lower surface; peduncles longer than the petiole, umbellate; calices acute; sem arboreous, erect, then twining, round, pubsecent; leaves very large, hairy on the upper surface, covered with a white down on the lower, and shiring like silver in the sun-beams; the lobes rounded, and very obscure; petioles round and puscent. – Native of the East Indies. See the sixth species.

27. Convolvulus Trinervius. Leaves cordate, oblong, smooth, htree-nerved; stem round; peduncles one-flowered; stem filiform, smooth, simple; leaves opposite, petioled, acuminate, quite entire, pale underneath, an inch or somewhat more in length.—Native of Japan.

28. Convolvulus Peltatus. Leaves peltate; peduncles many-flowered.—Native of Amboyna and the Society Isles. See the sixth species.

 Couvolvulus Jalapa ; Jalap Bindweed. Leaves ovate, 30.

subcordate, obtuse, obscurely repand, villose underneath; peduncles one-flowered ; root large, oval, full of milky juice ; stems many, herbaceous, triangular, twining, eight or ten feet high; flowers reddish on the outside, but dark-purple within, probably varying in colour; seeds covered with a very white down like cotton .- Native of Jalapa, between La Vera Cruz aud Mexico, in South America. The medicinal virtue of jalap resides in the resin. The powdered root is the part used. It is in general a safe and efficacious purge, and has been much celebrated in large doses as a hydragogue in dropsies. It is often prescribed in a compound form ; in cream of tartar, &c. The dose of the simple powder is commonly from one scruple to two. The roots of jalap, says Lewis, have scarcely any smell, and but very little taste while kept in the mouth, but after they are swallowed, the throat is affected with a slight pungency and heat, which continues for a considerable time. When reduced to powder, and taken in doses of a scruple and half a diachm, it proves in general an effectual and very safe purge, seldom occasioning any sickness or griping pains, which are the too common attendants of strong purgatives. Some of the faculty have prohibited the use of this root to children, but there appears no rational ground for such a prohibition. Young children, from the laxity of their solids, and the soft lubricating nature of their food, in general bear this kind of medicine better than adults, and adults of a weak lax habit of body better than those who are robust; and in both cases, few, if any, of the strong purgatives now made use of, are stronger than jalap. Motherby remarks, that jalap is of a duretic, as well as a purgative nature; on which account it is peculiarly serviceable in dropsies, for which purpose it is best given in wine, wherein it has stood some hours before taking it. There is a tineture made from the root of this plant, and kept in the shops, which has all the effects of the root in substance, and may be thought by some persons to be more agreeable to take. This plant must be preserved in the barkstove. It may be raised from seeds on a hot-bed, the young plants being removed into pots, must be plunged into the bark-bed, and treated in the same manner as the last mentioned set of plants, with this difference only, that as this has large, fleshy, succulent roots, it must have but little water. especially in winter. The proper soil for the jalap is a light sandy loam, not too rich; and the plants should always remain in the bark-stove. It may also be increased from slips or cuttings.

30. Convolvulus Sericeus. Leaves lanceolate, elliptic, tomentose, silky underneath; peduncles subumbellate; calices hairy; steu shrubby, smoothish; leaves alternate, petioled underneath, shiniug, marked with lines, acute.—Native of the East indies. See the sixth species.

31. Convolvulus Tomentosus, Leaves three-lobed, tomentose; stem langinose, round, whitish, climbing trenty feet high; flowers axillary, solitary; peduncles a quarter of an inch in length; corolla of a fine purple colour, with fine pater streaks.—Native of Jamaica, China, and Cochin-china. See the sixth species.

32. Convolvulus. Althaoides; Mallow-leared Binduced. Leaves cortales, sinuate, silky; lobes repand; peduncles two-flowered; root perennial, sending out many weak turning stalks, about three feet high when supported, and if not, lying on the ground; peduncles very long, two-flowered; corolla pale rose colour. It flowers from June to Angust, but rarely ripens seed in England.—Native of the Levant, county of Nice, &c. Neither this, nor the variety of this species, are propagated by offsets or shoots taken from the old plants. 4 X The hest time for parting and transplanted this sort, is about the beginning of May, when it may be taken out of the greenhouse, and exposed to the open air; but the young plants should be placed under a frame, and shaded from the sun till they have taken new root; they may then be gradually hardenied to the open air during the summer, but in autumn they must be placed in the green-house, and treated in the same manner as the tenth species. There is a variety of this species, with a pale rose-coloured corolla, with five stripes of a deeper red.

33: Convolvulus Cairicus; Jagged-Jenved Birduered, Leaves palmates, smooth, serulate; sipules leaf-shaped; palmate; axils tomentose; calices panicled, even. The whole plant is smooth, except the axils, which are closely hairy. The corolla is bell-shaped; the stigma capitate. It flowers in June and July, and is a native of Expt.

34. Convolvulus Copticus. Leaves pedate; serrate; peduncles ensiform, two-flowered; calices nurricate; stem herbaceous, angular, smooth, and even; corolla white, acute; stigma blood-red.—Native of the Levant.

35. Convolvulus Vitifolius; Vine-leaved Bindweed. Leaves palmate, five-lobed, smooth-toothed; stem hairy; peduacles many-flowered; racemes two-parted; calices villose.—Native of the East Indies. See the sixth species.

 Convolvulus Dissectus. Leaves palmate, seven-parted, tooth-sinuate, smooth; stem hairy; peduncles one-flowered; calix smooth.—Native of America. See the sixth species.
Convolvulus Macrocarpus; Long-fruited Bindweed.

37. Convolvulus Macrocarpus; Long:fruited Bindweed. Leaves palmate, pedate, five-parted; peduncles one-flowered. --Native of South America. See the sixth species.

38. Convolvulus Paniculatus; Panicled Bindweed. Leaves palmate; lobes seven, ovate, acute, quite entire; peduncles panicled. It varies with three or five-leaved lobes.—Found in the sands of Malabar. See the sixth species.

39. Convolvulus Macrorhizos. Leaves digitate in sevens, quite entire; stem smooth; peduncles three-flowered.—Native of America. See the sixth species.

40. Convolvulus Quinquefolins; Smooth Fier-teared Bindeced. Leave digitate, smooth, toothed; peduacles even; stem herbaccons, twining, filiform, round, hirsute; corolla bell-shaped, white; tube arrower at the base, swelling in the middle; border five-cornered, plaited, spreading.—Native of Jamaica. See the sixth species.

41. Convolvulus Pentaphyllus; Hairy Free-leaved Bindseed. Leaves digitate in fires, hairy, quite entire; sten hairy; leaflets quite entire, pedicelled; peduncles long, branching; flower while; two large bractes include the calk; two oblue stigmas; capsules oblues; annual.—Native of the West Indies. See the sixth species. 42. Convolvulus Martinicensis. Leaves elliptic; stem

42. Convolvulus Martinicensis. Leaves elliptic; stem creeping, somewhat twining i stems round, smooth, prostrate, long, rooting, twining a little; leaves elliptic, blunt with a proint, quite entire, smooth, petioled, two incles long. The three outer calveine leadles ovarte, acute yery large and loose, the two inmer much smaller, lanceolate, acute; corolla white.—Native of Martinico.

* Stem not twining.

43. Convolvulus Spinosus. Shrubby, crect: leaves lancoslate, sitky: flow-ch-earing branchlet's thoruy: stem subflexnose, scarcely twining; the whole white, with very short shining: hairs; leaves oblong or hunceolate, sessile; stems branching at top, the branches horizontal, rigid, terminated by one crect, small, whitish flower.—Observed by Professor Pallas on the saudy hills near the river Irtis in Siberia.

44. Convolvulus Siculus; Small flowered Bindweed. outside. It varies much in size, but may be known by its Leaves cordate ovate; peduncles one flowcred; bractes lan-straight stem, a little inclined, its villose white leaves and calix,

ceolate; flowers sessile. This is an annual plant, rising about two feet; the stem very little, and often not at all, twining. The dowers are small, of a bluish colour, and have little beauty.— It dowers in June, and will flowrish in the open air of England, although it be a uative of the south of Europe. If it be permited to scatter its seeds, the plants will rise in the spring, and require no other culture but to keep them clean from weeks (or if the seeds be sown in the spring where the plants are to remain, they will flower in June, and the seeds will ripen in August.

45. Convolvulus. Pentapetaloides. Leaves lanceolate, obtuse, nuked, marked with lines; branches declining; flowers solitary, half five-deft; flowers axillary on short peduncles; corolla blue with a yellow throat; the border almost fiveparted, with acministe divisions. In a poor soil it varies with simple filtorn stemas, a finger's length, and somewhat hairy towards the top.—Annual, and a native of Majorca. It is hardy cough to stand abroad in our climate.

46. Convoluting Lineatus; Durarf Bindneed, Leaves huncelate, silky, narked with lines, periodate; peduneles two-flowered; calices silky, somewhat leafy; stems four to six inclues high, prostrate, flexuose; leaves remover at the base, acute; corollas very hairy on the outside. The flowers are produced on the side and at the top of the stalks, in small clusters, sitting close together; they are much smaller than those of the forty-eighth species; (which see,) but of a deeper rose-colour. The roots perennial, and creeping—Native of the coasts of France, Spain, Nice, and Sicily, threfers a slight dry soil, and requires no other care but to keep the plants clean from weeds; it may be transplanted either in spring or autume.

47. Convolvulus Cueorum; Silvery-leaved Bindweed. Leaves lauceolate, tomentose; flowers umbelled; calices hirsute; stem erect; stems shrubby, upright, about three feet high; leaves lanceolate, blunt, silky, placed closely on every side of the stem ; they are near two inches long, and a quarter of an inch broad. The flowers are produced in clusters at the top of the stem, sitting very close; they are of a pale rose-colour, and come out in June and July, but do not perfect seeds in England .- Native of Spain, Italy, Sicily, and the Levant. If planted in a light soil and a warm situation, it will live in the open air in mild winters, but in severe winters it is destroyed; some of the plants therefore should be kept in pots, and sheltered under a common frame in winter, where they may enjoy the free air in mild weather, and yet be protected from frost: in summer they may be placed abroad with other hardy exotic plants, where the fine silky leaves will make a pretty appearance. It may be propagated by laying down the branches, and also by cuttings; but neither of them often puts out roots the same year, and many of them will fail, so that the best way is to procure seeds from Italy, especially as those plants which come from seeds grow much larger than those which are propagated by other means.

48. Convolvulus Cantabrica; Flas-Lared Binduced. Leaves linear-lanceolate, acute, luiry; lower peduncles longer than the leaves, bearing about two flowers; calices olog, lanceolate, hirsteir; root perennial, of the thickness of a quill, of a dirty brown colour, ruuning deep into the ground; stems several, annual, lirstute, round, half a foot high or more, slender; corolla flesh-coloured, or pale rosecoloured, with five broad red liues which are hairy on the outside. It varies much in size, but may be known by its straight stem. It the inclined, its villoss white leaves and calix.

CONVOLVULUS.

and pale purple flowers rolled in a spiral form. It delights in | warm rocky situations, and is a native of the south of Europe. It is propagated by seeds, which must be obtained from the countries where it naturally grows. They should be sown mon a warm dry border, where they are intended to remain; for as the plants run down with long tap-roots, they will not bear transplanting, for this has often been tried without any success. When the plants come up, they should be thinned where they grow too close, and afterwards constantly kept cleau from weeds ; which is all the culture it will require.-It flowers in July and August, and the stalks decay in autumn ; but the roots will last several years, and, if they be in a dry soil and a warm situation, will endure the winter very well without covering.

49. Convolvulus Doryenium. Leaves sublinear, silky; stem shrubby, panicled; calices almost naked, obtase; leaves sublanceolate, silky on the upper branches, smaller, and fewer ; branches rigid, seldom dichotomous, terminated with flowers, usually solitary ; shrubby,---Native of the Levant.

50. Convolvalus Scoparius; Broom Bindweed. Leaves linear, somewhat hairy; peduncles bearing about three flowers; calices silky, ovate, acute; stem shrubby; branches wand-like; root perennial, sending up several erect branching stalks about two feet high; the flowers come out singly on the side of the stalks, sessile, of a pale bluish colour, and spreading open almost to the bottom. It has the appearance of broom; stem round, very smooth; corolla white, hairy on the outside; the wood is white and hard, with radiating streaks; when scraped it has the smell of roses, together with a slight acrid taste, and probably may be the lignum Rhodium of the shops .- Masson found it about Santa Cruz, and Mr. Miller says it grows in Candia, and several islands of the Archipelago. Native of the Canary Islands. It may be propagated and treated in the same manner as the forty-eighth species; which see. It requires a dry soil and warm situation, to enable it to survive an English winter in the open air ; if the surface of the ground about the roots be covered with some old tanner's bark, it will preserve them in the hardest frosts,

51. Convolvulus Oenotheroides. Shrubby, erect: leaves linear, becoming hoary; peduncles axillary, solitary, crect, one-flowered, bracted; calices lanceolate, smooth; stems woody, round, reddish, somewhat glaucous; leaves narrow, the length of the finger, lax, flat; peduncles at the top of the stem, short, angular; bractes in pairs, recurved, subulate; corolla funnel-shaped, large, tawny-coloured .- Found by Sparmann at the Cape of Good Hope.

52. Convolvulus Floridus; Many flowered Bindweed. Leaves oblong-lanceolate, drawn to a point at the base, somewhat hairy; flowering branches and peduncles panicled; stems woody, procumbent; branches erect, stiff, hoary; leaves petiolate, linear, entire, waved, veined, smooth ; flowers very numerous, small; leaflets of the calix ovate, concave, acute; corolla pale red, hirsute on the outside .- Native of the Canary Islands; it flowers in August and September.

53. Convolvulus Corymbosus. Leaves cordate; peduncles umbellate; stem creeping .--- Native of America, and New Caledonia

54. Convolvulus Spithamæus. Leaves cordate, pubescent: stem straight; peduncles one-flowered .- Native of Virginia.

55. Convolvulus Persicus. Leaves oval, tomentose; peduncles one-flowered; corolla white .-- Native of Persia, on the shores of the Caspian Sea.

lanceolate, ovate, smooth; stem decliniug; flowers solitary. It is an annual plant, with several thick herbaceous stalks about two feet long, not twining, but bending towards the ground, upon which many of the lower branches lie prostrate; leaves sessile; the peduncles come out just above the leaves, at the same joint and on the same side ; they are about two inches long, each sustaining one large open bell-shaped flower, of a fine blue colour, with a white bottom, varying to pure white, and sometimes beautifully variegated with both colours ; the white flowers are succeeded by white seeds, but in the blue ones they are dark-coloured .- Native of Barbary, Spain, and Sicily. It has long been considered as an ornamental plant in the borders of our flower gardens, under the name of convolvulus minor. It is propagated by seeds, which should be sown on the borders of the flower-garden, where they are intended to remain: the usual method is to put two or three seeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the seeds all grow, there should be but two left in each place, which will be sufficient; the others should be drawn out carefully, so as not to disturb the roots of those which arc left, after which they will require nothing except weeding. If the seeds be sown in autumn, the plants will flower in May, but those which are sown in the spring, will not flower till the middle of June, and will continue flowering until the frosts set in : the seeds ripen in August and September. The plants which bear variegated flowers have frequently plain flowers of both colours intermixed with them, which should be pulled off as soon as they appear, in order to continue the variegated or striped flowers.

57. Convolvulus Repens. Leaves sagittate, obtuse behind; stem creeping; peduncles one or two-flowered; root perennial; stems strong, smooth, winding, extending wide, and putting out roots at the joints; flowers large, sulphurcoloured, on long peduncles from the side of the stalks, each supporting one flower, with a large swelling calix; flowers rather large, whitish .- Native of the sandy coasts of Jamaica.

58. Convolvulus Reptans. Leaves hastate, lanceolate; ears rounded; stem creeping; pedancles one-flowered; corolla pale purple .- Native of the East Indies, China, and Cochin-china, where it is a common potherb. See the sixth species.

59. Convolvulus Edulis. Leaves cordate, entirc, and three-lobed, smooth ; stem creeping, angular. This differs from the fifteenth species in having the leaves heart-shaped, entire, three and five-lobed, not narrowed in the middle, so as to become sagittate : the roots are often as big as the fist, tubercled, fleshy like the batatas, esculent, very soft and sapid: it flowers very seldom .- Brought from Japan, where it is not known far from the coast.

60, Convolvulus Hirtus. Leaves cordate and subhastate, villose; stem and petioles hairy; peduncles many-flowered; annual, rising with slender, stiff, twining stalks, eight or nine feet high; flowers many together, at the end of strong peduncles; corolla purple .- Found by Osbeck in the East Indies. See the sixth species.

61. Convolvulus Soldanella ; Sea Bindweed. Leaves kidney-shaped : peduncles one-flowered ; roots small, white. stringy, sending out several weak trailing branches; the flowers are produced on the side of the branches at each joint, they are of a reddish purple colour, appear in July, and are succeeded by round capsules, having three cells, with one black seed in it. Every part of the leaves abounds with 56. Convolvulus Tricolor; Trailing Bindweed. Leaves a milky juice; half an ounce of the juice, or a drachm of the powder, is an acrid purge; the leaves, applied externally, are said to diminish dropsical swellings of the feet. According to Hill, the whole plant should be gathered fresh when it is about to flower, and ought to be boiled in ale, with some nutmeg and a clove or two, and this decoction should be administered in proportion to the person's strength ; it is a strong purge, and sometimes also operates by urine, without any danger to the patient; it is best adapted for robust constitutions, but it will cure dropsies and rheumatism. Hill declares, that he has known a gonorrhœa cured by it, but the reader is strongly advised to place no reliance upon so precarious a remedy; his best method of proceeding is, to put himself into the hands of a regular surgeon, immediately after he discovers himself to be infected with that infamous disease, for there is no other way whereby he can so safely and easily obtain a radical cure. The juice which oozes from the stalk and roots of the sea-bindweed may be saved; it hardens into a substance like scammony, and is an excellent purge. As this plant grows naturally on the sea beech, it cannot be long preserved in a garden. It is found on the sea-coasts of Frisia, Piedmont, Carniola, frequently upon the coasts of Norfolk, Essex, and Kent, also upon the north coast, and in Scotland, where it is called Scottish scurvy-grass, and improperly sea colewort. See the sixth species.

62. Convolvulus Pescapræ; Thick-leaved Bindweed. Leaves two-lobed; peduncles one-flowered; stem suffruticose, procumbent, creeping, somewhat villose, red, long; leaves blunt at both ends, often two-lobed, pandurate, emarginate, thick, tomentose; flowers axillary; corolla purplish. --Native of the East Indies, China, Cochin-china, and the eastern coast of Africa: annual; flowering in June and July. See the sixth species.

63. Convolvulus Brasiliensis; Brasilian Bindueed. Leaves emarginate, with two glands at the base; peduncles threeflowered; stems perennial, trailing and spreading to a great distance; flowers large, purple, produced by threes on very long peduncles.—Native of the West India islands, and of South America, near the shore. See the sixth species. Browne says, that it is common near the sea in Jamaica, that the leaves are beautifully veined, that the whole plant is milky, and that the root is a strong purgative, sometimes used with success in hydropic cases; he calls it purging sea bindweed.

64. Convolvulus Sublobatus. Upper leaves tooth-repand at the end; stem procumbent; flowers in a head; involucre six-leaved; corolla large.—Annual: native of the East Indies. See the sixth species.

65. Convolvulus Littoralis. Leaves oblong; lobes palmate; peduncles one-flowered; stem creeping.—Native of America. See the sixth species, for its propagation and culture.

66. Convolvulus Palmatus. Leaves palmate; lobes seven, sinuate, pointed; peduncles one-flowered; calices very large, spreading; stem twining. This rises with a strong winding stalk to the height of twenty feet; the flowers are large, purple, on long peduncles, and are succeeded by roundish seedvessels, having three cells, in each of which is lodged a single seed.—Native of Vera Cruz in New Spain. See the sixth species.

67. Convolvnlus Aristolochifolius. Leaves hastate, lanceolate, with rounded ears; peduncles many-flowered; stem twining. This rises with a slender twining stalk ten feet high; the flowers are produced in small clusters on long peduncles, they are yellow, and are succeeded by three-cornered seed-vessels: it is an annual plant.—Native of Carthagena, in New Spain. See the sixth species.

15

68. Convolvalus Glaber. Leaves ovate-oblong, smooth; peduacles one-flowered: calices ten-parted; stem twining, An annual plant, with twining stalks seven or eight feet high; the flowers come out at every joint, on long slender peduacles, each supporting a large purple flower, with the calix cut almost to the bottom in ten parts.—It was imported from the island of Barbuda. See the sixth species.

69. Convolvulus Multiflorus. Leaves cordate, smooth; peduncles many-flowered; seed villose, ferruginous; stem twining; stalks slender, twining, eight or ten feet high; peduncles rather long, with many purple flowers in bunches growing upon each.—It is annual, and a native of Jamaica. See the sixth species.

70. Convolvulus Hederaceus. Leaves triangular, acnte; flowers many, sessile, spreading; calices acute, many-cleft; stem twining; the flowers are blue.—It is annual, and native of Jamaica. See the sixth species.

71. Convolvulus Roseus. Leaves cordate, acuminate; peduncles two-flowered; stem twining; leaves on very long petioles, and flowers on long peduncles; seeds large, and covered with a fine down. This plant is annual, and one of the most beautiful of the genus, the flowers being very large, and of a fine rose-colour.—Native of Jamaica. See the sixth species.

72. Convolvulus Betonicifolius. Leaves cordate, sagittate; peduncles one-flowered; stem twining; corollas white, with purple bottoms.—Native of Africa.

73. Convolvulus Tuguriorum. Leaves cordate, sagittate, acute; stem angular, twining; peduncles four-cornered, oneflowered.—Native of New Zealand.

74. Convolvulus Cœlestis. Leaves cordate, extremely acuminate, pubescent; peduncles elongated, umbellate, trifid; stem twining.—Native of the island of Tanna, in the South Seas.

75. Convolvulus Mucronatus. Leaves palmate, pedate; lobes ciliate, mucronate; peduncles one-flowered; stem twining,—It is a native of the island of Tanna in the South Seas.

76. Convolvulus Tridentatus; *Trifid Bindweed*. Leaves wedge-shaped, three-cusped, dilated at the base, and toothed; peduncles one-flowered; stem twining: annual; flowering in July and August.—Native of the East Indies. See the sixth species.

77. Convolvulus Bufallinus. Stem shrubby, scandent; leaves cordate, sagittate, smooth; peduncles many-flowered; antheræ spiral; corolla bell-shaped.—Native of the woods of Cochin-china. See the sixth species.

78. Convolvulus Aggregatus. Leaves palmate, sevenlobed, hairy; flowers aggregate; stem twining, perennial, round, extremely hairy, branched; flowers white, large, axillary; common peduncle long, solitary; proper none; corolla tubular, five-cleft; segments acute, hairy, closed.—Native of Cochin-china. See the sixth species.

79. Convolvulus Hastatus. Leaves lanceolate, hastate; peduncles axillary, in pairs, two-flowered; stem twining, hairy.—Native of Arabia. See the sixth species.

80. Convolvulus Lanatus. Leaves lanceolate, linear, tomentose, older branches spiny; flowers in involucred heads; stem shrubby, erect, branched at bottom; corolla bellshaped, hairy on the outside, of a pale rose-colour; filamenta unequal; antheræ linear.—Native of the lower Egypt, and Mount Sinai. See the sixth species.

81. Convolvulus Hystrix. Shrubby: leaves oblong; flowers sessile, subsolitary; branches spinescent. This is a rigid shrub, very much branched, diffused, and a foot high; the branchlets somewhat silky; calycine leaflets hirsute, the two outer oblong, rigid, larger than the rest; corolla hirsute, small. Native of Arabia. See the sixth species.

82. Convolvulus Imperati. Leaves panduriform or entire, emarginate, cordate at the base: peduncles one-flowered; stem creeping; calix smooth, with oblong leaflets.—Native of the sandy shore at Bagnoli, near Naples; flowering in August and September.

63. Convolvulus Arenarius. Leaves obloug, emarginate, lobed at the base, or entire; peduncles one-flowered; corollas tubular; stem twining; the whole plant is smooth; stems filiform, purplish, flexuose; stigma capitate.—Native of the Azorcs, or Western Islands.

84. Convolvulus Wheleri. Leaves sagittate, roundish behind, and entire; pedancles round, one-flowered. This species varies with ovate leaves, having straight, shorter, rounded, lanceolate ears, or a little divaricate and lanceolate on the same plant.—Native of Spain, by the lake Albufera, in the kingdom of Valencia.

85. Convolvulus Lanuginosus. Leaves cordate-oblong, subhastate, silky, tomentose; ears toothed; peduncles threeflowered; stem hairy, herbaceous, twining, pale; corolla almost like that of scammony, yellowish, having on the outside a lanceolate purplish line, with a pile of yellow hairs to each lobe of the horder; style bifid.—Probably a native of the Levant. See the sixth species.

86. Convolvalus Incanus. Silky, tomentose: leaves lanceolate, sagitate, blant, somewhat toothed at the base; peduncles two-flowered; stem twining, herbaccous, round; the petioles only one-fourth of the length of the leaf; peduncle the same length with the leaves; corolla villose on the outside.—Native of America. See the sixth species.

87. Convolvulus Emarginatus. Leaves lanceolate, the lower ones emarginate, mucronate; peduncles one-flowered, outer calycine leaflets semicovate, large; stem twining, rooting at the bottom, muricated upwards with little spines, and having minute hairs thinly scattered over it at top, evcn.—Native of the East Indies. See the sixtli species.

88. Convolvulus Filicaulis. Leaves linear, lanceolate, obtuse, mucronate, dilated and toothed at the base; calycine leaflets oblong; stem herbaceous, filiform, twining, branched; stigma simple, bluntish.—Found by Isert in Guinea. See the sixth species.

89. Couvolvulns Angustifolius. Leaves linear, hasta'e, obtuse, mucronate, smooth ; ears almost quite entirc; peduncles one-flowered; stem fillform, twining, smooth, branched; leaves petioled, an inch or rather more in length; ears lanceolate, acute, sometimes straight; stigma bifid.—Nutive of the East Indies. See the sixth species.

90. Convolvulus Dentatus. Leaves bastate, smooth; ears toothed; peduncles many-flowered, muricate; stem twining, round, smooth,—Native of the East Indies. See the sixth species.

91. Convolvulus Bracteatus. Leaves cordate, almost entire, and three-lobed, hastate, attenuated; peduncles oneflowered, outer calycine leadlets bracte-shaped; stem herbaccous, twining, with short hairs thinly scattered over it; leaves two inches long, veined; corolla villose on the onter side.—Native of the East Indies. See the sixth species.

92. Convolvulus Dicolor. Leaves cordate, villose, angular, sublobate at the base; peduncles one-flowered, outer calycine leaflets bracte shaped; corolla white, with a violet purple base, hairy on the outside.--Native of the East Indies. See the sixth species.

93. Convolvulus Platanifolius. Leaves cordate, three-lobed; side-lobes tooth-angular; peduncles subtriflorous, and calices 31.

almost equal, smooth; stem round; stigma capitate.-Native of America. See the sixth species.

CON

94. Convolvulus Acuminatus. Leaves cordate, and threelobed, attenuated ; peduncles elongated, many-flowered, and calices smooth; stem twining, with a few minute hairs scattered over it, pressed close to it, and visible only with a magnifer; flowers about five, alternate; pedicels an inch and half long, a little thicker under the leaf; corolla large, bell-shaped, purple, with a pale base, with five paler, lanceolate, attenuated rays, running to the edge; stigma capitate.—Native of the West Indies. See the sixth species.

95. Convolvulus Gemellus. Leaves cordate, somewhat villose underneath; peduncles two-flowered; stem twining, tender, pubescent at top; peduncles the length of the petiole, thickened at top, two-flowered, seldom one-flowered; pedicels a little shorter than the peduncle; one shorter, thicker, without any bracte, the other more tender, with two bractes in the middle, both turned back when ripe; corolla bellshaped, six times as large as the calix, smooth.—Native of the island of Java. See the sixth species.

96. Convolvulus Striatus. Leaves cordate, attenuated, smooth; peduncles longer than the leaf, having three or four flowers; corollas smooth, striated on the outside; stem herbaceous, twining, pubescent, round, slender.— Native of the East Indies. See the sixth species.

97. Convolvulus Guianensis. Leaves cordate, ovate underneath, with the calices tomeutose; peduncles elongated; flowers corymbed, in a sort of head; stem twining, branched, round, purplish, villose, rugged.—Native of Cayenne. See the sixth species.

98. Convolvulus Capitatus. Hispid: leaves cordate-ovate; flowers in a head, five in uumber; peduncles axillary, solitary, a little shorter than the leaves, without any joint; stem twining, herbaccous, rugged.—Native of the East Indies. See the sixtle species.

99. Convolvulus Hispidus. Extremely hirsute: leaves cordate-ovate; flowers nmbelled; peduncles very short. It is easily known from the other species by its shagginess; corolla smooth; stigmas capitate.—Native of the East Indies. See the sixth species.

100. Convolvulus Parviflorus. Leaves cordate, acuminate, smooth; peduncles many-flowered, and calices acuminate, villose; stem weak, slightly villose at top; corolla blue, smooth, twice as long as the calix, five cleft.—Native of Java. See the sixth species.

101. Convolvulus Violaceus. Leaves and the two outer leaflets of the calix cordate-ovate, acute; peduacles elongated, bifd, many-flowered; stem, as well as the petioles, peduacles, and calices, villose; corolla bell-shaped, violet-coloured, with five lanceolate paler rays.—Native of the island of Santa Cruz. See the sixt species.

102. Convolvulus Triflorus. Leaves cordate-lanccolate, attenuated, smooth, obtuse; pcduncles three-flowcred; stem hcrbaceous, twining, smooth; leaves two inches long, quite entire, simply veined; the veins underneath villose, when examined with a magnifier; the under surface is paler; they are rounded at the end, and mucronate; the lobes are rounded behind, and are sometimes, but seldom, obscurely angular.— Native of the East Indies. Sce the sixth species.

103. Convolvulus Bifidus. Leaves cordate-oblong, acuminate, very soft underneath; peduncles bifid, many-flowered; stem twining, villose; corolla almost funnel-shaped, three times as long as the calix, with five slender villose lines on the outside; lobes acute, bearded at the tip.— Native of the East Indies and the island of Java. See the sixth species.

104. Convolvulus Triqueter. Leaves cordate-acute, sub-4 Y villose; peduncles many-flowered; stem three-keeled, pubes- crowned with a sessile feather, with simple rays as long as cent, rendered triangular by three subfoliaceous very slender decurrent lines .- Native of the island of Santa Cruz. Sce the sixth species.

CON

105. Convolvulus Quinqueflorus. Leaves sagittate ovate, attenuated, smooth, crenate, subrepand; peduncles mostly five-flowered; stem slightly pubescent, round, branched; peduncles the length of the leaves; corolla twice as long as the calix, with the lobcs bearded at the tip; stigma bifid. Supposed to come from the Islc of Bourbon. See the sixth species.

106. Convolvulus Crenatus. Tomentose, silky: leaves cordate-oblong, extremely blunt, crenulate; peduncles one flowered; stem twining; leaves nerved, mucronate; ears straight, oblong, obtuse; stigma slightly bifid .--- Native of Brazil .-- See the sixth species.

107. Convolvulus Quinquelobus. Leaves palmate, fivetobed, scrrulate, blunt, smooth; axils tomentose; peduncles one-flowered; stem smooth, round, twining; corolla almost bell-shaped, smooth, purple .-- Native of the island of Santa Cruz, . See the sixth species.

108. Convolvulus Venosus. Very smooth : leaves digitate. quinate; leaflets petioled, acuminate, quite entire; peduncles many flowered; stem twining, round, smooth; corolla funnel-shaped .--- Native country unknown. Sce the sixth species.

109. Convolvulus Tennifolius. Leaves digitate, in fives; leaflets linear: peduncles four or five-flowered. The whole of this plaut is smooth; stem angular, twining; calix smooth, with oblong leaflets; stigma acute .-- Native of the West Indies. See the sixth species.

110. Convolvulus Saxatilis. Extremely hirsute: leaves linear; flowers in heads; calices acuminate. This differs from the forty-seventh species, which it otherwise resembles. in being wholly covered with a lanuginous shagginess, instead of the silvery-shining, appressed, scarcely distinct hairs, as that is .- Native of Spain.

Conuza ; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix: common, imbricate, roundish, squarrose; scales acute, the outer somewhat spreading, Corolla; compound, tubulose; corollets hermaphrodite, numerous, tubular in the disk : females apetalous, roundish in the circuit; proper of the hermaphrodite funnel-form; border five-cleft, patulous. Of the Females, funnel-form; border three-cleft. Stamina, in the hermaphrodites: filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil, in the hermaphrodites: germen oblong; style filiform, length of the hermanhrodite, more slender; stigmas two, very slender. Pericarp: none; calix converging. Seeds, to the hermaphrodites: solitary, oblong; down simple: to the females solitary, oblong; down simple; receptacle naked, flat. ESSENTIAL CHARACTER. Calix : imbricate, roundish. Corolla : of the ray three-cleft. Down : simple. Receptacle : naked .---- The species are,

1. Convza Squarrosa: Great Fleabane, or Plowman's Spikenard. Leaves lanceolate, acute ; stem herbaceous, corymbed; calices squarrose; root biennial; stems a foot in height, upright, panicled at the end, purplish, with a white woolliness; branches straight; numerous flowering heads terminate the stem and branches, on short downy peduncles, with each a small lanceolate bracte; corollas yellow, yellowish, or dusky purple; florets without pistils, in the circumference with pistils; individuals, with only pistils slightly cloven into three, have at first sight the appearance of a funnel-shaped floret, but are really more of the nature of a ligulate floret; seeds small, blackish, longitudinally furrowed, earth, and plunged into a hot-bed, observing to screen them

the calix : the smell is slightly but not ungratefully aromatic. Tragus reports it to be an emmenagogue, but it is scarcely known officinally. It is disputed, says Hill, whether this species of fleabane, or another which is smaller and has globous flowers, have the greater virtue ; but the majority contend for this. The juice of the whole plant curcs the itch by external application, and the very smell of the herb is said to destroy fleas. Meyrick informs us, that it is reckoned a good wound-herb, and frequently taken in decoction for bruises, ruptures, inward wounds, pains in the side, and difficulty of breathing .- Native of Denmark, Germany, Holland, France, Switzerland, Carniola, and Piedmont, chiefly upon dry mountainous pastures by hedge-sides and in woods. In Great Britain it is generally found upon a calcareous soil, as at Shelford, Whittlesford, Hildersham, and Abington in Cambridgeshire; it is common in a clayey soil in the woods of Norfolk; also in Charlton wood, and near Dartford and Greenhithe, in Kent: near Harefield in Middlesex, and Finshead in Northamptonshire also, but not commonly in Scotland. It flowers from July to October, and being a native is seldom admitted into gardens. If the seeds be permitted to scatter, the plants will come up in the following spring, and require no other care but to keep them clean from weeds.

CON

2. Convza Linifolia ; Flax-leaved Fleabane. Stems a foot or a foot and half in height, crect, hardish, green; branches slender, straight at the top of the stems; flowers on short peduucles, terminating; florets white, slender, reflex .- It flowers in August and September, and is a hardy perennial.

3. Convza Sordida: Small-flowered Fleabane. Leaves linear, quite entire; peduncles long, three-flowered; stcm undershrubby, like that of lavender, branched and white; peduncles straight, usually three-flowered at the end; calycine scales brown at the cdge .-- Native of the south of Europe. It flowers from July to September, and may be kept in a green-house, dry-stove, or glass-case.

4. Convza Saxatilis; Rock Fleabane. Leaves linear, almost entire, tomentose underneath; peduncles very long, one-flowcred; calycine leaves subulate; leaves heaped at bottom; peduncles naked; calveine scales black at the edge; stems first procumbent, then erect; calices cylindric, patulous and membranaccous at the end; very many naked festale florets in the circumference .- Native of Spain, Italy, Istria, Carinthia, the Valais, Palestine, and the Cape of Good Hope. Mr. Ray found it in abundance on walls and rocks about Messina in Sicily. It requires the protection of a green-house, dry-stove, or glass-case, in our climate.

5. Conyza Canescens; Hoary Fleabane. Leaves linear; panicle fastigiate: the whole plant is hoary; stems almost simple, columnar, striated, with short lateral branches; calix subovate, shorter by half than the flower and down; flower purple, and mixed with the down .- Native of the Cape of Good Hope, and requires the same protection as the preceding species in our climate.

6. Conyza Rupestris; African Fleabane. Leaves spatulate, somewhat toothed, tomentose; stem undershrubby; peduncles elongated, one-flowered; corollas yellow, with very numerous florets .- Native of Arabia, This and the seventh, tenth, cleventh, twelfth, from the fourteenth to the twentyfirst, from the twenty-second to the twenty-fourth, the twentyseventh, and from the thirty-first to the forty-third species, are too tender to thrive in the open air in England : their seed therefore must be sown upon a hot-bed in the beginning of April, and when the plants are fit to remove, they must be each transplanted into a small pot filled with light sandy

from the sun until they have taken new root; they must afterwards have free air admitted to them every day, in proportion to the warmth of the season, and should also be frequently watered in warm weather, but in small quantities at each time. As they advance in strength, their share of air should be increased, and in warm seasons they may be wholly exposed in the open air during a few weeks in the heat of if the nights prove cold, or much wet fall, they must be immediately removed under shelter. If these plants be placed in a moderate stove in winter, they will thrive better thau under great heat. With the above management they will flower well in July, but in general do not perfect their seeds in England.

7. Conyza Scabra; Rough Fleabane. Leaves oblong, somewhat toothed, sessile, scabrous; peduncles one-flowered, elongated; leaves rugged on both surfaces, with four or five teeth on each side.—Native of the East Indies. See the preceding species.

8. Conyza Asteroides; Starwort Fleabane. Leaves broadlanceolate, subserrate; corollas radiate; calices squarrose.— It flowers in August and September, and is a native of North America. It is a hardy perennial.

9. Conyan Bifrons; Oral-leaced Fleahame. Leaves orateoblong, siem-clashing. From a thick fibrous root spring upmany upright stalks; leaves rough, decurrent, terminating in round bunches, yellow, appearing in July.—Native of Canada. This is a hardy perennial, which is propagated by seeds sown on a bed of light earth in the spring, taking care to thin and weed the plants when they come up; they should be removed to where they are intended to remain in the next autumn, and they also must be kept free from weeks; the second year they will flower and produce ripe seeds, and will continue two years, if it be not too good, for they often rot when planted in a rich soil.

10. Conyza Bifoliata; *Two-leaved Fleabane*. Leaves oval, toothed; peduncles two-leaved; bractes opposite,-Native of the East Indies. See the sixth species.

11. Conyza Publicera. Leaves oblong, somewhat toolhed, subpetiolate: peduncles would, subtaining about two flowers: branches herbaceous, with a few scattered hairs on them; leaves alternate, wedge shaped at the base, green on both sides, with a few scattering hairs on them, having three or four narrow serratures, not scabrous; peduncles axillary towards the top, with from two to four flowers.—Native of the East Indies. See the sixth species.

12. Conyra Tortuosa. Stem tortuose, shrnbby; leaves orateoblong, quite entire; racemes reflex; branches subhirsute, straited, simple; flowers alternate, sessile, turned up, rounded; ealycine scales ovate, the inner lanceolate,—Native of Madagascar and Vera Cruz. See the sixth species, for its prographication and culture.

13. Couyza Caudida; Woolly Firabane. Leaves orate, tomentose; howers crowded; peduncles both lateral and terminating; stem suffruticose, six inches high, upright, nound, lairy, whishis, branched; leaves very while, quite entire, alternate; flowers purple, peduncled, heaped. It has a pleasant small: it sometimes varies with a short recurved ray.—Native of Caudia, Sicily, and Cochin-china. See the sixth species.

14. Conyza Authelminitica; Purple Fleabane, Leaves Ianceolate-ovate, scabrous; pedunckes one flowered; calices squarrose; root animal; stem erect, ronndish, branched, sightly tomenisose, spotted with purple; the branches erect, scattered; leaves alternate, serrate, with acute unequal teeth, narrowed at the base into the petiole, scattorous on the upper surface, smooth, and veined on the lower; flowers in panicles at the ends of the branches, on long peduwcles, thickening towards the flower, and having one leaf on each; a solitary peduncle terminates the stalk; corolla uniform, consisting of from twenty-five to forty hermaphroditie red florets; those of the ray reflex. The leaves of this plant have an exceeding bitter raste. It flowers in August and September; is bienmial, and a native of the East Indies. It requires the protection of a green-house, dry-stove, or glass-case, in our elimate.

16. Conyza Cinerea: Ash-coloured Fleabare. Leaves oblong; flowers panieled; corollas cylindric, twice the length of the calix; stem erect, panieled, pulesceut; corollas purple.—Annual; native of the East Indies. See the sixth species.

17. Conyza Odorata; Sweet-scented Fleabare. Leaves ovate, serrate, subtomentose, acute; stem a horescent, corymbed; corollas almost globular. This is an odoriferous plant, with an upright shrubby stem, four feet ligh, the branches rising in form of a corymb; flowers purple, lateral, and terrainting, several together; the corollets so short as not to emerge from the caix.—Native of the East Indics and Cochin-china. See the sixth species.

18. Conyza Chinensis, Chinese Ficabane. Leaves lance-otac, reflex, serrate, tonnentose underneath; flowers terminating, heaped; stem suffruticose, four feel high, upright, round, smooth, branched at top; leaves hardish, pe-tioled, alternate; flowers yellow, peduucled, terminating... Native of China, Coclini-china, Java, and Amboyna. See the sixth species.

19. Conyza Hirsula; Skaggy Fleabare. Leaves oval, quite entire, scabrous, hirsule anderneath ; stem herbaceons, a foot high, upright, simple, round, hairy, having few leaves; these are oblong, sharpish, toothletted, hairy, scattered; flowers yellow, crowded, terminating; flowers in racent enter structure. Statise of Java, China, and Cochin-china. See the sixth species.

20. Conyxa Arborescens; Tre Fleabare. Leaves orate, quie entire, acute, tomentose underneath; spikes recurved, oue-ranked; bractes reflex. This is a shrub, with a depressed tragged stem; corolla uniform, twelve hermaphrodulte corollets in the circuit, a little higher than the others, giving the flower a radiate appearance. It commonly rises to the height of three feet and a half or more in the low lands of Jamaica. See the sixth species.

21. Conyza Fruticosa; Shrubby Fleabane. Leaves ovate, quite entire, obtuse; flowers sessile, alternate; branchlets flexuose.—Native of South America. See the sixth species.

22. Conyza Virgata; Winged-stalked Fiedbane, Leaves decorrent, hanceolate, serulate; stems wand-like; Howers spiked, in scattered heaps. It is hairy, and rises generally to the height of two feet or more. The leaves are somewhat hoary; the flower-branches are very long and slender, and disposed in the form of spikes at top; the lower flowers are in threes, the upper solitary. It flowers in August and Septimater ember.—Native of Janaica and Carolina. It may be kept in a greenhouse, dry-stove, or glass-case. Net the sixth species.

23. Conyza Decurrens. Leaves decurrent, lanceolate, scrrulate; flowers axillary, sessile, glomerate; root annual; glomerules of flowers ash-coloured, from the axils of the leaves, globular.—Native of India. See the sixth species.

24. Conyza Aurita. Leaves dentate sinuate ; earlets sub-

CON

decurrent: root-leaves larger than the rest, stiffer, smoother, are white and are succeeded by long flat seeds,-Native of obovate, with red veins, widely serrate, and waved between the servatures; stem erect, stiff, a foot high, reddish, hairy, branched; the branches erect, simple; flowers from the top of the stem, peduncled, scattered in various ways : florets minute, white, with minute linear rays; pistils very long, erect, -Native of moistish places in the East Indies. See the sixth species.

25. Convza Inuloides ; Cluster flowered Fleabane. Leaves cuneiform, linear, obtuse, notch-toothletted, smooth : stem shrubby; antheræ two-bristled; stem proliferous, dichotomous, smooth : calix purplish : flowers yellow .- Native of the island of Teneriffe. This plant may be kept in a green-honse, stove, or under a glass-case.

26. Convza Sericea ; Snowy Fleabane. Leaves linear, filiform: they and the stems tomentose silky: flowers panicled. This is easily known by the silky whiteness of the branches, leaves, and peduncles, and by its vellow flowers. The bark and wood have an acrid pungent taste; and the inbabitants of the Canary Islands, where it naturally grows, use it in the tooth-ache. It may be kept in a green-house, dry-stove, or glass-case.

27. Conyza Ægyptiaca; Egyptian Fleabane. Leaves oblong-spatulate, toothed, hairy; flowers subpanicled, globular; calveine leaflets subulate, soft; stem erect, a foot and a half in height, somewhat striated, pubescent, and somewhat viscid; branches from the upper axils; flowers terminating, four or five, roundish, on purple peduncles; corollas yellow, with minute florets, naked in the ray, and very abundant ; pistils yellow, quickly vanishing, surrounding the disk with a kind of broad downy ring .- It flowers in July, is annual, and a native of Egypt. See the sixth species. This must be propagated from seeds.

28. Conyza Rugosa; St. Helena Fleabane. Shrubby: leaves wedge-shaped, serrate, villose, wrinkled, netted; peduncles villose, one-flowered ; flowers radiate .- It flowers in November, and is a native of the island of St. Hclena. It requires protection in our climate.

29. Conyza Incisa; Ear-leaved Fleubane. Leaves ovate, subcordate, hairy, viscid, toothed, eared at the base; disk of the receptacle honey-combed .- It flowers from June till August, and is a native of the Cape of Good Hope. It may be kept in a green-house or dry-stove.

30. Convza Patula; Spreading Fleabane, Leaves elliptic, serrate, villose underneath; calices subglobular; leaflets lanceolate, subulate; branches spreading; annual; stem taper, herbaccous, a foot and a half in height, covered lightly with a mealy down, and branching out almost the whole length; corollas purple .- Native of the northern parts of China. It may be kept in a green-house, dry-stove, or glasscase. The secds of this species should be sown upon a moderate hot-bed in the beginning of April; when the plants are fit to remove, they should be transplanted into a fresh hot-bed, observing to shade them from the sun till they have taken fresh root. In June they may be gradually hardened to the open air, and part of them may be planted in warm borders, where they will flower, and, if the season prove warm, ripen their sceds; but it will be prudent to keep some plants in pots, placed in an airy glass-case, in order to secure good seeds.

S1. Conyza Tomentosa. Arborescent: leaves oblong, ovate, tomentose, cinereous underneath; flowers terminating, on branching peduncles. It rises with a woody stalk, ten or twelve feet high, dividing into many branches, the bark of which is covered with a brown nap; leaves alternate on short middle; the smaller branches are set with very narrow, obpetioles; flowers in loose spikes, ranged on one side; they long, pointed leaves, which grow close to the stalks; and at

La Vera Cruz in New Spain. See the sixth species.

32. Convza Salicifolia: Willow-leaved Fleabane, Leaves linear, decurrent, serrate; flowers corymbcd, terminating, on branching peduncles. This has a percential root, from which spring several upright stalks, three feet high. The flowers are produced at the eud of the stalks in round bunches : they are small, and of a purple colour, and are succeeded by oblong flat seeds. - Native of La Vera Cruz in New Spain. See the sixth species.

33. Conyza Corymbosa. Arborescent: leaves lanceolate: flowers corymbed, terminating on branching peduncles: stem strong, woody, fourteen or sixteen feet high, covered with an ash-coloured bark, and divided at top into many woody branches; leaves alternate, on short petioles. The branches are terminated by roundish bunches of white flowers, on long peduncics, several together .- Sent from La Vera Cruz. See the sixth species.

34. Convza Viscosa, Herbaceous : leaves ovate, serrate, villose; flowers both axillary and terminating. This is an annual plant, growing in low moist places, where the water stands in winter. It has an herbaceous branching stalk, one foot high, with one oval sessile leaf at each joint, covered with a white hairy down. The flowers are produced from the side of the branches, on slender petioles, each for the most part sustaining three flowers, which are white, and succecded by chaffy seeds .- Native of La Vera Cruz. This plant will sometimes ripen its seeds in England, if the autumn prove favourable, but it has little beauty to recommend it. The seeds of the other natives of South America must be procured from that country; and being long upon their passage, will rarcly vegetate in the first year.

35. Conyza Symphytifolia; Comfrey-leaved Fleabane. Leaves oblong, ovate, scabrous ; flowers racemed, terminating; stem herbaceous; root perennial; stem three feet high, terminated by branching peduncles, each sustaining several yellow flowers, not much unlike those of the common sort : leaves from four to five inches long, and one and a half broad in the middle, rough like those of comfrey,-Native of La Vera Cruz. See the sixth species.

36, Conyza Scandens; Climbing Fleabane. Leaves lanceolate, scabrous, nerved, sessile ; racemes recurved ; flowers ascending; peduncles lateral; stem shrubby, climbing. This has a climbing shrubby stalk, fourteen or sixteen feet high, dividing into many branches; leaves the size of those of the bay-tree, aud full as thick in their texture, having as many deep transverse nerves, running from the mid-rib to the sides, and of a pale-green colour: flowers large and white, produced in long spikes ranged on the upper side only, from the side of the branches, and pointing upwards .- Sent from La Vera Cruz. This plant makes a fine appearance in the stove while in flower, and retaining its leaves all the year, makes an agreeable variety among other tender plants.

37. Conyza Trinervia. Leaves ovate, smooth, threenerved, quite entire, sessile; flowers in spikes, terminating; stem shrubby, six or seven feet high, dividing into several woody branches; flowers white, succeeded by oblong flat seeds.--Native of Carthagena in New Spain. See the sixth species.

38. Convza Uniflora. Leaves lanceolate, acute, sessile; flowers solitary, lateral; calices coloured; stem shrubby, branching. This rises with a shrubby stalk, eight or ten feet high, dividing into many long slender branches; leaves three inches long, and three-quarters of an inch broad in the

361

each joint is produced one pretty large white flower, with a purple calix; these flowers come out the whole length of the small branches, sitting close to the base of the leaves, so that the plants make a pretty appearance when in flower .-- Native of Carthagena in New Spain. See the sixth species.

39. Conyza Spicata. Shrubby: leaves ovate, three-nerved; flowers in axillary spikes. This has a strong woody stem, rising ten or twelve feet high, dividing into several branches, which have a dark-brown bark .-- Native of Carthagena in New Spain. See the sixth species.

40. Conyza Pedunculata. Leaves ovate, lanceolate, threenerved; peduncles very long, terminating; flowers in corymbs. It rises with a shrubby stem to the height of six or seven feet, dividing into several branches, which have a dark-brown bark .- Native of Campeachy. See the sixth species.

41. Conyza Baccharis. Leavés ovate-oblong, obtuse, serrate, half stem-clasping; flowers in terminating corymbs; stem shrubby, ten or twelve feet high, sending out many strong woody branches, covered with a dark-coloured bark. The flowers are purple, and are succeeded by flat seeds.----Native of Campeachy. See the sixth species.

42. Conyza Purpurascens. Leaves ovate, lanceolate, serrate, subtomentose; stem subherbaceous, simple at bottom, corymbed at top; flowers ovate. The flowers are purple, and are produced in round bunches at the end of the branches. -Native of the low marshy lands of Jamaica. See the sixth species.

43. Convza Rigida. Leaves petioled, obovate, entire, rugged, veined underneath; spikes flexuose; flowers in pairs, all directed the same way .- Native of Jamaica. See the sixth species.

Copaifera ; a genus of the class Decandria, order Monogynia.-GENERIC CHARACTER. Calix; none. Corolla: petals four, oblong, acute, concave, very spreading. Stamina: filamenta ten, filiform, incurved, a little longer than the corolla; antheræ oblong, incumbent. Pistil: germen round, compressed, flat, pedicelled ; style filiform, incurvate, length of the stamina; stigma obtuse. Pericarp: legume ovate, bivalve, pointed with part of the style. Seed : single, ovate, involved by a berried aril. ESSENTIAL CHARACTER. Calix : none. Petals : four. Legume : ovate. Seed : one, with a berried aril .---- The only known species is,

1. Copaifera Officinalis; Balsam of Capiva Tree. This is a lofty elegant tree, with a handsome head; the extreme branches at the axils are flexuose, and have a smoothish bark. of a brownish ash-colour .- It is a native of South America, and common near Tolu, about sixty leagues from Carthagena. This tree yields very considerable quantities of a fluid balsam or resin, which is obtained by perforating the trunk, and thickens by degrees. It is known in medicine by the title of balsamum capivi, and has an agreeable smell, with a bitterish taste ; on being shaken, easily unites with water, making the liquor turbid and milky, but soon separates, and rises to the surface when suffered to stand. Dropped on sugar, or triturated with thick mucilages, or with whites of eggs, it becomes more permanently miscible with water into an uniform milky fluid, in which form it is generally taken, as well as mixed with powders in a bolus or electuary. It readily combines with distilled oils ; and in rectified spirit of wine, dissolves into a transparent fragrant liquor, more agreeable than the balsam itself. It has been employed principally, and in preference to the other balsams, in fluor albus, and in ulcerations of the urinary passages. Fuller says, he has known dry deep coughs, expectoration of blood and pus, voiding of chyle in-31.

by it; and that, notwithstanding the warmth and bitterness of its taste, he has found it to agree in hectic cases. He observes, that it gives the urine a better taste, but not a violet smell, as the turpentines do, although it is, like them, of a purgative quality. The usual dose is from ten to thirty or forty drops. When given in too large doses, or too long continued, it has produced considerable inconveniences, exciting febrile heats, pains in the head, with other unfavourable symptoms. Hill observes, that it has the same virtues with turpentine, but is more powerful; and that it is excellent in the whites, and in all complaints of the urinary passages.

Coppices. See Planting.

Coprosma ; a genus of the class Polygamia, order Monœcia. -GENERIC CHARACTER. Hermaphrodite Calix : periauth one leafed, inferior, very short, permanent, with five acute distant toothlets. Corolla : one-petalled, funnel-form, five or six-cleft; segments acute, erect. Stamina : filamenta five, six, or seven, capillary; antheræ oblong, bifid at the base, erect, slightly incurved, acuminate. Pistil: germen oblong; styles two, filiform, cohering slightly at the base, longer than the corolla, divaricating; stigmas simple, Pericarp: berry ovate-globular, two-seeded. Seeds : two, ovate, flat on one side, convex on the other. Male Calix. Corolla and Stamina: as in the hermaphrodite. ESSENTIAL CHARACTER. Calix : one-leafed, five-toothed. Corolla : five or six-cleft. Stamina : five, six, or seven. Hermaphrodite Styles : two, long; berry containing two flattish weeds. The plants of this genus are shrubs .---- The species are,

1. Coprosma Fætidissima. Flowers solitary, remarkable for an abominably fetid smcll .-- Discovered in Queen Charlotte's Sound, New Zealand.

2. Coprosma Lucida. Peduncles compound; leaves petioled, ovate, acuminate both ways, quite entire; stipule, solitary, sharp, combining the leaves; peduncles solitary, opposite, two-leaved, divided into other peduncles, terminated by capitate flowers; calix and corolla greenish.

Coral Tree, See Erythrina.

Coral-wort, See Dentaria.

Corchorus ; a genus of the class Polyandria, order Monogynia .- GENERIC CHABACTER. Calix : perianth fiveleaved ; leaflets linear-lanceolate, acute, erect, deciduous, Corolla: petals five, oblong, obtuse, narrower beneath, erect, length of the calix. Stamina : filamenta numerous, capillary. shorter than the corolla; antheræ small. Pistil : germen oblong, furrowed; style thick, short; stigma two-cleft. Pericarp : capsule oblong, five-celled, five-valved. Seeds : very many, cornered, pointed. ESSENTIAL CHARACTER. Corolla : five-petalled. Calix : five-leaved, deciduous. Capsule : many-valved, many-celled .- All the plants of this genus are too tender to thrive in the open air in England, and therefore their seeds must be sown upon a hot-bed in spring; and when the plants are fit to remove, they should be transplanted into a fresh hot-bed to bring the plants forward. otherwise they will not ripen seeds. When they are rooted in this new hot-bed, free air must be every day admitted to them in proportion to the warmth of the season, for they must not be drawn up weakly; and when they have acquired strength, they should be transplanted each into a separate pot, and plunged into a hot-bed, always taking care to exclude the sunbeams until they have struck fresh roots; they should then have a large share of fresh air, and be refreshed with water every day. In June they ought to be gradually inured to the open air, and part of them may be shaken out of the pots, and planted in a warm border, where, if the season prove warm, they will flower and perfect their seeds; but as stead of urine, together with great pain and weakness, cured these will sometimes fail, it will be proper to put one or two 4Z

glass-case, where they may be screened from bad weather; and from these, good sorts may always be obtained .---- The species are.

COR

1. Corchorus Olitorius ; Bristly-leaved Corchorus, or Common Jews' Mallow. Capsules oblong, ventricose; the lower servatures of the leaves setaceous. It is an annual plant about two feet high, and dividing into several branches ; flowers sessile, solitary, yellow ; leaves three-nerved .- Native of the East and West Indies, and of Africa. Rauwolf says, it is sown in great plenty about Aleppo, as a potherb, the Jews boiling the leaves to eat with their meat. It flowers in July and August, and the seeds ripen in autumn.

2. Corchorus Trilocularis. Capsules three-celled, threevalved, three-sided; angles bifid, scabrous; leaves oblong, the lowest serratures setaceous; root annual; stems smooth and even, erect, a foot in height, round, green; stipules setaceous, small; leaves alternate, petiolate, marked with lines, naked, the under surface scabrous, lanceolate, waveserrate .- Native of Arabia.

3. Corchorus Tridens. Capsules linear, somewhat lumnar, scabrous; the lowest serratures of the leaves scabrous; stem smooth and even, green; stipules three-parted, setaceous; capsules linear, scabrous .- Native of the East Indies.

4. Corchorus Estuans; Hornbeam-leaved Corchorus. Capsnles oblong, three-celled, three-valved, six-furrowed, six-cusped; leaves cordate, the lowest serratures setaceous; stem strong, two feet high, divided at top into two or three branches; leaves on long petioles, and between them several smaller leaves nearly of the same form, sitting close to the branches .- Native of the West Indies.

5. Corchorus Capsularis; Heart-leaved Corchorus. Capsules roundish, depressed, wrinkled; the lower servatures of the leaves setaceous. This rises with a slender stalk, about three feet high, sending out several weak branches. At each joint is one leaf of an oblong heart-shape, ending in a long acute point, serrate, and on a short petiole. The flowers come out singly on the side of the branches, to which they very closely adhere ; petals emarginate .- Native of the East Indies and China.

6. Corchorus Hirsutus. Capsules roundish, woolly ; leaves ovate, obtuse, tomentose, equally serrate. This shrub grows to the height of a man, with many round branches, the young ones villose; leaves alternate, petioled, crenate, thickish, veined, hoary underneath; petals yellow, roundish, spreading very much, the length of the calix; stamina the length and colour of the corolla, which is orange-coloured; capsules cylindric, woolly .- Native of Japan, and of the West Indies. This plant should be removed into the stove in autumn, and plunged into the bark-bed, where it will flower early, and ripen seeds in the second year.

7. Corchorus Japonicus. Capsules round, smooth ; leaves doubly serrate; stem shrubby, two feet high or more, smooth; petiole a line in length; flowers terminating, solitary, ou short peduncles; corolla dark yellow, or orange-coloured .- Native of Japan, where it is cultivated for the elegance of its flowers, which come forth in February, and the following months.

8. Corchorus Hirtus. Capsules oblong; they and the stem hairy; leaves oblong, equally serrate; root annual; stem upright, round, branched, especially at top, from two to three feet high ; leaves alternate, lanceolate, acute, finely serrate, on short petioles, somewhat hairy, wrinkled on both sides; flowers without scent, axillary, peduncled, solitary, or in pairs ; calvcine leaflets hispid, spreading very much, flat, lanceolate-linear, acuminate, yellowish green; petals yellow, shorter than the calix, spreading much, very blunt, TIAL CHARACTER. Corolla: funnel-form. Style: dicho-

plants of each sort into pots, which should be placed in a narrowed a little towards the base; seeds black, angular, small,-Native of the West Indies.

9. Corchorus Siliquosus: Germander-leaved Corchorus. Capsules linear, compressed, two-valved; leaves lanceolate. equally servate. It is an herbaceous plant, but branched like a shrub, with a round smooth stem, and alternate, upright, nubescent branches; leaves vetioled, alternate, small, nerved, smooth, with smaller leaves in the axils; stipules subulate, opposite.-Native of the West Indies, where it flowers almost the whole year, though only from June till August in England. It is very common in dry places in all the sugar colonies, seldom rising above two feet and a half high, and is generally used for besoms by the negroes.

10. Corchorus Tetragenus. Leaves ovate-cordate, crenate ; capsules four-cornered, reflected at the points ; height about two feet, dividing into small branches; flowers very small, pale yellow, succeeded by swelling, rough, fourcornered seed-vessels, about an inch long, flatted at top, where there are four reflex horns, giving them some resemblance to the clove .- Native of both Indies.

11. Corchorus Linearis. Leaves lanceolate, serrate toothed; capsules linear, compressed, two-valved; height three feet, with several weak side-branches; leaves about three inches long, and one inch broad in the middle, lessening gradually to both ends, sitting close to the branches. The flowers come out singly opposite to the leaves ; they are very small, of a pale yellow, and are succeeded by seed-vessels nearly two inches long, flat, two-celled, with small angular seeds .- Native of Carthagena in New Spain.

12. Corchorus Bifurcatus. Leaves cordate, serrate ; capsules linear, compressed, having two horns at the points. It rises with a strong herbaceous stalk, between three and four feet high, sending out several side-branches, which grow erect. The flowers come out from the side of the branches. on short peduncles; they are very small, and of a pale vellow colour .- Native of Jamaica.

13. Corchorus Fascicularis. Capsules oblong, subsessile, hoary, mucronate, two or three together; leaves lanceolateoblong, smooth; serratures equal; branches round and smooth; leaves petioled, narrow, blunt, the lower serratures not bristle-shaped; fruits ash-coloured, with hairs, threevalved .- Native of the East Indies.

14. Corchorus.Flexuosus. Leaves doubly serrate, cuspi-date; stem flexuose, round, slightly angular by the decurrent leaves, smooth, erect, two feet high ; flowers at the ends of the branches vellow .- Native of Japan.

15. Corchorus Serratus. Leaves oblong, serrate, cuspi-date; branches smooth; stem erect, smooth; branches round, purple, erect; leaves alternate, petioled; serratures large, setaceous at the tip.-Native of Japan.

16. Corchorus Scandens. Leaves ovate, setaceous, serrate, opposite; stem and branches flexuose, scandent; leaves on very short petioles, rounded at the base, acuminate, an inch long; at the ends of the branchlets are solitary yellow flowers .- Native of Japan.

Cordia ; a genus of the class Pentandria, order Monandria. -GENERIC CHARACTER. Calix: perianth one-leafed, tubular, toothed at the top, permanent. Corolla: onepetalled, funnel-form; tube patulous, length of the calix; border erect, spreading, cut into five obtuse divisions. Stamina: filamenta five, subulate; antheræ oblong, length of the tube. Pistil : germen roundish, acuminate ; style simple, length of the stamina, bifid at top; divisions bifid; stigmas obtuse. Pericarp: drupe globose, acuminate, growing to the calix; seed, nut furrowed, four-celled. ESSEN-

COR

tomous. Drupe: with two-celled nuts .- As the plants of Isles, and being rather hardier than the other species, may this genus are all natives of hot countries, they are too tender to endure an English winter, unless they are preserved in a stove. They are all propagated by seeds, which must be procured from those parts where they naturally grow, and sown in small pots, which should then be plunged into a good hot-bed of tanner's bark in the spring; and if the seeds be good, the plants will begin to appear in six or eight weeks. They must be brought forward in the hot-bed, by being treated like other tender exotics, observing frequently to water them in summer; and in July, if the plants happen to be considerably advanced, they should be gradually hardened, in order to prepare them against the winter, which they will not survive, if too tenderly treated. As they acquire strength, they will become hardier ; but during the two first winters, it will be proper to keep them in the tan-bed in the stove ; but as soon as their stems begin to turn woody, they may be placed on shelves in a dry-stove, where, if they be kept in a moderate degree of heat, they may be preserved very well, especially the third species, which is somewhat hardier than the rest .---- The species are,

1. Cordia Myxa; Smooth-leaved Cordia Sebesten, or Assyrian Plum. Leaves ovate, smooth on the upper surface; corymbs lateral; calices ten, striated; leaves like those of the alder, serrate-angulate, scabrous underneath, three inches long, opposite, flat, entire, obtuse, on a round petiole, half an inch in length ; petals white, revolute ; fruit inferior, red, nearly an inch in diameter. The timber of this tree is tough and solid, and is used for procuring fire by friction ; the leaves, bruised with those of the datura metel, are applied to the forehead in the head-ache; and a glue is prepared from the fruits, which are also eaten by children. Hill informs us, that the fruit is like a plum, with an oblong kernel, and that the pulpy part of it is so tough and clammy, that being beat up with water, it makes good bird-lime : he adds, the fruit is the part used. It is sent over to us dried like a prune, and used to be a constant ingredient in decoctions for coughs, and disorders of the lungs, but is now disregarded .- Native of Arabia and the East Indies.

2. Cordia Spinescens. Leaves ovate, acute, serrate, scabrous ; petioles sabspinescent ; branches erect, tomentose, ferruginous; leaves alternate, petiolate, tomentose, more scabrous on the upper surface, the size of cherry leaves; fruits scattered, sessile, black, the size of currants; corolla bell-shaped, fivetoothed, twice as large as the calix .-- Native of the East Indies.

3. Cordia Sebestena; Rough-leaved Cordia. Stems several, shrubby, eight or nine feet high, having towards the top rough alternate leaves, on short petioles, of a deep green on their upper side; flowers terminating in large clusters, upon branching peduncles, sustaining one, two, and three flowers; corolla large, with a long tube, spreading open at top, and there divided into five obtuse segments; it is of a beautiful scarlet, and makes a very fine appearance. A small piece of the wood, laid upon a pan of lighted coals, will perfume a whole house with a most agreeable smell. Browne says, it is adorned with large bunches of fine scarlet flowers, which come out at the tops of the branches fifteen or twenty together, with fringed edges, and the surfaces sinuous and curled they are at first of a high vermilion colour, which changes to a scarlet, and afterwards becomes purple, but they have no scent; the fruit is in the form of an inverted pear. From the juice of the leaves, with that of a species of fig, is prepared the fine red colour with which the natives of Otaheite dye their clothes ; but we are informed that there are several other plants which will produce the same colour in conjunction entire, membranaceous, veined; racemes compound, lax.with the fig .- It is a native of both Indies, and of the Society Native of Jamaica, and other West India islands.

be placed abroad in a warm situation in the beginning of July, where the plants may remain until the middle of September, provided the season continue warm, but if not, they must be sooner removed into the stove.

Leaves lanceolate-ovate, sca-4. Cordia Gerascanthus. brous; panicles terminating; calices ten-striated; stem and branches unarmed, patulous, round, smooth; leaves petioled, scattered, acuminate, entire, veined (especially hehind) smooth ; panicles large, composed of patulous, alternate, trichomous, many-flowered branchlets; the last pedicels three-flowered; flowers rather large, veined, permanent, shrivelling. This tree rises to a considerable height, but seldom exceeds twenty or thirty inches in diameter; it is pretty much branched towards the top, and furnished with oblong nervous leaves : the flowers have no scent, are very white, and grow in great numbers at the extremities of the branches; as the germen enlarges, they fade, and turn of a dark or dirty brown colour, continuing upon the tree until the whole fruit, which seldom grows to a perfect state, falls off. The branches are used by the coopers to make hoops; and it is esteemed one of the best timber trees in Jamaica, where it is a native. The wood is of a dark-brown colour, and slightly striped, tough and elastic, of a fine grain, and easily worked. It is called Spanish elm, or prince wood ; and ju other islands of the West Indies. where it is also found, the French call it bois de chupre.

5. Cordia Macrophylla; Broad-leaved Cordia. Leaves ovate, villose, a foot and half in length. This tree attains to the height of fifty feet, but is seldom above twelve or sixteen inches in diameter, shooting generally by a straight trunk ; the leaves are very large and rough ; the berries white, of the size of small cherries; the heart of the tree is of a vellowish colour, and tolerably good timber .- It is called the broadleaved cherry-tree in Jamaica, where it naturally grows.

6. Cordia Callococca; Long-leaved Cordia. Leaves cordate-ovate, quite entire; flowers corymbed; calices tomentose within. It seldom exceeds fourteen or sixteen feet in height; the berries are red and succulent, the size of our smallest European cherries, and disposed in umbellated groups; the pulp is sweetish and clammy; turkeys and other fowls feed continually upon the berries, and hence it is called turkey-berry tree, and clammy cherry-tree, in Jamaica, where it is a native, and is also found in the other West India islands.

7. Cordia Patagonula; Spear-leaved Cordia, or Patagonula. Leaves oblong-lanceolate, smooth on both surfaces, upper ones serrate; branchlets hairy; stem straight; bark greenish ash-colour, spotted with white, the upper part, and particularly the ends of the branches, covered with long hairs; the flowers come forth among the leaves in small bunches, as in privets, smelling like elder-flowers, and being of a greenish colour : it flowers during the greatest part of the summer,-Native of Patagonia in South America.

8. Cordia Aspera. Leaves ovate acuminate, rough; flowers in cymes, wrinkled.-Native of the island of Tongataboo.

9. Cordia Dichotoma. Leaves oblong-ovate, scarcely cre-nate; corymbs dichotomous.-Native of New Caledonia.

10. Cordia Cetusa. Leaves in bundles, wedge-form, retuse, three-toothed; branches round, smooth, somewhat hairy at the tip; the buds are tomentose tubercles; fruit the size of pepper, the calix not growing to it, four-celled, in each cell several seeds; there is a transverse furrow in the middle of the partition .--- Native place unknown,

11. Cordia Micranthus. Leaves elliptic, lanceolate, quite

12. Cordia Elliptica. Leaves elliptic, acuminate, entire, coriaccous; branches compound, diffused; drupes acuminate.-Native of Jamaica.

COR

Coreopsis ; a genus of the class Syngenesia, order Polygamia Frustranea .- GENERIC CHARACTER. Calix: common, either simple, subimbricate; or doubled; the exterior usually with eight leaflets, which are coarse, and placed in a circle: the interior with as many large ones, membranaceous and coloured. Corolla: compound, rayed; corollets hermaphrodite, numerous in the disk; females eight in the ray; proper of the hermaphrodite tubular, five-toothed; female ligulate, four-toothed, spreading, large, Stamina, in the hermaphrodites : filamenta five, capillary, very short. Antheræ evlindric, tubular. Pistil, in the hermaphrodites: germen compressed; style filiform, length of the stamina; stigma bifid, acute, slender. In the females: germen like the hermaphrodites; style and stigma none. Pericarn; none: calix scarcely altered. Seed, in the hermaphrodite; solitary, orbiculate, convex on one side, concave on the other with a transverse protuberance at top and bottom, surrounded by a membranaccous edge with a two-horned tin; in the females none. Receptacle: chaffy. ESSENTIAL CHARACTER. Calix : erect, many-leaved, surrounded at the base with spreading rays. Down : two-horned. Receptacle : chaffy .---- The species are.

1. Corcopsis Verticillata. What-Leard Corcopsis, or Teksed Sun-flower. Leaves decompound, linear; root per-ennial; stems many, stiff, angular, upwards of three feet high; ray yellow; disk dark purple. Being a showy plant, growing very tall, and continuing long in flower, it is a great ornament to the shrubbery; the yellow florets, which appear from July till September, are used in North America to dye cloth red.—Native of North America. This species, and also the second, fifth, inith, twelfth, thirteenth, furetenth, fifteenth, and sixteenth, are hardy plants, and may be plentis in automn, when the stalks begin to decay. This requires a light loamy earth and sumy exposure.

2. Coreopsis Coronata. Leaves pinnate, servate, marked with lines, smooth.—It is an annual plant, and a native of Virginia. See the first species.

3. Coreopsis Lencantha. Leaves pinnate, serrate; ray of the flowers of a different colour from the disk; stem three or four feet high, four-cornered, smoothish, the opposite sides channelled; howers terminating, alternate, two or three on longish peduncles; ray of the corolla usually with five white forets, which are ovare, three-toothed at the end, the middle one longest, three-nerved underneath.—Annual: and a native of America.

4. Coreopsis Chrysantha. Leaves ternate, ovate-oblong, serrate; ray of the flowers concolor; stem quadrangular, simple, jointed; leaves on the branch opposite, smooth; on the flowering branches alternate, smaller; flowers terminating, of long peduneles, solitary, with is xi there-toothed florets in the ray, which are nevertheless often wanting.—Native of South America.

5. Coreopsis Troipteris; *Thre-leared Coreopsis*. Leaves subternate, quite entire; root perennial; stems strong, round, smooth, six or seven feet higb; flowers in bunches, on the top of the stem, in long peduncles; ray of the corolla pale yellow; disk dark purple.—Native of North America. It requires a light loamy earth, and sunny exposure. For its culture and pronagation, see the first snecks.

6. Coreopsis Alba; Climbing Coreopsis. Leaves subternate, cuneate, serrate. This is a climbing plant, the florets of the margin of which are all neuter, and rise immediately

7. Corcopsis Reptans; Trailing Corcopsis. Leaves serrate, ovate, upper ones ternale: stem creeping; root small, fbrons, annual with us; stem clinbuing, weak, five feet high, branching, leafy, straited, smooth, square at the base, roundish above; florets all gold-coloured, those of the ray with about four teeth and veined, those of the disk five-cleft.— Naive of the woody parts of Jamaica.

8. Corcopsis Baccata; Berried Corcopsis. Leaves serrate-oate; seeds herry-form; stem eight (herhaccours, erect; leaves opposite, petioled, three-nered; fowers at the ends, often three, peddneled, very small; ray of the corolla neuter, yellow, three-toothed, longer than the disk.—Native of Surinam.

 Coreopsis Auriculata; Ear-leaved Corcopsis, Leaves quite entire, orate, the lower ones termate; stem from nine inches to a foot in height, upright, covered with a soft down; flowers golden-coloured, with about eight florets in the ray. - Native of Virginia. See the first species.

10. Coreopsis Lanceolata; Spear-leaved Coreopsis. Leaves lanceolate, quite entire, ciliate; stems several, decumbent at bottom, and thence rising obliquely a foot and half or two fect in length; florets in the ray eight or nine, broad, with four deep large teeth at the end; calix double, each consisting of eight or nine leaflets, the outer thick and spreading. the inner larger, upright, and pressed close to the flower, transparent, and of a pale ochre-colour; the seeds, which resemble a small hemispheric beetle or bug, must be sown upon a gentle hot-bed in the spring, and when the plants are fit to remove, they should be set each in a separate small pot, and plunged into a fresh hot-bed to bring them forward. They must be gradually inured to the open air in June, and some of them may be afterwards taken out of the pots, and planted in a warm border, where, if the season be good, they will flower in the middle of July, and ripen their seeds in the beginning of September.

11. Coreopsis Bidens. Leaves lanccolate, serrate, opposite, stem-clasping,---A mere variety of bidens cernua, to which the reader is referred.

12. Corcopsis Alternifolia ; Alternate-leared Corcopsis. Leaves lanceolate, serrate, alternate, pediolate, decurrent ; root woody, perennial; stems several, annual, erect, angular, field with white pith, wnged, from five to ten feet high, simple, having only very short subdivisions at the top, into roundiab vilues peduncles; florets in the ray from four to eight, yellow; border slightly toothed, very concave, with the sides rolled in; the flowers have but little seent, and coming forth late in October or November, seldom perfect their seeds in England.—Native of Virginia, and Canada. It will thrive in almost every soil and situation. See the first succeis.

13. Coreopsis Aurea; Hemp-leaved Coreopsis. Leaves serrate, root-leaves three-parted; stem-leaves trifid and entire, lanceolate, linear.—It is perenail; flowers in August and September; and is a native of North America. See the first species.

14. Coreopsis Crassifolia; *Thick-leaved Corcopsis*. Leaves obovate, oblong, obtuse, quite entire, pubescent.—It is perennial; flowers from August till October; and is a native of Carolina. See the first species.

15. Coreopsis Angustifolia; Narrow-leaved Coreopsis Leaves alternate, linear lanceolate, quite entire, even; petals of the ray oblong, trifid, the middle segment largest.—Perennial: flowering in June, and native of Carolina and Florida. See the first species.

COR

365

16. Coreopsis Procera; Tall Coreopsis. Leaves elliptic, acuminate, serrate, petiolate, veined, decurrent, the lower in whorls, the upper alternate. It is perennial; flowers in September and October.-Native of North America. See the first species.

17. Coreopsis Radiata. Leaves linear-lanceolate, sharply serrate, opposite; ray of the flower large, entire; root annual: stems upright, four feet high; leaves acuminate, from three to four inches long, three quarters of an inch broad in the middle, deep green on their upper surface, and pale on their lower, on short petioles. It flowers in August, and if the autumn prove favourable, ripens its seeds in October .--Native of Carolina .- It is propagated by seeds, which should be sown on a warm border in autumn, and the plants will appear in the following spring; but if the seeds be sown in the spring, the plants seldom rise till the year after. When fit to remove, they should be taken up carefully, and either replanted where they are intended to remain, or placed in a nursery-bed, at four inches' distance, to get strength, observing to exclude the beams of the sun until they have taken fresh root, after which, those which are planted out to remain, will only require to be kept clean from weeds, and as they advance in height should be supported by sticks, otherwise the strong winds of autumn often break them. Those which are placed in the nursery-bed, should be taken up when they have acquired proper strength, and planted, with balls of earth adhering to their roots, wherever they are designed to stand for flowering. As these plants continue to produce flowers till arrested by the frost, they merit a place in every curious garden, especially those of them which do not ramble and spread too much.

18. Coreopsis Leucorhiza. Leaves pinnate, with five leaflets, serrate-gashed; ray six-flowered; down three-horned; stem herbaceous, a foot and half high, erect, four-cornered, grooved, arising from a simple, perpendicular, fusiform, white, fleshy root : flowers entire, saffron-coloured, few together on terminating peduncles; calix erect, many-leaved .- Native of Canton in China.

19. Coreonsis Biternata. Leaves biternate, ovate-lanceolate, serrate; panicle diffused; ray six-flowered; stem herbaceous, two feet high, erect, four-cornered, four-grooved; flowers entirely yellow .--- Native of China near Canton.

20. Coreopsis Foetida. Leaves three-lobed ; lobes acuminate, serrate, middle one longer; root annual; stem rough, upright, a fathom in height, branched, covered with a short glutinous nap; flowers corvmbed; corolla vellow; florets of the ray eight; border ovate-oblong, three nerved, shortly emarginate .- Native of Mexico.

Coriandrum ; a genus of the class Pentandria, order Digynia .- GENERIC CHARACTER. Calix: umbel universal, with few rays; partial with very many; involucre universal, scarce onc-leafed; partial three leaved, halved, liuear; perianth proper, five-toothed, standing out. Corolla : universal. difform, rayed : floscules of the disk abortive : proper of the disk hermaphrodite; petals five, inflex, emarginate, equal; proper of the ray hermaphrodite; petals five, inflex-hearted, unequal, of which the exterior is very large, two-parted; but the nearest lateral ones have a very large division. Stamina : filamenta five, simple. Antheræ roundish. Pistil: germen inferior: styles two, distant; stigmas of the ray headed. Pericarp : none ; fruit spherical, bipartile. Seeds : two, he mispheric, concave. ESSENTIAL CHARACTER. Corolla: rayed. Petals : inflex, emarginate. Involucre universal : one-leaved. Partial: halved. Fruit : spherical .- These plants are propagated by sowing their seeds in the autumn, in an open situation, on a bed of good fresh earth, hoeing out 31.

the plants to about four inches apart every way as soon as they appear, and also clearing them from weeds, which will enable the plants to acquire more strength, and produce a greater quantity of good seeds .----- The species are,

1. Coriandrum Sativum; Common or Great Coriander. Fruits globular; root annual, small; stem a foot or a foot and half in height, smooth, branched; root-leaves larger, doubly pinnate; pinnules broad, gashed on every side, serrate, and even half two-lobed ; petals white or reddish .- It flowers in June and July, in corn-fields, by road sides, and on dunghills; the seeds ripen in August; the leaves have a strong disagreeable scent; the seeds are grateful to the taste, and are sold by the confectioners encrusted with sugar. The Edinburgh college use them as correctors ; in the bitter infusion and the preparations of senna, nothing so effectually covering the disagreeable taste of that medicine. They have been considered as suspicious, if not deleterious ; but Withering informs us, that he has known six drachms of them to be taken at once, without any remarkable effect. Meyrick states, that the seeds are the only part used in medicine. While green, they have a strong unpleasant smell, which they lose in drying, and become sweet and aromatic : they are of great service in warming and strengthening the stomach, dispersing wind, and assisting the digestive faculties, and also relieve pains of the head, and operate as a check in violent purges. This plant is found wild in Essex, yet, though it has also been long cultivated about Ipswich, and in a few other places, it is not a native of this country, but the south of Europe, China, and Cochin china. It was formerly cultivated in the gardens as a salad herb, and is still used in the East Indies for the same purpose, being a principal ingredient in most of the compound dishes of the inhabitants of those regions, and much esteemed as a culinary herb. The seed is also employed in the same way, although Europeans have long almost entirely neglected it. For the field culture of coriander, see Carum or Caraway. The produce of coriander is from ten to fourteeu hundred-weight on an acre, and the price varies from 16s. to 42s. per hundred-weight, but is commonly at 24s. Unless great care be taken, the largest and best part of the seed will be lost; to prevent this, women and children are employed to cut it plant by plant, and to put it immediately into cloths, in which it is carried to some convenient part of the field, and there threshed upon a sailcloth : a few strokes of the fiail bring the seeds clean out, and the threshers are ready for a fresh bundle in a few minutes. There is a ready sale for coriander seed among the distillers. druggists, and confectioners; the former, especially, purchase very large quantities.

2. Coriandrum 'Testiculatum ; Small or Twin fruited Coriander. Fruits twin. This has a much stronger scent than that of the common sort; root annual; stem angular .-- Native of the south of Europe, China, and Cochin-china. It will rise easily from seeds if they be sown in the antumn, but those which are sown in the spring rarely succeed, or at least do not come up until the following spring.

Coriaria ; a genus of the class Diccia, order Decandria .--GENERIC CHARACTER. Male. Calix ; perianth fiveleaved, very short; leaflets subovate, concave, Corolla; petals five, very like the calix, connected. Stamina; filamenta ten, length of the corolla. Antheræ oblong, twoparted. Female. Calix : perianth five-leaved, very short : leaflets subovate, concave. Corolla : petals five, cuspidate. caliciform, converging. Stamina : filamenta ten, very short. Antheræ barren. Pistil : germen five, compressed, inwardly conjoined; styles as many, bristle-form, long; stigmas simple. Pericarp : none : five flcshy, ovate lanceolate, three-5 A

COR

sided petals, with one of the angles looking inwards, covering the seeds. Seeds: fee, kiney-form, ESSENTIAL CHA-RACTER. *Calix*: six-leaved. *Corolla*: five-petalled, very like the calix. *Male*. Anthreat two-parted. *Penale*. *Syster*. five. *Seeds*: five, covered with succulent berried petals...... The species are.

1. Coriaria Myrtifolia: Murtle-leaved Sumach, Leaves ovate-oblong. It seldom exceeds three or four feet high, creeping at the root, and sending forth many stems. The plant with male flowers only was common in England, until that which bears hermaphrodite flowers was raised in the Chelsea garden, from seeds sent from Italy. This plant possesses considerable astringency, and is used not only in tanning leather, but in dyeing black. It sends up so many stems as to form a thicket ; it is useful to fill up vacancies in plantations of shrubs, but is only proper for large gardens. It may be propagated in abundance from the suckers, which are plentifully produced from the creeping roots. They should be taken off in March, and planted into a nursery to form good roots, where they may continue one or two years, and must then be removed to the places where they are to remain. This plant delights in a loamy soil, which is not too stiff, and should be sheltered from the north and east winds, where it will endure the cold of our ordinary winters, and flower better than if preserved in pots under cover during the winter.

2. Coriaria Ruscifolia. Leaves cordate-ovate, sessile; flowers hermaphrodite.---Native of Chili.

 Coriaria Sarmentosa. Procumbent, diffused: leaves cordate-ovate, acuminate, quite entire, five-nerved, subpetiolate; racemes axillary, elongated, nodding,-Native of New Zealand.

Coris; a genus of the class Pentandria, order Monogynia. —GENERIC CHARACTER. Colis: periath one leaded, bellied, converging, five-toothed, externally crowned with spines, of which the five superior ones are simple, the inferior ones toothed. Corolla: one-petalled, irregular; tube the length of the calix, cylindrical; border flat, five-parted; divisions oblog, enarginate, obtuse, the two inferior ones shorter and more distant. Stamina: filmenta five, bristle-form, length of the corolla, declining. Anthera simple. Pistle ; germen roundish, superior; style filform, length of the stamina, declining; stigma thickish. Pericarp: capsule globose, phaed in the bottom of the calix, one-celled, five-valved. Seeds; very many, nearly ovate, small.——The only known species is.

1. Coris Monspeliensis; Montpellier Coris. This plant seldom grows above six inches high, and spreads near the surface of the ground like heath; the stem is red; the leaves are alternate, linear, thickish, spreading; the flowers in spikes, purplish or bluish, coming out in June, and making a beautiful appearance .- It is a native of the south of France, and may be propagated by sowing the seeds upon a bed of fresh earth in the spring. When the plants are about an inch high, they should be transplanted, some of them into pots filled with fresh light earth, that they may be sheltered in winter, and the others into a warm border, where they will bear the common cold of winter very well; but as they are generally destroyed by severe frost, it will be prudent to preserve some of the plants in pots, under a common hot-bed frame, and covered in frosty weather, but having a large share of free air admitted to them in mild seasons. These plants will sometimes produce ripe seeds in England ; but as that is seldom the case, it will be proper to increase them from slips and cuttings, which will strike root if planted about the end of August on a very gentle hot-bed, shaded from the sun, and duly watered.

Corisperantan ; a genus of the class Monandrin, order Digrain--GENERIC CHARACTER. Calix: none. Corolle: petals two, compressed, incurved, acuminate, opposite, equal. Stanitar: filamenta one, filiform, slorter than the petals. Antheræ single. Pisiti, genuen acute, compressed; styles two, capillary; stigmas acute. Pericarp: none. Stedi single, oval, compressed; gibbous on one side, with the margin acute. ESSENTIAL CHARACTER. Calix: none. Petals: two. Stedi one, oval, naked.-These plants having little beauty, are seldom cultivated except in botanic gardens.----The species are,

1. Corispermum Hystopffolum; Hystop-leaved Ticksed, Sykks terminating; leaves linear, nerveless, awnless; root annual. It is common all over the Russian empire, in sandy soils, sepecially on the banks of lakes and rivers, and in low moist places, where it afforts pasture for the caunels; in common with the next species, and the various sorts of atriplex and salsola. It is also found in the south of France, and will stock the ground plentifully, if it be only permitted to scatter its seeds.

 Corispermum Squarrosum; Rough-spiked Tickseed. Spikes axillary, squarrose; leaves lanceolate, acuminate, pungent, nerved; root annual.—Native of Russia. It will only grow in marshy places, and will soon cover the standing water, when once established.

An One Casamanti, Correras, Correli Cornelian Cherry. See Cornus. Corne Flag. See Gladiolus. Corn Marigold. See Chrysanthemum. Corn Salad. See Faleriana. Cornucopia ; a genus of the class Triandria, order Digy.

Corrucopia; a genus of the class Triandria, order Digyma-GENERIE C dHARACTER. Calits: periauth common, one-leafed, funnel-form, very large; mouth creanted, obtuse, from spreading upright, many-flowcred; glume one-flowered, two-valved; valves oblong, obtusely acuminate, equal. Corolla: one-valved, in figure, size, and situation, very much resembling the valves of the glume of the calix. Staminaz filamenta three, capillary, atigmas cirrhose. Periturbinate; styles two, capillary; stigmas cirrhose. Pericarp; none. Corolla: including the seed. Seed : simple, turbinate, on one side convex, on the other flat. ESENTIAL CHARACTER. Involvere: one-leafed, fumel-form, crenate, many-flowered. Caliz: two-valved. Corolla: one-valved. ----The species are,

1. Cornucopia Ciculiatum; Hoaded Cornucopia. Spike beardless, with a cerate lood or involutere; roat annual, fibrous, branched; culms numerous, ascending, jointed, round, smooth, striated, branched, leafy, dark purple at the joints; flowers in a little head or spike, projecting somewhat beyond the involucres, green, often tipped with purple: seed small. Of all grasses, this is perhaps the most singular, as well as the most uncommon.—Native of the vales about Smyrna.

2. Cornucopia Alopecuroides. Spike bearded, within a hemispheric hood, or involucre. It very much resembles alopecurus pratensis: culms ascending, even; leaves even, The singular mark of this species is, a hood in the form of a pitcher, quite entire, of the same consistence with the leaf, surrounding the base of the spike like a common calix.

Cornus; a genus of the class Tetrandria, order Monogynia.-Generic C untAncrene. Coliz: involucer generally four-leaved, many-flowered; leafts ovate, the opposite ones smaller, coloured, deciduous; perianth very small, fourtoohed, superior, deciduous. Corolla: petals four, oblong, acute, flat, smaller than the involuce. Mamina: filamenta four, subulate, erect, longer than the corolla; anithere

366

roundish, incumbent. *Pistil:* germen roundish, inferior; r zipie fikiform, length of the corolla; stigma obtuse. *Peri*corp: drupe roundish, umbilicated. *Seed Nut:* heartshaped, or oblog, two-celled. ESSENTIAL CHARACTER. *Involucre:* generally four-leaved. *Petals:* four, superior. *Drupe:* with a two-celled unt.—The species are,

1. Cornus Florida ; Great flowered Dogwood. Arboreous : involucre very large; leaflets obcordate. It seldom rises above seven or eight feet high, but is generally well furnished with large leaves. Although it be very hardy, it neither flowers freely, nor produces berries in England. There is a variety of this species, with a rose-coloured involucre, which was found wild in Virginia. They are great ornaments to the woods in America, by their early flowering in the spring, before the leaves appear, and by their berries hanging all the winter on the trees. The wood is white, has a close grain, and is very hard, like that of box .- It flowers in April and May, and is common in our nurseries, where it is known by the name of Virginian dogwood. All the sorts of dogwood may be propagated by their seeds, which if sown soon after they ripen in autumn, will generally appear in the following spring; but if not sown in autumn, they will lie a year in the ground before the plants will come up, and in dry seasons have been known to be two years in making their appearance ; for which reason, the ground where they have been planted ought not to be disturbed any sooner. When they spring up, let them be watered in dry weather, and weeded, and in the following autumn removed into beds in the nursery, where they may stay two years, and at the end of that time will be fit to transplant where they are designed to remain : the best season for transplanting them is in autumn. They are also propagated by suckers, and laying down the branches. Most of the dogwoods produce plenty of suckers, especially when planted on a moist light soil. These suckers may be taken off from the old plants in autumn, and planted into a nursery for a year or two, and may then be finally transplanted into those places where they are destined to remain. But the gardener ought to be informed, that the plants produced from suckers seldom have so good roots as those which are propagated by layers, and are not so valuable as the latter plants, because they are also so very liable to put out suckers themselves. Some of the scarcer species, from America, are often engrafted into the fourth or fifth species,

2. Cornus Mascula; Cornelian Cherry. Arboreous: umbels equalling the involucre; leaves servate; shoots ashcoloured, and pubescent; leaves in pairs, ovate-lanceolate, subhirsute. The flowers come out very early in the spring before the leaves; corolla yellow, spreading, and at length reflected, longer than the stamina. It is a shrub in its wild state, and about four or five feet high, but advances, when cultivated, into a tree twenty feet in height, and is very common in our plantations of shrubs. If the season be mild, the flowers will come out in the beginning of February; and though there be no great beauty in them, yet they come forth in great numbers at a time when few other flowers appear. It was formerly cultivated for the fruit, which was used to make tarts, and a rob de cornis was kept in the shops: Meyrick says, that the dried fruit, or the juice of it, hoiled up with sugar, is an excellent cooling astringent medicine, and of great utility in fevers attended with purging. Cornel. says Evelyn, grows with us of good bulk and stature, and is exceedingly commended for its durableness in wheel-work, pins, and wedges, in which it wears like the hardest iron. Native of Russia, Germany, Switzerland, Austria, Carniola, France, Piedmont, and the Milanese.

3. Cornus Japonica. Arboreous: umbels exceeding the

roundish, incumbent. *Pistil*: germen roundish, inferior; involucre; leaves serrate; stem erect, six feet in height; style fihform, length of the corolla; stigma obtuse. *Peri-* branches opposite, striated, ash-coloured, smooth.--Native *corp*: drupe roundish, unbilicated. Seed Nut: heart-] of Japan.

COR

4. Cornus Sanguinea ; Common Dogwood. A rhoreous ; cymes depressed ; branches straight ; leaves ovate, concolor ; height from four or five, to eight or ten feet ; leaves opposite, quite entire, but sometimes with the edge waving-Native of Europe, found in hedges, especially in a calcareous soil. It flowers in June, and the berries ripen in August. It has a variety of names in different parts of England, as female cornel, dog-berry tree, hound's-tree, hound's-berry tree, prickwood, from its use in making skewers, gaten, or gatten, gater, or gatter-tree. Mr. Miller informs us, that the fruit of this tree is often brought into our markets, and sold for buckthorn berries, from which, however, it may be easily distinguished, there being only one stone in this, whereas the buckthorn has four stones; the latter also stains paper green, but the juice of the former is purple. Dogwood is called virga sanguinea, or bloody-rod, by old authors, from the fine red colour of its young shoots. The wood, according to Evelyn's account, is like the cornel for compactness, and is used for cart-timber and rustic instruments, for mill-cogs, spokes, bobbins for bone-lace, for the best tooth-picks, and for butchers' skewers. Being hard and even, it is also fit for the turner. In foreign countries, a lamp-oilis extracted from the berries, by boiling them in water, and afterwards pressing them. Baron Haller observes, that these berries are very bitter and styptic, but not employed in medicine.

5. Cornus' Alba; White-berried Dogwood. Arboreous: yroms depressed; branches recurved; leaves broad, ovate, hoary underneath; stem woody, putting out many lateral branches near the ground, so that unless it be trained while young, it generally spreads low. During summer the branches are brownish, but change in winter to a fine red, The flowers are produced in large cymes, at the extremity of every shoot, towards the end of May, and are white.—Naitve of Siberia, and of North America.

6. Cornus Sericea ; Blue-berried Dogwood. Arboreous ; cymes naked, depressed; branches patulous; leaves ovate, ferruginous, silky underneath. This shrub grows two fathoms in height, with an upright, round, branched, gray stem; branches round, opposite, spreading, dusky purple; flowers pedicelled, horizontal, white, with the disk at first white, but afterwards brown, or dark purple .- Native of North America. The leaves are narrower and deeper veined than in the fifth species; the flowers grow in smaller cymes, and the fruit is smaller, and of a deep blue colour when ripe. The shoots are of a beautiful red colour in winter; and in summer, the leaves being large, of a whitish colour on their under side. and the bunches of white flowers growing at the extremity of every branch, render this a valuable shrub ; and in autumn, when the large bunches of blue berries are ripe, it makes a very beautiful appearance.

7. Cornus Alternitolia ; Alternate-leared Dogrood. Arboroous : leaves alternate ; branches subdeterminate, round, glossy, dark purple, with whitish vague dots or lines; leaves petioled, ovate, acute, quite entire, glossy, marked with lines, pale underneath. The branches are sometimes red, and sometimes green.—Native of North America.

8. Cornus Suecica; Herbaceous Degwood. Herbaceous, with branches in pairs. This elegant plant is about six inches high; stem four-cornered, thinly branched, forked at top; leaves oval, opposite, smooth, sessile, ribbed, with fire nerves, the lower oues rounder. The involucre consists of four or five white leaves resembling petals, in the centre of which are twenty or more small blackish flowers, on short

peduncles; the flowers are very small, in a simple nmbel; they are succeeded by a cluster of berries, which are red when ripe, and each contain a heart-shaped stone. The berries have a sweetish watery taste, and are acceptable to children. The Highlanders suppose, that they create an appetite, and hence the plant is called by the Erse language, lus a chrasis, or plant of gluttony.-It flowers in June, and in England is commonly known under the name of dwarf honeysuckle. It is found on the Cheviot hills, and other parts of the northern counties, and in moorish places near rivulets. on the sides of the Highland mountains in Scotland. Native also of the north of Europe, and of the whole northern tract of the Russian empire, which extends from the Baltic to the Eastern Ocean. It is very difficult to preserve this plant in gardens. The only method is to remove it from its natural place of growth, with good balls of earth adhering to the roots. and replant it in a moist shady situation, where it will not be annoyed by the roots of other plants. It may be preserved two or three years in such a situation, but will seldom continue longer.

9. Cornus Canadensis; Canadian Dogwood. Herbaceous, with no branches. It is only a hand in height; stems several, herbaceous, upright, four-cornered, pnrplish, having some opposite slightly clasping-leaves at bottom, which wither and fall off; flowers pedicelled, upright, white, with a violetcoloured bottom. It flowers in August, and is a native of Canada, Labrador, and Newfoundland.

10. Cornus Circinata. Branches warted ; leaves orbiculate, tomentose, and hoary underneath; cyines depressed; stem upright, branched, gray, about six feet high; flowers pedicelled, upright, white, five lines wide. It is distinguished by its orbicular, wrinkled, very green leaves, the cymes bracted at bottom, and also by its very thick tubercled branches .- It is a native of Pennsylvania, where it has long been cultivated, and may be met with, but not commonly, in France.

11. Cornus Stricta ; Upright Dogwood. Branches strict ; leaves ovate, concolor, almost naked ; cymes panicled ; stem several, upright, brownish, twelve feet high ; branches opposite, round, in younger plants strict, in older patulous. The twigs, and especially the suckers, stiffish, having rings at the joints, purple, warted closely at the base; flowers pedicelled, white, with the disk only red, four lines in diameter. The fruit appears too late to ripen in our climate, and the leaves continue green till the frost comes on .--- Native of North America.

12. Cornus Paniculata; New Holland Dogwood. Branches erect; leaves ovate, hoary underneath; cymes panicled; stems very many, upright, much branched, round, gray; leaves acuminate, almost entire; flowers pedicelled, upright, white, three lines in diameter. It is distinct from every other species, in having the cymes elongated into a thyrse, or panicle. It is also handsome, and very full of flowers, which come out in the spring, or early in the summer, and is loaded with fruit during several months in autumn .- Native of North America.

Cornutia ; a genus of the class Didynamia, order Gymnospermia .- GENERIC CHARACTER. Calix : perianth oneleafed, roundish, very small, tubular, five-toothed, permanent. Corolla : one-petalled, ringent ; tube cylindric, much longer than the calix ; border four-cleft, upper division erect, roundish, lateral ones distant, lower roundish, entire. Stamina: filamenta four, of which two project beyond the tube of the corolla; antheræ simple, inclining. Pistil: germen roundish; style very long, two-parted; stigmas thickish. Pericarp: berry globose at the base, comprehended by the It is easily propagated by sowing the seed, which it commonly

calix. Seed : single, kidney-form. ESSENTIAL CHARAC TER. Calix: five-toothed. Stamina : longer than the co rolla; style very long; berry one-seeded.----The species are.

1. Cornutia Pyramidata ; Hoary-leaved Cornutia. Leaves opposite, ovate; flowers in terminating corymbs. It grows to the height of ten or twelve feet. The branches are fourcornered, and grow straggling; flowers in corymbs at the ends of the branches, of a fine blue colour. They appear usually in autumn, and sometimes remain in beauty for two months or more .- It abounds in several of the West India islands, and also at Campeachy, and La Vera Cruz. It is propagated by seeds, which should be sown early in the spring, on a hot-bed. The plants should be each trans-planted into a small pot of light fresh earth, as soon as they appear, and immediately plunged into a hot-bed of tanner's bark, observing to shade them from the sun until they have taken root : after which, fresh air must be admitted in proportion to the warmth of the season ; and it should be frequently watered, as it naturally grows on swampy soils. When the plants have filled the pots with their roots, they ought to be removed into others of a larger size, and again plunged into a hot-bed, where they should remain till October, and should then be plunged into the tan or the barkstove; for unless this be done, it will be very difficult to preserve them through the winter. In the third year they will flower in the stove, and make a fine appearance; but they never perfect their seeds in England. They may also be propagated by cuttings, which, if planted into pots filled with earth, and plunged into a bark-bed, observing to shade and water them, will take root, and must be afterwards treated as above.

2. Cornutia Quinata. Leaves guinate, lanceolate-ovate : flowers in racemes. This is a middle-sized tree, with spreading round branches; leaves, acuminate, quite entire, smooth, on a long common petiole; flowers greenish yellow; corolla somewhat funnel-shaped, the upper lip trifid, the lower bifid, and shorter .- Native of China, in the woods near Canton.

Coronilla ; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix : umbellule simple : perianth one-leafed, very short, compressed, bifid, erect, the three inferior teeth smaller, the two superior conjoined, permanent. Corolla: papilionaceous; standard heart-shaped, reflected on all sides, scarce longer than the wings. Wings ovate, converging at top, gaping at bottom, obtuse; keel compressed, acuminate, ascending, usually shorter than the wings. Stamina: filamenta diadelphous, single, and ninecleft, ascending at almost a right angle, the tips widish ; antheræ simple, small. Pistil: germen columnar, oblong; style bristled, ascending ; stigma small, obtuse. Pericarp : legume very long, columnar, straight, contracted with an isthmus between each seed, two-valved, one-celled, parting by joints. Seeds : many. ESSENTIAL CHARACTER. Calix: two-thirds two-lipped, the upper teeth connate; standard scarcely longer than the wings; legume contracted between the seeds .---- The species are,

1. Coronilla Emeris; Scorpion Senna, Shrubby : peduncles with about three flowers; claw of the corolla three times the length of the calix; stem angular, not very straight, branched, and brachiate; height, when wild, from two to six feet, and in gardens from eight to nine; corolla vellow; standard cordate, broad, erect, or reflex, marked with lines at the base, very remote from the other petals .-- Native of Germany, Austria, Carniola, Switzerland, France, and Savoy.

.

produces in great abundance in March, upon a bed of light sandy earth. It should be kept clean from weeds, and refreshed with water in dry weather, which, especially after it comes up, will promote its growth. At Michaelmas, if the plants have thriven well, let the largest be drawn out, and transplanted into a nursery, where they should continue two years, and will then be fit to plant out where they are to remain. This species may also be propagated by laying down the tender branches, which will take root in about a year's time, and may then be transplanted into a nursery, and managed like the seedling plants.

2. Coronilla Juncea ; Linear-leaved Coronilla. Shrubby : leaflets quinate and ternate, linear-lauceolate, somewhat fleshy, obtuse. This rises from two to four feet high, with many slender woody branches, which resemble broom.-Na-tive of the south of France. This, together with the fourth and seventh species, are propagated by sowing the seeds in the spring, either upon a gentle hot-bed, or on a warm border of light fresh earth; and when the plants are come up about two inches high, they should be transplanted either into pots, or a bed of good rich earth, at about four or five inches' distance every way, where they are to remain, until they have acquired strength enough to be wholly planted out, which should be either into pots filled with good fresh earth, or a warm border; in which, if the winter be not very severe, they will abide very well, provided they are in a dry soil. Some of the plants of the second species should be sheltered udder a common frame in winter, because they are often destroved in hard frosts; but in mild weather, they ought to be freely exposed to the air, to prevent their drawing up weak.

Small Shrubby Coronilla. 3. Coronilla Valentina; Shrubby : leaflets about nine ; stipules suborbiculate. It at-tains to three or four feet high. The flowers appear in close bunches, on long axillary peduncles; they are small, and of a deep yellow colour, at all times diffusing a very powerful odour. The stipules are large, almost round, and strikingly conspicuous in the young plant .- Native of Spain and Italy. This, with the fifth and sixth species, are propagated by seeds sown in April, upon a bed of light earth. When they are fit to remove, some of them should be transplanted into a border, close to a warm wall or pale, to which the branches ought to be trained, observing carefully to shade them from the sun till they have taken fresh root, and also to supply them with water when they require it; after they are well rooted, they will require no farther culture, but weeding, and keeping their branches trained to the pale or wall. They flower in the second year, and will continue many years upon a dry soil, and in a warm situation. Some of these plants should be reserved in pots under shelter, during winter, where, if not too tenderly treated, they will flower great part of that season, but will seldom produce seeds, while those in the full ground generally ripen their seeds, if covered with mats in frosty weather.

4. Coronilla Glauca; Great Shrubby Coronilla. Shrubby: leaflets seven, very obtuse ; stipules lanceolate. This seldom exceeds three or four feet high, with a woody branching stem; flowers bright yellow, in a roundish bunch. Wings gaping widely at bottom, so as to discover the whole keel, This, according to Linneus, has little or no smell in the night, but is remarkably fragrant during the day. It flowers from September till May; indeed, almost the whole year .- Native of the south of France. See the second species.

5. Coronilla Coronata; Crowned Coronilla. Shrubby : leaflets nine, obovate, the inmost approximating to the stem; stipule opposite to the leaf, two parted ; stems erect, little, branched, round, smooth, about eighteen inches in height, 31.

woody at bottom only; calix a line long, yellowish; corolla vellow. The end of the keel is liable to be green, and this, with the glaucous hue of the leaves, indicates that a blue colour may be produced from these flowers by putrescence. It flowers in July, and is a native of the southern countries of Europe. See the third species.

COR

6. Coronilla Minima; Least Coronilla. Undershrubby, procumbent : leaflets nine, ovate ; stipule opposite to the leaf, emarginate; legumes angular, knotty; root perennial; stems several, woody, branched, two or three inches long, and prostrate; flowers about six, yellow, sweet-smelling; calix small green ; seeds oblong, brown, and the whole plant very smooth .- Native of the southern countries of Europe. See the third species.

7. Coronilla Argentea ; Silvery-leaved Coronilla. Shrubby : leaflets eleven, silky, the outmost larger than the rest. This is a very humble shrub, rarely exceeding two feet in height in a good soil. The stem is hard and woody; from which the branches are on every side produced near the ground. The flowers appear on long, slender, axillary peduncles, are yellowish, and have a strong sweet scent; and as the plants always produce an abundance of them, they make a fine appearance during the month of May, in which they flower. The seeds ripen in August and September. The silvery colonr of this plant is occasioned by its growing on a poor dry soil, which it will change for a glaucous colour, if removed into better ground.-Native of Crete. See the second species. 8. Coronilla Securidaca ; Hatchet Vetch. Herbaceous : legumes sickle sword-shaped; leaflets very many; root annual, composed of a few slender fibres, which run pretty

deep in the ground; stems herbaceous, trailing, a foot and a half long, dividing into several brauches. It sleeps with the leaflets converging above the petiole; flowers in July, and is a native of Spain. The seeds should be sown where the plants are destined to remain, on borders of light fresh earth in the spring, allowing them at least to be two feet distance every way apart.

9. Coronilla Varia ; Purple Coronilla. Herbaceous : legumes erect, cylindric, swelling, numerous; leaflets very many, smooth ; root perennial, creeping widely ; stems from four to six feet in height when supported, otherwise trailing. The flowers come out many together in roundish bunches, on peduncles which are about the same length with the leaves. The corolla varies from a deep to a light purple, whitish, and even wholly white; and sometimes there is a mixture of all. This plant was formerly proposed to be cultivated as a proper food for cattle; and being found to grow very readily, promised to be very beneficial to the farmer. Mr. Miller informs us, that he remembers to have seen a large spot of ground at Deepden, near Dorking in Surry, at the seat of the Honourable Mr. Howard, planted with it; where, although it had been neglected for many years, it was grown so rank, as to get the better of all the weeds, brambles, &c. He found some of the branches upwards of five feet long, and very tender in every part of that length, so that a small spot of ground will supply a considerable quantity of fodder, especially in dry seasons. Horses and cows, he adds, seemed to eat it greedily; though Mr. Curtis thinks that its bitterness will be an objection to its being cultivated for cattle, But notwithstanding this, a gentlemen, who had sown it upon Professor Martyn's recommendation, assured him, that cows eat it very readily. The roots creep very far under ground, by which it increases greatly, and when permitted to remain unremoved two or three years, it will overbear the plants growing near it, on which account the roots should be confined, and it should be planted at a distance from any other 5 B

360

plants .- It will grow in almost any soil and situation, but thrives best in a warm sunny exposure, in which the flowers appear in greater quantities, and are also more beautiful.

10. Coronilla Cretiea; Cretan Coronilla. Herbaceous: legumes five together, ereet, columnar, jointed; leaflets even; stems ascending, angular, even, two or three feet long; corollas blood-red ; the standard marked with purple veins ; the wings conflex on the outside; the keels dark purple at the end .- Native of Candia. Sow the seeds on a bed of light gle, ovate, three-sided. ESSENTIAL CHARACTER. Calizearth in the spring, where the plants are intended to remain. and take eare to thin them when too elose, and keep them clean from weeds.

11. Coronilla Seaudens; Climbing Coronilla. Stem elimbing, flaccid. This has a slender, hairy, twining stalk, of a brown colour, twisting round any of the shrubs that stand near it, whereby it rises eight or ten feet high; for the most part composed of five oval leaflets, one inch long, and half an inch broad, of a deep green. Flowers pale yellow .- Na-tive of South America. The seeds should be sown early in the spring, on a moderate hot-bed; and when the plants are come up, they should be transplanted into a halfpenny pot filled with fresh rich earth, and plunged into a hot-bed of tanner's bark, observing to shade them until they have taken root, after which time they should have air and water in proportion to the warmth of the season ; and when they have filled these pots with their roots, they should be shifted into pots of a larger size, and plunged into the hot-bed again, where they must remain until autumn, when they should be removed into the stove, and plunged into the tan. These plants must be kept constantly in the bark-stove, and placed among such as require a moderate heat, where they will thrive and flower They require to be supported by tall sticks, round which they will twine as hops do ; for if they have not this support. they will twist round other plants, and strangle them. They are very proper plauts to place against an espalier, on the back part of the stove, amongst other climbing plants, where they will make an agreeable variety, and if carefully managed in the winter, may be preserved two or three years, will flower annually in July, and sometimes produce ripe seeds in Englaud.

12. Coronilla Cochin-chinensis, Suffruticosc: leaflets about fifteen pairs ; peduneles subtriflorous ; legumes erect, torulose; stems four feet high, upright, branched; leaflets oblong, blunt, with a slender point; flowers yellow, axillary. -Native of Coehin-china.

13. Coronilla Hispaniea: Spanish Coronilla. Shrubby: leaflets nine, emarginate ; stipules large, roundish, supposed to be the same as the third species.

14. Coronilla Orientalis. Herbaceous: legumes numerous, radiate, thick, jointed; leaflets glaneous underneath; root perennial; stem aunual, creet, upwards of two feet high; leaflets five or six pairs, oblong; peduneles strong, upwards of six inches in length, supporting large bunches of yellow flowers, succeeded by short thick pods, about an inch long. It flowers in June and July, and in warm seasons will ripen its seeds in autumn. There is a variety, with large white flowers .- Native of the Levant. It is propagated by seeds sown on a warm border of light earth in the spring, carefully weeding the plants when they appear, and transplanting them, as soon as they are fit to remove, into a warm border, where they are to remain, and will only require to be shaded from the sun, and kept free from weeds. In autumn, when the stalks are decayed, if the surface of the ground be covered with some old tan to keep out the frost, it will be the surest method of preserving the roots, which will continue some years with proper care. The plants will flower in the second year. filamenta eight, very short, growing to the interior side of the

Corrigiola : a genus of the class Pentandria, order Digynia. -GENERIC CHARACTER. Calix: perianth five-leaved: leaflets ovate, coneave, spreading, size of the corolla, membranaecous on the margin, permanent. Corolla : petals five, ovate, spreading, searcely larger than the ealix. Stamina : filamenta five, subulate, small; antheræ simple. Pistil; germen ovate, three-eornered; style none; stigmas three, obtuse, Pericarp: none. Calix: converging, Seed: sinfive-leaved. Petals ; five. Seed ; one, three-sided .----The only species is,

1. Corrigiola Littoralis; Bastard Knot Grass. Stems many, slender, round, with a few branches at the end, two or three inches long, covered with leaves; flowers in glomerate raeemes, sessile, terminating; ealix of a whitish bay-colour, converging; corolla white. It flowers in June and July, and is annual .- Native of France, Germany, Denmark, Switzerland, and Piedmont, in sandy soils, generally on the banks of rivers, or near the sea. It has been found on Hapham sands, near Dartmouth, and in the neighbourhood of the Start Point.

Cortusa : a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth five-cleft. spreading, very small, permanent ; divisions lanceolate, threetoothed; eorolia one-petalled, wheel-shaped; tube scareely any; border flat, five-parted, ample; divisions ovate, acute; throat with an elevated ring. Stamina : filamenta five, obtuse; antheræ two-plaited, oblong, ereet, affixed to the outward part. Pistil: germen ovate ; style filiform, longer than the corolla ; stigma almost headed. Pericarp : capsule oval, acuminate, half five-valved. Seeds: numerous, compressed, cornered. Receptacle: columnar, free. ESSENTIAL CHARACTER. Corolla: wheel-shaped, the throat having an elevated ring; eapsule one-eelled, oval, five-valved at the end. These plants are difficult to keep in a garden; the only method by which they have been preserved, was by planting them in pots, and placing them in a shady situation. where they were regularly watered in dry weather; cold will not destroy them, but rich soils or dung is very injurious, and they should therefore be planted in a very light soil. The only method by which we can propagate them, as they never produce any seeds in England, is by parting the roots in the same mauner as is practised for aurieulas : the best time for this is about Michaelmas, soon after which the leaves decay. -The species are.

1. Cortusa Matthioli. Calices shorter than the eorolla. This plant sends out many oblong smooth leaves, a little indented on the edges. The peduncles come out in the centre of the leaves, rise about four inches high, and support an umbel of flowers, each on a slender short pedicel. The flowers are of a flesh-eolour, and spread open like those of the aurieula ; they appear in April and May .- Native of the Alps, Austria, Silesia, and Siberia.

2. Cortusa Gmelina. Calix longer than the eorolla, very like the first, but the flowers much smaller, and the caliees larger. The umbel has about three flowers; the corolla is white; and the leaflets of the involuere ovate .- Native of Siberia.

Corylus ; a genus of the class Monœcia, order Polyandria. -GENERIC CHARACTER. Male Flowers disposed in a long ament. Calix ament, common, imbricated on every side, cylindric, permanent; seales one-flowered, narrower at the base, wider at the top, and more obtuse, inflex, three-eleft; middle division equal in length to the others, but as wide again, and covering the others. Corolla: none. Stamina: calvcine scale; antheræ ovate, oblong, shorter than the calix, erect. Female Flowers remote from the males, on a very small subglobular ament, in the same plant, sessile, included within the bud. Calix : perianth two-leaved, leathery, lacerated on the margin, erect, length of the fruit, scarcely visible during the time of inflorescence; on account of its smallness. Corolla : none. Pistil : germen roundish, very small ; styles two, setaceous, much longer than the calix, coloured ; stigmas simple. Pericarp : none. Seed : nut-ovate, scalped as it were at the base, but little compressed at the tip, slightly pointed. ESSENTIAL CHARACTER. Male Calix : one-leafed, three-cleft, scale-form, one-flowered. Corolla: Stamina : eight. Female Calix : two-leaved, lacerated. Corolla : none. Styles : two. Nut : ovate. All the species of this well-known genus, may be propagated by sowing their nuts in February; which, in order to preserve them good, should be kept in sand in a moist cellar, where the vermin cannot come at them to destroy them; nor should the external air be excluded from them, which would make them grow mouldy. The method of sowing their seeds is well known, but not one in four of the plants so produced prove so good as those raised from the nuts. Mr. Miller, however, recommends the method of propagating them by layers, as being not only the surest, but also most expeditious plan, for those especially who cultivate the trees for the sake of their fruits. To sow the nuts, let the ground be well ploughed and harrowed; and let drills be drawn one yard asunder, into which drop the nuts, at about ten inches' distance, and let them be covered with two inches of earth. They must be carefully weeded and thinned, as soon as they appear, until the plants be left half a yard asunder each way. They may also be thus raised in a uursery, and removed thence when they are from a foot to two feet high, and planted finally at the distance before mentioned. In twelve years they may be cut down for poles, but may afterwards be cut every seventh or eighth year .---- The species are.

1. Corylus Avellana; Common Hazel-nut Tree. It is properly a shrub : the trunk is covered with a whitish cloven bark, which is smooth on the branches, frequently of a bay colour, and spotted with white; leaves alternately gashserrate, wrinkled; the male catkins appear in autumn, and wait for the expansion of the female germina in the spring; the styles are of a bright red colour, long and setaceous ; the flowering branches, especially those which bear the fertile flowers, are set with short fine hairs, terminating in globules; the white and red filberts are varieties of this species, and shrubs growing more erect than the common hazel: the cobput has a very large round fruit; and the cluster-nut is so called from the fruit growing in great clusters at the ends of the branches. The hazel, says Swinburn, has the name Avellana, from Avellino, a city in the kingdom of Naples, near which it is cultivated ; it covers the whole face of the neighbouring valleys, and in fruitful years produces an enormous profit. The nuts are mostly of the large round filbert kind, which we call Spanish, and were originally imported into Italy from Pontus, and therefore known to the Itomans by the appellation of nux Pontica, which in process of time was changed into that of nux Avellana, from the place where they had been cultivated with the greatest success. The common hazel-nut is found wild in many woods and coppices in England, where the country people gather the fruit, and send it in abundance to the London markets. As a shrub, it is well adapted for thickening woods; and when allowed to grow, will make poles of twenty feet; but it is generally cut down sooner for walking-sticks, fishing-rods, withes for faggoting, and other purposes for which it may be profitably employed.

tlings, and the chips to purify wine : he might have added, to make crates, springles to fasten down thatch, and the roots for inlaying or staining : where yeast is scarce, they twist the twigs, and steep them in ale during its fermentation, then hang them up to dry, and, when they brew, put them into the wort. The filbert can only be kept from changing by propagating it from suckers or layers, the last of which make the best trees. Plantations of filbert-trees are much attended to in some parts of Kent; they are never suffered to rise above six feet in height, and are regularly pruned like gooseberry bushes. They are planted twelve feet asunder, and, when full spread, the cup formed by the branches is six feet in diameter; the intermediate space is generally filled up with hoeing crops, the vigour of the trees greatly depending on the stirring of the ground; it is therefore the usual mode to raise them in hop-grounds, where cherry and sometimes apple trees are also planted. The Kentish men seem to know nothing of raising them from layers, but propagate them by suckers, which ought to be previously trained in a nursery. The best soil for them is what is called coomey in Kent, consisting of a strong loam, with a clayey or marley bottom. In this kind of ground they bear fruit in such great abundance, that an acre has been sometimes sold for fifty pounds. 2. Corvlus Rostrata: American Cuckold-nut Tree. Sti-

COR

Evelyn informs us that the uses of it are for poles, spars,

hoops, forks, angling rods, faggots, cudgels, coals and

springes to catch birds, withes and bands, hurdles and wat-

pules hanceolate; leaves oblong, cordate, acute; hranchlets smooth; calices of the fruit beaked. This is remarkable for the length of the calix, which continues to cover the nut entirely even after it is ripe.—Native of dragon swamps in Virginia.

3. Corylus Colurna; Constantinopit, or Byzantine Hazzinat Tree. Sipules linear, acute; the leaves in this are a lattle lacinaited at top; the raceme of nuts very large; the uots themselves roundish, and in shape like those of the common hazel, but more than twice their size.—Native of Constantinople.

Corymbium ; a genus of the class Syngenesia, order Monogamia.-GENERIC CHARACTER. Calix : perianth twoleaved, one-flowered, inferior, long, prismatic, six-cornered; leaflets erect, converging longitudinally, triangular on the back, truncated, obscurely three-toothed, permanent, having two very small leaflets at the base. Corolla: one-petalled, equal; tube very short; border five-parted, spreading; divisions lanceolate. Stamina: filamenta five, simple, erect, seated on the tube. Antheræ oblong, crect, shorter than the corolla, growing together into a cylinder. Pistil: germen within the calix, inferior to the corolla, hirsute; style simple, erect, length of the corolla; stigma oblong, two-parted, spreading. Pericarp : none. Calix : unchanged. Seed : single, oblong, almost the length of the calix, covered with a wool resembling down, in the manner of a pappus. Receptacle : naked. ESSENTIAL CHARACTER. Calix : two-leaved, one-flowered. prismatic. Corolla: one-petalled, regular. Seed: one, below the corolla, woolly .---- The species are,

1. Corymbium Scabrum. Leaves lanceolate, channelled, nerved, recurved, smooth, shorter than the stem. It rises with an erect rough stalk about a foot high, with a single leaf a each joint, which half embraces the stalk.—Native of the Cape of Good Hope. It should be propagated by seeds, sown in a small pot filled with light earth as soon as ever they arrive from abroad; the pots should be plugged into a bed of tanner's bark, where the leat is nearly spent, and covered with a common frame in winter, to protect the secols from frost, now, and hard rains: the plants will soon appear in the second second with a common frame in winter, the protect the secols from frost, now, and hard rains: the plants will soon appear

COS

in the spring, if the pots be removed into a moderate hotbed. They should be transplanted when about an inch high, each into a separate small pot, shading them until they acquire new roots, and gradually inaring them soon after to the open air. In June they should be placed abroad in a sheltered situation, where they may remain till October, and should then be placed in a common frame, to protect them from the frost.

2. Corymbium Glabrum. Very smooth : leaves ensiform, plaiu-nerved : panicle lax, diffuse ; flowers distinct.-Native of the Cape of Good Hope.

3. Corymbium Filiforme. Leaves filiform, very smooth, erect, shorter than the stem.—Native of the Cape of Good Hope.

4. Corymbium Villosum. Villose, woolly: stem-leaves clasping, subulate, straight, plain.-Native of the Cape of Good Hope.

Corymocorpus; a genus of the class Pentandria, order Momeyvia. — GENERIC CLARACTER. Colli: perianth inferior, five-leaved; lealths oblong, concave. Corolla: petial five, roundish, narrowed at the base, erect. *Neutary*: leaflets five, erect, shaped like the petals, hut narrower, scarcely shorter, having a globular gland at the base, laternate with the petals. Summar: fibmenta five, subulate, from the base of the petals. Anthera: oblong. *Pistili*: germen superior, plobular; style short, filtorm; stigma obuse. *Pericarp*: nut turbinate club-shaped, one-seeded. *Sced*: an oblong kernel. ESENTIAL CLARACTER. *Neutrotics*: five, petalshaped, alternate with the petals, glandulous at the base.— The only hown species is.

 Corynocarpis Lævigata. Leaves alternate, petioled, obovate or wedge-shaped, subemarginate, entire, veined, very smooth; panicle terminating, sessile, large, wrinkled; flowers white,--Native of New Zealand.

1. Corypha Umbraculifera; Great Fan Palm. Fronds pinnate-palmate, plaited, and having a thread between them; stipes ciliate, spiny. Linnens says, that this tree seldom flowers before it is thirty or forty years old, and Knox gives us the following description of it, under the name of tallipot. " It is as big and as tall as a ship's mast, and very straight; the leaves, which all grow on the top of the tree, are of great use, one being so broad and large that it will cover twenty men! Being dried, it is very strong and limber, and though it be very broad when open, will fold close like a fan, and is then no bigger than a man's arm ; the leaf when spread out is round, but is cut into triangular pieces, which the Malays and Ceylonese lay upon their heads as they travel, with the narrow end foremost, to make their way through thickets. Soldiers always carry them, not only to shade them from the sun, and to screen them from rain, on their march, but also to make

their tents to lie under. The tree hears no fruit until the year before it dies, and then the most heautiful strongerading yellow blossoms come out on the top, and spread out in group branches, terminating in a very hard round frait, about the size of our largest cherries, which are produced in such plenty, that one tree will yield seed eoungh for a whole country but unfortunately they are not fit to eat; and the flowers small so strong that the tree is generally cut down when it grows near to any houses; the trunk consists of nothing but pith, which the natives beat into a mortar to flour, and bake into cakes which have the taste of white bread; the leaves, besides the uses above named, also serve for thatching houses; and for writing on with an iron style; and most of the books shown in Europe for the Egytian papyrus are made from the leaves of this palm'—Native of Malabar, and the island of Ceylon, and of the Marquesas and Friendly Islands.

2. Corypla Minor. Fronds palmate, fan-shaped, plaied, subbifd, having a few threads interposed; sinpes unarread; flowers sessile, small, without scent, all hermaphrodite, nuerous; filamenta thick, white, the size of the corola; frait the size of a pea, and of a sweet taste, smooth, black, not very succulent.

Costmary. See Tanacetum.

Costus; a genus of the class Monandria.-GENERIC CHARACTER. Calix: perianth three-toothed, very small, superior. Corolla: petals three, lanceolate, somewhat erect. concave, equal. Nectary one-leafed, large, oblong, tubular, inflated, two-lipped, lower lip broader, longer than the corolla; border spreading, three-cleft, middle division threeparted; upper lip lanceolate, shorter, doing the office of a filamentum. Stamina: the office of a filamentum is performed by the upper lip of the nectary, to which grows a two-parted anthera. Pistil: germen inferior, roundish; style filiform, length of the filamentum ; stigma headed, compressed, emarginate. Pericarp: capsule roundish, crowned, three-celled, three-valved. Seeds : many, three-cornered. ESSENTIAL CHARACTER. Corolla: iuner inflated, ringent, the lower lip trifid .- These plants are propagated by parting their roots, the best time for doing which is in the spring, before the root puts out new stalks; the root must not be divided too small, for that will prevent their flowering, but should be planted in pots filled with light kitchen-garden earth, and plunged into a tan-bed in the stove, where they ought constantly to remain, and may be treated in the same manner as ginger. See Amomum .---- The species are,

¹ L Costus Arabicus; Arabian Costus, Leaves silky undernearh; root percennial, irregular, two inches thick, knotty; stems annual, simple, round, three or four feet high, near an inch in diameter at bottom, flexy, with a strong bark at bottom; splice very handboung, terminating, subsessile, solitary, erect, close, as big as the hand closed.—Naive of the East Indies, whence the roots were formerly imported, being much used in medicine, but of late years they have not been regarded, the roots of ginger being used in their stad.

2. Costus Glabratus. Leaves smooth on both sides; spike few-flowered; scales leafy at the tip, the upper ones fastigiate; spike or head of flowers imbricate, with ovate, blunt, concave scales, each one-flowered, permanent, green, not coloured.—Native of the West Indies.

3. Costus Spicatus. Leaves smooth on both sides; spike many-flowered, subovate, closely imbricate; scales ovate, simple; root perennial, fleshy, irregular, white; steus some what jointed, almost upright, round, smooth, one or two feet high; flowers yellow, scentless, and quickly withering.—Native of the Caribbee islands, where it is found by the side of torrents. It is called *came de reiseres*; in Martinique, where

COT

gonorrhœa as a cooling drink. 4. Costus Malacensis. Leaves very finely tomentose underneath; raceme terminating; bunches six-flowered; stems several, approximating, upright, simple, a little compressed, smooth, elothed with the sheaths of the leaves, half as nigh as a man; all the flowers are on very short club-shaped pedicels, somewhat compressed .- Native of thick woods near Tsing, in the neighbourhood of Malacca.

Cotton. See Gossupium.

Cotton Grass. See Eriophorum,

Cotton Silk. See Bombax.

Cotton Thistle. See Cnopordum.

Cotton Weed. See Athanasia.

Cotula; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix : common, convex, divided into about sixteen ovate parts, of which eight are exterior, of these the inferior ones are rather bigger than the interior ones. Corolla: compound, the length of the calix, a little convex ; corollules hermaphrodite, numerous in the disk; females in the circumference more than twenty; proper of the hermaphrodites tubular, four-cleft, unequal, the outer division larger; of the females searcely any. Stamina, in the hermaphrodites : filamenta four, very small. Antheræ tubular, the length of the corollule. Pistil, in the hermaphrodites : germen obovate ; style filiform ; stigmas two, obtuse: in the females; germen obovate, compressed, two-edged, larger; style filiform, length of the hermaphrodite; stigmas two, simple. Pericarp: none. Calix: unchanged, permanent, Seeds, of the hermaphrodites : solitary, smaller, ovate, three-sided, the interior angle obscure; down marginated; of the females solitary, larger, cordate on one side, flat on the other, gibbous, surrounded by an obtuse border; down bordered. Receptacle: almost naked, flat. ESSENTIAL CHARACTER. Receptacle: almost naked. Down : margined. Corollules : of the disk four-cleft, in the ray scarcely any .---- The species are,

1. Cotula Anthemoides ; Dwarf Cotula. Leaves pinnate, multifid, dilated; flowers floscular; root annual; stem about six feet high, at first erect, then procumbent; flowers drooping, much compressed before they open, the size of a lentil; florets yellow; down none; receptacle naked .- Native of Spain, and the island of St. Helena. If the seeds of this and of the second species be permitted to scatter, the plants will come up in the spring, and require no other care but to keep them clean from weeds and thin them.

2. Cotula Aurea; Golden Cotula. Leaves pinnate, setaceous, multifid; flowers floscular, drooping. The flowers have no chaffs, and the florets are four-cleft,-Annual ; and a native of Spain. For its propagation and culture, see the first species.

3. Cotula Stricta; Silvery Cotula. Leaves pinnatifid, plain, naked, dotted; stem erect, strict; flowers radiate; stem herbaceous, five feet high, erect, somewhat angular, even, covered with a bluish dew; corollets of the disk fourcleft .- Native of the Cape of Good Hope. This, as well as all the other natives of the Cape, must be raised on a moderate hot-bed in the spring, and when the plants have obtained strength, they may be transplanted into a warm border, where they will ripen their seeds very well. They all flourish best, however, under the protection of the dry-stove, and several of them may be increased, not only from seeds, but freely from cuttings.

4. Cotula Coronopifolia; Buckthorn Cotula. Leaves lanceolate, linear, stem-clasping, toothed; flowers floscular. It is an annual, and sends out trailing stalks about six inches 32.

a decoction of the roots and stalks is often given in the long, with succulent leaves, shaped like those of buckthorn plantain; the flowers grow from the divisions of the stalks, upon short weak footstalks, being destitute of rays; they are of a sulphur colour, appearing in July, and, like those of the eighth species, stand erect when they first appear, but as soon as the florets become impregnated, their colour changes, the footstalks become very flaccid towards the top, and the flowers hang downwards; but when the seeds are ripe, the footstalks become stiff, and their heads stand erect for the winds to disperse the seeds .- Native of the Cape of Good Hope. See the third species.

COT

5. Cotula Umbellata; Umbellated Cotula. Leaves lanceolate, hirsute; flowers umbelled; stem erect, round, hirsute, a foot and half in length; receptacle naked .- Native of the Cape of Good Hope. See the third species.

6. Cotula Quinqueloba. Leaves five-lobed, subtomentose ; stems erect, simple, pubescent; leaves petioled .- Native of the Cape of Good Hope. See the third species.

7. Cotula Viscosa ; Viscid Cotula. Leaves alternate, lyrate, pinnate; flowers radiate; stem a span high; receptacle conical, naked .- Found in the island of La Vera Cruz.

8. Cotula Turbinata. Receptacles underneath, inflated, turbinate ; flowers radiate. It sends out many branching stalks, which spread on the ground ; flowers solitary, on long peduncles, from the side of the branches they have a narrow border of white rays, with a pale yellow disk. Annual: flowering in July and August.-Native of the Cape of Good Hope. See the third species. 9. Cotula Tanacetifolia; Tansy-leaved Cotula.

Leaves tripinnate, the small segments acute: stem erect: flowers floscular, corymbed; stem searcely suffrutieose, but rather entirely herbaceous; corymb of flowers compound, fastigiate, large, terminating, consisting of several corymbiferous branches ; searcely any female florets, those of the disk foureleft .-- Annual: native of the Cape of Good Hope. See the third species.

10. Cotula Capensis. Leaves pinnate, somewhat fleshy and columnar, the lowest subbipinnate; flowers radiate; stems many, very much branched, diffused, a span in height, round, somewhat glossy .- Annual : native of the Cape of Good Hope. See the third species. This plant has the appearance of chamomile.

11. Cotula Pilulifera. Leaves bipinnate : heads globular : stems erect, subfastigiate, with a paniele .-- Native of the Cape of Good Hope. See the third species.

12. Cotula Sericea; Silky-leaved Cotula. Leaves superdecompound, tomentose, linear; root perennial; corolla floscular, shorter than the calix, yellow; stems herbaceous, short, tomentose, simple, procumbent, white .-- Native of the Cape of Good Hope. See the third species.

13. Cotula Pyrethraria. Leaves opposite, ovate, crenate, petioled; peduncles one-flowered; stem herbaceous, dichotomous .- Native country unknown.

14. Cotula Minuta. Leaves alternate, almost stem-clasping, oblong, toothed; flowers solitary, sessile, opposite to the leaf .- Native of New Caledonia.

14. Cotula Bicolor. (Specific character not given.)-Native of the isle of Tanna in the South Seas.

Cotyledon ; a genus of the class Decandria, order Pentagynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-cleft, acute, very small. Corolla: petal bellshaped, five-cleft. Nectary consisting of a concave scale, seated at the exterior base of each germen. Stamina: filamenta ten, subulate, straight, the length of the corolla. Antheræ ereet, four-furrowed. Pistil: germina five, oblong, thickish, ending in subulate styles, which are longer than the stamina; stignas simple. Pericarp: capsules five, oblong, bellied, accumate, one-valved, gapnig longitudinally inwards. Seeds: very many, small. ESSENTIAL CHARACTER. Caliz: five.cfch. Corolla: one-petailed, with five nectareous scales at the base of the germen. Capsule: five.——The species are,

1. Cotyledon Orbiculata; Round-leaved Navelwort, Leaves evate spatulate, obtuse, with a point, even; flowers panicled. This species varies much in the form of the leaves. Mr. Miller describes several of the varieties as distinct species : one of these, the oval-leaved navelwort, has a short thick succulent stalk, which rarely rises more than a foot high, branching out on every side, so as to spread over the pots in which it is planted. Another variety, called also the roundleaved navelwort, has likewise a thick succulent stalk, which becomes woody by age, and rises three or four feet high, sending out crooked branches which grow irregular, with thick fleshy succulent leaves about two inches long, and near as wide toward the top; flowers on thick succulent peduncles, from the ends of the branches, near a foot long, supporting eight or ten flowers hanging down; tube long, brims turning back ; stamina and styles longer than the tube, and hanging down ; they flower from July till September. This species, with the second, fourth, eighth, ninth, tenth, eleventh, twelfth, thirteenth, and sixteenth, are all propagated by planting cuttings in any of the summer mouths, which ought to be laid in a dry place a fortnight or three weeks after they arc taken from the plant before they are planted, for as they abound with juice in every part, they will certainly rot the cuttings, if they be not suffered to lie out of the ground, that the wounded part may heal over, and the great redundancy of san evaporate. They thrive best in a soil which is formed of one-third fresh light earth from a pasture, one third sand, and the other third part lime rubbish and rotten tan, in equal quantities, which should be well mixed, and laid in a heap six or eight months before it be used, turning it over five or six times, that the parts may be the better incorporated. It will also be proper to pass it through a screen, to separate the large stones, clods, &c. from it, before it be used. Having prepared this earth, and the cuttings being also in fit order for planting, you must fill as many halfpenny pots with earth as you have cuttings to plant, then put one cutting in the middle of each pot about two or three inches deep, or more, according to their strength, then give them a little water to settle the earth close about them, and set them in a warm shady place for about a week, to prepare the cuttings for putting forth roots, after which they should be plunged into a moderate hot-bed of tanner's bark, which will greatly facilitate their rooting, but observing to give them air by raising the glasses at all times when the weather will permit, as also to shade the glasses in the heat of the day. The best method to treat most of these plants, is to place them in an open airy dry glass-case, where they may enjoy as much of the sunshine as possible, and have a free open air; for if they be placed in a common green-house among shrubby plants which perspire freely, these succulent plants imbibe too much of the damp air, and thereby becoming too replete with moisture, often cast their leaves, and sometimes even their branches decay, and then the whole plant perishes. 2. Cotyledon Spuria; Narrow-leaved Navelwort. Leaves

 Cotyledon Spuria; Narrow-leased Natelwort. Leaves spathate, obtuse with a point, naked. This has a short, greenish, succulent stalk, seldom more than a span high; flowers on short pedicels, yellow; tubes long; brims reflex, tipped with purple; stamina longer than the tube.—See the first species for its culture and propagation.

3. Cotyledon Spinosa. Leaves oblong, spiny, mucronate;

stem spiked. This sort requires a very shady situation, for if it be exposed to the sun in summer, the plants will soon decay. It is propagated by offsets, like the houseleek, and requires a strong soil.—Native of Siberia.

4. Cotyledon Hemispherica : Thick-leared Narelwort. Leaves suborbiculate, dotted with scurf, convex underneaht; flowers subsessile. It has a thick succulent stalk, rarely more than a span high, dividing into many branches. See the first species.

5. Cotyledon Serrata; Notch-leared Narchwort. Leaves oral, crenate; stem spiked; stalk upright, succulent.—Native of Candia and Siberia. If this and the sixth and seventh species be sown upon a wall, they will thrive better than in the ground, and be less liable to suffer by frost; so that where the seeds scatter themselves on walls or rock-work, the plants thrive better than when the vare cultivated.

6. Cotyledon Umbilicus; Common Navelwort, Kidneywort, or Wall Pennywort. Leaves peltate, crenate; stem almost simple; flowers erect; bractes toothed, or leaves peltate, crenate; stem almost simple; flowers pendulous; bractes entire. Mr. Hudson has distinguished the yellow from the common navelwort, by the circumstances of the flowers being upright, and the bractes toothed in the first; whereas in the second the flowers hang down, and the bractes are entire. Morison remarks, also, that the root of the yellow navelwort is not round like a turnip, but oblong, and creeping. It is found in Somersetshire, and in the West Riding of Yorkshire. Meyrick informs us, that a decoction of the leaves is cooling and diuretic, and that the bruised leaves are a good application for slight burns or scalds. Hill says. that the leaves are cooling, and good against pains, when externally applied ; that they are used by outward application in the piles with great success; and that the juice of them taken inwardly operates by urine, and is excellent for stranguries, the gravel, and in inflammations of the liver and spleen. This plant is a native of India, Spain, Portugal, Italy, Britain, on moist rocks and walls; it is found in an old gravelpit close to Highberry Barn, near London; at Peterborough, Northampton, and Thorpe; between Peterborough and Wandesford ; in the slate pit rocks at Smithland, in Leicestershire; Church Brampton in Northamptonshire; about Noutbeck, in Westmoreland; at Godstow Bridge, in Oxfordshire; about Malvern, in Worcestershire ; Shepton Mallet, in Somersetshire ; Caernarvonshire and Merionethshire, in Wales ; in Cornwall, and other western counties; and in some of the Scotch islands. It flowers from June till August. See the fifth species.

7. Čotyledon Hispanica; Spanich Narchuort. Leaves oblong, almost columars; flowers fascieled; root fibrose; stem simple, columnar, almost erect, a finger's length in height; flowers in a terminating corynnb; corollas funnel-shaped, dusky red on the outside, somewhat hairy.—Biennial: native of Africa, the Leavan, and Spanis. See the fifth species.

8. Cotyledon Papillaris. Leaves opposite, columnar, ovate; flowers corymbed. Native of the Cape of Good Hope. See the first species.

9. Cotyledon Mamillaris. Leaves alternate, columnar, ovate; flowers alternate, subsessile.—Native of the Cape of Good Hope. See the first species.

10. Cotyledon Triffora. Leaves ovate, entire; flowers subpeduncled, in threes.—Native of the Cape of Good Hope. See the first species.

11. Cotyledon Caccalioides. Leaves columnar; flowers corymbed; stem shrubby.—Native of the Cape of Good Hope. See the first species.

12. Cotyledon Reticulata. Leaves columnar; flowers net-

CRA

corymbed; stem shrubby .- Native of the Cape of Good Hope, See the first species.

13. Cotyledon Paniculata. Leaves oblong-ovate, sessile; nanicle divaricated, racemed; stem shrubby .- Native of the Cape of Good Hope. See the first species,

14. Cotyledon Laciniata; Cut-leaved Navelwort. Leaves pinnatifid; flowers four-cleft in a panicle; stem leafy to the very top; the inflorescence panicled; stamina eight short, two long; peduneles terminating, about six inches long, sustaining seven or eight small flowers of a deep yellow colour. It flowers in July and August, and is a native of Egypt, and the East Indies. This and the fifteenth species require a warm stove to preserve them through the winter in England ; nor should they be exposed abroad in summer; for if they receive much wet, the stalks are very subject to rot, so that they should constantly remain either in the stove, or in summer should be placed in an airy glass-case with other tender succulent plants, where they may have free air in warm weather, and be screened from cold and wet : but they must be removed into the stove in autumn, where they should be kept in a moderate temperature of warmth. They are propagated by cuttings, which should be taken off in summer and planted into small pots, and plunged into a moderate hot bed, and when they have taken root they should be removed into the stove, and must have but little water, especially in winter.

15. Cotyledon Nudicaulis. Leaves spatulate, ovate; flowers four-cleft in a cyme; stem almost naked at the end. See the preceding species.

16. Cotyledon Fascicularis; Cluster-leaved Navelwort. Leaves wedge-shaped, fascicled, terminating, trunk thickened; branches fleshy, subconic .- It flowers from July till September. See the first species.

17. Cotyledon Viscosa. Leaves columnar; racemes terminating, villose, viscid; stem branched; root annual; corolla bell-shaped, pale yellow, with purple streaks .- Native of the mountains of Spain, near Toledo, and elsewhere.

18. Cotyledon Lanceolata. Leaves lanceolate, servate at the tip; panicle villose; flowers quadrifid .- Native country unknown.

19. Cotyledon Alternans. Leaves orbiculate, spatnlate, quite entire; flowers panicled, smooth, quadrifid, the whole plant smooth .- Native place unknown.

Crambe ; a genus of the class Tetradynamia, order Siliquosa. -GENERIC CHARACTER. Calix : perianth four-leaved ; leaflets ovate, channelled, somewhat spreading, deciduous. Corolla: four-petalled, cruciform; petals large, obtuse, broad, spreading; claws erect, spreading, length of the calix. Stamina: filamenta six, two the length of the calix, four longer. with a two-cleft tip. Antheræ simple, on the exterior branch of the filamenta; a melliferous gland between the corolla and the longer stamina on each side. Pistil : germen oblong ; style none; stigma thickish. Pericarp : berry dry, globose, one celled, deciduous. Seed : single, roundish. ESSENTIAL CHARACTER. Filamenta, the four longer two-cleft at the end, one only of the tips bearing an anthera. Berry : dry, globose, deciduous .---- The species are,

1. Crambe Maritima; Sea Colewort. Leaves and stem smooth. The roots creep under ground, and propagate it very fast. The whole plant is smooth; the flowers white, and on long peduncles. There are two varieties, one with jagged leaves, and another with yellowish blossoms. The young leaves, covered up with sand, and blanched, are boiled and eaten as a great delicacy, but when full grown they are said to produce giddiness, although all sorts of cattle eat them, -It is found on the sandy shores and beaches of Denmark, Sweden, and Britain ; as, at Roosebeck in Low Furness, Lancashire, near Megavissey in Cornwall, between Whitstable and the Isle of Thanet, near Colchester, about Lyde in Kent, and elsewhere, on the Essex and Kentish shores, and in great plenty on the coast of Sussex and Devonshire. It flowers in May and June. In order to cultivate the sea colewort, or sea-cole, prepare the bed intended to receive the seeds as for asparagus. Sow them in March. Before putting them in the ground, bruise the outer coat without wounding the seeds, which will accelerate their growth. Set three seeds in a triangular form, six inches apart, leaving a space of two feet between the triangles, and bury the seeds about three inches deep. They will make their appearance in four or five months, but should not be cut until the third spring. About the end of November, when the leaves are become rotten, let them be cleared away, and the bed covered with a coat of half-rotten dung. In the second year, about March, when the plants are beginning to perforate the surface, take or rake off lightly the coat of dung, and give the plants full liberty to grow. And in November, or sooner if the leaves be rotten, clear them off, and cover with rotten dung as in the preceding year. In the third year, immediately after removing the dung in the spring, cover the plants with a thick coat of sand or coal ashes, or small pebbles. As they grow, continue to keep them from the air until they be cut for use, and in cutting them remove the sand, ashes, or pebbles, and then cover the roots again. Some of them will bear cutting twice or thrice in a season. After the last cutting is finished, remove the cover, and let the plants grow until the leaves are decayed, afterwards clearing and covering them for the winter. Some prefer to cover their plants with earthen pans, or large garden pots, putting a tilesherd over the hole, for all air must be excluded in order to have them white.

CRA

2. Crambe Orientalis. Leaves scabrous; stem smooth, -Native of the Levant, has a biennial root, and may be propagated in the same manner as the preceding.

3. Crambe Hispanica; Spanish Colewort. Leaves and stem scabrous; root whitish, annual, fusiform; flowers in corymbs; calices yellowish; petals white. It flowers in June, and the seeds ripen in autumn .- Native of Spain and Italy. It must be propagated by seeds.

4. Crambe Tatarica. Leaves decompound, multifid ; root perennial, fusiform, as thick as the human arm, from two to four feet long, round, brown or blackish on the outside when fresh, within fleshy, white, with a tinge of dirty yellow, of a sweet taste. Flowers very numerous, in terminating branched corvmbs, smelling strong of honey. It flowers about the middle of April, and the fruits ripen in June, but few of them come to maturity. The roots are eaten, in a scarcity of bread, by the Tartars and Hungarians, and the bares also are very fond

of them.—Native of Hungary, Tartary, Moravia, and Bohemia. 5. Crambe Fruticosa; Shrubby Colewort. Shrubby: leaves ovate, pinnatifid, serrate, boary; racemes in a dishevelled dichotomous panicle. It is a stiff shrub, with leafy branches and flowers during most part of the year .- Found by Masson in the highest rocks of the island of Madeira. 15

This and the sixth species are inhabitants of the green-house, and grow freely from cuttings,

6. Crambe Strigosa; Rough-leaved Shrubby Colewort. Frutescent : leaves at the base unequal, two-eared, strigose. It is a rugged shrub; stem erect, round, loosely branched, ash-coloured, the height of a man; flowers pedicelled, erect, white .--- It flowers in May and June, and is found in the Canary Islands by Masson. See the preceding species.

Cranberry. See Vaccinium. Crane's-bill. See Erodium, Geranium, and Pelargonium. Cranichis ; a genus of the class Gynandria, order Diandria .- GENERIC CHARACTER. Calix : spathes wandering; perianth none. Corolla: petals five, oblong, subhorizontal, the three outer (or two upper lateral, and one anterior,) ovate, lanceolate, equal, spreading, the two inner anterior, scarcely smaller, more slender, ovate, lanceolate, erect ; nectary or upper petal (between the outer superior petals) galeate or vaulted, erect, ovate, gibbous, slightly keeled, entire at the tip, often bifid at the base, dotted within, covering and embracing the genitals behind. Stamina : antheræ two or four, pedicelled, placed on the apex of the style, turned towards the helmet, with an upright two-celled lid, fastened to the column of the style in front, they are covered at the back. Pistil : germen obovate, oblique, inferior ; style an erect column, shorter than the helmet, dilated at the tip, obtuse, bearing the stamina at the back; stigma funnelform, between the column of the style and the lid of the stamina. Pericarp: capsule oblong or obovate, attenuated at the base, three-cornered, three-keeled, one-celled, opening under the ribs, cohering at the tip and base. Seeds ; numerous, very small, like sand or saw-dust, affixed to a columnar receptacle. ESSENTIAL CHARACTER. Nectary galeated. The species, which are all natives of Jamaica, are,

1. Cranichis Aphylla. Bulbs in bundles, columnar, acute; scape almost naked ; petals converging.

2. Cranichis Oligantha, Bulbs in bundles, club-shaned leaves petioled, oblong, acuminate, shining; scape almost naked; spike filiform; petals converging,

3. Cranichis Diphylla. Bulbs in bundles, filiform, naked; leaves petioled, cordate, acuminate, twin; scape almost naked.

4. Cranichis Stachyodes. Bulbs in bundles, columnar, obtuse; leaves petioled, ovate, acuminate; scape sheathed; spike columnar; petals revolute.

5. Cranichis Muscosa. Bulbs filiform in bundles, tomentose; root-leaves petioled, ovate; stem-leaves sheathed; nectary dotted within.

Craniolaria ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix : perianth inferior, four-leaved ; leaflets liuear, short, spreading, permanent; perianth superior, ovate, inflated, large, cut lengthways on one side. Corolla: one-petalled, unequal; tube very long, very narrow; border flat, two-lipped, upper lip entire, roundish, like the other divisions, but larger; lower lip three-cleft, divisions roundish, the middle one wider. Stamina: filamenta four, length of the tube of the corolla, of which two are somewhat shorter; antheræ simple. Pistil: germen ovate; style thread-form, length of the tube of the corolla; stigma thickish, obtuse. Pericarp: coriaceous, ovate, sharp on both sides, two-valved. Seed Nut: woody, depressed, sharpened on both sides, with a bent two-parted point, marked on each side with three-toothed furrows, of the figure of a quadruped's skull, two-cleft on the sides. Es-SENTIAL CHARACTER. Calix : double of the flower ; perianth four-leaved; spathe one-leaved; corolla, tube very long ; capsule, the same as in martynia .----- 'The only known many-secded .---- 'The species are, species is,

1. Craniolaria Annua, Leaves cordate, angled : outercalix two-leaved. This is an annual plant, two feet high, the whole of it villose, and extremely viscid, from a single and very short trunk, divided into dichotomous, round, thick branches, procumbent at the base, but above the middle erect, diffused ; flowers handsome, but without scent, hirsute: calix green; corolla white, with three large dark purple spots at the bottom of the throat; nut black, abiding some days after the pericarp has fallen, not opening, or even separable with considerable force, though it appears to be four-valved. The throat of the corolla, which is clammier than any part of the plant, generally contains great numbers of small flies, which are attracted by the honey juice, and killed by being entangled in it. The root, which is brown without but white within, round, flesby, thick, has a sweet taste, and is eaten fresh with milk, or preserved with sugar. It is used in the Spanish West Indies for the same purpose as that of scornozonera is in Europe, and is called by the same name .--- Native of New Spain.

Cranzia ; a genus of the class Pentandria, order Monogynia -GENERIC CHARACTER. Calix : perianth five-parted. small, permanent; parts ovate, acute, concave, spreading, Corolla: petals five, oblong, sessile, erect, bluntish, channelled, vaulted at top, keeled behind the tip, shrivelling, Stamina : filamenta five, broader at the base, three-sided, subulate at the tip, erect, opposite to, and longer than the petals ; antheræ roundish, incumbent. Pistil : germen subglobular, five-lobed, each lobe scored with a longitudinal groove ; style cylindric, thicker in the middle, grooved longitudinally, scarcely longer than the germen; stigma threelobed, obtuse. Pericarp: berry angular, globose, acuminate, dotted on the outside, one celled. Seeds: a few, (three to nine,) kidney-form, oblong, full of pits. ESENTIAL CHARACTER, Calix: five-parted, Petals: five, Nectory: none. Berry : a berried capsule .---- The only species known is,

1. Cranzia Aculeata. A prickly shrub; leaves ternate, with pellucid dots; flowers panicled, axillary; fruit dotted like the orange--Native of the East Indies.

Craspedia ; a genus of the class Syngenesia, order Polygamia Segregata.-GENERIC CHARACTER. Calix : common, imbricate; florets in a few depressed bundles; perianth partial, none : corolla compound, tubular : corollets hermaphrodite. Stamina : filamenta five ; antheræ cylindric ; pericarp none, Seeds : with a feathered down. Receptacle : chaffy. ESSENTIAL CHARACTER. Calicle: none. Calix: imbricate. Florets: in depressed bundles, all hermaphrodite, tubular. Down: feathered. Receptacle: chaffy .---- The only known species is,

1. Craspedia Uniflora .- Native of New Zealand.

Crassula ; a genus of the class Pentandria, order Pentagynia. --GENERIC CHARACTER. Calix: perianth one-leafed, five-cleft; divisions lanceolate, channelled, concave, erect, acute, converging into a tube, permanent. Corolla: petals five; claws long, linear, straight, converging, connected at the base, with the ovate bractes at the border, reflex, expanding; nectaries five, each with a very small emarginate scale, annexed outwardly to the base of the germen. Stamina: filamenta five, subulate, length of the tube, inserted into the claws of the corolla; antheræ simple, Pistil: germen five, oblong, acuminate, straight, compressed, gaping inwards lengthwise. Seeds: many, small. ESSENTIAL CHARAC-TER. Calix: one-leafed, five-cleft. Petals: five nectareous scales, five at the base of the germen; capsule five,

CRA

* Shrubby.

1. Crassula Coccinea ; Scarlet flowered Crassula. Leaves ovate, plain, cartilaginous, ciliate, connate, sheathing at the base; stem reddish, jointed about three feet high; flowers at the ends of the branches in close umbels; corolla funnelshaped, erect, with a pretty long tube, cut at the top into five parts, of a fine scarlet colour, appearing in July or Au-gust .-- Native country unknown. This, and all the hardy species of this genus, are propagated by cuttings, during any of the summer mouths. These cuttings should be taken off about a fortnight before planting, and laid in a dry place, that the wounded part may heal over; they should then be each planted in a small pot of light sandy earth, and plunged in a moderate hot-bed, allowing them but little water. In about six weeks they will put out roots, and begin to grow, and should have a large share of air admitted to them, that they may be gradually inured to bear the open air, into which they should be taken, and placed in a sheltered situation until autumn, when they must be removed into a dry airy glass-case, where they may enjoy as much sun as possible, and be defended from the wet and cold. While they are abroad in warm dry weather, during the summer months, they should be gently watered twice or thrice a week, but should have very little water in winter, lest it rot their stems. They require no artificial heat, but merely to be secured from the frost and wet.

 Crassula Cymosa: Cyme-bearing Crassula. Leaves linear, cardiaginous, ciliate, comate, sheathing; stem shrubby; cyme terminating; stems a span high, erect, smooth, annual; roots perennial. See the preceding species for its propagation.

3. Crassula Flava; Yellow-flowered Crassula. Leaves plain, connate, perfoliate; even; flowers corymh-panicled, faseicled, but each pedicelled; petals yellow, erect.—For its propagation and culture, see the first species.

4. Crassila Pruinosa; Frosted-General Crassila. Leaves sublate, forsted, seabrous; flowers corynheed; stem shrubby, a foot high, dichotomous; the small branches round, blood-red, covered, as is the whole plant, with the resemblance of a crystalline hoar-frost.—For its propagation and culture, see the first species.

5. Crassula Scabra : Rugged Crassula. Leaves opposite, spreding, countet, scabrous, ciliate ; stem scabrous backward; stem weak, succulent, about a foot and a half high, divided at top into small branches; flowers in small clusters at the end of the branches, small and herbaceous : the corolla is so deeply divided, as to make it doubtful whether it be monopetalous or pentapetalous: leaves green, thick, succulent,-lt flowers in June and July. For its propagation and culture, see the first species.

6. Crassula Perfoliate; Perfoliate Crassula. Leaves lanceled; escolate, essile, comante, channelled; the stem upright, rising ten or twelve feet high, if not broken or injured; buit is requires support, the leaves being very weighty: the flowers terminating in large clusters, of a white herbaccous colour, with short tubes, and the brin eut into five parts; they appear in July.—For its propagation and culture, see the first species.

7. Crassula Fruticulosa. Leaves opposite, subulate, acute, spreading, somewhat recurved; stem shrubby.—For its propagation and culture, see the first species.

8. Crassula Tetragona; Square-leaved Crassula. Leaves subdate, somewhat incurved, obscurely four-cornered, spreading; stem erect, arborescent, rooting; root percunial; stem futseener, filform, branched at bottom, leavy, smooth, a foot high; flowers in narrow compound corymbs, appearing 92.

in July and August .- For its propagation and culture, see the first species.

CRA

9. Crassula Ramosa; Branching Crassula. Leaves subulate, plain, above connate, perfoliate, even, spreading very much: peduncles elongated; flowers cymbed; corolla white, with µurple autherea.—For its culture and propagation, see the first species.

10. Crassula Obvalla. Leaves opposite, sublanceolate, cultrate, approximating.—For its culture aud propagation, see the first species.

11. Crassula Cultrata; Sharp-leared Crassula, Leaves opposite, obvacte, subcultrate, objique, connate, quite entire. It rises about two feet high, with a weak succulent stalk, which sends out many irregular branches. The stalk which supports the flowers rises from the top of the branches, and is from four to six inches long, putting out several side-branches, which grow erect, and are terminated by large clusters of small greenish flowers, which never expand, but appear in Jane and July. As this species is rather hardy, if the cuttings be plated in a border of light earth, they will put out roots, and may afterwards be taken up and potted, to be sheltered in the white.

12. Crassula Cotyledon; Tree Crassula. Leaves roundish, fleshy, dotted on the upper surface; stem arboreons; the whole plant is smooth: flowers numerous, inodorous, at first while, but afterwards rose-coloured.—For its propagation and culture, see the first species.

 Crassula Pinnata; Wing-leaved Crassula. Leaves pinnate; stem arboreous; panicle axillary, shorter than the leaves, red; flowers red.—Native of China. For its propagation and culture, see the first species.

* Herbaceous.

14. Crassula Centauroides; Centanry-flowered Crassula. Stem dichotomous; leaves sessile, oblong, ovate, cordate, plain; peduncles axillary, one-flowered; stem roundish, brachiate, somewhat pubescent, flowering in May and June. --For its propagation and culture, see the first species.

15. Crassula Dichotoma; Forked Crassula. Stem dichotomos; leaves sessile, ovate, oblong, channelled, recurred; peduncles axillary, one-flowered; flowers purple on the outside, golden-coloured within, with a blood-red heart-shaped spot at the bottom of each petal; stem simple, round, pale green, dichotomous at top, scarcely a palm in height, flowering in June and July—For its propagation and culture, see the first species.

16. Crassub Glomerata; Clustered Crassula. Stem dichotomous; leaves lanceolate; the last flowers fascicled; stem a palm in height; erect, round, purplish; leaves opposite, feshsy, sessile, spreading very much, sharpish; annual, and flowering in June and July.—For its culture and propagation, see the first species.

17. Crassula Strigosa. Stem dichotomous, erect; leaves obovate, strigose: peduncles one-flowered; leaves opposite, obtuse, marked with lines, quite entire, the lower often on petioles.—For its propagation and culture, see the first species.

18. Crassula Muscosa. Stem prostrate; leaves opposite, ovate, gibbose, imbricate; flowers sessile, solitary. The smallest flowers in this genus, the length of the leaves.—For its propagation and culture, see the first species.

10. Crassula Ciliata; Ciliated Crassula. Leaves opposite, oval, fattish, disinet, ciliate; corymbs terminating; stems short, ending in a few leafy branches, which are elongated into round shoots, a long span in length, laaving leaves on them like the lower ones, but distant from each other in pairs; these are generally divided into two peduncles, sustaining 5 D.

yellowish flowers. Perennial, flowering in July and August. -For its propagation and culture, see the first species.

CRA

20. Crassula Punctata; *Dotted Crassula*. Leaves opposite, ovate, dotted ciliate, the lower oblong; stems slender, very full of joints, trailing. For its propagation and culture, see the first species. - Native of the Cape of Good Hope.

21. Crassula Subulata: Ant-Ioared Crassula. Leaves subulate, columnar, spreading: stem covered with transition columnar, spreading: stem covered with transition subessile, with an imbricate involuere. For its propagation and culture, see the first species. It is an annual plant.— Native of the Cape of Good Bope.

22. Crassula Alternifolia; Alternat-keered Crassule, Leaves serrate-toothed, plain, alternate; stem very simple; flowers pendulous, on short peduncles, yellow; branches two feet long, lax, purple, hairy.—For its culture and propagation, see the first species.

23. Crassula Rubens; Hardy Annual Crassula. Leaves scattered, semicylindric, samootil; flowers lateral, solitary, subsessile; branches villose; stem round, pubescent, decumbent, brauching, ascending a finger's length; flowers in the branches among the leaves, scattered, remote, on very short pedunctes; nectaries white, very small. For its propagation and culture, see the first species.—Native of the Cape of Good Hope.

24. Crassula Verticillaris; Whorl, flowered Crassula, Leaves spreading; flowers verticilled, awned. This never rises with a stalk, but the leaves come out close to the ground, forming a sort of head. They are succulent, taper, ending in points, and frequently put out roots; out of the centre of these arises the flower-stalk, branching into two or three shoots at top, each terminated by clusters of greenish flowers, which make no great appearance.—This is an annual, and must be propagated by seeds.

25. Crassula Nudiceaulis', Naked-stalked Crassula. Leaves subulate, radical; stem naked. This species never rises with a stalk, but the leaves come out close to the ground, forming a sort of head. They are succulent, taper, ending in points, and frequently put out roots, out of the centre of which arises the flower stalk, which is round, and from four incles to a foot in height. The howers do not open. This species has been long known in the gardens of the curious. It flowers in May, and sometimes again in the latter part of the summer; both this and the twenty-sixth species are propagated by the heads or offsets, laid to dry three or four days before they are planted, during any of the summer months. See the eleventh species.

20. Crassufa Orbicularis; Starry Crassula. Runners proliferous, determinately leafly; leaves very much spreading, imbricate. This is a very low perenuial plant, with open spreading heads, very like those of some sorts of house-leek, growing on the ents of very slender trailing stalks, produced in plently on every side of the parent plant, in the same maner as the childing marigold. Spike brachitate, verticilled, with few flowers; petals whitish red. See the preceding species.—Native of floope.

27. Crassula Pelluwida. Stem finacciá, creeping; leaves opposite. The flowers appear in small clusters at the end of the branches, and are white, with a blash of purple at their branches, and are often followed by seeds.—It is easily increased by its trailing branches, and is hardy, but will decay unless often renewed.

28. Crassula Columnaris. Stem erect; leaves conuate, orbiculate, ciliate, hemispherically imbricate; flowers in a head; flowers terminating, very copious, white; head hemispherical.—Native of the Cape of Good Hope.

29. Crassula Barbata; *Bearded leaved Crassula*. Leaves connate, orbiculate, bearded, hemispherical, imbricate; stem almost naked; flowers in whorls; root biennial.

30. Crassula Argentea; Silver-leaved Crassula. Leaves comute, ovate, cnire, silvery; stem covered; corymb superdecompound; root perennial; stem shrubby, branched, a foot or more in height; branches round, smooth; flowers terminating in an ovate corymb. —Native of the Cape of Good Hope.

31, Crassula Vestita. Leaves connate, deltoid, obtuse; stem covered; flowers terminating in a head; root fusiform, creeping, perennial; flowers sessile, yellow.

32. Crassula Corollina. Leaves commate, deltoid, obtuse; stem covered; flowers in an umbel; root fusiform, perennial; flowers from the ends of the branchlets, very many, terminating, upright, peduncled.—Native of the Cape of Good Hope.

33. Crassula Retrofexa; Orange-flowered Crassula, Leaves counter, oblong, remote; stem simple; yeue compound; pedicels bent back at an angle; root annual; stem filform, flexuose, erect, a finger's length, smooth, purple; stem-leaves two or four, ovate-lanceolate, blunt, spreading, entire; flowers creet, in a decompound subdicholomous cyme. There are three varieties: 1, with orange coloured flowers: 2, with middle-sized yellow flowers: 3, with smaller and more tender white flowers.

34. Crassula Deltoidea; *Deltoid-leared Crassula*. Leaves connate, deltoid; stem covered; flowers corymbed; stem herbaceous, fleshy, round, npright, naked at bottom; leafy above, branched.—Native of the Cape of Good Hope.

35. Crassula Cordata; Heart-keared Crassula. Leaves petioled, cordate; flowers solitary; root annual; steams herbaceous, weak, gradually more slender, leafy at bottom, branched at top, fleshy, round, flesh-colured, almost up-right, a palar in height; branches opposite, capillary, from spreading upright, smooth; flowers terminuting, on capillary peluncles, appearing from May till August.—Native of the Cape of Good Hope.

36, Crassula Montana. Leaves commte, ovate, acute, ciliate; stem almost naked; flowers headed, aggregate; not-leaves concave, very frequent, patulous, smooth, green, tinged with purple; stem-leaves about three pairs, similar, but smaller, and remote; stem filiform, upright, a finger's length, p -yle.

37. Crassula Mollis; Figmarigold-leaved Crassula, Leaves connatte, cylindric, triquetrons, smooth, soft, remote; stem erect, simple; corymb trichotomous, superdecompound; root varennial; stem frutescent; leaves acute, smooth on every line, subtomentose, patulous; flowers in a subfastigate corymb.-Ht flowers with us in August, and at the Cape of Good Hope, where it is a native of Jamaica, in January.

36. Crassula Crenukat; Notch-leared Crassula. Leaves connate, lanceolate, dotted, and crenukate, remote; coryanb decompound; stem herbaceous, upright, cylindrie, leafy, jointed, smooth, green, variegated with white lines, the thickness of a quill, a foot high; flowers white, in a trichotomous fastigiate cormb.

30. Crassila Alpestris. Leaves counste, orate, acute, entire, imbrirate, in four rows; heads pedualed; stem round, smooth, upright, branched at bottom, before flowering time wholly covered with leaves, a pain high, purple; flowers in several terminating heads, which are larger than peas; peduales purple.

40. Crassula Pyramidalis. Leaves connate, ovate, obtuse, entire, imbricate, in four rows; heads sessile; root perennial;

heads, larger than a pea .- Native of the Cape of Good Hope.

41. Crassula Spicata. Leaves connate, linear, subulate; scape almost naked; flowers in whorls; root-leaves fastigiately opposite, erect, concave above, convex below, smooth, a finger's length, very much crowded; stem-leaves, opposite, smaller; stem round, herbaceous, erect, smooth, a span high. -Native of the Cape of Good Hone.

42. Crassula Turrita. Leaves connate, imbricate, in four rows, ovate-oblong, acute, ciliate; root annual; stem herbaceous, weak, erect, round, jointed, covered with leaves, smooth, a palm high ; branches, if any, axillary, very short .-Native of the Cape of Good Hope.

43. Crassula Rupestris. Leaves connate, ovate, entire, smooth; stem covered; corymb superdecompound; root perennial, branched .- Native of the Cape of Good Hope.

44. Crassula Thyrsiflora. Leaves perfoliate, ovate, ciliate, patulous; corymb compound, spiked; stem round, herbaceous, upright, a span high, smooth; flowers white, in a thyrse, gradually attenuated, decompound, a palm in length. -Native of the Cape of Good Hope,

45. Crassula Capitella; Square-spiked Crassula. Leaves oblong, connate, cartilaginous, ciliate, patulous; flowers in headed whorls; stem round, smooth, erect, a span high, the thickness of a quill, sometimes branched at top: flowers white, in sessile, many-flowered, approximating whorls .- Native of the Cape of Good Hope.

46. Crassula Pubescens. Leaves connate, ovate, subulate, villose; stem branching; flowers corymbed; root perennial; corymb compound, trichotomous.

47. Crassula Cephalophora. Leaves connate, linear, oblong, obtuse, entire; heads lateral, peduncled; heads of flowers opposite, the size of a pea .- Native of the Cape of Good Hope.

48. Crassula Tomentosa. Leaves connate, lauceolate, villose, ciliate; stem almost naked; flowers in whorls; rootleaves bluntish, hirsute, imbricate; stem-leaves three pairs, smaller; stem angular, erect, villose, a foot high .- Native of the Cape of Good Hope.

49. Crassula Cotyledonis. Leaves connate, oblong, tomentose, ciliate; stem almost naked; flowers corymbed, aggregate; flowers white, pedicelled; peduncles dichotomous; corymb decompound .- Native of the Cape of Good Hope.

50. Crassula Tecta. Leaves connate-ovate, obtuse, ashcoloured, lamellose; scape naked; flowers sessile; stem scarcely any; flowers several, minute, collected into a head; leaves subradical, very abundant, imbricate, convex beneath, concave above, thick, covered with an ash-coloured meal, like the scales of a butterfly's wing.

51. Crassula Perforata. Leaves connate, perfoliate, ovate, ciliate, remote; stem erect, thyrse-bearing, round, jointed, gradually attenuated, leafy, smooth, a foot high; peduncles and pedicels filiform .- Native of the Cape of Good Hope.

52. Crassula Expansa ; Awl leaved Crassula. Leaves semicylindric, subulate, channelled above, spreading; peduncles axillary, solitary, one-flowered; stems dichotomous. Annual: flowering in June and July .-- Native of the Cape of Good Hope.

53. Crassula Lineolata; Channelled Crassula. Stem herbaceous; leaves cordate, sessile; peduncles almost terminating, axillary, approximating, umbel-shaped. Biennial : flowering from June to August.—Native of the Cape of Good Hope.

54. Crassula Pulchella; Reflex-leaved Crassula. Stem herbaceous, dichotomous; leaves ovate, oblong, fleshy, reflex; flowers in the forks peduncled; peduncles turbinate .- An- variety, which has the leaves deeply sinuated, pinnatifid, and

flowers at the ends of the branches, in solitary globular nual; flowering in July .- Native of the Cape of Good Hope.

55. Crassula Imbricata; Imbricate Crassula. Leaves ovate, acute, imbricate, in four rows, glossy; flowers axillary, sessile. It flowers in June .- Native of the Cape of Good Hope.

56. Crassula Obliqua; Oblique-leaved Crassula. Leaves opposite, ovate, oblique, quite entire, acute, distinct, somewhat cartilaginous at the edge; leaves of a lively green, half stem-clasping. Shrubby; flowering in April and May .- Native of the Cape of Good Hope.

57. Crassula Alooides ; Spike flowered Crassula. Leaves ovate, distinct, acute, ciliate; stem simple, somewhat hairy; raceme compound; branches panicle-shaped; bienuial; stem scarcely a span in height; leaves fleshy, smooth, with minute, red, impressed dots, scattered over them, and an inch in length; nectaries yellow; filamenta white. It flowers from June till August .- Native of the Cape of Good Hope.

58. Crassula Sparsa; Alternate-leaved Crassula. Leaves alternate, subspatulate, acute, quite entire; raceme compound. -Biennial; flowering in July, and a native of the Cape of Good Hope.

59. Crassula Diffusa ; Diffuse Crassula. Leaves obloug, attenuated at the base, remotely crenate ; peduncles opposite to the leaves, and axillary, solitary .- Annual ; flowering in July, and a native of the Cape of Good Hope.

60. Crassula Spathulata; Crenated Crassula. Leaves petioled, cordate, roundish, acutish, crenate; corymbs panicleshaped .-- Shrubby: It flowers in July and August, and is a native of the Cape of Good Hope.

61. Crassula Marginalis; Margined Crassula. Stem shrubby ; leaves cordate, perfoliate, acuminate, plain, spreading, dotted within the margin .- Shrubby: flowering in July and August, and a native of the Cape of Good Hope.

62. Crassula Lactea; Snowy Crassula. Stem shrubby; leaves ovate, attenuated at the base, connate, quite entire, dotted within the margin; cymes panicle-shaped .--- Shrubby: flowering in September and October, and a native of the Cape of Good Hope.

63. Crassula Cespitosa. Leaves globose, ovate, imbricate four ways; cyme three-flowered; flowers sessile. This is a thick annual plant, scarcely three lines in height; stem red, stamina four or five .-- Common near Madrid, flowering in March.

64. Crassula Umbella. Leaves roundish, perfoliate; racemes axillary and terminating, upper peduncles in whorls; root perennial, the whole plant smooth; stem one or two, annual, round, fleshy, the size of a quill, a span high, upright, subpellucid .- Native of the Cape of Good Hope,

Cratægus; a genus of the class I cosandria, order Digynia. -GENERIC CHARACTER. Calix: perianth one-leafed, concave, spreading, five-cleft, permanent. Corolla: petals five, roundish, concave, sessile, inserted into the calix. Stamina: filamenta twenty, subulate, inserted into the calix. Antheræ roundish. Pistil: germen inferior; styles two, filiform, erect; stigmas headed. Pericarp : berry fleshy, rounded, umbilicated. Seeds : two, somewhat oblong, distinct, cartilaginous. ESSENTIAL CHARACTER. Calix: five-cleft; petals five; berry inferior, two-seeded .---- The species are,

1. Cratægus Aria; White Beam Tree. Unarmed: leaves ovate, gashed, serrate, tomentose underneath. It rises to the height of thirty or forty feet, with a large trunk, dividing into many branches : the young shoots have a brown bark covered with a mealy down, and the flowers are produced at the ends of the branches, in bunches or corymbs, two inches or more in diameter, and very much branched. There is a Swedish

wid take very well by grafting or budding upon pear-stocks, as the pear-tree will also take, when engrafted upon it; and though both will sometimes succeed upon the Mespilus, yet in that case they never thrive so well, nor last so long, as when they are grafted or budded upon each other. The straight and handsome growth of the tree, the smoothness of the bark, the extreme whiteness on the under surface of the leaves, the handsome bunches of white flowers on thin mealy peduncles, which are succeeded by red berries, all conspire to render this desirable for mixing among other ornamental plants, especially as it bears lopping, and permits the grass to grow under it. The wood being very white, hard, tough, and smooth, is used for axle-trees, walking-sticks, and the handles of tools: the fruit is eatable when mellowed by the autumnal frosts, and yields an ardent spirit when distilled .--It flowers in May, and is a native of most parts of Europe, being chiefly found on dry hills and open exposures, in gravel, clay, or chalk, and from the fissures of limestone rock : it is found in all parts of Great Britain, but principally in Derbyshure, where it is called the wild pear tree; and at Norwood, near London: it was formerly found upon Hampstead Heath, and, according to Mr. Ray, in Worcestershire and Staffordshire; it is called red chess apples, and sea owlers, in Lancashire and Westmoreland ; and mehlbeerbaum or mehlbaum by the Germaus; axelbar, by the Danes; oxel. oxeltræd, or oxelbær, by the Swedes; alizier, by the French; aria or sorbo peloso, by the Italians ; and mostaco, by the Spaniards. It may be propagated by seeds, which should be sown soon after they are ripe, for if they be kept out of the ground till spring, they must remain at least one year in the earth before they can appear. On this account the fruit should be buried in the ground, in the same way as the haws, hollyberries, and those other hard seeds which do not come forth in the same year that they are sown; they should also be treated in the same manner when they appear, but ought by no means to be headed or cut down. It may also be propagated by layers in the same manner as the lime and elm, but these should be laid in the young wood ; two years will elapse before they produce sufficient roots to transplant. It may also be raised from cuttings planted in a shady border in autumn, although scarcely an eighth part will ever succeed; so that the trees raised from seeds are greatly to be preferred. because they are more productive, and grow much larger and straighter, than those raised from layers or cuttings.

2. Cratægus Torminalis; Wild Service, or Sorb; Mapleleaved Service. Unarmed : leaves smooth, seven-angled, the lowest lobes divaricate ; calices villose. It rises to the height of forty or fifty feet, with a large trunk, spreading at the top into many branches, so as to form a a large head : the young branches are covered with a purplish bark, marked with white spots; the flowers are produced in large bunches towards the end of the branches; they are white, and shaped like those of the pear-tree, but smaller and on longer peduncles; they appear in May, and are succeeded by roundish compressed fruit, shaped like common haws, but larger, ripening in autumn, when they are of a brown colour, and when kept till soft, in the same manner as medlars, have a very agreeable acid flavour in their taste; the fruit is sold in the London markets in autumn, and the wood being very bard and white, is very serviceable in mill-work .- It is a native of Denmark, Germany, Austria, Switzerland, Burgundy, and Piedmont. It is found in many parts of England, and principally upon strong soils, especially in Caen Wood, and Bishop's Wood, near Hampstead, in Hertfordshire. There is an Alpine variety, with a dark-brown fruit about the size fruit; but no thorns, which is called Carolina hawthorn in the

even pinnate, which is never the case with it in England. It of the common haw, which is a native of Monte Baldo, and other mountains of Italy. It may be propagated in the same way as the first species, (which see,) but requires a strong soil.

3. Cratægus Coccinea : Great American Hawthorn Thorny : leaves cordate, ovate, gash-angled, smooth; petioles and calices glandular; flowers five-styled. It rises to the height of twenty feet in England ; the flowers come out from the side of the branches in large clusters, and as they are large, make a noble show in the month of May: they are also succeeded by large pear-shaped fruit of a bright scarlet colour, which ripers in September .- Native of Virginia and Canada. All the sorts of American hawthorn may be raised from seeds sown in autumn, in the same manner as the first sort, or as the common hawthorn : but as these seeds can only be procured from America, and frequently do not arrive here till spring, the fruit may be buried in the ground till the autumn following, when they may be taken up and sown in drills, taking care to cover them, so that birds cannot destroy them. The plants will come up in the following spring, and should be moderately watered twice or thrice a week in dry weather, and if not often weeded will soon be destroyed. In the second spring they should be planted out, before they begin to shoot, into a nursery-bed, where they may grow two years to get strength, and afterwards be transplanted wherever they are to remain. In a light moist soil their roots will extend to a considerable distance, and put up many shoots, which may be taken off in the spring, and thereby may be increased; these will also take, if grafted on the pear; and the young branches also will take root, if laid down. The several kinds of hawthorn are generally planted among flowering shrubs of the same growth, where they add to the variety. Although the largest and most beautiful plants can only be raised from seed, the varieties of the hawthorn are continued by budding upon stocks of the common sort; which is also the method that is commonly adouted for several of the species. See Inoculating.

4. Cratagus Viridis; Green-leaved Virginian Hawthorn. Unarmed : leaves lanceolate-ovate, subtrilobate, serrate, smooth .- Native of North America, propagated in the same manner as the third species, of which it seems to be a mere variety.

5. Cratagus Punctata; Great-fruited Hawthorn. Thorny, or unarmed: leaves obovate, wedge-form, smooth, serrate; caliccs subvillose ; leaflets subulate, entire ; branches diffuse, no thorns; leaves obovate, acute; fruit orange-red dotted with brown .- Native of America. For its cultivation and propagation, see the third species.

6. Cratægus Crus Galli; Cockspur Hawthorn. Thorny: leaves subsessile, glittering, coriaceous; calycine leaflets lanceolate, subserrate; flowers two-styled; stem strong, ten or twelve feet high ; bark of the stem rough, and of the branches smooth and reddish; flowers axillary, in roundish clusters, generally two together; petals white, with a blush of red, they appear in June ; the fruit is globular, and of a fine red colour .- Native of North America. Propagated in the same manner as the third species.

7. Cratægus Tomentosa ; Woolly-leaved Hawthorn. Branches thorny: leaves wedge-form, ovate, serrate, somewhat angular, villose underneath. It has a slender shrubby stem, about six or seven feet high, sending out many irregular branches, armed with long slender thorns. It flowers at the beginning of June, and ripens fruit very late in the autumn. -Native of North America. There is a variety of this species, which has longer and whiter leaves, larger flowers and

CRA

381

nurseries. For its propagation and culture, see the third if you do not sow them immediately as soon as they are gaspecies.

8. Cratægus Indica; Indian Hawthorn. Unarmed: leaves lanceolate, serrate; corymbs scaly.—This is a large thornless tree; native of the East Indies and Cochin-china. The wood is heavy, reddish, and so tough that it is well adapted for ons; and other purposes where elasticity is required.

9. Cratægus Oxyacantha; Common Hawthorn, or White Thorn. Leaves obtuse, trifid, servate ; styles two, sometimes three or four ; seeds usually two, but sometimes one, three, or four. The common hawthorn flowers and dried fruit are said, by Hill, to be used in medicine as diuretics, and serviceable in all gravelly complaints, but are not much esteemed. The varieties of this species usually flower in May, and particularly the Glastonbury variety, which usually flowers in January or February, so that it may happen to be in flower on Christmas-day. The great-frnited variety has an exceedingly large, oblong, smooth, and bright scarlet-coloured fruit ; the buds of the yellow variety are of a fine yellow colour, and are succeeded by a golden-coloured fruit, which it continues to bear throughout the winter, and was originally imported from Virginia. The white variety is but a paltry tree; the doubleflowered, however, is one of the greatest ornaments of which our shrubberies can boast, and may be kept down to any size; its beautiful flowers come out in large bunches in May, they are of a pure white, and often appear entirely to cover the shrup : they change at length to a faint red, and are frequently succeeded by a small imperfect fruit. Few trees can surpass the hawthorn in beauty, during the season when it is in bloom; it is therefore well adapted for ornamental plantations, and particularly proper for standing single in lawns or parks, where it will grow to the height of twenty or even thirty feet, and sometimes measure from five to nine feet in the circumference of its trunk. The wood is tough, and may be employed for axle-trees, and the handles of tools. The root of an old thorn, says Evelyn, is excellent both for boxes and combs; when planted singly, it rises with a stem big enough for the use of the turner, and the wood is scarcely inferior to box. A decoction of the bark affords a yellow dye, which, with the addition of copperas, is used for dyeing black. The berries are the winter food of the thrush, and of many other birds; and hogs and deer are also very partial to them. The peasants of many countries are known to eat them, and the Kamtschadales even make wine from them. In addition to the name of white thorn, the English call it Mau-bush and quick, when used for hedges, for which purpose it surpasses all other live fences; (see Hedge and Quick;) the Germans call it hagedorn ; the Danes, hagetorn ; and the Swedes hagtorn, whence the English also derive the name hawthorn. and apply the contraction haws to the fruit; in France it is known by the appellation of aubepine, or epine blanche; in Italy, by the term bianco spino ; and in Spain, espino blanco ; all of which signify white thorn. In order to raise the whitethorn, the most usual practice is, to sow the herries either in October or November, or else very early in the spring, either broadcast or in drills, in beds of about four feet wide, with valleys of eighteen inches in width between them, and covering the berries an inch deep with fresh light mould. Thus, though most of them should not come up until the second spring, yet they will have the continual benefit of the sun. air, and rain, all of which it may be presumed will make them come up better and shoot stronger, than when they lie buried in a heap during more than a year. The following plan of Mr. Bortcher's is subjoined, as containing some useful directions on this subject. The haws should remain on the bushes till the end of October, when they become blackish : 32.

thered, spread them on an airy floor for five or six weeks, till the seeds are dry and firm, then plunge them into water, and rub off all the pulp between your hands with the assistance of a little sand; spread them again on the loft for three or four days till quite dry, mix them with a fine loose sandy mould, in quantity not less than the bulk of the seeds, and lay them in a heap against a south wall, covering them over three or four inches deep with soil, of the same quality as that with which they are mixed. If you do not sow them in the first, let them remain in this situation till the second spring, as the seeds, when sown, will not appear in the first year. That the berries may be as equally mixed with the soil as possible, turn over the heaps once in two months, blending the covering with the seeds, and at every turning give them a fresh covering in the winter months. They must be sown in the first dry weather in February or the beginning of March: let them be separated from the loose soil in which they were mixed with a wire sieve; choose good fresh dry well-prepared land; divide it into beds of three feet and a half broad, with alleys of eighteen inches; push over a little of the surface of the beds into the alleys; sow them with great care, so that they may not rise in clusters, and that the plauts may in general be at least an inch asunder; clap them into the earth with the back of a spade, draw the soil back from the alleys, and cover the seeds only half an inch deep. In the succeeding spring draw out all the largest plants, wherever they rise too close together; shorten their roots, and lay them in lines a foot asunder, and four inches distant in the rows, having cut off so much of their tops as to leave them about two inches above ground; and there let them remain for two years. Those who are not straitened for ground may drop the seeds in drills that are eight inches asunder, and double that distance between each pair of drills; they also may be drawn off, wherever too thickly sct, in the following spring, and the rest cut with a spade five or six inches below ground, to remain another year. Thorns also may be propagated to much advantage, and two years' time be saved, by cutting from their roots : for this purpose, at removing a nursery of these plants, cut off all unnecessary roots that are straight and clean, and only of one or two years' growth, let them not exceed four or five inches, and either early in October or February lay them in drills cut out by the spade, with their tops a quarter of an inch below the surface; let these drills be a foot asunder, and lay the roots three or four inches separate: in the next spring cut them within three or four inches of the surface, for they will be in general about eighteen inches high, and well rooted, at two years old. In whatever way thorns are propagated, in October they should be planted out in rows, at least eight inches asunder, and six inches in the row, their roots having been shortened, and their tops cut off, so as to stand four or five inches above ground : in this nursery they should remain no more than two years, the ground being dug in spring and autumn, and the plants cut in the first season, an inch or two above the former cutting : when again removed, they should be placed in rows four feet asunder, and two feet distant in the row; they should also be cut to the height of a foot or fourteen inches; and about the end of June clipped straight in the sides, and then in the tops. Having stood a year longer, they should be again cut to the height of thirty inches, and clipped as before. At Midsummer in the third season they may be cut at about three feet and a half high, and may be planted in the succeeding autumn for handsome hedges at four feet high : if plants of a larger size be desired, they must be removed once more, and will be six feet high in three years. Quick, thus 4 E

removed, and planted out at large, will make an almost immediate fence, and be a great saving, wherever fencing is expensive.

10. Cratægus Monogyna. Leaves subtrifid, acute; lobes spreading, quite entire below ; flowers one-styled ; trunk ascending, round, very much branched; bark smooth. This is supposed by some to be our English whitethorn described above: but as Linneus thought otherwise; and Mr. Lyons observes, that the style, though simple at first, is afterwards divided into two; and Dr. Withering, whose testimony is very decisive, also observed two styles in one plant; their opinion has been preferred before that of their opponents.

11. Cratægus Azarolus; Parsley-leaved Hawthorn Azarole. Leaves obtuse, subtrifid, somewhat toothed. It has a strong stem twenty feet high, having many strong irregular branches, covered with a light-coloured bark .- Native of the south of Europe, and of the Levant.

12. Cratagus Maura. Leaves oblong, toothed at the end ; bark ash-coloured, no spines; flowers in branched corymbs, resembling those of the common hawthorn .- Native of Barbary.

13. Cratægus Villosa. Leaves oblong, acuminate, smooth, serrate; flowers in a compound umbel; styles two; fruit villose .- Native of Japan.

14. Cratægus Lævis. Leaves ovate, acuminate, smooth, serrate; flowers in an almost simple umbel; stem smooth; flowers terminating, spreading very much; peduncles capillary, callous, an inch long; perianth only half the length of the corolla .- Native of Japan.

15. Cratægus Glabra. Leaves oblong, acute, smooth, serrate; flowers in a compound panicle; branches and branchlets subverticilled, striated, smooth, spreading .-- Native of Japan.

16. Cratægus Cordata; Maple-leaved Hawthorn. Thorny: leaves cordate-ovate, gash-angled, smooth; petioles and calices without glands; flowers five-styled. It rises with a strong woody stem about four feet high, seuding out many spreading branches, which incline to a horizontal position. It flowers the latest of the genus .- Native of North America. For its culture and propagation, see the third species.

17. Cratægus Pyrifolia. Thorny, or unarmed : leaves ovate, elliptic, gash-serrate, somewhat plaited and hirt; calices a little villose; leaflets linear lanceolate, serrate; flowers three-styled .- Native of North America. Propagated in the same manner as the third species

18. Cratægus Elliptica; Oval-leaved Hawthorn. Thorny: leaves elliptic, unequally serrate, smooth ; petioles and calices glandular; berries globnlar, five-seeded.-Native of North America. Cultivated in the same way as the third species.

19. Cratægus Glandulosa ; Hollow-leaved Hawthorn. Thorny: leaves obovate, wedge-form, angular, smooth, glittering; petioles, stipules, and calices glandular; berries oval, five-seeded .- It has very stout thorns; flowers in May and June, and is a native of North America. For its culture and propagation, see the third species.

20. Cratagus Flava; Yellow Pear-berried Hawthorn. Thorny : leaves obovate, wedge form, angular, smooth, glittering; petioles, stipules, and calices glandular; berries turbinate, four-seeded. There are often small leaves on the thorns, which are slender .--- It flowers in May, is a native of North America, and propagated in the same manner as the third species.

21. Crattegus Parviflora; Gooseberry-leaved Hawthorn. Thorny: leaves wedge-form, ovate, gashed, serrate; calycine leaflets gashed, the length of the fruit; flowers five-styled. It is a humble shrub, seldom rising more than six or seven feet high, sending out a great number of slender branches, serrate. This species grows to a great height, with a large

interwoven and armed with very long, slender, sharp thorns : the flowers are produced at the end of the branches; the fruit is smaller than that of the common hawthorn, and is of an herbaceous yellow colour when ripe .- It flowers in May and June, and is generally known by the name of Lord Hay's hawthorn. See the third species.

22. Cratagus Sanguinea. Thorny : leaves seven-angled serrate, produced at the base; petioles submarginate; height often extending to two or three fathoms: trunk the thickness of the human arm or thigh, very much branched from the bottom, and spreading; flowers in corymbs at the ends of all the branchlets, and so abundant that the tree is very handsome in May, when in flower and fruit : the latter is large. very red, subglobular, two-celled, two or four-seeded, and ripens at the end of August, and, after the first frosts in September, becomes very eatable .- Native of Siberia, probably of Kamtschatka.

23. Cratægus Bibus, Unarmed; leaves lauceolate, serrate, tomentose; racemes terminating, hispid. It is a middle-sized tree, with spreading branches; leaves unequally serrate, scattered on short petioles; flowers white, in large bunches; styles two; fruit middle-sized, pear-shaped, yellow, lanuginose, of a sweet acid flavour, juicy, eatable; the skin thin; the pulp white, one-celled, containing two or three seeds .- Cultivated in abundance about Macao and Canton, in China.

Crateva; a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, four-cleft, deciduous, flat at the base; divisions spreading, ovate, unequal. Corolla: petals four, oblong, bent down to the same side; claws slender, length of the calix, inserted into the divisions. Stamina: filamenta sixteen, or more, bristle-form, declining to the side opposite the petals, shorter than the corolla. Antheræ erect, oblong. Pistil: germen on a very long filiform pedicel, ovate; style none; stigma sessile, headed. Pericarp: fleshy, globose, very large, pedicelled, one-celled, two-valved. Seeds : many, roundish, emarginate, nestling, ESSENTIAL CHARACTER, Calix : four-cleft. Corolla : three-petalled ; berry one-celled, many-seeded .- All the plants of this genus are propagated by seeds, which must be procured from the places where they naturally grow, and must be sown upon a good hot-bed in the spring. When the plants are fit to remove, let them be transplanted each into a small pot of light kitchen-garden earth, and plunged into a hot-bed of tanner's bark, shading them every day from the sun, until they have taken fresh root, and watering them sparingly in winter. For further particles, see the directions under the genus Annona, which equally relate to these plants .---- The species are,

1. Crateva Gyuandra; Thin-leaved Crateva. Unarmed: leaflets ovate, quite entire ; flowers gynandrous ; trunk more than twelve feet high ; branches spreading, round, unequal ; leaves alternate; flowers rather large, purple .- It flowers in May and June, and is a native of Jamaica, in dry coppices near the sea.

2. Crateva Tapia ; Smooth Crateva, or Garlic Pear. Unarmed : leaflets ovate, acuminate ; petals ovate, roundish, blunt, germina globular; trunk very large, rising to more than thirty feet high; leaves all smooth, of a light green on the upper side, but pale underneath, and their edges entire. The fruit is about the size of an orange, and has a strong smell of garlic, which is communicated to the animals that feed upon it, and to which the tree owes its name .- Native of the West Indies.

3. Crateva Marmelos; Prickly Crateva. Thorny: leaves

trunk, sending out many long branches, garnished with trifoliate leaves; the leaflets are oblong, entire, and end in acute points, between which the branches are armed with long sharp thorns, which come out by pairs, and spread asunder; the flowers are produced in small clusters from the side of the branches, five or seven standing upon a common branching peduncle; the flowers have each five acute petals, which are reflex, sweet-scented, green on the outside, and whitish within; after the flower is past the germen, it swells to a large fruit the size of an orauge, having a hard shell, which encloses a fleshy viscous pulp of a yellowish colour, having many oblong plain seeds situated within it : the pulp of this fruit has an agreeable flavour when ripe, and is frequently eaten in India, where the fruit is served up, mixed with sugar and orange, and accounted one of their greatest delicacies .--Native of the East Indies.

4. Crateva Religiosa. Thorny: leaves serrate: trunk of amiddling beight, upright; branches spreading, round, ascending, covered with an olive bark dotted with white; common petioles spreading, sensitylindric, smooth and even, a hand in length; partial petioles very short; cyme terminating, subcorymbed, and sometimes solitary flowers from the axils of the upper leaves; flowers an inch and half in diameter; greenish white, with red stamina.—Native of the Saciety Isles. In the latter it is planted at the burial places of the natives, and supposed to be sacred to their idols. In Otaheite it is called *pura-au*, or *purataruru*, and the fruit of its eaten.

5. Crateva Obovata. Leaflets and petals obovate; germen oblong; leaves and leaflets petioled; peduncle heaped at the top; style longer than the filamenta.—In other respects it has the habits of the rest, and is a native of Madagascar.

Crepis ; a genus of the class Syngenesia, order Polygamia Æqualis .- GENERIC CHARACTER. Calix : common, double. Exterior : very short, spreading, deciduous. Interior : ovate, simple, furrowed, permanent; scales linear, converging. Corolla: compound, imbricate, uniform; corollets hermaphrodite, very many, equal. Proper: one-petalled, ligulate, linear, truncate, five-toothed. Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: germen somewhat ovate ; style filiform, length of the stamina; stigmas two, reflex. Pericarp : none ; calix roundish. Seed: solitary, oblong, fusiform, sometimes columnar; down hairy, generally stipitate. Receptacle : naked, with cells or pits. ESSENTIAL CHARACTER. Calix: calicled, with deciduous scales; down hairy, stipitate. Receptacle: naked. Some of these plants are weeds in gardens and pastures, and they may all be easily propagated by sowing their seeds in the spring, where they are designed to remain, so that if six or eight seeds be sown in each patch, and when the plants come up they may be reduced to three or four, and if these be kept clean from weeds, they will require no other culture, except putting down small sticks, to which the stalks are to be fastened in order to prevent their being broken by winds or rains. If the seeds be sown in autumn, or permitted to scatter, the plants will come up, and live through the winter without any shelter, and will flower early in the spring .-The species are,

1. Crepis Pygmaa. Leaves ovate, entire, villose, petioled; stem procumbent, height not more than six feet; flowers yellow,-Native of the mountains of Italy.

2. Crepis Bursifolia. Leaves pinnatilid, crenate; scape maked, few-flowered; stems not above a span in height, having on them a few short laciniate leaves.—Perennial: found in the county of Nice, near Palermo, and in other parts of Sicily.

3. Crepis Barbata; Spanish or Bearded Crepis, or Purple-cyed Succory Hawkweed. Involucres longer than the calix ; scales setaceous, scattered, annual, putting out leaves next the root, nine inches in length, and almost two broad in the middle, of a light green colour; stems a foot and a half high, dividing into many branches, and having leaves with the same form as the others, but smaller and sessile. The flowers are produced at the ends of the branches, they are vellow, and purplish at the base ; but the florets in the disk are almost entirely of a dark purple. There are two varieties of this species, one in which the flowers are of a deep vellow. and the other in which they are of a sulphur colour, inclining to white, but both have a very dark purple bottom or middle, and make an elegant appearance in the flower-garden, where they come forth in June and July, and ripen seeds in autumn .- Native of the south of Europe. It is an annual plant,

4. Crepis Vesicaria. Involucres scariose, the length of the calix; flowers corymbed; bractes ovate; root thick; stem short; flowers yellow.—Native of Apulia.

5. Crepis Alpina. Involucres scariose, the length of the calks; dowers solitary ; stems strong, upright, two feet high, dividing into three or four erect branches, terminated by pale-coloured dowers, enclosed in a strong hairy calks, which contracts close towards the top.—It flowers in June, ripens seed in autumn, and is a native of the Alps.

6. Crepts Rubra: Purple Crepts. Leaves stem-chaping, lyrate, runcinate; root annual; root-leaves many, lancedate, deeply jagged. From these arise the stalks, which are a foot and a half high, dividing into many sleucher branches, each terminated by one large red-coloured flower. The calix nods before the flower opens. A nunual.—Native of Italy.

7. Crepis Fætida; Stinking Crepis, or Succory Hawkweed. Leaves runcinate, pinnate, rough with hairs ; petioles toothed : stem a foot or eighteen inches in height, erect, round, angular, grooved, round, with hairs standing out ; the stem and branches appear panicled, with the flowers, which are yellow purple on the outside, and nodding before they open. Villars remarks, that this plant varies in size, form, colour, and smell; but that in all the varieties the root is fusiform; the stem rough, channelled, and branched; the leaves ash-coloured, and more or less indented at the base : that it has generally the smell of bitter almonds, especially the bruised calix :- in which Linneus and Tournefort coincide : while Haller more justly attributes a bituminous scent to it : and Ray informs us, that both it and the preceding species smell strongly of castor; and Mr. Miller, to complete this discord of opinion, declares, that to him the flowers always seemed to have the smell of opium. It is biennial, (although Linneus calls it annual,) and flowers from June to August. Petiver distinguishes it by the name of castor hawkweed .---Native of Germany, Switzerland, Austria, France, Piedmont; and of England, near Cambridge, on Banstead Downs in Surry, near Charlton, Northfleet, and Greenhithe in Kent, and near Swaffham in Norfolk.

8. Crepis Aspera. Leaves toothed, lower ovate, eared, npper sagitate; stiff bristles scattered over the stem.—Native of Sicily, the Levant, and Palestine.

 Crepis Rhagadioloides. Leaves entire, stem-clasping, oblong, interior; calices torulose, jointed, hispid; leaflets boat-form. Annual: stem half foot high, erect, striated, scabrous, branched; corolla yellow, purplish on the outside,

10. Crepis Sibirica; Sibirian Crepis, Leaves stemclasping, oblong, winkled, toothed at bottom; stem rough with hairs; calices ciltate on the lecel. Perennial: stem stiff, two feet high, strated, hispid. It flowers in July and August.—Native of Siberia and Switzerland.

CRE

11. Creps Fectorum; Smooth Crepts. Leaves lanceolateruneinate, sessile, even, the lower toothed. This is a very common plant, of an ash-coloured green; stem angular, furrowed, with branches as long as the stem; root annual; leaves very variable, smooth, or slightly hirsute; flowers yellow, in a kind of loase corymb. The flowers, heads, and seeds of this plant, are smaller than any English hawkweed. The flowers expand about four in the morning, and close about noon. Our old writers calls it pellow saccory, succory dandelion, and saccory flankweed. Petiver calls it hawkbeard; and Dr. Withering applies that name to the whole geruns.—It flowers from June till September, and is a native of Europe, in pastures, by way-sides, on bauks, and on walls.

12. Crepts Biennis; Biennial Crepts, Rough Succery Hanckreed. Leaves runcinate, pinnatiful, scabrous, toothed at the base above; calices muricate; stem angular, scabrous, from four to sis feet ligh, britle; flowering branches divaricate, hearing several flowers on separate peduncles. The flowers close between three and four in the afternoon.—Native of Scania, Switzerland, Italy, Germany, and of England, where it is found in calcarcous soils, near Northfleet, and between Sittingbourne and Roehester, in Kent, and about Linton in Cambridgeshire. It is biennial. The flowers close between three and four in the afternoon, and appear in July and August.

13. Črepis Virens. Leaves runeinate, smooth, stemclasping; calices subtomentose; root-leaves lanceolate, obtuse, smooth, somewhat toothed; flowers small, and yellow. —Native of France, Switzerland, Silesia, and Italy.

14. Crepis Disscorides: Disscorides Crepis. Root-leaves runcinate; steam-leaves hastate; e calices subtomentose: annual; stem a foot high, somewhat angular, smooth, and even; branches but few, round, and spreading; corolla yellow, purple beneath hefore it expands.—It flowers in June, and is a unity of France, the Palatimate, Sliksia, Haly, and Siberia.

 Crepis Pulchra; Small-flowered Crepis. Leaves sagittate, toothletted; stem panieled; flowers pyramidal, smooth. —It is an annual, flowers from July till August, and a native of France and Italy.

16. Crepis Neglecta. Leaves, stem-clasping, runcinate, toothed, somewhat hairy; stem panicled; calices with one or two spines on each leaflet; stem a foot high, branched, somewhat hairv, erect. The flowers are small.—Native of Italy.

17. Crepis Abida; Pade-flowered Crepis. Leaves rundinate, toothed, somethat hours; pednueles maked, one-dowered; calycine scales whitish at the edge; stems several, twice or thrie dichotomous, with a assetle leaf at each division of the branches; root-leaves elliptic, gradually lessening into a leafy petiole, thickish toothed, seddom quite entire; stem-leaves half embracing, rougher, sharper, with a more evident pricke; flowers larce, pale yellow, or whitish, eomposed of a great number of florets.—Native of France and laly.

19. Crepis Rigens: Bristly-leaved Crepis. Leaves oblong, doubly serrate, bristly stem naked, branched; flowers panicled; calices eylindric, smooth; down sessife.—It flowers in July and August, is perennial, and a matice of the Azores, or Western Isles. It requires the shelter of a greenhouse.

19. Crepis Filiformis; *Fine-leaved Crepis*. Leaves linear, filiform, very cutire, smooth; down sessile : biennial, flowering in June, and native of Madeira.—It must be sheltered in a green-house.

20. Crepis Succulenta; Fleshy-leared Crepis. Leaves enough to hold a gallon, and are so thin and close, that they planatifid, or toothed, somewhat fleshy, even; ealiees some-serve to boil water as well as an carthen pot, and will hear what tomentose; down sessing.—This plant, like the two pre-

11. Crepis Tectorum; Smooth Crepis. Leaves lanceolateneinate, sessile, even, the lower toothed. This is a very muon plant, of an ash-coloured green, stem angular, furderina.

Crescentia ; a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, two-parted, short, deciduous; divisions roundish, concave, obtuse, equal. Corolla: one-petalled, unequal; tube gibbous, erooked, torulose; border ereet, five-cleft; divisions unequal, tooth-sinuated. Stamina : filamenta four. subulate, length of the corolla, spreading, of which two are a little shorter ; antheræ incumbent, obtuse, twin. Pistil ; germen pedicelled, ovate; style filiform, length of the corollastigma headed. Pericarp : berry oval, hard, one-celled. Seeds : very many, subcordate, nestling, two-celled. Essen-TIAL CHARACTER. Calix: two-parted, equal. Corolla-Berry : pedicelled, one-celled, many-seeded. gibbous. Seeds : two-celled .- These trees require a warm stove, to preserve them in England. They are easily propagated by seed. which must be procured from the country where they naturally grow; the best way of doing which, is to import the entire fruit when fully ripe, for when the seeds are taken out of the pulp abroad, if they be long in their passage, they will become useless before they arrive. They must be sown on a good hot-bed in the spring, and when fit to remove should be each transplanted into a small pot filled with light sandy earth, and plunged into a hot-bed of tanner's bark, where they must be shaded from the sun until they have taken fresh root, and be afterwards treated in the same manner as other plants which are natives of the same countries. They should be gently watered two or three times a week in summer, according to the warmth of the season, and must have a large share of air in hot weather. In winter they should be placed in the tan bed of the bark-stove, and should have but little water during that season. . With this management the plants will make great progress, and their leaves being of a fine green, they make a pretty variety in the stove, but have not yet flowered in England .---- The species are,

1. Creseentia Cujete ; Narrow-leaved Calabash Tree. Leaves wedge-lanceolate, erowded. This tree grows to the height of about twenty feet, and is easily distinguished from all others by its peculiar appearance. It divides at top into very long, thick, scarcely subdivided branches, stretching out almost horizontally, adorned with leaves disposed in bundles or tufts, seatteringly, at irregular distances. The wood is light and pliant, the bark unequal, ash-coloured, or whitish; flower large, sometimes entirely green, but often differently variegated, with purple, red, and yellow; it does not wither, but becomes putrid, and in that state exhales a cadaverous, very nauscous, and intolerable stench. The form of the fruit varies on different trees, being spherical, spheroidal, or shaped like a bottle; and differing in size, from two inches to a foot in diameter : but it must be confessed, that if these be only varieties, they are very constant. . The fruit is covered with a thin skin, of a greenish yellow colour when ripe, and under this is a hard, thin, woody, shell, inclosing a pale yellowish soft pulp, of a tart unsavoury flavour, surrounding a great number of flat seeds. The shells, when cleansed of their pulp, deprived of the outer skin, and dried, are used in the West Indies for drinking cups, tipped with silver, and with handles fastened to the neck. The long small fruit is formed into spoons and ladles; that which is round is cut through the middle, and used as choeolate cups, and other domestic utensils. They are frequently large enough to hold a gallon, and are so thin and close, that they serve to boil water as well as an carthen pot, and will bear

into button-moulds throughout the colonies. The Caribs engrave the outside of these shells with a variety of grotesque figures, which they sometimes colour black or red. They also eat the pulp occasionally, but it is not esteemed to be either agreeable or wholesome, although much used as a ponltice, and yielding a syrup, which is greatly esteemed by the natives, in inward bruises, contusions, and disorders of the The wood being very tough and flexile, is well hreast. adapted for the coach-maker, and is frequently used for making saddles, stools, and other furniture. In times of scarcity, the leaves and branches are eaten by cattle, as well as the pulp of the fruit .- Native of the low lands of Jamaica, the Leeward Islands, and of the neighbouring continent.

2. Crescentia Cucurbitina ; Broad-leaved Calabash Tree. Leaves ovate, subcoriaceous, distinct ; fruits ovate, acuminate. The trunk of this tree is middle-sized, unarmed, smooth, and even; leaves opposite, alternate, or scattered, never in tufts, larger, broad, ovate; petioles short, thick, smooth; corollas nodding, the size of the preceding, but more dusky; the base of the tube and throat white, the belly red, the border pale, the segments dusky: the fruit is pedicelled, ovate, oblong, with a short point, one-celled : the wood is very hard, and white .- It flowers the whole year, and is a native of dry rocky places on the coasts of Jamaica. Cress. See Cardamine.

Cress, Bastard. See Thlaspi. Cress, Garden. See Lepidium. Cress, Indian. See Tropæolum.

Cress, Rock. See Iberis.

Cress, Rocket. See Vella.

Cress, Swine's. See Cochlearia.

Cress, Water: Cress, Winter. See Sisymbrium.

Cressa ; a genus of the class Pentandria, order Digynia .-GENERIC CHARACTER. Calix: perianth five-leaved; leaflets ovate, obtuse, incumbent, permanent. Corolla : onepetalled, salver-form; tube length of the calix, bellied below; border five-parted ; divisions ovate, acute, spreading. Stamina: filamenta five, capillary, loug, sitting on the tube of the corolla; antheræ roundish. Pistil: germen ovate; styles two, filiform, length of the stamina; stigmas simple. Pericarp: capsule ovate, one-celled, two-valved, a little longer than the calix. Seeds : single, ovate, oblong. Es-SENTIAL CHARACTER. Calix : five-leaved. Corolla : salver-form. Filamenta : sitting on the tube. Capsule: twovalved, one-seeded.——The species are, 1. Cressa Cretica. Corollas beardless; capsules one-

seeded. This is a small, and very shrubby plant ; root long, slender, jointed, white. The small flowers come out at the ends of the twigs .- Native of the sea-shores of Crete, and of Ostia near Rome.

2. Cressa Indica. Corollas bearded at the tip; capsules four-seeded ; corolla snowy white, hairy on the outside .- Native of salt marshes in the East Indies.

Crimson-grass Vetch. See Lathyrus Nissifolia.

Crinodendron ; a genus of the class Monadelphia, order Decandria .- GENERIC CHARACTER. Calix: none; corolla bell shaped ; petals six, oblong, erect, spreading at the tip. Staming: filamenta ten, erect, united at the bottom; antheræ ovate, erect. Pistil : germen superior, ovate; style subulate, a little longer the stamina. Pericarp : capsule coriaceous, obtusely three-cornered, one-celled, gaping elastically at top. Seeds : three, roundish. ESSENTIAL CHARACTER. Calix : none. Corolla: bell-shaped, six-petalled. Capsule: one-celled, gaping elastically at top .---- The only known species is.

1. Crinodendron Patagua. Lily-tree, with opposite, lanceolate, serrated leaves. This is a superb evergreen branchy 33.

tree, with a body of seven feet in diameter. The leaves are opposite, much longer than the petioles, of a bright green, lanceolate, and serrated. There are no stipules: the flowers are scattered, and axillary ; the peduncles one-flowered, the flowers having the odour of lilies. The seeds are of the size of a lentil .- It is a native of Chili.

Crinum ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix: involucre spatheform, two-leaved, oblong, umbelluliferous, after gaping, reflected. Corolla: one-petalled, funnel-form; tube oblong, cylindric, inflected; border six-parted; divisions lauceolatelinear, obtuse, concave, reflected, of which the three alternate ones are distinguished by a hooked appendicle. Stamina: filamenta six, subulate, from the base of the border, of the length of the border, 'converging; antheræ oblong, linear, rising upwards, incumbent. Pistil: germen inferior. Style : filiform, length of the flower; stigma three-cleft, very small. Pericarp: capsule subovate, three-celled. Seeds: several. ESSENTIAL CHARACTER. Corolla: funnel-form, half six-cleft; tube filiform; border patulous, recurved, segments subulate, channelled ; filamenta inserted in the throat of the tube, distinct. These bulbs are very ornamental plants for the stove, and are easily propagated by offsets, which the roots put out in plenty; or by the bulbs, which succeed the flowers, and ripen perfectly in England. They must both be planted in pots of rich earth, and if plunged into the tan-bed in the stove, will make greater progress, and flower oftener, than when placed on shelves, even when kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots, and starve the old plants : they must be frequently refreshed with water, but it must not be given them too plentifully, especially in winter. They flower at every season of the year, which increases their value; for where there are many plants, there will be almost a perpetual succession of flowers, which emit a very agreeable odour. -The species are,

1. Crinum Asiaticum, Leaves keeled ; root solid, turbinate, surrounded with long branching fibres; flowers white, large, in a simple flat umbel. Rumphius extols the efficacy of the roots in expelling the poison of both serpents and arrows, and also in cedematous swellings .- Native of Malabar, Ceylon, Tranquebar, and Cochin-china.

2. Crinum Americanum; Great American Crinum. Leaves oblong-lanceolate, very smooth at the edge, with the end contracted and hooked; flowers pedicelled, with the tube shorter than the border; flowering-stem a foot and a half in height, the thickness of a finger, slightly compressed, coming out, not from the centre of the leaves, but on one side; leaves two feet or more in length, and a hand broad; flowers pale yellow before they open, each opening successively, aud lasting a day or two; when open, of a milky whiteness, not disagreeable in scent .- They appear in July and August, and the plant is a native of South America.

3. Crinum Erubescens; Small American Crinum. Leaves lanceolate, cartilaginous-crenulate, the end produced and unfolded; flowers sessile; tube longer than the border. The flower-stem arises immediately from the root, on the outside of the leaves, and is about two feet high; on the top are eight or ten flowers, in the form of an umbel, closely joined at their base, but spreading above. They are of a beautiful white colour, and smell very sweet. The stamina are stretched out to a considerable length beyond the petals. After the flowers are past, the germen swells, and becomes an oblong bulb. The plants generally flower three or four times in a year, but at no regular season; and as the petals

5 F

CRI

are of a very tender texture, they do not continue in beauty above four or five days.-Native of the Spanish West Indies.

4. Crinum Tenellum. Spathe many-flowered; corollas equal; leaves filiform, linear; corollas bell-form, with two segments narrower than the rest.—Found by Sparrmann at the Cape of Good Hope. 5. Crinum Lineare. Leaves linear; corollas hell-form,

5. Crinum Lineare. Leaves linear; corollas bell-form, with two segments narrower than the rest; flowers large and white.—Found by Thunberg at the Cape of Good Hope.

6. Crinum Nervosum. Leaves roundish, nerved; filamenta widened at the base; scape many-flowered, many-leaved; flowers ou long peduncles.—Native of the Philippine Islands.

Crithmum i a genus of the class Pentandria, order Digyna.-GENERIE CHARACTER. Calix umbel universal: manifold, hemispheric. Partial: similar. Involuce universal: mani-denved; leafelts inaccolate, obluse, refax. Partial: lanceolate-linear, length of the umbellule. Perianth proper: scarcely observable. Corolla universal: uniform liberts all fertile. Proper: petals five, ovate, inflex, equal. Staminer filamenta five, simple, longer than the corollar, anthere roundish. Pistil: germen inferior; styles two, reflex; stigmas obtuse. Pericarp: none. Fruit: oval, compressed, bipartile. Scels: two, elliptic, compressed, flat, strated on one side. ESSENTIAL CHARACTER. Fruit. oral, compressed. Florets: equal.---- The species are.

1. Crithmum Maritimum ; Sea or Rock Sampire. Leaflets lanceolate, fleshy. Perennial : stems smooth and even, entirely simple ; roots triternate, the middle one often fiveleaved. It has a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high. The flowers are produced in circular umbels at the top of the stalks, and are of a yellow colour, resembling fennel-flower, but larger. This herb when pickled is very agree-able to the palate, and is esteemed as a stomachic. It operates also as a gentle diuretic, removes the obstructions of the viscera, and creates an appetite, on which account it is commonly used for sauce, Meyric and Hill agree in saying, that the leaves make an excellent and very agreeable pickle ; that their jnice operates very powerfully by urine, and is good for the gravel, stone, suppressions of the menses, and the jaundice. It is not only used as a pickle, but fresh as a potherb, by the inhabitants of the sea-coast. It is gathered upon rocks, where it naturally grows; but those persons who supply the market with it, seldom bring the right herb, but gather the inula crithmoides instead of it, which they call golden sampire, but which has a very different flavour from the true, and is wholly destitute of its virtues. This golden sampire, as it is called, grows more abundantly, especially upon flat ground, overflowed by salt-water; whereas the true sampire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at, and on this account is with great difficulty propagated in gardens, where it never grows so vigorously, however carefully cultivated, as upon the rocks. It may be propagated either by seeds or by parting the roots, and, if planted on a moist gravelly soil, will thrive tolerably well, and may be preserved some years, but will grow best when rooted in a wall, or on an artificial rock-work .- Native of the rocky shores of the European ocean. Allioni informs us, that it grows on old walls in the Alps. It is found on Dover Cliff, near Winchelsea, Rye, Southampton, in the Isle of White, and on all the cliffs of the Cornish coast. Not only the inula crithmoides abovementioned is used for sampire, but the salicornia is the only herb known by that name on the east coast, where it is called marsh sampire, and is tasteless, having a tough string run-

ning through the middle; whereas the true sampire has a warm aromatic flavour, and presents no impediment to the teeth in eating. Mr. Pennant asserts, that coves and sheep eagerly eat is, and soon grow fat upon it. It has the name sampire, or sampier, sometimes incorrectly spelt samphire, from the French SZ. Pierre. Gerarde says, some call it errest marine, which is also from the French crist marine, in which language it is also name bacille maritime, franuli marin, passe-pierre, and herbe de St. Pierre, evidently from the roots striking deep into the crevices of the rocks. In fundan, it is oritmo, tinocchio marino, and herba di Santo Pietro; in Spanish, kinoje marino; in Portuguese, funce marino; saefenkel: in Swedish, sojefankat.

 Crithmum Pyrenaicum; Pyrenæan Sampire. The side leaflets twice trifid.—This is a biennial plant, and a native of the Pyrenees. See the next species.

3. Crithmum Latifolium: Wedge-taved Sampire. Leaflets wedge-form, cleft. This, fike the second species, is propagated by seeds, which should be sown in the autumn, where they are designed to remain, and will require no other culture but to keep them clean from weeds, and thin them where they are too close.—They should be preserved in the green-house or conservatory.

1. Crocus Officinalis: Officinal Crocus, or Saffron. Leaves narrower, rolled in at the edges ; stigma trifid to a considerable length. This plant has a roundish bulbous root, as large as a small nutmeg, which is a little compressed at bottom, and covered with a coarse, brown, netted skin; from the bottom of this bulb are sent out many long fibres, which strike pretty deep into the ground. The flowers come out from the upper part of the root, and, like the young leaves, the tops of which just appear, are closely wrapped about by a thin spathe or sheath, which parts within the ground, and opens on one side .- It flowers in October, and the leaves keep growing all the winter, but it never produces any seeds in England. Haller remarks, that the autumnal saffron differs from the spring crocus, in having the stigma divided into three long segments, the ends of which are also trifid. These three horns of the stigma are also odorous and aromatic, which is not the case with the vernal crocus, and the flowers are much larger. Add to this, that the corolla does not vary much from its high native purple; that they differ also in the root and leaves, the time of flowering, and the place of growth. The native country of saffron is not well ascertained; the most probable opinion seems to be, that it came originally from the East, where it had acquired that high reputation in medicine, which it has now almost lost in Europe, although it is still cultivated in Italy, Sicily, Germany, Hungary, France, Spain, and also sparingly in England, where it is commonly said to have been introduced in the reign of Edward the Third, by Sir Thomas Smith, who brought it into the neighbourhood of Walden in Essex, which place has, on that account, since received the name of Saffron Walden. Although Essex was not the only county into which saffron was introduced, it was cultivated there in

great abundance, at the end of the sixteenth and beginning of the seventeenth century. About the middle of the eighteenth century, it had migrated into the parishes of Huxton, Ickleton, and Triplow, bordering on the Roman way, called the Ikenild-street; and westward of these to Gogmagog Hills, in the parishes of Duxford, Newton, Hareton, Hauxton, Great and Little Shelford, Sawston, Stapleford, and even as far as Fulborn, which is to the north of the hills; all in the county of Cambridge. The quantity of land occupied in cultivating saffron, has been gradually decreasing during the last twenty or twenty-five years, which is supposed to arise from the importation of foreign saffron. It is now confined to two or three parishes only, of which Stapleford is one: and if some means be not employed to encourage it, the cultivation of saffron will probably soon be entirely lost in this country. Whether, says Mr. Miller, saffron be of any national consequence, I am not a competent judge; I only know, that when the culture is entirely dropped, it will be no easy matter to revive it. Formerly the superiority of English saffron was as much celebrated as it has been lately decried; which is not owing to the deterioration of British saffron which has at all times come pure and genuine out of the hands of the growers; but probably because the foreign dealers are now wise enough to omit their old sophistications with bastard saffron or safflower, marigolds, &c. and on that account their commodity coming from a warmer climate may have the superiority, and if it can be afforded cheaper, will of course be encouraged. Our modern Enropean term of saffron is derived from the Arabic sahafaran; hence the Moorish and Spanish azafaron, azafraon, safra; the Italian zaffarano ; and the German, Danish, Swedish, and French, saffran or safran. Lewes assures us, that saffron is a very elegant and useful aromatic, of a strong penetrating smell, and warm, pungent, bitterish taste; it is said to be more cordial and exhilarating than any of the other aromatics, and is particularly serviceable in disorders of the breast, in female obstructions, and hysteric depressions. Hill also says, that the whole class of medicinal subjects cannot afford a greater corcordial than saffron ; which also promotes perspiration, and removes obstructions of the viscera. With respect to propagation and culture, the autumnal crocuses are not so productive as the vernal; and as they do not bring forth seed in our climate, they are less common in gardens. These plants must be taken up every third year, or the roots will run long, and produce no flowers : they should not, however, be kept out of the ground longer than the beginning of August, for they commonly produce their flowers at the beginning of October, otherwise they will not produce so many nor such strong flowers as when planted early. Mr. Miller enumerates four varieties of the autumnal crocus; 1. the sweet-smelling, with deep blue flowers, varying to a sky-blue, growing naturally on the Alps and Swiss mountains; 2. autumnal mountain, which has a flower of a paler blue colour; 3. manyflowering bluish, with many sky-blue flowers; 4, smallflowering, with a deep blue flower. The following is the method of cultivating saffron, as it was presented to the Royal Society by Sir James Douglas. 1. The choice and preparation of the Ground. The greatest part of the tract between Saffron Walden and Cambridge, is an open level country with few inclosures, and the custom there is to crop two years, and let the land lie fallow the third. Saffron is generally planted on fallow ground, and if all other advantages be equal, that will be preferred which has borne barley the year before. The saffron grounds are seldom above three acres, or less than one, and the principal rule in choosing is, that they be well exposed, the soil not

poor, nor a very stiff clay, but a temperate dry mould, such as commonly lies upon chalk, and is of an hazel colour. The ground being made choice of about Lady-day, or the beginning of April, it must be carefully ploughed, the furrows being drawn much closer together, aud deeper if the soil will allow it, than is required for any grain; and hence the charge is greater. Five weeks afterwards, or any time in the month of May, between twenty and thirty loads of dung are laid upon each acre, spread with great care, and ploughed in as before: the short rotten dung is the best ; and the farmers who possess the conveniency of making it, spare no pains to make it good, being sure of a proportionable price for it. About Midsummer they plough a third time, and between every sixteen feet and a half, or pole in breadth, they leave a broad furrow or trench, which serves both as a boundary to the several parcels, when there are several proprietors to one inclosure, and to throw the weeds in at the proper season. To this head likewise belongs the fencing of the grounds, because that is generally, though not always, done before planting. The fences consist of what they call dead hedges or hurdles, to keep out not only cattle of all sorts, but especially hares, which would otherwise feed during the winter on the saffron leaves. Concerning the weather, it is only necessary to observe, that the hottest summers are certainly the best, and therefore if there be gentle showers from time to time, they can hardly miss of a plentiful crop, unless the extreme cold, snow, or rain, of the preceding winter, have injured their heads. 2. Planting or setting the Roots. The only instrument used for this is a narrow spade, commonly termed a spit-shovel. The time of planting is commonly in the month of July, a little sooner or later, as the weather answers; the method is: One man with his spitshovel raises between three and four inches of earth, and throws it before him about six or more inches; two persons, generally women, following with heads, place them in the farthest edge of the trench he makes, at about three inches' distance from each other; as soon as the digger or spitter has gone once the breadth of the ridge, he begins again at the other side, and digging as before, covers the roots last set, and makes the same room for the setters to place a new row, at the same distance from the first that they are from one another. Thus they proceed, until a whole ridge, commonly containing one rod, is planted; and the only nicety in digging, is to leave some part of the first stratum of earth untouched to lie under the roots, and in setting, to place their roots directly upon their bottom: what sort of roots ought to be preferred, shall be shown under the fourth head, but it must be here observed, that formerly, when roots were very dear, they did not plant them so thick as they do now, and that some notice is always taken of the size of the roots, so as to leave the largest farther apart. The quantity of roots planted in an acre, is generally about sixteen quarters, or an hundred and twenty-eight bushels, which, according to the distances before assigned to be left between them, and averaging the diameter of the plants at one inch, ought to amount to three hundred and ninety-two thousand and forty in number. From the time that the roots are planted, till about the beginning of September, or sometimes later, there is no farther labour required, but as they begin to spire, and are ready to show theniselves above ground, (which is ascertained by digging a few out of the earth;) the ground must be carefully pared with a sharp hoe, and the weeds be raked into the furrows, otherwise they would hinder the growth of the plants. 3. Gathering and drying the Flowers. The flowers are gathered as well before as after they are fully blown, and the most proper time for gathering is early in the

number of hands, who place themselves in different parts of the field, pull off the whole flowers, and throw them handful by handful into a basket, till they are all gathered. As soon as they have carried them home, they immediately spread them out upon a large table, and fall to picking out the stigmas, together with a considerable part of the style itself; the rest of the flower they throw away as useless. The stigmas being all picked out of the flowers, the next labour is to dry them on the kiln, which is built upon a thick plank, supported by four short legs, that it may be moved from place to place: the outside consists of eight pieces of wood about eight inches thick, in the form of a quadrangular frame, about twelve inches square at the bottom on the inside, and twenty-two inches at top, which is likewise equal to the perpendicular height of it; a hole about eight inches square is left in the front, about four inches above the plank, through which the fire is put in; over all the rest are laid laths close to each other, nailed to the frame already described, and then plastered over very thickly on both sides. as are also the planks at the bottom, which serve for a hearth; over the mouth or widest part is placed a hair-cloth, fixed to the sides of the kiln, and also to two rollers, or moveable pieces of wood, which are turned by screws, in order to stretch the cloth, instead of which many persons now use a net-work or iron-wire, with which, it is observed, that the saffron dries sooner and with less fuel; but the difficulty of preserving the saffron from burning, occasions the hair cloth to be preferred by the nicest judges in drying. The kiln is placed in a light part of the house, and they begin by laving five or six sheets of white paper on the hair-cloth, upon which they spread the wet saffron two or three inches thick : this they cover with other sheets of paper, and over this lay a coarse blanket five or six times double, or instead thereof, a canvass pillow filled with straw; and after the fire has been lighted for some time, the whole is covered with a board having a large weight on it: at first they apply a pretty strong heat to make the chives sweat, as they term it; and in this, unless very careful, they are in danger of scorching, and thereby of spoiling all that is on the kiln. When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the saffron off from that which lies next it, raising at the same time the edges of the cake with a knife, then laying on the paper again, they slide in another board between the hair-cloth and upper papers, and turn both papers and saffron upside down, afterwards covering them as before: the same heat is continued for an hour longer; they then look on the cake again, free it from the papers, and turn it; then they cover it, and lay on the weight as before. If nothing detrimental occur during these first two hours, they reckon the danger to be over, for they have afterwards only to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, twenty-four hours' attention is required. In drying the larger plump threads, they use nothing more; but towards the latter end of the crop, when these begin to be smaller, they sprinkle the cake with a little small beer, to make it sweat as it ought, and have latterly begun to think that using two linen cloths next the cake, instead of the two innermost papers, may be of some advantage in drying, although that practice is followed by few: the fire may be made with any kind of fuel, but that which smokes the least is best, and therefore charcoal is preferred. What quantity of saffron a first crop will produce, is very uncertain; sometimes five or six pounds of wet threads are got from one

morning. The owners of the saffron get together a sufficient | enough to make it worth while to gather and dry it; but this is always to be observed, that about five pounds of wet saf. fron make one pound of dry, for the first three weeks of the crop, and six pounds during the last week; and when the heads are planted very thick, two pounds of dried saffron may at a medium be allowed to an acre for the first crop, and twenty-four pounds for the two remaining, the third being considerably larger than the second : in order to obtain these crops, the labour of hoeing, gathering, picking, and drying, must be repeated every year, without any addition, except that they let cattle into the fields after the leaves are decayed, to feed upon the weeds; or perhaps mow them for the same use. 4. Management of the Roots. About the Midsummer after the third crop is gathered, the roots must all be taken up and transplanted. To take up the saffron heads, or break up the ground, they sometimes plough it, and sometimes use a forked kind of hoe called a pattock, and then the ground is harrowed once or twice over, during all which time of ploughing, or digging, and harrowing, fifteen or more persons will be sufficiently employed in following and gathering the heads as they are turned up ; they are next to be carried to the house in sacks, and there cleansed and dressed, which consists in clearing the roots thoroughly from the earth, and from the remains of old roots, old skins, and excrescences, and thus they become fit to be planted in new ground immediately, and to be kept for a considerable time without danger of spoiling. The quantity of roots which will be taken up, in proportion to those which were planted, is uncertain; but it may be calculated at a medium. allowing for all the accidents which happened to them in the ground, and in breaking up, from each acre, to be twentyfour quarters of clean roots, all fit to be planted. The owners are sure to choose the largest, plumpest, and fattest roots for their own use, but most dislike the longest pointed ones, which they call spickets or spickards, for very small, round, or flat roots are sometimes observed to flower well. Mr. Miller calculates that the charge of cultivating saffron for three years, will be upwards of £.23 per acre, which he supposes to average twenty-six pounds of saffron during each year, which at thirty shillings per pound, will leave five pounds four shillings annual profit per acre .- In the annexed Plate, a shews the filaments of the flower, from which the saffron is prepared.

2. Crocus Vernus; Spring Crocus. Leaves broader, with flat edges; stigma very shortly trifid. This species has a largish compressed bulb, covered with a light-brown netted skin, from which arise four or five leaves of a purplish colour on their lower part, from among which one or two flowers come out, sitting close between the young leaves. never rising above two inches high, and having an agreeable odour; out of the centre of the tube arises a slender style, crowned by a broad flat stigma of a golden colour : after the flowers are past, the germen pushes out of the ground. Haller says that it is white, with a purple base in Switzerland, in a wild state, and purple and white in Austria. According to Jacquin, Gesner gathered it with a yellow flower on the mountains of Glarus. Scopoli does not mention its colour. but says that it is not uncommon in Carniola. It is also a native of Italy and Spain, but not indigenous in Britain. though Mr. Miller states that he remembered to have seen it apparently wild, in a considerable quantity, in Battersea meadow, near the mill; and it has also been found by Dr. Deering in the meadows near Nottingham. Though the varieties of spring crocus are very numerous, Mr. Miller only enumerates the following twelve: 1. the broad-leaved purple vagood, sometimes not above one or two, and sometimes not riegated, which has a flower of a deep blue, and striped;

2. broad-leaved plain purple ; 3. broad-leaved violet- | ing very much, trifid. Pericarp : hemispherical, grooved, coloured, or large deep blue; 4. white with a purple bottom; 5. broad-leaved white variegated; 6. broad-leaved with many violet purple flowers striped with white; 7. broadleaved ash-coloured; 8. broad-leaved large yellow; 9. broad-leaved small pale yellow; 10. broad-leaved small vellow striped with black; 11, narrow-leaved small brimstone ; 12. narrow-leaved small white. Modern catalogues set down many varieties of the several colours, which are blue and purple, yellow and white, or striped : new ones are also constantly imported from Holland, each of which has a French or Dutch title. The most common varieties now in our gardens are, the Scotch, beautifully striped; the blue; the blue-striped white; yellow of several shades, larger and smaller; yellow striped with black, cloth of gold. All these several varieties of crocuses are very hardy, and will increase exceedingly by their roots, especially if they be suffered to remain two or three years unremoved: they will grow in almost any soil or situation, and are very great ornaments to a garden, early in the spring of the year, before many other flowers appear: they are commonly planted near the edges of borders on the sides of walks, in doing which, care should be taken to plant such sorts in the same line as flower at the same time, and are of an equal growth, otherwise the lines will seem imperfect. These roots lose their fibres with their leaves, and therefore may then be taken up, and kept dry until the beginning of September, observing to keep them from vermin, for the mice are very fond of them. When you replant these roots, after having drawn a line upon the border, make holes with a dibble about two inches deep or more, according to the lightness of the soil, and about two inches apart, in which you must place the roots with the bud uppermost; then with a rake fill up the holes in such a manner as that the upper part of the root may be covered an inch or more, taking care not to leave any of the holes open, for this will entice the mice to them, and when once they have found them out, they will destroy all your roots, if not prevented. The best way, however, to dispose of these flowers in gardens, is to plant them six or eight near each other in bunches, between small shrubs, or on the borders of the flower-garden, where, if the varieties of these flowers be planted in different patches, and properly intermixed, they will make a much better appearance than when they are disposed in the old method of straight edgings. In January, if the weather be mild, the crocus will often appear above ground, and their flowers will come out in February, before the green-leaves are grown to any length, so that the flowers seem at first to be naked, but soon after the flowers decay, the green leaves grow to be six or eight inches long, and should not be cut off until they decay, notwit'istanding they appear a little unsightly, for by cutting off the leaves the roots will be so weakened as not to arrive at half their usual size, nor will the flowers of the succeeding year be half so large. Their seeds are commonly ripe about the latter end of April, or the beginning of May, when the green leaves will begin to decay.

Crossostylis; a genus of the class Monadelphia, order Polyandria,-GENERIC CHARACTER. Calix: perianth turbinate, quadrangular, fastened to the germen, four-parted; segments ovate, spreading, permanent. Corolla : petals four, elliptic; claw narrow, inserted into the calix. Nectary: corpuscles twenty, filiform, ciliate between the stamina. Stamina: filamenta twenty, filiform, shorter than the calis, connected at the base into a little pitcher. Antheræ small, roundish. Pistil: germen convex, superior; style superior, the length of the stamina, permanent; stigmas four, spread-33

one-celled. Seeds: very many, on a columnar receptacle in the centre of the fruit. ESSENTIAL CHARACTER. Ca-lix: simple, four-parted. Corolla: four-petalled; nectary twenty, corpuscles between the filamenta; stigmas four, jagged .---- The only known species is,

1. Crossostylis Biflora .--- Native of the Society Isles.

Crosswort. See Valantia.

Crotalaria; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix: perianth threeparted, large, rather shorter than the corolla, the two superior divisions lanceolate, leaning on the standard, the third lanceolate, concave, supporting the keel, three-cleft. Corolla : papilionaceous ; standard cordate, acute, large, depressed on the sides; wings ovate, shorter by half than the standard; keel acuminate, length of the wings. Stamina: filamenta ten, connate, rising with a split line on the back and gaping base. Antheræ hirsute. Pistil: gcrmen oblong, reflex, hirsute ; style simple, bent inwards at an angle, rising ; stigma obtuse. Pericarp : legume short, turgid, one-celled, two-valved, pedicelled ; seeds one or two, globose, kidney-ESSENTIAL CHARACTER. Legume: turgid, inform. flated, pedicelled; filamenta connate, with fissures on the back .- Most of these plants are propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up an inch high, they should be transplanted to another hot-bed to bring them forward, observing to shade them from the sun till they have taken new root, after which they should have free air admitted to them in proportion to the warmth of the season, to prevent their being drawn up weak. When the plants have acquired strength in this bed, they should be carefully taken up, with balls of earth to their roots, and each planted in a separate pot, filled with light kitchen-garden earth, and plunged iuto a moderate hot bed of tanner's bark, carefully shading them till they are rooted again; they must afterwards be treated in the same manuer as other tender exotics, giving them a due proportion of air and water in warm weather, and when they are grown so tall as nearly to reach the glasses of the hot-bed, the nots may be removed into an airy glass-case or stove, where they will be screened from inclement seasons, and have sufficient air in hot weather. With this treatment the plants will flower in July, and continue to produce fresh spikes of flowers till the end of August; and those spikes of flowers which appear early in the season, will be succeeded by ripe seeds in September, soon after which the plants will decay.----The species are,

* Leaves simple.

1. Crotalaria Perforata; Perforated Crotalaria, Leaves perfoliate, cordate, toothletted, eight feet high; stem smooth and even, with alternate branches; flowers smooth, yellow, in a kind of umbel, two together, terminating the branches. -Native of the Cape of Good Hope, where a decoction of the leaves is esteemed a powerful diuretic.

2. Crotalaría Perfoliata; Perfoliate Crotalaria. Leaves perfoliate, cordate-ovate; stem shrubby, four or five feet high, round, covered with a light brown bark ; leaves smooth, about four inches long and nearly three broad, much resembling those of our common thoroughwax, or bupleurum, both in shape and size, only stiffer and more veined : the flowers are almost the size of those of the pea, all the petals being large; they are of a pale yellow colour, and come out singly from the upper part of the branches, sitting close on the axils of the leaves, and appearing in August: it has the appearance of being shrubby, but the branches perish every year .- It rises to the height of two feet, and is a native of open woods.

389

CRO

two hundred miles from the back settlements of Carolina, in North America.

3. Crotalaria Amplexicaulis; Stem-clasping Crotalaria. Stem-leaves clasping, cordate, alternate ; floral leaves opposite, kidney-shaped, coloured ; flowers solitary. This is a smooth shrub : leaves smooth : flowering branches dichotomous, the flowers yellow .- Native of the Cape of Good Hone,

4. Crotalaria Sagittalis; Virginian Crotalaria. Leaves lanceolate: stipules (not petioles) decurrent, solitary, twotoothed; root annual; stem herbaceous, half a foot high and more, erect, subdivided, strict, round, pubescent; leaves on very short petioles, alternate, entire, rounded at the base, hoary underneath, and somewhat hirsute, but sometimes smooth; flowers yellow, pedicelled .- Native of South America and Jamaica.

5. Crotalaria Chinensis: Chinese Crotalaria Leaves ovate, subpetioled; stipules very minute, shrubby; stems and branches pubescent, round ; leaves bluntish, very entire, somewhat hairy on both sides ; calices rough with hairs, the length of the corolla, which is yellow, with a striated banner ; stinules subulate .- Native of China

6. Crotalaria Juncea: Channel-stalked Crotalaria, Leaves lanceolate, petiolate, sessile; stem striated, stiff, angular, rushy, three or four feet high, dividing into three or four branches, at the end of which the flowers are produced; corolla large, deep yellow, with the axils of the wings black, having the appearance of Spanish broom; leaves narrow, lanceolate, closely covered with soft silvery hairs, on very short petioles .- Native of the East Indies.

7. Crotalaria Imbricata; Imbricate, leaved Crotalaria. Leaves ovate, acute, villose, sessile; flowers subsessile. This is a shrub, warted with knots from falling leaves, which are crowded, subimbricate, silky, small, without stipules ; flowers solitary, purple .- Native of the Cape of Good Hope.

8. Crotalaria Retusa; Wedge-leaved Crotalaria. Leaves oblong, wedge-shaped, retuse. This rises with an herbaceous stem nearly three feet high, dividing into several branches; leaves pale green, and smooth; the flowers are produced in spikes at the end of the branches, and are large, and of a vellow colour, with the banner often purplish above .- Annual : native of the East Indies.

9. Crotalaria Sessiliflora; Sessile-flowered Crotalaria. Leaves lanceolate, subsessile; flowers scssile, lateral; stem equal. Annual, scarcely a foot high ; stem erect, round, little bianched, striated, furrowed : flowers axillary, blue, with two oblong bractes .- Native of China.

10. Crotalaria Triflora ; Three-flowered Crotalaria. Leaves ovate, sessile, smooth; branches angular; peduncles in threes, lateral, one-flowered. The whole plant is smooth; leaves almost three inches in length. Biennial : flowering in June. -Native of the Cape of Good Hope.

11. Crotalaria Verrucosa; Blue-flowered Crotalaria. Leaves ovate; stipules lunate, declined; branches four-cornered. Annual: stem herbaceous, four-cornered, two feet high; flowers alternate, smooth, of a light blue colour, appearing in July aud August, and ripening seeds in autumn .- Native of the East Indies.

12. Crotalaria Bifloia. Leaves obtuse; stems prostrate, herbaceous; peduncies two-flowered; stem erect, a palm in height, round, hairy, terminated by the peduncle: branches from the base of the stem, many, alternate, simple, much longer than the erect stem ; corolla vellow .- It has a very different appearance in the garden, to that which it presents in its native soil in the East Indies. Konig found it also in the island of Joanna.

obloug, sessile; peduncles axillary, two-leaved. Shrubby: stems simple, very smooth; leaves obtuse, erect; the flowers come out between the leaves of the peduncle, and is single, nodding, and vellow .- Native of the Cane of Good Hope.

14. Crotalaria Linifolia ; Flax-leaved Crotalaria. Hirsute : leaves linear, obtuse, hirsute : petioled, without stipules : stem angular ; raceme terminating ; racemes long ; flowers nodding, vellow; legumes short, obtuse,-Observed by Kænig in the East Indies,

15. Crotalaria Bifaria, Pubesceut, diffused, stipuled : leaves in two rows, the lower orbicular, the upper oblong; peduncles one-flowered; leaves on short petioles, spreading very much : stipules ovate, tubular, reflex ; peduacles terminating, erect, filiform; corollas bluish, of the larger size .-Found by Kœnig in the garden of Amma Koil, queen of Taniour in Hindoostan.

16. Crotalaria Serica: Silky-leaved Crotalaria, Leaves lanceolate, acute, silky beneath ; racemes elongated. This plant is annual in England, but by the lower part of the stem growing woody, it appears to be of longer duration in the country where it naturally grows; though it will not live through the winter here, for if the plants be placed in a stove. the heat is too great for them, and in a green-house they are very subject to mouldiness in damp weather. When the seeds were sown in the full ground, the plants have grown upwards of three feet high, and have flowered very well, but no pods were formed upon them; and when they have been tenderly treated, they have grown much larger, and produced a greater number of flowers, but no seeds : the only way by which seeds could be obtained, was by raising the plants in pots upon hot-beds, and turning them out of the pots in the beginning of July, into the full ground, in a very warm border, under a wall, where they flowered very well, and some few pods of seed were ripened. A lofty plant, appearing to be shrubby, but in reality annual: stem brauched, striated; flowers peduncled, solitary, yellow .- Native of the East Indies.

17. Crotalaria Fruticosa. Leaves simple, linear-lanceolate, hirsute : netioles decurrent : stem shrubby. It rises with a shrubby taper stalk nearly four feet high, sending out many side-branches, which are very slender, ligneous, and covered with a light-brown bark; the flowers are produced nearly at the end of the branches, three or four growing alternately on a loose spike ; they are small, and of a dirty yellow colour .--Native of Jamaica.

18. Crotalaria Villosa. Leaves simple, ovate, villose; petioles entirely simple; branches round; stem about five feet high, dividing into several branches, at the ends of which the flowers are produced in loose spikes; they are of a fine blue colour, and come out in June and July, and, when the season is warm, ripen into seed in autumn .- Native of the Cape of Good Hope.

19. Crotalaria Angulata. Leaves ovate, sessile; branchlets angular, hirsute; flowers lateral, very simple. An annual plant, rising nearly three feet high, with a taper upright stem, dividing at top into several hairy upright branches; leaves ovate-lanceolate, pale green; the flowers are produced singly from the side of the branches, are of a bright yellow, and succeeded by short turgid pods, having one row of kidnev-shaped seeds. It flowers in July, and perfects seeds in autumn .- Native of Campeachy.

20. Crotalaria Heptaphylla; Seven-leaved Crotalaria. Leaves pinnate, with seven leaflets; spikes long; stem arboreous. This is a tree ten feet in height, with diffused 13; Crotalaria Opposita. Smooth, without stipules; leaves branches; leaves unequally pinnate; flowers white, axilfive-toothed, villose, short .- Native of Cochin-china.

21. Crotalaria Scandens; Climbing Crotalaria. Leaves oblong; peduneles many-flowered, axillary; stem shrubby, climbing. It is a large shrub, with long, woody, scandent branches; flowers white; calices smooth; petals nearly equal, swelling .- Native of Cochin-china.

** Leaves compound.

22. Crotalaria Lotifolia; Lotus-leaved Crotalaria. Leaves ternate, obovate ; flowers lateral, subracemed ; stem sarmentose, slender and weak, at bottom stiff and woody, but higher up herbaceous, round, from a foot to more than eighteen inches high; flowers axillary on peduncles shorter than in some other species, three or four together, yellow, resembling those of the common lotus. It flowers in June and July. The seeds were imported either from the Havannah or Mexico .--- Native of Jumaica.

23. Crotalaria Lunaris. Leaves ternate, ovate, acute; stipules semicordate, lunate .- Native of the Cape of Good Hope.

24. Crotalaria Laburnifolia. Leaves ternate-ovate, acuminate; stipules none; legumes pedicelled; stem shrubby, four or five feet high, dividing into many branches ; flowers large, yellow, in large bunches from the side of the branches, appearing from July to September, and making a fine display. It is easily propagated by cuttings during the summer months, They should be planted in pots, and plunged into a moderate hot-bed, earefully shading them until they have taken root, and frequently refreshing them with water. They may be exposed to the open air in a sheltered situation, where they will produce many flowers, during the months of July, August, and September, but must be placed in a temperate stove in the autumn, to preserve them during the winter.

25. Crotalaria Cordifolia ; Heart-leaved Crotalaria. Leaves ternate, obcordate, mucronate; flowers in eorymbs; stem shrubby. This is a shrub eight feet in height; petioles shorter than the leaves .- Native of the Cape of Good Hope, upon rocks.

26. Crotalaria Ineana; Hoary Crotalaria. Leaves ternate, oval, villose beneath; racemes spike-form; keel tomentose at the edge; legumes sessile, hirsute; root annual; stem from two to four feet high, almost simple, erect, pubescent; flowers subracemose, greenish yellow, rather large. It has the common smell of the leguminose tribe, but is fetid. -It flowers in June and July, and is a native of the West Indies.

27. Crotalaria Incanescens; Spreading Shrubby Crotalaria. Leaves ternate, obtuse; stipules leafy; branches hoary. A hoary branched shrub, very finely tomentose, white; leaves petioled, naked; flowers yellow, appearing from June to October .- Native of the Cape of Good Hone.

28. Crotalaria Heterophylla, Leaves ternate, elliptic, emarginate, the lower simple. Annual: stem erect, a foot high, smooth, a little branched at top; lower stem-leaves elliptic, oleraceous, smooth, ribbed with nerves; upper obovate alike; corollas yellow, somewhat testaceous on the outside .- Native of the East Indies.

29. Crotalaria Quinquefolia; Five-leaved Crotalaria. Leaves quinate ; flowers in racemes, alternate, smooth.-Native of the East Indies.

30. Crotalaria Floribunda; Small-flowered Crotalaria. Leaves ternate, wedge-form; branches pubescent; legumes pedicelled, smooth, wrinkled, compressed, keeled. It flowers in July and August, and is a native of the Cape of Good Hope.

31. Crotalaria Axillaris; Two-flowered Crotalaria. Leaves

lary, and terminating in long simple solitary spikes; calix | ternate, ovate, elliptic, hairy beneath; stipules subulate, minute: peduneles axillary, twin, one-flowered. Annual: flowering in June and July, and native of the coast of Guinea.

32. Crotalaria Pallida; Pale-flowered Crotalaria. Leaves ternate, lanecolate, smooth; racemes terminating, spike-form. Annual: flowering in June and July .- Native of Africa.

Croton ; a genus of the class Monœcia, order Monadelphia. -GENERIC CHARACTER. Male Flowers smaller than the females. Calix: perianth cylindric, five-toothed. Corolla : petals in some five, scareely larger than the calix, oblong, obtuse. Nectary : five glands affixed to the receptaele, small. Stamina : filamenta ten or fifteen, subulate, conneeted at the base, length of the flower; antheræ roundish, twin. Female Flowers remote from the males, on the same plant; calix perianth many-leaved; leaflets ovate, oblong, erect. Corolla : petals as in the males, in some searce mani-Pistil: germen roundish; styles three, reflex, spreadfest. ing, length of the flower, half two-eleft ; stigmas reflex, twoeleft. Pericarp : capsule roundish, three-lobed at the sides, three-celled, each of the cells two-valved, size of the calix, frequently much larger. Seeds: solitary, ovate, large. Es-SENTIAL CHARACTER. Male Calix : cylindric, fivetoothed; corolla five-petalled. Stamina: ten to fifteen. Female Calix : many-leaved. Corolla : none : styles three. bifid ; capsule three-celled. Seed : one .- All these plants, except the sixth species, are natives of warm countries, and will not thrive in England, unless they be tenderly treated. They are all propagated by seeds. Those which are annual perfect their seeds in England; but the shrubby roots very rarely arrive to that perfection, and therefore their seeds must be procured from the countries where they naturally grow. The seeds must be sown on a hot-bed early in the spring; and when the plauts are fit to remove, they should be each transplanted into a small pot, and plunged into a moderate hot-bed of tanner's bark, where they should be shaded from the sun until they have taken fresh root, and afterwards must have air daily admitted to them, and be watered in proportion to the warmth of the season. After the plants are become too tall to remain in the frames, they should be removed, either into the stove or a glass-case, where there is a hot-bed of tanner's bark, into which the pots should be plunged, and there the annual sorts will flower and perfect their seeds; but the shrubby kinds must be removed into the bark-stove in the autumn, and should have but little water during the winter season. The stove should be kept in a good temperature of heat, otherwise they will not live through the winter in England. As these plants retain their leaves all the year, they make a pretty variety in winter, when they are intermixed with other plants whose leaves are of a different colonr and form .---- The species are,

1. Croton Variegatum ; Variegated-leaved Croton. Leaves lanceolate, very entire, smooth, painted, petioled .- Native of Amboyna, Japan, and of Mallicollo, and Tanna in the South Seas.

2. Croton Lineare ; Willow-leaved Croton. Leaves linear, very entire, obtuse, tomentose beneath ; stem shrubby, six or seven feet high, sending out many side-branches, which are covered with a smooth bark, of a yellowish white colour, a long loose spike of whitish green flowers arises from between the branches. The whole plant has an aromatic odour when rubbed. It resembles the European rosemary, and is therefore called wild rosemary in Jamaica, where it is a native, and generally used in warm resolutive baths, and fomentations. It flowers in July, and may be found in other parts of the West Indies.

3. Croton Castaneifolium; Chestnut-leaved Croton. Leaves lanceolate, obtuse, serrate, petioled, smooth.—Native of South America.

4. Croton Palustre; Marshy Coton. Leaves ovate, lan-ceolate, plaited, serrate, scabrous; root anuual; stems round, fungous, smooth, procumbent, or erect; flowers axillary towards the top of the stem.—Discovered near La Vera Cruz, where it flowers in July, and the seeds ripen in autumn.

5. Croton Glabellum; Lauret-leared Croton. Leaves ovate, blantish, very entire, smooth, and even; fruits peduneled. This grows in a shrubby form, and is seldom under seven or eight feet in height. All the parts of the plant are of an active nature, and have a pretty agreeable smell.— Common in all the low lands about Spanish Town and Kingston, in Jananica.

6. Croton Tinctorium : Officinal Croton. Leaves rhombed, repand; capsules pendulous; stem herbaceous, branching, about nine inches high; root annual; flowers in short spikes, from the sides of the stalks at the ends of the branches. Nissole dyed both silk and wool of an elegant blue colour : but the French attempt to extract a material from it for dyeing, similar to indigo, did not succeed. The women about Albudebar dye their stockings with it. This is also the plant from which the tournsol, used for colouring wines and jellies, is made. It is made from the juice that is lodged between the calix and the seeds ; this, if rubbed on cloths, at first appears of a lively green, but soon changes to a bluish purple. If these cloths be put into water, and afterwards wrung, they will dye the water of a claret colour. The rags thus dyed are brought to England, and sold in the druggist shops under the name of tournsol .- Native of the south of France, Spain, Italy, and the kingdom of Tunis. The seeds of this plant should be sown in the autumn, soon after they are ripe, in a small pot filled with light earth, and plunged into an old tan-bed in a frame, where they may be screened from the cold in the winter; and in the spring following, the pot should be removed from a fresh hot-bed, which will bring up the plants in a month's time; and when grown large enough to remove, they should be each planted into a small pot, and plunged into a fresh hot-bed, being careful to shade the glasses daily, until the plants have taken new root : they should then have air daily admitted to them, in proportion to the warmth of the season, but must be sparingly watered. Mr. Miller declares, that the above is the only treatment under which he has known these plants to succeed, and that they have by this management, not only flowered, but produced good seeds.

7. Croton Clandulosum. Leaves oblong. serrate, biglandular at the base; fruits sessile. It seldom exceeds seventeen or eighteen feet high. The seeds are small, and picked up every where in the fields, both by the wild and tame fowls, in the island of Jamaica, of which it is a native, in the savannas of Liguanea.

- 8. Croton Argenteum; Silvery-leaved Croton. Leaves cordate-ovate, tomentose beneath, entire, serrate; root annual; stem a foot high, angular.—Found in La Vera Cruz.

9. Croton Schiffrun; Peptar-leared Croton. Leaves fromb-ovate, acuminate, flat, smooth; glands subpetiolar; leades broader than they are long, and involute. The leaves dye a very fine black. They wither in October, turn to a dirty crimison colour, and fall off hefore the capsules. The young leaves shout out again in March. Each capsule contains three hand black shells, the size of pepper-coms or common peas, covered entirely with a delicately snow-white substance, which does not produce the tallow, as it is componly supposed. It is made from the oil expressed from

the kernel; and the white substance above mentioned must be well eleaned from the shell be developed are broken, for that will absorb a considerable quantity of oil. For this parpose, the shells should remain ten or fifteen days in water to soak, and then they may be cleared of the white substance by rubbing, although it will not easily separate from the shelt. The oil drops from the press like thick glutinous lamp-oil, and sonh nariems by cold to the consistence of common tallow, and by boiling becomes as hard as bees' wax.—Native of China.

10. Croton Japonicum. Leaves undivided, and threelobed, ovate, acuminate, entire, smooth; stem subangular, naked at bottom, tomentose at top, simple, a foot high and more.—Native of Japan, flowering in July and August.

11. Croton Acutiun. Leaves ovate, serrate, acuminate, two-ghanded; stem herbaceous, angular, simple, smooth; petals white, woolly, the length of the calix.—It flowers in September, and is cultivated in Japan, where it was introduced by the Portuguese.

12. Croton Tiglium; Purging Croton. Leaves ovate, smooth, acuminate, serrate; stem arboreous. This is a middle-sized tree, with few spreading branches; flowers in ercet, simple, terminating racemes.—Native of the East Indies, China, and Occhin-china.

13. Croton Lucidum; Smooth Croton. Leaves ovate, smooth; flowers in spikes; styles many-cleft, depressed, pubescent, becoming shrubby.-Native of Jamaica.

14. Croton Lacciferum; Lac Croton. Leaves ovate, tomentose, serrulate, petioled; calices tomentose; flowers white, with five-leaved calices; leaves subacuminate, unequally toothed, scattered over the branches. When infused in warm water or milk, they purge and vomit. It exudes a very fine lac sparingly, which appears like a bud at the origin of the branches; and is employed by the Cevlonese to varnish their lances, the handles of their tools, &c. It is said to be much finer and superior to that formed by the ants in Siam and Pegu. Lac is said also to exude in small quantities from every species of this genus; but all that substance which we commonly call gum-lac in Europe, is the work of the red ants, who are supposed to collect or suck the resinous juice from this, and perhaps other trees, to digest it with the animal acids in their stomachs, and then to encrust the branches with it, to serve as a nest or comb for their young. It is not properly a gum-resin or oil, not being soluble either in water or fat oils. The use of this substance is well known in dyeing silks, woollens, and morocco leather, of a scarlet colour, which it also communicates to sealing-wax and varnish. The wood is white, light, and brit-tle. The bark and resin are reputed to be serviceable in ulcers of the mouth, in the gonorrhea, flour albus, dysentery, &c .- Native of the East Indies, the southern provinces of Cochin-china and Cambodia. It is called bihar on the borders of Thibet.

15. Crotou Balsamiferum; Balsam Croton. Leaves ovatelanceolate, scabrous, very entire, tomentose beneath. This is an upright, branched, diffused, sweet-smelling shrub; flowers white, with small petals.—Native of Martinico, Curacao and Jannica.

16. Croton Aromaticum; Aromatic Croton. Leaves cordate-orate, schorous, scratte at the base beneath, and on the edge, having petioled glands; racenes terminating. This is a middle-sized tree, with spreading branches, subdivided, round, ragged, with minute dots interspersed with other larger ones, tomentose towards the end; hairs stellate.—Native of the island of Ceylon, and near Canton in China.

17. Croton Humile; Humble Croton. Leaves cordate,

very entire, scabrous, subciliate, tomentose beneath. A shrub two feet high, with a smooth branching stem; the branches hoary at the end.-Native of Jamaica.

16. Croton Ricinocarpos; Surinam Croton. Leaves subcordate, crenate; peduncles racemed, opposite to the leaves; stem herbaceous; branches and leaves alternate, the latter petioled, naked.—It is an annual plant, and a native of Sorinam.

19. Croton Moluccanum; Molucca Croton. Leaves cordate, angular, scabrous, tomentose beneath. This is a tree eight feet high, with long reclining branches; flowers white, in short racemes; capsule smooth and even, bigger than a walnut: a great quantity of oil is extracted from it.—Native of Ceylon, and the Molucca Islands.

20. Croton Flaveus; Yellow Croton, or Balasm. Leaves cordate, oblogs, very entire on both sides; branchlets more closely tomentose. It frequently rises to the height of two or three feet, is easily distinguished by the thickness of its extreme branches, which are pretty soft and luxoriant. All parts of the plant are equally sharp, and sometimes used in resolutive baths.—Native of Jamaica, in savannas about Kingston.

21. Croton Capense; Cape Croton. Leaves hastate, and undivided, lanceolate, very entire, and very smooth.—Found at the Cape of Good Hope by Thunberg.

22. Croton Lobatum; Faricus-leared Croton. Leaves unamed, serrate, the lower five-lobed, the upper three-lobed; stems round, furrowed, herbaceous, slightly hairy, erect, branched, a four and a half in height; flowers of a purple colour. Annual: flowering in July.—Found by Houstoun, near Vera Cruz.

23. Croton Spinosum; Thorny-leaved Croton. Leaves palmate, five-lobed and three-lobed, thorny, serrate; flowers scattered over the stem, and subsessile,—Native of the East Indies.

24. Croton Astroites; Woolly Croton. Leaves oval, subcordate, very entire, starry, tomentose on both sides; branchlets more closely tomentose, shrubby, flowering in July and August, and a native of the East Indies.

25. Croton Punctatum; Dotted-leaved Croton. Leaves ovate, acute, entire, tomentose and dotted underneath; stem shrubby.—Native of Ceylon.

26. Croton Nutans. Leaves rhomb-ovate, acuminate, waved, smooth; glands marginal.—Native of the Society and Friendly Islands, and of the New Hebrides.

27. Čroton Inophyllum. Leaves obovate, very entire; stem arboreous.-Native of New Caledonia.

28. Croton Hirtum. Leaves ovate, serrate, with glanduliferous hairs at the base; spikes sessile; stem hispid. It is an annual, and a foot in height; stem herbaceous, erect, round, glandular.—Native of Guiana.

20. Croton Althreafolium, Leaves oblong, cordate, tomentose; stem shrubby, branched; flowers in terminating spikes. It rises with a shrubby stalk, six or seven feet high, dividing upwards into several branches, which are covered with a yellowish down, garnished with long heart-shaped leaves, ending in acute points; flowers white.—Native of Jamaica.

30. Croton Salviæfolium. Leaves cordate, acute, tomentose beneath; stem shrubby; flowers in spikes, terminating, ad axillary. It rises nearly four feet high, with a shrubby stalk. The flowers are produced in short spikes at the ends of the branches; they are small, white, and have woody calicea.-Native of the West Indies.

31. Croton Sessiliflorum. Leaves ovate, acuminate, quite entire, smooth; flowers sessile, axillary, diœcous, five-stamined.-Native of Hispaniola. 33. 32. Croton Globosum. Leaves ovate, obtuse, entire; peduncles in pairs; flowers diœcous; fruits globular, echinatehispid,-Native of Jamaica.

CRO

393

33. Croton Divaricatum. Leaves oblong, obtuse, serrate, rough with hairs, biglandular at the base; racemes terminating, solitary; stem shrubby; branches dichotomous, divaricate.—Native of the West Indies.

34. Croton Nitens. Leaves cordate-elliptic, acuminate, almost entire, smooth, shining above, dotted and silvery underneath; racemes axillary; leaves shorter, erect.—Native of Januaica.

35: Croton Laurinum. Leaves oblong, acute, quite entire, of some consistence, smooth; petioles rugged, they and the leaves dotted underneath; racemes axillary, very long, patulous; stem arborescent.—Native of Janaica.

36. Croton Pallena, Leaves ovate, acuminate, quite entire, smooth on both sides; racenes solitary, erect, terminating; calices larger than the fruit. It rises with a shubby stem to the height of seven or eight feet, is covered with an ab-coloured bark, and divides at top into many slender branches; flowers of an herbaceous colour.—Native of Jamaica.

38. Croton Populifolium. Leaves broad-ovate, acuminate, serrate-toothed, somewhat rough with hairs, with one gland at the base above; petioles the length of the leaves; raccnes terminating, erect, solitary; stem shrubby; branches smooth, searred.—Native of Jamaica, and other parts of the West Indies.

39. Croton Cochin-chinense. Leaves lanceolate, quite entire, hoary underneath, shining, dotted; capsules scurfy. This is a middle-sized tree, with spreading branches. The flowers are white, in simple, oblong, terminating racemes.— Native of the woods of Cochin china.

40. Croton Lanatum. Leaves ovate-hanceolate, quite entre, smooth, opposite; corollas woolly; capsules six-valved. This is a large tree, with spreading branches, and white flowers in simple terminating racemes. The wood is white, heavy, and very durable; it is used in building, and for the joiles of bridges—Native of mountain-woods in Cochin-china.

41. Croton Congestum. Leaves ovate, gash-serrate, smooth, veined; flowers heaped, naked, axillary; stem suffruticose, five feet high, with many reclining branches; leaves alternate, unequal.—Native of China, about Canton.

42. Croton Dioicum. Leaves oblong, obtuse, hoary; flowers terminating on the male in spikes, on the female by threes; stem suffruitose, round, with divaricating branches; the whole plant covered with a soft nap.—Native of Mexico.

43. Croton Plicatum. Leaves ovate, plaited, crenate, hirstue; stem herbaceous; branches round, somewhat rugged, hoary, hirsute above, as are also the leaves, with close stellate hairs; capsules pendulous, of a violet purple colour. --Native of Arabia.

44. Croton Obliquum. Leaves ovate, lanceolate, quite entire; stem herbaceous, tomentose.-Native of Egypt,

45. Croton Coccineum. Leaves ovate, acuminaie, quite entire, smooth, biglandular at the base, dotted with scarlet underneath; racemes terminating; branches round, with a brown bark, mealy, villose at top; flowers subsessile,—Found by Kengi in Ceylon.

46. Crovon Lævigatum. Leaves elliptic, very smooth and even, without glands, entire, and serrate, obtuse; racemes terminating, elongated; branches round, proliferous, sealy with meal, and ash-coloured at top.—Observed by Dahl in Hainam.

5 H

47. Croton Betulinum. Leaves ovate-obtuse, crenatetoothed, rugged, with dots on the upper surface, somewhat rough with hairs underneath; racemes axillary. This has the appearance of betula or birch: branches round, with a purplish bark, tomentose, hoary at the end; flowers small, rough with hairs .- Native of the island of St. Thomas in the East Indies.

CRU

48. Croton Gossypifolium. Leaves cordate, three-lobed. tomentose, biglandular at the base uuderneath ; stem arboreous. This is a tall tree, with round branches, tomentose and hoary at top; leaves alternate, heaped, towards the end of the branches; flowers copious, scattered males intermixed with females .- Native of the island of Trinidad.

49. Crotou Procumbens. Leaves wedge-shaped, acute, quite entire. This plant is shrubby, inodorous, smooth, three feet high; the stems partly procumbent, partly erect; leaves petioled, alternate, two inches long; flowers small and green .- Common at Carthagena.

50. Croton Niveum. Leaves cordate, acuminate, serrulate, tomentose, shining beneath ; stem shrubby. It is ten feet high, erect, having a pleasant aromatic smell through all parts of it ; corolla white .- Native of Carthagena.

51. Croton Polygamum. Leaves lanceolate, serrate, thinly set with decumbent hairs. This is an upright shrub, four feet high, but little subdivided; branches round, smooth, ash-coloured ; flowers whitish, inodorous, hermaphrodite, male and female on the same or different plants. It flowers in June and July .- Native of Carthagena.

52. Croton Cyanospermum. Five-leaved, small, turned back below the capsule, which is globular, smooth, very obscurely three-grooved, three-celled, tricoccous. The Cevlonese call it lyan-gheddie. This and the next species are very doubtful .- Native of Ceylon.

53. Croton Cardiospermum. Capsule globular, terminated by a three-sided three-tubercled point, smooth, without any groove, tricoccous; rind corky, thick, opening into six parts from the base; shells the substance of paper, elastic, white, ovate. This the Cevionese call kebella and kebbele .- Native of Ceylon.

Crow Berry. See Empetrum.

Crowfoot. See Ranunculus.

Crow Garlic. See Allium.

Crown Imperial. See Fritillaria.

Crucianella ; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth twoleaved, inferior; leaflets lanceolate, slightly keeled, acuminate, stiff, couverging, compressed. Corolla: one-petalled, funnel-form; tube cylindric, filiform, longer than the calix; border four-cleft; divisions tailed, with the points inflex. Stamina: filamenta four, placed in the mouth of the tube; antheræ simple. Pistil : germen compressed, between the calix and corolla; style two-cleft, filiform, length of the tube; stigmas two, obtuse, oblong. Pericarp: capsules two, connate. Seeds : solitary, oblong. ESSENTIAL CHARACTER. Calix : two-leaved, (according to Gærtner, involucre two or three-leaved, chaffy none.) Corolla: one-petalled, funnelform, with a filiform tube, and tailed border. Seeds : two, linear. Gærtner says, inferior, naked, bald. The plants of this genus are all herbaceous, with leaves stellate, from four to six in a whorl, often linear; flowers bracted, in close terminating spikes, or sometimes, but not so commonly, in corymbs .---- The species are,

1. Crucianella Angustifolia; Narrow-leaved Crucianella. Erect : leaves in sixes, linear ; flowers in spikes. It has several upright stalks, which rise a foot high, having six or seven

grow in close spikes at the top and from the sides of the branches; they are small, while, not longer than the calix, and not remarkable for beauty. They appear in June and July, and ripen seeds in autumn .- Native of the south of France, and Italy. This species, as well as the second, fifth, aud sixth, are preserved in some gardens for the sake of variety. If the seeds be sown on a bed of light earth early in the spring, where they are designed to remain, they will require no other culture, but to thin them where they are too close, and keep them clean from weeds ; or, if the seeds be permitted to scatter, the plants will come up in the spring, and require no other treatment.

2. Crucianella Latifolia ; Broad-leaved Crucianella. Procumbent ; leaves in fours, lanceolate ; flowers in spikes, This is an annual plant, sending out several branching stalks from the roots, which lie prostrate. The flowers are produced in long spikes, at the extremities of the branches; they are very small, and make no great appearance .- It flowers in June and July, and is a native of the south of France. and the islands of the Archipelago. For its propagation and culture, see the first species.

Ægyptiaca; 3. Crucianella Ægyptian Crucianella, Leaves in fours, sublinear ; flowers in spikes, five-cleft, Annual : stems not at all woody, a palm iu height, at first erect, then spreading at the root, diffused or prostrate; flowers hirsute, longer than the bractes, yellowish white, five-cleft, and awned .- Native of Egypt.

4. Crucianella Patula; Spreading Crucianella. Diffused; leaves in sixes; flowers scattered .- It is an annual plant, and a native of Spain.

5. Crucianella Maritima; Sea Crucianella. A procumbent undershrub: leaves in fours, mucronate; flowers opposite, five-cleft; stems perennial, woody; flowers trist, yellowish colour, closed in the day, opening in the night, and of a strong smell .- Native of the south of France, Italy, and Sicily. It flowers in June and July, but will not ripen its seeds in England when the autumn is unfavourable. See the first species.

6. Crucianella Monspeliaca ; Montpellier Crucianella. Procumbent: leaves acute, those on the stem in fours and ovate, on the branches about five and linear; flowers in spikes; root annual, creeping; plant small, glaucous all over ; stems thickish, diffused .- Native of the south of France, about Montpellier and Vienne, and also found in Palestine. For its propagation and culture, see the sixth species.

7. Crucianella Hispida. Stem hispid ; leaves lanceolate. hirsute, opposite; flowers umbelled, terminating. This plant has four-cornered, rough, prickly stalks, which bend downwards. The flowers are produced in small clusters at the ends of the branches; the corolla is blue, and cut into four parts at the top .- Native of La Vera Cruz in New Spain.

8. Crucianella Americana. Leaves linear, lanceolate, hirsute, opposite; stem erect, villose; flowers solitary, axillary. This rises with a shrubby branching stalk, nearly three feet high, with narrow lanceolate leaves, covered with stinging hairs; flowers pale blue,-Native of La Vera Cruz in New Spain.

9. Crucianella Capitata. Procumbent, suffruticose : leaves in sixes, sublinear; flowers in heads, five-cleft; root perennial, horizontal, strong, woody; stem suffruticose, weak, naked at bottom; branches filiform; leaves usually six together, ovate-lanceolate, acute, rugged, rolled back on the sides, on the fruit-bearing branches remote, on the others approximating; border of the corolla five cleft, the segments very narrow leaves in whorls, at each joint. The flowers bent in, and having a claw at the tip; filamenta five, very

CUC

short : authera oblong, two-grooved, dark-coloured .- Native | The flowers are produced in little clusters from the bosons of Mount Lebanon, near the summit.

CRY

Crus Corvi. See Panicum. Crus Galli. See Cratagus.

Cruzita : a genus of the class Tetrandria, order Digynia. -GENERIC CHARACTER. Calix : perianth three-leaved, the anterior leaf linear, acute, the lateral ones ovate, concave, permanent. Corolla: petals four, of the appearance of the calix, ovate, concave, the two onter ones perfectly entire, the inner ones with a very thin lacerated border. Stamina : filamenta four, capillary, a little shorter than the calix. Antheræ: small. Pistil: germen ovate, obtuse, compressed ; style very short, two-parted, with spreading divisions; stigmas simple. Pericarp : none. Corolla : diverging, deciduous with the seed. Seed : single, naked. ESSENTIAL CHARACTER. Inner calix four-leaved, outer three-leaved. Corolla : none. Seed : one .- The only known species is, 1. Cruzita Hispanica. Stem high; leaves opposite, lanceolate, quite entire; flowers spiked, collected into a panicle. -Native of South America.

Crypsis ; a genus of the class Diandria, order Digynia .--GENERIC CHARACTER. Calix: glume one-flowered, twovalved; valves oblong, lanceolate, keeled, awnless, outer smaller. Corolla: glume two-valved; valves lanceolate, oblong, awnless, inner longer, and outer shorter than the calix. Stamina: filamenta two, capillary; longer than the corolla; antheræ oblong, cordate, incumbent. Pistil : germen superior, oblong ; styles two, capillary, shorter than the stamina ; stigmas hairy. Pericarp: none. Corolla : inclosing the seed. Seed : single, subcolumnar. ESSENTIAL CHARAC-TER. Calix: glume two-valved, one-flowered. Corolla: glume two-valved, awnless.----The only known species is, 1. Crypsis Aculeata; Prickly Crypsis. Root annual: culms many, diffused, four inches high, branching, covered with the sheaths of the leaves, which are smooth, except at the edge, the upper ones gradually broader ; spike subglobular, almost fastigiate, with the flowers almost sessile in the bosom of the involucre, which is three-leaved, and a little longer than the spike .- It is a native of Europe, of Siberia, and is also common in Barbary.

Cruptostomum ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, funnel-form, ventricose at the base, coloured, with a five-cleft border; segments lanceolate, unequal. Corolla : one-petalled, funnel-form : tube very short, inserted into the throat of the calix : border five-cleft : segments lanceolate, acute, unequal, converging; nectary fastened to the base of the corolla, broad, arched, closing the mouth of the corolla, five-toothed. Stamina : filamenta none; antheræ five, each inserted below each toothlet of the nectary. Pistil : germen roundish in the bottom of the calix ; style cylindric, the length of the calix; stigma capitate. Pericarp: berry globular, three-celled; seeds solitary, ovate, acute, marked with a large hilum or scar. ESSENTIAL CHARAC-TER. Calix: ventricose, five-cleft; tube of the corolla in serted into the throat of the calix ; border five-cleft. Nectary : five-toothed, closing the mouth of the corolla. Berry : seeds scarred .---- The only known species of this genus is,

1. Cryptostomum Gujanense ; Gujana Cruptostomum. It is a kind of spreading shrub, which grows in the isle of Cayenne, and in Guiana, where it is called aimoutabu. The root puts forth several twiggy and branching stems, five or six feet long, and sometimes longer. By means of these twigs and branches, it forms bushes more or less thick. These branches are garnished with alternate, nearly sessile, smooth, green, entire, oval leaves, terminating in a point. deadly nightshade, itself .-- It is a native of Germany, Flan-

of the leaves, and exhale an odour much like that of the syringa. The ovary becomes a three-celled yellow berry, each cell containing a kind of almond, of an agreeable substance, and gelatinous nature, of which the Creoles are very fond.

Cubæa; a genus of the class Dodecandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, turbinate, spreading, permanent, five-parted ; parts roundish, concave, four erect, the fifth and lowest larger, declined, Corolla: netals five, oblong, almost equal, furnished with claws inserted into the neck of the calix, the three apper ones erect, the two lower declined. Stamina : filamenta ten, villose at the base, inserted into the calix below the petals, the three upper ones shorter, filiform, erect, pressed close to the upper petals, the seven lower ones longer, capillary, incumbent on and longer than the lower petals. Antheræ oblong. Pistil: germen oblong, pedicelled; style capillary; stigma acute. Pericarp : legume long, coriaceous, villose, ventricose, obliquely acuminate, one-celled. Seeds : several. somewhat kidney-form. ESSENTIAL CHARACTER. Calix: turbinate, five-parted, unequal, permanent. Petals: five, unequal; filamenta villose, three shorter; germen pedicelled; legume villose, six or seven-seeded .---- The species are,

1. Cubæa Paniculata; Panicled Cubæa. This is a tree sixty feet high, extremely branching at top; the branches are thick, the smaller ones or ramulets trigonal, growing in a scattered manner; the leaves are large, alternately pinnate; the leaflets in six pairs, opposite, subovate, acute, quite entire, green and smooth above, somewhat downy beneath, and of an ash-coloured green ; there are two opposite stipules at the base of the leaf-rib; the flowers are spicated, terminal, and disposed into a very ample panicle, the ramulets of which are long, trigonal, and many-flowered; the flowers are alternate, subpedunculated .- It grows near the banks of rivers.

2. Cubæa Trigona ; Trigonal Cubæa. This is probably a mere variety of the former.

Cuckold Tree. See Mimosa.

Cuckow Flower. See Cardamine.

Cuckow Pint, or Pintle. See Arum Maculatum.

Cucubalus ; a genus of the class Decandria, order Trigynia .- GENERIC CHARACTER. Calix : perianth one-leafed, tubular, five-toothed, permanent. Corolla: petals five; claw the length of the calix; border flat; divisions often bifid; nectary none, crowning the corolla, Stamina ; filamenta ten, subulate, the alternate ones later, alternately inserted into the claws of the petal. Antheræ oblong, Pistil; germen somewhat oblong; styles three, longer than the stamina, subulate; stigmas pubescent, oblong, bent in an opposite direction to the sun. Pericarp : capsule covered, acuminate, three celled, gaping five ways at the tip; seeds very many, roundish. ESSENTIAL CHARACTER, Calix: inflated. Petals: five, having claws, but no crown. Capsule: threecelled .---- The species are,

1. Cucubalus Bacciferus; Berry-bearing Campion. Calices bell-shaped ; petals distant ; pericarps coloured ; branches divaricate; root perennial, creeping, and spreading far in the ground; the whole plant somewhat hairy; stems mounting four or five, and even eight or ten feet, among bushes, but trailing if not supported, herbaceous, and dving to the root every year; the leaves grow opposite at every joint, and resemble those of chickweed, both in shape and colour; flower axillary, standing single on slender pedoncles, and nodding. Mr. Miller asserts, that the berries of this plant are as poisonous as those of the atropa, or 396

found in woods and hedges : it has only been noticed in one place in Great Britain, being found in the isle of Anglesea by Mr. Foulkes, of Llandeber, near Ruthin. It delights in shade, and will thrive in almost any soil, but multiplies too fast by its creeping roots.

2. Cucubalus Behen: Bladder Campion, or Spatling Poppy. Calices subglobular, smooth, netted-veined; capsules three-celled; corollas almost naked; root perennial, woody, yellow on the outside, white within ; plant generally free from hairs ; stem decumbent at the base, branched, and dichotomous near the summit, round, green or red, a foot or eighteen inches in height, the joints large ; leaves below the forkings of the stem, connate, frequently tinged with purple; flowers some solitary at the divisions of the stem, others crowded at the ends of the branches, some on long peduncles, nodding; calix inflated, longer than the claws of the petals, veined with green or brownish purple, but sometimes without veins; petals white, cleft beyond the middle, distant, the segments frequently slightly serrulate. This species varies with broader and narrower leaves, smooth and hairy, and also with a double flower; it is a native of almost every part of Europe, in corn-fields and dry pastures, flowering in June, July, and August. Schreber says, that cattle reject it : but Linneus informs us, that horses, cows, sheep, and goats eat it, and that in Gothland they apply the herb externally in erysipetalous eruptions. The boiled leaves have something of the flavour of peas, and proved of great use to the inhabitants of Minorca, in the year 1685, when a swarm of locusts had destroyed the harvest: it is frequently called, white corn campion, and white bottle. It is a rambling weed, and seldom cultivated ; the root strikes so deep into the ground as not to be easily destroyed by the plough, and hence it is frequently growing in bunches among the corn.

3. Cucubalus Fabarius. Leaves obovate, fleshy; root bieunial, putting out many succulent leaves near the ground. out of the middle of which arises an upright stalk, about fifteen inches high, the lower part of which has leaves of the same form and consistence as those at bottom, but smaller, these are placed opposite; the upper part of the stalk divides into two smaller, on which staud a few small herbaceous flowers at each joint; it flowers in June, and sometimes ripens seeds in autumn .-- It was discovered in the Levant by Tournefort : it is a native of Sicily. This is a biennial plant, generally perishing when it has produced seeds; and unless it be sown upon very dry rubbish, and is a warm situation. it will not survive an English winter, for when they are in good ground they grow large, and become so replete with moisture as to be affected by the first frost in the autumn ; those which have grown upon an old wall often escaping, when the plants upon the ground have been killed.

4. Cucubalus Viscosus; Clammy Campion. Flowers lateral, every way decumbent; stem undivided; leaves reflex at the base; root biennial; root-leaves narrow, lanceolate, almost smooth, acuminate; stem-leaves broader, clasping, viscid, villose, somewhat waved, reflex at the base, not on the sides; peduncles opposite, short, three-flowered; flowers decumbent, not all turning one way, as in most of the species, nodding every way, and smelling sweet at night .-- Native of the Levant, Italy, Carniola, and Sweden. Linneus observes, that this is one of the many plants common to Sweden and Mount Ararat, as we find from Tournefort's collections .- It is satisfactorily ascertained that it is not the Dover campion.

5. Cucubalus Stellatus; Four-leaved Campion. Leaves in fours. This plant has a perennial root, from which arise two or three slender upright stalks, about a foot high, their I taly.

ders, France, Switzerland, Carniola, Italy, and Spain, and is Hower part having four leaves at each joint, placed in the form of a cross; the flowers appear in June, and in warm seasons the seed will ripen in England .- Native of Virginia and Canada.

6. Cucubalus Ægyptiacus; Egyptian Campion. Flowers erect: netals emarginate retroflex, with a toothlet on each side : stem weak, branching, spread upon the ground : leaves linear, not smooth, the younger ones ciliate at the base : flowers axillary, solitary, sessile; calix cylindric, in the fruit obovate, ten-cornered, with the interstices membranaceous, and the teeth small; petals minute, hardy, longer than the calix; styles often four .- Found by Hasselquist in Egypt.

7. Cucubalus Italicus; Italian Campion. Petals semibifid; caliccs club-shaped; panicle dichotomous, erect; stamina and pistils declined; stem erect, about two feet high, viscid, hoary, especially at bottom, with a scarcely visible cotton; flowers on peduncles, erect; calices club-shaped, marked with ten grooves; petals broadish, white, beneath lead-colour. Retzius considers our Dover campion as a variety of this, not being able to distinguish the one from the other. This is indeed more tender and delicate, that of Dover stiffer, larger, and hardier, the petals somewhat deeper cloven, and not stained underneath as the Italian is; although he does not regard these differences as sufficient to constitute a distinct species, and therefore regards them as varieties. Mr. Miller says that the root is perennial, the corolla pale red, and that it flowers in May and June, and ripens seeds in autumn.—Native of Italy. This, with the eighth, ninth, tenth, aud twelfth species, is propagated by seeds which should be sown where the plants are intended to remain; for as they send out long tap-roots, they do not bear transplanting, unless it be performed while the plants are young.

8. Cucubalus Tataricus; Hyssop-leaved Campion. Petals two-parted; flowers in one row, decumbent; peduncles opposite, solitary, erect; stem entirely simple. Perenuial: flowering from June to August .-- Native of Siberia. See the seventh species.

9. Cucubalus Sibiricus ; Siberian Campion. Petals emarginate; flowers subverticilled; whorls umbellate, leafless. This is a perennial plant, sending out many long leaves near the ground ; flowers in a nodding panicle ; calix ventricose, inflated .- It flowers in August, and is a native of Italy and Silesia. For its culture and propagation, see the seventh species.

10. Cucubalus Catholicus: Panicled Campion. Petals two-parted ; flowers panicled ; stamina long; leaves lanceolateovate. It is a perennial plant, sending out many long leaves near the ground; between these arise round viscid stalks, three feet high, having at the joints two long narrow branches, ending in acute points; flowers in a nodding panicle; calix ventricose, infleted, not sinuated or angular; petals white, antheræ reddish; styles white; capsule subglobular .- It flowers in July and August, and is a native of Italy, Sicily, and Silesia. There is a percnnial variety, which puts forth flowers in June and July; the calices are oblong, cylindric, smooth, pale, and glaucous; the corollas herbaceous, or yellowish green; petals narrow, divided to the middle, and opening at night. See the seventh species.

11. Cucuballus Mollissimus; Velvet Campion. Petals half two-parted; panicle dichotomous; stem and leaves soft like velvet ; root-leaves spatulate ; stems many, rather stiff, erect, a foot high, somewhat tomentose, very soft; branches at bottom alternate, shorter; lower leaves spatulate, the rest lanceolate; flowers white, erect; stamina the length of the calix : perennial and shrubby .- Native of the sea-coasts of water of the local division of the local div

12. Cucubalus Otites; Spanish Campion, Catchfly, or Star of the Earth. Flowers diacous; petals linear, undivided ; root long, fusiform, slender ; the root-leaves form a thick tuft, aud are wedge-shaped, or rather spatulate, entire, and acuminate, diminishing into a long channelled footstalk; from these rise one or several stems, from one to two feet high, upright, and the lower part clothed with a few opposite leaves, shaped like the root-leaves, the upper part of which is naked and clammy; at the bottom of the panicle are two membranaccous connate bractes, and the same under each set of flower-stalks; the lower part of the panicle, both of the male and female flowers, consist of opposite branches, each topped with a kind of umbel; the male flowers often produce abortive pistils, and the females abortive stamina. According to Scopoli, the male flowers are apetalous, and have the rudiment of a three-styled germen. In England, both sexes have the same narrow, entire, yellowish petals, and in Tartary it is found with an hermaphrodite flower. Neither Gerarde nor Parkinson seem to have been aware that this plant is a native of England. Ray seems to have been the first who noticed this, and says, it was known in Suffolk by the name of star of the earth, being in great repute as a remedy for the hydrophobia; but although Mr. Ray entertained no doubt of its efficacy, we should be sorry now to depend on such a remedy in such a disorder. This plant flowers in July and August, and is a native of Germany, Denmark, Switzerland, the Valais, France, Italy, Carniola, Spain, Siberia, and of England, in gravelly and sandy soils, as in gravel pits on the north side of Newmarket, about Chippenham; beyond Barton Mills in the way to Brandon; beyond Brandon in the road to Hillborough; and near Swaffham and Narborough, in Norfolk. For its propagation and culture, see the seventh species.

13. Cucubalus Reflexus. Flowers spiked, alternate in one row, subsessile ; petals subbipartite, obscure. According to Magnol, root white, fibrous; stem a palm and half in height; root-leaves hairy, forming a tuft on the ground, like those of the daisy; stem-leaves two, opposite at each joint, narrow and oblong; at the top of the stem a spike of flowers, bent down at first like a scorpion's tail, but becoming gradually erect after the fall of the flowers; petals whitish, deeply cloven, bending inwards when they begin to wither .-- Annual: and a native of Montpellier.

14. Cucubalus Saxifragus. Petals bifid; calices striated, the terminating ones subsessile, the side ones peduncled; root perennial; stem a palm in height, with linear leaflets .---Native of the Levant.

15. Cucubalus Pumilio; Dwarf Campion. Stems oneflowered, shorter than the flower; root-leaves forming a tuft. linear, obtuse, smooth and even ; stem very simple and short. bearing one flower, but having often three joints; corolla red, the horders elliptic; germen sessile; styles short .- Found near Geneva. In Styria, and the mountains bordering on Carinthia. and also in the mountains of Italy and Moravia: perenuial.

16. Cucubalus Glutinosus. Pctals two-parted; calices club-shaped; panicle dichotomous, sprcading very much; stamina and pistils straight; root flowering the second year; stems erect, dichotomous, somewhat villose, here and there covered with a tenacious viscid juice; leaves lanceolate, acute, very entire, hispid, especially the midrib, the upper ones linear; corolla greenish white; claws the length of the calix; border cloven almost to the base; stamina straight, the length of the corolla, or rather longer; antheræ incumbent .-- Native country unknown.

17. Cucubalus Paniculatus. Root-leaves ovate, acute: 34.

root-leaves many, on long petioles, from among which rises an upright stalk, sending out two opposite side-branches at each joint, under each of which is one lanceolate acute leaf: these side-branches, and also the upright stems, are terminated by whitish flowers, formed into a panicle, and standing erect. They appear in June. The plant itself is biennial, and a native of Spain and Italy.

Cucumis ; a genus of the class Monœcia, order Syngenesia. -GENERIC CHARACTER. Male Flowers. Calix: perianth one-lcafed, bell-shaped, the margin terminated by five subulate teeth. Corolla: five-parted, growing to the calix. bell-shaped ; divisions ovate, veiny, wrinkled. Stamina: filamenta three, very short, inserted into the calix, converging, of which two are bifid at the tip. The antheræ are lines creeping upwards and downwards, outwardly adnate. Receptacle : three-cornered, truncated in the centre of the flower. Female Flowers : on the same plant with the males. Calix : perianth as in the males, superior, deciduous. Corolla: in the males. Stamina : none; filamenta three, acuminate, very small, without antheræ. Pistil : germen inferior, large: style cylindric, very short; stigmas three, thick, gibbous, two parted, turned outwards. Pericarp : pome three-celled, or, according to Gærtner, four-celled ; cells membranaceous, soft, separated, Gærtner says, into two secondary ones. Seeds : numerous, ovate-acute, compressed, placed in a double order. ESSENTIAL CHARACTER. Calix : five-toothed. Corolla : five-parted. Male: filamenta three. Female. Pistil: threecleft; pome with acute seeds. The species are, 1. Cucumis Colocynthus; Bitter Cucumber, or Gourd

Coloquintida. Leaves multifid ; fruits globular, smooth, dark green, rough, and deeply laciniated; the flowers are small. and of a dull yellowish colour; the fruit round, and the size of an orange; it is green at first, but grows yellow when quite ripe; the pulp, or internal part, is light, spongy, and white : it is most intensely and intolerably bitter, and, when dricd, constitutes the coloquintida of the shops, which is an extremely strong and irritating cathartic, and has been sometimes commended, not only as an efficacious purgative, but also as an alterative in obstinate chronical disorders: others, however, have considered it as a dangerous drug. It has been principally used as a stimulus to other purgative medicines, as, for instance, an extract has been ordered in conjunction with aloes, and for mixing with various other purgative pills. It flowers from May to August. Native place unknown .- This species, together with the second, third, fourth, fifth, tenth, eleventh, twelfth, and thirteenth, arc raised from seeds, and coming from hot or warm climates, require the protection of the dry bark or stove,

2. Čucumis Prophetarum ; Globe Cucumber, Leaves cordate, five-lobed, toothletted, obtuse; fruits globular, spiny, muricate. This plant is every way smaller than the common melon, and has a nauseous odour; it is variegated with uncertain streaks, alternately greenish and yellowish, and is as bitter as coloquintida itself .--- Native of the Levant, flowering from June to September. Its specific name is an allusion to Jonah's gourd. See the preceding species.

3. Cucumis Anguria; Round Prickly fruited Cucumber. Leaves palmate sinuate; fruits globular, echinate; stems angular, hispid; flowers small, like those of bryony; the fruit seldom grows so large as a pullet's egg, which it resembles in shape : but the rind is closely beset with blunt prickles, somewhat like the skin of a hedgehog : where it is exposed to the full air, it is of a dark green colour, but when closely covered, either by the leaves or weeds, it becomes white. It is is as indigenous as the cucumber in the West Indics, but far stem-leaves lanceolate, opposite; flowers panicled, erect; inferior to it, although the inhabitants of the West India. 5 I

CUC

islands often eat it, and in the sugar islands frequently use it in souns, and reckon it an agreeable and wholesome ingredient. See the first species.

4. Cucumis Africanus; African Cucumber. Leaves palmate-sinuate; fruits oval, echinate; stems numerous, somewhat angular, prostrate; leaves five-cleft; flowers small .---Native of the Cape of Good Hope. See the first species.

5. Cucumis Acutangulus : Acute-angled Cucumber, Leaves rounded, angular; fruits with ten acute angles; flowers vellow: the fruit is very insipid, but it is eaten boiled and pickled .- Native of India: flowering from June till September

6. Cucumis Melo; Common or Musk Melon. Angles of the leaves rounded; fruits torulose; it has the stems procumbent, or trailing to a great length, and very much branched, furnished with tendrils for climbing; leaves palmate-sinuate, or entire, waving about the edge, and slightly toothed, with rounded corners rough with bristles ; flowers pale yellow, lateral, solitary; corolla wrinkled, ribbed, and having bristles along the ribs on the outside; fruit roundish or oval, blunt, commonly furrowed longitudinally, sometimes neited, sometimes warted or carbuncled, four to ten inches in length and diameter, yellowish green, or white; pulp firm, musky, reddish, seldom green ; seeds many, oblong, pale, in a watery pulp .- Some say it is a native of Calmuc Tartary, but as it has been cultivated from time immemorial, it is difficult to determine its native country; however, it was first introduced into Europe from Persia. There are many varieties of this highly esteemed fruit cultivated in different parts of the world, and in England there are too many of them propagated which are of no value, especially by those who supply the markets, where the size is principally regarded, so that by endeavouring to augment their bulk, the fruit is rendered of no value; on this account we shall only mention a few of the varieties which are the most deserving of care, excluding the common melons, as being unworthy of the trouble and expense of cultivation. 1. The melon most esteemed is the Cantaleupe, so named from a place near Rome, where it has been long cultivated : it was brought thither from that part of Armenia which borders on Persia, where it is so plentiful that a horse-load is sold for a French crown. This melon is delicious when in perfection, may be safely eaten, and will not offend the tenderest stomach : the Dutch are so partial to it, that they scarcely cultivate any other, but call it Cantaleupe by way of preeminence, never adding the surname melon, as in all the rest : its outer coat is rough, and full of knobs and protuberances like warts; it is of a middling size, rather round than long; and the flesh is for the most part of an orange colour, though there are some in which it has a greenish hue. 2. The romana is a good melon, when perfectly healthy, in dry seasons; and as it may he brought more forward than the Cantaleupe, those who desire to have early melons should cultivate this sort. 3. The succado may also be cultivated for early fruit, but is not to be compared to the Cantaleupe. 4. The zatte is good, but very small, being seldom bigger than a large orange, and a little flatted at each end, but contains so little flesh, that it is hardly worth the trouble of propagating. 5. The small Portugal, or Dormer melon, is a pretty good fruit, and may be cultivated for an early crop ; they are produced in plenty, and are preferred by those who are uot nice respecting the quality, if the quantity be but sufficient. 6. The black Galloway, which will ripen in a shorter time from its first setting than any other sort here named, and is not a despicable fruit when suffered to ripen naturally .- Of the Seeds. Place no dependence upon seeds brought from abroad; they best position is where they are open to the south, or a little

are not only generally unproductive, but when they do produce, the fruit is hardly ever tolerable. Different sorts of melons or gourds should not be planted near each other, as the farina from each, by impregnating other plants, makes it impossible to preserve the different sorts distinct; and as this mixture always occasions a great deterioration in point of quality, it ought the more carefully to be avoided. As it is very difficult to clean the seeds properly, Mr. Miller advises every one to do it for himself; as every person will then know from what sort it has been taken, and will not be deceived by the duplicity or ignorance of others. The seeds should not be sown before they are three years old, nor after they are six ; seeds that will swim upon the water are to be avoided ; the heavy seeds should be preferred .- Methods of Cultivation. It is common, says Mr. Miller, to hear many persons valuing themselves upon having two or three early melons, which, when brought to the table, are not better than a pumpkin, though raised at great trouble and expense : and in order to have them ripe a little earlier than they would naturally come, if suffered to grow to their full size, the stem of the fruit is commonly twisted, to prevent the nourishment from entering it, by which the growth is checked : then the fruit is closely covered with the mowings of grass plants, laid of a sufficient depth to cause a fermentation, by which the fruit becomes coloured; but where this unnatural method is practised, the fruit has but little flesh. without either moisture, firmness, or flavour ; so that after three or four months' attendance, with a great expeuse of dung, &c. there may perhaps be three or four brace of melons produced, which are fitter for the dunghill than the table. He therefore advises never to attempt to have these fruits ripe earlier than the middle or latter end of June, or from that time till the end of September, during which period, if skilfully managed, they may be plentifully obtained. -Sowing the Seeds. But in order to continue the fruit so long, the seeds must be sown at two or three different times first at the end of February in forward seasons, in backward springs at the end of that month. As the success greatly depends on raising the plants with strength, which cannot be so well effected if the severity of the weather should preclude the admission of fresh air, on this account it is advisable not to be too early in sowing the seeds. When the weather favours, they should be sown on the upper side of a cucumber-bed, where there are any ; aud otherwise, a quantity of new horsedung must be provided, thrown in a heap to ferment, and turned over that it may acquire an equal heat, in the same manner as is directed for cucumbers: the plants also must be raised in the same manner as prescribed for the cucumber : to which article, to prevent repetition, the reader is referred. The second season for sowing is about the middle of March. This, as well as the former, must be planted under frames, for those which are designed for bell or handglasses, or to be covered with oil-papers, should not be sown till about a week in April, otherwise they will extend their roots to the sides of the glasses, before it will be safe to let them run out, that is, during the sharp frosty mornings which often happen in the month of May; and if when they fill the glasses they are not allowed to run out, they will suffer as much from the heat of the sun during their confinement in the day, as from the frosts of the morning and the cold of the night: the seeds of those plants intended for the glasses, should be put a little later into the hot-bed than those which are to be covered with the oil-papers .- Preparing the Beds or Ridges. The ridges into which the plants are to be put out to remain, should always be in a warm situation; the the other points : the ridges should be enclosed with a good reed fence, but at such a distance every way from the bed, as not to obstruct the rays of the sun during any part of the day, with a door wide enough to admit the wheelbarrows, dung, &c. and kept locked up, to prevent children or ignorant persons from taking up the glasses, and letting in the cold air to the young plants .- Preparation of the Earth and Dung. The next thing is the preparation of the earth, in which the Dutch and German gardeners are very exact: the mixture which they generally prepare, is one-third of hazel loam, onethird of the scouring of ditches or ponds, and one-third of very rotten dung; these are mixed up at least one, and often two years before they are used, and are often turned, to incorporate and sweeten their parts: but the compost in which they succeed best in England, is two-thirds of fresh gentle loam, and one-third of rotten cow-dung, which if mixed together one year before it be wanted, so as to have the benefit of a winter's frost and summer's heat, observing to turn it over often, and never suffering weeds to grow upon it, will be found equal to any other compost whatever. As these plants succeed best when they are planted young, so before the plants appear, there should be a quantity of new dung thrown in a heap, in proportion to the number of lights intended, allowing about fifteen good wheelbarrows-full to each light; this must be two or three times turned over, in the same manner as directed for cucumbers, and will be fit for use in a fortnight: the trench must then be made to receive the dung, and the bed must be made wider than the frames. but in length proportioned to the number of frames intended : the trench should be a foot or more deep in dry ground, for the lower these beds are made, the better they will succeed. In the well-laying and mixing of the dung, the same precautions must be taken as for cucumbers. When the bed is made, the frames should be placed over it to keep out wet, but there should be no earth laid upon it till after it has been three or four days made, and is found to be of a proper temperature of heat .- Planting and Management of the Beds. As soon as the bed is found to be of a proper warmth, the earth should be laid upon it, not more than two inches thick at first, except in the middle of each light where the plants are to be placed, where a hill terminating in a flat cone, fifteen feet high or more, must be raised ; and in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants, which must be transplanted in the evening when there is little wind stirring: the roots must be raised with a trowel, carefully preserving all their fibres, for if they be broken off, the plants do not soon recover, nor ever after flourish so well as those which have been carefully removed ; for these plants are more tender than those of the cucumber, especially the Cantaleupe melon, which if planted out soon after the third, or what the gardeners call the rough-leaf, is put out, is long in recovering its vigour: so that when the beds cannot be ready for them in time, it will be a good method to put each plant into a small pot while they are young; they may also be plunged into the hot-bed where they were raised, or into the cucumber-bed, where there is room, so that they may be brought forward : and when the bed is ready turned out of the pots, with the whole ball of earth to their roots, whereby they will receive no check in removing, which is the best method that can be pursued with the Cantaleupe. When the plants are placed on the top of the hills, they should be gently watered, which should be repeated once or twice till after the plants have taken good root; after which they seldom require more, for

inclined to the east, and sheltered at a distance by trees from I good fruit. When they have taken root, there should be a greater quantity of earth laid on the bed, beginning round the hills where the plants grow, that their roots may have room to strike out, and as the earth is put in from time to time, it must be trodden or pressed down as closely as possible; and it should be raised at least a foot and a half upon the dung all over the bed, observing also to raise the frames, that the glasses may not be too near the plants, lest the sun should scorch them. When the plants have got four leaves, the tops should be pinched off with the finger and thumb, but not bruised or cut with a knife, because in either of these cases the wound will not so soon heal over: this pinching is intended to compel the plants to put out lateral branches, for they will produce the fruit; therefore, when there are two or more of these lateral shoots produced, they must also be pinched, to force out more; and this must be practised often, that there may be a supply of what the gardeners call runners, to cover the bed. The management of these beds must be nearly the same as is directed for cucumbers; it needs only be observed, that the melons require a greater share of air, and very little water, which should be given at a distance from their stems. If the plants succeed well, they will spread over the bed, and reach to the frames in about five or six weeks, at which time the alleys between the beds should be dug out; or where there is but one bed, there should be a trench made on each side, of about four feet wide, about as low as the bottom of the bed, and hot dung wheeled in to raise a lining to the same height as the dung of the bed. which should be trodden down close, and afterwards covered with the same earth, a foot and a half thick or more, as was laid upon the bed, treading it down as closely as possible. This will add to the width of the bed, so as to make it in the whole twelve feet broad, which is absolutely necessary, for the roots of the plants will extend themselves quite through it; and it is for want of this precaution, that it is common to see the vines of melons decay before the fruit is well grown ; for where there is no addition made to the width of the beds. the roots will have reached the sides by the time that the fruit appears, and having no room to extend themselves, their extremities are dried by the sun and the air, which is soon discovered by the plants hanging their leaves in the heat of the day, many of which decay near the stem; and the plants from that time gradually languish, so that the fruit cannot be supplied with nourishment; and when ripe, will be found to have little flesh, and even that mealy and ill-flavoured ; whereas those plants which have sufficient breadth for their roots to run, and the earth laid of a proper depth, and closely trodden down, will remain in vigour until the frost destroys them, so that a second crop of fruit has sometimes ripened very well upon them, even after the first had been produced, of an unusually large size and excellent quality; whereas in most places where the Cantaleupe melous have been raised in England, the beds have been no wider than they were first made, and had not generally more than three inches' thickness of earth upon them, so that the plants have decayed many times without producing a single fruit; and from thence people have imagined, that this sort of melon was too tender for this climate, while their ill success was entirely owing to their not understanding the culture, There is also another advantage attending this widening the beds, as above directed, which is that of communicating fresh warmth to them, by the hot dung which is buried on each side, which will cause the dung in the bed to renew its heat; and as the plants will by this time show their fruit, this additional heat will be of great service in setting the fruit. too much wet cankers their roots, and then they never produce especially if the season should prove cold, which frequently

ànn

happens even in May. When the beds are made up in the manner here directed, and the vines have extended so far as to fill the frames, and want more room, the frames should be raised about three inches upon bricks, to admit the shoots of the vines to run from under them ; for if the plants be strong, they will run six or seven feet each way from the stems, and ought therefore to have room allowed them. On this account, only one plant should be put in each light; for when the vines are crowded, the fruit will seldom set well, but will often drop off when they are about the size of an egg ; neither should the frames be small, but about six feet wide, for the wider they are, the better the plants will thrive, and the more fruit they will produce .- Pruning and Management of the Plants. Mr. Miller observes, that there is no part of gardening in which practitioners differ more than in this ; indeed, he savs, rules laid down in books, and the different methods pursued by different individuals, have appeared so absurd to him. that no one that follows them ought to expect to succeed. Having before advised the pinching off the ends of the plants to produce lateral shoots, and their tops to force out more runners, after a sufficient number are put out, the fruit should be waited for, which will soon come out in abundance ; at which time the vines should be carefully looked over two or three times a week, to observe the fruit, and make choice of one upon each runner, which is situated nearest the stem, having the largest footstalk, and appearing to be the strongest fruit; then immediately pinch off all the other fruit, which may appear upon the same runner, and also the end of the runner at the third joint above the fruit; and if the runner be greatly pinched at the next joint above it, that will stop the san, and set the fruit. Those who are so covetous of having a number of fruit, as not to suffer any to be taken off, generally fail in their expectation, for one fruit is as much as a single plant can properly nourish. As the pinching the three joints of the runners above the fruit will cause fresh runners to come out a little below the places where the others were pinched, the vines should be carefully looked over, to stop these new runners soon after they come out, as well as to pull the superfluous young fruit which will appear; and this must be repeated as often as necessary, which will be until those intended to stand are grown so large as to draw off all the nourishment which the plants can supply, for then the plants will begin to abate of their vigour. These few directions, if properly made use of, is all the pruning that will be necessary; they will only want to be watered at a distance from their stems, which will assist in setting the fruit, and cause it to swell; but this must be done with great caution. They should have as much air as possible in warm seasons, and in alterations of heat to cold should have their extremities covered every night with mats. Culture under Hand or Bell Glasses. They must be raised in the same manner as the preceding; and at the latter end of April, in forward seasons, the beds should be made of a quantity of hot dung in proportion to their intended number. They must not be placed nearer than four feet apart, or the vines will not have room to run without entangling, which will fill the bed so closely as to prevent the fruit from setting. The beds should be made as above directed ; if the plants intended for them be in pots, one only should be put under each glass ; if not in pots, two, one of which may be afterwards removed, if both should happen to grow. They must be watered at first planting, to settle the earth to their roots, and shaded every day until they have taken new root; but if the night be cold, it will be proper to cover the glasses with mats, to preserve the warmth of the bed. After they

under frames. It must however be remarked, that as the Cantaleupe is very impatient of wet, the beds where it is raised must be arched over with hoops, to support the mats and defend them at all times from the rain, which is the only means of ensuring their success in our variable climate . for melons under these glasses, in as fine order as possible, have been destroyed totally by one day's heavy rain in June. Water must be given them with great caution, and never applied to their stems .- Raising under Paper Corers. Many persons, of late years, have raised melons under oiled paper, and have often succeeded very well ; but care must be taken not to keep the covering too close over them, in which case the vines draw up weak, and rarely set their fruit in any plenty. Mr. Miller, therefore, advises the bringing up of the plants under hand or bell glasses, in the manner before directed, until they are grown far enough to be let out from under the glasses, and then, instead of the covering with mats, to cover them with oiled paper, which, if prudently managed, will be the best that can be used. The best sort of paper for this purpose is that which is strong, and not of too dark a colour; and it should be done over with linseed-oil, which will dry soon. A proportionable number of these sheets of paper should be pasted together, such as will spread to the dimensions of the frame for which it is intended; and if it be fixed before the oil be rubbed over, it will be an improvement, only observing that the paper should be oiled so long before they are used, that the oil may be thoroughly dry, and the stench gone off, otherwise it will destroy the plants. Some persons make these frames of broad hoops, in initation of waggon-covers ; but as they are too cumbersome to move, and have no convenience for admitting air to the plants, (except by raising the whole frame on one side,) frames made of pantile laths, shaped like the ridge of a house, and each slope having hinges by which each side may be raised at pleasure to admit the air to the plants, should be preferred .- Alanagement after the Fruit is set. Continue to pinch off all superfluous fruit, and weak runners; turn the fruit gently twice a week, that each side may have equal benefit of the sun and air. They will only require a little water in dry weather, once in a week or ten days will be sufficient, and will encourage the growth of the fruit, and cause the flesh to be thick ; but the great caution to be observed is, not to overwater them, and to give them as much free air as possible whenever the weather will permit, for this is absolutely necessary to render the fruit good .- Time of Cutting. When the fruit is fully grown, they must be daily watched, to cut them at the proper time; for if left too long upon the vines, they will lose much of their delicacy. They should be looked over at least twice every day; and if the fruit intended for the table be cut early in the morning, before the sun has warmed them, they will be much better flavoured; but should any of them be wanted in the course of the day, they should be put into cold spring water, or ice, before they are brought to the table : those cut in the morning should also be kept in the coolest place possible until served up to table. The sign of this fruit's maturity is, that of its beginning to crack near the footstalk, and its beginning to smell, which never fail ; for as the Cantaleupes seldom change their colour until too ripe, that should never be waited for. The directions here given for the raising of the Cantaleupe will answer equally well for all the other sorts, and are greatly superior to the common methods of raising this delicious fruit. The seeds only are used in medicine, and not often, though they are not destitute of virtues. They are very cooling, and have a tendency to promote the urinary discharge, when have taken root, they must be treated as directed for plants beaten into an emulsion with barley-water; they make an ex-5

CUC

with light dry earth, and plunged into the tan-bed, in the

cellent drink to be given in fevers, and other disorders, where mon hot-bed. The seeds should be sown in small pots filled a cooling regimen is necessary. It must, however, be confessed, that these are very old prescriptions, which are now little esteemed.

8. Cucumis Chate; Hairy Cucumber. Hirsute: angles of the leaves entire, rounded; fruits fusiform, drawn to a point at each end, rough with hairs ; stems decumbent, cirrhose, obscurely five cornered. The whole plant covered close and thick with soft, white, pellucid hairs, like the germen in the common melon, which differs in this, in being rough, with stiffish, conical, distant hairs. The fruit swells in the middle, is rough with erect white hairs, and has a beak at each end. It is found in the fertile earth round Cairo, after the inundation of the Nile, but no where else in Egypt; (Linneus adds,) and in Arabia .- It is a native of the The fruit is rather watery; the flesh almost of the Levant. same substance as the melon; the taste somewhat swect and cool, but not equally so with the water-melon. The grandees and Europeans, in Egypt, eat it as the most pleasant fruit they have, and that from which they have least to apprehend; but in England it is very indifferent, and is rarely cultivated, except for the sake of variety, especially as it rambles so as to require a great deal of room.

9. Cucumis Sativus; Common Cucumber. Leaves straight between the angles; fruit oblong, scabrous. It is only necessary to remark, that the leaves differ very much in their form from those of the melon. They run out into very sharp angles, especially at the end, with the line between the angles straight, having the nerves prominent on the upper surface, and very rough with bristles; they are also of a firmer texture. In the flowers, the segments of the calix are much longer; the corolla of a deeper yellow, each petal or part much wrinkled, commonly rolled in at the edges; the ribs at the back bristly as in the melon, and the principal rib ending in a long green point. The principal varieties are, 1. Common rough green prickly, six or seven inches long, with a dark green skin, closely set with small prickles. It is hardy, and a plentiful bearer, but does not fruit early: 2. short green prickly, three or four inches long, skin rather smooth, but having small black prickles; one of the hardiest and early sorts : 3. long green prickly, from six to eight or nine inches long, thinly set with prickles; this is a good bearer, and the best for the main crops; there is also a variety of it with white fruit: 4. early green cluster, shortish, early, and remarkable for the flowers appearing in clusters; 5. long smooth green Turkey; the stalks and leaves much larger than those of the former sorts; the fruit generally twice as long, say from 'ten to fifteen inches, and has a smooth rind without prickles : 6. long smooth white Turkey, differs little from the foregoing, except in colour; it is however less watery, and is therefore generally better esteemed : 7. large smooth green Roman; the plants are very strong; and the fruit large, long, and quite smooth : 8. long white prickly Dutch ; fruit eight or ten inches long, white, with small black prickles. It is a bad bearer in England, and not so hardy as the common sorts ; but the fruit is less watery, and has fewer seeds. Ray observes, in his Travels. that the Italians call our cucumbers citrulli; and watermelons and pompions, cucumeri ; in Spanish it is called cohombro; in French, concombre ; in Swedish, gurka ; in Danish, angurke, agurke ; in Dutch, komkommer ; in German, gurke kukummer. Those persons who wish to be early with their cucumbers, generally put them in before Christmas; but the generality of gardeners commonly put their seeds into the not-bed before Christmas. A stove will raise these plants of a better quality, and with less danger of failure, than a com-34.

warmest part of the stove, three or four days before the seeds are sown, that the earth may be properly warmed to receive them : the seed should be at least three or four years old, or more, provided it will grow the better. The plants will appear in a week or nine days; then as many small pots filled with dry light earth, as there are plants intended for planting, should be prepared by plunging them into the bark-bed, that the earth may be warmed to receive the plants, two of which should be pricked into these pots as soon as the two first leaves are raised above the ground ; but when they have taken root, and are safe, the worst should be drawn out, taking care not to disturb the roots of those which are left. The water given to these plants should be lukewarin, and they must be guarded from the moisture which frequently drops from the glasses of the stove. They should not be kept long in the stove, but a hot-bed must be prepared to receive them, the size of which must be in proportion to the quantity of plants. A cart-load of dung will make a bed large enough for a middling family. The dung should be new, not too full of straw, with some sea-coal ashes well mixed together, and thrown in a heap, until it has fermented a few days, when it should be turned over and mixed, laying it up again in a heap. The bed should be well sheltered by reed hedges, and the ground should be dry. The trench ought at least to be a foot deep, into which the dung should be wheeled, and carefully stirred up and mixed, so that no part of it should be left unseparated; for where there is not this care taken, the bed will settle unequally; there should also be great care taken to beat the dung down close alike in every part of the bed. The frame and glasses should then be put upon it to keep out the rain, but no earth ought to be laid upon the surface until two or three days after, that the steam of the dung may have time to evaporate. If there should be any danger of the bed burning, it will be proper to lay some short old dung, two inches thick, over the top of the other, which will prevent it by keeping down the heat. After this, there should be a sufficient number of threefarthing pots placed upon the bed, filled with light dry earth, and all the interstices between them filled up with any common earth. In two or three days the earth in these pots will be of a proper temperature to receive the plants, which should then be turned out of the first small pot, and planted into these with the ball of earth adhering to their roots. taking care not to give them too much wet; and as they will have such large balls of earth, as not to feel their removal, they will not require shading from the sun ; but the glasses should be raised up a little on the contrary side to the wind, to let the steam of the bed pass off; and the glasses should be frequently turned in the day-time, that the wet occasioned by the steam of the dung may be dried, otherwise the moisture will fall on the plants, which will be very injurious to them. If the bed should heat too violently, so as to endauger scalding the roots of the plants, the pots may be raised so as to allow of a little hollow at their bottoms, which will effectually prevent it; and when the heat declines, the pots may be settled down again. The glasses of the hot-bed should be well covered with mats every night, to keep the bed in a proper temperature of heat ; and great care must be taken to admit fresh air every day to the plants, which must be cautiously done, so as to guard against the cold winds, which usually blow at that season. A mat or canvass ought to be hung over the opening made by the raising of the glasses, to prevent the cold from rushing in too violently, If the weather prove inclement, and the heat of the bed

402

to renew the heat, which must not be suffered to fail; for as the plants have been tenderly brought up, the cold would soon destroy them. In this bed the plants may remain three weeks or a month, in which time, if they have been properly managed, they will have acquired sufficient strength to be put out altogether; therefore a proper quantity of dung should be mixed, and turned before-hand, for making the beds into which they are now to be removed. The quantity usually allowed is one good cart-load to each light, which should be well mixed and turned over in the manner before directed, and then wheeled into a trench of the length and breadth of the intended bed, and worked and covered with old cow-dung as before. The frames and glasses should then be put on the bed, and raised every day to let the steam pass off, and in about three days the bed will be in a proper temperature of heat to receive the plants. The dung should then be covered over with dry earth, four inches thick, or eight inches in the middle of the bed, which should be done at least twenty-four hours before the plants are removed into it, in order that the earth may be properly warmed. The plants should then be carefully shaken out of the pots, preserving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two, or at most three, of these plants will be sufficient for each light; they should be placed seven or eight inches asunder, but never close together. There should always be a magazine of good earth laid under cover to keep it dry, for the earthing of these beds; for if it be taken up wet it will chill the beds, and occasion great damps therein; it is therefore quite necessary to have a sufficient quantity of earth prepared long before it is used. When the plants are settled, they must have proper air and water, but not too much of either. The glasses should be kept well covered with mats every night, to keep up the warmth of the bed, and some fresh earth should be introduced at different times, which should be laid at some distance from the roots of the plants until it be warmed, and should then be drawn up round the heap of earth in which they grow, to increase its depth. By this method of supplying the earth, the whole bed will be covered nine or ten inches deep with it, which will cherish the roots of the plants, and prevent them from hanging their leaves in the heat of the day. It will however be necessary to raise the frames, after the earth has been laid to the full thickness on the bed, otherwise the glasses will be too close to the plants ; but when this is done, there must be care taken to stop the earth again very close round the side of the frame, to prevent the cold air from entering under them. When the fruit appears, many male flowers will also come out on different parts of the plant; but as the female flowers have the young fruit situated under them, and the male have none, they are thus easily distinguished, especially as the male have three stamina in their centre, with their antheræ, which are loaded with a golden powder. This is designed to impregnate the female flowers, and the plants are fully exposed to the open air ; the soft breezes of wind convey this male powder or farina from the male to the female flowers ; but if the air be too much excluded at this season, the plants will drop off for want of it. Bees have been observed to creep into the frames when the glasses were raised to admit the air, and being accideutally shut in, have supplied the want of those gentle breezes of wind, by carrying the faring of the male flowers on their hind legs into the female flowers, where they have left a sufficient quantity to impregnate them, and have thus taught the gardener a method to supply the want of free air, which

decline, there should be some hot dung laid round the sides | purpose. This is done by carefully gathering the male flowers at the time when the farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger gently striking the outside of the male, so as to cause the powder on the summits to scatter into the female flowers, by which means the crop is much more certain to be produced. After the cucumbers are thus fairly set, if the bed be of a proper temperature of warmth, they will soon swell, and become fit for use; it is therefore only necessary to water the plants properly, which is done by sprinkling the water all over the bed, for the roots will extend to the sides of the bed; therefore, those who wish to continue these plants as long as possible in vigour, should add a sufficient thickness of dung and of earth all round the sides of the beds, so as to enlarge them to nearly double their first width ; this will supply nourishment to the roots of the plants, whereby they may be continued fruitful during great part of the summer; whereas, when this is not practised, the roots of the plants, when they have reached the side of the beds, are dried by the wind and sun, so that they languish and decay long before their time. Those gardeners who are fond of producing early cucumbers, generally leave two or three of their early fruit, which are situated uear the main stem of the plant, upon the root, for seed ; which, when fully ripe, they carefully save to a proper age for sowing, and thus greatly improve the seed, which they always use for their early crops only, for the later crops do not deserve so much care and attention. In gardens where there are no stoves, the seeds should be sown upon a well-prepared hot-bed. It should be sown in halfpenny pots, that they may be easily removed from one bed to another, if the heat should decline; or raised up, if the heat should prove too great. When they are come up, a fresh hot-bed must be prepared, as was before directed, and the after management of the plants must be nearly the same; but as the steam of the hot-bed frequently occasions great damps, the glasses must be frequently turned, and have the condensed moisture wiped off them, which is very destructive to the plants on which it falls. Care also must be had to let in fresh air at all proper times, and also to keep the bed in a proper temperature of heat; for as there is no fire to warm the air, that must be supplied by the heat of the dung; and finally, the plants may be ridged out as before directed. In about a month after they are ridged out, you may expect to see the beginnings of fruit, which is often preceded by male flowers. which ignorant persons sometimes pull off, calling them false blossoms; which is very absurd, as these flowers are of absolute service to promote the welfare of the fruit, which very often falls away and comes to nothing, in consequence of the removal of these false blossoms, as they are ridiculously termed. Neither ought the vines to be pruned, as is the custom of unskilful people, especially when they are too luxuriant, which often occurs when the seeds were fresh, or of the last year's saving, and the plants in good heart. When this is the case, it is very proper to pull up one of the plants before it has run so far as to entangle with the other; for it often happens that one or two plants, when they are vigorous, are better than four or five; for when the frame is too much crowded with vines, the fruit is seldom either so good or so plentiful as when there is a moderate quantity of shoots, for the air being thereby excluded from the young fruit, they are consequently liable to decay and fall off. The glasses must be covered every night, and during the extreme heat of the day; and when the vines are spread so as to cover the hotbed, it will be very serviceable, when you water them, to is so indispensable in the natural way of accomplishing that sprinkle them all over gently, so as not to hurt the leaves,

CUC

but never to do this when the sun is very hot; or the exhalations, which his beams might draw up from this watering, would destroy the plants .- Culture of Cucumbers under Hand or Bell Glasses. In the middle of March, or a little later, according to the earliness of the season, you must put in your seeds either under a bell-glass, or in the upper side of your early hot-bed; and when the plants are come up, they should be pricked upon another moderate hot-bed, which should be covered with bell or hand-glasses, placed as closely as possible to each other: the plants should be pricked in two inches apart, observing to shade and water them until they have taken new root, which will be in a very short time. This is to be understood of such places where a great quantity of plants are required, which is constantly the case in the kitchen-gardens near London; but where a family only is to be supplied, there may be plants enough raised on the upper side of the beds, where the first crop is growing ; or if the vines should have extended themselves so far as to cover the whole bed, whereby there will not be sufficient room to prick the plants, a single light will contain such a number of young plants for planting out in ridges, as will supply the largest family with cucumbers during the latter part of the season. In severe weather, and at night, the glasses should be covered with mats, but raised during the day in hot weather, on the opposite side from the wind, to give air to the plants, which will greatly strengthen them; but they must be very sparingly watered while young. By the middle of April these plants will be strong enough to ridge out, you must therefore be provided with a heap of new dung, in proportion to the quantity of holes you design to plant, allowing one load to six holes. When the dung is fit for use, dig a trench about two feet four inches wide, and in length just as you please, or the place will allow: if the soil be dry, it should be ten inches deep; but if wet, very little in the ground, levelling the earth in the bottom, then putting in the dung, mixing and stirring up every part of it, as was directed for the first hot-beds, laying it close and even. When this is done, you must make holes about eight inches over, and six deep, just in the middle of the ridge, and three feet and a half distance from each other; but if there be more than one ridge, eight feet and a half from each other; fill the holes with good light earth, put a stick into the middle of each for a mark, and afterwards cover the ridge over with earth about four inches thick, laying the same thickness of it round the sides. When the earth is thus levelled smooth, set the glasses upon the holes, leaving them close down about twenty-four hours, in which time the earth in the holes will be sufficiently warmed to receive the plants; then stir up the earth of these holes with your hand, hollowing it out in the form of a bason, in each of which set three or four plants, taking care to shade and water them until they have again taken root; they must afterwards have air admitted to them, in proportion to the heat of the weather, by raising the glasses on the side opposite to the wind, which must only be done in the middle of the day; the glasses should then be raised by a forked stick on the south side, in height proportioned to the growth of the plants, that they may not be scorched by the sun, which will also harden and prepare them to endure the open air, to which, notwithstanding, they ought not to be prematurely exposed, as they are often killed by the morning frosts in May. Towards the latter end of that month, when the weather appears settled and warm, turn your plants down gently out of the glasses, not in hot sunny weather, but when the sky is cloudy, with an appearance of rain. In doing this, raise the glasses either upon bricks or forked sticks, upon which they may stand securely at four or five inches from the

ground, that the plants may lie under them without bruising. The glasses should not be wholly removed till the latter end of June or the beginning of July, for they will preserve the moisture much longer at the roots than when the plants are exposed to the open air. About three weeks after you have turned the plants out of the glasses, they will have made a considerable progress, especially in favourable weather: the spaces of ground between the ridges should be then dug up, making it very even, and laving out the runners of the vines in exact order, taking care not to disturb them too much, nor to break or bruise the leaves : this digging of the ground will loosen it, and make it more penetrable for the roots of the plants to strike into, and at the same time make the surface of the earth more suitable to the vines that run upon it. After this, there will be no farther care needful, except to keep them clear from weeds, and to water them as often as they shall require, which is when they hang their greater leaves. The ridges thus managed, will continue to produce large quantities of fruit, from June until the latter end of August, after which time the coldness of the season renders them unwholesome, especially if the autumn prove wet, From these ridges it is common to select cucumbers for seed, reserving two or three of the fairest fruit upon each hole, never leaving above one upon a plant, and that situated near the root, for if more be left, they will weaken the plant so much as greatly to diminish the size and quantity of the other fruit. Those persons who value themselves upon producing cucumbers very early in the season, generally leave three or four of the first produce of the earliest crop when the fruit is promising, and the seeds of these early fruit are generally preferred to any other for the first crop: they should remain upon the vines till the middle or end of August, that the seeds may be perfectly ripe; and when you gather them from the vines, it will be proper to set the fruit in a row upright against a wall, where they may remain until the outer covers begin to decay, at which time you should cut them open, and scrape out the seeds, together with the pulp, into a tub, which ought to be afterwards covered with a board, to exclude dirt of every kind; let it remain eight or ten days in the tub, observing to stir it well to the bottom every day with a long stick, in order to rot the pulp, that it may be easily separated from the seeds; then pour some water into the tub, stirring it well about, which will raise the scum to the top, but the seeds will settle to the bottom, so that by two or three times pouring in water, and afterwards straining it off, they will be perfectly cleared from the pulp: the seeds ought then to be spread upon a mat, and exposed three or four days to the open air till perfectly dry, when they may be put up in bags, and hung up in a dry place out of the reach of vermin, where they will keep good for several years, but are generally preferred when three or four years old, as being apt to produce less vigorous but more fruitful plants .--Culture of Cucumbers in the open Ground. The season for sowing these is towards the latter end of May, when the weather is settled; the ground where they are commonly sown is between cauliflowers, in the wide rows between which, four feet and a half space is allowed at planting: in these rows square holes should be dug three feet and a half distance from each other, breaking the earth well with a spade, and afterwards smoothing and hollowing it into the form of a bason with your hand, then put eight or nine seeds into the middle of each hole, covering them over with earth half an inch thick; and if it should be very dry weather, it will be proper to water the holes gently in a day or two after the seeds are sown, in order to facilitate their vegetation. In five or six days, if the weather be good, the plants will begin to thrust

their heads above ground, at which time it will be very necessary to keep off the sparrows, which are extremely fond of the young tender seed-leaves of these plants, and will soon destroy the whole crop, if not prevented. But as the plants do not remain above a week in danger, it will be no great trouble to look after them during that time: for when the plants have appeared, and expanded their seed-leaves, the sparrows will no longer molest them. You must not fail to water them gently, according to the season; and when the third or rough leaf of the plants begin to appear, pull out all the weakest plants, leaving only three or four of the most promising and best-situated in each hole, stirring the earth round about them with a small hoe, to destroy the weeds, and raise the earth about the shanks of the plants, introducing a little earth between them, and pressing it down gently with your hand, to separate the plants more distinctly from each other to a greater distance : they must be carefully watered in dry weather, and kept it entirely free from weeds. When the cauliflowers are drawn off the ground from between the cucumbers, you must hoe and clean the ground, drawing the earth up round each hole in the form of a bason, the better to retain the water that is given them. The plants must also be laid out in the exact order in which they are to run, and to extend so that they may not interfere with each other. A little earth must theu be laid among them, and pressed down gently with the hand, giving them at the same time a little water to settle the earth about them, repeating it as often as is necessary, and taking care to remove the weeds. The plants thus managed will begin to produce fruit towards the end of July, when you may either gather them young for pickling, or suffer them to grow for large fruit. The quantity of holes necessary for a family is about fifty or sixty, for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expense of pickling, without keeping them too long in the house; for from fifty holes, more than two hundred cannot be gathered at each time, but this may be done twice a week throughout the season, so that about two thousand may be gathered if they be taken small, which will not be too many even for a private family: but should so many not be wanted, they may he left to grow to a proper size for eating.

10. Cucumis Anguinus; Serpent Cucumber or Mcban. Leaves lobate; fuit cylindric, very long, smooth, and even writhed; flowers smaller than others of the genus, with a long tube, they scarcely exceed the size of jessamine flowers; the fruit or cucumber is three feet, or three feet and a half long, never straight, but strangely twisted, so as to resemble a snake; it is externally of a grayish green, and grows very red in time; the odour is rank, and the taste bitter.—For its culture and propagation, see the first species.

11. Cucumis Texuosus; Flexuos Cucumber or Melon. Leaves angular, sublobate; fruits cylindric, furrowed, curved; fruit the size of a large pear, of an oblong cylindric form, smooth, even, eatable, and delicious. It ripens in June, is called *banket melon* by the Dutch, and is cultivated about Nagasaki, and in other parts of Japan. For its propagation and culture, see the first species.

12. Cucumis Conomon. Leaves angular, sublobate, toothei ; fruit fusiform, ten-furrowed, smooth; s ten decumbent, striated, hispid, with scattered hairs, as are the petioles; leaves cordate, nerved, pale underneath; forwers axillary, peduncled, aggregate, yellow; peduncles very short, hispid; fruit the size or a maris head or large; oblog.—It is cultivated every where in Japan; the fruit preserved is sold under the name of connewon, and is a common food among the Japanes; it as also frequently ratem by the Dutch at

Batavia, and is sometimes brought to Holland. For its propagation aud culture, see the first species.

13. Cucumis Maderaspatamus. Leaves cordate, entire, toothielted; fruits globular, smooth; steen herbaceous, angular; leaves frequently angular at the base, oblong, acute, smooth. Loureiro informs us, that it is very nearly allied to melothria: according to him the stem is round, slender, branched, climbing; leaves roundish, petioled, alternate, small; flowers white, axillary, on many-flowered pedundes; fruit yellow, half an inch in diameter.—Native of Ceylon, and other parts of the East Indies, of Cochin-china, and also of the Cape of Good Hope. For its propagation and culture, see the first spaceies.

Cucurbita; a genus of the class Monœcia, order Syngenesia .- GENERIC CHARACTER. Male Flowers. Calix: perianth one-leafed, bell-shaped, the margin terminated by five subulate teeth. Corolla: five-parted, growing to the calix, bell-shaped ; divisions veiny-rugose. Nectary a gland in the centre of the flower, concave, triangular. Stamina: filamenta three, converging, connected above, distinct below: growing to the calix. Antheræ creeping upwards and downwards, linear. Female Flowers. Calix : perianth as in the male, superior, deciduous. Corolla: as in the male : nectariferous glandule concave, spreading. Stamina ; margin surrounding, ending in three very short cusps. Pistil: germen large, inferior; style conic, three-cleft at the top ; stigma single, with a thick convex margin creeping upwards and downwards, three-cleft. Pericarp : pome threecelled; cells membranaceous, soft, distinct. Seeds: very many, compressed, swollen on the margin, obtuse, placed in double order. ESSENTIAL CHARACTER. Calix : fivetoothed. Corolla: five-cleft. Male: filamenta three. Fsmale: pistil five-cleft; seeds of the pome with a swelling

margin.— The species are, 1. Cucurbita Lagenaria; Bottle Gourd, or Long Gourd. Leaves somewhat angular, tomentose, biglandular at the base underneath; fruit woody; stems thick, long, climbing with tendrils, extending nearly twenty feet in length, covered with a fine soft hairy down; flowers large, white, on long peduncles; fruit shaped like a bottle, with a large roundish belly, and a neck very smooth, when ripe of a pale yellow colour, some nearly six feet long, and eighteen inches round; the rind hardens on being dried, and will contain water: the Arabians call it *charrab*. The poor people eat it boiled with vinegar, or fill the shell with rice and meat, thus making a kind of pudding of it. In Jamaica the shells are generally used for water-cups, and frequently serve for bottles among the negroes, and poorer sort of white people, in that country, A decoction of the leaves is strongly recommended in purging clysters; and the pulp of the fruit is often employed in resolutive poultices; it is bitter and purgative, and may be used instead of coloquintida. The large gourd, a variety of this species, is cultivated on account of the woody shell of the fruit, which will frequently contain betweeu twenty and thirty quarts: where aloes is manufactured in any quantity, it is commonly preserved in these shells; but in Jamaica they are only employed to hold water and small grain. The shells are of different forms, some shaped like a pear, others like a bottle, others again like an orange. They grow in all parts of Egypt, and in Arabia, wherever the mountains are covered with rich soil; and is also a native of both Indies. The first, second, third, fourth, fifth, and sixth species, may be propagated by sowing their seeds on a hot-bed in April, and transplanted, when the plants come up, to another moderate hotbed, where they should be brought up hardily, and have a great deal of air to strengthen them; and when they have

404

CUC

got four or five leaves, they should be transplanted into the seeds, fill the void with sliced apples, adding a little holes made upon an old daughill, allowing them ample room, as some of them will run to a great distance. The first species requires to be more tenderly treated than the others, in order to procure ripe fruit; the seeds therefore should be sown upon a moderate hot-bed in April, and the plants afterwards planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward, but must not nevertheless be tenderly treated, for if they have not a large share of free air admitted to them every day, they will draw up weak. When the plants are grown too large to remain in the pots, holes must be dug wherever they are designed to grow, and three or four barrows-full of hot dung be put into each; these must be covered with earth in which the plants must be set, and covered with hand-glasses till they run out : there are some persons who place these plants by the sides of arbours, over which they train the vines, so that in a short time they will cover the whole arbour, and afford a strong shade: others plant them near walls or hedges, to which they fasten the vines, and train them to a considerable height ; the orange-shaped gourd is the sort that is commonly so planted, for the ornament of its fruit, which has a pretty effect when seen at some distance. All these plants require a large supply of water.

2. Cucurbita Hispida. Leaves angular: stem and petioles hispid; stem furrowed, climbing, covered with ash-coloured hairs; leaves petioled, having five angles, or sublobed with straight angles, nerved, villose on both sides ; petioles round, hispid, a finger's length; flowers axillary, very closely set with ferruginous hairs, the lower a finger's length, the upper shorter; tendrils simple, bifid or trifid; calix and peduncle very closely hirsute, with ferruginous hairs .- Native of Japan, where it flowers in September. For its propagation and culture, see the first species.

3. Cucurbita Ovifera; Egg Gourd. Leaves lobed; fruits obovate; tendrils in sevens, digitated. The herb and flowers are very like the pompion, but not so rough; the leaves are not many-cleft, neither is the frnit bitter : the tendrils are straight, and end in small spiral tendrils, usually seven in number; fruit smooth and even, the size and form of a hen's egg, with the rind so hard as to be scarcely cut with a knife, painted with ten milk-white longitudinal lines .- Native of Persia, in the neighbourhood of Astracan. For its propagation and culture, see the first species.

4. Cucurbita Pepo; Pompion or Pumpkin Gourd. Leaves lobed; fruits glossy; stems thick, angular, extremely hispid, or spreading to the distance of forty feet, so that a single plant, if properly encouraged, and all the side-branches be permitted to remain, will overspread twenty rods of ground : leaves cordate, large, roundish, angular, toothed, wrinkled, hairy on both sides, on alternate, thick, flexuose, hirsute petioles ; flowers yellow, lateral, solitary, on peduncles resembling the petioles, but shorter; teeth of the calix large, gashed, waved, reflex; fruit roundish, ovate, globular, or oblong-ovate, pale green on the outside, and commonly hispid, with bristly hairs; within having a spongy insipid white pulp or flesh, divided in the middle into three primary cells, each of which is double, and again subdivided into the proper cells of the seeds, which are very numerons, horizontal, elliptic, of a compressed lens-shape; the fruit varies in form and size; two hundred and sixty of them, on an average, have been produced from a single New England plant. In Europe, the pompion, which we have corrupted to pumpkin, is frequently planted by the country people on their dunghills, and suffered to trail at length over the grass of an orchard. 34.

sugar and spice, and bake it; but it is unfortunately hard of digestion, although the Eastern nations esteem it to be the most wholesome of its genus, and give it to the sick as a cooling dinretic. In England, pompions were formerly called English melons, or, corruptly, millions ; and the true melons, musk melons. The pompiou flowers from June to August, but its native place is not known. For the propagation and culture, see the first species.

5. Cucurbita Verrucosa; Warted Gourd. Leaves lobed; fruits knotty, warted. The plant, flower, and seeds of this are the same as in the pompion ; but the fruit is smaller, with a harder and almost woody rind .- It is very common in most parts of America, where it is cultivated as a culinary fruit : the form and size are various, being round, flat, shaped like a bottle, or oblong: the rind becomes white when the fruit is ripe, and is covered with large protuberances or warts. It is commonly gathered when half grown, and boiled by the inhabitants of America, to eat as sauce with their meat. In England it is cultivated merely as a curiosity. See the first species, for its propagation and culture.

6. Cucurbita Melopepo; Squash Gourd. Leaves lobed; stem erect; fruits flatted, knobby; stem roundish, hairy, procumbent or climbing, with trifid tendrils; branches many, long; leaves lobed, angular, serrate, hairy, alternate on long petioles; flowers yellow, on lateral one-flowered peduncles; segments of the calix linear, spatulate, spreading; antheræ linear, distinct, erect; fruit large, reddish, yellow or yellowish white within and without, commonly roundish, often flatted at top and bottom, always tornlose, sometimes ovate, seldom warted. Linneus seems to be mistaken in describing the tendrils on the stem as neither climbing nor procumbent; for Loureiro informs us, that in India it is always scandent when a support is at hand, but when there is none, always procumbent. Mr. Miller also remarks, that it often grows with a strong bushy erect stalk, without putting out runners from the sides like the other sorts, but that after it has been cultivated a few years in a garden, it will become trailing, and that seeds out of the same fruit have produced erect plants, bearing the same fruit with the parent in one garden, and trailing plants, with larger fruit of a different shape, in another .- It is common in North America, where it is cultivated like the preceding species as a sauce, and also in the East Indies and China. The fruit is of great use in long voyages, for it may be kept several months fresh and sweet. For its propagation and culture, see the first species.

7. Cucurbita Citrullus; Water Melon. Leaves manyparted ; stem round, striated, long, branched, hairy, procumbent, diffused with lateral bifid tendrils; flowers yellow, ou short, solitary, lateral peduncles; frnit large, smooth, round, oblong, a foot and half in length, within watery, sweet, very red or pale; seeds black or rnfous; the fruit varies much in form and colour : it serves the Egyptian for meat, drink, and physic, and is eaten by them in abundance during the season, which is from the beginning of May until the overflowing of the Nile, that is, to the end of July or the beginning of August. It is the only medicine the common people use in ardent fevers, for which purpose they have a variety, which is softer and more juicy than the common sort; when this is very ripe, or almost putrid, they collect the juice, and mix it with rose-water and a little sugar. Europeans, however, should be cautious in eating this fruit, for when taken in the heat of the day whilst the body is warm, colics and other bad consequences often ensue; and it is well known that worms are a very prevalent complaint while this fruit is in season. When the fruit is ripe, they cut a hole in the side, take out Gerarde calls the water melon citruls, cucumber citruls, and 5 L

pome citruls ; Parkinson the citrull, or Turkey million. The water melon is cultivated in the warm countries of Europe. and also in Asia, Africa, and America, where it is greatly esteemed for its wholesome cooling quality. The best sorts to cultivate in England, are those with small round fruit which come from Astracan; those which have large fruit seldom ripen in this climate. First procure the seeds three or four years old; prepare a heap of new dung in the beginning of February, which should be thrown in a heap for about twelve days to heat, turning it over twice, mixing it well, then make a hot-bed, in which those seeds and also encumber and musk melon seeds may be sown : the dung should be well wrought in making the bed, and should be beaten down pretty close with a dung-fork, that the heat may not be too violent, but of longer continuance : when the dung is thus laid, cover it about four inches thick with a good light earth, and having spread it very even, put the frame and glass over it, leaving it to warm four or five days before the seed be sown, and observing, if much steam arise, to raise the glass that it may pass off. When the bed is in proper temper, sow the seeds in drills, covering them over with about half an inch of earth; after this, if you find the bed very warm, air must be admitted by raising the glasses in the day-time; but if the bed be cool, cover it well with mats in cold or wet weather, and every night. In four or five days' time another hot-bed must be prepared to receive these plants, which will be fit to transplant in ten days, or at farthest in a fortnight, after the seeds are sown. This second bed need not be very large, for a few of these plants, when planted out, will fill a large quantity of frames; and while they are young, the same quantity may be kept in one light, so that those persons who raise early cucumbers and musk melons, may also raise these plants in the same bed, for two or three lights will be sufficient to raise plants of all the three kinds to supply the largest families, until they are planted out to remain. In the management of these plants while young, there is little difference from the directions given for raising musk melons, which need not be repeated here. The chief thing to be observed is to let them have a large share of air whenever the weather will permit, otherwise the plants will draw up weak, and be good for little. As they will require two or three hot-beds to bring the fruit to perfection, it will be the better way to put the plauts into baskets, when they have put forth four leaves, two in each basket will be sufficient, for when both plants succeed, the weakest must be drawn out, which must be done before they put out their side-shoots, otherwise they will entangle, and then one can hardly be removed without seriously injuring the other. The baskets need only be twelve inches in diameter, so that one light will contain twenty-four of them, which will be sufficient to stock twenty-four others when they are planted out to remain; for where they are vigorous, a single plant will spread so far as to cover three lights, which they must be allowed to do, as they seldom set their fruit well when restrained from spreading : the baskets may remain in the nursery-bed until the plants have spread and put out many runners; for when the heat of the bed declines, it is soon revived by adding a proper lining of warm dung quite round the sides of the bed; so that when the plants are taken out and planted in the ridges where they are to remain, the heat of the beds will last so long as to set their fruit, which is of great consequence, for when the plants are ridged out very young, the beds are generally made of great thickness in dung in order to continue their heat, so that for some time after they are made, they are so extremely hot as

fruit begins to appear, there is fittle heat left in the beds, which often causes the fruit to drop off and come to nothing. After these plants are placed in the beds where they are to remain, carefully lead the shoots as they are produced, so as to fill each part of the frame, but not to crowd each other; and he careful to keep them clear from weeds, and also to admit fresh air whenever the weather will permit, and to water them, but only in small quantities. In short, there is iftle difference to be obscreed in the management of these from that of musk melons, except that they require more room.

Cudweed. See Athanasia.

Cumin. See Cuminum.

Cumiuma: a genus of the class Pentandria, order Digyria. -GENERIC CHARACTER. Celiz: numbel universal and partial often four-parted. *Involutere universal*: of as many leaves, which are very loag, perfectly entire, but in some three-cleft; partial similar; periantly proper scrueely manifest; florets all fertile. *Corolla*: universal, uniform; proper of five petals, inflex, emarginate, somewhat unequal. Stamina: filamenta five, simple. Anthere simple. *Pistil:* germen ovate, larger than the flower, inferior; styles two, very small; stigmas simple. *Periorp:* none side and convex, on the other flat. ESSENTIAL CHARACTER. *Involucees:* four cleft; unbellnles four; fruits ovate, striated.—The only known species is,

1. Cuminum Cyminum; Cumin. Root annual, round, scarcely branched; stem a palm in height; leaves divided into long narrow segments like those of fennel, but much smaller, of a deep green, and generally turned back at the end; peduncles opposite to the leaves, spreading the length of the internodes; rays of the umbel from four to six, nearly equal, spreading the third of an inch in length; corollas purplish, or pale blush-colour, rayed; fruit oblong, thicker in the middle, the same size as those of fennel, and aromatic: seeds convex on one side, on which are nine streaks, with minute bristles scattered over it, the other side is flat. They are kept in the shops, and have a very disagreeable flavour, but possess considerable virtues, being excellent against the colic, and wind in the stomach? bruised, and externally applied in the form of a plaster, they will frequently remove stitches, and other pains in the sides and breast; a large quantity of them must be laid on, when used in the latter case .- This plant flowers in June and July, and is a native of Egypt, cultivated in the south of Europe, and all over Lesser Asia. It is also commonly sold in Malta, where they call it cumin aigro, hot cumin, to distinguish it from anise, which they term cumin dolce, or sweet cumin. If the seeds of this plant be sown in small pots, filled with light kitcheugarden earth, and plunged into a very moderate hot-bed to bring up the plants, which, after having been gradually inured to the open air, may be turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth which adhered to their roots in the pots, and taking care to keep them clean from weeds: the plants will flower pretty well, and by thus being brought forward in the spring, will probably perfect their seeds when the seasons happen to be very warm.

are taken out and planted in the ridges where they are to remain, the heat of the beds will last so long as to set the -Genvlat; a genus of the class Dindria, order Monogynia. Fight, which is of great consequence, for when the plants are ridges out very young, the beds are generally made of great thickness in dung in order to continue their heat, so that here the results of the class Dindria conceptable, riggert some time after they are made, they are so extremely hot as to endanger the scalding of the plants and by the time the imentative, filtiong, and two rudineuts of filments i anthere roundish, twin. Pisitl: germen four-parted; style filtorm, length of the stamina; sigma two-clef, sharp. Pericarp; none; calix with its throat closed with shaggy hairs. Seed: four, oval, minute. EASEWIAL CHARACTER. Corolla: ringent; upper lip erect, flat. Filamenta: two, barren Seeds: four. These plants are all hardy, and may be propagated by seeds which they sometimes produce here.—— The species are.

1. Cmuila Marina; Mint-laced Cunila. Leaves ovate, serrate; corymbs terminating, dichotomous. There are two varieties of this species; one has narrower leaves and larger heads, and the lcaves have very little scent; whereas those of the common sort smell so like pennyroyal as scarcely to he distinguished from it.—It is pereminal, flowering from July to September, and a native of North America. It may be increased by planting entitings in the spring in the same manner as is practised for mint, as they will take root freely, and flourish exceedingly, if planted in a moist soil.

2. Cunita Pulegioides; Pennyrogal-leared Cunita. Leaves oblog, two-loothed; flowers in whorks. Annual, a span high, and brachiate; whorks of flowers the whole length of the plant; corolla white, with a vielt-coloured throat; the upper lip scarcely emarginate. It has a strong scent, and an infusion of it used in North America, by persons who have taken cold, or have pains in their limbs—Native of, dry places in North America, but so in Agust.

3. Cunita Thymoides; Thyme-Laved Cunita. Leaves oval, very entire; showers in whork; stem four-connered; stem creet, a span in height, with a few simple short branches; whorks of flowers like whole length of the stem.— It is an annual plant, and native of the country about Montpellier.

4. Cunila Capitata. Leaves ovate; flowers terminating; umbel roundish; stem a palm in height; leaves somewhat oblong, naked; catices smooth and even. streaked; corollas purple; antheræ black.—Native of Siberia.

Comminglamia; a genus of the class Tetrandria, order Mologvia.-GENERIC CHARCTER. Coliz: perianth oneleafed, four-toothed, very small, permanent. Corolla: onepetalled; tube short; border four-cleft, acute; nectary a rin surrounding the base of the style. Stamina: filamenta for, the same length with the border of the corolla, inserted in the throat; anthere roundish. Pistil: germen roundish, inferior; style filtform, bifdl; stigmas obtuse. Pericory: berry ovale; crowned, one-celled. Szed: single, ovate, twocelled, with oblong kernels. ESENTIAL CHARACTER. Abort Lube. Derry; crowned with a two-celled two-seeded ntt.--The outy species known is,

1. Cunninghamia Sarmentosa. A sort of ramping shrub, with the stem about six fect ligh, and four or five inches in diameter. The bark is reddish, wrinkled, and eloven; the wood whitish. As the shrub grows it pushes out towards right and left long twiggy branches, which apply themselves to the trunks of large trees, and insensibly climb to their tops, where they also spread, but in the same kind of long twiggy branches, many of which hang pendent to willin is are eight fer of the ground. The flowers, which are small, grow in spikes, proceeding from the bosons of the leaves to wards the extremittes of the twigs; their colour is bluish; the ealix reddish. This shrub is found on trees which grow near the Crique de Galibis.

Cunonia; n genus of the class Decandria, order Digynia. -GENERIC CHARACTER. Calix: perianth five-leaved, very small; leaflets ovate, eoncave, acute. Corolla: petals five, obovate, spreading, sessile. Stamina: filamenta ten, subulate, the length of the corolla; antheræ roundish, twin. Pisiti: germen conic; styles two, subulate, longer than the corolla; stigmas obluse. Pericarp i capsule oblong, acuminate, two celled. Steds: very many, roundish. Ess Ex-TIAL CHARACTER. Corolla: five-petialed. Calix : fiveleaved; capsule two-celled, acuminate, many-seeded; styles longer than the flower.— The only known species is,

I. Cunonia Capensis. A shrub: leaves opposite, pinnate, with an odd leaflet, sessile, and not larger than the rest; leaflets often seven, lanceclate, smooth, serrate; glads spatule-form, axillary, petioled; racemes terminating, in pairs, simple, with many one-dowered scattered pedicels springing from one point—Native of the Cape of Good Hope.

Cupania ; a genus of the class Octandria, order Monogyma; or class Polygamia, order Monoccia-GENERIC CHA-RACTER. Calix: perianth five-kwed, inferior; leaffets oblong, creet. Corolla: petals five, cowled at top, upright. Stamina: filamenta eight, capillary, longer than the calix, structure in cumbent. *Pistil:* germen ovate; style short, trifid; stigmas blunt. *Pericarp*: capsule coraccous, turbinate-ovate, three-lobed, three-celled, three-valved. Scal: solitary, roundish, with a bell-shaped cremate arit, *flowers are abortice*. ESSENTIAL CHARACTER. *Calix: flowers are abortice*. ESSENTIAL CHARACTER. *Calix: Chevelavel. Petals:* five, cowled at the top. *Style:* trifid. *Capadia:* three-celled. *Sceds:* solitary, arilled.—The species are,

1. Cupania Tomentosa. Leaves pinnate, obovate, retuse, ferruginous, tomentose underneath. Jacquin describes this tree as twelve feet high, the younger branches and ribs of the leaves slightly tomentose; leaves alternate, half a foot long; flowers small, numerous, with yellowish petals, in the shape of an isosceles triangle invested.—Native of the woods of Hispaniola.

2. Cupania Glabra. Leaves pinnate, ovate, obtuse, crenate, smooth. It rises to the height of twelve or fourteen feet. The leaves are large, and the wood soft and useless. This shrubby tree is common in the lower hills of Januaica, where it is called loblolly-tree.

3. Cupania Saponarioides. Leaves pinnate, oblong, entire, rugged underneath.-Native of the West Indies.

Cupressus ; a genus of the class Monœcia, order Monadelphia,-GENERIC CHARACTER. Male Flowers: disposed in an ovate ament. Calix : ament common, ovate, composed of scattered flowers, consisting of single-flowered scales, roundish, acuminate on their fore-part, peltate, opposite, about twenty in number. Corolla: none, their office is assumed by the calycine scale, to which grow four antheræ on the lower part. Female Flowers: heaped into a roundish cone on the same plant. Calix : strobile common, roundish, composed of from eight to ten florets, consisting of singleflowered seales, which are opposite, ovate, convex beneath, gaping. Corolla: none. Pistil: germen scareely evident. Numerous points appear within each calycine scale ; are they germina without styles, each with a single stigma? subtruncate, concave at the tip. Pericarp : none, strobile-globose, shut, gaping with orbiculate scales, which are angular and peltate beneath. Seeds: several, oblong, angular, subulate. small. ESSENTIAL CHARACTER. Male Calix: seale of an ament. Corolla: none. Anthera: four, sessile, without filamenta. Female Calix : of a strobile ; scale one flowered. Corolla : none ; styles concave ; dots nut angular .--The trees of this genus are all propagated by seeds, which should be sown early in the spring, on a bed of warm dry sandy earth, which must be levelled very smooth. The seeds should be sown rather thick, sifting the same light earth over

407

them, half an inch deep. If the weather should prove very warm and dry, it will be proper to shade the bed from the sun in the day, and water it carefully, lest the seeds should be washed out of the ground. If the seed sown be good, the young plants will appear in about two months' time. They must be kept clean from wecds, and often refreshed with water in dry weather. If the seeds be sown upon a moderate bot-bed, covered with mats, they will come up much sooner, and with greater certainty, than when they are sown in the cold ground. When the young plants have remained two years in this bed, they will be strong enough to bear transplanting into the nursery ; but as they are very tender while young, they should be covered with mats in severe frosts. The best season for removing them is the beginning of April, when the drying easterly winds of March are over, selecting if possible a cloudy day, w'an the weather inclines to rain. In taking them out of the seed-bed, preserve the roots as en-tire as possible, and, if you can, a ball of earth to each plant. The soil for the two first sorts should be a warm sand or gravel, which should be levelled, after it has been dug and cleansed from all noxious weeds. Then draw the lines where the trees are to be planted, at three feet asunder, planting them at eighteen inches' distance in the rows, observing to close the earth well to their roots, as well as to lay a little mulch upon the surface of the ground about their stems, and water them well, so as to settle the earth to their roots, which should be separated twice a week until the plants have taken fresh root. They may remain in the nursery three or four years, according to the progress they make, or till the ground where they are to be planted is ready. If, however, you desire to lct them remain longer, you should take up every other tree in the row, to transplant them out, for otherwise their roots will be matted together, so as to make it difficult to transplant them, as well as to endanger their future growth. They ought on no account to be left too long in the nursery, before they are transplanted out to remain, because they do not mat together so closely as many other sorts of evergreen-trees, whereby they may be taken up with a good ball of earth to their roots; but the roots of the cypress being apt to extend out in length, it is one of the most difficult trees to remove when grown large; therefore most curious persons prefer putting the young plants into small pots, when they first take them up out of the seed-bed, and so train them up in pots two or three years, uutil they are fit to plant out where they are to stand for good, and by this management they are secure of all the plants ; for these may be shaken out of the pots at any time of the year without dan-ger, and planted with their whole ball of earth, which is likewise a great advantage. When they are planted out to remain, if they be intended for timber, they should be placed twelve or fourteen feet every way apart. Those in the full ground should be carefully removed, observing not to shake the earth from their roots; to prevent which, you should open the ground about each tree, cutting off all long roots, then, working under the ball of earth, cut the downright roots off, and after pairing off all the earth from the upper part of the ball, to reduce the bulk of it, (so that its weight may not be too great for its fibres to support,) they may be carried upon a hand-barrow by two persons, to the place where they are to be planted, which, if very distant, will make it necessary to put them into baskets, or have their roots closely matted up. When they are planted, you must settle the earth close to their roots as before, laving a little mulch upon the surface of the ground about their stems, to prevent the sun and wind from entering the earth and drying their fibres. They must also be well watered, to settle the ground to their roots,

which must also be repeated, if the weather prove dry, until they have taken root; after which time, they will require little more care than to keep them clean from weeds.—— The species are,

CUP

1. Cupressus Sempervirens ; Evergreen Cupress, Leaves imbricate; fronds quadrangular; stem upright, with many round branches, either growing upright or spreading abroad, strigose and toothed, with the rudiments of leaves; fronds dichotomous, subquadrangular; fruits globular, or somewhat ovate on the sides or at the ends of the branches, when unripe dark green; seed linear, oblong, subcolumnar, bay-coloured. Mr. Miller specifically distinguishes the upright from the spreading cypress : according to his account, the former is very common in most of the old gardens in England. but are not at present so much in request as formerly: though it is not destitute of advantages, for it serves to add to the beauty of wildcrnesses, or clumps of evergreens, and has considerable effect where properly disposed. It was formerly planted in the borders of pleasure-gardens, and kept shorn to a pyramidal or conic form, while others, who thought that cutting would destroy them, tied them up with cords, in order to form the same figure in which they are naturally disposed to grow ; but this winding them about prevented the air from entering the inward parts of the branches, so that the leaves decayed, and became unsightly, and the growth of the whole plant was greatly retarded : even those which are sheared, if the operation be not performed in the spring or early in the summer, are very subject to be injured by sharp winds and cutting frosts in winter. Upon the whole, therefore, it is much better to suffer them to assume their natural form, planting them among other evergreen trees, where, by the darkness of their green leaves, together with their waving heads, they will greatly add to the variety. The second is by far the largest-growing tree, and is the most common timber in some parts of the Levant : this, if planted upon a warm, sandy, gravelly soil, will prosper exceedingly; and though the plants of this sort are not so fively shaped as the first, yet they greatly compensate that defect by their vigorous growth, and strength in resisting all weathers. This tree is very well adapted for intermixing with evergreeus of a second size, next to pines and firs, to form clumps, in which class it will keep pace with trees of the second line, and be very handsome. The wood of this tree is very valuable, when grown to a size fit for planks, which it will reach as soon as oaks; why, therefore, should not this tree be cultivated for that purpose, since there are many places in England where the soil is of a sandy or gravelly nature, and seldom produces any thing worth cultivating? Now in such places these trees will thrive wouderfully, and greatly add to the pleasure of the owner while growing, and produce afterwards as much profit to his successors probably as the finest plantation of oaks; especially if the timber prove as good in England as in the islands of the Archinelago, where we find it was so gainful a commodity to the island of Candia, that the plantations were called dos filior, the felling of one of them being reckoned a daughter's portion. The timber of this tree is said to resist the worm, moth, and all putrefaction, and to last many hundred years. The doors of St. Peter's Church at Rome were made of this material, which lasted from the time of the Emperor Constantine to that of Pope Eugenius II. and were then sound and entire, when the Pope exchanged them for gates of brass. Thucydides informs us, that the coffins in which the Athenians used to bury their heroes, and the mummy-chests brought with those condited bodies out of Egypt, were made of this wood, which is of a dusky brown red colour, has a sweet

409

st is fit, says Evelyn, for chests, and other domestic furniture ; harps and other musical instruments, being a sonorous wood ; for stakes to vines, pales, rails, and planks, of which there were some of this wood at Venice, above four feet in breadth. It is used for building by the Maltese and Cretans. It is recommended for the improvement of the air, and as a specifie for the lungs, by sending forth great quantities of aromatie and balsamic scents; hence, many of the ancient physicians of the Eastern countries, used to send their patients, who were afflicted with disorders of the lungs, to the island of Candia, which at that time abounded with these trees. The cypress, among the ancients, was sacred to Pluto and Proserpine, and was used at funerals, especially of persons of fashion. It was placed in front of the house, or in the vestibule, that no person who was to perform any sacred rites might enter a place polluted by a dead body; and the reason assigned for its use on this melancholy occasion was, that the cypress, when once cut down, never springs up again ; hence it would be an improper emblem in a Christian country, for the use of evergreens is yet not uncommon among us; but they are supposed to be significant of immortality, at the same time that their balsamic scent guards the attendants against the offluvia and infection that may be apprehended from a putrid body. On account of its extreme durability, Plato would have the laws and sacred rites inscribed on cypress tablets; and Pliny informs us, that the statue of Jupiter in the capitol, made of this wood in the year of Rome 661, was sound in his time. Notwithstanding all the excellent qualities it possesses, it is not much cultivated in England, principally because it cannot endure the frost of our winters, and the severe blasts which follow in the spring. The upright cypress above described is the most common sort in England, although it seldom produces good seeds ; it is therefore the best way to have the cones brought over entire from the south of France and Italy, where they ripen perfectly well, and take them out just before you sow them. When you wish to extract the seeds, expose the cones to a gentle heat, which will cause them to open, and easily emit their seeds. Dr. Hunter recommends the ground, in which the seeds are to be sown, to be well worked, turned over, and mellowed by frost; and, if the soil be not naturally sandy, to work in some drift-sand all over the bed, six inches deep, to sow the seeds moderately thin, because when they are sown too thick the roots become matted together, so that the plants cannot be removed out of the seed-bed into the nursery without great danger. Mr. Boutcher informs us, that if in the beginning of winter some sawdust be sifted over them, it will much contribute to their preservation, in case of severe weather. In the spring after sowing, the plants, if well managed, will be six or seven inches high, and should be removed and planted in rows eighteen inches asunder, and eight or nine inches from each other: they should remain here only one year, when they ought to be upwards of a foot high. In the second spring, they ought to be planted in the common nursery in rows three feet asunder, and eighteen inches from each other; and after having stood two years in this nursery, they may be removed to the place where they are to remain. As it is no uncommon thing for a hard winter to destroy whole beds of these plants, it becomes necessary to provide against such a misfortune, by sowing some seed in pots, which must be placed in a sheltered situation, so as to receive the morning sun till eleven o'clock, kept moderately watered, and removed in October under a frame. In the succeeding spring, let them be shaken out of these pots, and planted in others of fourteen or sixteen | very short, imbricated, and resemble those of the arbor vite; 35.

smell, and is fitted by its hardness for a variety of purposes. | inches diameter, each of which will admit from sixteen to twenty plants, which must be placed in the shade till in a free growing state, and removed in winter under a frame. Mr. Miller declares, that the spreading cypress is rare in England, and that the tree which has passed under that title, is only a variety of the common sort, the branches of which grow much looser; but that the true spreading cypress extends its branches horizontally from the first year, and continues to extend them to a great length, as the tree advances. He affirms, that it is certainly a distinct species, growing to a much larger size, and that there are some of a considerable stature in Italy. The fruit of the cypress, gathered before it is quite ripe, and dried, is an excellent balsamic and styptic medicine. It stops bleeding at the nose, the bloody flux, spitting of blood, and is beneficial in excessive discharges of the menses. Hill observes, that the fruit, which is the only part employed in medicine, ought to be gathered before it bursts, and carefully dried, and given in powder; five and twenty grains is the dose. Few are aware how powerful this remedy is, or it would certainly be held in greater estimation.

2. Cupressus Distieha; Deciduous Cypress Tree. Leaves distich, spreading .--- It is a native of America, where it grows in watery places, and rises to a prodigious height and wonderful bulk, some reaching seventy feet high, and being several fathoms in circumference. They grow constantly in water, and may therefore be of singular advantage to plant in such swampy or wet soils where few other trees will grow. especially of the resinous kind. That they are very hardy with respect to cold, is evident from some few trees of this kind, which were formerly planted in England; particularly one in the gardens of John Tradescant, at South Lambeth, near Vauxhall, which is upwards of thirty feet high, and of a considerable bulk : though in a common yard, where no care is taken of it, but, on the contrary, many hooks are driven into the trunk to fasten cords thereto for drying clothes, yct the tree is in great health and vigour, though it has not produced any fruit, which is often occasioned by want of moisture; for it is common to see many aquatic plants growing upon a drier soil, but seldom so productive either of flowers or fruit as those which grow in the water. The tree above described has however been long destroyed, and is only introduced here, to show how well this species will resist the cold of our climate. The cones may be easily procured from Virginia or Carolina, of which it is a native; and the seeds will rise as easily as those of the first species, for it is at least equally hardy. It was formerly kept in pots, and housed in winter; but did not succeed so well with this management. as since it has been planted in the full ground ; and it has always been observed to thrive best in a moist soil. By casting its leaves in winter, it does not suit with plantations of evergreens at that season, but in summer it has much the appearance of an evergreen. It may also be propagated by cuttings, which should be planted in a bed of moist carth in the spring, before they begin to shoot.

3. Cupressus Thyoides; White Cedar, or Arbor-vitæleaved Cupress. Leaves imbricate : fronds ancipital .- This tree grows to a considerable size in North America, where it is a native. It seldom exceeds fifteen feet high in England ; and when raised from cuttings, has rather the appearance of a shrub, not being above nine or ten feet high. Loureiro informs us, that in China and Cochin-china, where it grows naturally, it is only eight feet high. The branches are numerous, and stand two ways; the tree naturally forms itself into a regular head; the leaves are evergreen, flat, sharp, 5 M

they are small, and of a browner green than the common cypress. The fruit is blue, and not larger than the berry of the juniper, from which it is not easily distinguished at a little distance; but it is a perfect cone or strobile, having several nuts, like that of the common sort .- It abounds in the swamps of New Jersey, and in some parts of Pennsylvania and New York, but not further northward than lat. 41. 25. The number, however, has been greatly reduced; and as this tree requires to be of eighty years' growth from the seed before it can be used for timber, posterity will probably feel the want of this useful tree in America. It is used for fencing, and even for posts, but does not last in the ground so well as the red cedar, or juniperus Virginiana, but makes good canoes, poops, and other coopers' ware. Many houses are built of it, but it is in the highest esteem for shingles, and great quantities of it are sent for that purpose to New York ; and it is also exported to the West Indies, both for shingles and pipe staves. This tree, if planted in a strong moist soil, may become profitable for timber, and growing in a climate much colder than England, would undoubtedly succeed in the open air of our climate; and as it is an evergreen of regular growth, thrives in cold situations, and a moist soil which is unfavourable to other species of the same genus, besides being a great ornament to large plantations, it certainly deserves to be much encouraged. It is propagated by seeds sown in the spring, in boxes or tubs filled with light fresh earth, and placed where they are to enjoy the morning sun till eleven or twelve o'clock. They must be watered in dry weather, and kept clear from weeds. At Michaelmas they should be removed to a warmer place, for the plants seldom appear till the following spring, so that it will be proper to place the boxes or tubs near a south fence during the winter season, lest by being too much shaded, the wet should rot the seeds. In the second spring, if the tubs or boxes be placed on a moderate hot-bed, it will bring up the plants very soon, and greatly forward their growth; but as the spring advances, they should be advanced into the open air by degrees, and placed in a sheltered situation, where they may enjoy the morning sun, taking care to remove all weeds, and supply them with water in dry weather. In the following winter, it will be proper to remove the tubs near a south wall or pale; for while the plants are young, they are sometimes tenderer than they afterwards become. At the end of March, or the beginning of April, just before the plants begin to shoot, they should be carefully taken up out of the boxes, and having prepared a bed or two of fresh earth (according to the quantity of plants raised) in a sheltered situation, place the plants in it in rows about eighteen inches asunder, and about a foot from each other. This should be done in cloudy weather, when there is rain ; for in dry weather, when easterly winds commonly blow at this season, it will be very dangerous to transplant these plants; so that in dry weather, it had better be deferred a fortnight longer. until a change in the weather. When first planted, they should be watered, to settle the earth to their roots; and then the surface of the ground should be covered with mulch, to prevent the sun and wind from penetrating to the roots of these plants, for nothing is more injurious to them than to have their fibres dried when they are transplanted. They ought not, therefore, to be taken out of the tubs, until the ground be ready to receive them, for they cannot lie any time out of it, without great danger of perishing.

4. Cupressus Juniperoides; African or Cape Cypress. Leaves opposite, decussated, subulate, patulous. The young plants of this species, raised from seeds in England, have loose spreading branches, closely beset with narrow straight

leaves, alternately opposite, nearly an iach long, of a light green colour, and continuing in verdure all the year. The cones are black when ripe.—Native of the Cape of Goad Hope. This is too tender to thrive while young in the open air of England, but would probably do well in warmer situations, after the plants have acquired considerable strength. Young plants, placed under a frame which had no glass, but only wooden shutters, were not injured by the cold, though the earth of their pots was frequently fozen hard. The practice now is to keep them in pots, and house them in winter, till litey are a yard in height. When they are committed to the open air, they must have a dry warm soil, and a well-sheltered situation; nothing, however, can ensure them but the drystove.

5. Cupressus Pendula ; Portugal Cupress. Leaves imbricate, glandulose; fronds quandranglar, glaucous; branches hanging down. This is a small tree, with a glaucous appearance. The leaves are glandulous. The flowers resemble those of the first species. It is at present rare in the English gardens, though there have been many plants raised here, which, as it is not quite so hardy as the rest, have either perished, or been irrecoverably injured in severe winters. There are plenty of these trees growing at Busaco, near Coimbra in Portugal, where it is called the cedar of Busaco. and grows to be a timber tree, so that from thence the seeds may be easily obtained. It grows naturally at Goa, whence it was originally brought to Portugal, where it flourishes as above stated, although in England it seldom exceeds fifteen feet high. The branches extend horizontally to a great distance every way, quite from the ground ; they grow without much order, and have a very different appearance from the rest. Thunberg describes the cupressus pendula of Japan, to be a tree of a man's height, or rather more, erect and smooth ; and adds, that this handsome singular tree is easily distinguished from all the evergreens of this order, by its abundance of very long, dichotomous, pendent branchlets. It may be propagated from seeds, in the same manner as the common cypress, and the plants treated as directed for that species, with this difference only, that it will be proper to cover them during the two first winters after they are come up, especially if the frost should be severe, which might destroy them while young and exposed. It may also be propagated by cuttings, which, if planted in autumn, and screened in winter, will take root; but are generally two years before they will be rooted enough to transplant; nor will the plants so raised thrive so fast as the seedlings, which are therefore greatly to be preferred whenever she seeds can be obtained.

6. Captressus Japonica; Japan Cypress. Leaves in four rows, sickled, compressed, furrowed, decurrent. 'This is a very lofty straight tree, with a trunk the thickness of the human thigh, or more. The wood is very soft, and is much used for cabinets, and other furniture, that are varnished or japanned, as it is termed.—Naitve of Japan.

7. Cupressus Columnaris. Leaves imbricate, subulate, furrowed; strobiles cylindric, elongated.—Native of New Caledonia, and Norfolk Island.

Curacila : a genus of the class Polyandria, order Digynia. -GENERIC CHARACTER. Caliz: perianth five-leaved, rounded : leaflets roundish, concave, the fifth interior, estremely like the petals. Corolla: petals three or four, roundish, concave, very like the calix. Stamina: filamenta very many, filiform, shorter than the corolla; anthere roundish. Petali : germen two-parted, roundish; styles two, filiform, ereet, length of the stamina; stigmas headed. one-celled; seeds in pairs, obloug, shining. ESSENTIAL CHARACTER. Calix: five-leaved; petals four; styles two; capsule two-parted, with two seeds in a cell.— The only known species belonging to this genus is,

 Curatella Americana. It is of the stature of coccobba. Leaves alternate, oblong, subsessile, large, very rough; flowers in racemes from the axils of the leaves, which have already fallen, the division of the raceme having two bractes. —Native of South America.

Curveilgo: a genus of the class Polygnnia, order Monecia. GENERIC CIABACTEM. Hirraphrodit: flowers few, below. Caliz: none. Corolla: petals six, oblong, spreading, withering. Stamina: Ifianenta six, very short. Authere linear, erect. Pistil: germen sessile, lanceolate; style very short; stigma large, tapering with a three-cleft apex. Pericarp: enpsule, when a germen, three-celled, with the peaked. Male Flowers: several shove. Corolla and Stamina: sh before. Pistil: wanting. ESENTIAL CHARAC-TER. Caliz: none. Corolla: six-petalled; filmenta six. Pistil: one. Capsule: seeds beaked.——The only known species is,

1. Curculige Orchioides. Root tuberous, with many fleshy vernicular fibres; leaves numerous, all radical, petioled, sword-form, nerved, slender, with very few soft white hairs on them while young, from six to eighten inches long; flowers pretty large, yellow, the one or two lowest most hermaphrodite, above all male.—Native of the shady unculit, wated places about Samulotath; it is the *nallatady* of the Telingas. Gerther remarks, that it differs from all other plants in the singular structure of the style and capsule, and the seed, thickening upwards, and being slightly incurved.

Curcuma; a genus of the class Monaudria, order Monogynia .- GENERIC CHARACTER. Calix : perianth superior, obscure. Corolla: tube of the petals narrow; border threeparted; divisions lanceolate, spreading, gaping more on the sinus: nectary one-leafed, ovate-acuminate, larger than the divisions of the petal, inserted into the more open sinus. Stamina: filamenta five, of which four are erect, linear, barren; one, (the fifth,) within the nectary, linear, petal-form, with a two-cleft tip. Antheræ adnate. Pistil: germen roundish, inferior; style length of the stamina; stigma simple, hooked. Pericarp : capsule roundish, three-celled, three-valved. Seeds : very many. ESSENTIAL CHARAC-TER. Stamina: four barren, fifth fertile. Corolla: fourparted; nectary three-lobed; filamenta flat .-- These plants must be placed in the bark-stove; they are only propagated by parting their roots in the spring, before they put out new leaves: plant them in rich kitchen-garden earth, and keep the pots constantly plunged in the bark-bed. In summer, when the plants are in a growing state, refresh them frequently with water, but not in large quantities, and admit a large share of air to them in warm weather. When the leaves are decayed, they should have very little wet, and should be kept in a warm temperature. They usually flower in August, but strong roots only produce flowers .----- The species are.

1. Curcuma Rotunda; Round-rooted Tarmeric. Leaves lanceolate-ovate; lateral nerves very few; root perennial, with a large ovate bulb, frequently as big as a goose's egg, covered with a thin rufescent pellicite, that has parallel rooting rings, within solid, fleshy, reddish yqlow, of a bittersish taste, and slightly aromatic smell; stem none; leaves annual, there feet high; flowers in a loose spike of ayellowish colour.

-Native of the East Indies, and the mountains of China and Cochin-china.

CUR

2. Curcuma Longa; Long-rooted Turmeric. Leaves lauceolate; lateral nerves very numerous; root perennial, creeping, fleshy, palmate, with columnar branches, and parallel rooting rings, the skin thin and pale, the flesh sailron-coloured, with a bitterish taste, and a smell of salve; stem none; leaves broad lanceolate, large, quite entire, smooth, annual, pale green, grooved with oblique, slender, frequent lines; flowers sessile, white, with a yellow nectary, solitary, and enclosed within the scales of the spike; corolla one-petalled, funnelshaped; tube slender, equal to the calix, widening above ; seeds round, few; it has no barren filamenta .- Native of the East Iudies, China, and Cochin-ceina. It very seldom produces seed, but was much used formerly in cookery, to give things a colour, for which purpose it is still used in the East. as well as for dyeing. The root of this plant had the reputation of being a powerful aperient and resolvent, being commonly prescribed in obstructions of the liver, and other chronic complaints : the disease in which it has been thought to be most efficacious, is the jaundice; it is now, however, very rarely employed in Europe: the general dose, in substance, is from a scruple to a drachm; it tinges the urine of a deen yellow colour. It is yet in high repute in the East, where the first species being stronger, is seldom internally applied, but is used externally as a cataplasm, with the root of crinum zevlanicum, and the leaves of artemisia, and are esteemed a sovereign remedy in swellings of the abdomen, arising from a suppression of the menses. The English druggists, says Hill, keep the dried roots, which are good in the jaundice, and all obstructions, operating as a diuretic, and promoting the menses. Mevrick declares the root of turmeric to be one of the most effectual remedies known in obstructions of the viscera and mesentery, as also of the menses, strangury, and affections of the kidneys ;- many also, he remarks, esteem it as a specific in the jaundice; the dose in substance is from a scruple to a drachm, and three or four times as much in decoction or infusion.

3. Curcum Palida. Bulbs knotted ; scape long, bracted. An annual plant, without any stem, apright, three feet higt ; root perennial, horizontal, creeping, oblong, columnar, twisted and knotty, within and without pale, flesity, with little smell or taste ; leaves lancolate, large, with several oblique slender grooves; corolla yellowish white.—Native of China near Canton, and of Cochim china.

Currants. See Ribes.

Curtisia ; a genus of the class Tetrandria, order Monogynia-GENRETC CHARACTER. Calit: perianth one-leafed, four-parted ; parts ovate, acute. Corolla: petals four, ovate; obtuse, esseil, clonger than the calix. Stamisa: filamenta four, inserted into the receptacle, subulate, shorter than the petals. Antherae vorate. Pitili: genue superior, ovate; style subulate, the length of the stamina; stigma four or fivecleft. Pericary: drups subglobular, smooth. Seed: nut roundish, bony, four or five-celled kernels, solitary, oblong. ESENTIAL CHARACTER. Calix: four-parted. Petals: four. Drupe: superior, roundish, succulent, with a four or five-celled nut.—The only known species is.

1. Curtisia Fagimen : Brech-leared Curtisia, or Hassaggy Tree. This is one of the largest trees in the African woods, with very diminutive flowers. The Hottentots and Caffres make the shad of their javelines or assaggasy from the wood of this tree: they always carry one or two of these with them on their journeys, which consist of an iron spear hollowed out on each side about six inches long, with or without an iron shaft, which is sometimes round and smooth, and some-

CYA

times grooved; it is fastened with thongs of leather to a among pulse and on heaths; it has been also often seen on slender round stick five feet long, tapering towards the end, and made of this wood. With these lances, which they throw with great dexterity to the distance of an hundred paces. the Hottentots aud Caffres defend themselves, and kill buffaloes and other wild animals. The Dutch call this tree witeelse, stink hout, and assagay-hout; the English, hassagay or assugay tree, from its use among the natives of the Cape of Good Hope.

Cuscuta; a genus of the class Tetrandria, order Digynia. -GENERIC CHARACTER. Calix : perianth one-leafed, cup-form, four-cleft, obtuse, fleshy at the base. Corolla: one-petalled, ovate, a little longer than the calix ; mouth fourcleft, obtuse; nectary of four scales, which are linear, twocleft, sharp, and growing to the corolla at the base of the stamina. Stamina : filamenta four, subulate, length of the calix. Antheræ roundish. *Pistil* : germen roundish ; styles two, erect, short ; stigmas simple. *Pericarp* : fleshy, roundish, two-celled, cut round, or opening horizontally. Seeds: in pairs. ESSENTIAL CHARACTER. Calix: four-cleft. Corolla: one-petalled. Capsule: two-celled.—This genus consists of parasitical plants, fastening themselves to, and drawing their nourishment from others; the seed does not split into lobes, but opens and puts forth a little spiral body, which is the embryo; the stalks twine about some other plant, contrary to the apparent motion of the sun. They adhere to the ground by the original, and at first draw a part of their nutriment thence; but the original root withers away as soon as the young stem has fixed itself to any other plant .---- The species are,

1. Cuscuta Europæa; Common Dodder. Flowers conglomerate, sessile; corolla pitcher-shaped, with bluntish segments ; number of parts generally four ; stem slender, filiform, smooth, four-cornered, reddish; a small, single, ovate-acute scale under each ball of flowers, where also it frequently puts forth a branch; corolla white, or with a tinge of purple; seeds generally two in each cell .- Native of Europe, in hedges, usually upou hops, brambles, woody nightshade, fern, thistles, hemp; also on flax, nettles, clover-grass, &c. and lofty plants in general : it flowers in July and August. The whole plant is bitter; an infusion of it, according to Meyrick, in the proportion of an ounce to a pint of water, is a brisk purge, and is of coniderable efficacy in obstructions of the viscera, as well as in the sciatica and scorbutic complaints. The fresh herb, bruised and applied externally, is excellent in dispersing scrophulous tumors. Dodder, says Hill, is best tresh gathered ; it is to be boiled in water, with a little ginger and allspice, and the decoction works by stool briskly; it also opens obstructions of the liver, and is good in the jaundice, and many other disorders arising from the same cause. The dodder which grows upon garden thyme has been usually preferred to others, and supposed to possess peculiar virtues from the plant on which it grows; but this is imaginary, as experience shows it to be only a purge like the other, only less powerful : the common dodder is preferable, because we can gather it fresh; while the other is imported, and we can only have it dried, in which state it often loses a great deal of its virtues in the hands of the druggist.

2. Cuscuta Epithemum; Small Dodder. Flowers conglomerate; corolla bell-shaped, deeply cloven with acuminate segments; number of parts constantly five; corolla paler than that of the common sort, deeper cut; the segments sharper and smaller; the balls of flowers closer. From its destructive quality of suffocating plants, it has the opprobrious names of hell-weed and devil's guts .- It is annual, and flowers from June to August. It is found in cultivated fields, particularly

beans, nettles, and heath, furze, flax, thyme, wild thyme, lavender, spurge, hops, grass, &c.

3. Cuscuta Americana ; American Dodder. Flowers peduncled. This is a very branching, leafless, twining, parasitical plant, tender, shining, and vellowish; common peduncles very short; flowers small, without scent, aggregate, vellowish or greenish. Sloane says, the stems are very long and strong, stretching themselves over very large trees, and whole fields and pastures .- Native of America, ou shrubs and trees. and, according to Brown, creeping on the grass and lower bushes.

4. Cuscuta Lupuliformis; Hop Dodder. Flower racemed, sessile : number of parts four ; stem round, brauching, very thick like hop-binds ; bark reddish green or brown purple, rough and studded with stiff rising grains like millet; flowers on racemes, coming out laterally, an inch or two in length, sometimes branched; they are scattered, solitary, or only two or three together, not glomerate, sessile, not peduncled. This species also climbs trees -It is annual, a native of Silesia, and flowers in July and August.

Cussonia: a genus of the class Pentandria,-GENERIC CHARACTER. Calix : umbel none, but three or more peduncles, umbelled, collecting the flowers into a raceme or spike; involucre none, but scattered bractes at the base of the peduncles; periauth one-leafed, truncate, obscurely fivetoothed, shorter than the corolla, permanent. Corolla: petals five, oblong, acute. Stamina : filamenta five, very short. Antheræ ovate. Pistil: germen inferior, turbinate; styles two, filiform, patulous; stigmas simple, obtuse. Pericarp: twin, compressed, angular, crowned with the calix and styles, two-celled, two-valved. Seeds: solitary. ESSENTIAL CHA-RACTER. Petals: three-cornered; margin of the receptacle dilated into a five toothed calix .---- The species are,

1. Cussonia Thyrsiflora. Leaves digitate; leaflets sessile, wedge-form, truncate, three-toothed; flowers racemed; stem frutescent, at bottom scabrous, unequal, simple, the thickness of a finger, very simple at top. There is a variety of this with jointed leaflets, the lowest joint dilated at the end iuto smaller lobes, whence the leaflets are as it were proliferous .---Native of the Cape of Good Hope.

2. Cussonia Spicata. Leaves digitate; leaflets petioled, spatulate; ligule three or five palmate, finely serrate; flowers in spikes .- Native of the Cape of Good Hope,

Custard Apple. Sce Annona.

Cuanella : a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix : none. Corolla : petals six, cohering by their claws, oblong, concave, patulous, the three inferior ones hanging forwards. Stamina : filamenta six, contiguous at the base, very short, somewhat spreading, the lower one declined, and twice the length of the others. Antheræ obloug, erect, gaping at the tip, with four obtuse teeth. Pistil: germen three-cornered, obtuse; style filiform, declinate, length of the lower stamina; stigma somewhat sharp. Pericarp : capsule superior, roundish, three-furrowed, three-celled, three-valved. Seeds: many, oblong. ESSENTIAL CHARACTER. Corolla: six-petalled, the three lower petals hanging forwards; stamina lower, declined, longer than the rest. The roots of these plants should be planted in pots filled with light earth, placed in winter in a frame, and treated in the same manner as is directed for Ixia. -The species are.

1. Cyanella Lutea; Yellow-flowered Cyanella. Leaves ensiform; branches creet .--- It flowers in July, and was found by Sparrmann at the Cape of Good Hope.

2. Cyanella Capensis; Purple-flowered Cyanella. Leaves

413

waved; branches spreading very much; the root is shaped | The native Indians of Ternate, Tidore, and all the spice islands. like that of the spring crocus ; leaves long, narrow, with a groove on their upper side; the peduncle arises immediately from the root, supporting one flower of a fine blue colour. which appears in May, but are not succeeded by seeds in England : the roots are roasted and eaten, in Africa .- Native of the Cape of Good Hope.

3. Cyanella Alba; White-flowered Cyanella. Leaves linear, filiform .- Found by Thunberg at the Cape of Good Hope.

Cycas ; a genus of Palms, class Diœcia, order Polyandria. -GENERIC CHARACTER. Male. Calix: spathe none; spadix none; ament strobile-form, ovate, squarrose, imbricated with scales; scales spathule form, smooth, fleshy, coloured, keeled beneath, with a reflected point, distant. Corolla: none, Stamina: filamenta none. Antheræ none; pollen spread with the upper surface of the scales of the ament, sessile, very plentiful, very crowded, somewhat globose, one-celled, bursting longitudinally on one side. Fe-male: in a distinct individual. Calix: spathe none; spadix very simple, compressed, ancipital, long, sharpened; perianth none. Corolla : none. Pistil: germina solitary, immersed beyond the middle into the corners of the spadix, remote, roundish ; style cylindric, very short ; stigma simple. Pericarp: drupe oval, one-celled. Seed: nut woody, one-celled. ESSENTIAL CHARACTER. Male: ament strobile-form, with the scales covered every where beneath with pollen. Female, Spadix: sword-form. Germen: immersed into the corners of it, solitary. Style: one. Drupe: with a woody nut. The trees of this genus require to be plunged into the bark bed in the stove, which should be kept up fully to temperate heat in winter, but in summer should be much hotter. In hot weather they will require to be frequently refreshed with water, but must have it sparingly administered in autumn and winter .---- The species are,

1. Cycas Circinalis; Broad-leaved Cycas. Fronds pinnate: leaflets linear, flat .- Native of the East Indies, the Friendly Islands, and the New Hebrides in the South Seas.

2. Cycas Revoluta; Narrow-leaved Cycas. Fronds pinnate; leaflets linear, revolute about the edge; trunk round, branched, a fathom or more in height, the thickness of the thigh, ferruginous, and hirsute from the falling off of the leaves; the stipe of the fronds has spines below; the leaflets are nearly opposite, linear, somewhat sickle-shaped towards the inside; the fruit is an ovate, flat, red drupe, an inch and half in length; the fruit is eaten by the Japanese, but the pith of the trunk is most esteemed for its highly nutritive quality; they affirm that a soldier can subsist on a very small piece of it. It is not used for food in China or Cochinchina, but is cultivated there for its beauty. In Tonquin, however, they make a sort of bread called sugu, from the pith of the trunk. Dampier says, that the inhabitants of Mindanao, one of the Philippine Islands, call the sago-trees libby-trees, and that they grow wild in great groves of five or six miles long, by the sides of the rivers. Its body and shape are much like the palmeto or cabbage-tree, but is not so tall as the latter; the wood is full of white pith, like that of elder : they cut down the tree, split it in the middle, and scrape out all the pith, which they beat lustily with a great pestle in a wooden mortar or trough, and then put it into a cloth or strainer held over a tub, and pouring water in among it, they stir it about, so that the water carries all the substance of the pith through the cloth, leaving a sort of husk behind. which is thrown away : that which runs into the trough settles to the bottom like mud, which, when the water is drawn off, they bake into cakes, and make very good bread. The Mindanese live three or four months of the year on this food, 35.

have plenty of these trees, and use them for food ; the sago, which is transported into other parts of the East Indies, is dried in small pieces like little seeds or comfits, and commonly eaten with milk of almonds by those that are troubled with the flux.

Cyclamen; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth half fivecleft, roundish, permanent; divisions ovate. Corolla; onepetalled : tube somewhat globose, twice as large as the calix. small, nodding; border bent upwards, five-parted, very large; divisions lanceolate; neck prominent. Stamina : filamenta five, very small, in the tube of the corolla. Antheræ straight, sharp, in the neck of the corolla, converging. Pistil: germen roundish; style filiform, straight, longer than the stamina; stigma sharp. Pericarp: berry globose, one-celled, gaping five ways at the top, covered with a capsular cell. Seeds : very many, somewhat ovate, cornered. Receptacle: ovate, free. ESSENTIAL CHARACTER. Corolla: rotate, reflex, with a very short tube and prominent throat; berry covered with a capsule. All the sorts are propagated by seeds, which should be sown soon after they are ripe, in boxes or pots filled with light kitchen-garden earth, mixed with a little sand, and covered about half an inch deep, placing them where they may have only the morning sun till the beginning of September, when they may be removed to a warmer exposure .---The species are,

1. Cyclamen Coum ; Round-leaved Cyclamen. Leaves orbicular, cordate, quite white; it has plain orbicular leaves, with short weak petioles, their under side is very red in the beginning of winter, but that colour goes off in the spring ; their upper side is smooth, of a lucid green, and spread flat open: whereas the other sorts are hollowed, and reflex at the base; the flowers are very bright purple, and as they appear in the middle of winter, when there are few other flowers. they are the more valuable. This and the second and fourth species may be plunged into the ground, close to a south wall, a pale, or reed-hedge, in October, where, if the frost be very severe, it will be proper to cover them either with mats or pease haulm, but in common winters they will not waut covering.

2. Cyclamen Europæum; Common Cyclamen. Leaves orbicular, cordate, crenate; root tuberons, oblately spheroidal. white within, brown without; leaves kidney-form, roundish, very blunt, slightly crenulate, deep green and spotted above, beneath commonly red purple, smooth, on very long round red petioles; flowers drooping, sweet-scented, purple; seeds large, rufous, kidney-form.—Native of Austria. 3. Cyclamen Persicum; Persian Cyclamen. Leaves ob-

long, ovate-cordate, small; leaves stiff, on strong fleshy petioles, nearly six inches long, of a purple colour, as are also the veins of the leaves underneath, but the upper side is veined, and marbled with white; the corolla is pure white, with a bright purple bottom, but it varies in colour, and is sometimes entirely white; this variety smells very sweet. It flowers in March and April, and ripens seeds in August. It is admirably adapted to decorate the parlour or the study, and varies with fragrant flowers with the eye more or less red .- By its name it should be a native of Persia, but from Mr. Curtis we learn that it comes from the East Indies ; and Dr. John Sibthorp found it in the island of Cyprus. The pots in which it is sown should be placed under a common hot-bed frame, where they may be protected from frost and hard rains, but the glasses may be taken off every day in mild weather, to admit the fresh air. This species is more impatient of cold than any of the others, and must be con-5 N

stantly preserved in pots filled with light sandy earth, or a mixture of loam and lime rubbish, and housed in winter, but should be placed near the glasses, where the plants may enjoy as much free open air as possible, when the weather will permit, for if they be crowded too closely under other plants, they are very subject to mould and rot.

CYL

4. Cyclainen Hederæfolium; Iry-leaved Cyclamen. Leaves cordate, angular, toothletted; root large, orbicular, compressed; leaves numerous, on petioles six or seven inches long; the leaves are marked with black in the middle; the flowers appear before them on long fleshy scapes in August or September, soon after the leaves come out, continue growing all the winter and spring till May, when they begin to decay, and in June are entirely dried up. There are two varieties of this species, one with a white, and the other with a purplish flower .- Native of Italy. Found by Mr. Ray in the neighbourhood of Rome.

5. Cyclamen Indicum. Border of the corolla nodding. It differs only in having the divisions of the corolla not reflected but hanging down, and the whole corolla being much larger than in the European species .- Native of Ceylon.

Cuclas ; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: neriauth oneleated; tube short, turbinate; border four-parted, patulous; segments ovate-oblong, acute. Corolla: none. Stamina: filamenta ten, capillary, inserted into the neck of the calix, and longer. Autheræ ovate. Pistil: germen ovate-oblong, villose, pedicelled; style capillary, flexuose; stigma obtuse. Pericary : legume roundish, depressed, wrinkled, surrounded by an orbicular, membranaceous, broad, waving wing, onecelled, not opening. Seed : single, kidney form. ESSEN-TIAL CHARACTER. Calix: four-parted, spreading, with a short turbinate tube. Corolla: none; filamenta inserted into the neck of the calix ; style flexuose ; legume rouudish, winged, one seeded .---- The species are,

1. Cyclas Spicata. Leaves pinnate. The trunk of this tree is from thirty to forty feet high, and a foot and half in diameter; the bark is gray and smooth, and the wood whitish; it has several large boughs at top spreading in all directions ; leaves alternate, unequally pinnate; stipules in pairs at the base of the common periole ; flowers in long spikes, axillary, and terminating in short pedicels .- Native of the great forests of Guiana, flowering there in November, and fruitiug in January. The Caribbee name is apalatona.

2. Cyclas Aromatica. Leaves ovate. The trunk of this tree is from forty to fifty feet high, and more, and about two feet in diameter; bark gray; wood white, and not compact; branches very numerous, spreading in every direction; leaves alternate, large, stiff, ovate, acute, smooth, quite entire. The wood is white, and a little aromatic. The Caribbees call this tree montinchiraou .- It is a native of marshy places in the great forests of Guiana, where it flowers in December, and fruits in May.

Cylista; a genus of the class Diadelphia, order Decandria. -GENERIC CHARACTER. Calix : perianth one-leafed, four-parted, very large, permanent, the upper division reflex, bifid, the rest erect, oblong, acute. Corolla : papilionaceous, a little longer than the calix, and permanent ; banner roundish, emarginate, with a small lobe on each side of the base; wings oblong, obtuse, shorter than the banner, with a process on each side of the base; keel oblong, cleft at top and bottom, longer than the wings. Stamina: filamenta diadelphous, (simple and nine-cleft) ascending. Antheræ roundish. Pistil: germen superior, ovate, compressed; style subulate, aseending; stigma subcapitate. Pericarp: legume ovate-ob-long, compressed, one-celled. Seeds: two, oval. ESSEN- from its having stems without any leaves on them. It sends

TIAL CHARACTER. Calix: very large, four-parted, the upper division cleft at the end. Corolla ; permanent .----The only known species is.

1. Cylista Villosa ; Hairy Cylista. A shrub requiring the heat of a stove to preserve it ; flowering in April and May .----Native country unknown.

Cumbachne: a genus of the class Polygamia, order Monœcia.-GENERIC CHARACTER. Hermanhrodite Flowers. Calix: glume two-valved, one-flowered, so placed that each valve is pressed close to the rachis and parallel, not one hid by the other; outer valve linear, blunt, ciliate at the back, inner equal in length, semiovate, acute, boat-shaped, very much compressed, striated, coloured, ciliate at the back, inclosing the corolla. Corolla: two-glumed, hyaline, smaller than the calix. Stamina: filamenta three. Antheræ black. Pistil: germen minute; style simple; stigmas two, blackbearded. Female Flowers, Calix ; one-valved, ovate, slightly bifid at the tip, ciliate at the edge, opposite to the rachis, pressed close, Corolla: none, Pistil: as in the hermaphrodite, but with longer stigmas. ESSENTIAL CHARAC-TER. Inflorescence: half-spiked. Hermaphrodite. Calix: two-glumed, one flowered, parallel to the rachis, outer valve linear, the opposite boat-form. Female. Calix : one-glumed. ovate, opposite to the rachis .---- The only known species is,

1. Cymbachne Ciliata. This is a slender grass, a foot in height, with several culms, simple or branched, with a single leaf or leafless ; leaf short, slender, ciliate on the edge above the sheath, with long separate hairs; sheath truncate, with a pale brown mouth, and ciliate; spikes two, terminating, linear, an inch and half long, a line broad, some hermaphrodite, others female .- Native of Bengal.

Cymbaria; a genus of the class Didynamia, order Angiospermia.-GENERIC CHARACTER. Calix: perianth tentoothed, erect, two opposite teeth stronger and more spreading, the rest erect, linear, permanent. Corolla : one-petalled, ringent ; tube oblong, bellied ; border two lipned, upper lip two-parted, reflex, obtuse, lower lip three-cleft, obtuse. Stamina: filamenta four, length of the tube. Antheræ two cleft, prominent. Pistil: germen ovate; style filiform, length of the stamina ; tip incurved ; stigma obtuse. Pericarp ; cansule ovate, one-celled, two-valved; receptacle quadrangular. Seeds: very many, cornered, smooth. ESSENTIAL CHA-RACTER. Calix: ten-toothed ; capsule cordate, two-celled. The only known species is, 1. Cymbaria Daurica. The whole plant is hoary, and

nearly allied to antirrhinum; branches opposite, barren; flowers lateral, very few, subsessile, large, upper lip of the corolla vaulted; lower equal; palate gibbous .-- Native of the mountains of Dauria.

Cunanchum : a genus of the class Pentandria, order Digynia .- GENERIC CHARACTER. Calix: perianth one-leafed, five-toothed, erect, very small, permanent. Corolla: onepetalled; tube scarcely any; border five-parted, flat; divisions linear, long; nectary in the centre of the flower, length of the corolla, erect, cylindric, with a five-cleft mouth. Stamina : filamenta five, length of the nectary, parallel. Autheræ touching, within the mouth of the corolla. Pistil: germen oblong, two-cleft; style scarce any; stigmas two, obtuse. Pericarp : follicles two, oblong, acuminate, one-celled, gaping lengthwise. Seeds: numerous, oblong, crowned with a down, placed in an imbricate manner. ESSENTIAL CHA-RACTER. Contorted. Nectary: cylindric, five-toothed. -----The species are,

1. Cynauchum Viminale; Naked Cynanchum. Stem

out a great number of slender taper stalks, of a dark green | springing aggregately from a tubercle among the leaves; colour, which are smooth, and twist about each other, or any neighbouring support, and then will rise to the height of ten or twelve feet, putting out branches at top, which also twine about the other stalks. It has not flowered in England. -Native of the Cape of Good Hope. This, and the eleventh, twelfth, and fifteenth species, come from the Cape, and must be preserved in the dry-stove. They may be increased either by layers or cuttings.

2. Cynanchum Acutum ; Acute-leaved Cynanchum. Stem twining, herbaceous ; leaves cordate, oblong, smooth ; root perenuial, creeping; stems annual, twisting like hops round whatever plants are near them, and rising to the height of six or eight feet ; leaves ending in acute points ; flowers in small axillary bunches, of a dirty white colour .-- It flowers in June and July, but does not produce seeds in England, occasioned probably by the roots creeping so far under ground; for most plants which propagate themselves so much by their roots become barren, especially if their roots have full liberty to extend. This and the eighth species, being natives of the south of Europe, are hardy, and propagale too fast by their creeping roots, which are not easily extirpated, when they have once got possession of the ground. The roots may be transplanted any time after the stems decay, till they begin to shoot in the spring.

 Cynanchum Planiflorum; Flat-flowered Cynanchum.
Stem twining; leaves cordate, smooth, tonientose under-neath; peduncles subracemed. This is a milky plant, with twining, round, smooth stems; leaves oblong, cordate, acuminate, quite entire, very soft, with a scarcely conspicuous nap underneath, smoothish on the upper surface, but bearded at the origin of the petiole, with abrupt, rigid, ferruginous cilias : common pedancles smooth, lateral, solitary, sustaining about five flowers, on pedicels elongated beyond the common one; flowers void of scent, very flat, half an inch in diameter: corollas veined and aruginose: calices greenish white .- It flowers in July and August, and is a native of This, with the fourth, fifth, Carthagena in New Spain. seventh, ninth, tenth, thirteenth, sixteenth, seventeenth, eighteenth, nineteenth, twentieth, twenty-first, twenty-second, third, fourth, fifth, sixth, and seventh species, are all tender, and will not thrive in this country, unless placed in a bark-stove. As they abound with a milky juice, they must have but little water in winter. They may be propagated by laying down the young shoots, which in three or four months will put out roots, and may then be transplanted into pots filled with light sandy earth, and plunged into the tan-bed, where the plants should continue all the year. They may also be increased by parting their roots, or by cuttings from such as produce good seeds in Europe, which are tender, but will succeed when propagated in that way.

4. Cynanchum Racemosom ; Racemed Cynanchum, Stem twining; leaves cordate, smooth, acute; racemes simple; stem herbaccous, twining, smooth, scandent, full of a white milky juice; leaves quite entire, shining, slightly waved, bright green on the upper surface, æruginose on the back, petioled ; racemes lateral, three inches long, solitary, but by the side of the principal a smaller branch comes out, which is also loaded with flowers ; they are scentless, small, and white .- It flowers in October and November, and is a native of Carthagena. See the third species.

5. Cynanchum Maritimum; Sea Cynanchum. Stem twining; leaves cordate, hirsute, tomentose underneath; peduncles aggregate. A milky plant, with twining, round, hirsute stems; leaves acuminate, quite entire, petioled, from two to

flowers scentless, with a a green calix, and a dark purple corolla .- It flowers in November, and is a native of the coast of Tierra Bomba. For its culture and propagation, see the third species.

ĊÝŇ

6, Cynanchum Suberosum; Cork-barked Cynanchum. Stem twining, cork-barked at bottom, and cleft ; leaves cordate, acuminate; root perennial; stems slender, hairy, twining, and, if supported, rising six or seven feet high ; the lower part is covered with a thick fungous bark, somewhat like cork, and full of fissures. At each joint is a pair of leaves, on long hairy footstalks. The flowers are in small axillary bunches; they are star-shaped, and green when they first appear, but afterwards change to a dusky purple colour. --Native of Carolina. It will live in the open air of England, if it be planted in a dry soil, and a warm situation. It may be increased by laying down the young shoots about Midsummer, which, if they are now and then refreshed with water. will put out roots, and may be transplanted in the autumn where they are designed to remain. The roots should be covered in winter with some rotten tan, to keep out the frost,

7. Cynanchum Hirtun; Hairy Cynanchum. Sten twin-ing, slirubby, cork-barked, aid cleft at bottom; leaves ovate-cordate. It rises to the height of twenty feet, or more, with a twining stem, if supported. The lower part is corkbarked and full of fissures, like the preceding ; leaves on long footstalks, smooth; flowers of a vellowish green colour. not succeeded by pods in England .- Native of Jamaica. For its propagation and culture, see the third species, and also the following.

8. Cynanchum Monspeliacum; Montpellier Cynanchum. Stem twining, herbaceous; leaves reniform, cordate, acute ; stems filiform, green, smooth, swelling at the joints, very long, climbing; leaves acute, glaucous, about the same length as the petioles; flowers on solitary peduncled racemes, between two petioles, the peduncles thickening toward the top; calix small, five-cleft; corolla deeply fiveparted; segments linear, white above, pale rose-coloured beneath; in the centre is a white pitcher-shaped body, tencleft at the top, with five broad shorter segments, and five sharp longer ones. Both this and the seventh species abound with a milky juice like the spurge, which issues out wherever they are broken, and when concreted, has been frequently sold for scammony .- Native of the south of Europe. For its propagation and culture, see the eighth species.

9. Cynanchum Extensum; Hairy-flowered Cynanchum, Stem twining, frute-cent; leaves cordate, acute; peduncles elongated; pedicets filiform; corollas hirsute at the edge; follicles ramentaceous. From an annual root, divided into whitish fibres, a foot and a half long, and not so thick as a quill, arises a twining stem, very much branched, twelve feet high, round, viltose, with longer hairs thinly interspersed, rough, glaucous, when far advanced slightly tinged with purple. The branches are the same ; leaves quite entire, almost smooth on both sides, on a long round villose petiole; flowers pendulous, sweet-smelling, beginning to open about six o'clock in the evening, and closed by morning; they are of a greenish pale colour. The plant is elegant, and abounds with a white nulk .- It flowers in July and August, and is a native of the East Iudies. For its propagation and culture, see the third species.

10. Cynanchum Undulatum; Wav'd-leaved Cynanchum, Stem twining; leaves lanceolate, ovate, smooth; umbels globular. A milky plant, entirely smooth, with twining round stems ; leaves quite entire, fat to the touch, on very four inches long; peduncles one-flowered and shortish, short petioles, four inches long; flowers small, without scent,

firm; calices ash-coloured; corollas nearly of the same colour on the outside, and dirty purple within.—It flowers in July, and is a native of Carthagena in New Spain. For its culture and propagation, see the third species.

CYN

11. Cynanchum Capen-e; Cape Cynanchum. Stem twining, conform on every side; leaves subcordate, ovate; peduncles many-flowered; stem lofty, scarcely pubescent, even at top, by no means cork-barked; leaves petioled, mucromate, even; the younger ones ovate, the more advanced emarginate.—Observed by Kemig and Sparrmann at the Cape of Good Hope. It must be preserved in the drystove, where it may be increased with layers, cuttings, &c.

12. Cynanchum Obtusifolium; Blunt-leaved Cynanchum. Stem twining, herbaceous; leaves oblong, rounded at the tip with a point; umbels lateral.—First observed by Thunberg at the Cape of Good Hope. It must be preserved in the dry-stove, and may be increased from layers, cuttings, &c.

13. Cynanchum Tenellum. Stem somewhat twining, herbaceous; leaves ovate, oblong.—Found by Mutis in New Grenada. See the third species.

14. Cynanchum Erectum; Upright Cynanchum, Stem recet, divaricated ; leaves cordate, smooth,—This is a per-ennial plant, which rises with slender upright stalks, about three feet high; leaves broad, smooth, ending iu points; flowers avillary, in small buuches, on branching peduacles; they are small and while, greatly resembling those of the common white asclepias—It flowers in July and August, and is a native of Syria. It requires a warm situation to live abroad in Eggland, and is propagated by parting the roots before they shoot in the spring.

15. Cynanchum Filiforme. Stem erect, quite simple; leaves linear; flowers virticilled, axillary,—Found by Thunberg at the Cape of Good Hope. It must be preserved in the dry-stove. They may be increased by layers, cuttings, &c.

16. Cynanchum Crispilorum ; Curied-flower Cynanchum, Stem twining ; leaves underneath villose, oblong, cordate, with the sinus closed ; petals curied at the end.—It flowers in July, and is a native of South America and the West Indies. For its culture and propagation, see the third species.

17. Cynanchum Reticulatum. Stem twiuing, cork-barked at botton, and chinky; leaves orate, acute ; stem woody, covered with a thick whitish bark; the branches opening, striated, smooth; leaves far from each other, petioled, smooth, upper one lanceolate; flowers small, hairy on the outside, uuequally pedicelled in peduncled axillary umbels.—Observed by Komig in the East Indies. For its culture and propagation, see the third species.

16. Croanchum Asperum; Rough-tawad Cymanchum, Stem twining, shrubby ; leaves cordale, a cutte, rough; flowers lateral; stem shrubby twining, twenty feet high, or more, very slender, and armed with small stinging hairs; leaves broad, heart shaped, on slender foststalks. The flowers are produced in small clusters, sitting close to the stalks; they are percty large, yellow, and star-shaped, spreading open to the bottom,—Native of La Vera Cruz in New Spain. For its propagation and culture, see the third species.

10. Cynanchum Rostratum : Back-flowered Cymanchum. Stem and petioles hirster; leaves cordate, oblong; petals lanceolate, flat; stem twining, shaggy, with reversed hairs, as are also the petioles; leaves two or three inches long, acuminate.-Found by Rohr on the island of Trinidad. For its propagation and culture, see the third species.

 Cynanchum Parviflorum; Small-flowered Cynanchum.
Stem twining, filiform; leaves ovate, subulate at the end; umbels subsessile.—Native of the West Indies. For its propagation and culture, see the third species.

21. Cynanchum Prostratum; Prostrate Cynanchum, Stem prostrate; leaves heart-shaped, orbiculate-cente, tomentose underneath; stems a foot high, round, filiöray, branched, knotted, tomentose, subherbacenous; leaves in pairs at each knot, nearly equal to the petioles, quite entire, soft, glaucous underneath, having an unpleasant smell; flowers in solitary umbels; corolla deep green, deeply partef into five spreading segments, with a revolute border.—Native of Mexico. For its propagation and culture, see the third species.

22. Cynanchum Grandiflorum; Great flavered Quanchum, Stem twining; laves heart shaped, ovate, cuspidate, glaucous underneath; corollas coriaceous; corolla before it expanda folled up in a spiral form, built afterwards spereding very much, deep green on both sides, and somewhat coriaceous, divided into five lanceolate very sharp segments, nearly an inch in length.—Native of South America. For its propagation and culture; see the third species.

23. Cynanchum Odoratissimum; Sieet Cynanchum, Stem twinig, corky, and cloven at bottom; leaves heart-shaped, acuninate, wrinkled; cymes reflex; stem very long, round, shining, and very smooth, except at bottom, where it has a bark like cork; leaves wared, smooth, on long petioles; flowers yellow, very sweetscented, in large hemispherical, axillary, recelling cymes. This plant is not inferior to the Arabian jasmin in fragrance.—It is a native of Siam ad Cochin-china, where the women of fashion use it to adorn their hair. For its propagation and culture, see the third species.

24. Cynanchum Altissinum; Lofy Cynanchum. Stem twining: leaves hart-shaped, tomentose on both sides; flowers umbelled. This is a milky shrubby plant, climbing trees to the leight of fifty feet; stems round, when old woody, smooth, ash-coloured, leafless, when young green, tomentose, leafy; flowers titch, firm, scenless; calices greenish ash-colour; corollas dirty purple. For its propagation and culture, see the third species.

25. Cynanchum Longidorum; Long-flowerd Cynanchum, Sum twining; leaves obloug, acute, vilose; flowers umbelled; stens round, hairy, climbing to the height of fifneen feet; flowers destitute of either smell or beauty; the unusual elongation of the tube gives them a very different appearance from the others.—For its propagation and culture, see the third species.

26. Čynanchum Filiforme Americanum. Stem twining: leaves orate-acuminate, flat, shining: umbels globular: stems round, filiform, shining, branched, very nunerous; flowers without scent, small ; the petals and nectaries snow-white.— Native of Carthagena in New Spain. For its culture and propagation, see the third species.

27. Cynanchum Clausun; Class.flowered Cynanchum, Sten twining: leaves acuminate, oblong, rolled back at the edge; flowers umbelled; stems round, smooth, numerous; flowers scentless, with anow-white corollas and unctaries.— Native of Carthagena in New Spain. For its propagation and culture, see the first species.

Cynara; a genas of the class Syngenesia, order Polygania Equalis.—GENERIC CHARACTER. Califie: common ventricose, imbricate; scales numerous, roundish, fleshy, increased by a membranecous, scale-formed appendicle, which is larger, roundish, channelled, and emarginated with a spine. Corolla: compound, tubulous, uniform; corollets hermaphrodite, nearly equal. Proper: one-petalled, funnelform; tube very slender; border erect, ovate, five-cleft; divisions linear, one more deeply serated. Stamina : fin menta five, explicary, subort; antitere eylindirc; tube1. Cynara Scolymus ; Common Artichoke. Leaves somewhat spiny, piunate, and undivided ; calycine scales ovate. In its wild state, the artichoke is said to attain the height of a man, but the cultivated artichoke seldom exceeds four feet in height, with a stout, furrowed, leafy stem, slightly tomentose, sometimes a little branched at top. The root is large, thick, and perennial. Mr. Miller divides the artichoke into two species. 1. The green or French, and 2. the globe artichoke. The former, being the sort most commonly cultivated in France, is generally known here by the title of French artichoke, and is the only sort in Gnernsey and Jersey. Its heads are of a green colour, like those the globe artichoke, but the bottoms are not near so thick of flesh; and they have a perfumed taste, which to many persons is very dis-agreeable, so that it is seldom cultivated in the gardens near London, where the globe or red artichoke is the only sort in esteem.-The artichoke is a native of the south of Europe, as in Italy, Sicily, and the south of France. In some parts, it is eaten raw in its wild state, by the common people, and must certainly be a most wretched food. It is said to dye a good yellow, and the flowers are used instead of rennet, to turn milk for cheese. The whole plant has a peculiar smell, and a strong bitter taste. It was formerly in great repute for qualities which it is not now allowed to possess, though it is still reputed to be aperient, stomachic, and somewhat heating. According to Meyrick, the juice of the leaves, or a strong decoction of the roots, is powerfully diuretic, and of great efficacy in the jaundice and dropsy, which will frequently yield to this medicine. Hill also observes, that the root fresh gathered, sliced, and boiled in water in the proportion of six ounces to a quart, makes a decoction which works by urine, and which he has known to cure the jaundice alone. The artichoke has the same name, with very little variation, in all the European languages. The Germans call it artischoke, corruptly erdschocke ; the Dutch, artisjok or artichok ; the Danes, ærteskok ; the Swedes, ærtskocka ; the French, artichaut ; the Italians, carciofs ; the Spanish and Portuguese, alcachofa ; the Poles, karciof ; and the Russians, artitschok. The way of propagating the common artichoke is, from slips or suckers taken from the old roots in February or March, or rather some time in March or the beginning of April, which, if planted in a good soil, will produce large fair heads in the autumn following .- Method of Planting. To make a new plantation, dig and bury some very rotten dung in the ground set apart for that purpose. Choose such plants as are taken from clear, sound, but not woody old stocks. Cut off with your knife the knobbed woody part that joined them to the stock; if that cuts crisp and tender, it is good, but if tough and stringy, throw it away as useless. Cut off also the large outside leaves pretty low, that the middle or heartleaves may be above them. If the weather be very dry, or the plants have been any time taken from the stocks, it will be expedient to set them upright in a tub of water, three or four hours before they are planted, which will greatly refresh them. To plant them, range a line across the ground, and with a measure-stick place them at two feet distance from each other in the rows; and if designed for a full crop, five feet distance row from row. The plants must be set about four inches deep, and the earth closed very fast to their 35.

or three times a week until they are growing; after which, they seldom require any. A thin crop of spinach may be sown upon the ground before the artichokes are planted, observing to clear it from about them after it appears. But whenever it is intended to plant any thing between the arti-chokes, nine or ten feet must be allowed between the rows, which is the space left by the kitchen-gardeners near London, who sow the ground between with radishes or spinach, and plant two rows of cauliflowers at four feet distance from row to row, and two feet and a half asunder in the rows, so that there are always five feet allowed for the artichokes to grow; and in May, when the radishes and spinach are taken off, they sow a row of cucumbers for pickling, exactly between the two rows of cauliflowers, at three feet distance from each other; and between the rows of cauliflowers and the artichokes, plant a row of cabbages or savoys for winter use, which, when the cauliflowers are drawn off, and the artichokes gathered, will have full liberty to grow; and by this means, the ground is fully employed throughout the whole season. This has long been the practice of the kitchen gardeners near London, who pay large rents for their land, and are obliged to get as many crops in a year from it as possible. In those which are planted at five feet distance from row to row, a line of cabbages or savoys may be planted for winter use in every other row, which will be gone by the time of landing them up; in doing this, you must lay the whole five feet of earth into one ridge, except the ground be extremely stiff, or the plants young, in both which cases you may lay only three feet and a half of the ground in the ridge over the roots, and the remainder may be laid in a small ridge between : the same compass of ground must also be allowed, where they are planted at a wider distance. If in the spring you find your stocks shoot very weak, which may be occasioned either by hard frost or too much wet, you must then cover them, and loosen and break the earth about them, raising a small hill round each stock, levelling the rest between the rows, which will greatly assist them, and in three weeks or a month after, they are commonly fit to slip. If any of the plants which are set in the spring should not fruit in autumn, you may, at the season of earthing up the roots, tie up the leaves with a small willow twig, and lay up the earth close to it, so that the top of the plant may be above ground; and when the frost comes on, if you will cover the top with a little straw or pease-haulm, to prevent their being killed by frost, these plants will produce fruit in winter, or early in the spring. If you intend to continue your artichokes through a whole season, you must make a new plantation every year, otherwise you cannot possibly have fruit longer than two or three months. Those artichokes which are planted in a moist rich soil, will always produce the largest and best fruit, especially in kindly seasons; so that where such a soil can be obtained, it will be advisable to make a fresh plantation every spring, to succeed the old stocks, and supply the table in autumn. But the roots will not live through the winter in a moist soil, so that the stocks which are intended to remain to supply the table early, and to furnish plants, should be in a dry soil, and ought always to be planted in an open situation, not under the drip of trees, where they will draw up very tall, and produce small insignificant fruit .-- Winter Dressing and Landing. Since we have experienced, that in very severe frosts these roots are sometimes destroyed, (though it rarely happens in dry ground,) the earthing of artichokes should be deferred till the latter end of November, or the beginning of December, provided the season continue mild; and towards Christmas, when there

appears any danger of severe frosts, lay a quantity of long dung, pease-haulm, tanner's bark, or any other light covering, over the ridges of earth, which will keep out the frost, and, being at a distance from the roots will not injure them : but this should be carefully removed in the beginning of February, or at least as soon as the weather is mild, otherwise the plants will be injured by its lying too long upon them. It will also be a good method, whenever any roots of artichokes are dug up in autumn, either to bury them deep in the ground in a pit till spring, or lay them in a heap, so as that they may be easily covered in hard frosts; and these may be a supply, if those in the ground be destroyed. When you have thus earthed them up, you have nothing more to do till February or March, by which time they will have grown through the ridge of the earth : and when the weather is favourable, must be dressed as before directed .- Spring Dressing. At the end of February, in March, or at the beginning of April, according to the earliness of the season, or forwardness of the old artichoke roots, will be the proper time for dressing them, which must be thus performed : with the spade remove all the earth from about the stock down below the part whence the young shoots are produced, clearing the earth by hand from between the shoots, so as to be able to judge of the goodness of each, with their proper position upon the stock; then make choice of two of the clearest, strongest, and most promising plants that are produced from the under parts of the stock, which are much preferable to the strong thick plants, which generally grow upon the crown of the roots : for these having hard woody stems, never produce good fruit, but are generally what the market people call rogues, which have very little bottom, and the scales of their heads are irregularly placed. In slipping off the plants, be careful not to injure those which are to remain for a crop, but with your thumb force off all the other plants and buds, also close to the head of the stock whence they are produced, taking care not to overlook any of the buds, which would soon produce plants to the great detriment of those which are left; round which two you must draw the earth with a spade, and close it fast to each of them by hand, separating them as far as possible without breaking them, observing also to crop off the tops of the leaves that hang down with your hands. The ground being levelled between the stocks, you may sow thereon a small crop of spinach, which will be taken off before the artichokes can cover the ground. They must be kept clear from weeds; and towards the latter end of April, or the beginning of May, when your old plants begin to show their fruit, carefully inspect the stocks, and draw up all young plants from them, which may have been produced after their dressing, cutting off all suckers that are produced from the stems of the artichokes, leaving only the principal head; which will increase the size of the fruit. When they are fit to gather, they ought not to be broken down close to the surface of the ground, that your stocks may make strong fresh shoots before the end of October : the season for earthing, or, as the gardeners term it, landing them up, is the middle or latter end of November, and is thus done; cut off all the young shoots quite close to the surface of the ground, then dig between every stock, raising all the earth between every row of stocks into a ridge, as is done in the common method of trenching ground, so as that the row of artichokes may be exactly in the middle of each ridge; which will be sufficient to defend them from frost, and is infinitely preferable to long dung, which is often used by the unskilful, and causes the fruit to be small, with scarcely any bottoms to them; for nothing is more injurious to these plants than new dung buried near, or laid about them.

2. Cynara Horrida; Madeira Artichoke. Leaves pinnatifid, tomentose underneath, spiny; spines at the base of the leaves, and pinnas connate at bottom.—Native of the island of Porto Santo, near Madeira.

3. Cynara Cardunculus; Cardoon Artichoke. Leaves spiny, all pinnatifid; calycine scales ovate. Bauhin asserts. that this is a hybrid plant, or mule, from the seed of the common artichoke: the corollets and pistils are of a deep blue colour, but the stamina are gray. Parkinson says, that he was assured by John Tradescante, that he saw three acres of land about Brussels planted with this kind of artichoke, which the owner whited like endive, and then sold them in the winter, but that we cannot yet find the true manner of dressing them. In some parts of Spain they substitute the down of this plant for rennet, in making cheese; a strong infusion is made over night, and the next morning, when the milk is warm from the cow, they put nearly half a pint of the infusion to nearly fourteen gallons of milk. This plant has the same name, with slight variations, in all the languages of Europe, as kardonen, kardon, cardone, and cardo. It is propagated in the kitchen-gardens to supply the markets, being annually raised from seeds, which should be sown upon a bed of light earth in March: and when the plants come up they should be thinned where they are too close, transplanting those which are drawn out into a bed at about three or four inches' distance, where they should stay until finally removed to where they are to remain : these young plants must be kept clean from weeds, and should be transplanted out in the beginning of June, on a moist rich spot of ground, at about four feet asunder every way: the ground should be well dry before they are planted, and the plants should be well watered until they have taken new root, after which it must be very diligently weeded to encourage the growth of the plants, and as they advance in height, there should be some earth drawn up about each plant; and when they are fully grown, their leaves should be closely tied up with a hayband, and the earth round them drawn up in hills almost to the top, being careful to keep the earth from falling between the leaves, which may occasion the rotting of the plants: the earth should be smoothed over the surface, that the wet may run off, and not fall into the centre of the plants, which would also rot them. In about eighteen weeks after they have been thus earthed, they will be blanched enough for use, so that if a succession of them be wanted for the table, there should be but few plants earthed up at each time. Towards the middle or latter end of November, if the frost should be severe, it will be proper to cover the tops of those plants which remain with pease-haulm or straw, to prevent the frost from penetrating to the tender leaves, which frequently pinches them where they remain totally uncovered ; whereas if the covering be only removed in fine weather, the, plants may be thus preserved for use during most part of the winter. If a few of the plants be placed out in a warm situation to stand for seed, they should not be blanched but only in a very hard frost; some light litter or pease-haulm may be laid round them to keep out frost, which should be removed in the spring, and the ground gently dry between the plants, which will not only destroy the weeds, but also encourage the roots of the plants to shoot out on every side, and thereby add fresh strength to their stems. They will flower about the beginning of July, and if the season prove dry, their seeds will ripen in September ; but in cold wet seasons they will not come to maturity in England. The stalk of the leaf, which is thick and crisp, and by many thought to be palatable, is the part eaten ; it is rendered white and tender, like celery, by the blanching, and is about a yard or more in
CYN

used in salads, soups, stews, &c. it is not, however, in great estimation, and therefore not much cultivated in England. Never tie up the leaves for blanching before they be full grown, unless they are wanted in September and October, in which case they must be tied up and earthed in August, but then the stalk of the leaf will never be broad and thick, and in that its chief excellence consists. The proper time to begin blanching, is at the end of September or October, when the plants will come into use in December, and continue all the winter: observe also to tie up the leaves in a dry day, adding fresh hay-bands as the plants advance in height, taking care to cover their tops with long litter, if the frosts should be severe.

4. Cynaris Humilis; Dwarf Artichoke. Leaves spiny, pinnatifid, tomentose underneath; calycine scales subulate. The heads have some resemblance to those of the French artichoke, but have no fleshy substance in their bottoms .- Native of Spain and Barbary. This may be planted in the same manner as the preceding species ; the plants being set three or four feet apart, they require only to be kept clean from weeds; they will flower in the second year, and if the season prove dry, the seeds will ripen in September ; they generally decay in the following winter, if it be severe, especially if they remain uncovered.

5. Cynara Acaulis. Stemless: leaves pinnate, unarmed. smooth above. - Native of Barbary.

6. Cynara Integrifolia. Leaves lanceolate, toothletted : calycine scales lanceolate-acuminate. It is a low smooth plant, with a simple striated stem; leaves petioled, broad lanceolate; corollas blue.- Found by Barnadas in the mountains near Toledo in New Castile.

Cynoglossum ; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. Calia: perianth five parted, oblong, acute, permanent. Corolla: one-petalled, funnel-form, length of the calix; tube cylindric, shorter than the border; border half five-cleft, obtuse; mouth closed, with five squamules, which are convex, prominent, converg ing. Stamina : filamenta five, very short, in the mouth of the corolla. Antheræ roundish, naked. Pistil : germina four; style subulate, length of the stamina, permanent; stigma emarginate. Pericarp : none, but four arils of the seeds, depressed, roundish, outwardly more obtuse, scabrous, not gaping, somewhat flattish on the exterior side, affixed by their tip. Seeds: as many, somewhat ovate, gibbous, acuminate, smooth. ESSENTIAL CHARACTER. Corolla: funnelform, the throat close with arches. Seeds : flat, affixed to the style by the inside only .---- The species are.

1. Cynoglossum Officinale; Common or Great Hound's-Stamina shorter than the corolla; leaves broad tongue. lanceolate, attenuated to the base, tomentose, sessile; calycine segments oblong. The whole plant is downy, and soft to the touch ; root biennial ; stem two or three feet in height, upright, grooved, angular, villose, very leafy; root-leaves large, a foot or more in length, on petioles, ovate or lanceolate, pointed, covered with a silky down which gives them a grayish colour, veiny; stem-leaves, at least the uppermost, sessile, half stem-clasping, quite entire, with a waving edge, seven or eight inches long, crowded, placed irregularly on the stem, upright, lanceolate, and broadest at the base; flowers at first of a dull red, marone or mulberry colour, afterwards becoming bluish. The evergreen horehound is a remarkable variety of this species, the leaves are nerveless, much narrower and rougher than the common sort, but entirely destitute of its hoariness, so that the leaves are therefore of a full green colour ; it also wants that strong scent

length. The season for it is autumn and winter, when it is | which distinguishes the common hound's-tongue; the stem has a slight hairiness, and the flowers are blue and smaller ; hound's-tongue is also frequently found with a white flower. The large Dutch hound's-tongue, which is the size of the common sort, is probably nothing more than a variety arising from luxuriancy of soil. Hound's-tongue has a disagreeable smell, much resembling that of mice; it is suspected to possess narcotic qualities; and in the Historia Oxoniensis, vol. iii. p. 350, an instance is related, in which the leaves, boiled by mistake for comfrey, disordered a whole family, and proved fatal to one person; but many will not admit the fact. Mr. Ray informs us, from Dr. Hulse, that a decoction of the roots inwardly, and cataplasms of them outwardly, were used in his time to relieve strumous and scrophulous cases. It is, says Meyrick, a plant of very considerable virtues, being of an astringent balsamic nature, and excellently adapted to ease those coughs which proceed from a thin acrid humour falling upon the lungs, or other parts of the breast. A decoction of the roots drank freely relieves the bleeding of the piles, and stops the overflow of the menses and the whites; the root powdered, and taken in doses of half a drachm twice or three times a day, is excellent against purgings and the bloody flux : an ointment made of its leaves, with honey and turpentine, is a good application to dress old fistulous ulcers. Cattle in general dislike this plant; the goat alone is said sometimes to eat it .- It grows wild by road-sides in most of the uncultivated parts of Europe, particularly in Germany and Switzerland. In England it may be met with in the London road between Kelvedon and Witham in Essex, but more abundantly about Southend by Eltham, beyond Waltham Abbey, towards Harlow ; at Norbury, near Leatherhead, in Surry; about Braxted, and near Worcester. It flowers in April and May.

2. Cynoglossum Virginicum; Virginian Hound's-tongue. Leaves spatulate, lanceolate, lucid, three-nerved at the base ; bracte of the peduncles stem-clasping. This rises with an upright branching stem nearly four feet high; the flowers grow scatteringly towards the ends of the branches; they are small and white, appear in June, and are succeeded by four small seeds, which ripen in autumn, and then the plants decay .- Native of Virginia, and other parts of North America. This, with the third, fourth, fifth, and tenth species, are hardy plants, which will grow plentifully without much care, if they only be permitted to scatter their seeds.

3. Cynoglossum Cheirifolium; Silvery-leaved Hound'stongue. Corollas twice the length; leaves lanceolate; root perennial, branched; stems several, a foot high, round, branching; leaves half stem-clasping, obversely lanceolate, or spatulate, quite entire, covered on both sides with a white silvery down; flowers in racemes, without any bractes; corollas white, with red, blue, or purple veins .- Native of Silesia niola, Italy, the south of France, Spain, Gibraltar, and the Levant. It flowers in June and July. See the second species

4. Cynoglossum Apenninum; Apennine Hound's-tongue. Stamina equalling the corolla. The leaves of this species are much larger, the petal of the flower much shorter, and the stature taller, than the first sort ; it also flowers earlier .- Biennial; flowering from April to June; and a native of the Apennines. See the second species,

5. Cynoglossum Lævigatum. Leaves lanceolate-ovate. smoothish; calices tomentose; seeds glossy; stem erect, a foot in height, striated, panicled at top; root-leaves petioled, soft ; stem-leaves small, sessile .- Native of Siberia. See the second species.

6. Cynoglossum Lusitanicum; Portugal Hound's-tongue, 1

or Venus's Navelwort. Leaves linear, lanceolate, smooth, toothletted, and rugged about the edge. The whole of this plant is very smooth; stem erect, a foot high, round ; branches axillary, alternate, quite simple .- Native of Portugal. Both this and the seventh species are annual plants, commonly sown in gardens, with other low annual flowers, to adorn the borders of the flower-garden; but the seeds should be sown in autumn, for those which are sown in the spring often fail, especially in dry seasons; and the autumnal plants always grow much larger, and flower earlier ; the seeds should be sown where the plants are intended to remain, for they will not bear transplanting, except while they are young. The plants require no other culture but to be thinned where they are too close, and kept clean from weeds: they flower in June and July, and ripen seed in autumn; but the autumnal plants appear a month earlier.

7. Cynoglossum Linifolium ; Flax-leaved Hound's-tongue, or Venus's Navelwort. Leaves linear, lanceolate, smooth, toothletted, and rugged about the edge. It seldom rises more than five or six inches high, and the stalks do not branch nearly so much as those of the preceding; the leaves are very narrow, long, smooth, and of a gravish colour ; the flowers grow in short loose panicles at the ends of the branches, they are white like those of the sixth species, but smaller, and have the seeds of the same form, namely umbilicated, from which circumstance they both derive the name of navelwort .--- Native of Portugal. For its propagation and culture, see the sixth species.

8. Cynoglossum Omphaloides; Comfrey-leaved Hound'stongue. Creeping: root-leaves cordate; root perennial; branches trailing, and putting out roots from the joints; leaves bright green, on long slender footstalks; flowers shaped like those of borage, but smaller, and of a lively blue colour: it flowers from March till May in England, and about Christmas in the woods of the south of Europe, of which it is a native .-- This plant propagates very fast by its trailing roots, which require to be kept within compass, on this account it seldom produces seeds, and delights in cool moist situations.

9. Cynoglossum Japonicum. Leaves oblong, villose; stems prostrate; root annual; stems four or five, round, villose, flexuose, and erect, unequal; flowers terminating in racemes; calix wholly villose; corolla purple, longer than the calix; style simple, with an obtuse stigma .- Native of Japan.

10. Cynoglossum Pictum; Painted Hound s-tongue. Corollas nearly equal to the calix; segments roundish, dilated; leaves lanceolate, tomentose, the upper ones cordate at the base; leaves much shorter, softer, and more hoary than those of the common sort; stems a foot and half in height, more branched; seeds smaller. It agrees with the common species in habit, size, and manner of growth, and has therefore been confounded with it by those who have not seen both ; it differs from it in having the leaves not narrowed but cordate at the base, and the flowers pale blue or pale purple. beautifully painted with darker veins. It is a perennial, and flowers in August. Mr. Miller informs us, that it grows naturally in Andalusia, and that he received the seeds from Gibraltar .- Native of the south of Europe, and of Barbary, and also of Madeira, where it was found by Masson.

11. Cynoglossum Lanceolatum. Leaves lanceolate, drawn to a point at both ends, rngged, with dots on the upper surface; stem herbaceous, upright, angular, rough with bairs, hoary at top; lower leaves drawn out into a petiole an inch in length, upper ones sessile, veiny, nerved .- Native of Egypt.

smooth, striated, tubercled, toothed on the edge: leaves hairy, tubercled, entire : root-leaves spatulate, lanceolate : root perennial ; stems usually several, pipe-form, ascending, scarcely half a foot high, hairy, usually simple; leaves rough next the root, petioled, on the stem sessile, linear, lanceolate: calix hairy, with subovate segments; corolla very small, scarcely longer than the calix, blue .- Native of the very summit of mount Lebanon.

Cunometra; a genus of the class Decandria, order Mopogynia .-- GENERIC CHARACTER. Calix : perianth fourleaved, oblong, reflex, length of the corolla, Corolla; petals five, lanceolate, equal, acute. Stamina : filamenta ten, twice the length of the corolla; antheræ oval, two-cleft at the tip. Pistal: germen boat-form : style filiform, length of the stamina; stigmas simple, Pericarp : legume crescentshaped, compressed, fleshy, tuberculate. Seed: Single, kidnev-form, large. ESSENTIAL CHARACTER. Calix : fourleaved. Antheræ: bifid at the tip. Legume: fleshy, crescent shaped, one-seeded. These trees are natives of the East Indies. Their leaves are conjugated, aud the peduncles many-flowered .----- The species are,

1. Cynometra Cauliflora. Trunk floriferous : roots knotty and large, appearing above ground, and having smaller ones between them, which are curled, and look like pigs' tails : trunk very irregular and short, seldom above two feet high. It is rugged, unequal, ugly, in hills and holes, covered with a thick hard cloven bark, the colour of liverwort. The flowers come out on the trunk and large branches, and on the root when above ground .- The corolla is small and white.

2. Cynometra Ramiflora. Branches floriferous .- This is a lofty tree, sixty feet in height; trunk thick, solid, ash-coloured ; bark blackish, within red ; branches many, ash coloured or greenish. It is always green in Malabar, and bears flowers and fruit in August and November.

Cynomorium ; a genus of the class Monœcia, order Monandria .--- GENERIC CHARACTER. Male Flowers: disposed in an imbricated ament with the female ones. Calix: ament erect, club-shaped, on every side covered with floscules; perianth proper, four-leaved; leaflets three, clavate, and the fourth inferior one larger, very obtuse, channelled. Corolla: none. Stamina: filamenta single, firm, straight, longer than the calvcine scale ; antheræ twin. Female Flowers; mixed with the males in the same plant, and scarce remote from them. Calix ; ament common with the males ; perianth proper, superior ; leaflets four, club-shaped, tuberculated, equal, permanent. Corolla: none. Pistil: germen ovate, inferior; style single, erect, firm, spreading, length of the calvcine scale; stigma obtuse. Pericarp: none; seed single, roundish. ESSENTIAL CHARACTER. Male Calix: an imbricate ament. Corolla: none. Female Calix : in the same ament. Corolla: none. Style: one. Seed : one, roundish .---- The species are,

Stipe scaly; ament cylin-1. Cynomorium Coccineum. drical; scales imbricate, ovate, retuse. This is a fungiform plant, the whole consisting of a long, thick, radical spadix, growing upon the roots of trees in salt-marshes under water; stem commonly half a foot long, upright, solid, tough, as thick as the finger .- Native of Barbary, on the coast, at the roots of lentiscus myrtle, &c. or on the halimus, or portulaca marina. It is also found at Cadiz, in Malta, and in Sicily.

2. Cynomorium Jamaicense. Stipe scaly; ament elongated ; scales imbricate, halved, rhomboidal. It grows in beds, and rises generally to the height of three, four, or five inches, but is commonly smallest towards the bottom. At first it is rather thickly covered with scales of the figure of a 12. Cynoglossum Myosotoides. Arils basket-shaped, heart, which fall off gradually as it rises, and expose the body

of the plant, closely beset with little transparent denticles, intermixed with a few tubular trifid flowers that jet above the level of the surface. The stem is succulent and fleshy, and all the parts astringent.—It is seldom met with but in the most shady inland woods, and is a native of Jannica.

3. Cynomorium Cayanense. Stipe naked ; ament subglobular; scales roundish, peltate .-- Native of Cayenne.

Cunosurus ; a genus of the class Triandria, order Digynia. -GENERIC CHARACTER. Calix: receptacle common, unilateral, often leafy; involucre, in some one-leafed, lateral; glume many flowered, two-valved ; valves linear, acuminate, equal. Corolla: two-valved; the outer concave, longer, the inner flat, awnless; nectary two-leaved; leaflets ovateacute, gibbous at the base. Stamina : filamenta three, capillary ; antheræ oblong. Pistil : germen turbinate ; styles two, villose, reflex ; stigmas simple. Pericarp : uone ; corolla closely coating over the seed, and not gaping. Seed: single, oblong, acuminate to each end. ESSENTIAL CHA-RACTER. Calix: two-valved, many-flowered. Receptacle: proper, unilateral, leafy .- Several species of this genus are natives of the West Indies, and more of the East Indies. Few of them are known in Europe, otherwise than by specimens or descriptions; and the seeds must be brought from their native places, and kept in the bark-stove. Those from the Cape of Good Hope are of course preserved in the drystove. For the culture of the European sorts, particularly the first, see Grass. The species are,

1. Cynosurus Cristatus; Crested Dog's-tail Grass. Bractes pinnatifid ; root perennial ; culms from one to two feet in height, erect, strict, having three or four joints, smooth, and even ; leaves narrow, flat, smooth on both sides ; spike compound .- It is common in dry pastures in July and August, and is called bent-grass, in common with many others; and in Scotland, windle straw-grass. Most modern writers. echoing Stillingfleet, have celebrated this grass as excellent for sheep. Mr. Curtis justly thinks less favourably of it, and considers it as greatly inferior to many other grasses It predominates on sheep-downs, and in many parks, but is Mr. Ray sets down a variety of this late and unproductive. species, which he calls square-crested grass, because the spike has four rows of flowers. It was found at Notley in Essey

2. Cynosurus Echimatus; Rough Dog's-tail Grass. Bractes pinnate, chaffy, awned; raceme glomente, pointing one way; bractes only on the outside of the flowers, alternately pinnate, one flowered; the rays ending in an awn. Annual — Native of Europe and the Levant. Fonad near Sandwich, and in a saudy part of the island of Jersey, flowering in July. Of this grass/liter remarks, that it is incorrectly named echimate, for the spike is rather languinous than beset with pickles; he adds, that it is sometimes yery tall among the com, and that on a rock he has seen it only two or three inches high.

3. Cynosurus Lina; Imbricate Drg's-tail Grass. Spik facing one way; the inner glume of the calix lying below the spikelets, searcely a span in height; leaf small, the sheath swelling a little; spike closely imbricate, oblong, composed of assile flowers, compressed, and keeled, directed one way, in a double row; cultus slender, upright: seed oblong, sharp at both ends, - It is annual; towers in England during July and August, and in May in Spain, of which country it is a native.

 Cynosurus Durns; Rigid Dog's-tail Grass. Spicules one-ranked, alternate, sessile, rigid, obtuse, pressed close; culms few, scarcely a palm in height, procumbent; leaves even; florets compressed, awnless; flowering-spike straight, 36.

stiff. The plant when adult is entirely of a brown baycolour. Annnal; flowering in May, June, and July.--Native of the southern parts of Europe, in Carniola, Switzerland, the Palatinate, Silesia, and other parts of Germany.

5. Cynosurus Sphirerocephalus. Bractes entire; spiker globular. The spike resembles a head of garlic; spikelets imbricate every way, and subsessile; calix two or three-downerd; glumes nearly equal, at first longer than the corolla, but afterwards shorter, blue, with white edges, ending in a sort of crest, and editate on the middle of the back. There is a variety, with white flowers in large beads.—Native of the Alos.

6. Cynosurus Ceruleus ; Blue Dog's-lail Grass. Bractes entire ; spikes subovate ; cuins oblique, surrounded at the base with a bandle of root-leaves, inclosed in a whitishborn wrinkled skin, giving the appearance of a brauched root; above bare of leaves; florets on short peduacles, purplish, livid, or brownish white, from half an inch to an inch in length; calax mostly two-flowered, sometimes just longer, and sometimes just shorter than the florets; edges and keel bearded; germen reddish brown; seed hairy. This flowers the earliest of all our grasses, and wonld well deserve to be extensively cultivated, if it were not for its low growth—Naive of Europe, in mountainous and boggy pastures; upon the highest lime-stone rocks, and upon Ingleborough in York-shire.

7. Cynosurus Uniola. Without bractes: spike turned one way; spikelsts in two rows, alternate, pressed close, ovate, keeled, oblique. A very smooth grass; spike linear; spikelst seasile, pressed close to the rachis, in two rows, alternate, spreading at the sides, oblique, very smooth, many flowered.—Native of the Cape of Good Hope.

8: Cynosurus Coracanus; Thick-spiked Dog'stail Graas, Spikes digitate, incurved; calix compressed, erect; leaves nearly opposite. Annual: culms four feet high, covered with leaf-staiks; spikes four or six, terminating, (sometimes one below,) striated, almost erect, the length of the finger, growing broader as they ripen, often bent in; flowers ovate, oblong, compressed, awnles; seeds nearly globular, large, unform tor six is, terminating, discussion, where it is cultivated for the catable seeds. It flowers from July to September.

9. Cynosurus Ægyptiacus; Creeping Dog'stall Grass, Spikes digitate, obtuse, in tours, spreading very much, mucronate; stem creeping; leaves opposite; cultu even, slender, long, pale, jointed, bent, and procumbent at the joints, smooth, and very tough, with many short upright branches. Annual: flowering from July to September, and a native of Asia, Africa, and America.

10. Cynosurus Indicus; Indian Dog's-tail Grass. Spikes digitate, linear; evalue compressed, declined, knotty at the base; leaves alternate; eulm slender, almost upright, red-dish, sometimes creeping, leafy; leaves many, small, stiff; spikes heaped, linear, four or sk, from horizontal spreading, from a thick base growing gradually more slender to the top, foriferous at bottom; valves of the cailx acute; the inmer longer, ciliate, lanusjionse. It flowers in August, is annual, and a native of both Indies and Japan.

11. Cynosurus Virgatus; Fine-spiked Dog's tail Grass, Panicle with simple branches; flowers assile, six together, the last barren, the lowest sometimes awned; height two feet and a half, with a spreading panicle at the top, generally composed of many delicate, simple, stender spikes.—It is perennial, flowering from July to August, and a native of Jamaica.

12. Cynosurus Domingensis. Panicle with simple 5 P

branches; spikelets subsessile, six-flowered, all the flowers wared; root perennial; culms several, crech, from two to three feet high, round, smooth, slining, slender-jointed, leafy, frequently putting out a single branch from one of the lower joints, otherwise quite single,---It flowers and seeds in the stove during the whole year.—Native of St. Domingo in the West Indies.

CYP

13. Cynosurus Aureus; Golden-spiked Dog's-tail Grass, Pauicles with barren, pendulous, ternate spikelets; flowers awned. Annual.—Native of the south of Europe, among stones and rocks, and of the Levant. It flowers in June and July.

14. Cynosurus Eruceformis; Linear-spiked Dog'stail Grass. Spike compound; spikelets scattered, the fruitbearing ones erect; calices one and two-flowered; glumes obtuse, boat-shaped; keel obtuse; corollas acuminate.—It is annual, flowers in July, and is a native of Russia and Hudson's Bay.

15. Cynosurus Retroflexus. Spike compound; spikelets aggregate; calices two-flowered, awned; corollas awnless; culms round, smooti; leaves awl-shaped, a span long, smooth; flowers on one side of the rachis, compressed, smooth.—Native of the East Indies.

16. Cynosurus Filfornis. Spike solitary, distich; calices awl-shaped, three flowered, barren; florets awnless; culms creeping, branched, filform, compressed at bottom; internodes an inch long; spike au inch long, linear; flowers small, alternate, compressed, smooth; awn a little longer than the calix.—Native of the East Indies.

17. Cynosurus Monostachyos. Spike terminating; calices awl-shaped; awnless, subtriftorous; forets awned, one-sided; culm upright, a foot and a half high, smooth; leaves awlshaped, narrow; spike solitary, a span long; flowers alter mate, imbricate on the inner side, smooth.—Native of the East ladies.

18. Cynosurus Penicillatus. Spikes digitate; calices fourflowered, awned at the back; outer petals of the hermaphrodite awned, with bearded pencils; culm round, upright, very finely streaked, pubscent at top; spikes in threes, bat sometimes solitary, on very short pedicels, bearded at the base, four or five inches long, upright, sometimes a little recurved at the end; flowers from the inner side ouly.— Native of the East ladies.

10. Cynosums Paspaloides. Spikes digitate; calices twoflowered, subglobular, or outer valve of the calix awned; corollas awnless; culm very simple, almost leafless, a foot high; spikes two, sessile, au inch and a half long, and more, woolly at the base, linear, narrow, ferruginous, shining.— Observed by Bulow at the Cape of Good Hope.

20. Cynosurus Floccifolius. Spikes linear, straight; leaves doubled together, alternately bearded on the edge; sheaths not ciliate; leaves not bairy. It differs from all the other species, in having all the single leaves folded together.—Native of Expt.

Cyperus'; a genus of the class Triandrin, order Monogynia.-GENERIE CHARACTER. Colliz: spike imbricate two ways: scales ovate, keeled, flat, inflected, separating the flowers. Corolla: none. Stomina: filamenta three, very short; antherae oblong, furrowed. Pistli: germen very short; antherae oblong, furrowed, pistli: Pericarp: none. Seed: singly three-sided, acuminate, destitute of villus. ESSENTIA. CHARACTER. Glume: chafty, imbricate, in two rows. Corolla: none. Seeds: one, naked, Most of these plants are maives of the East or West Indies, and will therefore require the protection of the bark-stove. ----The species are.

* With a round Culm.

 Cyperus Articulatus; Jainted-stalked Cyperus. Culm maked, jointed; root tuberous, red, having a very grateful smell, like that of calamus aromaticus; stalk three feet highs smooth, with very strong and frequent transverse partitions; or membranes. At the top several brown chafty panieles; made up of small long spikes—It is a native of the rills of the Savannah, beyond Two-mile Wood, in Jamaiea; and of Egypt, on the banks of the Nile.

 Cyperus Minimus; Least Cyperus. Culm naked; spikes under the tip; roots composed of many capillary brown fibres, whence arise many small narrow leaves, as inchlong, and reddish underneath.—Native of Jamaica and Brazil.

3. Cyperus Lateralis; Lateral-spiked Cyperus. Culm roundish, naked; spike lateral, sessile; culms the length of a needle, many, bristle-form, not stiff. Annual.—Native of the Cape of Good Hope.

 Cyperus Monti. Culm round; umbel superdecompound; leaves even on the keel; culm smooth and even, leafless. Perennial.—Native of India; lately found wild in Italy.

5. Cyperus Tenellus. Culm naked, setaceons; spikes solitary, and twin sessile; culm not a finger's length, the thickness of a horse-hair; spikes below the top of the culm, compressed, ancipitate, ovate, even, with ten or twelve scales--Native of the Cape of Good Hope.

** With a three-cornered Culm.

6. Cyperus Monostachyos; Single-spiked Cyperus. Culm naked; spike simple, ovate, terminating; scales mucronate; root-leaves numerous, linear, very narrow, even, loose, a span in length; culm filiform, weak, scarcely a foot high,— Naitwe of the East and West Indies.

 Cyperus Lævigatus. Culm naked; head two-leaved; flowers levigated; culms even, two feet high; leaves twe, stiff, convolute, subulate. Perennial.—Native of Coromandel in the East Indies.

8. Cyperus Haspan. Culm leafy; umbel superdecompound; spikelets umbellate, sessile; culm a foot high, lax, yellowish, striated, tender; leaves linear, striated, yellowish, dotted with brown, longer than the culm; spikes linear, compressed, distich, tender, and very delicate, one-third of an inch long, scarcely half a line broad. Perennial.—Native of the East Indies, Cevlon, and the Cape of Good Hope.

9. Cyperus Longus; Sueed Cyperus, on English Galingale. Calm leafy: unibel leafy, superdecompound; peduncles maked; spikes alternate; root long, odoriferous; peduncles sometimes twelve, unabelled; the rays gradually shortening to the middle; the outer one half a foot in length; spiklets corymbed, slender, acuminate, chestnut-coloured. The root is agreeably aromatic to the smell, warm and bitter to the taste; and although disregarded by modern practitioners, it is probably not inferior to some of the more costly melicines imported from abroad. Perennial: flowering in July.--Naztive of France, Germany, Italy, Sicily, and Caruiola, in bogs, marshes, and ditches. It has been found in the isle of Purbeck in Dorschine, and near St. David's in Wales.

10. Cyperus Esculentus. Culm naked; umbel leafy; tubers of the roots ovate; zones imbricate; roots fibrous, with small round tubers or bulbs hanging from them, of the size of peas or beans, and tasting sweet like chestnuts; stems about eighteen inches high. Perennial.—Native of the country about Montpellier, Italy, Sicily, and the Levant.

11. Cyperus Rotundus. Culm almost naked; umbel decompound; spikes alternate, linear; culm scarcely a foot high, having four alternate leaves at bottom. The root CYP

Japau.

12. Cyperus Squarrosus. Culm naked ; nmbel leafy, glomerate; spikes striated, squarrose; culms several, one or two inches high, filiform, three-sided ; leaves linear, bristleshaped, longer than the culm, embracing the base of it with purple sheaths, glaucous when young, when old ferruginous. -Native of Tranquebar, and the Cape of Good Hope.

13. Cyperus Difformis. Culm naked, umbel two-leaved, simple, trifid; spikes cuspidate, the middle one sessile; culm three-sided, flaccid, very weak, a foot high, having two linear soft leaves, two inches long, of a brownish green colonr, above the base, in other parts naked .- Native of the East Indies.

14. Cyperus Iria. Culm half naked ; umbel leafy ; peduncles unequal, subumbellate; floscules distinct; peduncles in the unbel very many, umbelliferous at top; umbel of three or four rays alternately bearing spikelets, of threecornered and very obtuse grains, covered with a scarcely discernible chaff, and little distant from each other: it is an elegant plant .--- Native of Japan.

15. Cyperus Elatus. Culms naked; umbel leafy, superdecompound; spikes a finger's length, imbricate; spikelets subulate. This is a large plant, with an even culm ; umbel leaves many, three feet long, nearly an inch broad at bottom, unequal .- Native of the East Indies.

16. Cyperus Glomeratus. Culm naked, decompound, simple, leafy; pedicels spiked in a double row. Supposed to be a variety of the preceding .- Native of Italy.

17. Cyperus Glaber. Culm naked, even; umbel threeleaved ; flowers glomerate, the lower brachiate ; leaves smooth ; culm a palm in height; root-leaves erect, wholly smooth, the length of the culm; flowers ovate, compressed, imbricate, in two rows, growing brown by age .- Annual; found in wet places about Verona and Piedmont.

18. Cyperus Elegans. Culm naked; umbel leafy; peduncles naked, proliferous; spikes crowded, with spreading points; root leaves from two to three feet and a half in length; stalk two feet and a half high, with two or three leaves on the top, one whereof is a foot long .- Native of the sea marshes in Jamaica, also of the island of Santa Cruz.

19. Cyperus Odoratus, Culm naked; umbel decompound, simple, leafy; pedicels spiked in a double row: root long, roundish, frequently jointed, reddish on the outside, very odoriferous, creeping, and making a large tuft, whence rise many leaves with a prominent sharp cutting keel .- It is found by river-sides in Jamaica and most of the Caribbee islands, as well as in Surinam and the Society Isles.

20. Cyperus Compressus. Culm naked ; universal umbel three-leaved; glumes mucronate, with the sides membranaceous. This species is distinguished by its green panicle and spikes, by its mucronate glumes, not spreading, but the side edges membranaceous .- Native of Jamaica, Virginia, and Malabar : it is generally found in sandy pastures.

21. Cyperus Flavescens; Yellow Cyperus. Culm naked ; umbel three-leaved; peduncles simple, unequal; spikes crowded, lanceolate; fibres of the root loaded with little tubers; culms obtusely three-cornered, smooth, from an inch to a hand and a span in height; root-leaves spreading, smooth, keeled, two or three inches long, mucronate; besides these there are two or three under the umbel of unequal lengths, narrower than the others, and longer than the umbel. It is biennial, flowering from July to September .- Native of France, Germany, Switzerland, Carniola, and Piedmont.

22. Cyperus Fuscus; Brown Cyperus. Culm naked; umbel trifid ; peduncles branched, unequal ; spikes crowded,

bears some bulbs .- Native of Arabia, India, Ceylon, and having narrower brown spikelets, and the leaves more scabrons; culm regularly three-cornered, thicker, higher, and not so shining; seed ovate, not subcordate, and pounced with small holes, as in the preceding species; root annual; culms a span in height, smooth, with two or three leaves at the base, which are keeled, smooth, and the length of the culm. It flowers from July to September .- Native of Denmark, France, Germany, Switzerland, Carniola, Piedmont, and Egypt.

CYP

23. Cyperus Pumilus. Culm naked; umbel two-leaved, compound ; spikelets alternate, digitate, lanceolate ; glumes mucronate : culm about three inches high, with a few leaves at bottom; involucres three-leaved, unequal .- Native of the East Indies.

24. Cyperus Triflorus. Culm naked ; nmbel three-spiked, the middle oue sessile; spikelets even; culms even, a foot high .- Perennial; and a native of the East Indies.

25. Cyperus Strigosus, Culm naked ; umbel simple ; spikelets linear, very much crowded, horizontal; root roundish; leaves channelled, entire, smooth, shorter than the culm .-Native of marshes in Japan, Virginia, and Barbadoes.

26. Cyperus Ligularis. Spikelets of the umbel capitate. oblong, sessile; involucres very long, serrate, and rough; ending in a thick point, and making a large tuft; stalks as thick as the finger, three feet high; seeds brownish red, and shining .- Native of Barbadoes, near Bridge Town ; and also of Guinea in Africa.

27. Cyperus Papyrus: Paper Cyperus, or Egyptian Papyrus. Culm naked; umbel longer than the involucres; involucels three-leaved, setaceous, longer ; spikelets in threes; involucre eight-leaved, the four outer leaflets broader ; universal umbel nearly equal, very copious, with the rays sheathed at the base; involucels erect, the length of the universal umbel; spikelets many, alternate, subulate, sessile. Native of Egypt, Syria, Calabria, Sicily; and found, according to Strabo, in the lake Thrasimene, near Perugia. Papyrns was called biblus by the Grecians; in Egypt it had the name of el berdi : and is said to be known in Syria by the name of babeer, which very nearly approaches to the sound of papyrus and paper. The general figure of this plant, as Pluty has correctly stated, resembles a thyrsus; the head is composed of many small grassy filamenta, each about a foot long; about the middle, each of these filamenta part into four, and in the point or partition are four branches of flowers; the head of this is not unlike an ear of wheat in form, but in fact is only a chaffy, silky, soft husk: these heads or flowers grow upon the same stalk alternately, and are not opposite to, or on the same line with, each other at the bottom. Pliny says it has no seed; the seed is indeed very small, and by its elevated situation, and the thickness of the head of the flower, requires the extraordinary covering which protects it from the violent hold the wind would otherwise have upon it. For the same reason the bottom of the filamenta, composing the head, are sheathed in four concave leaves, which keep them close together, and prevent injury from the wind getting in between them. The stalk is of a vivid green, and of a triangular form ; it has but one root, which is large and strong ; Pliny says, as thick as a man's arm; which it probably was when the plant was fifteen feet high, but the whole length of the stalk, including the head, being little more than ten feet in the plants we now find, they are proportionably smaller in circumference : in the middle of this long root arises the stalk at right angles, the whole inverted having the figure of a T. From each side of the large root proceed smaller elastic roots linear. It scarcely differs apparently from the foregoing, in or fibres in a direction perpendicular to it, and which, like the 424

strings of a tent, steady it, and fix it to the earth at bottom : about two feet or little more of the lower part of the stalk is clothed with long, hollow, sword-shaped leaves, covering each other like scales, and fortifying the foot of the plant; they are of a dusky brown or yellow colour. It grows in the lakes of Ethiopia and Egypt; in the river Jordan, between Paneas and the lake of Tiberias; and at the confluence of the Tigris and Euphrates; but was not probably imported into Greece until the use of it, as manufactured into paper. was first known. It does not grow in the midst of the Nile. but in the calishes or places into which that river overflows, and is stagnant. The head is too heavy, the stalk too slender, tall, and feeble, and the root too short and weak, to resist the violent pressure of wind and current in an open plain country, and a deep rapid river. The papyrus seems to have come down from Ethiopia at a very early period, and to have been used in Upper Egypt immediately after the discontinuance of hieroglyphics. According to Varro, it did not come into general use in Greece, till after the conquest of Egypt by Alexander; yet it is plain from Anacreon, Alcæus, Æschylus, and the contic poets, that it was known in their time. Plato and Aristotle speak of it, and so do Herodotus and Theophrastus; we also know that it was anciently in use among the lonians, who probably brought it in very early days directly from Egypt: Numa, who lived three centuries before Alexander, is said to have left a number of books written on papyrus. The ancients divided this plant into three parts : the top, with the thyrse of flowers, adorned the temples, and crowned the statues of their gods ; and Agesilaus, the Spartan king, preferred this crown before any other, on account of its simplicity. Antigonus made use of nothing else but the stalk, for ropes and cables to his fleets, before spartum became known, which, though very little better, still serves that purpose in small ships on the coast of Provence to this day. The top of the papyrus was likewise used for caulking the vessels, by forcing it into the seams, and afterwards covering it with pitch. Pliny tells us, that the whole plant together was used for making boats, a piece of the acacia-tree being put in the bottom to serve as a keel; and this is still the only boat used by the Abyssinians, who call it tancoa. Probably the junks of the Red Sca, said to be made of leather, were first built with papyrus, and covered with skins. The bottom, root, or woody part of this plant, before it turned hard, was chewed for the sweet juice contained in it ; indeed the Abyssinians still chew it, as well as the root of the Indian coru, and of every species of cyperus. Herodotus states, that about a cubit of the lower part of the stalk was roasted over the fire and eaten. On account of the great scarcity of wood in Egypt, this lower part was likewise used in making cups, moulds, and other utensils, as also for boards or covers to their books. Paper was prepared from it in the following manner : the thick part of the stalk being cut in half, the pellicle between the pith and the bark, or perhaps the two pellicles, were stripped off, and divided by an iron instrument, which probably was sharp-pointed, but did not cut at the edges ; this was squared at the sides, so as to be like a ribband, then laid upon a smooth table or dresser, after being cut into the lengths required for each leaf: these stripes or ribbands were lapped over each other by a very thin border, and then pieces of the same kind were laid transversely, the length of these last answering to the breadth of the first; a weight was then laid on them while moist, and they were thus left to dry in the sun. It was supposed that the water of the Nile had a gummy quality in it ; but this is without foundation, as the saccharine juice of the plants causes the adhesion of the stripes, and the water Indies.

merely serves to dissolve and diffuse that juice. Paper, says the abbé Rochon, is manufactured in Madagascar from the papyrus, which the natives call sanga-sanga. They pull off with great dexterity the inner bark, divide it into very thin filamenta, which they moisten with water, and having laid them across each other in various directions, press them well down; they are then boiled in a strong lye of ashes, and afterwards pounded in a strong wooden mortar, till they are reduced to a paste : this paste is washed and drenched with water, upon a frame made of bamboos in the form of a grate. When this operation is finished, the leaves are spread out to dry in the sun, and are glazed with a decoction of rice-water. This paper is of a yellowish colour, but when it is well glazed does not imbibe the ink. The pens used by these islanders are made of the bamboo, their ink from a decoction in water of the bark of a tree which they call arandrato; this ink is not so black as the European, but more shining. As, however, the abbé Rochon unfortunately calls the papyrus nilotica a tree, we cannot judge with certainty from what materials the Madagascar paper is really made.

28. Cyperus Spathaceus. Culm clothed with sheaths of leaves; peduncles pinnate, lateral. Size of the sugar-cane.--Perennial: native of Virginia, and the Cape of Good Hope.

20. Cyperus Alternifolius; Alternate-leared Cyperus. Culm naked, alternately leafy at the end; pednucles lateral, proliferous; culms a foot hing; leaves at the top crowded, ensiform, half a foot long, even, roughish at the edge; a small subulate bracke from each axil. It flowers in February and March.—Native of the island of Madagascar: perennial.

 Cyperus Denudatus. Involucre scarcely any; culm two feet high, with one sheath in the middle of it; umbel compound, not much expanded.—Native of the Cape of Good Hope.

31. Cyperus Distans, Culm naked; umbel leafy, superdecompound; spikes alternate, filform; floscules distant; root tuberous; culm two feet bigh, three-sided, strated, yellowish; leaves alternate, lanceolate, keeled, refex, glucous, investing the lower half of the culm with their sheaths.—Native of Malabar.

32. Cyperns Pannonicus; Dirarf Cyperus. Culm obscurely three-connered, prostrate; splitscabout foru together, sessile; root annual; the whole plant smooth and shining; culms in a very thick tuft, from half an inch to six inches in length, leafless scales membranaceous; roundish, blunt, pale, with green streaks; seeds pale bay, smooth.—Native of Hungary. Annual; flowering in July and August.

33. Cyperns Viscosus; Clammy Cyperus. Culm threesided, clammy; leaves rough, triangular at the tip. Perennial; flowering from May till August.—Native of Jamaica.

34. Cyperus Pigmæus. Culm round; umbel compound, involucrat jspikes lancoaltat; glumes mucronate; root-leaves filiform, twice as long as the culm, which is striated, and scarcely an inclu and half in height; umbell with five or six umbellulate peduncles; involucre four-leaved, three times as long as the umbel.—Native of the sands of Tranquebar.

³⁵. Cyperus Arenarius. Culm compressed, måked; spiker of the head glomenta, sessile; involuter one or two-leaved; roots jointed, creeping, from which proceed bunches of leaves sheathed at the base; i eaves filform, naked, from three to six inches long, compressed, striated, channelled on one side, yellowish green.—Native of loose sands in the Bast Indies.

36. Cyperus Capitatus. Culm subangular, striated, leafy in the middle; head terminating, three-leaved; spikes sessile; glumes imbricate, scariose, ending in a recurved daggered point somewhat awned.—Probably a uative of the East Indies. 37. Cyperus Stoloniferus. Culm maked, three-cornered; umbel compound, involutered; spikelte lanceolate; root bulbous; leaves narrow, linear, complicate, a hand or half a foot in length; culm a span in height; involuter oue or two-leaved, the longer an inch and half in length, the shorter half an inch long; besides these there is another leaf or two still shorter; they are all subulate and striated.—Native of Tranquebar in the East Indies.

38. Cyperus Pangorei. Culm three-cornered, lesfy at the base; involucre three-leaved; universal umbel decompound; partial ones subtrifid; culm two feet and a half high; leaves long, unarned, loose; peduneles of the umbellules flexusoe; involucre longer than the umbel.—Native of Tranquebar.

39. Cyperus Cinnamomeus. Culm three-cornerd, leafy; umbel consisting of spikelets in a head, peduncled, and sessile; involucer invel-leaved, serrulate, scabrous; root annual; culms three feet high, leafy at the base, naked above; leaves longer than the culm, near half an inch broad, plaited, with an unarmed keel; heads ovate, compound, ciunamon-coloured.—Native place unknown.

40. Cyperus Setaceus. Culus setaceous, striated, angular, nakci ş sujke terminating, with about four flowers, and nakci ş seeds none; glume purplish; style trifid; seed whitish, utribunet, somewhat wrinkled; the angles rise above the seed, with a truncated dagger point.—Frequently found in the neighbourhood of Calcutta.

41. Cyperus Compactus. Culm round, leafy: unbel decompound; involucre five-leaved; spikelets heaped, subspiral; culm two feet or more in height; leaves nearly as long as the culm, linear, with purplish sheaths, the edge and keel unarmed, strated; the longest leaf of the involucer a foot and half in length, the shortest three inches, all scabrous about the edge; unbellules three or five-raved.—Native of China.

42. Cyperus Mucronatus. Culm round, naked; spikes lateral, sessile ; involucre one-leafed; culms a foot high, with brown truncet sheaths at the base; one or two root-leaves short and narrow; head composed of a few sessile spikes, placed an inch and half from the end of the culm ; involucre scarcely longer than the spikes; scales ovate, acute, convex, withish.—Native of Visagapatnam in the East Indies.

43. Cyperus Diplyllus, ¹ Culm subtriangular, two-leaved; umbel superdecompound; spikelets roundish, subpinnate; culm six feet high; umbel terminating, four inches long; involucre of many short acute leaves; peduncles compressed; a lanceolate whithis involuced under each partial peduncle: spikelets acute, pale, having about twelve flowers; scales imbricate, ovate, acute, striated—Native of the East Indies.

44. Cyperus Leucocephalus. Culm setaecous, three-connered, naked, head sessile; involucre four-leaved, or thereabouts, spreading very much; flowers one-stamined; root bulbous, oblong; culms six incles high; leaves even, half the length of the culm; head small, snow-white; spikes eight to twelve, sessile, broad, ovate; scales linear, compressed, the lowest long, the upper ones gradually shorter, obtuse, strated; stigmas three, villose; seed long, linear, black.— Naive of the East Indies.

45. Cyperus Exaltatus. Culm three-cornered, one-leafed at the base; umbel superfectompound, many-leaved; spike-lets linear, peduncled; culm five feet high, striated; rootheaf nearly three feet long, flat, striated; rough about the edge; umbel more than a foot high, fastigiate; involuere many-leaved, the longest leaf two feet in length, the others decreasing to an inch, all rough about the edge; umbelludes many-eaved, the rays unequally divided and compounded; involuees unequal in number, short, filiform; spikelets com-36.

37. Cyperus Stoloniferus. Culm maked, three-cornered; pressed, ferruginous on the sides, having twenty flowers in bale compound, involucred; spikelets lanceslate; root them; there are two minute scales at the base of the pediibnow; leaves narrow, linear, complicate, a hand or half a cles; scales compressed, acute, keeled; seed white.—Native of in lemeth: culm a sam in height: involuce one or two- 100 Tranqueber in the East Indies.

46. Cyperus Nireus. Culm three-cornered, filform, naked; umbel terminating, sessile, two-leaved; spikes compressed, lanceolate; culms a foot and half in height, striated; rootleaves few, short, narrow; sheath entire, with a short obtuse ligule opposite to the leaf; umbel composed of snow-white spikes, usually sessile; involucre reflex, longer than the head; spikes half an inch in length, with thirty flowers in some; glumes compressed, keeled, striated; seed black, like buckwheat.—Native of the East Indies.

47. Cyperus Imbricatus. Culm three cornered, naked; umbel decompound; rays of the umbellules imbricate; involucre six-leaved, with three leaves very long, and three very short; umbel unequal four inches long, some of the umbellules sessile, others on peduncles of three inches and a half in length; no involucels; spikelets convex on both sides, compressed longitudinally in the middle, lanceolate, scarcely two inches long, and pedicelled; scales imbricate, three, ovare, acute, with membranaceous edges,—Native of Tranquebar in the East Indies.

40. Cyperus Cruentus. Culm three-cornered, and one-leafed at the base; unbel terminating, two-leaved, very simple; culm four or five inches high, filiform; leaf linear, shorter than the culm; spikelets from two to ten, hancedate, sanguineous, brown, two to three lines long; involuer two-leaved, four times as long as the unbel.—Native of Tranquebar.

49. Cyperus Nitens. Culms three-cornered, leafy at the base; unblest almost simple; involuce there-leaved; flowers one-stamined; culms many, at inch or two in height; leaves two to four, linear, longer than the culm; umbel glomerate, some of the spikes simple, others forming an almost sessile unbellule; the longerst leaf of the involucre an inch and half in length, the others gradually shorter; spikelets linear, narrow, shining, whitish, but longitudinally brown in the middle, with the scale diverging at top, and from ten to fourteen flowers; scales ovate, compressed, keeled, striated, hyalinous; seed ash-coloured.—Native of Tranquebar, in the East Indies.

50. Cyperus Flavidus. Culm three-cornered, straied ; umbel compound, three-leaved ; spikes lanceolate; flowers one-stamined ; culms half a foot in height, oue-leafed ; rootleaves in bunches, short, narrow, some spikes of the umbel sessile, others in umbellules; involucre erect, three or four times as long as the umbel, linear; about twenty-six flowers in the spikes; scales scariose, purplish on both sides, separate, narrow.-Native of Tranquebar.

51. Cyperus Venustus: Cyperus Stuppeus; Cyperus Linctus.-Natives of the Society Islands.

Cypress, Summer. See Chenopodium.

Cypripedium; a genus of the class Gynandria, order Diandria, — GENERIC CHARACTER. Calix: spathes vague; spadix simple; perianth none. Corolla: petals four or five, lanceolate, linear, very long, spreading, erect; neatray with the lower petal slipperform, inflated, obtuse, hollow, shorter than the petals, broader, upper lip ovate, flat, inflex, small, Staminar, filamenta two, very short, seated on the pistil, Antheræ erect, covered by the upper lip of the nectary; Pistil; germen long, twisted, inferior; style very short, growing to the upper lip of the nectary; eriarg: capsule obovate, obtusely three-cornered, with 50

....

three sutures, under which it gapes in the corners, threevalved, one-celled; seeds numerous, very small; receptacle linear, growing lengthwise to each valve of the pericarp. ESSENTIAL CHARACTER. Netarry: ventricose, inflated, hollow. Every plant of this genus is difficult to preserve in gardens; they must be planted in a loamy soil, and in a situation where they may have the morning sun only; they must be procured from the places where they naturally grow, for they cannot be propagated in gardens; and the roots should be seldom removed, for transplanting them prevents their flowring.— The species are,

CYP

1. Cypripedium Calceolus: Common Lady's Slipper. Roots fibrous; leaves ovate-lanceolate on the stem; petals acuminate; root composed of many fleshy black fibres spreading obliquely near the surface, the fleshy part retaining the mark of the stalk produced the former year, a new root being annually formed on the side of the old one; stalks two, three, or more, in proportion to the strength of the root, nine, ten, or twelve inches high, and a little hairy; leaves from three to four inches long, and then only two inches broad at their base, of a deep green, and ending in acute points; four or five of these leaves are placed alternately along the stalk : in the bosom of the upper leaf is enclosed the flower-bud, supported by a slender peduncle, which generally turns a little on one side, and advances above the sheath before the flower opens; the corolla has four narrow petals of a dark purple colour, placed in the form of a cross, and spreading wide open; in the centre the nectary is situated, shaped like a wooden shoe, of a pale yellow colour, with a few broken streaks; the opening is covered with two ears, the upper one tender, white, and spotted with purple, the lower thick, and of an herbaceous colour. There is a variety which rises with a stalk nearly a foot and half high, which has longer and smoother leaves than the European sort, and is a native of Virginia, and other parts of America, where there is also another variety found, which is of the same height as the former, but has the leaves of an oblong oval form, and is called the moccasin flower. The old English name of this plant was Our Lady's shoe or slipper, from the Latin calceolus Domina Mariæ or Marianus, and it is the same in the European languages ; in German, Marienschub ; in French, sabot de la Vierge, or soulier de Notre Dame; in Italian, pontoffala, or scarpa della Madonna, &c.-It is a native of Lapland, Sweden, Switzerland, Savoy, Piedmont, Germany, Hungary, Poland, &c. In the woods and thickets of the north of England, it is rarely found. Parkinson and Ray remarked its growing in Helk's Wood, Lancashire, and near Ingleborough in Yorkshire; but Mr. Woodward has sought there for it in vain, a gardener of Ingleton having eradicated every plant for sale. Mr. Miller found it in the park of Borough Hall in Lancashire, about Clapton and Ingleton, in the neighbourhood of Kilnsay, and about Kilnsay Craig, in Yorkshire; and near Castle Eden-dene in the county of Durham. It flowers at the end of May, and the stalks decay to the root in autumn, new ones rising in the following spring, It succeeds very well in a pot, set under a hedge, where it has the morning sun only, and will last thus for many years; the roots will spread so as to fill the pot, and the plant may be propagated by parting the roots, but it must be done with caution, and the American varieties will require a little shelter in severe weather. The gardeners, says Dr. Stokes, might make the botanists amends for rooting out these rare wild plants in their natural places of growth, and at the same time enrich themselves, if they would prove by experiment that one at least of the orchis tribe may be raised from seed.

2. Cypripedium Bulbosom ; Bulbous Lady's Slipper, Bulb roundish ; leaf roundish at the root, which is a bulb, throwing out a few thick fibres from its lower part, and invested with a semitransparent, acute, erect membrane, rising far above its top; leaf radical, solitary, petioled, oval, somewhat pointed, entire, ribbed, smooth, dark green spotted with brown, very like the dog's-tooth violet ; stalk three inches high, erect, round, one-flowered, invested with two tubular membranaceous sheaths; bracte solitary, not far from the flower, linear lanceolate, acute, purplish; flower a little inclined : petals five, all pointing upwards, spreading, lanceolate, acute, three-nerved, purple, three on the outside of the other two; lower lip of the nectary as long as the petals, very large, pendulous, streaked with purple, having a prominent cloven point in the forepart beneath, gaping above, with a spreading, reflex, dependent margin, and bearded in the orifice with a little tuft of yellow hairs; the upper lip shorter than the petals, erect, broad, oval, entire, almost of the same substance and colour with the petals .- Native of Lapland, Russia, Siberia, and Nova Scotia,

3. Cypripedium Japonicum ; Japanese Lady's Slipper-Leaves on the stem roundish, nearly opposite, nerved; stem round, erect, villose, a foot high; leaves in the middle of the stem, two, embracing, acute, simate(, waved, smooth, a hand broad; below the flower, a sessile, solitary, oblong, acute, entrie Laflet, scarely an inch in length; flower terminating, solitary, of the same size as in the common species, --Native of Japan, where it flowers in April and May.

4. Cypripedium Album; White Lady's Slipper.¹ Roots fibrous; leaves orate-lanceolate on the stem; peths obtuse. This species derives its name from the whiteness of its petals. The large nectary is tinged with purple. It is the most magnificant flower of the genus to which it belongs; and hence, Mr. Salisbury justly names it spectabile, for there are few flowers, that to such singularity of structure add such elegance and beauty.—It grows spontaneously in the woods, in various parts of North America.

5. Cypripedium Acaule; Two-leaved Lady's Slipper, Roots fibrous; leaves oblog at the root. It rarely has more than two radical leaves; a very short flowering stem, compared with the others; a large nectary in proportion to the size of the plant, divided on its upper part throughout its length, so as in a great degree to destroy that shoe or slipperlike form, from (which this genus has taken its name.-It flowers with us in May, and is a native of North America.

Cyrila ; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. Calix: perianth superior, five-leaved, permanent; leaflets linear, lanceolate, acute, spreading. Corolla: one-petalled, funnel-form; tube cylindric, subcompressed, inflated, declined, straight, larger than the calix ; border almost equal, inclined, five-parted ; parts rounded, revolute, spreading; the three lower more produced. Stamina: filamenta four; the two lower longer, filiform; then capillary, incurved, converging, finally spiral, thickened at the base, inserted into the lower margin of the corolla, shorter than the tube; antheræ ovate, two-celled, peltate, distinct before flowering time, but afterwards united into a square, white. Pistil : germen half emerging, conic at top, with a nectareous lid, below turbinate, villose ; style filiform, pubescent, becoming bent down, the length of the stamina; stigma two-lobed. Pericarp : capsule turbinate, half twocelled ; partitions two, extending half way, each ending in a two-parted receptacle. Seeds: numerous, small. ESSEN-TIAL CHARACTER. Calix: superior, five-leaved, linear, lanceolate. Corolla: dcclined, funnel-form; tube cylindric, gibbous on its lower edge; throat tricallous; border inclined,

five-parted; segments roundish; the three lower more produced; filaments inserted into the margin of the corolla, incurved, with a fifth barren. *Autheræ*: cohering; germen inferior, half emerging, with a nectareous idt; style bent down; stigma two-lobed; cospule half two-celled, with twoparted receptacles; seeds numerous.—The only known species is,

1. Cyrilla Pulchella. A handsome plant : root branched, fibrose, stoloniferous. The young shoots resemble aments or catkins, are cylindric and closely imbricate, with ovate pubescent scales, thickened at the base, emarginate, and red; stems several, almost upright, branched, round, extremely villose, dusky purple, herbaceous; branches ternate, spreading; stem-leaves in threes, on the branches usually opposite, petioled, ovate or ovate-lanceolate, sharp at both ends, loosely serrate, entire at the base, with nerves prominent below, grooved above, villose on both sides, bright green, beneath paler, and very frequently blood-red; petioles round on one side, on the other flattish, and slightly channelled, one-third only of the length of the leaves; flowers resembling those of ruellia, axillary, solitary, peduncled, inclined, red ; peduncles spreading very much, round, villose, red, twice the length of the petioles; calix villose, ending in a turbinate germen, red at the base. It flowers in England at the end of summer, and in the beginning of autumn .- Native of Jamaica. It must be kept in the barkstovc, and may be propagated by suckers, but never produces seed in England. In the West Indies, where it thrives best in a cool moist gravel, mixed with rich mould, it well deserves to be cultivated for its beauty and elegance.

Cyrtanthus; a genus of the class Hexandria, order Monogynia.-GENERIE CHARACTER. Calks: none. Corolla: one-petalled, club-shaped, bent, six-cleft at top; segments ovate-oblong; the three inner blunt, the three outer terminating in a little horn. Stamina: filamenta six, fastened to the tube, filtorm, subulate, a little shorter than the corolla; anthera oblong, erect. Pistil: germen inferior, ovate, obtusely three-cornered; style filform, the length of the corolla; stigma trifid. ESSENTIAL CHARACTER. Corolla: tubular, club-shaped, crocked, six-cleft; segments ovate, oblong. Filamenta: inserted into the tube, converging at top. These plants may be increased by offsets or seeds, and require the same treatment as other bulbs from the Cape. See Crinum. ---The species are,

1. Crytanthus Angustifolius; Narrow-leaved Cyrtanthus, Leaves obtusely keeled, straight; flowers drooping, narrow, purple, with a bent tube, from which latter circumstance it takes the name. The small glundular hook at the extremity of each alternate segment of the corolla, is deserving of notice. —It flowers from May to July, and is a native of the Cape of Good Hope.

 Cyrtanthus Obliques; Oblique-teared Cyrtanthus, Leaves flat, oblique; flowers pendulous. This plant is singular for its oblique long leaves; flowers purple; tube turbinate; border bell-shaped, erect.—It flowers from May to July, and is a native of the Cape of Good Hope.

Cytimus ; a genus of the class Gynandria, order Octandria. -GENERIC CHARACTER. Caliz: perianth on-leafed, tubular, bell-form, permanent ; tube cylindrie ; border patuloss, four-parted, somewhat obluse, coloured. Corolla ; none. Stamina ; sixteen ; filamenta none ; anthere oblong, growing to the tip of the style under the stigma, oblong, twovalved. Pistd: germen inferior, rounded; style cylindric, length almost of the calix; sigma cight-left, gibbous, obtuse. Pericarp: berry crowned, roundish, coriaccous, eightcelled ; seeds numerous, minute, roundish, ESEENTIAL CHARACTER. Style: one. Calix: four-cleft, superior. Corolla: none; antheræ sixteen, sessile; berry eight-celled, with many seeds. — The only species is,

CYT

1. Cytimus Hypocistis: *Kape of Cistus*. A parasitical plant, growing at the root of the cistus; leaves sessile, closely imbrinate; flowers terminating, heaped; below the flowers are two opposite scales, becoming purple by age. The colour of the flower tiself is a dirty yellow. The number of anthera, and the divisions of the stigma, vary; the number of the anthera is double the divisions of the stigma, vary; the number of the anthera is double the divisions of the stigma, plant, is an annual plant, and a native of the county of Nice, Spain, Portugal, and Barbary.

Cytisus ; a genus of the class Diadelphia, order Decandria. GENERIC CHARACTER. Calix: perianth one-leafed, bell-form, short, obtuse at the base, smooth, two-lipped; upper lip two-cleft, acuminate, lower three-toothed. Corolla: papilionaceous; standard ovate, rising upwards; sides reflex; wings the length of the standard, straight, obtuse; keel somewhat bellied, acuminate. Stamina : filamenta diadelphous, (single and nine-cleft,) rising upwards; antherae simple. Pistil: germen oblong; style simple, rising npwards ; stigma obtuse. Pericarp : legume oblong, obtuse. attenuated at the base, stiff. Seeds : a few, kidney-form, compressed. ESSENTIAL CHARACTER. Calix: two-lipped : upper lip two-cleft, lower three-toothed; legume attenuated at the base. All the species of cytisus are shrubs without spines, most of them very fit for ornamental plantations. They are chiefly hardy ; the leaves ternate ; the flowers, except in the twelfth, yellow, and growing in bunches,----The species are,

1. Cytisus Laburnam; Laburnum, anciently called Beautrefoil Tree. Racemes simple, pendulous; leaflets ovate, oblong. The common height of the laburnum is from eight to fifteen feet; but in a good ground, and when planted thick, it will run up much higher ; leaves ternate, on long petioles, commonly three together from one point; leaflets quite entire, smooth, and pale green on the upper surface, glaucous, and covered with short appressed hairs on the lower, which has a strong prominent nerve or mid-rib. The flowers come out from the same short spurs with the leaves, in naked, handsome, villose racemes, a span in length; and beyond these, young shoots are produced, which are white, and bear the ternate leaves singly. Each flower hangs from a long pedicel; calix yellowish, small, two-lipped; the upper lip cloven, the lower having three minute teeth; corolla pale yellow; standard broad, emarginate, with dusky spots and dots within at the base; wings longer than the keel, hooked; keel in two parts ; staminiferous sheath in one piece ; the two upper filamenta standing crosswise ; germen smooth ; legnme from an inch to nearly two inches in length, covered with white appressed hairs, containing from one or two, to six or seven ripe seeds, which are black and shining, several at one or both ends are frequently abortive. There are two varieties of laburnum: the first broad-leaved, which formerly was more common in the English gardens than it is at present; and the second narrow-leaved, which having much longer spikes of flowers, makes a finer appearance, and has in a manner supplanted the other from our ornamental plantations. The first, however, grows to be the largest tree. and the wood of it is very hard, of a fine colour, and will polish very well. It approaches nearly to green ebony, and is called ebony of the Alps by the French, for the Swiss use it for many kinds of furniture ; but in England there are few of these trees that have been suffered to stand long enough to arrive to any considerable size; for as they have only been looked upon as ornamental, the frequent alterations which

most of the gardens in England have undergone, have occasioned their destruction ; but in some of the old gardens in Scotland, where they have been permitted to stand, there are large trees of this kind, fit to cut down for the use of the timber. Even where it had been broken and injured, it has been observed to girth more than a yard, at six feet from the ground; and if properly treated, would, of course, have been much larger. It grows fast, and is extremely hardy, and may therefore be well worth propagating upon poor shallow soils, and in exposed situations. The Duke of Queensberry sowed a great quantity of the seeds of this tree, upon the side of the downs, at his seat near Amesbury in Wiltshire. where the situation was very much exposed, and the soil so shallow that few other trees would grow; yet even here, the young trees were twelve feet high in four years' growth, and became a shelter to the other plantations, for which purpose they were designed; but as the hares and rabbits greatly injure these trees by feeding upon the bark in winter, they should be fenced, if possible, from these animals. On this account, however, Mr. Boutcher ingeniously suggests, that the laburnum is very proper to sow in plantations infested with hares and rabbits, who will not touch any other plant while a twig of laburnum remains. And although they eat it to the ground in winter, yet it will spring again the next season, and thus constantly supply these mischievous animals, so that five shillings worth of laburnum-seed will effectually secure a whole plantation from their destructive depredations. But the laburnum is not only useful in preserving more valuable trees; the wood is very strong, and is much used for pegs, wedges, musical instruments, handles of knives, and a variety of furniture. Mr. Boutcher informs us, that he had seen a large table and a dozen chairs made of it, which judges of elegant furniture thought the finest they had ever seen. Pliny has remarked, that its wood is the hardest of any, next to ebony; and Matthiolus speaks of it being used for making the best bows. It chars remarkably well; and, if planted thick to run up tall, would make durable hop-poles. For this purpose, it might be planted in large clumps in parks, where it would be also very ornamental; the branches being generally loaded with long strings of flowers hanging down from every part of them in the month of May. Haller says. it is very bitter, and that the seeds purge and vomit violently. He also remarks, that the Latin name laburnum was evidently formed from the Alpine name, l'aubours. It was formerly called beau-trefoil, and peascod-tree, in England ; but the Latin name has superseded these. The Germans call it bohnenbaum ; and the French, cutise des Alpes, aubours, and faux ebenier .- It is a native of Switzerland, Austria, and Provence. It is easily propagated by seeds, which the trees produce in great plenty. If they be sown upon a common bed in March, the plants will appear by the middle or end of April, and will require no other care but to be kept clear from weeds during the following summer; and if the plants be too close together. they should be transplanted in the autumn following, either into a nursery, where they may grow a year or two to acquire strength, or into the places where they are designed to remain. Where they are cultivated for timber, it will be the best method to sow their seeds upon the spot where they are intended to grow, because these trees send out long, thick, fleshy roots to a great distance, penetrating even gravel and rocks; and if their roots be cut or broken, it generally retards their growth; therefore, when they are not sown upon the intended spot, they should be transplanted thither young, otherwise they will not grow half so large, as the removing them twice will stop their growth, and cause them to be more productive in flowers: hence all trees intended for timber

are much better sown on the ground where they are designed to stand, than if transplanted into it from another place. If the seeds of these trees be permitted to scatter, in winter the plants will rise in abundance in the following spring ; so that a few trees will soon supply any person with a sufficient number of the plants. There is a variety with variegated leaves. which can only be continued by cuttings or layers; the cuttings should be planted in autumn, when the leaves begin to fall: and the plants must have a poor soil, for in good ground they are apt to become plain. The laburnum however will thrive upon many different soils, and in such situations as few other trees will make any progress in, especially in a poor hungry soil, where, if there be any depth, it will increase surprisingly. Mr. Boutcher recommends the seedling plants to be removed to the nursery in February or March, shortening their roots, which are not injured by cutting them freely when young, and planting them two feet and a half distant from row to row, and a foot asunder in the rows, there to remain during two seasons. Hence they may be removed either in October or February, still reducing the downright roots, and smoothing the extremities of those which spread, pruning off all ill-placed side-branches, but leaving some of the smallest at proper distances. The rows may now be five feet apart, the plants two feet asunder; and here they may remain three or four years : but these directions are more adapted to raising trees for ornamental plantations than for use. If they be designed for poles, they should be kept to smaller distances. The autumn after they are sown, they may be pricked out three or four inches apart, and the following spring to the distance of nine inches or a foot, there to remain three or four years, according to their growth ; when they may be removed, being fourteen or sixteen feet high, to the places where they are designed to remain, only shortening the lateral roots, and just topping the tap-root, and they will then run up with few lateral branches. to the height of from twenty to forty feet.

2. Cytisus Nigricans ; Black Cytisus. Racemes terminating, erect; calices hairy, with minute toothlets; leaflets elliptic, hairy underneath. This shrub seldom exceeds three or four feet high in England; it naturally puts out many lateral branches near the ground, which spread out on every side, forming a low shrubby bush, which is with difficulty raised to a stem. The branches are very slender, and their ends are frequently killed in severe winters. The leaves grow by threes, are equal in size, and of a dark green colour. The branches grow erect, and are terminated by bunches of yellow flowers, about four or five inches in length, and making a fine appearance .--- Native of Austria, Hungary, Silesia, and Italy. This, with the third, seventh, ninth, eleventh, twelfth, thirteenth, and seventeenth species, may be propagated by seeds, which should be sown upon a bed of light earth in March, covering them about one-third of an inch with fine screened mould ; and in the beginning of May the plants will appear, when they must be carefully weeded, which is all the culture they require till autumn, when it will be very proper to arch the bed over with hoops, that in frosty weather the plants may be covered with mats, to prevent their tender shoots from being killed; for as these young plants are apt to continue growing later in the autumn than those which are become woody, they are much more susceptible of cold ; and if some care be not taken to cover them in severe winters, many of them may be entirely destroyed, and others killed to the ground. In the next spring, after the danger of hard frost is over, they should be carefully taken up, and planted out at the distance of one foot row from row, and six inches asunder in the rows; they should 1

be placed in a sheltered situation, and as they do not shoot till late in the spring, they need not be transplanted before the end of March or the beginning of April; and if the scason should then prove warm and dry, it will be proper to give the plants some water, to settle the earth to their roots ; and if the drought continue, and the waterings are three times repeated at a week's interval from each, it will be of service to the plants. When they have taken new root, they will require no further care, but to keep them constantly clean from weeds ; in this nursery, the plants may remain two years, in which time they will have acquired strength enough to be transplanted where they are to remain.

3. Cytisus Wolgaricus ; Winged-leaved Cytisus. Hoary : racemes simple, erect; flowers pointing the same way; leaves pinate ; leaflets, roundish ; stipules subulate. This is a very handsome shrub, scarcely growing two feet high. The leaves have from three to nine, but usually six or seven pairs of leaflets, terminated by an odd one; they are smooth above, silvery beneath, and mostly orbiculate. The flowers are large, and of a deep yellow colour, in axillary and terminating racemes, erect on peduncles much longer than the leaves, about ten in number, generally opposite, or nearly so, in pairs, with a small acuminate bracte to each pedicel ; calix and pedicels lanuginose, and having reddish glutinous glands scattered over them; seeds large, gray, testaceous, variegated. -Native of Siberia, in the deserts between the Tanais and the Wolga. For the propagation and culture, see the second species.

4. Cytisus Sessilifolius ; Common Cytisus. Racemes erect ; calices with a triple bracte ; floral leaves sessile. This rises with a woody stalk, putting out many branches covered with a brownish bark; leaflets obovate, ternate, on very short etioles; flowers in close short terminating racemes, of a bright yellow colour; legumes short and broad. This shrub rises to the height of seven or eight feet, and becomes very bushy. The leaves are upon long petioles, but sessile on the flowering branches; filamenta all connate at bottom; legumes blackish. This shrub is easily known by its smoothness, the uprightness of the stalks and racemes, and particularly by the triple bracte immediately below the flower. Ruminating animals greedily devour the leaves and young brauches of this species, while the goat alone will feed upon the laburnum .--Native of the south of Europe. This is a hardy plant, that will thrive in any situation, and almost in any soil that is not too wet. It is propagated by seeds, which may be sown upon a common bed of light earth in the spring; in autumn the plants may be removed into the nursery in rows one foot apart, and at six inches' distance in the rows, where they may remain two years to acquire strength, and should then be removed to the places where they are designed to grow.

5. Cytisus Cajan ; Pigeon Cytisus, or Pigeon Pea. Racemes axillary, erect; leaflets sublanceolate, tomentose, the middle one on a longer petiole. This rises with a weak shrubby stalk, eight or ten feet high, sending out many sidebranches, which grow erect. The flowers come out from the side of the branches, singly or in clusters; they are of a deep yellow colour, and about the size of those of the common laburnum; stamina truly diadelphous; seeds roundish, a little inclined to kidney-shape. The leaves are very soft, and in some views white. The pigeon-pea is frequently planted in the West India islands, chiefly in rows, as a fence to the sugar plantations, and will thrive on barren lands. The fruit is much eaten by poor people and negroes, and is esteemed a wholesome pulse ; even the better sort of people in the island of Martinico hold it in estimation, and prefer it to the European pea. In Jamaica it is chiefly used for feeding pigeons ; whitish hairs, which are frequently soft, and scarcely visible; â6.

whence its name. The branches, with the ripe seed and leaves, are given to feed horses, cattle, and hogs, which grow very fat upon them .- Native of both Indies, and of Africa, whence they are supposed to have been originally brought to the West Indies, where they are called Angola-peas, and pois d'Angola. It grows only in hot countries, and cannot therefore be preserved in England, except in the bark-stove. It rises easily from seeds in a hot-bed, and will grow three or four feet high the first year, provided it have proper heat; and in the second year, the plants will produce flowers and seeds. They must be treated in the same manner as other tender plants from the same countries; should have little water in winter, and a large share of air in warm weather.

6. Cytisus Hirsutus; Hairy or Evergreen Cytisus. Peduncles simple, lateral; calices hirsute, trifid, obtuse, ven-tricose, oblong. This plant has a soft shrubby stalk, dividing into many branches, which grow erect, and frequently rise to the height of eight or ten feet ; the stalks, branches, and leaves are very hairy; the leaves are ternate, ovate, and placed closely on the branches; the flowers come out from the side of the stalk in short racemes; they are of a pale yellow, appearing in June, and are succeeded by long, narrow, hairy legumes, which ripen in September .- Native of the south of Europe and Siberia. This may be propagated in the same manner as has been directed for the second sort : but as it is sometimes killed in severe frosts, it should be planted only on a dry soil, and in a warm situation; it is also very difficult to remove, when grown to any size, because it shoots long roots deep into the ground, and, when they are either broken or cut, mostly dies.

7. Cytisus Capitatus; Cluster-flowered Cytisus. Flowers in heads; branches erect, strict, round, villose; leaves ovate-elliptic, villose; bracte linear beneath the calix; stem and petioles pubescent; leaves smoothish; calix tubular, bellying, pubescent. It differs from the preceding, in having most of the flowers terminating in a genuine head; the leaves more obtuse, and hairy on both sides; the stems scarcely ever a cubit in height, and extremely hirsute .- Native of Austria, Carniola, and Silesia. For its propagation and culture, see the second species.

8. Cytisus Austriacus; Siberian Cytisus. Flowers in umbels, terminating; stem erect; leaflets lanceolate. This has a shrubby stalk, which rises nearly four feet high, dividing into many branches, which, when young, are covered with a green bark ; the flowers are produced in close heads at the ends of the branches, having a cluster of leaves under them; they are of a bright yellow colour, appear in the beginning of May, and are sometimes succeeded by short woolly legumes, containing three or four small seeds .- Native of Austria, Hungary, Silesia, Italy, and Siberia. It is propagated by seeds, which should be sown early in April, on a border of strong ground, exposed to the east; for if they be sown where they will have full sun, the plants will not thrive. It requires a cold situation, and a strong soil

9. Cytisus Supinus; Trailing Cytisus. Flowers peduncled, about two together; leaves villose; stem decumbent, becoming shrubby. The stems of this are almost wholly procumbent, round, dusky, a little divided ; the ends are closely beset with leaves and flowers, which come out together from spreading buds, formed of a few subovate simple bractes ; the longer stems are frequently decorated with flowers for a foot in length ; two flowers usually proceed from each bud, but sometimes only one, and rarely three or more, ou short peduncles. The younger branches, the petioles, pedancles, and leaves, especially underneath, are covered with soft

CYT

flowers erect, deep yellow, but becoming reddish before they late, elliptic, whitish about the edge, small, acute, scarce decay ; seeds several, shining, brown. In the garden it becomes more pubescent, and by age more shrubby, branched, and diffused, rising to four feet in height, with long recurved branches loaded with flowers .- Native of the south of Europe and Siberia. For the propagation and culture of this plant, see the second species.

10. Cytisus Proliferus; Silky Cytisus. Flowers in lateral umbels; stems erect; leaves elliptic, acute, silky under-neath; calices woolly. The stems, but especially the small branches, are almost tomentose ; leaves alternate, petioled ; peduncles axillary, (four to eight,) equal, one-flowered, a little longer than the petiole, filiform, villose, with two opposite filiform bractes near the flower; corollas large, white. When the flowering is past, a branch grows out in the centre of the peduncles. It flowers in April and May, and is found in the mountain woods of Teneriffe. This, with the fifteenth, sixteenth, and seventeenth species, will not bear the open air of our climate, but require the protection of a green-house, or dry-stove.

11. Cytisus Argenteus; Silvery Cytisus. Flowers generally two together, subsessile ; leaves tomentose ; stems decumbent; stipules minute. It has herbaceous stalks. The flowers are produced either single, or two, three, or more together, at the ends of the branches. It is a hoary shining plant; the branches towards the root become shrubby, but above they are herbaceous ; bractes two or three, growing to the base of the calix, the segments of which are longer than in the other species .- Native of the south of France, and Istria. For its propagation and culture, see the second species.

Flowers peduncled, solitary; 12. Cytisus Purpureus. leaves smooth; stems decumbent, becoming shrubby; legumes sickled above. This is suffruticose; stems the thickness of a goose-quill, naked, smooth, brownish, pliant, prostrate; from these spring slender, soft, ascending, branched twigs, at first slightly pubescent, but afterwards smooth ; leaves scattered, alternate, petioled ; leaflets sessile, ovate, sharpish, dark green, quite entire; flowers axillary, solitary, erect, on a short pedicel; calix tinged with purple; upper lip shorter, two-toothed, lower a little longer, ovate-acute, entire; corolla large, bright red; standard obcordate, broad, villose, ciliate on the sides at bottom; wings oblong, oval, entire, convergiug; keel blunt; both that and the wings villose, ciliate at the base .- Native of Carniola, flowering in April and May. See the second species.

13. Cytisus Glaber. Flowers solitary, lateral, subsessile, pendulous; leaves ternate, petioled; leaflets equal, lanceo- and June .- Native country unknowu.

perceptibly hairy underneath; stipules none; peduncles shorter than the flowers; calix oblong, somewhat bellying, trifid : corolla vellow, rather large,-Native of Austria, For its propagation and culture, see the second species.

14. Cytisus Græcus. Leaves simple, lanceolate, linear: branches angular. It rises with a woody stalk, six or seven feet high, sending out many angular lateral branches. The flowers are produced in short bunches from the sides of the branches; they are small, yellow, and appear in July and August, but are not succeeded by seeds in Eugland. It is propagated by cuttings, which, if planted on a bed of light earth in the beginning of July, and closely covered with a bell or hand glass, shaded from the sun in the middle of the day, will put out roots by the middle or end of September, when they should be carefully taken up, planting each in a separate small pot, carefully watering and shading them until they have taken new root; after which, they may be exposed in a sheltered situation until the end of October, when they must be removed into shelter.

15. Cytisus Tener. Leaves simple, lanceolate; branches round. This is an erect shrub, branching very much, three feet high, with a trunk the thickness of a finger, round, and upright; leaves quite entire, subpetioled, pale beneath, somewhat villose on both sides, scarcely half an inch in length ; flowers few, in terminating racemes on short pedicels, smelling sweet; legumes hirsute; seed few .- Native of Madeira

16. Cytisus Foliolosus ; Leafy Cytisus. Racemes terminating, erect; calices villose; segments sickle-shaped; leaflets obovate, oblong .- It flowers in July and August, and was found in the Canary Islands.

17. Cytisus Divaricatus; Clammy Cytisus. Racemes terminating, erect; calices and legumes ramentaceous, viscid; leaflets oblong; leaves ternate, with ovate oblong leaflets, short petioles; racemes simple; flowers peduncled, solitary, supported by one or two subulate bractes. Before the corolla opens, the whole is tawny; but when open, the standard about the middle only is of that colour ; the rest is then yellow; the calix is also tawny. It flowers in July and August, and is a native of the south of France, Spain, and Madeira. For its propagation and culture, see the second and tenth species.

18. Cytisus Biflorus. Smooth Cytisus. Peduncles generally in pairs, lateral; calices oblong, villose, two-lipped; upper lip bifid; leaflets oblong, elliptic. It flowers in May

DAC

DACTYLIS ; a genus of the class Triandria, order Digy- | feathered. Pericarp: none; corolla including the seed, and nia,-GENERIC CHARACTER. Calix: glume manyflowered, two-valved, collecting the floscules into an ovateoblong spicule ; valves concave, keeled on one side ; convex broader, half ovate, on the other narrow, the inner largest. Corolla: two-valved ; the lower valve larger, concave, acute, mucronate, or awned, the inner lanceolate, acutely bifid, scarcely shorter than the lower; nectaries two, lanceolate, acuminate, gibbous at the base. Stamina : filamenta three, capillary, longer than the corolla; antheræ oblong, two-forked.

DAC

dropping it. Seed : single, obloug, grooved on one side. ESSENTIAL CHARACTER. Calix : two-valved, compressed, one valve larger, keeled. For the propagation and culture of this genus, see Grass .---- The species are,

1. Dactylis Cynosuroides; American Cock's-foot Grass. Spikes scattered, numerous; flowers closely imbricate, and pointing one way; culm erect, two feet high, reedy; leaves on the culm six broad, longer than the culm, very glossy, scabrous about the edge, bent in, more glaucous on their Pistil: germen ovate; styles two, spreading; stigmas inner surface; spikes six or more, diverging, chaffy; floscules

scabrous behind; calices one-flowered, scabrous on the keel, mucronate, longer than the floscule, sessile, turned one way; pistils villose, very long.—Native of Virginia and Canada; perennial.

2. Dactylis Glomerata; Rough Cock's foot Grass. Panicle turned to one side, glomerate; root perennial; culms from two to three feet high, ancipital, naked and rugged at top, having four or five smooth purplish knots or joints, and three leaves, with ancipital, villose, or rugged sheaths, sharply keeled; leaves six inches or more in length, and three or four lines broad, spreading, somewhat glaucous, very rugged on both sides, with extremely minute spinules; ligule white, oblong, obtuse, cloven; panicle close, often coloured; peduucles solitary, alternate, angular, stiff, rugged, with a callous tumor at the base, twice and thrice cloven, the lowest sometimes two. more, remote, longer, spreading, at length becoming horizontal, and even somewhat reflex : spikelets all turned the same way, subsessile, twin-glomerate, oblong, very obtuse, having two, three, and sometimes four flowers, pressed close, and diverging during florescence; seed dropping. It is a rough coarse grass, and hence has the names of rough grass and hard grass, as well as that of orchard grass, from its flourishing particularly under the shade of trees. No grass is more common than this, but it is extremely hardy and unproductive; its flourishing under the drip of trees may be a recommendation; but the head is so large, that in heavy rains it is apt to be laid .- It is rather early, flowering from June to August ; and should always be cut while young and tender, either for hay or fodder.

3. Dactylis Ciliaris. Spike in a head, turned to one side; calices three-flowered; stem creeping; rot filform, creeping, with long white fihres; cutna a palm high, ascending, very simple, even, with one joint; root-karses involute, filiform, even, the length of the culm; stera-leaf one, even, the length of the head; shcal somewhat bellying; head termining, orate, with many sessile flowers; glune of the calix three-flowered, compressed, naucroate, the length of the colla, lawing scattered hairs on the back under the tip; outer glune of the corolla ovate, strated, hearded below with while hairs.—Native of the Cape of Good Hope.

4. Dactylis Lagopoides. Spikes roundish, pubescent; culm prostate, branched; root perzenial, fibrons; culms a palm high, several, covered on every side with the sheaths of leaves; leaves spreading, subulste, like spines, contracted at the base narrower than their sheaths; spike glomerate, ovate, pubescent; flowers essile, many together, pointing nearly one way; calix eight-flowered, but effen only four-flowered, nearly equal; valves acuts, stif, striated, outer valve of the fields of Mahar.

5. Dactylis Capitata. Spikes in a head, even; culm prostrate, branched; root perennial; leaves even, three on the enlm, which is of the thickness of a fowly squill, a foot and half in height, and even; panicle in form of a spike, as it were conglomente, marrower at top, a pallo in in length, the colour of chaff; flowers always twin, depressed; calix nearly the length of the flower, containing about five flowers; the outer valve much attenuated; corolla oblong, awnless,— Found by Sparmann at the Cape of Good Hope.

6. Dactylis Stricta; Sea Cock's foot Grass. Splites terminating, usually twin; flowers renote, pressed close; colms and leaves strict; the calix contains one floret only, which has but one style, and the style is longer than the stamina. It is perennial, and flowers from July to September.—Native of the marshes in Essex, and very common on the sea-coast, and also in Portugal.

7. Dactylis Patens; Spreading Cock's/oot Grass. Spikes scattered, turned one way, few; flowers closely imbricate; culm decumbent; leaves spreading very much.—This is a perennial, flowering in August, and a native of North America.

Daffodil. See Narcisus.

Daffodil, Sea. See Pancratium.

Data; a genus of the class Decandria, order Monogynia. —GENERIC CHARACTER. Caliz: involuer four-leaved, sessile, many-flowered; leaflets scariose, erect; perianth none. Coralle: one-petalled, funcel-form, longer than the involuere; tube filiform, rude; border five-deft; divisions lanceolate, obtuse. Stamina: filamenta ten, inserted into the throat, shorter than the border, the alternate ones shorter. Anthera shorter than the border, the alternate ones shorter. Anthera simple. PistI1: germen somewhat oblong, growing on the base of the corolla; style filiform, length of the tube; stigma globose, ascending. Poricarp: berry ovate, one-celled, Med.simgle. Corolla: four or five-cleft; berry one-seeded, —The species are,

1. Dais 'Cotinifolia: Cotinus-leared Dais. Flowers fivecieft, ten-stannined : leaves opposite, obovate, quite entire, smooth, petioled : flowers in a bunch, aggregate, terminating, pubscent, with a genmaceous four-valued involuere; the fruit is a small nut, of an ovate-acuminate form, with a thin bark over it, and clothed with a permanent corolla; the epidermis is membranaceous, pale, diaphanous, thickening on each side into a permanent whitish edge, easily separating; shell bony, thin, brittle, livid white on the outside, black within, one-celled, and valueless.—Native of the Cape of Good Hope. This ornamental deciduous green-house shrub, not having yet seeded in England, as it does in Holland, and no other way having been yet discovered of increasing it freely, keeps up a very high price among the nursery-men.

2. Dais Octandra, Flowers four-cleft, eight-stamined ; leaves opposite, elliptic, oblong, acuminate, petioled, even; involucre one or two, terminating, peduncled, shorter than the flowers, which are smooth; stamina placed upon the tube, and longer than the corolla.—Native of the East Indies.

3. Dais Disperma. Flowers eight and ten stamined; leaves ovate-lanceolate, acuminate, nerveless.-Native of Tongataboo.

Daisy. See Bellis.

Daisy, Great, or Oxeye. See Chrysanthemum.

Daisy, Blue. See Globularia.

Dalbergia ; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix : perianth one-leafed, bell-shaped, five-toothed; teeth bluntish. Corolla: papilionaceous; standard large, ascending, cordate-ovate, emarginate, retuse, with a linear claw; wings oblong, straight, obtuse, with a reversed tooth above; keel scarcely shorter than the wings, two-parted at the base, straight, obtuse, Stamina : filamenta ten, united in two equal lateral bodies, free at top, ascending. Antheræ roundish. Pistil: germen oblong, compressed, pedicelled; style subulate, ascending, or reflex; stigma simple. Pericarp : legume oblong, compressed, flat, pedicelled, not gaping, one-celled. Seed ; single, or few, reremote, kidney-form, compressed. ESSENTIAL CHARAC-TER. Filamenta two, four-cleft at top. Fruit: pedicelled, not opening, leguminose, membranaceous, compressed,-The species are

 Dalbergia Lanceolaria. Leaves pinnate; leaflets elliptic, hairy underneath; fruits lanceolate. This is a tree with wand-like, pendulous, hairy branches; leaves alternate, unequally pinnate; leaflets elliptic, alternate, remote, from ten to sixteen, quite entire, waved, smooth underneath, hirsute branched; flowers ferruginous; calix rough with hairs; the teeth almost equal; corolla larger than in the second sort: standard more dilated; filamenta two, lateral, four-cleft at the end, with the rudiment of a fifth on each side, but without any loose or single filamentum, such as the other species exhibit; style bent upwards; the fruit is a membrane, exactly the figure of a little lance, attenuated at the base, not opening, not divisible into two skins by a knife, the length of a finger or less; in the middle of this membrane, a single, compressed, oval seed is immersed ; and when there are two seeds, they are placed longitudinally, at a distance from each other .-- Observed by Koenig in Ceylon and Malabar.

2. Dalbergia Monetaria. Leaves ternate ; leaflets smooth, ovate; fruits oval, veinless. This is a shrub: leaflets petioled, 'quite entire, veined, acuminate, alternate; peduncles several, axillary, spiked, directed one way, toothed at bottom, where the flowers have fallen; flowers extremely minute, white; calix blunt, with five small equal teeth; filamenta two, lateral, equal, four-cleft at top, with a third, which is single, below the germen, hence there are nine filamenta; antheræ nine, globular, twin; style filiform, erect; stigma headed; the fruit is of an oval form, like a piece of coin, compressed, cartilaginous within, one-celled, deciduous, not opening; seed single, compressed, kidney-form; the root when cut yields a purple juice; the wood is red, and yields a resin resembling dragon's-blood,-Native of wet parts of Surinam

Dalechampia ; a genus of the class Monœcia, order Monadelphia .- GENERIC CHARACTER. Involucre : common, exterior smaller; leaflets four, lanceolate, spreading; interior very large ; leaflets two, heart-shaped, three-cleft, converging; for the male flowers a foot-stalked umbel, simple, tenflowered, shorter than the interior involucre. Calix: involucel two-leaved, erect, blunt : leaflets somewhat three-lobed : scales numerous, obovate, pressed in an imbricate manner to the exterior side of the involucel, and of the same length with it; perianth proper five-leaved, foot-stalked ; leaflets ovate, acute, deciduous. Corolla : none. Stamina : filamenta very many. growing together into a column longer than the calix. Antheræ roundish. In the females, three florets within the same common involucre, approximate to the inferior side. Calix : involucel three-leaved : leaflets emarginate, small ; perianth proper, inferior; leaflets eleven, linear, toothed, acute, converging, permanent. Corolla : none. Pistil: germen roundish, shorter than the perianth; style filiform, ascending, length of the males: stigma somewhat headed, perforated. Pericarp: capsule roundish, three-berried, threecelled; cells two-valved. Seeds : solitary, globose. ESSEN-TIAL CHARACTER. Outer common involucre with four leaflets, inner with two trifid leaves. Male: umbellule tenflowered; involucel two-leaved, with numerous chaffs; proper five-leaved. Corolla: none; filamenta very many, connate. Females: floscules three; involucel three-leaved; proper perianth with eleven leaflets. Corolla: none; style filiform. Capsule: tricoccous .- These plants are propagated by seeds, sown early in the spring on a hot-bed, transplanted into small pots when three inches high, plunged into a bark bed, and frequently watered; they should be afterwards re moved into larger pots, and placed at the back of the bark stove, where they may have an espalier or trellis to run up on. They seldom continue more than two years .---- The species are.

1. Dalechampia Colorata ; Coloured Dalechampia. Leaves quite entire. This resembles the second species, and the leaves are three-lobed, but less deeply cut, and not serrate; two principal varieties of the mezereon, one with a white

above, veinless, small; petioles hairy; racemes axillary, hairy, | the involucre is more oblong, resembling a petal, or coloured. not cordate at the base, or green. Found in New Granada, by Mutis.

2. Dalechampia Scandens; Climbing Dalechampia. Leaves trifid, serrate; stem branched, hairy, the hairs standing out; leaves alternate, petioled, remote, cordate, three-parted, much veined, wrinkled, serrate, pubescent; lobes lanceolate; petioles round, slightly channelled, the length of the leaf: the genuine stipules semicordate, reflex, short; besides these there are two spurious stipules from the sinus at the base of the leaf, which are subulate, erect, and small; peduncle axillary, solitary, very short .- It flowers in June and July, and is a native of the West Indies.

Damasonium; a genus of the class Hexandria, order Hexagynia .- GENERIC CHARACTER. Calix : spathe one-leafed. oblong, five-winged; wings waved, two running down into the petiole ; mouth five-toothed ; teeth sharp, membranaceous at the edge ; perianth one-leafed, three-parted, superior ; leaflets lanceolate, blunt, surrounded by a membranaceous edge. spreading. Corolla: petals three, roundish, waved, spreading, longer than the perianth. Stamina: filamenta six, very short. Antheræ linear, erect, blunt, emarginate at the base, shorter than the corolla. Pistil: germen oblong, inferior; styles six, linear, emarginate, erect, longer than the stamina; stigmas villose hairs on the side of the styles. Pericarp: berry oblong, ten-celled, crowned by the calix; seeds very many, oblong, small. ESSENTIAL CHARACTER. Spathe: Petals: one-leafed. Perianth: one-leafed, three-parted, three : berry ten-celled, inferior .---- The only known species is.

1. Damasonium Alismoides. Leaves heart-shaped, nerved, floating, unarmed; scape naked, quadrangular, one-flowered; there are only six stamina in the flower, with six bifid styles. Native of the East Indies, Malabar, Ceylon, &c.

Dame's Violet. See Hesperis.

Dandelion. See Leontodon.

Danewort. See Sambucus.

Daphne; a genus of the class Octandria, order Monogynia .--- GENERIC CHARACTER. Calix: none. Corolla: onepetalled, funnel-form, withering, including the stamina ; tube cylindric, imperforate, longer than the border; border fourcleft : divisions ovate, acute, flat, spreading, Stamina : filamenta eight, short, inserted into the tube, the alternate ones lower. Antheræ roundish, erect, two-celled. Pistil: germen ovate; style very short; stigma headed, depressed. flat. Pericarp : berry roundish, one-celled. Seed : single, roundish, fleshy. ESSENTIAL CHARACTER. Calix: none. Corolla: four-cleft, corollaceous, withering, including the stamina. Berry : one-seeded .---- The species are,

* Flowers lateral.

1. Daphne Mezereum ; Mezereon. Flowers sessile, in threes on the stem; leaves lanceolate, deciduous. It is a shrub growing in gardens to the height of five or six feet, with a strong woody stalk, putting out many woody branches on every side, so as to form a regular head; the flowers come out before the leaves very early in the spring, in clusters surrounding the shoots of the former year; the leaves are smooth, about two inches long, and three quarters of an inch broad in the middle, placed without order. In its wild state it is only from one to two feet in height, and the branches then are not numerous, they are very flexible ; the leaves are entire, and of a pale green; the fruit is a superior berried drupe, first green, then red, of an ovate globular form, with a thin succulent pulp, and a crustaceous, thin, brittle, black, shining shell; it is, however, commonly called a berry. There are

433

flower, succeeded by yellow berries, the other with peach- about two months she recovered her power of swallowing: coloured flowers and red fruit; the latter has sometimes flowers of a much deeper red. There is also a variety with variegated leaves, the flowers of which appear in February and March, and even in January, when the earth is mild; the berries will be ripe in June, if they be not previously devoured by birds. Villars mentions another variety, with the leaves a little villose, or having small hairs at their base, and the flowers four together: he remarks, that the parts of fructification are so perfectly formed the year before the flowers unfold themselves, that the character may be easily determined by the naked eye .- Mezereon is a native of Lapland, Sweden, Denmark, Germany, Switzerland, France, Carniola, Savoy, and Piedmont, Great Britain. Mr. Miller is the first who declared it to be a native of our island, near Andover in Hampshire ; since that it has been found at Laxfield, in Suffolk ; in Selborne-hanger, Hants; and frequently observed in the beechwoods of Buckinghamshire. As it has escaped all our herbarists, and even the indefatigable Ray, and his immediate successors, aud birds are remarkably fond of the berries. there is reason to suspect that they may have disseminated this beautiful shrub; unless we can suppose that it remained unnoticed, on account of its flowering before the time at which the herbarists sally out upon their vernal excursions. Gerarde informs us, that he had plenty thereof for his garden from Elbing in Poland : he calls it German olive spurge, or spurge olive, spurge-flax, and dwarf bay, and says that the Dutch call it mezereon. Parkinson calls it dwarf-bay, or flowering spurge; the Germans have named it kellerhals, kel lerhere, kellerkraut, &c, the Dutch, peperboompie; the Danes, kielderhals; the Swedes, kiællerhals; the French, laureole gentille or femelle, bois gentil, bois joli ; the Italians, laureola femina, dafnoide, camelea, calmolea, biondella ; the Spaniards, laureola hembra : the Portuguese, loireola femea, or mezereo major; and the Russians, woltschje-luke. The branches afford a good yellow dye. The whole of this vegetable is extremely acrid, especially when fresh, and, if retained in the mouth, excites great heat and inflammation, particularly of the throat and fauces : the berries, when swallowed, prove a powerful poison, not only to man, but to many quadrupeds : both the bark and the berries of mezereon, in different forms, have been long used externally in cases of obstinate ulcers, and ill-conditioned sores. In France, the bark is used as an application to the skin, which, under certain circumstances, produces a serous discharge without blistering, and is thus rendered very useful in chronic cases of a local nature, answering the purpose of what is called a perpetual blister, while it occasions less pain and inconvenience. In England, the mezereon has been principally employed in syphilitic cases; and in this way, Dr. Donald Monro was the first who testified its efficacy in the successful use of the Lisbon dietdrink. Several cases were afterwards published by Dr. Russel, then physician to St. Thomas's Hospital, fully establishing the utility of the bark of mezereon in venereal nodes. In the above cases, the decoction of the root was made usc of, but it has been found necessary in some cases to join with it a solution of sublimate. Dr. Collen informs us, that Dr. Home has not only found the decoction of mezercon to cure schirrhous tumors, which remain after the lues venerea, and after the use of mercury, but that it has also healed them when proceeding from other causes. The considerable and longcontinued heat and irritation that is produced in the throat when mezereon is chewed, induced Dr. Withering to give it in a case of difficulty of swallowing, apparently the effect of a paralytic disorder : the patient was directed to chew a thin slice of the root as often as she could bear to do it, and in dance, on the confines of New Castille, towards Navarre. 37.

this woman bore the pain and irritation, and the ulcerations it occasioned in her mouth, with amazing fortitude, but she was almost reduced to a skeleton, and had for three years before suffered very much from hunger, without being able to satisfy her appetite, for she could not swallow solids at all, and liquids only with the greatest difficulty; she was attacked with this complaint after lying-in. A woman gave only twelve of the berries to her daughter, who laboured under a quartan ague, and she, after vomiting a good deal of blood, expired immediately. An ointment prepared from the bark or the berries has been found serviceable to sore ulcers. A decoction made of a drachm of the bark of the root, in three pints of water till one pint is wasted, and this quantity taken daily for a considerable time together, has been found very efficacious in resolving and dispersing venereal swellings and excrescences. The bark of the root, says Hill, or the inner bark of the branches, is to be used, but it requires caution in the administration, and must only be given to persons of robust constitutions, and even to them very sparingly, for if it be given in too large a dose, or at all to a weakly person, it will cause vomiting and bloody stools ; but to the robust it acts only as a brisk purge, and is excellent in dropsies, and other stubborn disorders : a light infusion is the safest and most efficacious mode of giving it. It is propagated by seeds, which should be sown on a border exposed to the east, soon after the berries become ripe; for if they be not sown till the spring following, they often miscarry, and always remain a year in the ground before the plants appear: whereas those which are sown in August will grow the following spring, so that a year is saved; and these never fail. When the plants come up, they will require no other care, but to keep them clean from weeds; and if the plants be not too close together, they may continue in the seed-bed to have the growth of two summers, especially if they do not make great progress the first year ; then at Michaelmas, when the leaves are shedding, they should be carefully taken up, so as not to break or bruise their roots, and planted into a nursery, about sixteen inches row from row, and eight or nine inches asunder in the rows. In this nursery they may remain two years, by which time they will be fit to remove to the places where they are designed to remain for good. The best season to transplant these trees is in autumn, for as these plants begin to vegetate very early in the spring, it is hazardous to transplant them in that season. They grow hest in a light, dry, sandy earth, but become mossy, and make little progress, in cold wet lands, so that upon such soils they are small, and produce but few flowers. Notwithstanding the berries of this tree are so very acrid as to burn the mouth and throat of those who may incautiously taste them, yet the birds greedily devour them as soon as they begin to ripen; so that unless the shrubs be covered with nets to preserve the berries, they will all be destroyed before they are fit to gather. The mezereon is a very ornamental shrub in gardens, flowering before others, very carly in the spring; and when there are plenty of them growing together, perfuming the air to a considerable distance.

2. Daphne Thymelæa. Flowers sessile, axillary; lcaves lanceolate; stems very single. This plant rises to the height of three or four feet, with a single stalk, covered with a lightcoloured bark ; the flowers come out in clusters on the sides of the stalk, and being of an herbaceous colour, make but attle appearance. They come forth early in the spring, and are succeeded by small berrics, which are yellowish when ripe .- Native of Spain, where Valil found it in great abun-5 S

This species, together with the fifth and twelfth, are hardy, and will live through the winters in England in the open air, provided they are placed in a dry soil and a warm situation. They should be planted on a very warm dry border, where, if there be a foundation of lime-rubbish or chalk under the npper surface of the ground, the plants will thrive more, and continue much longer, than in better ground; and all the culture they require, is to keep the place clear from weeds, for the less the ground is stirred near the roots, the better the plants will thrive; for they grow naturally on poor shallow and, and out of crevices in rocks, and therefore the nearer the soil approaches to this, the more likely the plants are to succeed.

3. Daphne Pubescens. Fowers sessile, aggregate; leaves lanceolate-linear; stem pubescent, simple; leaves alternate, remote, almost naked, anunal, submucronate; flowers axillary, narrow, five, or fewer, with a filiform pubescent tube, shorter than the leaves.—Found by Jacquin in Austria.

4. Daphne Villosa. Flowers sessile, solitary; leaves lance-olate, flat, ciliate, hairy, crowded. This is a shrub with alternate branches; leaves like those of knotgrass, scarcely petioled, with white remote hairs on hoth sides, fewer on the upper surface, and more towards the edges; in the axils are very many rudiments of branchlets, where it is as it were verticilled; flowers narrow, small, shorter than the leaves.— Observed by Alstoemer in Spain and Portugal.

5. Daphne Tartonriar; *Xitery-leaved Daphne*, or *Tur-tornriar*. Flowers sessile, aggregate, lateral, imbricate, with scales at the base; leaves obovate, nerved, silky. This is a long shrubby plant, which sends out several weak stalks from the root, about a foot long, and a spreading about irregularly. They seldom become woody in England, but are tough and stringy, covered with a light bark; the leaves are small, very soft, white, and shining like satin, and is it perty close to the stalks; between these, white flowers come out in thick clusters; they are commonly two or three together, very seldom solitary, bell-shaped, silky on the outside, but yellowish within, imbricated at the base with four or more ovate keeled scales.—Native of the south of France. See the second species, for the propagation and culture of this plant.

6. Daphne Alpina; Alpine Daphne. Flowers sessile, aggregate; leaves lanceolate, somewhat obtuse, tomentose underneath. This species rises about three feet high; the flowers come out in clusters from the sides of the branches early in the spring, and are succeeded by small roundish berries, which turn red when ripe; the root fixes itself deeply in the crevices of the rocks; the little stems are shrubby and upright, scarcely a palm in height, as it were brachiate, leafy, and flowering at the top; leaves lanceolate or obovate, usually emarginate, hoary with hairs when viewed with a glass, as are also the calices and fruits; the younger leaves appear hirsute to the naked eye, but afterwards appear bald, unless to the magnifier .- Native of the south of France, and of the mountains near Geneva, Austria, and Italy. This sort is a beautiful sweet shrub, and deserves a place in gardens as much as any of those we cultivate for ornament. Both this and the eleventh species may have a cool situation; if these be sown where they can only have the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants which may require transplanting, or to have the ground dug and loosened. The seeds of these plants coming from distant countries, rarely arrive here time enough to sow in autumn; so that when they

are sown in the spring, the plants do not appear till the succeeding spring, and have sometimes remained even till a second spring in the ground: but as this may be too long for many people to leave the ground undisturbed, they had better put the seeds into small pots of earth, and bury them in the ground the first summer, and take them up in autumn, and sow them where they are to stand; by this method the seeds will be forwarded so as to vegetate in the following spring. They are both very difficult to keep in gardens, because they will not bear to be transplanted: they are as hardy as the common mezereon, and are not in danger of being hurt by the frost in England, but have always died upon being removed, though they have been transplanted at different seasons and with the greatest care; and even when plants of all sizes, from the youngest seedling to the oldest plants, have been tried. Those therefore who desire to have these plants in their gardens, must procure their seeds from the countries where they naturally grow, and should be sown as soon as they arrive.

7. Daphne Laureola; Spurge Laurel. Racemes axillary, five-flowered; leaves lanceolate, smooth. This is a low evergreen shrub, rising with several stalks to the height of two or three feet, dividing at top into several branches: the leaves come out irregularly on every side, sit pretty close to the branches, are thick, smooth, and of a lucid green; among these, towards the upper part of the stalks, come out the flowers in small clusters, they are of a yellowish green, and appear soon after Christmas, if the season be not very severe: they are succeeded by oval berries, which are green till June, when they ripen, turn black, and soon afterwards fall off; the flowers are of a dull colour, with an unpleasant scent, and they appear at a gloomy season .- It is a native of Britain, France, Switzerland, Austria, and Carniola. Gerarde did not know that it grows wild in England, although it is common enough in our woods and hedges; and, notwithstanding Linneus's censure, the spurge laurel is a shrub of some value, on account of the green of its leaves, which continuing all the year, render it ornamental in winter, but particularly because it flourishes under trees, and is therefore very proper to fill up spaces in plantations. Very happy effects have been produced by the use of this plant in rheumatic fevers; it is a rough purgative, and an efficacious medicine in worm cases, but requires some caution in the administration, and might be productive of dangerous consequences in unskilful hands. The whole plant has the same qualities, but the bark of the root appears to be the strongest, and should never be given in a dose of more than ten grains. An infusion of the leaves is a good medicine for those of robust constitutions, who are subject to dropsical complaints; it operates by vomit and stool, but so roughly that few constitutions can bear it: dried and reduced to powder, the leaves are useful in the venereal disease. Some other species of this genus possess nearly similar powers with the mezereon and spurge laurel, and are used in similar cases; but, like the former, require caution in their use, and should not be trusted to inexperienced hands. The plants may be easily obtained from the woods, as it is propagated by seeds, layers, or cuttings.

8. Daphne Pontica. Peduncles two-flowered; leaves lance colate-oate; stems about two-fet bigh, branched sometimes from the very bottom, about three lines in thickness, very pilable, covered with a gray bark; leaves towards the top without order, of the figure and consistence of those of the lemon, the largest four inches long, and two wide, pointed at each end, smooth, bright green, and shiming, having a thick mid-rib underneath. At the end of April, young shoots

terminated by new leaves, push from the extremities of the stems and branches, among which spring the flowers commonly in pairs, on a peduncle nine or ten lines in length. The corolla is of a greenish yellow, inclining to lemon colour, and has a sweetish smell, which is soon lost.—It flowers in autumn, and is a native of Pontus and Sheria.

9. Daphne Dioica. Flowers axillary, twin; leaves linearlanceolate. This is a shrub, a foot in height, stiff, and branched, with a corky bark; branches alternate, erect, stiff, roughened by the scars of fallen leaves; leaves crowded, so as almost to be indivicate, very smooth, resembling those of myrtle, four lines long, and hardly a line broad, not ciliate; flowers sessile, always two together, on-flowering, later than the other, diæccous; corolla yellowish white, or pale sulphur colour, with a belying tube.—Native of the Pyrenees.

** Flowers terminating.

10. Daphne Indica; Chinese Daphne. Head peduneled ; leaves opposite, oblong, ovate, smooth. A small shrub; leaves commonly acute, quite entire, petioled ; pedunele very short, from six to eight sessile flowers at top.—Native of China near Canton, but probably from Nankin, since it is commonly called the Nankin shrub.

11. Diphae Cneorum ; Trailing Daphae. Flowers in bunches, sessilie; leaves lanceolate, naked, mucroate. It is a very humble strub, seldom more than one foot high; stems branched; leaves anrow, lanceolate, placed without order. The branches are terminated by small clusters of purple flowers, which stand erect. The tube of the corolla is longer and narrower than in the mezercon. The flowers emit a pleasant odour, and appear early in the spring.—Native of France, Germany, Switzerland, Austria, Monte Baldo, the Pyrenees, and Hungary.

12. Daphne Gnidium; Flaz-leaved Daphne. Panicle terminating; leaves linear-lancelate, acumate. It rises with a shrubby stalk, two feet high, dividing into small branches, terminated by panicles of flowers, which are much smaller than those of the mezereon, having swelling tubes, contracted at the mouth, and appearing in June. The stems spread on the ground; the leaves are annual, and smooth; it flowers heaped, surrounded with leaves, sweet-swelling, red above. It flowers twice a year. Gerarde calls it spurge flaz, or mountein widow-wayle. Parkinson names it spurge lite.—Native of the south of France, Spain, and Italy.

13. Daphne Squarrosa. Flowers peduncled ; leaves scattered, linear, spreading, mucronate. It rises to the height of five or six feet, dividing at top into several erret branches, out of which come the flowers in small clusters; they are white, have oblong tubes, and the segments of the border are obtuse and spreading.—Native of the Cape of Good Hope. It requires a good green-house to preserve it, and is very difficult to keep in our gardens.

14. Daphne Oleoides. Flowers twin, sessile ; leaves elliptic, lanceolate, smooth ; stem rather shrubby, compound.— Native of the Levant. It requires the protection of a greenhouse to preserve it in England.

15. Daphne Fœtida. Smooth: flowers heaped, sessile; leaves opposite, petioled, ovate, oblong, acute, —Native of the Society Isles. It requires the protection of a greenhouse.

16. Daphne Rotundifolia. Hirsute: flowers heaped, seasile: leaves opposite, elliptic, subpreioled, obtuse, smooth; branches tomentose, hoary.—Native of Tongatabuo or Namoka in the South Seas. It requires the protection of a greenhouse.

17. Daphne Odora; Sweet-smelling Daphne. Heal sub-sessile, many-flowered; leaves scattered, oblong, lanceolate, smooth; stem becoming sirubby, dichotomous, smooth, naked, erect; branches like the stem, from divaricating erect; leaves at the top of the last branches approximating; sessile, acute, quite entire, spreading, bent back at the tip, deep green on the upper surface, with a groove along the middle, paler underneath, unequal, thick, evergreen, an inch length; flowers about leeven; corolla smooth; tube purple; filamenta inserted below the mouth; antheræ oblong, four, included, and four standing out; seed ovate, smooth, --Native of Japan, where it flowers in February, and also of the flowers, which, in England, appear from December to March. It must be protected by a green-house.

18. Daphne Penduin. Heads fateral, peduncled, involuced, noduling; leaves lancelate, elliptic, alternate, smooth. A tree or shrub, with alternate round branches, leafy at the end, covered with a smooth, brown, outer bark; leaves on short petioles, acute, quite entire, veined, paler underneath, deciduous; the primordial ones minute, like stipules, silky on the back, and abortive; I ofwers in solitary heads, from the axils of the leaves of the former year. A pair of small, recet, linear, obtue brackes, hairy on the outside, at the base of the pednneles, which are an incl long, round, smooth, growing gradually thicker to the end.—Found by Thunberg in the island of Java. It is a stoveplant, and must be treated in the same manner as coffice. See Coffica.

19. Daphne Altaica. Flowers in bundles, terminating, sessile; leaves oblong, ovate, smooth ; stems straight, slender, covered with an even testaccous bark ; the lower branches are short, flowering, hairy next the flowers ; the upper ones, which continue the growth of the shrub, are smooth ; leaves alternate, quite entire, drawn to a point at the base, sessile ; on the flowers on the baren branches more oblong, very like the leaves of mezercon, and emulating their consistence ; flowers mostly five together, collected into a head, without any bractes or stipules ; corola white, with a longish tube, swelling at the base, pubescent, with many hairs, and a spreading border, with lanceolate smooth segments ; anthere in a double row in the tube on very short filmenta; germen subglobular, with an obtuse stigma. This elegant shrub was discovered by Patrin on the Ataic Alps.

20. Daphne Triflora. Flowers sessile, axillary, heapdej calies three-flowered; leaves lanceolate, scattered; stem three feet high, simple, with ascending branches; leaves quite entire, smooth, on short perioles; flowers yellowish; common calix three-leaved, three-flowered; corolla tubular, four of two-cleft.—Native of China, in the suburbs of Canton.

21. Daphne Cannabina. Unibels terminating ; leaves lanceolate, opposite. This is a tree ten feet high, with ascending branches, and a very tough bark, like that of hemp; leaves ovate-lanceolate, quite entire, smooth; flowers yellow, in subterminating umbels; corolla salver-shaped, with a long tube, and a small border, with ovate segments; filamenta in two rows within the tube, with oblong antheræ; berry ovate, red, small .- Native of the woods of Cochin-china. An excellent writing paper is made from the bark, prepared like hemp. Shapeless, heavy, brown, resinous, woody fragments, resembling the wood of aloe, and having somewhat of its smell in the fire, are frequently found within the trunk of this tree, near the root. The bark and root may be medicinally used in dropsical complaints, without incurring any of those ill effects which are too often produced by the other species. 22. Daphne Colina; Neapolitan Mezereon, Flowers in bundles, terminating, sessile; leaves obovate, obtuse, very smooth on the upper surface, villose on the lower; stems three feet high, much branched; the branches often forked; bark tough, wrinkled, void of down or hair, except on the younger branches; leaves evergreen, alternate, on short footstalls, a little revolute on the edge, having a silky down undementh.—Native of the low hills in the south of Italy. It covers the hills and fields on the banks of the Vulturus, as furze does on commons in England; and, since it thrives here like the mytte, becomes a valuable addition to our shrubs.

DAT

23. Daphne Lagetto; Lace-bark Daphne. Spikes panicled, terminating; leaves ovate, acute. The wood of this tree is white ; leaves about four inches long, and two and a half broad, broadest near the base, having one middle and several transverse ribs, of a yellowish green colour, shining, thick, and smooth. The outer bark is smooth, light brown, fine or gray, and striated; the inner is solid and white, of a very fine texture, tough, and divisible into several coats or layers, which may be drawn out into thin webs resembling lace, and have been worn instead of it. King Charles II. had a cravat of it, which was presented to him by Sir Thomas Lynch, then governor of Jamaica, where it is principally used for ropemaking, but would undoubtedly make fine paper, if properly prepared .- Native of Jamaica, where it is called lagetto, or lace-bark tree; and of Hispaniola, where it is known by the name of bois dentelle. It is a stove plant. See the eighteenth species,

24. Daphne Tinifolia. Racemes compound, ercet; dowers terminating, crowded; leaves oblong. It rises with a woody stalk to the height of twenty feet, dividing into many branches covered with a gray rough bark. The leaves of this tree are about two inches long, and one inch broad, rounded at the top, and entire, on very short footstalks. —Native of Jamaica. It is a stove plant, and must be treated like coffer. See Coffra.

25. Daphne Occidentalis. Peduncles axillary; flowers terminating, in umbellets, diæcous; leaves alternate, lanceolate, smooth.—Native of Jamaica. It is a stove plant, and requires the same propagation and culture as coffee. See *Ceffee*.

26. Daphne Vermiculata. Flowers sessile, lateral, solitary, smooth; leaves linear, lanceolate, villose. This is an humble, stiff, and very branching shrub; branches purple, wasted, villose at top; leaves sessile, crowded, thick, obtuse; flowers axillary, opposite, biorter than the leaf.—Native of the kingdom of Arragon in Spain. 27. Daphne Sericea. Flowers aggregate, terminating, ses-

27. Daphne Sericea. Flowers aggregate, terminating, sessile; leaves lanceolate, villose underneath; segments of the corolla obtuse. It is a very branching shrub; branches round, brown, villose at top; leaves towards the ends of the branchlets crowded, sessile, lanceolate, elliptic, veinless, quite entire, acute, smooth above, villose underneath; flowers purple, five.—Native of Candia and Naples.

28. Daphne Buxifolia. Flowers aggregate, sessife, terminating: leaves oblong, very blunt, villose underneath. This shrub has round, villose, naked branches; leaves towards the ends of the branchets approximating, sessife, a little narrower at the base, rounded at the end, the younger ones villose on both sides, the rest only underneath, veinless; flowers six; nube of the corolla villose, silky on the outside, gibbose at the base; segments oblong, obtuse. It differs from the foregoing in the form of the leaves, and the white ness of the corolla,—Native of the Leavent.

Darnel Grass. See Lolium. Date Plum. See Diospyrus. Date Tree. Sce Phænix. 2

Datisca ; a genus of the class Diæcia, order Dodecandria. -GENERIC CHARACTER. Male. Calix : perianth fiveleaved ; leaflets linear, acute, equal, Corolla ; none, Stamina : filamenta scarcely any ; antheræ about fifteen, oblong, many times longer than the calix, obtuse. Female. Calix: perianth two-toothed, the third tooth wanting, erect, very small, superior, permanent. Corolla : none. Pistil : germen oblong, inferior, longer than the calix; styles three, two-parted, short; stigmas simple, oblong, shaggy, length of the germen. Pericarp : capsule oblong, triangular, threevalved, three-horned, one-celled. Seeds : numerous, small. adhering longitudinally in three directions to the capsule, ESSENTIAL CHARACTER. Male. Calix : five-leaved. Corolla : none : antheræ sessile, long, fifteen, Female, Calir : two-toothed, Corolla ; none. Styles : three, Capsule: triangular, three-horned, one-celled, pervious, many-seeded, inferior. These plants may be propagated by parting the roots, which should be performed in autumn, when the stalks decay; but they must not be parted too small. They may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds. They may also be propagated by seeds, which should be taken from such plants as grow in the neighbourhood of male plants, or they will not succeed ; and if the seeds be not sown in autumn, they seldom grow the first year. When the seedling plants appear, they will require no other care than to be kept clean from weeds till autumn, when they may be transplanted whither they are to grow .---- The species are,

1. Datisca Cannabina : Smooth-stallted Bastard Hengy, Stem even. This plant has a percunial root, from which rise several herbaceous stalks, about four feet high, with pinnate leaves, placed alternately, each composed of three pairs of leaflets, terminated by an odd one; these are two inches long, and half an inch broad, ending in acute points, deeply serrate, and of a light green. The flowers come out in long loose spikes from the upper part of the stalks, at the axils, but having no petals make a poor appearance : the antheræ of the male flowers being pretly long, and of a bright yellow colour, are most visible at a distance. It flowers in June or July, and the seeds ripen in September.— Native of Candia or Crete.

2. Datisca Hirta; Rough-stalked Bastard Hrapp. Stem hirstue, larger. The stem rough on every side with hairs that stand out; leaflets larger, more alternate, more decurrent, and confluent at the basc.-Found in Pennsylvania, This is as hardy as the first species, but requires a shady situation, and a moister soil.

Datura ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, oblong, tubular, bellied, five-cornered, five-toothed, horizontally deciduous near the base, the remaining circular part permanent. Corolla: one-petalled, funnel-form ; tube cylindric, almost longer than the calix ; border erect, expanding, five-cornered, five-plaited, almost entire, with five acuminate teeth. Stamina: filamenta five, subulate, length of the calix; antheræ oblong, compressed, obtuse. Pistil: germen ovate; style filiform, straight; stigma thickish, obtuse, two-plaited. Pericarp : capsule somewhat ovate, two-celled, four-valved, seated on the base of the calix ; receptacles convex, large, dotted, affixed to the dissepiment. Seeds : numerous, kidney-form. ESSENTIAL CHARACTER. Corolla: funnel-form, plaited. Calix : tubnlar, angular, deciduous ; capsule four-valved. Most of the plants of this genus have a strong aromatic smell, are natives of hot countries, and therefore require a stove or glass-case.---- The species are,

DAT

1. Datura Ferox; Rough Thornapple. Pericarps thorny, erect, ovate, the upper thorns very large, and convergent. It seldon rises more than a foot and a half high, spreading out into many branches. Annual, flowering from July to Spetenber; and a native of China. This, and the fourth and fifth species, may be raised by sowing the seeds upon a gentle to the spring, and treating them afterwards in the same manner as the marvel of Peru, and other hardier kinds of munis, transplanting them into the fail ground in the latter end of May: they will flower in July; and if some of the plants to place tin a glass-case, will produce ripe seed in automan.

2. Datura Stramonium; Common Thornapple. Pericarps thorny, erect, ovate; leaves ovate, smooth; stem from one to six feet in height, according to the soil, but seldom more than two feet, round, smooth, dividing into many strong irregular branches, which are hollow, and covered with a fine down : leaves from the forking of the stem and branches, single, scarcely six inches long, petioled, pointed, deep green on the upper surface, paler beneath, and on the edges, with strong ribs or nerves, unequally sinuated, and toothed about the edge, extending farther down the petiole on one side than on the other; flowers single from the axils, on short peduncles, upright; calix pale green; corolla white; seeds blackish. Gerarde says, the thornapple was brought in seed from Constantinople. Mr. Miller thinks it was probably first introduced from Italy or Spain. It is, however, now become so common about London and other towns, as to appear like a native plant, there being few gardens or dunghills without it in summer. That it is a native of America, we have, however, the most undoubted proof; for in the earth brought with plants from various parts of that extensive country, we are sure to have the thornapple come up. Kalm says, that it grows about all the villages, and that it and the phytolacca are the worst weeds that infest that continent. Onr old writers call it thorny-apple of Peru. Gerarde declares that he first " dispersed the seeds through this island, and that he made great use of it in chirurgerie, as well in burnings and scaldings, as also in virulent and maligne ulcers, apostemes, and such like." An ointment made of the leaves gives ease in external inflammations and hemorrhoids, being cooling and repelling. The leaves, stalks, and apple of this plant, when smoked, has been found efficacious in asthmatic and consumptive cases. The Edinburgh College direct an extract from them, which has been given with great advantage for convulsions and epilepsies, in doses from two to sixteen grains a day. These and the seeds, when internally given, are liable to bring on delirium, tremors, swelling, itching, eruption, and inflammation, on the skin. Baron Stoerck informs us, that the juice pressed out of the fresh plaut, and inspissated to an extract, has been given, in doses from half a grain to the amount of a drachm every twenty-four hours, in epileptic disorders, convulsions, and madness, and proved to be a medicine of singular efficacy in those deplorable maladies, several persons being cured by it, whose disorders were both violent and of long standing. Hill observes, that the leaves are used externally by the country people, who lay them upon burns and inflammations; but this is not always safe, The root and seeds are of a sleeping nature, and ought not to be taken internally; opium itself being considerably less dangerous. The leaves of this beautiful plant, particularly the upper ones, rise up, and enclose the flowers. It deserves a place in every garden, and is very easily propagated; for it is, together with the next species, very hardy, and if only permitted to seed, will furnish a supply of plants for several years to come, for the seeds will lie long in the ground, and, when turned up to the air, soon begin to vegetate. 37.

3. Daturn Tatula; *Ibhe Thornopple*. Pericarps thoray, recei, ovait: leaves cordate, smoothed, touthed. This resembles the common sort, but is twice the size; stems purplish with white dots, divided at an acute angle, smooth, and even; corollas pub blue; leaves more finely toolled, and, if they be flatted, cordate.—This is a hardy plant. See the preceding species.

4. Datura Fastuosa ; Purple Thornapple. Pericarps tubercled, nodding, globular ; leaves ovate, angular. This rises with a finely polished purple stalk, four feet high, dividing into several branches; leaves large, smooth, sinuated, on pretty long footstalks. The flowers are produced at the divisions of the branches; they have large swelling tubes. which spread very broad at the top, their brims having ten angles each, ending in a long slender point. The flowers are of a beautiful purple on their outside, and a satiny white within; some of them are single, others have two or three flowers standing one within another, and some are double. having four or five petals within each other, of equal length, so as to appear a full flower at the brim ; they have an agreeable odour at first, but if long smelt to, become less so, and are narcotic .- Native of Egypt, and the East Indies. For its propagation and culture, see the first species.

5. Daturn Metel; Hairy Thornapple. Pericarps thorny, nodding, globular; leaves cortate, almost entire, pubescent. It has a strong stem, three feet high, dividing into many woolly branches. The leaves have only two or three slight indentures on their edges; the flowers have long tubes, and are of a zone white above, but the tubes have a tincture of green within; they are succeeded by roundish fruit, closely cover, stings, the seds, when ripe, are of a light brown closur. Native of Asia, Africa, and the Canary Islands.

6. Datura Arborea ; Tree Thornapple. Pericarps smooth, unarmed, nodding; stem arboreous. It rises to the height of twelve or fourteen feet, with a woody stalk, dividing into several branches; leaves oblique, six inches long, two inches and a half broad in their widest part, growing narrower at each end, downy, on long footstalks, which stand nearer to one side than the other. The flowers come out at the divisions of the branches; they have a loose tubular calix, nearly four inches long, which opens at the top on one side like a spathe; the tube of the flower is narrow; but above, it swells very large, nearly six inches in length, then spreads open at the brim, where it is divided into five angles, which terminate in very long points; they are white, with some longitudinal stripes of a pale yellow on their outside, and are succeeded by round smooth capsules, filled with kidneyshaped seeds .- Native of South America, and one of the greatest ornaments to the gardens in Chili, where the inhabitants propagate it with great care. When the trees are fully blown, they make a fine appearance ; and a single tree will perfume the air of a large garden. This and the seventh species are both too tender to endure the open air of our climate, and must be sheltered in the stove,

 Datura Lævis. Pericarps smooth, unarmed, erect; leaves smooth; stem fistular, herbaceous. The corollas are white.—Native of Africa, flowering from July to September. See the preceding species.

8. Datum Innovia. Pericarps ovate, nodding, set with hannless spines; leaves cordate, pubscant. This species rises three or four feet high, with a purplish stem, dividing into several strong branches; leaves oblog, heart-shaped; stems, branches, and leaves, covered with soft hairs. The 5 T flowers come out at the divisions of the stalk and branches, | standing erect; they are large, white, and are succeeded by oval fruit, covered with long, soft, innocuous spines, and opening within in four cells, full of brown seeds .- Native of Vera Cruz. It may be propagated, in favourable seasons, from scattered seeds, which will rise in the spring, and, when the summer proves warm, will flower, and perfect their seeds.

Daucus ; a genus of the class Pentandria, order Digynia. GENERIC CHARACTER. Calix : umbel universal, manifold, flowering flat, fruiting, concave, converging; partial manifold, similar; involucre universal many-leaved, length of the umbel ; leaflets linear, pinnatifid ; partial more simple, length of the umbellule; perianth proper, scarce manifest; corolla universal, difform, somewhat rayed; floscules of the disk abortive ; proper of five petals, inflex-hearted, the exterior ones larger. Stamina: filamenta five, capillary; antheræ simple. Pistil: germen iuferior, small; styles two, reflex; stigmas obtuse. Pericarp: none; fruit ovate, often hispid on every side, with stiff hairs, bipartile. Seeds : two, somewhat ovate, on one side convex, hispid, on the other flat. ESSEN-TIAL CHARACTER. Corolla: subradiate, all hermaphrodite: fruit hispid with hairs ; according to Gærtner, muricate with prickles, forming longitudinal crests, ----- The species are,

1. Daucus Carota ; Wild Carrot, or Bird's Nest. Seeds hispid; petioles nerved underneath. In its wild state, the common carrot has a slender, hard, whitish, or brownish fusiform root; stem upright, grooved, hispid, two feet high, with alternate branches which are commonly from seven to nine or ten inches long, have one leaf on them, except the primary or terminating one, which is naked, and a single umbel of flowers at top. The flowers are white, those in the middle sometimes tinged with purple, and fertile: but those in the circumference, which are irregular and larger than the others. are frequently either neuter, or have pistils only. The fruit is spheroidal, composed of two plano-convex seeds, on the back of which are four membranaceous narrow crests, pectiuated with linear, setaceous, innocuous, flexible teeth; and between these, three raised nerves, having very minute prickles on them along each side, bowing outwards; the belly is flat or slightly concave, marked with obscure longitudinal streaks. It is common in pastures, balks, and headlands, and is a biennial, flowering from June till August. Carrot-seeds have been recommended as a powerful diurctic, and an infusion of them has been found to give relief in fits of the gravel and stone. They have a slight aromatic smell, and a warm pungent taste. They communicate an agreeable flavour to malt liquor, if infused in it while working in the vat, and render it an useful drink in scorbutic disorders. They have not only been used as diuretics, and in the stone and gravel, but to disperse wind in the stomach: and, as they operate very powerfully by urine, they are excellent in obstructions of the viscera, in the jaundice, suppressions of the menses, and in the beginning of dropsies. A poultice made of the roots, has been found to mitigate the pain of foul cancerous ulcers, and remove the intolerable stench. Mr. Miller informs us that the shops are supplied with old seeds of the garden carrot, instead of fresh seeds of the wild plant. This is one of the many ways in which efficacious medicines are brought into disrepute; but the remedy consists in every person's gathering wild carrot-seeds fresh for himself: he informs us, that he cultivated the wild carrot for many years, but could never get the seeds which were sown in the spring to grow, but that part of the seeds which he sowed in autumn came up well. These plauts are treated in the same manner as the garden-carrot, but could not in the least improve the root, for they invariably continued to be seldom properly performed by workmen, who are apt to

small, sticky, and of a hot biting taste, from whence he inconclusively infers, that the wild carrot and the garden carrot are specifically different, for the improvement has probably been the effect of accident, or of time and care in a warmer climate; and the uncultivated plants, if left to themselves in a dry undunged soil, would probably relapse into their primitive state. Mr. Ray observed a variety of the wild carrot on the sea-shore near Dover, with leaves of a dark green and glossy colour. Dr. Stokes adds, that in a specimen from the coast of Cornwall, the leaflets are remarkably broad, and but slightly cut. Moles are so fond of the roots, that carrots are a proper bait to ensnare them with; but garden carrots answer best for that purpose, as well as for destroying crickets. being made into a paste with powdered arsenic and wheatmeal. The females of this polished age will smile at the simplicity of aucient times, when they are informed, the autumnal beauty of carrot-leaves allured many gentlewomen formerly to stick them in their hats or heads, or pin them on their arms, instead of feathers. The garden carrot is three feet high in its flowering state, and differs but little from the wild one, except in the largeness and succulency of the plant. and particularly of the root, which, with its superior size, usually takes a tincture of yellow in different shades as far as a deep orange, and becomes of a softer texture, without any of that acrimony and aromatic flavour which are found in the wild root. There are several varieties differing in the colour of their roots, as white, yellow, orange, and dark red or purple, which variations may be perpetuated by simply observing not to mix them together in the same garden. In London, the orange carrot is most generally esteemed. Mr. Miller conceives the red or purple carrot to be a distinct sort ; it is much more tender than the others, insomuch that the roots were all destroyed by the first frosts in autumn: the seeds were sent from Aleppo, and the roots were smaller than the common sort, and purple, like a deep-coloured radish, very tender and sweet, with leaves more finely cut and less hairy than those of the common carrot .-- Garden Culture. The carrot is commonly cultivated in gardens for the kitchen : they are propagated at two or three different seasons, and sometimes oftener, where people are fond of young carrots. The first season for sowing the seeds is soon after Christmas, when the weather is open ; they should be sown in warm borders, near walls, pales, or hedges, but not close to them, which would draw them up weak, and prevent them from producing any tolerable roots; they delight in a warm, light, sandy soil, which should be dug pretty deep, that the roots may the better run down, for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, especially where the ground is too much dunged in the same year that the seeds are sown, which will also cause them to be worm-eaten ; it is best therefore to dung the ground intended for carrots the year before they are sown, that the manure may be consumed and mixed with the earth; but in such places where there has not been ground so prepared the year before, and there may be a neccessity for dunging it in the same year that the carrots are sown, the dung should be well rotted, and thinly scattered over the ground, while in digging it into the ground care should be taken to distribute it equally, and not to bury it in heaps, which would stop the roots of the carrots in their downright growth, and cause them to be short and forky. Wherever the ground is inclined to binding, too much trouble cannot be taken to break and divide the parts; hence, in digging land for carrots, large spits should never be used, but thiu ones, that the clods may be well broken, which, if not attended to by the master, is

burry over their work, if they be not well observed. The ground, when thus dug, must be laid level, or when it is raked over after the seeds are sown, part of them will be too deeply buried, and others will run the risk of being drawn up into heaps, which will compel the plants to come up in bunches. while large plots of ground will be left unoccupied; all of which should always be carefully avoided. The seeds have a great quantity of small forked hairs upon their borders, by which they adhere so closely, that it is difficult to sow them so as to prevent them from coming up in patches; they should therefore be rubbed well through both hands, whereby the seed will be separated before it is sown: a calm day should be chosen to sow it in, for it is impossible to sow it equal when the wind blows, as the seeds being very light will be blown into heaps. As soon as it is sown, the ground should be trodden pretty closely with the feet, that the seed may be buried, and then the surface may be raked to make it level. When the plants are come up, and have got four leaves, the ground should be hoed with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to four inches' distance each way, that they may acquire strength; and in about a month or five weeks after, when the weeds begin to grow again, the ground should he hoed over a second time, in which two carrots ought not to be left close to each other, but should be separated to a greater distance, cutting down every weed, and slightly stirring the surface of the ground in every place, the better to prevent young weeds from springing, as well as to facilitate the growth of the young carrots : in about a month or five weeks afterwards they must be hoed a third time, and the weeds removed as before. The carrots should now be cut out to the distance they are to remain, which must be proportioned to the size at which it is intended they should arrive : if they be intended for drawing young, five or six inches asunder will be sufficient, but if it grow large before they are pulled up, they should be left eight or ten inches every way apart; the weeds must also be again removed, as they will greatly retard the carrots, if suffered to grow among them. The second season for sowing is in February, on warm banks situated near the shelter of a wall, pale, or hedge; those which are intended for the open large quarters should not be sown before the beginning of March, nor any later than the end of that month, for those sown in April or May will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry. In July you may sow again for an autumnal crop, and at the end of August some more to stand for the winter, by which method you will have early carrots in March, before the spring sowing will be fit to draw; but these are seldom so well tasted, and are often very tough and sticky: however, as young carrots are generally expected early in the spring, most people sow some at this season; but these should be sown upon warm borders and dry land, otherwise they are seldom good. If the winter should prove very severe, it will be proper to cover the young carrots with pease-haulin, the haulm of asparagus, or some such light covering, to prevent the frost from destroying the roots; but if in very hard winters all the carrots should be killed, a hot-bed may be made early in the spring, to sow some, which will be fit for use long before any that are sown in the full ground ; these beds, however, should be earthed fifteen or sixteen inches deep, that the roots may have a proper depth of soil to run down. If these beds be lined with hot dung twice, at those times when their heat begins to decline, it will greatly forward the growth of the carrots, but great care should also be taken to avoid drawing the plants up too weak ; these may be allowed to grow

closer together than those sown in the full ground, because they will be drawn up for use when very young. Many persons mix several other sorts of seeds, as leek, onion, parsnep, radish, amongst their carrots, and others plant beans ; but none of these methods are good, for if there be a full crop of one of these plants, there can be no room for any thing else amongst them; so that what is got by one, is lost by another, It is not only more sightly, but actually better for the plants of each kind to be sown separate ; for by this means the ground will be clear, when the crop is gone, to sow or plant any thing else ; but when three or four kinds are mixed together, the ground is seldom at liberty before the succeeding spring ; besides, where beans or any other tall-growing plants are introduced among the carrots, they are apt to make them grow more in top than root, so that they will not be half so large as if sown singly, without any other plants among them, The covetousness of some gardeners will not permit them to cut out their carrots to a proper distance when they hoe them, so that by leaving them too close they draw each other up weak, and never recover their strength when drawn, so perfectly as those which are properly thinned at the first hoeing; therefore where the carrots are designed to have large roots, they must never stand too close, nor should they have any other crop mixed with them .- Culture in the Field. It is only of late years that the carrot has been cultivated for cattle in the fields, although it has been long cultivated in gardens for the table. Even now there are not many parts of England where field-culture is practised; which is much to be regretted, for, where the soil is suitable, there is scarcely any root yet known which more deserves the attention of the farmer. One acre of carrots, if well planted, will fatten a greater number of sheep or bullocks than three acres of turnips, and the flesh of the animals will at the same time be firmer and better tasted. Horses are extremely fond of them, and there cannot be a better food for hogs. They have been cultivated in parks for feeding the deer, and have been found an excellent resource in hard winters, when great numbers of deer must otherwise have perished through the scarcity of other food, and when even those which have survived without them have been so much reduced as not to recover their flesh during the following summer; while those fed upon carrots have been kept in good condition all the winter, and upon the growth of the grass in the spring have been fat early in the season, which is an important advantage wherever the grass is generally backward in its growth. There is also a material advantage in the cultivation of this root beyond that of the turnip, because the crop is not so liable to fail; for as the carrots are sown in the spring, the plants generally come up well; and unless the months of June and July turn out very unfavourable, the crop is almost sure not to fail : whereas turnips are frequently destroyed by the flies at their first coming up, and in dry autumns they are attacked by caterpillars, which in a short time devour whole fields, while the carrots remain unmolested by these vermin. Carrots have some advantages over turnips, besides the principal one already mentioned, of their being better adapted to that sort of soil which best suits them both ; they are less liable to be damaged by frost, are not subject to the same distempers and accidents, and last till April, the season of great difficulty, when farmers frequently know not what to provide for their stock, especially sheep; being also a spring crop, if the plant fail, the seed only is lost, and the land is in perfect order for turnips at midsummer; or if scattered plants only be produced, the intervals may be filled by sowing turnips or planting cabbages. Carrots are also an excellent preparation for barley in sands and sandy loams, that are not foul

440

with quick or spear-grass, for in such lands the boeing for carrots increases rather than destroys the quick, by hacking it in pieces. No crop, when such lands are clean, can be better for them than carrots; because it admits no summer ploughing whatever, and is put on ouc earth given with a trench-plough in March, so that as much tenacity is given to these natorally loose soils as possible : the crop may be left late in the ground, and if the soil be very sandy, a crop of buck-wheat may follow, for which any degree of cleaning from quick may be given if required. Every farmer therefore, who has a stock of cattle or sheep, if he have land proper for the purpose, which must be light, and of a proper depth to admit of the roots running down. should always have a supply of these roots. In preparing land for carrots, if it have never been in tillage before, it should be ploughed early in autumn, and then across again before winter, laying it up in high ridges to mellow by the frost; and if the ground be poor, some rotten dung should be spread over it in winter, and ploughed in at the beginning of February. The ground should be ploughed again in March, to receive the seeds; to perform which, some employ two ploughs, one following the other in the same furrow, so that the ground is loosened a foot and a half deep; others have men with spades following the plough in the furrows, turning up a spit of earth from the bottom, which they lay upon the top, levelling it smooth, and breaking the clods : the latter method is attended with a little more expense, but is much preferable to the former, because the clods are better broken, and the surface left more even. If the land should have been in tillage before, it will require but three ploughings : the first just before winter, when it should be laid in high ridges, for the reasons before given; the second crossploughing should be in February, after which, if it be well harrowed to break the clods, that will be very beneficial ; the last time must be in March, to receive the seeds as above directed. If great clods of earth remain unbroken after this third ploughing, it will be necessary to harrow it well before the seeds be sown. One pound and a half of seeds will be sufficient for an acre of land, but as they are apt to adhere together, it renders them more difficult to sow even than most other sorts, therefore some mix a quantity of dry land with their seeds, rubbing them well together, so as to separate the carrot-seed from each other, which is a very judicious method; after the seeds are sown, they must be gently harrowed in to bury them; and when the plants come up they should be hoed in the manner before directed. The field-culture of carrots is best carried on in a tract of Suffolk, called from the nature of its soil the Sandlings; it is a triangle formed by Woodbridge, Bawdsey Cliff, and Orford, at the three angles. They sow five pounds of seed to the acre, on a double furrow about fourteen inches deep; the time of sowing is about Lady-day, and they begin to hoe at Whitsuntide; they give three hoeings in all, which cost from fifteen to eighteen shillings an acre, sometimes more; ten loads of forty bushels each, topped clean, on an acre, in good land, is reckoned to be a middling crop : they feed with them from before Christmas, and coutinue sometimes till Whitsuntide, taking them up, and housing them in the latter part of the season, to have the land clear for barley sowing. The time of sowing among the sandy-field gardeners, is the first week in March; some sow in the middle, and others again at the end of March, but the time must in some measure be regulated by the season, and the convenience of the farmer. The time of sowing is by some extended from the beginning of February till the end of April; but this is too wide a range, if it can be avoided. New seed will appear a week sooner

than the old; and the crop depends very much upon the quality of the seed. Mr. Miller, as above, directs only a pound and a half of seed to be sown, which is certainly too little: on the other hand, in the Sandlings we have seen that they sow five, eight, ten, and some even twelve nounds which is generally a waste of seed. The common rule for the first hoeing is seven weeks after the seed is sown, or generally at the beginning of May, and the second at the middle of June, or somewhat later, according to the state of the crop. The usual produce on poor lands is 200, and on good land 400 bushels per acre; we have had accounts of 250, 300, 312, 326, 340, 352, 368, 400, 460, 482, and even 640, and 700 bushels produced from an acre; but let the husbandman always bewaye of calculating upon great crons. which are commonly produced on a small scale, or on very rich land, or by extraordinary tillage and manuring, or by some unusually fortunate and unforeseen circumstances. Several methods are prescribed for preserving carrots during winter: it is the practice in the Sandlings to take up the carrots as they are wanted, only keeping a store beforehand in case of frost ; but this way of proceeding in some years leaves many to rot upon the ground : soon after Michaelmas, in dry weather, they may be taken up with a common dung-fork, and piled up, or stacked in a corner of the field in the following manner; lay a platform of earth six inches above the level. two feet and a half wide, and of a length proportioned to the quantity of the crop, suppose from ten to twenty yards; on this earth scatter a light layer of straw, upon which place a row of carrots with their tops on, and turned outwards; the tails lapping over one another, so that the width covered with carrots be about two feet; top the small roots, and lay them in the middle crosswise, to keep the two sides from parting, by pressing the weight more on the centre; on every two or three rows scatter a little straw, and thus continue to build up about four feet high; then cover the tops carefully with dry straw, and lay some sedge or other coarse material over all by way of thatch: then begin another line parallel to the first, just leaving room to pass between them, and so continuing until the whole crop is taken up; fill the alleys with dry straw, and guard the outside with bundles of straw staked down, or set fast with hurdles, to prevent the wind from removing the straw and covering. Other persons take up their carrots during some dry days in October, put them directly into small upright cocks of ten bushels each, entirely covered with the tops cut off, and being thus dried, carry them iuto a barn or shed, throwing some straw over them, but taking care not to pack them too close. Another way is, to leave them in cocks well covered over with straw or fern till they are quite dry, and then cover them with earth, beaten smooth with a spade : some twist off the tops with the hand, and others take off an inch of the roots to keep them from sprouting ; but these attentions can only be bestowed on small crops. If they be barrelled up with very dry sand, after being previously well dried, they may be preserved a considerable time at sea; and long experience has confirmed what Mr. Miller asserts, that they are a hearty food for sheep, cattle, horses, hogs, and deer, particularly for horses; they may also be applied to feeding hounds and pointers when boiled, and mixed with milk and barley meal. A very good spirit may also be distilled from carrots, and the refuse will be excellent for feeding hogs. One ton eight stone, after being exposed a few days to dry, weighed 160 stone, and measured fortytwo bushels; after being washed, topped, and tailed, they lost eleven stone in weight, and seven bushels in measure. From this quantity fifty gallous were distilled, which were rectified, and twelve gallons of unexceptionable spirits were 4

DEC

from the still measured 112 gallons, so that the refuse greatly exceeds that of an acre of barley: and an acre of carrots, allowing the produce to be twenty tons, will yield 240 gallons of spirit, which is considerably more than can be obtained from five quarters of barley. But as the produce of an acre ought not to be estimated at more than from ten to fourteen tons, the quantity of spirit extracted from an acre of carrots will not exceed 168 gallons. Carrot-seed has been for many years raised at Wathersfield in Essex, perhaps because it possesses two soils best adapted to this culture ; rich sand to raise the carrots the first year, and strong loam for the year of seeding. 'The preparation of the soil consists in making it very fine by repeated ploughings and harrowings; usually three or four earths are given; and twenty pounds of seed per acre (apparently too great a quantity) are sown in April; they hand-hoe twice, setting the plants out seven inches asunder. At Michaelmas they dig up, cut off the tops to the length of an inch, and pack up the roots in barns with straw, taking care that they are dry enough when laid up. Securing them is a work of some difficulty, for the air must be admitted, and the frost at the same time excluded. The crops are large; a good produce is three bushels on a rod, but four have been produced. For replanting in the spring, they choose a piece of fresh land, if there be any on the farm: if not, such as is in good heart, but they never manure it : the preparation is, to throw two three-feet ridges together in a dry season, in February or March ; cut the top-end of the carrots off, to the amount of one-third of the root, and plant a double row upon each ridge, at three feet between the plants, and two feet row from row, in a quincunx order, so that the plants of one row may be ranged against the spaces of the other: they are twice hoed, and twice earthed up, the second time very high; the heads are cut off when quite dry, as they ripen, by women, and being laid on pack-cloths, are thrashed and dressed by men.

2. Dancus Mauritanicus: Fine-leaved Carrot. Biennial.— 8. Dancus Sinaga: Spanish Carrot, or Pick-tooth. Annual.—4. Dancus Gingidum; Shiring-leaved Carrot. Dancus Maritiman. A maritime variety of the last-mentioned species.—6. Dancus Lucidus; Shiring Carrot. Biennial. —7. Dancus Hispanicus; Fireaus Carrot. Biennial. ——These are all natives of the south of Europe and Barbary; and Bower from June to August.

Day Lily. See Hemerocallis.

Deadly Carrots. See Thapsia.

Deadly Nightshade. Sce Atropa.

Deadnettle. See Galeopsis.

Decumaria : a genus of the class Dodecandria, order Monogvini : or, according to the Hortus Kerensis, of the class Polyandria, order Monogynia.—GENERIC GHARACTER. Galiz: perianth superior, with about ten leaves, very small ; leaflets ovate, coloured, acute, reflex. Carolle: petals ten, hanceolate, obtuse, copul, disposed in a simple circle, espanding. Stamina : filamenta from sixteen to twenty-five, filform, length of the corolla. Anthera twin, depressed. Fisidi : germen top-siaped, inferior: style cylindric, shorter than the corolla; stigma gibbose, lobed, with about ten litle swellings. Pericary: caspule eight-celled, manyseeded. Seeds : solitary. ESSENTIAL CHARACTER. Cadiz: cight to twelve-leaved, superior. Petals: eight to twelve; capsule eight-celled, with many seeds.—The only known species is,

1. Decumaria Barbara; Climbing Decumaria. A tree with irregular branches, rooting by knotty joints; leaves op-37.

obtained; the refuse weighed forty-eight stone, and the wash posite, petioled, leathery, veined, towards the base remotely from the still measured 112 gallons, so that the refuse greatly serrate; no stipules; buds pubescent; paniele corymbed, exceeds that of an arc of barley; and an arc of carrots, terminating; flowers like those of the lime-tree, whitish, and allowing the produce to be twenty tons, will yield 240 (very sweet-scented—Native of Carolina.

DEL

Delima; a genus of the class-Polyandria, order Monogyna-Genkrenc CutaRactres. Caliz: perianth five-leaved; leaflets ovate, obtuse, equal, permanent. Corolla: none. Stamina: filamenta numerous, capillary, nearly equal to the calix. Anthera roundish. Pistli : genmen superor, somewhat ovate; style cylindric, length of the flower; stigma simple, permanent. Pericary: herry larger than the calix, ovate, acuminate, two-valved. ESSENTIAL CHARACTER. Caliz: five-leaved. Corolla: none; berry with two seeds. — The only known species is.

1. Delima Sarmentosa. A tree with scabrous leaves, resulting those of beech; Howers peduncied, loosly panioled, both axillary and terminating; fruit a corinceous swelling capsule, ending in an incurved beak, very smooth, of a yellow bay colour, opening on one side only by a longitudinal cleft; seeds two, globular, crooked next the base, berried, red, becoming blackish when ripe, fixed to the bottom of the capsules; their aril is incomplete, spongy, membranaceous, snow-white, tron at the edge, scarcely covering the lower half of the seed. The leaves being very thick and rugged, are used by the inhalitants of Ceylon, where it naturally grows, for polishing, and hence they name it korosunad, or korosacaucaf, from korosac, to smooth or polish.

Delphinium ; a genus of the class Polyandria, order Trigynia .- GENERIC CHARACTER. Calix : none. Corolla : petals five, unequal, disposed in a circle, of which the uppermost in some is more obtuse than the rest in front, and is extended behind into a tubular, straight, long, obtuse horn, and the rest ovate-lanceolate, spreading, nearly equal; nectary two-cleft, seated in front within the circle of petals on the upper part, behind stretched out, involved within the tube of the petal in the second species. Stamina : filamenta very many, (fifteen or thirty,) subulate, wider at the base, very small, inclined towards the petal in the second species. Antheræ erect, small. Pistil: germen three or one, ovate, ending in styles, the length of the stamina; stigmas simple, reflex. Pericarp ; capsules as many, ovate, subulate, straight, one-valved, gaping inwards. Seeds: very many, cornered. ESSENTIAL CHARACTER. Calix: none. Petals: five: nectary cloven, produced into a horn behind ; siliques three or one. These are mostly specious hardy annuals or perennials; the lower leaves digitate or palmate, the upper less divided, and sometimes even, entire ; the flowers are in loose spikes or panicles at the ends of the stem and branches, of various colours, chiefly blue, never yellow .---- The species are,

Unicapsular.

1. Delphinium Consolida; Branching Larkspur. Nectaries one-leafed; stem subdivided; root annual; stalk upright, a foot high or more, round, pubescent, divided into alternate dividing branches; leaves alternate, the lower ones on petioles half an inch long, the upper ones sessile or nearly so; corolla blue, varying to purple, pink, and white, and in gar-dens to striped, and many different shades of colour: in English, it is called wild or corn lark's-spur, lark's-claw, and lark's toes ; in French, pied d' allouette ; in German, rittersporn ; in Danish and Swedish, ridderspore ; in Italian, speronella ; and in Spanish, espuela de caballero. It grows wild in corn-fields in Germany, France, Switzerland, Carniola, Italy, and Spain; it was observed by Sherard in Swaffham-fields, Cambridgeshire, and found there by professor John Martin in 1730, and has been seen in abundance in most of the open fields round Cambridge, with 5 U

The expressed juice of the petals, with the addition of a little alum, makes a good blue ink : the seeds are acrid and poisonous. Meyrick informs us, that a decoction of the leaves is good for the bleeding piles; stopping the hæmorrhage, and cooling the body at the same time, contrary to most of the other restringent medicines. A conserve made with the flowers is an excellent medicine for children, who, from a redundancy of acrid humours in the intestines, are subject to violent purgings. Hill also prescribes the juice of the flower, and an infusion of the whole plant, against the colic, and pains in the bowels. The first, second, third, fourth, and fifth species, are propagated by seeds, which must be sown where the plants arc designed to remain, for they do not bear transplanting well, especially when they are not removed while very young. Those seeds which are sown in autumn, produce the strongest plants and most double flowers. and ripen their seeds better than those which are sown in the spring, as they come earlier to flower; but to obtain a succession of these flowers, there should be some seed sown in the spring. When they are sown upon the borders of the flower-garden for ornament, they should be in patches of about a foot in diameter, in the middle of the borders, at proper distances; in each of these patches may be scattered ton or a dozen seeds, covering them over about a quarter of an inch with earth, and in the spring the plants may be thinned, leaving about five or six of the upright sort in each patch to stand for flowering, but of the branching sort not more than three or four, because they occupy so much more room. The plants will now require nothing farther, except careful weeding; and when they begin to flower, should be supported by flower-sticks, to prevent their being broken by the wind, especially if they be in an unsheltered situation. If the seeds be well chosen, there will be very few ordinary flowers among them ; and if different-coloured flowers spring up in each patch, they will make a pleasing variety; but the upright sort should never be mixed in the same patches with the branching, because they do not flower at the same time. But in order to preserve the two sorts fine, without degenerating to single or bad colours, there should be a bed of each sort sown in autumn, in some separate part of the garden, where the plants should be properly thinned, and kept clean from weeds, till they begin to show their flowers ; they should then be carefully looked over every other day, to pull out all those plants whose flowers are not very double, nor of good colours, for if these be permitted to stand among the others till their farina has impregnated them, it will certainly cause them to degenerate : hence those persons who are contented with only marking their good flowers for seed, and suffer the others to stand for seed among them, will always find themselves disappointed in the goodness of their flowers the following season; therefore those who propose to have these flowers in perfection, should never gather the secds of such as grew in the borders of the flower-garden, because there it will be almost impossible to preserve them so true, as when they are in beds at a distance from all other kinds. When the seed-vessels turn brown, they must be carefully watched, to gather them before they open and discharge their seeds; because those which are situated on the ower part of the stalk, will open long before the others on the upper part are ripe; hence the pods ought to be gathered as they ripen, and not suffered to stand till the stalks are pulled up, which is often practised. Those pods which are situated on the lower part of the stalks, are much preferable to such as grow near the top, for which reason those who are very

pink, purple, and white flowers, ever since the year 1752. the spikes of flowers, and never suffer them to seed. As these plants are so very hardy, and require so little care in their culture, they deserve a place in every good garden: and during their continuance in flower, there are few plants which make a better appearance ; especially for gathering to make flower-pots to adorn rooms, there is scarcely any flower so proper, because by their upright growth and long spikes they rise to a proper height above the pots, and, when the several colours are skilfully intermixed, form a rich appearance, and continue long in beauty.

2. Delphinium Ajacis; Upright Larkspur. Nectaries one-leafed; stem simple; the stalk is eighteen inches and more in height, and seldom branched; leaves finely divided, commonly by threes, on broad petioles; segments linear, quite entire, channelled above; spike of flowers erect and more dense than the preceding; commonly only one capsule or silique. This species affords a great variety of colours in both the single and double flowers, some of which are very large and numerous, in close spikes, making a fine appearance from the end of June until August .- Native country unknown. For its propagation and culture, see the preceding species,

3. Delphinium Aconiti. Nectaries one-leafed, with four teeth in front; branchlets one-flowered; stem a foot high, panicled, branching, hoary, pubescent ; leaves pedate, multifid, linear, becoming hoary; the upper ones only three-parted; flowers terminating, solitary, peduncled, small, livid, variegated within with purple and green .- Annual : Native of the Dardanelles. For its propagation and culture, see the first species. * Tricapsular.

4. Delphinium Ambiguum; Doubtful Larkspur, Nectaries one-leafed ; corollas six-petalled ; leaves many-parted ; branches divaricating in a simple stem ; corollas blue, with a green outside; stalk three feet high or more; the branches come out horizontally at first, but afterwards turn up so as to make an acute angle with the stalk; the leaves are long, and finely divided; the flowers also are placed thinner in the spikes than those of the upright sort, are large, and some of them very double and of various colours. It flowers later than the upright larkspur .- Native of Barbary. For the propagation and culture, see the first species,

5. Delphinium Peregrinum ; Broad-leaved Annual Larkspur. Nectaries two-leaved ; corollas nine-petalled ; leaves many-parted, obtuse. This has a very branching stalk about two feet high; the lower leaves are divided into many broad obtuse segments, but those which are upon the stalks are generally single; the flowers grow scatteringly towards the upper part of the branches, are small, and of a deep-blue colour ; they are succeeded by very small seed-vessels, which are single or double, rarely three together .- Native of the south of Europe and the Levant. For the propagation and culture, see the first species.

6. Delphinium Grandiflorum; Great-flowered Larkspur. Nectaries two-leaved, with entire lips; flowers usually solitary : leaves compound, linear, many-parted. It has a perenuial root, which puts out two or three branching stalks every spring, rising a foot and a half high. The flowers come out towards the upper part of the stalks singly, each on a long naked peduncle; they are large, and of a fine azure colour, appearing in June and July, and ripening seed in autumn .- Native of Siberia. The sixth, seventh, eighth, ninth, and tenth, are propagated by seed, which, if sown in autumn, will more certainly succeed than those which are sown in the spring; when the plants come up, they should be weeded, and some drawn out wherever they grow too close together; in the following autumn they must be planted curious in the choice of their seeds, crop off the upper part of where they are to remain; they will flower in the following DEL

summer, and the roots continuing to increase in magnitude for many years, will produce a great number of flower-stalks.

7. Delphinium Intermedium; Palmated Bee Larkspur. Nectaries two-leaved, with ovate cloven lips and ovate divisions; leaves three-parted, with trifid gashed divisions; root perennial, with annual stems growing to the height of six or seven feet; leaves broad, divided into five or seven parts, cut into many narrow segments towards the top; flowers in long spikes at the extremities of the stalks; corollas of a fine blue colour .- Native of Silesia. For its propagation and culture, see the sixth species.

8. Delphinium Elatum; Common Bee Larkspur. Nectaries two-leaved, with ovate emarginate lips, and very short unequal divisions; leaves subpeltate, three-parted, with multifid divisions six feet high; root perennial; leaves slightly villose, becoming smooth by age, half five-lobed, petioled; lobes acute, often half three-lobed, sharply serrate; spikes of flowers very long and handsome; peduncles oneflowered, lanuginose; corollas deep blue, with a wrinkled spur. It flowers from June to September, and is a native of Switzerland and Siberia. For its culture and propagation, see the sixth species.

Nec-9. Delphinium Exaltatum; American Larkspur. taries two-leaved, with oblong cloven lips and lanceolate equal divisions; leaves three-parted, with trifid divisions; root perennial; stem upright, five or six feet high, branching; lower leaves large, divided into three lobes to the petiole, and these cut on their borders into acute segments : they are a little hairy, and of a grayish colour, standing apon pretty long petioles; stem-leaves smaller, and not so deeply divided; the principal stalk is terminated by a long loose spike of flowers, which is often a foot and a half long; the flowers are not much larger than those of the common larkspur, and are of a pale blue colour; the bearded nectary has, at first sight, the appearance of a large fly in the tube of the flower. It flowers at the end of June or beginning of July, and in cool seasons there is frequently a succession of flowers till the end of August .- Native of most parts of North America, where it occasions great disorders in the cattle that feed upon the leaves. For its culture and propagation, see the sixth species.

10. Delphinium Puniceum; Scarlet-flowered Larkspur. Lips of the nectary two-parted, hairy; horn straight; leaves many-parted; no calicine bractes; it differs from all the other sorts in the dusky red colour of the flowers .- It is a perennial plant, and a native of Siberia. For its propagation and culture, see the tenth species.

11. Delphinium Staphisagria; Palmated Larkspur. Stavesacre, or Lousewort. Nectaries four-leaved, shorter than the petal; leaves palmate, with the lobes obtuse. This is an annual plant, rising with a strong hairy plant about two feet high; leaves hairy, composed of five or seven oblong lobes, which have frequently one or two acute indentures on their sides ; the flowers form a loose spike at the upper part of the stalk, each on a short peduncle, and are of a pale blue or purple colour; a variety with leaves, veined with white, differs in having the leaf gashed, seven-parted, the divisions acuminate, the horn or spur of the corolla not obscure, but the length of the pedicel. The common people use the powder of the seed to kill lice; whence it is elegantly named lousewort. The seeds should be sown where the plants are to remain. They are kept by druggists, and have been given in small doses against rheumatic and venereal disorders; they vomit and purge, and that in so rough a manner, that it is not safe to take them internally; when chewed in the mouth, they excite a very large dis- of the stalks. Ray observed this plant in abundance on 15

charge of watery humours from adjacent parts, and frequently prove serviceable in disorders of the head, but are chiefly used to destroy the lice with which children's heads are generally infested; and the seeds, coarsely powdered and strewed among the hair, never fails to remove them.

DEN

Dentaria; a genus of the class Tetradynamia, order Siliquosa .- GENERIC CHARACTER. Calix : perianth fourleaved; leaflets ovate-oblong, converging from parallel, Corolla : four-petalled, cruciform .--obtuse, deciduous. Petals: roundish, obtuse, scarcely emarginate, flat, ending in claws the length of the calix. Stamina : filamenta six, subulate, length of the calix, of which two are shorter; antheræ cordate-oblong, erect. Pistil : germen oblong, length of the stamina ; style very short, thick ; stigma obtuse, emarginate. Pericarp : silique long, columnar, two-celled. two-valved, bursting open elastically with the valves rolled back; dissepiment a little longer than the valves. Seeds: many, somewhat ovate. ESSENTIAL CHARACTER. Silique bursting elastically with the valves rolled back. Stigma: emarginate. Calix : converging lengthwise .-- These plants are propagated by seeds, or parting their roots; the seeds should be sown in autumn, soon after they are ripe, in a light sandy soil, and a shady situation; in the spring the plants may be taken up, where they grow too close, and transplanted out into the same kind of soil and situation. where, after they have taken root, they will require no farther care, but to keep them clear from weeds; in the second year they produce their flowers, and sometimes perfect their seeds. The best time for transplanting the roots is in October, when they should be planted in a moist soil and a shady situation; for they will not live in a dry soil, or when they are exposed to the sun. The bulbs produced on the stalks of the second sort, if planted, will grow, and produce other plants .---- The species are,

1. Dentaria Enneaplylla; Nine-leaved Toothwort. Leaves in three-times-three; root perennial, white, toothed, long, of a pleasant taste; stem a foot or a foot and half in height. branched, round, and smooth; leaves biternate; leaflets lanceolate, serrate, acuminate, smooth; flowers from three peduncles, forming a panicle or raceme, erect, fascicled ; calix pale green or yellowish ; petals reddish yellow, or yellowish red : most of the upper flowers are abortive. Gerarde calls it coral-toothed violet. It flowers in April and May, and is a native of the woods of Hungary, Austria, Silesia, &c.

2. Dentaria Bulbifera; Bulbiferous Toothwort, or Coralwort. Lower leaves pinnate, upper simple; stem simple; corollas flesh-coloured; the scaly bulbs in the axils of the upper leaves falling off, take root, and propagate new plants. so that it rarely produces seed ; root perennial ; plant more tender than the others ; petals purple, white, or reddish. It flowers in April and May. Gerarde calls it the toothed, or dog-tooth violet .- Native of Germany, Carniola, Piedmont, and England, in moist woods and shady places.

3. Dentaria Pinnata; Seven-leaved Toothwort. All the leaves pinnate : lower leaves with seven, and the upper with five leaflets. It may be fairly separated from the fourth species. there being a permanent difference in the leaves, although they agree in the flowers .- Native of Switzerland, the south of France, and Silesia, Mount Jura, and Saleya.

4. Dentaria Pentaphylla; Five-leaved Toothwort, Leaves digitate. This rises with a strong stalk a foot and a half high, with a leaf at each joint composed of five lobes four inches long, and nearly two broad in the widest part, ending in acute points, and deeply serrate; the flowers, which are small and of a bluish colour, grow in loose spikes at the top Mount Jura .- Native of Switzerland, Savoy, the south of a hand in length; flowers panicled, nodding .- Native of France, Carniola, and Silesia.

DIA

Dentella : a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth fiveparted, superior ; segments subulate, Corolla; one-petalled, funnel-form, longer than the calix ; tube gradually widening into a five-cleft spreading border : segments acute, threetoothed: the middle toothlet more produced. Stamina : filamenta five, short, awl-shaped, inserted at the base of the tube; antheræ oblong. Pistil: germen roundish, inferior, villose; style cylindric, short, thickish; stigmas two, thicker than the style, longer, spreading, Pericarn ; cansule globular, crowned by the calix, two-celled, Seeds ; very many, ovate, ESSENTIAL CHARACTER, Corolla: tubular, fivecleft, with three-toothed segments. Calix: five-parted; stigmas two; capsule globular, inferior, two-celled, manyseeded .---- The only known species is.

1. Dentella Repens .- A native of New Caledonia.

Devil in a Bush. Sce Nigella.

Devil's-Bit. See Scabiosa.

Devil's-Guts. See Cuscuta.

Deutzia : a genus of the class Decandria, order Trigypia. -GENERIC CHARACTER. Calix: perianth one-leafed, somewhat bell-form, one-third of the length of the corolla, tomentose, five-cleft, seldom six-cleft; divisions ovate, obtuse, erect. Corolla: five-petalled, seldom six-petalled; petals inserted on the outside of the edge of the germen, oblong, obtuse, cntire, white. Stamina : filamenta tcn, placed without the edge of the germen, linear, filiform at the tip, below the tip emarginate, trifid, white, the length of the corolla, alternately somewhat shorter; antheræ globular, twin. Pistil: germen superior, like a wreath, concave in the middle; styles three, seldom four, filiform, a little longer than the corolla; stigmas simple, club-shaped. Pericarp : capsule globular, truncate, perforated, somewhat three-cornered, callous, scabrous, three-awned, with the permanent bases of the pistils three-valved, three-celled, seldom four-celled, the size of a pepper-corn, ash-coloured, gaping at the base. Seeds: several in each cell. ESSENTIAL CHARACTER. Calix: oneleafed; capsule three-celled; filamenta threc-cusped .--The only species hitherto discovered is,

1. Deutzia Scabra. A tree about the height of a man, and very much branched; branches alternate, round, even, purplish; branchlets villose, scabrous, spreading; leaves opposite, petioled, ovate, acuminate, serrate, veined and wrinkled, scabrous with hairs in stars, spreading, an inch or more iu length; petiole villose and scabrous, a line in length; flowers on the outer brauchlets in compound panicles, on alternate pedicels; peduncles and pedicels angular, tomentose, and scabrous .- It flowers in May and June, and is a native of Japan, where the leaves are used by joiners in smoothing and polishing.

Dewberry. See Rubus.

Dialium; a genus of the class Diandria, order Monogynia.-GENERIC CHARACTER. Calix: noue. Corolla : petals five, equal, sessile, elliptic, obtuse, deciduous. Stamina : filamenta two, conic, very short, situated at the upper side of the receptacle; antheræ oblong, obtuse, as if of two conjoined. Pistil: germen superior, ovate; stylc subulate, declined, length of the stamina; stigma simple, ascending towards the tip of the antherae. Pericarp: legume. EssEN-TIAL CHARACTER. Calix: none. Corolla: five-petalled, Stamina : at the upper side of the receptacle .---- The only known species of this genus is,

1. Dialium Indicum. A tree with alternate pinnate leaves, having seven ovate, oblong, acuminate, petioled, even leaflets,

the East Indies.

Dianthera ; a genus of the class Diaudria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-parted, tubular; divisions lanceolate, equal. length of the tube, permanent. Corolla: one-petalled, ringent; tube short; upper lip flattish, reflex, cloven, very obtuse, lower lip three-parted; divisions oblong, equal. obtuse, distant, the middle one wider. Stamina: filamenta two, filiform, shorter than the corolla, growing to the back of it, leugth of the upper lip; antheræ on each filamenta double, obloug, the onc a little higher. Pistil : germen oblong; style filiform, length of the stamina; stigma obtuse. Pericarp: capsule two-valved, two-celled, compressed above and below, but alternately, with boat-like valves, bursting asunder with an elastic nail. Seeds : solitary, in form of a lens. ESSENTIAL CHARACTER. Corolla: ringent ; capsule two-celled, bursting with an elastic nail. Stamina: each a pair of alternate anthera .- All these plauts, except the first species, being uatives of the East or West Indies. and other hot countries, must be preserved in the bark-stove; but few of them have been hitherto introduced among us. -The species are,

1. Dianthera Americana. Spikes solitary, alternate. It is a low herbaceous plant, with a perennial root, which sends out several weak stalks about four inches long; the leaves are roundish, hairy, sessile, of a dark green colour, and an aromatic odonr; the flowers are produced from the side of the stalks in small spikes, and are in shape and colour very like those of clinopodium .- They come out at the end of July, but rarely produce seeds in England, where the seeds have hitherto been imported from Virginia and other parts of North America, of which this plant is a native. This plant is very difficult to preserve in England; for although it be hardy enough to endure the open air, yet it is very subject to rot in winter; and if it be placed under shelter, is apt to draw up weak, and soon after to decay.

2. Dianthera Comata. · Spikes filiform, verticilled, the lower umbelled; stem herbaceous, a foot high, somewhat branched and erect, angular, jointed, smooth; the joints swelling. According to Brown, it generally rises to the height of two or three feet, and is plentifully furnished with slender subdivided branches near the top; seeds two in each cell .- Native of the low lands of Jamaica, where it is called the balsam herb.

3. Dianthera Japonica. Peduncle axillary, solitary, sustaining from two to four flowers; bractes oblong, ciliate ; root annual; stem herbaceous, erect, six-cornered, very finely villose, kneed, swelling above the knee, but little branched, a foot in height; corolla purple, a little longer than the bractes, with a curved cylindric tube : filamenta longer than the tube; antheræ alternate at the end of each filament, membranaceous, and of a pale colour .-- Native of Nagasaki in Japan: flowering in August.

4. Dianthera Cærulea. Umbel fascicled, sessile, quite simple .- Native of Botany Island, near New Caledonia.

5. Dianthera Clavata. Panicle subumbelled, compound ; peduncles dilated at the end.—Native of the Society Islands. 6. Dianthera Paniculata. Panicles axillary; leaves lan-

ceolate, tomentose; a shrub five feet high, with an erect stalk and brachiate branches; leaves quite entire, opposite; segments of the calix filiform; corolla white, with a long slender tube; the upper lip filiform and emarginate, the lower large and trifid ; antheræ two on each filamentum, one over the other .- Native of Cochin-china.

7. Dianthera Punctata. Stem herbaceous; spikes termi-

DIANTHUS.

nating; leaves lanceolate-ovate, acuminate; antheræ awn- | four-cornered, shorter by half than the pericarp. ESSENTIAL less; stem erect, roundish, even, jointed; joints three inches long, narrowed at bottom; branchlets axillary, filiform, the length of the joints; leaves opposite; those on the stem petioled, lanceolate, ovate, acuminate, scarcely crenate, smooth, simply veined, with the veins mostly opposite, only half the length of the joints; those on the branchlets sessile; spike at the top of the branchlets, peduncled, an inch long, and smooth; peduncle filiform; flowers in whorls, two or three on each side, on very short pedicels and small, the lower ones more remote; bractes lanceolate, acumiuate, a line in length; corolla twice as long as the calix, smooth on the outside, the throat dotted with violet.

8. Dianthera Sulcata. Stem herbaceous, grooved; leaves cordate, ovate; spikes terminating; lower antheræ awned; stem erect, angular, six-grooved, pubescent, jointed; the internodes two or three inches long, and the joints swelling; leaves opposite, obtuse, scarcely crenate, somewhat rugged along the nerves, a little villose, paler underneath, an inch and half long, with alternate veins; petioles the length of the leaves: corolla villose on the outside, white, veined with purple; lower lip three-lobed; the lobes oblong, obtuse, equal; antheræ purple, the lower ones with a white awn .-Native of Arabia Felix.

9. Dianthera Flava. Suffruticose: leaves elliptic, lanceolate; spikes terminating; lower antheræ awned; stem shrubby, roundish, the thickness of a goose guill ; branches obscurely quadrangular, subpubescent, scored with a line along the sides; the internodes an inch long; the joints swelling ; leaves opposite, guite entire, thinly hairy, twice as long as the internodes, with alternate veins, on short petioles.

10. Dianthera Debilis. Stem shrubby; spikes solitary, imbricate, axillary, and terminating ; bractes ovate, ciliate ; stem shrubby; branches obscurely quadrangular, fourgrooved, with hairs pointing backwards, and internodes half an inch; leaves opposite, lanceolate, narrowed at the base into a very short petiole, quite entire, bluntish, veinless, having four parallel villose nerves underneath, and being only half the length of the internodes.

11. Dianthera Violacea. Stem shrnbby; spikes terminating, imbricate ; bractes lanceolate, ciliate ; flowers bicalicled; branches powdered and villose, obscurely quadrangular; the angles scarcely scored with a line; the internodes an inch and half; leaves opposite, lower oblong, upper lanceolate, rounded at the base, quite entire, smooth, bright green, veinless, nearly the length of the internodes, on short petioles ; spike cylindric, half an inch long, on a very slender peduncle. 12. Dianthera Bicaliculata. Flowers panicled, bicalicled ; panieles dichotomous; stem herbaceous; leaves opposite, ovate, acuminate, quite entire, petioled, panicled, axillary; pedicels bifid, often trifid ; corolla purple, bilabiate, divided; antheræ divaricated. It is annual; and flowers here in August .- Native of the East Indies and Arabia Felix.

Dianthus ; a genus of the class Decandria, order Digynia. -GENERIC CHARACTER. Calix : perianth cylindric, tubular, striated, permanent, five-toothed at the mouth, surrounded at the base with four scales, of which the two opposite are lower. Corolla: petals five; claws length of the calix, narrow, inserted into the receptacle; border flat; the plates outwardly wider, obtuse, crenate. Stamina : filamenta ten, subulate, length of the calix, with spreading tips ; antheræ oval, oblong, compressed, incumbent. Pistil : germen oval; styles two, subulate, longer than the stamina; stigmas bent back, acuminate. Pericarp : capsule cylin-38.

CHARACTER. Calix ; cylindric, one-leafed, with four scales at the base. Petals: five, with claws. Capsule: cylindric. one-celled .-- These beautiful plants are chiefly herbaceous ; some few, however, are suffruticose. Most of them are hardy and perennial, or biennial; some of the smaller wild sorts only are annual .---- The species are,

* Flowers aggregate.

4. Dianthus Barbatus; Bearded Pink, commonly called Sweetwilliam. Flowers in bundles : calicine scales ovate. subulate, equal to the tube in length; leaves lanceolate. It has a perennial fusiform root; stem upright, jointed, smooth, a foot and half high, upright, jointed, branched; leaves soft, veined, connate, from half an inch to almost an inch broad in the widest part, bright green; bundles of flowers compact, umbelled, sessile; petals serrate when wild, red, either plain or spotted with white, smaller than in many of the genus. The variations of colour are numerous, and might have been more so if this species had attracted the same minute attention as the pink and carnation. The principal varieties are, 1. broad-leaved sweetwilliam; 2. narrow-leaved, or sweetjohn : each of these have the flowers one single and two double. The principal variations of colour are, 1. deep red; 2. pale red, rose-coloured, flesh-coloured; 3. purple, inclining to blue; 4. purple and white; 5. white-spotted; 6. red with white borders, and purple with white borders; 7. pure white, with all the intermediate shades of the above colours, both single and double. The broad-leaved, with very double flowers of a deep purple, inclining to blue, bursting the calix, is not so much esteemed. The doublerose sweetwilliam, with flowers of a fine deep rose-colour, and smelling sweet, is much valued, for it does not burst. The mule, or fair-child's sweetwilliam, is one of the narrow-leaved sorts; it is supposed to have been produced from the seeds of a carnation, impregnated by a sweetwilliam; the flowers are of a brighter red than either of the former, and have an agreeable odour, but their branches are not quite so large; some of the single flowers have very rich colours, which frequently vary in those of the same bunch; there are others with fine variegated flowers, and others whose middles are of a soft red bordered with white, which are called painted ladies; but whoever is desirous of preserving any of these varieties in perfection, should par-ticularly mark the best flowers of each, and permit no other to stand near them, lest their farina should impregnate them, which would produce varieties. That which is called the painted-lady sweetwilliam, is a very beautiful variety; the stalks of this do not rise so high as most of the others; the bunches of flowers are larger, and produced more in the form of an umbel; the flowers stauding equal in height, make a better appearance : there are others whose stalks rise three feet high, and the flowers of a very deep red or scarlet colour. These all flower at the same time as the carnations, which reduces their value, as they have no scent. They must be renewed annually, to retain them in perfection; for though they are perennial, they are subject to decay. The single sorts are generally propagated by seeds, which must be sown in the latter eud of March or the beginning of April, in a bed of light earth, and in June they will be fit to transplant out; at which time prepare some beds ready for them, and set them at six inches' distance every way ; in these beds they may remain till Michaelmas, and ought then to be transplanted into the borders of the pleasure-garden or wilderness. They will flower the next year in June, and perfect dric, covered, one-celled, gaping open at top four ways, their seed in August. The seeds should be saved from the Seeds : a great many, compressed, roundish ; receptacle free, best coloured flowers for a supply. They may also be pro-

DIA

pagated by slipping their roots at Michaelmas; but this is seldom practised, because seedling roots always blow the strongest, and produce new varieties. Double sweetwilliams are propagated by cuttings, pipings, or layers, like pinks and carnations; they love a middling soil, not too light, nor too heavy or stiff, nor too much dunged, which very often occasions their rotting. They continue flowering a long time, and arc extremely beautiful, especially the mule, which produces two full blooms of flowers, one in June and the other in July; it is very subject to canker and rot, especially if planted in a soil too wet or dry, or if watered with sharp spring water. These flowers, planted in pots, are very proper to adoin court-yards.

2. Dianthus Carthusianorum : Carthusian Pink. Flowers subaggregate; calicine scales ovate, awned, shorter than the tube; leaves linear, three-nerved. This differs from the foregoing sort in having the leaves parrower by half, stiffer, and marked with three principal nerves, not one only, as in that; the stem is a little scabrous, not perfectly smooth as in the former; the petals are distant and villose, not smooth on their upper surface; the pistils are longer than the tube. In a fertile soil there will be fifteen flowers on a stem, in a barren soil fewer, and sometimes only one: this, therefore, is an intermediate species between the aggregate and one-flowcred dianthi. There are sometimes seven calicine scales ; the petals are of a deep-red colour, ovate, and five-toothed. It does not flower in July .- Native of Germany, Switzerland, Carniola, Italy, Sicily, and Spain.

3. Dianthus Atrorubeus. Flowers aggregate ; calicine scales ovate, awned, shorter than the tube; leaves connate, striated ; height from two to three feet ; leaves smooth, flat, counate at the base, an inch from the joint, striated underneath, lanceolate, erect. The head of flowers at the end of the stem is formed in this manner; a pair of elliptic leaves emitting a long awn, has two short peduncles rising from it on each side; hence the stem, rising a little higher, has three other very short peduncles, each bearing three flowers; petals scarlet, rhomb-shaped, with few unequal tceth .- It has hardly any smell, is percnnial, and a native of Piedmont, in dry hilly places by the sides of woods.

4. Dianthus Ferrugineus; Rusty Pink. Flowers aggregate; petals bifid; segments three-toothed. This species very much resembles the third, but the stem is narrower, and the leaves are more grassy and keeled. It has the entire habit of sweetwilliam : the flower-stems are upright, and about a foot and half high : the bundles of flowers are close. some of the corollas vellow, and others of a rusty iron-colour. in different bundles, and sometimes even in the same bundle. The season of flowering is in July, but when the weather proves cool and moist, there will be a succession of flowers. till the end of September. The roots will abide two or three years, but the young plants of the second year produce the most flowers .- Native of Italy and Spain.

5. Dianthus Armeria; Deptford Pink. Flowers in bundles; calicine scales lanceolate, villose, equal to the tube in length; root annual; stems erect, a foot or a foot and half or eighteen inches high, decumbent at bottom, jointed, in height, round, pubescent, roughish, swelling at the joints, towards the upper part a branch comes forth at each joint, terminated with a small bundle of from two to four flowers; leaves linear-lanceolate, connate, bright green, erect, entire, pubescent ou both sides and roughish, three-nerved, three rior beauty and rich spicy odour, must have been unknown inches long, and two lines broad; claws of the petals long; to the ancients in its cultivated state; otherwise it would border purple, dotted with red and white, smooth, except have been described by the naturalists, and sung by the that they are slightly hairy towards the throat, obtuse and poets, as well as its rival: the rose carnations and pinks finely notched at the end, acumiuate, with one or two teeth; have, however, been cultivated time immemorial in Europe, antheræ violet-coloured; stigmas red, purple, flexuose, pu- and were among the few favourite flowers of our remote

bescent. It flowers in July and August .-- Native of Gothland, Denmark, Upper and Lower Silesia, the Palatinate and other parts of Germany, France, Switzerland, Italy, Spain, and England. From having been found in a meadow near Dentford, it obtained the name of Deptford pink, and is met with in Charlton-wood and other parts of Kent; near Croydon, between Dorking and Mickleham, Dulwich, Oak-ofhonour Hill, and Streatham, in Surry; in Notfolk; about Pershore and Eckington in Worcestershire : near Ketley in Shronshire: and at Clarkson-leap near Worcester. It is also found near Reading in Berkshire ; near Cavesham ; on the road from Harefield to Chalfont St Peter's; in a little wood near Highgate; and in Tuddington-field.

6. Dianthus Japonicus. Flowers in bundles; calicine scales acute, ciliate, shorter than the tube: stem decumbent at the base, then erect, round, even, smooth, simple, or very rarely divided at top, a foot in height; leaves opposite, petioled, ovate, acute, entire, smooth, nerveless, erect, an inch in length, the upper ones smaller; petioles broad, stemclasping; flowers terminating, fastigiate; calix the length of the tube of the corolla, striated, smooth ; calicle ovate at the base, then lanceolate, acuminate, kceled, half the length of the calix : corolla crenate .-- Native of Japan.

7. Dianthus Prolifer: Proliferous Pink. Flowers in heads ; calicine scales ovate, obtuse, awnless, exceeding the tube in length; root annual; stem usually single, ercct, decumbent only at bottom, very smooth, swelling at the the joints, a span or a foot high, sometimes more; flowers in a crowded head on the summit of the stalks, three or four together, surrounded by large scaly bractes nearly binding them; they open one at a time, the uppermost first, rising up from the bractes, when they fade, drying up or withdrawing again, so that they are a considerable time in flowering : corollas small, slightly bifid, not crenate, red or rose-coloured, sometimes varying to white; they expand about eight in the morning, and close about one in the afternoon. Gerarde calls it catchfly or limewort, but he has confounded it with the true catchfly .- Native of Denmark, Germany, France, Switzerland, Carniola, Italy, Sicily, Spain, and England. With us it is rare, in sandy pastures, and has been observed at Selsey Island in Sussex; near Norwich; on Landridgehill: at Hanley Castle in Worcestershire; and between Hampton Court and Tuddington.

** Flowers solitary, several on the same Stem.

8. Dianthus Diminutus. Calicine scales eight, longer than the flower. This seems evidently to be a mere variety of the preceding species. It is a diminutive plant, seldom rising six inches high, terminated by a single flower of a palered colour; the leaves are short and narrow, and grow in close heads. Annual .- Native of Germany and Switzerland.

9. Dianthus Caryophillus; Clove Pink, and Common Carnation. Calicine scales subrhombed, very short; petals crenate, beardless. This species, so well known by the gardener in its improved state, is thus described by Haller in a state of nature : Root large, woody, branched; stein a foot branched; leaves glaucous, smooth, linear, a line in breadth; every branch is terminated by one, two, or three flowers; it grows on rocks, walls, and in dry soils. This fine flower, which has long been deservedly esteemed, both for its supe-

DIA

and thirty of gillyflowers. Though these have been supplanted by modern flowers, and the florists are daily producing new ones, yet it may not be unacceptable to the curious, to recite the names of those which were in favour almost two centuries ago .- Carnations. Gray, red, and blue hulo; grimelo, or prince; white, or delicate; French; grand or great Harwich, or old English ; chrystall or chrystalline; red chrystall; fragrant; striped savadge; blush and red savadge; Oxford; king's or ordinary Bristow; greatest granado; grand pere; cambersine; great Lombard red .---Gilly flowers. Lusty gallant or Westminster; Bristol blue; Bristol blush; red Dover; light or white Dover; fair maid of Kent, or rnffling Robin ; queen's dainty ; Brazil ; Granado ; Turky; Poole; light or pale pageant; sad pageant; Bradshaw's dainty lady; best white; London white; hamell; purple; gredeline; blue; blush; John Wittie his great tawny ; divers other tawnies ; many sorts of blushes ; some varieties of reds; striped tawny; marbled tawny; Master Tuggie's princess; flaked, feathered, and speckled tawny; Master Tuggie his rose gillyflower. This Master Tuggie appears to have been the most famous man of his time for the cultivation of those fine flowers; and Johnson, referring to the work of his friend Parkinson, says, " if they require any further satisfaction, let them at the time of the year repair to the garden of Mistress Tuggie, the wife of my lately deceased friend Mr. Ralph Tuggie, in Wesminster, which, in the excellency and variety of these delights, exceedeth all that I have ever seen."-Modern florists distinguish the the carnation into four classes. First, flakes, of two colours only, and their stripes large, going quite through the leaves. Second, bizarrs, with flowers striped or variegated, with three or four different colours, in irregular spots or stripes. Third, piquettes or piquettées. having a white ground, and spotted or pounced with scarlet, red, purple, or other colours. Fourth, painted ladies, which have the petals of a red or purple colour on the upper side, and are white underneath. Of each class there are numerous varieties, but chiefly of the third, which some years ago was in most esteem with the florists; but of late years the flakes have been in greater request. To enumerate the varieties would be useless, as they are not permanent, and every country produces new flowers almost every year, which, though at first raising they may be greatly valued, in two or three years become so common as to be of little worth, especially if they prove defective in any one property; and arc turned out to make room for new comers. For the variety of pompous names, we refer, therefore, to the lists published yearly by florists and nurserymen, who either raise these flowers from seed, or import them from abroad. The following are what the florists call the good properties of a carnation: 1. The stem of the flower should be strong, and able to support the weight of the flower without hanging down; 2. the petals should be long, broad, and stiff, and pretty easy to expand, or, as the florists term it, should make free flowers; 3. the middle of the flower should not advance too high above the other parts ; 4. the colours should be bright, and equally marked all over the flower; 5. the flower should be very full of petals, so as to render it, when blown, very thick in the middle, and the outside perfectly round. To this we may add, that the stem should not only be strong, but straight, and not less than thirty, or more than forty-five inches high. The flower should be at least three inches in diameter, and the petals well formed, neither so many as to appear crowded, nor so few as to appear thin. The lower or outer circle of petals, commonly called the guard-leaves, should be par-

ancestors. Parkinson recites nineteen varieties of carnations, | ticularly substantial, and rise perpendicularly about half an inch above the calix, turn off gracefully in a horizontal direction, thus supporting the interior petals, which should decrease gradually in size as they approach the centre, which should be well filled with them; all the petals ought to be regularly disposed, and lie over each other in such a manner, as that their respective and united beauties may meet the eve all together; they should be nearly flat, or at most have a small degree of inflection at the broad end; their edges should be perfectly entire, without notch, fringe, or indenture: the calix should at least be an inch in length, and sufficiently strong at top to keep the bases of the petals in a close and circular body; the colours ought to be distinct, and the stripes regular, narrowing gradually to the claw of the petal, and there ending in a fine point; almost one half of each petal should be of a clear white, free from spots .-Pinks do not seem to have been much noticed by our ancestors, and it is only within the present century, and particularly of late years, that they have been so much improved and varied as to be highly valued by the florists: the principal varieties are, the damask, white shock, pheasant's eye, common red, cob's, dobson's, white cob, and bat's eye: the old man's head, and painted lady pinks, rather belong to the carnation. The damask pink is the first of the double sorts in flower: it has but a short stalk, and the flower is not very large, nor so double as many others; the colour is of a pale purple, inclining to red, but the scent is very sweet. The next which flowers is the white shock, which was so called from the whiteness of its flowers, and their jagginess and fringed borders; but the scent of it is not so agreeable as that of some of the other sorts. After this appear all the varieties of pheasant's eye, of which new varieties are frequently raised, which are either titled from the persons who raised them, or the place where they were raised; some of these have very large double flowers, but those which burst their pods are not so generally esteemed. The cob pink comes out next, the stalks of which are much taller than any of the former; the flowers are very double, and of a bright red colour, and as it has the most agreeable scent of all the sorts, it well deserves a place in every good garden. The old man's head, and the painted lady, do not flower till July, coming out at the same season with the carnation, to which they are more nearly allied than to the pink : the first, when it is in its proper colours, is purple and white, striped and spotted, but this frequently is of one plain colour, which is purple, and will continue flowering till stopped by the autumnal frost : it has an agreeable scent, for which it is esteemed, while the painted lady is chiefly admired for the liveliness of its colour, being neither so sweet nor of so long continuance as the other. The times of flowering for the pinks is from the latter end of May till the middle of July; and that sort of pink which is called bat's eve, will frequently flower again in autumn .--Propagation and Culture of Carnations. Having obtained a quantity of good seeds, prepare a proportionable number of pots or boxes, filled with fresh earth mixed with rotten cowdung, incorporated well together; then sow the seeds, but not too thickly, in them, covering them with about a quarter of an inch of the same kind of earth, placing the pots or boxes so as to receive the morning sun till eleven o'clock, observing also to refresh the earth with water as often as it may require. In about a month's time the plants will come up, and, if kept clear from weeds and duly watered, will be fit for transplanting about the end of July; at which time prepare some beds of the same sort of earth as they were sown in, in an open airy situation, in which plant them about three inches square, observing to water and shade them until

they have taken new root, observing to keep them clear from weeds; in these beds they may remain till the end of August. by which time they will have grown so large, as almost to meet each other; then prepare some more beds of the like good earth, in quantity proportionable to the flowers you have raised, in which plant them at six inches' distance each way, and not above four rows in each bed, for the more conveniently laying such of them as may prove worth preserving, for in these beds they should remain to flower: the alleys between these beds should be two feet wide, to afford room for passing between and clearing them. If the season should prove very dry, they ought not to be transplanted till there is some rain, so that in some years it may happen to be the middle or end of September, before there may be wet enough to moisten the ground for this purpose; but if there be time enough for the plants to strike root before the frost commences, that will be sufficient. If the winter should prove severe, the beds must be arched over with hoops, that they may be covered with mats, otherwise many of the plants may be destroyed, for the good flowers are not so hardy as the ordinary ones. They will only require weeding, and to be supported by sticks, to prevent their breaking when they shoot up their stalks to flower; they ought to be attentively looked after as soon as they begin to blow, to ascertain which of them promise to be good flowers, as all the layers should be laid down upon them. Those which are well marked, and blow whole, without breaking their pods, should be reserved to plant in borders, in order to secure seed ; and those which burst their pods, and seem to have good properties, should be planted in pots, to try what their flowers will be when managed according to art, for until the second year no one can pronounce what the value of a flower will be. Having chosen such flowers as promise well for the large sort, mark them separately for pots, and the round whole-blowing flowers for borders; pull up all single or ill-coloured flowers. to allow the rest more air and room. When these have been laid at a proper season, as soon as they have taken root, which will be some time in August, they should be taken off and planted out; those that blow large, in pots, and the others in borders. The whole-blowing flowers have been latterly much more esteemed than those large flowers which burst their pods, but especially those round flowers, which have broad stripes of beautiful colours and round rose-leaves, of which kind there have been a great variety introduced from France within these few years ; but as the French flowers are extremely apt to degenerate into plain colours, and are much tenderer than the English, less prices are now given than for some years past : from the present taste for the whole-blowing flake flowers, many of the old varieties have been revived, and large prices paid for such as some years before were sold for one shilling a dozen, or even tess; so variable is the taste, so capricious the fancy, of the florists. To propagate these plants by layers, strip off the leaves from the lower part of the shoot intended to be laid, making choice of a strong joint about the middle part of the shoot, not too near the heart of it, nor yet in the hard part next to the old plant: then with a small knife make a slit in the middle of the shoot from the joint upwards, half way to the other joint, or more, according to their distance; then with your knife cut the tops of the leaves, and remove the swelling part of the joint where the slit is made, so that the part slit may be shaped like a tongue; for if that outward skin be left on, it would prevent their pushing out roots ; then having loosened the earth about the plant, and, if necessary, raised it with fresh mould that it may be level with the shoot intended to be laid down, lest by the ground being too low, by forcing

down the shoot you should split it off: then make a hole in the earth with your finger, just where the shoot is to come, and bend it with your finger and thumb gently into the earth. observing to keep the top as upright as possible, that the slit may be open, and being provided with forked sticks for that purpose, thrust one of them iuto the ground, so that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the shank of the layer with the same sort of earth, giving it a gentle watering to settle the earth about it, which should be repeated as often as it is necessary to promote their rooting. They will have taken root in about five or six weeks afterwards, and may then be transplanted into earth proper for them, which should have been previously prepared in the following manner: Select some good upland pasture, or a common that is of a hazel earth, or light sandy loam ; dig eight inches deep from the surface, taking all the turf, and laying the whole in a heap to rot and mellow for one year: this heap must be turned once a month to sweeten, and ought then to have about a third part of rotten cow-dung, or rotten dung from a cucumber or melon bed, well mixed with it six or eight months before it be used, the better to incorporate their pods. In the middle or latter end of February, if the season be good, you must transplant these layers into pots for their bloom; the pots should be full eight inches over at the top, and should have the holes stopped with oystershells or potsherds, to draw off the water; these pots should be filled about half way with the same good compost as was before directed: the plants should then be shaken out of the small pots with all the earth about their roots, and you must take off some of the earth round the outside of the ball, and from the surface removing the fibres of the roots on the outside of the ball of earth, plant one good plant exactly in the middle of each pot, but neither so low as to bury the leaves of the plant, nor so high that the shank may rise above the rim of the pot, which must now be filled up with the before-mentioned earth, closing it gently to the plant with your hands, and giving it a little water in dry weather, to settle the earth about it, and placing it afterwards where it may be sheltered from the north wind, and watered as the season may require : here they are to remain till the middle of April, when a stage of boards should be prepared to set the pots on. This stage should be so ordered that the plants may have little cisterns of water round their pots, to prevent iusects, particularly the earwig, from attacking the flowers in bloom; as those insects never fail to destroy the petals of the flowers, which are very tempting to them on account of their sweetness. But since the making of these stages is somewhat expensive, and not very easy to be understood by such as have never seen them, we shall here describe a very simple one, which will answer the purpose as well as any other. First prepare some common flat pans about sixteen or eighteen inches over; in each of these whelm a flowerpot, (which should be about six inches over at the top,) upsidedown, and lay a flat piece of timber about two feet and a half long, and three inches thick across, from pot to pot, till you have finished the whole length of your stage; then lay your planks lengthways upon these timbers, which will hold two rows of plants in the pots, of the size ordered for carnations; and when you have set your pots upon the stage, fill the flat pans with water, replenishing them whenever it decreases, which will effectually guard the flowers against in-sects. This stage should be placed in a situation open to the south-east, but defended from the west winds, which would probably blow the plants down, being particularly violent at the season in which the flowers begin to appear. The stage indeed should be defended by trees, at some dis-

tance, from the wind of every point; but care ought to be taken that the trees be not too near. In the middle of April the layers will begin to shoot up for flower, when some square deal sticks, about four feet and a half long, which should be thicker toward the bottom, and planed off taper at the top, should be carefully stuck into the pots as near to the plants as possible without injuring them ; then fasten the spindle to the stock with a slender piece of bass-mat, to prevent its being broken ; repeating this as the plant advances in height, observing also to pull off all side-spindles as they are produced, never suffering more than two spindles to remain upon one root, nor above one when you wish the flower to blow exceeding large. Towards the beginning of June, the flowers will have attained their greatest height, and their pods begin to swell, and some of the earliest begin to open on one side; observe therefore to open it in two other places at equal angles, which must be done as soon as you perceive the pod break, otherwise your flower will run out on one side, and be in a short time past recovering, so as to make a complete flower, and in a few days after the flower begins to open, you must cover them up with glasses, which are made for that purpose in the following manner: Upon the top of the glass, exactly in the centre, is a tin collar or socket, about three-fourths of an inch square, for the flower-stick to come through : to this socket are soldered eight slips of lead at equal distances. which are about six inches and a half long, and spread open at the bottom about four inches asunder; into these slips of lead are fastened slips of glass, cut according to the distances of the lead, which when they are fixed in, are bordered round the bottom with another slip of lead, quite round, so that the glass has eight angles, with the socket in the middle, and spread open at the bottom, about eleven inches wide. When the flowers are opened enough to be covered with these glasses, make a hole through your flower-stick, exactly to the height of the under part of the pod, through which put a piece of small wire about six inches long, making a ring at one end of the wire to contain the pod, into which ring fix the stem of the flower ; then cut off all the tyings of bass, and thrust the stem of the flower so far from the stick, as may give convenient room for the flower to expand without pressing against the stick, to which distance you may fix it by turning your wire so as not to draw back through the hole ; then make another hole through the stick, at a convenient distance above the flower, through which put a piece of wire, an inch and a half long, which is to support the glasses from sliding down upon the flowers; and be sure to observe that the glasses are not placed so high as to admit the sun and rain under them to the flowers, nor so low as to scorch their leaves with the heat. At this time also, or a few days after, as you shall judge necessary, cut some stiff paper, cards, or some such thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three-fourths of an inch in diameter, for the bottom of the flower to be let through; then place these collars about them to support the collars of the flowers from hanging down; this collar should be placed withinside the calix of the flower, and should be supported thereby; then observe daily what progress the flowers make, and if one side come out faster than the other, turn the pot round with that side towards the sun, and shade the glasses with cabbage leaves in very hot weather during the heat of the day, to prevent their being scorched or forced out too soon; and when the middle pod begins to rise, take out the calix thereof with a pair of nippers made for that purpose, lest the middle part of the 38.

greatly diminish its beauty; you must also observe whether there be more leaves in the flower than can be properly expanded in the space allotted to it, and if that be the case, put out some of the lowermost, or most unlikely leaves to spread, drawing out and expanding the others at the same time; and when the flowers are fully blown, if you cut them off, put on a fresh collar of stiff paper, which should be cut exactly to the size of the flower, that it may support the petals to their full width, but not to be seen wider than the flower in any part; when this is put on, draw out the widest leaves to form the ontside of the flower, which although they should be in the middle, yet by removing the other leaves they may be drawn down, and then the next longest flowers upon them again, that the whole flower may appear equally globular, without any hollow parts : in the doing of this, some florists are so curious as to render an indifferent flower very handsome; and on this, in a great measure, depends the skill of the artist to produce large fine flowers. During the flower season, particular care should be taken not to let them suffer for want of water, which should on no account be raw spring water, nor compound waters, such as are enriched with various sorts of dung; but the |best and most natural water is that of a fine soft river, next to that is pond-water, or standing water; but if you have no other than spring water, it should be exposed to the sun and air two days before it is used, otherwise it will give the flowers the cankers, and spoil them. The directions here introduced are chiefly intended for the management of those large carnations, which require the greatest skill of the florists, although of late years they have been less esteemed than formerly, and those flowers which do not break their pods, and are termed whole blowers. have now the preference. These are generally planted in pots, and treated in the same way as the large flowers, but do not require so much trouble to blow them; all that is necessary to be done for these, is to fasten their stems up to flower-sticks, to prevent them from being broken, and to take off the pods which proceed from the side of their stalks, leaving only the top-bud to flower, if they be intended to be large and fair; and when the flowers begin to open, if they be screened from the sun in the heat of the day, and also from the wet, they will continue much longer in beauty; but although the most valuable of these flowers are usually planted in pots, and thus carefully treated, yet many of these whole-blowing flowers may be planted in beds, or borders of the flower-garden, where they form a principal ornament during their continuance in flower, which is from the beginning of July till the middle of August, especially if the several colours be properly intermixed, for the flakes and bizarrs should be intermixed with the picqueites, and not planted separately, unless where they are designed for saving the seeds, in which case, those which are the finest of each sort should be planted in beds at a distance from each other, especially where persons are desirons to keep them distinct; for where the sorts are blended together, there will be an admixture of their farina, so that the seeds will vary, and not produce the particular kinds : the flowers that are planted in the full ground, generally produce such seeds better than those in pots ; but whoever proposes to raise a supply of new flowers from seeds, must always observe to save the best of their seedling flowers for this purpose, for it is well known, that after any of these flowers have been a few years propagated by layers, they become barren, and do not seed ; which is also the case of most other plants that are propagated by slips, lavers, or cuttings, so that the young plants which have been newly obtained from seeds, are always the most productive of seeds; flower should advance too high above the sides, which will the plants which are propagated by layers or slips, will

DIA

fine variety is obtained, it is thus propagated and maintained ; but all the new varieties come from seed, so that every person that is curious in these flowers must sow the seeds annually. Carnations may also be increased by cuttings and pipings as pinks are, but not so successfully in general as by layers, unless the operation be performed on a hot-bed under glasses: the cuttings for piping should have two joints, which ought to be thrown into water for a few minutes, and planted not more than half an inch deep : they are to be gently watered, and to continue open till their leaves are dry. before they are covered ; after this, they are to be kept moist till they have rooted, and to have only the morning sun and air admitted occasionally; but notwithstanding every precaution, success will be very uncertain, and many of the cuttings will frequently perish .- Propagation and Culture of Pinks. The common pinks are propagated by seeds, which is the best way to obtain new varieties; or by layers, as is practised for carnations; or by slips, or pipings as they are commonly called, which, if carefully managed, will take root very well. In raising them from seed, care should be taken to save only the sorts which will produce the finest flowers; the seeds may be sown in the spring, and the plants treated in the same way as is above pointed out for the carnation: the old man's head and painted lady pinks, are commonly propagated by this method, and most of the others. The time most proper for piping will vary with the season, but it should always be done immediately before or during the bloom, or indeed as soon as the young shoots are of a sufficient length for the purpose, that is, to form pipings from two to three inches in length : the striking will be much facilitated by covering the beds or pots with glasses, after having given them a good watering; not taking off the glasses till the cuttings or pipings begin to grow, but applying the water, when necessary, round the outside of the glasses. In a month or six weeks they may be rooted, and grow though they may be fully exposed. The only difference between cuttings and pipings is, that the former are cut through a joint horizontally, and the latter are drawn out at the joint from their sockets, so that they leave a hollow like a pipe, and thence derive their name. At the time of planting, if any rain should fall it will be of great service, but should the weather prove dry, the cuttings or pipings will require to be watered every other day until they have taken root; they should be planted in a shady border, and the ground should be dug well, and all the clods broken; and if no rain falls, it would be well soaked with water a few hours before they are planted; they ought then to be taken from the plants, all their lower lips stripped off, and planted as soon as possible after, for if suffered to lie long, they will wither and spoil. They need not be planted at a greater distance than three inches square, with the ground closed very hard about them: after which, watering and weeding is all they will require. Pinks may also be increased by slipping off the young shoots from the sides of the main ones, any time in the spring from February to April; the slips ought to be from three or four to six or eight inches in length.

10. Diauthus Pomeritianus. Calicine scales ovate, acute, very slort, upper haif of the calix strated; yetals emarginate, almost entire. The stem has only three or four simple, long, one-flowered branches; the corolla is yellow, and underneath pale green; stamina white, the length of the calix; the dowers open at half after twelve at noon, and close at en at night--Found near Constantinople and in Palestine.

11. Dianthus Deltoides; Maiden Pink. Calicine scales second year will produce a greater number of flowers than ovate-lanceolate, acute, about two; petals crenate; leaves the first. There is a great variety of very rich colours in

always continue to produce the same flowers, so that when a bluntish, subpubescent; barren stems numerous, reclining, putting forth roots : flowering-stems six to eight inches high. columnar below, square at top, slender, weak, but usually erect, sometimes simple, sometimes branched or dichotomous, swollen at the joint, slightly pubescent; the petals vary much in colour, being sometimes of a very pale flesh-colour, sometimes deep red, but always marked with a ring of deeper red dots near the centre of the flower. Dillenius distinguished this species by the scales of the calix being much more pointed; the corolla of a deeper colour, with numerous silvery, dots; and its flowering later, namely, in June and July; it continues flowering till late in autumn. There is a variety of this species common in gardens, which has white flowers with a beautiful purple ring, and leaves rather more glaucous than in the common sort. It is found on pastures and heaths on a light soil in Sweden, Denmark, Germany, Spain, and is not uncommon in England, being found on Hampstead Heath, Dupper's Hill near Croydon, about Hampton Court Park, Beacon's Hill, near Feversham in Kent; not far from Slough, near Windsor; near Sandy, in Bedfordshire; in Cambridgeshire, Suffolk, and Norfolk; at Clay, near Hillborough, in the way from Brandon, in Nottinghamshire, Derbyshire, Westmoreland, Shropshire, Somersetshire; and at King's Park, near Edinburgh.

12. Dianthus Rupertis." Calicine scales two, very obtuse; petals crenate; leaves linear, very narrow, three-sided, chan-nelled, stiffish, connate, in tufts, scabrous on the edge and keel; stem filiform, prostrate, bearing one or two flowers, which are remote, and sweet-scented; petals blood-red, cre-nate, not feathered or villose; styles standing out, recurved, -Prennial; native of mountains in the south of Europe.

13. Dianthus Corsias; Montain Pink. Flowers subsolitary; caliciene scales roundish, short; petals crenate, pubescent; leaves rugged at the edge. The circle is purple, and there is a purple tinge on the upper surface, from a number of very fine lines; stem rather angular, that and the leaves covered with a microscopical woollines; peduncles solitary, or in pairs; petals stained with pink at the base of the lamina; receptacle nearly as long as the seed-vessel; the flowers have no scent.—Native of Switzenland; and in England it is found on Chedder rocks, in Sourcestbire.

14. Dianthus Albens; Cape Pink. Calicine scales lanceolate, four, short; corollas emarginate; petals white above, greenish white underneath, with the tip violet-coloured on both sides.—It is a perennial, flowering in August, and a native of the Cape of Good Hope. This is the only plant of the genus which will not bear the open air of our climate.

15. Dianthus Chinensis; China Pink. Calicine scales subulate, patulous, leafy, equalling the tube; corollas cre-nate; leaves lanceolate. The flower-stems rise from six to eight or nine iuches high, branching out on every side; the branches grow erect, and are terminated each by one flower, which possesses no scent, but exhibits a great variety of colours: they are a considerable ornament to the flower-garden from July till autumn, when the frost stops them. They have been greatly improved by culture; some flowers being as full of petals as the best double pinks, and displaying the most glowing and vivid red colours: it is known in the nurserygrounds by the name of *Indian pink*, and was originally imported from China by way of Paris. It is generally supposed to be an annual plant, because the plants which are raised from seeds, flower and produce ripe seeds in the same season, so that their roots are not often preserved; but where they are planted on a dry soil they will continue two years, and the second year will produce a greater number of flowers than
these flowers, which annually vary when raised from seeds, I The double flowers are most esteemed, though the colours of the single ones are most distinct and beautiful ; for the multiplicity of petals in the double flowers in a great measure hides the deep shades, which lie towards the lowest part of the petals. These plants are propagated by seeds, which should be sown upon a gentle liot-bed about the beginning of April : this moderate heat is merely intended to accelerate the vegetation of the seeds; therefore, when the plants come up, they must have a large share of air admitted to them, to prevent their drawing up weak; and as soon as the weather will permit, they should be exposed to the open air. Three weeks or a month afterwards, they will be fit to remove, and should then be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches asunder. being careful to shade them from the sun until they have taken new root, and in dry weather to water them three or four times a week ; they will then only require weeding till the end of May, at which time they may be transplanted to the places where they are designed to remain for flowering, when they may be taken up with large balls of earth to their roots, so as scarcely to feel their removal, especially if it happen to rain at that time. As they do not grow large plants, so when they are planted singly in the borders of the flower garden, they do not make so fine an appearance as where they are planted by themselves in beds; or if they be planted in small clumps of six or eight roots each, where the flowers being of different colours, will set each other off to advantage. Those who are curious in those flowers, take particular care in saving their seeds, never permitting any single flowers to stand among the double, but pull them up as soon as they display their flowers, and also draw out all those which are not of lively good colours. Where this is observed, the flowers may be kept in great perfection; but where the seeds can be exchanged once every two or three years, with trusty friends who live at some distance, it is much better to change than to continue sowing seeds in the same place many years in succession; and this observation applies to most sorts of seeds : but the great difficulty is, to meet with an honest person of equal skill, who will be as careful in the choice of his plants for seed, as if he were to sow them himself.

16. Dianthus Monspeliacus. Calicine scales subulate, straight, a little shorter than the tube; corollas many-cleft; stem erect .- It is a perennial plant, and grows wild about Montpellier, Verona, and in Piedmont,

17. Dianthus Plumarius; Feathered Pink. Calicine scales subovate, very short, much blunted and awnless; corollas many-cleft ; stems ascending a foot or eighteen inches in height, branched; flowers one, two, seldom three, at the ends of the branches, sweet-scented ; petals large, light red, or bright purple, sometimes white, with a circle of red deeply jagged, having a red down at the base of the lamina or border; antheræ red. It flowers from June to August, and is perennial .-- Native of rocks, mountain pastures, and dry woody places, in North America.

18. Dianthus Crinitus. Calicine scales oval, mucronate, subdiverging, one-third of the length of the tube; petals manycleft, beardless ; stalks a span high, smooth, and even; flowers two or four on a stalk, erect ; petals narrow, irregularly cut to the base in very fine segments. It varies with a white flower. Found by Tournefort in Armenia.

19. Dianthus Superbus ; Superb Pink. Flowers panicled ; calicine scales very short, acuminate ; petals cloven into many capillary segments ; stem erect, a foot or eighteen inches in height, procumbent at the base, and then creet, round, somewhat two-edged on the upper part, smooth, feet high, brittle, hard, covered with a dark cloven bark; 2

branching only at top ; leaves like those of the narrow-leaved sweetwilliam; petals pale-red colour, sometimes white, hairy at the base of the border, sprinkled with bloody spots : the flowers smell very sweet, especially in the evening; capsule cylindrical, a little longer than the calix, glittering like gold-dust, smooth, four-parted. According to some, it is perennial, while others reckon it biennial, and even annual. Mr. Miller asserts, that the roots will live three or four years, but that the flowers are in their greatest beauty the second year from seeds .--- Native of Denmark, Lapland, Germany, Switzerland, France, Italy, and Spain : flowering from July to September. This deserves a place in every garden, on account of the elegance and delicious fragrance of the flowers. It grows naturally in a calcareous soil, and will thrive luxuriantly in a garden, if chalk be mixed with the common mould, but not otherwise.

20. Dianthus Attenuatus. Calicine scales short, lanceolate, acuminate, about six; tube attenuated at the top; petals crenate; stalks diffused, woody at bottom, twisted, branching very much; flowering-branches ascending a foot long, leafy, round, smooth, divided at top into two or three branches, which are one-flowered; flowers flesh-coloured, void of scent .- Native of the coast of the south of France.

*** Stem one-flowered, herbaceous.

21. Dianthus Arenarius; Sand Pink. Stem bearing one or two flowers; calicine scales ovate, obtuse; petals manycleft; leaves linear; root-leaves aboudant, in bundles, smooth, narrow, obtuse, stiffish; petals white, not crenate, smelling very sweet, especially in the evening. Mr. Miller says that the flower is sweet, but pale-coloured and small .-It flowers in May and June, and is a native of Scania, in drifting sand; of Silesia, on the borders of Saxony; of the mountains of Caruiola and Piedmont; and is found on old walls and buildings in many parts of England.

22. Dianthus Alpinos. Corollas crenate; outer calicine scales leafy, almost equalling the tube; root woody, perennial, putting forth many stems of a finger's length, having three joints; leaves on the stem linear, bluntish, flat; rootleaves in tufts, linear-lanceolate .- Native of the Alps, Silesia, Austria, Stiria, and Siberia, in rough stony places : flowering in June and July.

23. Dianthus Virgineus; Upright Pink. One or two inodorous flowers on the stem; petals crenate; calicine scales very short and blunt, in pairs ; 100t perennial ; lower leaves copious, erect, in an imbricate tuft, acuminate, like those of thrift; stems few, a span in height, having four very simple joints with smaller leaves, the uppermost very small, arising from a perfoliate sheath; stems decumbent, not prostrate. It flowers in June and July .- Native of the Alps, the south of France, Austria, and Carniola.

sava Shrubhy.

24. Dianthus Arboreus. Stem shrubby: leaves oblong, somewhat fleshy; calicine scales numerous, blunt, closely imbricate, very short; stalks eighteen inches and more in height, white, round, smooth, jointed, woody, branched; leaves glaucous, an inch an half long, narrow, rigid, mucronate; petals pale, purple, striated, a little beyond the middle marked with a dark-red dotted line, forming a ring, below which they are lanuginous; they are also cut about the edge. -Native of the island of Candia. This, with the two following species, are noble ornamental plants, which, it is to be lamented, are lost to our gardens.

obtuse, fleshy, brittle, bitter as gall, growing in tufts ; flowers commonly solitary, but sometimes several together; petals an inch and half long .- Native of the Levant: see the preceding species.

DIA

26. Dianthus Juniperinus. Stem shrubby, with a lacerated chinky bark ; leaves awl-shaped ; calicine scales about four, obovate, mucronate and pungent, patulous, only balf the length of the tube : flowers two or three at the tops of the branchlets, pedicelled, small,-Native of the island of Candia: see the twenty-fourth species.

27. Dianthus Pungens; Prickly-leaved Pink. Flowers solitary; stems full of alternate branches, few-flowered; calicine scales very short, mucronate, spreading; tube gibbous; petals entire; the stem-leaves are connate and sheathing at the base, crowded and covering the branches with their sheaths; the leaves on the branches are slightly connected with distant sheaths; all are flattish, acuminate, aud somewhat prickly; the peduucles arise from the ends of the lateral branchlets; the pedicels sustain from one to three flowers, which appear from August until October .- It is a native of the coast of Spain.

28. Dianthus Hispanicus. Stem usually one-flowered : calicinc scales ovate; petals linear, quite entire; plant a span in height; root woody; root-leaves in a tuft, linear, subulate; stems seldom two-flowered, smooth. There is a variety with roundish petals, white and red .- Native of the province of Arragon in Spain.

29. Dianthus Libanotis. Flowers subaggregate : calicine scales six, acuminate, recurved : corollas multifid-capillary, bearded at the throat ; stem erect ; root perennial, thickish, and somewhat branched; stem herbaceous, a foot high; leaves lanceolate, glaucous, those next the root obtuse, on the stem acute, recurved; flowers panicled; calicine scales six, sometimes eight, seldom four, awl-shaped, dilated at bottom, membranaceous, a little shorter than the tube of the calix petals yellowish, with a few hairs and red dots within at bottom : the claws are the length of the calix : filamenta filiform, a little longer than the calix ; styles swelling at the base. scarcely the length of the stamina .- Native of monut Libanus.

30. Dianthus Pumilus. Stemless; leaves linear. This plant grows in a tuft; the leaves are acute, smooth, and half an inch long; flowers sessile, solitary; petals toothed.

Diapensia; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth eightleaved; the five interior leaflets placed in a circle, the rest leaning upon them in an imbricated manner, all equal, ovate, obtuse, crect, permanent. Corolla : one-petalled, salvershaped; tube cylindric, open, length of the calix; border five-cleft, obtuse, flat. Stamina : filamenta five, compressedlinear, erect, terminating; the tube at the incisures of the border short; antheræ simple. Pistil: germen roundish; style cylindric, length of the stamina ; stigma obtuse. Pericarp : capsule roundish, three-celled, three-valved. Seeds : very many, roundish. ESSENTIAL CHARACTER. Corolla: salver-shaped. Calix : five-leaved, imbricate with three other leaflets. Stamina : placed on the tube of the corolla. Capsule: three-celled .----The only species hitherto discovered is,

1. Diapensia Lapponica. Root perennial; stem rising immediately from the root, and divided into several simple diffused branchlets, clothed all round with leaves at most a finger's height; leaves linear, blunt, almost membranaceous, having a longitudinal nerve, concave above, prominent be neath, a little broader outwards, imbricate at the base, spreading at the top, perennial, the lower ones finally wither spreading at the top, perennial, the lower ones finally wither superdecompound, villose; leallets almost entire; stem

leaves lanceolate, an inch long, and three or four lines broad, ing but not falling; peduncle from the top of the branch straight, slender, one-flowered ; corolla shining, snowy white, -Native of the mountains of Lapland, among stones covered with moss; also found in Norway.

Dicera : a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth four or five-parted ; leaflets equal. Corolla : petals four or five, obovate, trifid; segments obtuse, the middle one longest; nectary of four or five small emarginate corpuscles surrounding the germen. Stamina: filamenta (twelve to twenty) several between the nectary and the germen, capillary, short; antheræ linear, two-horned at top. Pistil: germen roundish; style awl-shaped, longer than the stamina; stigma simple. Pericarp: berry, ovate, two-celled. Seeds: very many. ESSENTIAL CHARACTER. Petals: four or five. obovate, trifid; nectary of four or five emarginate corpuscles; antheræ two-horned.— The species are, 1. Dicera Dentata. Style one; leaves oblong, acuminate,

toothed; racemes simple, axillary, loose. This is an elegant tree, bearing at the extremities of the branches abundance of leaves, which are alternate, oval, or oval-oblong, bluntish, smooth, veined, bluntly serrate, petioled, with a double gland at their base ; racemcs axillary, simple, loose, solitary, the length of the leaves; flowers on very minute pedicels, nodding; stamina sixteen when there are four, and twenty when there are five petals. Linneus remarked twenty stamina in the Ceylonese plant, and only eight in that from Java .- Native of New Zealand.

2. Dicera Serrata. Styles four ; leaves opposite, cordateovate, unequally serrate; racemes lateral, compound. This agrees with the preceding species in the structure of the flower, but differs in the fruit .- Native of New Zealand.

Dichondra ; a genus of the class Pentandria, order Digynia .- GENERIC CHARACTER. Calix : five-leaved ; leaflets obovate, netted-nerved, hairy without, smooth within, permanent. Corolla: monopetalous, inferior, rotate, subcampanulate, five-cleft, the length of the calix. Stamina: filamenta five, subulate, spreading, placed alternately between the divisious of the corolla, and only half the length; autheræ roundish. Pistil: germina two, hairy ; styles two, divaricate, setaceous, the length of the stamina, arising on the inside from the base of the germina ; stigmas capitate. Pericarp : capsules two, globalar, subhirsute, one-celled. Seeds : one in each cell, globular. ESSENTIAL CHARAC-TER. Calix: five-leaved. Corolla : rotate, inferior. Capsule : dicoccous .---- The only known species is,

1. Dichondra Repens. Stem prostrate, creeping, branched, round ; leaves alternate, petioled, erect, kidney-shaped, sometimes emarginate, above almost naked, below silky, radiate-veined; petioles round, silky; flowers small, rather nodding, on axillary, filiform, simple, silky peduncles, scarcely the length of the petioles, and usually solitary. The specimens from different countries differ in having the leaves naked above, or silky on both sides; also in the length of the petioles and peduncles; but these seem only to be varieties. Mutis sent it to Linneus from New Granada; Commerson found it at Buenos Ayres, and in the island of Mauritius; and it is likewise known to be a native of Peru, Jamaica, and New Zealand.

Dicksonia; a genus of the class Cryptogamia, order Filices .- GENERIC CHARACTER. Fructifications : kidney-shaped, lying under the edge of the frond at the lower surface; outer valve formed of the substance of the leaves

DIGITALIS PURPUREA __ Purple Foxglove.

arboreous. It flowers during the greater part of the winter, works powerfully by urine, and gives ease in those colicky and was found by Sir Joseph Banks and Dr. Solander, in the island of St. Helena.

DIC

2. Dicksonia Culcita; Shining-leafed Dicksonia. Fronds superdecompound, smooth; leaflets servate. Found in the island of Madeira, where it is called feila brom ; and in the island of San Miguel, one of the Azores. The inhabitants make pillows and cushions of the roots. There is little doubt but that this plant, and the baromets, or Scythian lamb, are one and the same, though they come from countries so remote.

Dictamnus; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth fiveleaved, very small, deciduous ; leaflets oblong, acuminate. Corolla : petals five, ovate lanceolate, acuminate, with claws, unequal, of which two are bent upwards, two placed obliquely at the sides, one bent downwards. Stamina : filamenta ten, subulate, length of the corolla, situated between the two lateral declining petals, unequal; small point-like glands scattered over the filamenta; antheræ four-sided, rising up-Pistil: germen five-cornered, elevated from the wards. receptacle ; style simple, short, bent downwards, incurved ; stigma sharp, rising upwards. Pericarp: capsules five, conjoined inwardly at the border, compressed, acuminate, with distant tips, two-valved. Seeds : in pairs, ovate, very smooth, within a common aril, which is two-valved, and cut ESSENTIAL CHARACTER. Calix: five. Petals: down. five, patulous; filamenta having glandulous dots scattered over them. Capsule : five, conjoined .---- The species are,

1. Dictamnus Albus ; Fraxinella, Leaves pinnate ; stem simple; root perennial, striking deep into the ground, and the head annually increasing in size; stalks many, two or three feet high, round here and there, slightly grooved, sometimes subancipetal, not branched, at bottom green and beset with white hairs, ferruginous red towards the top, with resinous glands; leaves alternate, the larger above a foot in length, spreading out horizontally, ascending towards the end; the midrib flat at top and edged on both sides, convex beneath, and hairy, the whole somewhat resembling an ashleaf: flowers in a long pyramidal loose spike or raceme, nine or ten inches in length; corolla large and bandsome, the common natural colour pale purple, with dark purple veins, but varying to white; filamenta pale purple, concealing the germen and style, ascending or turning up at the end, glandular, especially at top; antheræ green; germen covered with pedicelled glands; style with white hairs; stigma blunt, dark purple. The whole plant, especially when gently rubbed, emits an odour like that of lemon-peel; but when bruised, has something of a fine balsamic scent, which is strongest in the pedicels of the flowers, which are covered with glands of a rusty red colour, exuding a viscid juice or resin, which exhales in vapour, and in a dark place may be seen to take fire. Gerarde calls it bastard or false dittany : and Parkinson, false or while dittany. It flowers with us at the end of May and in June, and the seeds ripen at the end of September. Its beauty and fine scent should introduce it into every good garden. The tops of this plant, says Meyrick, afford a resinous matter, which is of a fragrant smell, and so very inflammable, that if a lighted candle be brought near enough for the flame to touch the resin, the whole immediately takes fire, and goes off with a smart explosion, but without damaging the plant in the least. The roots are the only parts used in medicine, and they are of a cordial sudorific nature, and are good in fevers, and in nervous bysteric complaints. A strong infusion of the young 39.

pains which so frequently attend that disorder .- Native of Germany, France, Spain, Austria, and Italy. It is propagated by seeds, which, if sown in the autumn soon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the spring, the seeds seldom succeed; or if they do grow, it is the following spring before the plants appear, so that a whole year is lost. When the plants come up, they must be constantly kept clean from weeds; and in the autumn, when their leaves decay, should be carefully taken up, and planted in beds at six inches' distance every way: these beds may be four feet broad, and the paths between them two, that there may be space left for weeding them. The plants may stand two years in these beds, during which time they must be constantly kept clean from weeds; and if they thrive well, they will be strong enough to flower. In the autumn they should be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more stems of flowers in proportion to the size of the roots. All the culture these require, is to be kept clean from weeds, and the ground about them dug every winter.

2. Dictamnus Capensis. Leaves simple; stem branching. -Native of the Cape of Good Hope.

Didelta; a genus of the class Syngenesia, order Polygamia Frustranea.-GENERIC CHARACTER. Calix: common, double, permanent ; outer three-leaved or three-parted, umbilicated at the back ; leaflets cordate, acuminate, much expanded, tomentose, hoary above; inner placed on the disk of the outer, shorter, composed of eleven or twelve leaflets, which are linear-lanceolate, very acute, serrate, prickly, oncnerved, spreading, five or six alternately shorter by half than the others, the twelfth often wanting. Corolla: compound, radiated; corollets hermaphrodite, numerous, shorter than the calix, barren in a deltoid disk, fertile in the outer triangles of the receptacle; females eleven or twelve in the ray, each opposite to one of the calicine leaflets, and double the length of the calix; proper in both hermaphrodites funnel-shaped, half five cleft; border five-parted, linear, acute, patulous, revolute, brown at the tip; female ligulate, four or three-toothed, three-furrowed, tubular at the base, spreading. Stamina : in both hermaphrodites. Filamenta : five, capillary, very short, inserted into the tube; antheræ cylindric, tubular, five-toothed, brown at the tip, the length of the corollet: in the females the rudiment of one stamen inserted at the top of the tube. Pistil: in the perfect hermaphrodites germen inferior, immersed in the receptacle, oblong, compressed, crowned with a thin short pappus or down, like the eye-lashes; style slender, finally standing out; stigma two parted, subulate, revolute; in the barren hermaphrodites germen roundish, very small, immersed; in other respects as in the fortile; females scarcely any rudiment of a germen. Recentacle: deltoid, flat, honey-combed, with labyrinthed membranes, distinct, and finally resolvable into four petals, deltas, or triangles; the central naked, barren; the side ones producing seeds, roughened with stiff brown bristles, becoming hard, and in separating from each other forming a pericarp ; nuts three, bony, three-cornered, flatted, stiff, bristly, from the outer triangles of the receptacle gaped and hardened, each retaining an outer leaf and the opposite inner calicine leaflets, or one-third part of the calix, and many-celled. Seeds: small kernels, as many as there were germina, but some abortive, oblong; down simple, thin, short, stiffer than in the flower. ESSENTIAL CHARACTER. tops is a pleasant and efficacious medicine for the gravel: it Calix: expanding, outer leafy. Receptacle: honey-combed, 5 Z

453

dividing into many parts which retain the seeds. Down: chaffy, many-leaved. These plants may be propagated both from seeds and cuttings, must have the protection of a drystove or a glass-case, and may be managed like other Cape plants.—The species are,

DIG

1. Didelta Carnoar, Succutent-leaved Didelta. Leaves alternate, lanceolate-oblog, fleshy, seed-leaves two, clasping, obovate, fleshy, seed-leaves two, clasping, obovate, fleshy, senoth; stem herbaceous, very much branched, erect, round, eighteen inches in herbacebas, very much branched, erect, round, eighteen inches in herbacebas, spreading, acute, attenuated at the base, quite entire, revolute, wooly above, beneath non-nerved, amooth, veinles, two or three inches long, six or eight lines broad, in the stove permanent; flowers solitary, terminating, on long peduncles, searcely nodding, yellow. It is an annual, but, fike some other annuals, will last several years in the stove, and become somewhat shrubby—It flowers in July, and is a native of the Cape of Good Hope.

2. Didelta Spinosa; Opposite-leared Didelta. Leaves opposite, somewhat stem-clasping, ovate. This plant is very smooth; the leaves are broad, and the outer calix is ive-leaved. —It flowers in June and July, and is a native of the Cape of Good Hone.

Didymodon, one of Hedwig's genera of mosses. Dier's-broom, or Dier's-weed. See Genista. Dier's-weed. See Reseda.

Digitalis; a genus of the class Didynamia, order Angiospermin .- GENERIC CHARACTER. Culix: perianth five-parted; divisions roundish, sharp, permanent; the superior longer than the rest. Corolla: one-petalled, bellform; tube large, expanding, bellied downward; cylindric, and close at the base; border small, four-cleft; upper division more expanding, emarginate, inferior division larger. Stamina : filamenta four, subulate, inserted into the base of the corolla, bent downwards, of which two are longer; antheræ two-parted, acuminate on one side. Pistil: germen acuminate; style simple, in the situation of the stamina; stigma sharp. Pericarp : capsule ovate, length of the calix, acuminate, two-celled, two-valved, valves bursting in two directions; according to Gærtner, partition double from the inflex edges of the valves. Seeds: very many, small; Gærtner says, subprismatic. ESSENTIAL CHARACTER. Calix: fiveparted. Corolla: bell-form, five-cleft, bellying. Capsule: ovate, two-celled. The species are,

1. Digitalis Purpurea; Purple Foxglove. Calicine leaflets ovate, acute; corollas obtuse, upper lip entire, according to Withering very slightly notched; root biennial; stem three to six feet high, simple, upright, leafy, round, pubescent ; leaves alternate, ovate, acute, serrate, veiny, wrinkled underneath, whitish with pubescence, gradually lessening to both ends ; petioles short, winged ; flowers on a long spike, nodding, imbricate, all directed the same way; peduncles one flowered, pubescent, thickest at top; calix also pubescent; corolla purple; the bellying part sprinkled in the inside with spots like little eyes, or elegantly mottled; upper segment entire and truncate; lower bent in, obtusely lobed above, and four-cleft, the lower segment somewhat longer; filamenta a little broader at top, crooked at bottom; antheræ at first large, turgid, ovate, cloven almost to the base, yellowish, and often spotted, afterwards changing both their form and situation in a singular manner; germen rather conical, very hairy; stigma bifid; nectary a gland surrounding the base of the germina; the lowermost valve of the capsule splits in two; seeds dark-brown, truncate at both ends. The corolla is generally of a fine purple; but it varies

into different shades of that colour, and is frequently white or cream-coloured. Some, says Parkinson, thinking foxglove to be a foolish name, do call them finger-flowers. because they resemble the fingers of a glove with the ends cut off .- It flowers from June to August, and is a native of Denmark, Germany, Switzerland, and Britain. It is found in sandy and gravelly soils, and grows plentifully about Charlton-wood, and Norwood, near London. The digitalis purpurea, or common purple foxglove, has long been considered as a plant possessed of very powerful virtues. A drachm of the powdered leaves, taken inwardly, excites violent vomitings, It is certainly a very active medicine, and merits more attention than is at present bestowed upon it : and it is singular that a plant, so powerful in its operations, should not sooner have been introduced into the modern materia medica. The country people in Somersetshire are said to have been long in the habit of using it, in decoction, for fevers, to purge and vomit, which it often brings on in too violent a degree. The Italians call this plant aralda, and have a proverb concerning it, aralda tutte piaghe salda. fox-glove cures all sores. Parkinson declares it to be effectual in the falling-sickness, if two handfuls of it be boiled in ale with four ounces of polypody of the oak, and the decoction drank by the patient; and that they who had laboured under that disease twenty-six years, falling down twice or thrice every month, were perfectly restored by the use of this decoction, and did not fall into a fit for the space of fourteen or fifteen months after. The dried leaves applied, or the juice made into an ointment, has been highly commended in ulcers, king's evil, &c. as well as the bruised flowers made into an ointment with fresh or May butter. The diuretic effects of foxglove, for which it is now so deservedly celebrated, and on which account, as well as for its other powers. it is so much used in dropsical cases, seem to have been first ascertained by Dr. Withering ; yet he observes that it seldom succeeds in nien of great natural strength, tense fibre, warm skin, and florid complexion, or in a tight cordy pulse. If the belly in ascites be tense, hard, and circumscribed, or the limbs in anasarca be solid and resisting, we have but little hope. On the contrary, if the pulse be feeble or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcous limbs readily pitting under pressure of the finger, we may expect the diuretic effects to follow in a kindly manner. In hydrothorax, or water in the chest, striking proofs are said to have been afforded of the efficacy of foxglove. The dose of the dried leaves in powder is from one to three grains a day; but if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. It is to be continued in these doses, till it either acts upon the kidneys, the stomach, the pulse, or the bowels. If the seeds of this plant be permitted to scatter, the young plants will come up in the spring, and require only to be weeded out where they are too numerous. The seeds of this, and of the other sorts, should be sown in autumn; for those which are sown in the spring seldom succeed, or at least lie a year in the ground before they grow.

2. Digitalis Minor. Calicine leaflets ovate, acute; corollas obtuse; upper lip entire, according to Withering very slightly notched; stem shorter by half than that of the first species; peducels villose; flowers very like those of the first species in form, size, and colour, but the dots of the palate are more copious and without the pale iris; the upper lip is more deeply two-lobed, the lower very obtuse, and the lateral segments reflex.—Native of Spain; perennial.

455

3. Digitalis Thapsi; Spanish Forglove. Leaves decurrent, tomentose, viened, serrate; the lower lanceolate-orate, the upper broad-hanceolate, all decurrent, and having the decurrent sides reflex; the bunch or spike of flowers the same as in the first species; the corolla purple, with a pale throat, over which are sprinkled blood-red dots; border four-cleft; the upper lobe undivided, the lower longer and clinte. Perennial; flowering from June to August, and a native of Spain.

4. Digitalis Lattes; Small Yellow Forglow. Calicine leaftes incredate; corollas eaute; upper lip blid. It has very long obtuse leaves near the root; the stalk is small, and rises from two to three feet bigh. It is distinct from the next species, in laiving the leaves smooth, harder, and narrower; the flowers small, thicker in the spike, pale, not spotted; the segments of the calis and corolla acute; triangular; the spike nods at top from the beginning. Ferennial; flowering in July and Augus.—Native of France, of the government of Aigle, and about Geneva in Switzerland, Silesia, Carniola, and about Saleron and Naples.

5. Digitalis Ambigua; Greater Yellow Forglow. Calicine Enfets lanceolate; helmet of the corolla emarginate; leaves pubescent underneath; the upper part of the stalk is adorned with large yellow flowers, nearly of the same size with those of the first sort, the brim having acute points, and the upper lip heing entire; the stem is two fet high, and pubescent. It flowers in July and August.—Native of Germany, Switzerland, Geneva, Austria, and Piedmont.

6. Digitalis Ferruginea; Iron-colourd Fozglove. Calicine laftes ovate, obiuse, spreading; lower lip of the corolla bearded; stem strict, even, six feet high; leaves sessile, lancolate, even, marked with lines, quite entire; flowers in an upright raceme from each of the upper raxils; bratets linear, lanceolate, reflex; pedicels very short, solitary; the tbree upper leaves of the calix approximating; corolla a little longer than the calix, pubescent, yellowish within; the two upper divisions obscure, the side ones sharp, the lowest longer; stamina flexuose, without any rudiment of a fifth; siyle the length of the flower, which expands in Jance, and has the colour of rusty iron.—Native of Italy, and found about Constantinople.

7. Digitalis Obscura; Willow-leared Forglove. Leaves inear-lanceolate, quite entire, growing together at the base; stem undershrubby, with a few opposite branches; flowers on terminating racemes; bractes hanceolate; calicine leaflets ovate, acutish, patulous; corollas draoping, obtuse, yellowish within, reticulated, and rufowas at the bottom; pale rufous on the outside, especially at the back; upper lip half cloven and recurved, lower three-parted, the middle part a little longer than the others.—It flowers in July and August, and is a native of Spain.

8. Digitalis Canariensis; Canary Starubby Forglore, Calicine leafdest lanceolate; corollas two-linped, acute; stem shrubby, rising sometimes four, and even five or six feet high, dividing into several branches; leaves lanceolate, rough, nearly free inches long, and two broad in the middle, gradually decreasing to both ends, having a few short serratures on their edges, placed alternately on the branches, each of which is terminated by a loose spike of flowers, nearly a foot in length; they are of an orange colour, internixed with yellow, and are shaped somewhat like the flowers of a canthus, — Native of the Canary Islands. It begins to flower in May, and there is generally a succession of flowers on the same plant, till the writer puts a stop to them, which renders the plant more valuable. It is propagated by seeds, which isolud be sown in pots filled with light earth, in the automn,

soon after the seeds are ripe. Those nots ought to be plunged into an old bed of tanner's bark, the heat of which is exhausted, and in mild weather the glasses ought to be drawn off to admit the air ; but in hard rains and frosts they must be kept on, to protect the seeds from both, which frequently destroy them when exposed in our climate. The plants will come up in the spring, and should enjoy the free air in mild weather, but must be protected from the cold. When these are large enough to transplant, they should be each planted into a separate small pot filled with light earth. and placed under the frame till they have taken new root, and ought then to be gradually inured to the open air. They must have a sheltered situation during the summer, but in the winter must be placed in a green-house, for they will not live abroad in England. They must not be kept too warm and close in the house, for they only want protection from the frost, and in mild weather require abundance of free air and frequent waterings.

9. Digitalis Scepirum; Madeira Skrubby Forglow: Calicine leaffets subulate; bractes linear, longer than the flowers; corollas obtuse; leaves elliptic, serrate; stem shrubby. This is a very handsome plant, the branches of which are rough with hairs; peduacle terminating the branch, solitary, round, upright, a hand or more in length, porous on the inside, ending in an ovate spike with the flowers hanging down. It flowers in July and August,— Native of Madeira. For the propagation and culture of this plant, see the preceding species.

10. Digitalis Orientalis. Calicine leaflets acute; leaves oval-lanccolate, nerved; root-leaves many, smooth; among these arises the stalk ahout a foot high; the leaves on it are smooth, from four to five inches long, and one inch and a half broad in the middle, half stem-clasping; spike of flowers terminating, short, loose; corollas yellow, almost as large as those of the fifth species, but shorter. It flowers in May, and the seeds ripen in autume.—Native of Tartary.

11. Digitalis Cochin-chinensis. Leaves lanceolate, rough; flowers solitary, axillary; calices acute; corollas obtuse, emarginate at top; stem herbaceous, a foot and half high, almost upright; capsule ovate, acute, two-celled.—Native of Cochin-china.

12. Digitalis Sinensis. Leaves ovate, hairy on both sides; flowers solitary, axillary; segments of the calix awl-shaped; corollas obtuse, entire at top; stem cespitose, erect, a foot and half high; stigma screw-shaped.—Native of China.

Dilatris; a genus of the class Triandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla: six-petalled, superior ; petals ovate-lanceolate, concave, from erect spreading, equal, hirsute on the outside, permanent, Stamina : filamenta three, subulate, shorter than the corolla, the third less than the other two. Antheræ ovate-lanceolate, two-furrowed, that on the smaller filamenta larger. Pistil; germen inferior; style filiform; stigma simple, obtuse, Pericarp : capsule globular, extremely hirsute, three-celled, three-valved. Seeds : solitary, orbicular, compressed, smooth, perpendicular. ESSENTIAL CHARACTER. Calix: noue, Corolla: six-petalled, hirsute; filamenta one less than the others; stigma simple .- For the propagation and culture of this genus of plants, see Wachendorfia .---- The species are.

 Dilatris Umbellata. Petals ovate; corymb fastigiate, hirsute. The whole plant hoary and very villose, except the inside of the flower; root fibrous; root-leaves like those of cyperus, even, stirict, erect, one or two only on the stem, lanceolate, short.—Native of the Cape of Good Hope.

2. Dilatris Viscosa. Petals linear; corymbs fastigiate,

villose, viscid. This species has never been described .-- Na- | CHARACTER. Calix: perianth one-leafed, rounded at the tive of the Cape of Good Hope.

DIM

3. Dilatris Paniculata. Petals lanceolate : panicle oblong. villose, viscid; flowers of a yellowish purple colour .-- Native of the Cape of Good Hope.

Dill. See Anethum.

Dillenia : a genus of the class Polyandria, order Polyginia. -GENERIC CHARACTER. Calix: perianth five-leaved ; leaflets obovate, obtuse, concave, leathery, smooth within, villose without, permanent. Corolla: petals five, obovate. narrowed at bottom, very blunt, very finely subcrenate, somewhat concave, longer than the calix, deciduous. Stamina : filamenta scarcely any. Antheræ numerous, inserted into the base of the germen, linear, orange with a black line, shorter than the calix. Pistil: germen superior, ovate: styles several, erect, simple, longer than the antheræ; stigmas simple. Pericarn : roundish, outwardly coated with as many oblong capsules, which are longitudinal, and divided by a furrow, inwardly by a columnar, very large, pulpy receptacle, Seeds : numerous, very small, nestling under the capsules. ESSENTIAL CHARACTER. Calix : five-leaved ; petals five ; capsules many seeded, connate, filled with pulp .- This genus consists of beautiful trees, which are natives of the East Indies; their leaves are large, and of a leathery substance; their flowers axillary or terminating, sometimes very large, -The species are.

Leaves obovate, obtuse, almost 1. Dillenia Integra. entire; peduncles one-flowered; branches alternate, wrinkled, dusky, smooth; flowers terminating on the extreme branchlcts, subsolitary, peduncled .- Native of the islands of Cey-Ion, where the inhabitants use a decoction of the leaves for cleansing foul ulcers, and have named the tree gudapara and runumidale.

2. Dillenia Speciosa. Leaves oblong, rounded, acute, toothletted; peduncles one-flowered. This is a lofty tree, with thick, wrinkled, ash-coloured, smooth branches; petioles thick, scarcely an inch in length; flowers on the branchlets terminating .--- Native of Java and Malabar.

3. Dillenia Elliptica. Leaves elliptic, ovate, acute, serrate; peduncles one-flowered ; flowers terminating .- Native of Amboyna, Celebes, and Macassar.

4. Dillenia Retusa. Leaves obovate, truncate, serrate; peduncles one-flowered; branches alternate, wrinkled, dusky, smooth ; petioles semi-cylindric, channelled, hirsute at the cies are, base, scarcely an inch long; flowers terminating .- Native of the woods of Ceylon.

5. Dillenia Serrata. Leaves elliptic, ovate, acute, serrate ; peduncles three-flowered, pedicelled .-- Native of Celebes, Macassar, and Java.

6. Dillenia Dentata, Leaves ovate, retuse, toothed ; peduncles three-flowered; branches alternate, wrinkled, ashcoloured, smooth; petioles augular, smooth, a little shorter than the leaf; pedicels alternate, smooth, half an inch long. According to Vahl, the peduncles are frequently from four to eight-flowered, branching at the base .-- Native of Ceylon, where the natives call it *diapara*. 7. Dillenia Pentagynia. Leaves ovate-lanceolate, serrate,

sharp; flowers pentagynous. It is a large tree, with numerous ascending branches; peduncles collected in bundles, from tuberosities over the naked wood of the two or three years old branchlets, erect, round, smooth, two inches long, undivided, one-flowered; flowers middle-sized, yellow; petals oblong; pericarp pendulous, size of a small nutmeg; seeds reniform .--- It flowers in March and April, and is a native of the mountainous parts of Coromandel.

base, dceply three or four-cleft, obtuse. Corolla : petal very wide, ventricose, convolute at the sides, crenulate, inserted into the calix below the stamina, placed at the lower side, Stamina : filamenta diadelphous, (single at the opening of the petal, and nine-cleft, incumbent on the middle of the petal,) ascending, longer than the corolla. Antheræ parallelopiped, incumbent. Pistil : germen pedicelled, compressed, short ; style longer than the stamina; stigma simple. Pericarp; legume large, oblique, compressed, oue-celled. Seed : single, or few. ESSENTIAL CHARACTER. Petal : one, large, convolute, in place of the keel; standard and wings none. -The species are.

1. Dimorpha Falcata. Leaves piunate; pods falciform. A tall tree, upwards of sixty feet high, very much branched at top, and branches much scattered; flowers numerous, spiked : spikes alternate, extremely long, pendulous, axillary, aud terminal.-Native of the woods of Guiana, where it flowers in September.

2. Dimorpha Grandiflora, Flowers larger than in the other species. A large tree, with a trunk more than two feet in diameter : the wood is reddish, solid, and compact, and is used for various important purposes : it flowers in September. -Native of Guiana.

3. Dimorpha Tomentosa. Legume tomentose. A tree upwards of twenty feet high, very much branched at top, and branches much scattered; flowers scattered, terminal, axillary, appearing in September .- It grows on the banks of the rivers in Guiana.

Diodia ; a genus of the class Tetrandria .-- GENERIC CHARACTER. Calix: perianth two-leaved, according to Gærtner two or four-leaved; leaflets subovate, superior. equal, permanent. Corolla: one-petalled, funnel-form; tube slender, long; border small, spreading, four-parted; divisions lanceolate. Stamina: filamenta four, bristle-shaped, upright. Antheræ versatile. Pistil: germen roundish, four-sided, inferior; style filiform, length of the stamina; stigma twocleft. Pericarp: capsule ovate, four-cornered, crowned, larger than the calix, two-celled, two-valved; according to Gærtner, valveless, bipartile, eight-furrowed. Seed : solitary, ovate-oblong, even, convex on one side, flat on the other, shining. ESSENTIAL CHARACTER. Corolla: one-petalled, funnel-form. Capsule: two-celled, two-seeded, ---- The spe-

1. Diodia Virginica. Stem branching, procumbent, smooth and even; leaves opposite; flowers white; the calix in some is two-leaved only, in others unequally four-leaved, that is, with two very minute leaves placed in the interstices of the larger, and this even seems to be the more natural number. -Native of Virginia.

2. Diodia Simplex. Stem herbaceous, simple, almost erect, smooth and even; leaves ovate-lanceolate .- Native of the island of Jamaica.

3. Diodia Prostrata. Stem suffruticose, subdivided : branches prostrate, filiform; leaves linear, somewhat hirsute, revolute .- Native of Jamaica.

4. Diodia Scandens. Stem scandent, suffruticose; leaves ovate-lanceolate, rigid, rugged .- Native of Hispaniola,

5. Diodia Sarmentosa. Stem flaccid, shrubby; branches opposite, spreading; leaves oblong, acute, somewhat rugged. -Native of Jamaica.

6. Diodia Verticillata. Smooth : leaves lanceolate, in whorls, rugged at the edge; stem herbaceous, erect, simple, a foot high, smooth like the whole plant, and even; flowers several together, in whorls, inclosed by the stipule, the ter-Dimorpha; a genus of the class Diadelphia,-GENERIC minating whorl larger than the others; capsule two-celled,

DIO

linear, somewhat compressed, ciliate on both sides at top, crowned with two teeth .- Native of the island of Santa Cruz.

Dionæa ; a genus of the class Decandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth five-leaved, upright : leaflets oblong, acute, permanent. Corolla: petals five, sessile, oblong, obtuse, concave. Stamina: filamenta ten, subulate, shorter. Antheræ roundish ; pollen tricoccous. Pistil; germen roundish, depressed, crenate; style filiform, shorter than the filamenta; stigma spreading, fringed on the edge. Pericarp : capsule one-celled, gibbous; seeds very many, subovate, very small, affixed to the base of the capsule. Observe. The number of stamina is not always constant, ESSENTIAL CHARACTER, Calix: five-leaved; petals five. Capsule: one-celled, gibbous, containing many seeds .---- The only known species is,

1. Dionaea Muscipula; Venus's Fly Trap. This is a very singular plant: root squamous, sending forth but few fibres, like those of some bulbs, and perennial; stalk about six inches high, round, smooth, without leaves, ending in a spike of flowers, many inclining to bend downwards, and placed in a circular order, jointed, succulent, the lower joint, which is a kind of stalk, is flat, longish, two-edged, and inclining to heart-shaped; in some varieties they are serrate on the edges near the top; the upper joint consists of two lobes, each semioval, the margins furnished with stiff hairs, like the eyelashes, embracing or looking into each other when they are close, this they do when they are irritated within ; the upper surface of these lobes is covered with small red glands, appearing, when highly magnified, like the compressed fruit of the arbutus; among the glands, about the middle of each lobe, are three very small erect spines: when the lobes enclose any substance, they never open again while it continues there; if it can be extracted so as not to strain the lobes, they expand again, but if force be used to open them. so strong has nature formed the springs of their fibres, that one of the lohes generally snaps off rather than yield; the flowers are milk-white, on peduncles, with a little pointed bracte at the bottom of each. What Mr. Ellis calls the lower joint of the leaf, Linnens looks upon as the petiole winged in the same manner as in the orange; the stem is a scape; the flowers grow in a corymb, resembling an umbel; the petals are marked with seven streaks, and bend at the end. Linneus asserts, that when the entrapped insect ceases to struggle, and is quiet, the leaf opens and permits it to escape; which disagrees with Ellis's account, for the latter affirms, that the lobes never open again, so long as the animal continues there. He thinks it probable that a sweet liquor discharged by the red glands, tempts the insect to its destruction; and adds, that if a straw or pin be introduced between the lobes, they will grasp it as fast as if it were an insect .- It is a native of the swamps of North Carolina, near the confines of South Carolina, where the winters are short, and the summers very hot: it flowers in July and August, Being a swampy plant, a north-east aspect will be the most proper to plant it in, to avoid the direct rays of the meridian sun; and in winter it will be necessary to shade it with a bell-glass, which should be covered with straw or mat in hard frosts. Its sensitive quality will be in proportion to the heat of the weather, as well as the vigour of the plant. It may also be planted in pots of light moorish carth, for in such the plants are imported, and should be placed in pans of water in an airy stove, where the heat of such a situation, being like that of its native country, will make it surprisingly active, but the heat of our summers is not sufficient to ripen the seed. 30

Dioscorea; a genus of the class Diæcia, order Hexandria. -GENERIC CHARACTER. Male, Calix : perianth oneleafed, bell-form, six-parted; divisions lanceolate, spreading at top. Corolla ; none, unless the calix be so termed. Stamina : filamenta six, capillary, very short. Antheræ simple, Female, Calix; perianth as in the male, Corolla; none, Pistil: germen very small, three-sided; styles three, simple; stigmas simple. Pericarp: capsule large, triangular, threecelled, three-valved. Seeds : in pairs, compressed, girt with a large membranaceous border. ESSENTIAL CHARACTER. Male. Calix : six-parted. Corolla : none. Female. Calix : six-parted. Corolla : none. Styles : three, Capsule: threecelled, compressed. Seeds: two, membranaceous .- These plants may be propagated by laying their branches into the ground, where in about three months they will put ont roots, and may then be taken from the old plants and put into separate pots, which should be plunged into the tan-bed in the stove; during winter they should have a little water, but in summer, when they are growing vigorously, they should be watered three or four times a week, and have their glasses open, to admit a large portion of free air in warm weather. When seeds are received, they should be immediately sown in pots, and plunged into a hot-bed, where, if it be early in the spring, the plants will come up in the same season; but when they are sown late, the seeds often remain in the ground till the following season before they vegetate, in which case the pots must be screened from frost during the winter, and put into a new hot-bed in the spring. They may also be increased by cutting the roots in pieces, as is practised for potatoes, putting each piece in a pot filled with fresh earth, and plunged into the bark-pit, giving them little water until they shoot, lest they should rot; the roots do not grow to any great size in our climate, and the plants having little beauty, seldom flowering, and requiring much care and room. are seldom allowed a place in our stores, except in very curious collections .---- The species are,

1. Dioscorea Pentaphylla. Leaves digitate; root very large and thick; stalks spiny, slender; flowers first yellow, then turning blackish.-Native of the East Indies, and the Society Isles,

2. Dioscorea Triphylla. Leaves ternate, above dusky green, beneath smooth and shining, with whitish prominent nerves, on long petioles; stalks round, slender, smooth, spiny; seeds in pairs, semiclliptic, about an inch long, of a cinnamon colour .- Native of Malabar.

3. Dioscorea Trifida. Leaves cordate, trifid ; stem winged, bearing tubers .- Native of Surinam.

4. Dioscorea Aculeata. Leaves cordate; stem prickly, bulb-bearing, suffruticose, turning round, slender, very much branched, with many straight, short, scattered prickles; flowers in long, spiked, lateral racemes; the calix has from three to six acute, very short, nnequal, spreading leaflets ; the corolla exhibits six ovate concave petals, almost closed, and of a dusky purple colour; filamenta awl-shaped, equal to the corolla, with roundish antheræ; germen inferior .--- Native of Malabar and Cochin-china.

5. Dioscorea Alata ; Wing-stalked Dioscorea. Leaves cordate ; stem winged, bulb-bearing ; root a foot or more long, as big as a man's leg or thigh, brown on the outside, within white, or reddish purple, viscid, but when boiled very mealy; stalk the size of a goose-quill, square, with a thin reddish membrane at each corner, winding itself round poles nine or ten feet high, and putting out leaves at every three inches' distance, opposite, on square winged footstalks, two inches long; peduncles axillary, an inch or more in length, with small flowers of a yellowish green colour .- Native of both 6 A

457

and seventh species.

DIO

6. Dioscorea Bulbifera. Leaves cordate : stem even, bulbbearing, somewhat slender .- Native of both Indies, and of the islands in the South Seas.

7. Dioscorea Sativa. Leaves cordate, alternate; stem even, round. It has slender stalks, climbing to the height of eighteen or twenty feet, winged, but not round. There is much confusion in the synonyms of this plant, which is a native of the East and West Indies, and of Japan. The yam is largely cultivated for food in Africa, and in both Indies, especially by the negroes of the West Indies: the roots grow to a great size, are mealy, and esteemed to be easy of digestion, they are palatable, and not inferior to any roots now in use, either for delicacy of flavour, or nutritive qualities : they are eaten instead of bread, either roasted on the embers or boiled, and the flour of them is also made into bread and puddings. In Otaheite they make a dish which the natives esteem very delicious, from the roots of the yam, with the kernel of the cocoa nut scraped, and the pulp of the banana. There are many varieties of the roots, some spreading out like the fingers, others twisted like a serpent, others again very small, scarcely weighing more than a pound, with a whitish ash-coloured bark, whereas the bark is commonly black; the flesh of the raw vam is white or purplish, aud viscid, but becomes farinaceous, or mealy, when dressed, The above-named varieties were found in Otaheite .- The vam is a native of Florida and Maryland. Brown affirms, that the roots of the yams must be cut so as to have a little of the skin to each piece, for by that alone they germinate ; the roots having no apparent buds or eyes, but casting out their weakly stems from every part of the surface alike : two or three plants are put into each hole, which holes are dug pretty regular, a foot and a half or two feet square : these are afterwards filled from the adjoining banks, and the whole piece is covered with cane trash, which serves to keep the ground cool and fresh, and to prevent the growth of weeds, from which they must be carefully preserved, until they grow sufficiently to cover the mould. They are planted commonly in August, and are ripe about November and December following ; care should be taken to wound the roots as little as possible in digging them up, for such as are cut throw out their sprouts very early, and are therefore seldom fit for any thing but planting. They should be rubbed over with ashes, and piled regularly on beds or hurdles raised above the floor, that the air may come easily between them ; or if they be piled in heaps, some ashes should be strewed between the layers.

8. Dioscorea Villosa; Hairy Dioscorea. Leaves cordate, alternate, and opposite; stem even. The flowers come out on long loose strings on short pedicels .- Native of Florida, and Maryland.

9. Dioscorea Oppositifolia. Leaves opposite, ovate, acuminate; stem round, woody, twining, unarmed; racemes of male flowers axillary, opposite, solitary, subvillose, composed of three cylindric aments; the flowers are almost sessile .--Native of the East Indies, Japau, and Cochin-china, where the roots are preferred to all others.

10. Dioscorea Septemloba. Leaves cordate, seven-lobed, seven-nerved. The whole of this plant is smooth; stem round, climbing; flowers axillary, in racemes, very small; capsule ovate, triangular, with the corners winged, emarginate, with the style permanent .- Native of Japan.

11. Dioscorea Quinqueloba. Leaves cordate, five-lobed, nine-nerved; stem filiform, twining, very long, with the rest of the plant smooth; petioles swelling at top and bottom,

Indies, where it is cultivated for food, as well as the sixth | reflex, a finger's length; racemes axillary, two or three, loose, near a span in length; flowers on patulous pedicels, a line in length, three or four together; bractes ovate, acute; calix saffron-coloured ; germen inferior, smooth .- Native of Japan.

12. Dioscorea Japonica. Leaves cordate, acuminate, ninenerved. The whole plant is smooth ; stem filiform, angular, twining, branched; branches scattered, few, resembling the stem : petiole somewhat angular, reflex, spreading, nearly the length of the leaf; spikes axillary, one or two together. spreading, longer than the leaves; the rachis regular. The root of this species is cut into slices, boiled, and eaten, in Japan, where it is a native.

13. Dioscorea Hastata. Leaves hastate; stem even: racemes very long. This differs from the seventh species in the shape of its leaves, which have two round ears at their base, but the middle extends to an acute point, like that of an halbert; the bunches of flowers are also longer and looser than those of the seventh species.

14. Dioscorea Eburina. Leaves heart-shaped, seven-nerved, alternate : flowers hermaphrodite, in simple long racemes. stem shrubby, unarmed, long, twining; the branches and petioles four-cornered; calix three-leaved, with ovate erect leaflets; corolla three-petalled, ovate, fleshy, yellow, concave, nearly equal to the calix; filamenta hardly any; antherae roundish, two-celled, very small; germen inferior, oblong, three-sided, without any style, but three oblong reflex stigmas : capsule oblong, oval, the angles entering deep ; seeds ovate, few; root vertical, consisting of one or two tubers, three feet long, round, regular, sharpish, curved a little, in shape and whiteness resembling elephants' teeth, whence the vernacular name khoai ngu, and the trivial, eburina .- Native of Cochin-china.

15. Dioscorea Cirrhosa. Leaves ovate-lanceolate, threenerved; flowers hermaphrodite, three-stamined; stem cirrhose : stem shrubby, long, slender, climbing ; flowers very small, axillary, on three-flowered peduncles ; calix six-leaved. superior; leaflets ovate, thick, curved, almost closed, permanent, in a double row, of which the inner is smaller; corolla and filamenta none .- Native of Cochin-china.

Diosma : a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth five-leaved; leaflets ovate, acute, permanent. Corolla: petals five, ovate, obtuse, sessile, erect, spreading; nectaries five, placed on the germen. Stamina : filamenta five, subulate. Antheræ subovate, erect. Pistil: germen crowned with the nectary; style simple, the length of the stamina ; stigma obscure, Pericarp: capsules five, ovate-acuminate, compressed, conjoined inwardly at the margin, distant at the tips, gaping at the upper suture. Seeds : solitary, oblong, ovate, depressed, acuminate at the point; an elastic aril, gaping on one side, involving each seed. ESSENTIAL CHARACTER. Corolla: five-petalled. Nectary : five on the germen ; capsule three or five, conjoined. Seeds: veiled .-- All these plants are propagated by cuttings, which may be planted during any of the summer months, in pots filled with light fresh earth, and plunged into a very moderate hot-bed, where they should be shaded in the day time from the sun, and frequently refreshed with water. In about two months the cuttings will have taken root, when they should be each transplanted into a small pot, and placed in a shady situation, until the plants have taken fresh root, when they may be placed in a sheltered situation with other plants: they may remain abroad until the beginning of October, or later, if the season continue favourable; for they only require to be sheltered from frost, so that in a very dry airy green-house they may be preserved very well in winter, and in summer they may be

exposed to the open air with other green-house plants.----The species are,

1. Dissma Oppositibilia: Opposite-leaved Dissma. Leaves sublate, acute, opposite. It rises to the height of three feet; the branches are very long and slender, and are very irregularly produced from the stem; the leaves are placed crosswise, in pairs, and are pointed; every evening they close up to the branches; It le flowers are produced along the branches from between the leaves, and in the evening, when they are expanded, and the leaves closely embrace the branches, the whole plant appears as if covered with spikes of white flowers; and as it continues along time in flower, it makes a fine appearance when intermixed with other exotics in the onen air.—Native of the Cane of Good Hope.

¹2. Disama Hirsuta; Hairy-kaned Disama. Leaves linear, birsute. This sort makes a very handsome shrub, growing to the height of five or six feet; stalks woody, sending out many sender branches; the leaves come out alternately on every side; flowers in small clusters at the ends of the shoots, they are white, and are succeeded by starry seed-vessels, luaving five corners, like those of the starry anise; each of these corners is a shell, containing on esmoth, shhuing, oblong, black seed; these seed-vessels abound with a resin which affords agrateful scent, which is common to the whole plant. This species frequently ripens its seeds in England; but if the each sare not sown soon affer they are ripe, they rarely grow, or at least lie a whole year in the ground.—Native of the Cape of Good Hope.

3. Diosma Rubra; Red. Jouered Diosma. Leaves linear, mucroate, smooth, keeled, dotted in two rows beneath; this plant seldom exceeds three inches in height, and sprends out into many branches, with leaves resembling those of heath; flowers in clusters at the ends of the branches, like those of the second species, but smaller, and the bunches not so large. The leaves, when bruised, emit a strong balsamic odour.— Native of the Cape of Good Hope.

4. Dissma Ericoides; Sweet-scented Diosma. Leaves linear-lanceolate, convex beneath, imbricate in two rows. It is a low bushy shrub, which seldom rises above two feet high, but spreads out its branches far on every side; the leaves are narrow and smooth, of a light-green colour, and being ranged on each side the branches, appear fat on the upper and under side, and when bruised, emit a very strong penetrating odour; the flowers are produced singly from between the leaves; they are while, and tinged on their upper surface. It is a native of the Cape of Good Hope.

5. Diosma Capensis. Leaves linear, three-sided, dotted beneath, opposite; flowers white in a corymb. The barren stamina have almost the appearance of petals.—Native of the Cape of Good Hope.

6. Diosma Capitata. Leaves linear, imbricate, scabrous, ciliate; flowers in spiky heads; stem proliferous, two feet high, erect, brown, having the appearance of a large heath; flowers purple, sessile, and forming a head; cialki imbricate; leaflets (the inmost and true ones only five) ovate, pubescent at the edge; petals roundish, with the claws the length of the calix; nectaries very small, awnless.—Native of the Cape of Good Hope.

7. Diosma Unicapsularis. Leaves linear-lanceolate; capsubsconce-elled; branches wand-like, even; leaves alternate, subpetioled, linear-lanceolate, even above, longitudinally winkled underneath, smooth, quite entire at the edge, but as it were serrate with pellucid dots; peduncles lateral, fewflowered, much shorter than the leaves; flowers minute; capsules usually solitary, bent in, and having a beak of the sme length,-Naitve of the Cape of Good Hope. 8. Diosma Latifolia. Leaves ovate-create; peduncles axillary, solitary; sten villoe; branches somewhat pubes-cent; leaves petioled, creaulate above the edge with pellucid dots, every notch dotted on the disk, bluntish, searcely acute. —Native of the Cape of Good Hope.

9. Diosma Marginata. Leaves cordate-attenuated, membranous-edged, erect, with the branches scarcely pubescent; leaves remote; flowers from the upper axils of the leaves, solitary or in pairs; the peduncles longer than the leaf; staming five, real; nectaries five from alternate filamenta, having at the tip a black larger authering eland, bifd at the base, with a small yellow head.—Native of the Cape of Good Hope;

10. Diosma Barbigera. Leaves cordate, stem-clasping; petals bearded, branching; leaves sessile, opposite, mucronate, even, dotted underneatli; corymbs terminating, subsessile; calix five-cornered; petals small, and bearded with white.—Native of the Cape of Good Hope.

11. Diosma Tetragona. Leaves cordate, retuse, folded together and keeled, cilitate; branches one flowered. This species is singular, and is distinguished from the rest by the leaves being so closely together, that the whole stem is covered with them; by the branches being quadrangular and thicker toward the top; and by the large, solitary, and terminating flower.—Native of the Cape of Good Hope.

12. Diosma Cupressina. Leaves ovate, three-cornered, imbriate; fowers solitary, terminating, esselie; branches filiform, erect, alternate, covered with alternate minute leaves like those of heath, subscherbous, sessile, creet, terminating in a coloured callosity; calix membranaceous, lauceolate, erect; terminated gradually into the claws; stamina erect, the length of the calix.—Native of the Cape of Good Hope.

13. Diosma Imbricata; *Imbricated Diosma*. Leaves ovate, nucronate, imbricate, ciliate. The petals are purplish and roundish, with the claws three times the length of the calix.--Native of the Cape of Good Hope.

14. Diosma Lanceolata; Spear-shaped Diosma. Leaves elliptic, obtuse, smooth. They have a few hairs on both sides.--Native of the Cape of Good Hope.

15. Diosma Ciliata; *Ciliated Diosma*. Leaves lanceolate, ciliate, wrinkled; petals oblong, with the claws scarcely longer than the calix.—Native of the Cape of Good Hope.

16. Diosma Crenata; Crenated Diosma. Leaves lanceolate-oval, opposite, glandular-crenate; flowers solitary; leaves of the calix subulate and crenate.—Native of the Cape of Good Hope.

17. Diosma Uniflora; One-flowered Diosma. Leaves ovate, oblong; flowers solitary, terminating; leaflets of the calix ovate, large, and almost broader than the leaves.— Native of the Cape of Good Hope.

18. Diosma Puthella; Oral-leared Diosma. Leaves ovate, obtuse, glandular-create; folwers twin, axillary. The flowers are hermaphrodite, but the fruit is three-celled. The borns of the germen are earlier to the treminated by two glands. The Hottentots use the leaves of this species dried and powdered, under the name of buday, to mix with the grease with which they anoint themselves, which gives them so rank an dour, that the chevaler Thunberg declares be could not bear the smell of the men who drove his waggon. Native of the Cape of Good Hope.

10. Diosma Asiatica. Leaves lanceolate, alternate; racemes subterminating. It is a small tree, six feet high, spreading, and very nuch branched; leaves quite entire, smooth; flowers yellow, in compound racemes; anthere sessile, linear, at the side of the neetary, couverging at top;

seeds destitute of aril .- Native of Cochin-china.

Diospuros ; a genus of the class Polygamia, order Diœcia ; or, according to Thunberg, of the class Octandria, order Monogynia .-- GENERIC CHARACTER. Hermaphrodite. female, Calix : perianth one-leafed, four-cleft, large, obtuse, permanent, Corolla: one-petalled, pitcher-shaped, larger, four-cleft; divisions sharp, spreading. Stamina: filamenta eight, bristle-form, short, almost inserted into the receptacle; antheræ oblong, unproductive. *Pistil:* germen roundisk; style single, half fon-cleft, permanent, longer than the sta-mina; stigmas obtuse, two-cleft. *Pericarp:* berry globose, large, eight-celled, sitting on a very large spreading calix. Seeds : solitary, roundish, compressed, very hard. Male, in a distinct plant. Calix : perianth one-leafed, four-cleft, sharp, upright, small. Corolla: one-petalled, pitcher-shaped, leathery, four-cornered, four-cleft ; divisions roundish, rolled back, Stamina: filamenta eight, very short, inserted into the recep-tacle; antheræ double, long, sharp, the interior shorter. Pistil ; rudiment of a germen. ESSENTIAL CHARACTER. Hermaphrodite. Calix: four-cleft. Corolla: pitcher-shaped, four-eleft. Stamina : eight. Style : four-cleft ; berry eightseeded. Male. Calix, Corolla, and Stamina : of the other. All the species, except the first and second, are natives of the East Indies, and on that account require the protection of the bark-stove. They have never been cultivated in England .----- The species are,

1. Diospyros Lotus; European Date-plum. The two surfaces of the leaves of different colours. The smaller branches spread a little, and are yellowish; leaves ovallanceolate, large, quite entire, paler underneath, somewhat hoary, with the veins somewhat hairy ; flowers small, reddishwhite, rotate; fruit the size of a cherry, yellow when ripe, astringently sweet, sessile in the bosom of the leaves within the calix, which is increased, somewhat cartilaginons, flatted, usually five-cleft, scldom four-cleft. These berries are rccommended as a cure for the diarrhea. The broad-leaved variety grows up into very large trees in the southern parts of Caucasus. It is also abundant in the woods of Hyrcania. and along the whole coast of the Caspian sea. Gesner was informed that it grows upon the mountains in the neighbourhood of Verona; and Mr. Ray is pretty confident, that he saw it in his way from Lerici to Lucca, and not far from the latter place. It is also found in the woods on the hills about Turin, plentifully about Lyons, and upon the eastern coast of Africa, whence it is supposed to have been first imported into Europe. Gerarde says, that, in English, it is called bastard meuunwood, which name is now quite lost; and Parkinson calls it India date-plnm. This, and the second species, are both propagated by seeds, which will come up well in the open ground, but will appear much sooner if sown upon a moderate hot-bed, as well as make a greater progress; but in this case the seeds should be sown in pots or boxes of earth, and plunged into the hot bed, because the plants will not bear transplanting till autumn, when the leaves fall off; so that, when the plants are up, and have made some progress, they may be inured by degrees to the open air, and in June they may be wholly exposed, and may remain abroad until November, when it will be proper to set the pots under a hot-bed frame to protect them from hard frost, which might kill the tops while they are very young, but they must have as much free air as possible in mild weather. The following spring, before the plants begin to shoot, they should be transplanted into a nursery, in a warm situation, where they may be trained up for two years, and then removed to the places where they are designed to sessile .- Found by Thunberg, in Ceylon.

capsules somewhat kidney-form, each on its proper peduncle; | remain. They are both hardy enough to resist the severest winters of our climate, after they have acquired strength

2. Diospyros Virginiana; American Date-plum. The two surfaces of the leaves of the same colour. In England it rises to the height of fourteen or sixteen feet, but generally divides into many irregular trunks near the ground, so that it rarely forms a handsome tree. The branches are many, and grow slender to the end, covered with a thin greenish bark . leaves many, broad, green, without dent or notch on the edges, Our European lotus has a lighter-coloured bark, inclining to yellow on the branches, and yellow and shining on the twigs: the American has a dark-brown bark on the branches, and on the twigs it is gravish from pubescence, so that they are soft to the touch, whereas the others are smooth : fruit, in form, size, and firmness, like a date, and almost as sweet, with a great flat thick kernel within. It produces this fruit plentifully in England, but never brings it to perfection. Captain Smith, in the discovery of Virginia, says, if it be eaten while it is green, it draws the mouth awry by its harsh and binding taste, but is pleasant when ripe ; which, however, is not the case till it has been mellowed by the frost, being then very sweet and glutinous, with a little astringency ; and a considerable quantity may be eaten without inconvenience. The North Americans extract a spirit from it, and make a palatable liquor with it and malt. The time of ripening is from the end of September to December. The wood is very hard, but brittle, and rather white, and very suitable for joiners' tools, such as planes, handles to chisels, &c. but it soon rots if exposed to the weather. It spreads very much, and is not easy to extirpate; but, in the northern provinces of the American states, it is often killed by frosts in hard winters. In Virginia and Carolina it is called pishamin or persimon, and there is plenty of it in the woods, as well as in Pennsylvania, New Jersey, Philadelphia, &c. where it is generally found in wet places, round water pits. For its propagation and culture, see the first species.

3. Diospyros Kaki. Peduncles three-parted. A middlingsized tree, very branching; branches and twigs alternate, round, dotted, smooth, tomentose at the ends, spreading; leaves alternate, petioled, ovate, acuminate, quite entire, paler underneath, scarce apparently villose, netted-nerved, smooth above, an inch or more in breadth, from an inch to three inches in length, spreading; petioles semicylindric, subtomentose, half an inch long; flowers axillary; peduncles tomentose, half an inch in length ; pedicels one-flowered, like the peduncles; fruit a subglobose pome, obscurely fourcornered, smooth, when unripe green, when ripe yellow, truncate at the base, where the calix remains, obtuse, with the stigma also permanent, eight-valved, eight-celled, the size of a middling apple, having nearly the taste of a sweet white plum, fleshy; seeds half-mooned, compressed at one edge, smooth, some of the cells are occasionally barren. The fruit eaten plentifully occasions a diarrhœa in the autumnal months. It is preserved in the same manner as the fig, by sprinkling meal or sugar over it. There is a variety of this species, in which the leaves are oblong-ovate, acute, nerved, a finger's length; the petioles channelled; pome ovate, very obtuse, yellow, with a soft astringent pulp like that of the orange, usually eight-celled, sometimes ten-celled, but very seldom nine-celled, the size of a pigeon's egg, and always barren .--Native of Japan, China, and Cochin-china, with other parts of the East Indies. It differs from the American sorts in its branches, and the pubescence on the lower surface of the leaves.

4. Diospyros Hirsuta. Branches and leaves villose underneath; leaves elliptic, obtuse; flowers axillary, heaped,

15

DIP

5. Diospyros Ebenaster. Leaves oval-oblong, leathery; | obtuse, augmented longitudinally on each side by a membrabuds smooth. This is a very large tree, very smooth in all its parts, and the timber very hard; the small branches have an ash-coloured bark, those which bear the leaves are blackish; the leaves are alternate, on very short petioles, quite entire, obtuse, shining, often spotted, beneath wrinkled with small veins, and as it were a little hoary; berry sessile, ovate, on the four-cleft reflex calix ; seeds six to eight, ovate, black, somewhat compressed. It is very like the first species, but the leaves are more ovate, and more hoary underneath. The wood is heavy, compact, and hard, whitish next the bark, but towards the middle very black; this blackness gradually tinges the whole body, in the same manner as the resinous part of the fir pervades the body by decaying the branches. The fruit, says Loureiro, has an austerity mixed with its sweetness, and a strong unpleasant smell, but is nevertheless sold to be eaten in the markets of the northern provinces of Cochin-china. The wood of this tree, when of a sufficient age, is excellent for cabinets and all elegant works, being of a compact, fine, regular grain, heavy, very white, veined with black, and sometimes black at the heart. -Native of the vast woods of Ceylon, Amboyna, Cochinchina, and the East Indies.

DIP

Leaves ovate-lanccolate, acumi-6. Diospyros Ebenum. nate ; buds rough with hairs ; leaves about three inches in length, thin, flexible, dark green .- Native of Ceylon, and observed in the woods near Calcutta.

7. Diospyros Lobata. Leaves ovate-lanceolate, smooth on both sides; peduncles one-flowered, axillary; berries eight-lobed. This is a small tree, eight feet high, with spreading branches; leaves small, quite entire, pale green, petioled, alternate; filamenta always eight, with double antheræ on each ; flowers white, hermaphrodite ; tube fourcornered, ventricose; border small, four-cleft; style scarcely any; stigma oblong, deeply four-cleft; berry pale yellow, an inch in diameter, compressed, eight-celled, one-seeded, with a sweetish austere pulp, without any smell .-- Native of Cochin-china.

8. Diospyros Dodecandra. Flowers twelve-stamined, axillary; berries lenticular. This is a large tree; leaves broadlanceolate, quite entire, alternate; flowers white; tube subglobular, large, with a short four-cleft border; stamina eighteen, placed on the bottom of the tube; berry pale, compressed, shaped like a lens, one-celled, with eight compressed ovate, bony, large seeds : the pulp is sweetish, astrin-gent, eatable, but not pleasant. The wood is like that of the fifth species, but has not the black veins. This tree is much used for supporting the black-pepper shrubs .- Native of Cochin-china.

9. Diospyros Tetrasperma. Leaves membranous, shining, wedge-form; berries four-seeded .- Native of Jamaica.

Diphysa ; a genus of the class Diadelphia, order Decandria. GENERIC CHARACTER. Calix: perianth one-leafed, bell shaped, slightly compressed, half five-cleft; the two upper segments roundish, obtuse, plane, spreading very much; the two lateral ones ovate, acute, erect, flattish; the lowest lanceolate, acuminate, concave, erect, a little longer than the rest. Corolla: papilionaceous; standard obovate-oblong, emarginate, plain, broad, reflex, on a claw the length of the calix; wings shorter than the standard, oblong, obtuse, ascending, converging behind, diverging in front ; keel sickleshaped, acuminate, compressed, ascending, shorter than the Stamina : filamenta ten, diadelphous, simple and wings. nine-cleft, ascending; antheræ ovate, small. Pistil : germen subcylindrical, pedicelled; style capillary, rising; stigma simple, acute, Pericary ; legume linear, compressed, flat, 39,

naceous, very large, inflated bladder, closed all round, onecelled. Seeds : several, oblong, obtuse, compressed, furnished with a little hook. ESSENTIAL CHARACTER. Calix; half five-cleft; legume with a bladder on each side. Seeds : hooked .- The only species is,

1. Diphysa Carthaginensis. A small, unarmed, inelegant, erect, branching tree, ten feet in height, and approaching to the arborescent mimosas; leaves pinnate, smooth, two inches long, on the younger branches there are usually five leaflets on each side, with an odd one, though not unfrequently more or less, they are oblong, emarginate, small, some alternate, others opposite; common peduncles two-flowered or threeflowered, axillary, filiform, the length of the leaves; flowers yellow, with scarcely any smell; legumes have thin, dry, whitish bladders to them, and hence the name. They continue long upon the tree without opening, till at length they fall in transverse pieces at the joints ; seeds five or six, yellowish .- It flowers in August and September, and is a native of Carthagena in New Spain.

Dipsacus : a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth common, many-flowered, many-leaved; leaflets longer than the floscule. loose, permanent; perianth proper, scarce manifest, superior. Corolla; proper universal, equal, one-petalled, tubular; border four-cleft, upright, outer division larger, more acute. Stamina: filamenta four, hair form, longer than the corolla. Antheræ incumbent. Pistil: germen inferior; style filiform, length of the corolla; stigma simple. Pericarp: none; seeds solitary, columnar, crowned by the entire calicine margin. Receptacle: common, conical, separated by longer chaffs. ESSENTIAL CHARACTER. Calix: common, many-leaved; proper superior. Receptacle: chaffy .---- The species are,

1. Dipsacus Fullonum; Cultivated Teasel. Leaves sessile, serrate : involucres short, horizontal : chaffs bent back. This plant is cultivated in great quantities in the west of England. for raising the nap upon woollen cloths, by means of the crooked awns or chaffs upon the heads, which in the wild sort are straight, or at least not hooked; for this purpose they are fixed round the circumference of a large broad wheel, which is turned round while the cloth is held against them; the heads are collected in August. Parkinson calls it fuller's thistle; and Gerarde, tame, or garden teasel; the Germans name it kardendistel, weberdistel, weberkarten, karten, kartenschendistel, walkerdistel, tuchmacherdistel; the Dutch call it, vollers kaarden, kaarden, or kaardenkruid; the Danes, kardetidsel, kradsetidsel; the Swedes, kardor, kardtistel; the French, chardon a foullon, à carder, à bonnetier, cardere a foullon, cardiere, cure de Venns, bain de notre Dame ; the Italians, dissaco, cardo da cardare, labbro di venera ; the Spaniards, cardencha, cardo peinador ; the Portuguese, cardo penteador, and the Russians, sukonnaja, tschotka. The root of this plant is bitter, and, given in a strong infusion, strengthens the stomach and creates an appetite, and is also good for obstructions of the liver, and the jaundice. Many people think that the water contained in the bason formed by the leaves, is a good cosmetic; but our fair readers are most solemnly assured, that there is no real foundation for such a conjecture .- Teasel is propagated by sowing the seeds in March, upon a soil that has been well ploughed; about a peck of seed will sow an acre, for the plants should have sufficient room to grow, or the heads will not become either so large or so numerous. When the plants are come up, hoe them in the same manner as is practised for turnips, cutting down all the weeds, and singling out the plants to about six or eight inches' distance; and as 6 B

461

the plants advance, and the weeds begin to grow again, hoe them a second time, cutting out the plants to a wider distance, for they should be finally left at least a foot asunder : and you should be particularly careful to clear them from weeds, especially during the first summer, for when the plants have spread so as to cover the surface of the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up stalks with heads, which will be fit to cut about the beginning of August, and should afterwards be tied up in bunches, setting them in the sun if the weather be fair, but if not, placing them in rooms to dry. The common produce is about one hundred and sixty bundles or staves upon an acre, which they commonly sell for about one shilling a stave, Some persons sow caraway and other seeds among their teasels, but it is not a good method, for the one spoils the other : nor can you so easily clear them from weeds as when alone : this, however, is still the common practice in Essex, where the teasel is chiefly cultivated, on account of the neighbouring manufactures of ordinary cloth and baize, in which it is used for raising the nap. Old pasture land, the soil of which is a strong clayey loam, is best adapted to the culture of teasel. The method of managing the land for their compound crop, has already been given under the article Carum. or caraway; we have only to add, therefore, for the instruction of the hoers, that the first appearance of teasel is much like that of a lettuce; that the heads being ready about the middle of September the second year, are to be cut as soon as they begin to turn brown, with a stalk a foot long, and tied up in bundles or bunches, twenty-five in each ; twenty-four of these bunches are fixed on a small stick, and called a row, two hundred and forty of which make a load, in bulk equal to a ton of hay from the meadow. The work of cutting and bunching the teasel can only be done by those who are well acquainted with it: the crop must be looked over, and the heads cut at several times as they ripen : the produce is sometimes a load on an acre, the average price of which is twelve pounds, but it often happens that there is not more than onefourth of a load.

2. Dipsacus Sylvestris: Wild Teasel. Leaves connate. crenate, uppermost entire; involucres long, bending up; chaffs straight; root biennial, simple, with large fibres; stem from three to six feet high, branched, round, striated, hollow, spinous, but the spines few near the base, very numerous near the heads, long and sharp; root-leaves of the first year's plant spread on the ground in a circular form, ovate-oblong, bluntish, notched, wrinkled, and rough, with spines thinly scattered over the leaf; stem-leaves, at least the lowermost, less wrinkled, uniting at the base so as to form a large cavity containing water after rain, and hence the names of dipsacus, and labium Veneris; flowers blue purple, first breaking forth about the middle of the heads; corolla-tube whitish, and appearing slightly villose if magnified; filamenta straight, inserted into the tube of the corolla; antheræ oblong, violetcoloured ; germen four-cornered, whitish, grooved ; style a little longer than the corolla : stigma channelled, and bent a little in .- Native of most parts of Europe, on the edges of pastures, in cultivated places, and by road-sides, flowering from June or July to September. The water contained in the basin formed by the leaves, is absurdly said to cure warts on the hands, and to serve as a beauty wash for the face; it is also supposed to be good for the eyes. Cattle in general, even asses, appear to avoid it; small moths, earwigs, and other insects, take refuge in the head. Although Linneus thought this to be a mere variety of the first species, Mr. Miller, after having cultivated both for nearly forty years,

hesitates not to declare them to be distinct species .- It is found about Newcastle, and in Scotland.

3. Dipsacus Laciniatus; Cut-leared Tesel. Leaves ennate; root biennial, long, branching; sitem three feet high, upright, angular, prickly, branched; leaves pinnatifid, lacinate or simulate, bright green, smooth above, pubescent benachs, having short prickles along the nerve, and being cliate on the edge; heads ovate, obtuse, terminating the stem and branches, with an involuter at the base, consisting of stiff prickly leaves, spreading out like a star; chaffs lancedate, straight, ending in a stiff prickle; flowers whitish; antheras reddish. It differs from the common teasel, not only in the leaves being cut so deeply, but in the prickles being weaker, and having lateral flowers, rising ligher than those in the indle: the goldfinch is four of of the seeds, as well as those of the common sort.—Native of Germany, France, Alsace, Austrin, and Carniola.

4. Dipsacus Pilosus; Small Teasel. Leaves petioled, with little appendages. It differs from its congeners in having a fragile stem, from two to six feet high, sharp, with short prickles pointing upwards, angular, and grooved; leaves with little appendages at the base, but these are sometimes wanting, aud the upper leaves are nearly entire, slightly hairy on both sides, and with short prickles along the midrib underneath: scales of the receptacle longer than the corollas, ciliate, in hemispherical heads; corollas white, sometimes with a purple tinge; antheræ dark purple; seeds ovate-quadrangular, crowned with the calix; stigma sometimes simple, but most frequently trifid, with the lower lobe shorter than the upper, as it is likewise in the common sort ; sometimes it is slightly cloven into three parts; the heads of flowers hang down during the time of flowering, but afterwards become upright. This plant is called shepherd's rod, and shepherd's staff'; it flowers in July, and in September ripens seeds, which are eaten by the small birds; the flowers are frequented by great numbers of moths after sun-set. It is the handsomest species of the genus, and very distinct from the three others, which are very nearly allied .- It is a native of France, Germany, Switzerland, and Austria: in England, it is found in moist and watery places, by brooks and damp hedges and ditches; and has been found between Deptford and Lewisham: at Edgecombe near Croydon, at Guildford, and Godalmin, in Surry; in Beckenham church-yard, near Chislehurst; Footcray and Farnborough in Kent; about Finchley in Middlesex; at Fulham, between the bishop's palace and the field; at More-hall, and near Harefield; near Thame Park in Oxfordshire; at Littleshall abbey, in Shropshire; at Eversham in Worcestershire; in the way from Braintree to Hedingham, and from Dunmow to London; in Garanton park, and Hollinghall wood, in Leicestershire; and in Scotlaud.

Dipterys: a genus of the class Diadelphia, order Decandira.—Gus Rent C UARACTER. Calitz perianth one-leafed, turbinate: two upper segments wing-shaped, oblong, concave, spreading, the third lower, small, entire, or three-toolhed. Corolla: papilonaceous; standard longer, obovate, bent in at the sides, crect; wings two, oblong, shorter than the standard; keel shorter, two-petalled. Stamina: filamenta eight to ten, united into a cylinder, cloven at top. Antheras small, roundish. Pistil: germen pedicelled, oblong; istyle avisinped, ascending; sigma acute. Pericerp: legune large, ovate, compressed, thick, one-celled. Sed: single, ovate, ESENTAL CHARACTER. Caliz: two, upper segments winged. Legume: ovate, compressed, one-seeded.—The species are,

1. Dipteryx Odorata; Coumarouna. Leaves alternate. This is a large tree, sixty feet high, very much branched at

entire, two or three on each side, affixed alternately on the times two, and then the second comes out on a longer pedunmidrib; the flowers are borne on racemes, which are axillary and terminal; their colour is purple, dashed with violet; the almonds or fruits are fragrant, and are put by the Creoles into chests, in order to drive away insects, as well as for the sake of their smell .- It grows in the large forests of Guiana.

2. Dipteryx Oppositifolia; Taralea. Leaves opposite. This, like the former, is a tall tree, and very branchy at top; the leaves are opposite, and pinnate; the leaflets large, ovate, sharp, strong, and perfectly entire; the flowers are panicled, axillary, and terminal, and when blown, their fragrance is very diffusive .- Native of the woods of Cayenne.

Dirca ; a genus of the class Octandria, order Monogynia. -GENERIC CHARACTER. Calix : none. Corolla: one-petalled, club-shaped; tube bellying above; border obscure, with unequal margin. Stamina: filamenta eight, capillary, inserted into the middle of the tube, longer than the corolla. Antheræ roundish, upright. Pistil: germen ovate, with oblique tip ; style filiform, longer than the stamina, crooked at the tip; stigma simple. Pericarp: berry one-celled. Seed: single. ESSENTIAL CHARACTER. Calix: none. Corolla: tubulous, with an obscure border. Stamina : longer than the tube. Berry : one-seeded .---- The only known species is.

1. Dirca Palustris; Marsh Leatherwood. Height five or six feet, but in Europe seldom exceeding three; it sends out many jointed branches near the root; leaves oval, pale yellowish, and smooth; the flowers come out from the side of the branches, two or three upon each peduncle; they are of a greenish white colour, and appear early in the spring, when the leaves begin to shoot. It is a little shrub, growing on hills towards swamps and marshes in North America: the bark is very tough, as is also the shrub itself, insomuch that the branches cannot easily be separated without cutting; the twigs are used for rods, and the bark for ropes, baskets, &c. for which it is very suitable, being equal in strength and toughness to the bark of the lime-tree. The French in Canada call it bois de plomb, or leaden-wood. This shrub is very difficult to propagate in Europe, where it does not produce seeds, and can therefore only be propagated by layers or cuttings, and these are generally two years before they put out roots; and as it naturally grows in very moist places, it is with difficulty preserved in gardens, unless it be planted in wet ground: it is seldom injured by cold.

Disa; a genus of the class Gynandria, order Diandria .--GENERIC CHARACTER. Calix : spathe one-valved, acuminate, oblong, gaping longitudinally on one side. Corolla : petals three, ovate, spreading, large, nearly equal, the opper one unequal, somewhat horned obtusely at the base behind. Stamina : filamenta subulate. Antheræ two, connected into a lanceolate form, a little shorter than the corolla, subulate at the base, gaping, mounted on the style. Dorsal petal of the stamina two-parted, shorter than the stamina; divisions oblong, obtuse, converging. Pistil: germen inferior, length of the spathe: style tongue-shaped, short, hollowed at the base, two horned backwards. Pericarp : capsule oblong, three-valved. Seeds : numerous, minute. ESSENTIAL CHA-BACTER. Spathe : one-valved. Petals: three, the third less, two-parted, gibbous at the base.---- The species are.

1. Disa Grandiflora. Horn shorter than the petals, with about two flowers on the stem ; stem a foot high, erect, quite simple, even; leaves shorter than the stem, those next the root lanceolate-linear, those on the stem sheathing, alternate,

top; the leaves are large and pinnate; the leaflets perfectly | at the end; flower terminating, peduncled, inclined, somecle from the spathe of the former; this flower is very conspicuous and heautiful .- Native of the Cape of Good Hope.

DOD

2. Disa Racemosa. Horn shorter than the petals; flowers in racemes. This plant has never been described .- Native of the Cape of Good Hope.

3. Disa Longicornis. Horn longer than the petals; scape one-flowered; flower blue, beautiful, and singular in its form. -Native of the Cape of Good Hope.

4. Disa Maculata. Horn conical, very short; scape oneflowered ; root-leaves oblong ; stem and sheath spotted with red ; flowers blue .- Native of the Cape of Good Hope.

Disandra ; a genus of the class Heptandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth oneleafed, from five to eight-parted; divisions straightish, permanent. Corolla: one-petalled, wheel-shaped; tube very short; border five-parted; divisious ovate. Stamina: filamenta from five to eight, bristle-form, from erect becoming patulous, shorter than the corolla. Antheræ sagittate. Pistil: germen ovate; style filiform, length of the stamina; stigma simple. Pericarp : capsule ovate, length of the calix, two-celled. Seeds : several, ovate. ESSENTIAL CHARAC-TER. Calix: seven-leaved. Corolla: seven-parted, flat; capsule two-celled .---- The species are,

1. Disandra Prostrata. Leaves reniform, crenate; peduncles in pairs; stems from a foot to two feet in height, prostrate, round, pubescent; leaves alternate, petioled, with about thirty notches, pubescent; peduncles axillary, usually two together, but sometimes one or three, erect, filiform, oneflowered, higher than the petioles; corollas yellow. The foliage greatly resembles that of ground-ivy; the branches also trail upon the ground in a similar manner, to the length of several feet : it varies extremely in the number of stamina, and in the divisions of the calix and corolla; seven is thought to be the most usual number of the former, and five the most natural .- It flowers during most part of the summer, and is a native of Madeira. It grows readily from cuttings: in the winter it must be kept in the green-house, but will bear the open air in summer; it should be planted in rich earth, and plentifully watered in dry weather : it appears to most advantage in a pot placed upon a pedestal, or in some elevated situation, where its branches may hang carelessly down.

2. Disandra Africaña. Leaves orbiculate, entire, crenate ; peduncles solitary. It is doubtful whether this be a distinct species .- Native of Africa.

Distaff Thistle. See Atractylis.

Dittander. See Lepidium.

Dittany, of Crete. See Origanum.

Dittany, White. See Dictamnus Fraxinella.

Dock. See Rumex.

Dodartia: a genus of the class Didynamia, order Angiospermia .- GENERIC CHARACTER. Calix: perianth oneleafed, bell-form, five-toothed, with ten corners, tubular, nearly equal, flat, permanent. Corolla: one-petalled, ringent ; tube cylindric, bent downwards, much longer than the calix; upper lip small, emarginate, ascending; lower lip spreading, wider, three-cleft, twice longer, obtuse; middle division narrower. Stamina : filamenta four, ascending towards the upper lip, and shorter than it. Antheræ small, roundish, twin. Pistil : germen roundish ; style subulate, length of the corolla; stigma compressed, oblong, obtuse, two-cleft, the lamellas converging. Pericarp: capsule globose, two-celled. Seeds: numerous, very small. Receptacle: three in number; the disk shorter than the sheath, acuminate convex, growing to the dissepiment. ESSENTIAL CHARAC-

TER. Calix: five-toothed. Corolla: lower lip twice as long as the upper. Capsule: two-celled, globular.——The species are,

DOD

1. Dodartia Orientalis; Oriental Dodartia. Leaves linear, quite entire, smooth. It has a perennial root, which creeps far under the surface, and sends out new stalks at a great distance from the parent plant; these stalks are firm, a little compressed, and grow a foot and half high, sending out several side-branches; leaves long, narrow, fleshy, opposite, of a deep green colour, those on the lower part of the stalk are shorter and broader than those above, those on the upper part of the stalk are entire; at these joints the flowers come out singly on each side, the stalk sitting close to it; they are nearly an inch long. The flowers are of a deep purple colour, and appear in July, but rarely produce seeds in England. First discovered by Tournefort near Corvirap, not far from the foot of mount Ararat, in Armenia. This plant propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough ; it loves a dry light soil, and may be transplanted, either in autumn when the stalks decay, or in the spring before the new stalks arise.

2. Dodarita Indica. Leaves ovate, serrate, villose; stems roundish, villose, somewhat branching; raceme terminating with small leaves; flowers opposite, pointing one way, subsessile; calix obtuse, villose; corolla yellow, with the outer lip straight and short.—Native of India.

Dodder. See Cuscuta.

Dodecas ; a genus of the class Dodecandria, order Monograia.-GENREIC CHARACTER. Calix: perianth oneleafed, turbinate, permanent, half four-clefl, superior; divisions ovate, spreading. Corolla: petals roundsis, sessile, inserted into the calix. Stamina: filamenta twelve, capillary, aborter than the calix, inserted into the receptacle. Anthera oblong. Pistil: germen half superior; style filform, longer than the stamina; stigma simple. Pericarp: capale ovate, one-celled, inferior, growing to a patulous calix, within which the apex is maked and four-valved. Szeds; numerous, oblong, minute. ESENTIAL CHARACTER. Corolla: free petalled. Calix: half four-cleft, bearing the corolla, superior. Copsule: one-celled, connate with the calix.----The only known species is,

Î. Dodecas Surinamensis. A shrub somewhat four-cornered, even; the branches opposite, short; leaves opposite, obovate, oblong, or wedge-shaped, subpetioled, even, obtaus, quie entire; sitpules none; pedunclesaxillary, one-flowered, short, solitary, the length of the calix; livates in pairs, minute under the calix; calix before it unfolds four-cornered, four-valved, turbinate at bottom, columnar; petale inserted into the calix at the divisions; stamina inserted into the receptacle, next the germen, not into the calix.—Native of Surinam.

Dodccalheon : a genus of the class Pentandria, order Moongynia.--GRNERIC CHARCTER. Coll:: involucer manyleaved, many-flowered, very small; perianth one-leafed, half five-cleft, permanent; divisions reflex, finally longer, permanent. Corolla: one-petalled, five-parted; tube shorter than the calix, naked at the throat; border reflex; divisions very long, lanceolate. Stamina: filamenta five, very short, obuses, seated on the tube. Antheras sagittate, converging into a beak. Pisitl: germen conic; style filform, longer than the stamina; sigma obtuse. Pericary: capsule oblong, onecelled; gaping at the tip; according to Gartner, subcylindric, opening into five parts. ESENTIAL CHARACTER. Corolla: rotate, reflex. Stamina: placed on the tube. Capsule: one-celled; oblong.---The only known species is,

1. Dodecatheon Meadia; Virginian Cowslip, or Meadia.

This plant has a yellow perennial root, from which come out in the spring several long smooth leaves, nearly six inches in length, and two and a half in breadth, at first standing erect, but afterwards spreading on the ground, especially if it be much exposed to the sun; from among these leaves arise two. three, or four flower-stalks, in proportion to the strength of the roots, which reach to the height of eight or nine inches, and are smooth, naked, and terminated by an umbel of flowers, of a purple inclining to a peach-blossom colour. They appear at the end of April, or the beginning of May, and the seeds riven in July, soon after which the stalks and leaves decay, and the roots remain inactive till the following spring. It is propagated by offsets, which the roots put out pretty freely when they are in a loose moist soil and shady situation; the best time to remove the roots, and take away the offsets, is in August, after the leaves and stalks are decayed, that they may be fixed well in their new situation before the frost comes on. It may also be propagated by seeds, which the plants generally produce in plenty, and which should be sown in autumn, soon after they are ripe, either in a shady moist border, or in pots, which should be placed in the shade. In the spring the plants will come up, and must then be kept clean from weeds, and, if the season prove dry, be frequently refreshed with water; nor should they be exposed to the sun, for while the plants are young they are so impatient of heat that great numbers have been destroyed by being placed two or three days full in the sun. These young plants should not be transplanted till their leaves are decayed, then they may be carefully taken up and planted in a shady border, at about eight inches' distance from each other, where the soil is loose and moist, where they may remain for a year, by which time they will be strong enough to produce flowers, and may then be transplanted into some shady borders in the flower-garden, where they will appear very ornamental while they continue in flower. This plant is not only very elegant, but also hardy, and deserves a place in every good garden.

Dodonae ; a genus of the class Octandria, order Monogyna-GENERE C CMARACTER. Collis: perinnth fon-leaved, flat : leaflets ovate, obtuse, concave, deciduous. Corolla: none. Stamina: filamenta eight, very short. Anthere oblong, bowed, converging, length of the calix. *Pistil:* genmen three-sided, length of the calix, style cylindric, threefurrowed, upright; sigma slightly three-cleft, a little acute. *Pericarp:* cospute three-furrowed, inflated, three-celled, with large membranaceous corners. Seeds: in couples, roundish, ESENTIAL CHARACTER. Collis: four-leaved. Corolla: noue. Capsule: three-celled, inflated. Seeds: in couples. —The species are,

1. Dodonæa Viscosa; Broad-leaved Dodonæa. Leaves oblong. This sends up several stalks from the root about the size of a man's arm, with several upright branches, covered with a bright brown bark, which frequently separates from the wood and hangs loose; leaves stiff, varying in shape and size, some being four inches long, and an inch and a half broad; they are spear-shaped, entire, and of a light green, growing with their points upwards, and having very short footstalks; the flowers are produced at the end of the branches in a sort of raceme, each standing upon a slender footstalk about an inch long : the taste of the whole plant is acrid and bitterish. In Jamaica it is called the switch sorrel. -Native of the countries between the tropics. It is propagated by seeds, which, if obtained fresh from abroad, will rise easily upon a hot-bed. When the plants are fit to remove, they should be each planted in a separate small pot filled with light loamy earth, and plunged into a hot bed of tanner's bark, shading them from the sun until they have taken new | one end; seeds three or five, flatted a little, smooth, but not root; they then may have free air every day admitted to shining, black or ferruginous, edged on one side with a funthem, in proportion to the warmth of the season, and must neither be drawn up weak, nor should they have too much water. In the autumn the plants must be removed into the stove, where they should have a temperate warmth in winter, but during that season little water should be given them nor should they have too much heat : for either of these will soon destroy them. As the plants obtain strength they will become hardier, and may be set in the open air for two or three months in the heat of summer, but should always be placed in a sheltered situation; in winter they must be placed in a stove, kept to a moderate temperature of warmth, for the plants will not live in a green-house here. This plant was formerly shewn for the tea-tree, in many parts of the European gardens; and passed for it during many years, among those who knew no better.

2. Dodonæa Angustifolia; Narrow-leaved Dodonæa. Leaves linear. It resembles the foregoing ; the fructification is polygamous .- It flowers from May to August, and is a native of the Cape of Good Hope. The second sort is less tender than the first, and requires only the protection of a green-house or glass-case.

Dogberry Tree. See Cornus. Dog's Bane. Sce Apocynum. Dog's Grass. See Triticum. Dog's Mercury. See Mercurialis. Dog's-tail Grass. See Cynosurus. Dog's Tooth. See Erythronium. Dogwood. See Cornus.

Dolichos; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix : perianth one-leafed, very short, four-toothed, equal; the superior tooth emarginate. Corolla: papilionaceous; standard roundish, large, emarginate, the whole reflex; two calluses oblong, parallel and longitudinal, growing to the standard beneath towards the base, compressing the wings, not hollowed on the back ; wings ovate, obtuse, length of the keel. Keel: linulate, compressed, beneath couverging closely, length of the wings, ascending at the tip. Stamina : filamenta diadelphous, simple, and nine-cleft, the simple one curved at the base. Antheræ simple. Pistil : germen linear, compressed ; style ascending; stigma bearded, running on inwardly from the middle to the tip of the style, which on the fore part is callous, obtuse. Pericarp : legume acuminate, large, oblong, two-valved, two-celled. Seeds : several, elliptic, usually compressed. ESSENTIAL CHARACTER. Two parallel oblong calluses at the base of the standard, compressing the wings underneath. Most of these species come from the East and West Indies, are tender, and seldom perfect their seeds in quently lost in our stoves. The s England; they are principally annual plants, and are fre--The species are,

1. Dolichos Benghalensis. Shrubby: legumes ending in long dagger-points, perennial; the stem is rather roughish to the touch, and scandent, as well as producing several branches; flowers seated on very short peduncles, uncertain as to number, snow-white, and slightly odorous; leaves roundish, ovate, ending in a point, furnished with a bristle; stipules lanceolate; peduncles racemose, four or five inches long; legume oblong, pointed, compressed, first green, afterwards growing pale; seeds fcw, roundish, oblong, compressed, brown, with deeper-coloured points, and with a long protuberant, snow-white hilum,

2. Dolichos Lablab; Black-seeded Dolichos. Legumes ovate, salver-shaped ; seeds ovate, with a bowed eye towards 39.

gous snow-white callus, proceeding from the umbilicus, they have no albumen; stems and branches round, scabrous backwards; peduncles forming half whorls. Alpinus says, that this plant grows wild in Egypt, but is only cultivated there in gardens: the Egyptians call it ful Frangi, or European bean, and thence we might conjecture that the Europeans first brought it into Egypt, where the natives make pleasant arbours of it, not only supporting it with trellis work, but fastening it with twine, by which means the leaves form an excellent covering and an agreeable shade. This species, together with the fourth, are cultivated for the table in warm countries, but seldom perfect their seeds in England; and were they to thrive here as well as in the warm countries, they would be little esteemed, because we already have much better sorts in our gardens; for the scarlet-flowering kidneybean is preferable to all of them for eating, and deserves to be cultivated more than any other.

3. Dolichos Sinensis; Chinese Dolichos. Legumes pendulous, cylindric, torulose; peduncles erect, many-flowered; stem annual, long, round, slender, twining, somewhat branched ; leaves ternate, broad-lanceolate, smooth, with two or three lanceolate stipules at the base of the common petiole; flowers pale violet, on few-flowered, suberect, axillary peduncles; standard ascendiug, very blunt .- Native of Amboyna, China, Cochin-china, and the East Indies generally.

4. Dolichos Uncinatus ; Hook podded Dolichos. Legumes cylindric, hirsute, with a hooked subulate claw at the end; peduncles many-flowered ; stem rough with hairs .- Native of Jamaica. For its propagation and culture, see the second species.

5. Dolichos Luteolus. Legumes in several cylindric heads : seeds rounded; stem rather angular, branched, round. A scandent plant; branches three or four cubits long; leaves ovate, entire, subacute, glossy; stipules small, and roundish; peduncles axillary, supporting from six to ten elegant yellow flowers; the stigma is much bearded .-- Native of the Society Isles.

6. Dolichos Unguiculatus; Bird's foot Dolichos. Legumes in subcylindric heads, recurved, and concave at the tip. This is an annual smooth plant, with a climbing stem ; leaves fanced ovate, and sharp; peduncles upright, supporting but few flowers; flowers whitish; stigma loug and bearded; seed whitish, with a snow-white hilum. Loureiro says it is a native of China, and was imported into Portugal .- Native of the West Indies.

7. Dolichos Tranquebaricus. Legumes few, in cylindric heads, with a straight dagger-point : the whole plant is very smooth ; the vexillum or standard of the flowers, pale yellow behind, and bluish red in front, the wings more blue, and the keel white.

8. Dolichos Ensiformis : Horse Bean. Legumes gladiated. three-keeled at the back; seeds arilled; stem three or four feet high, with shoots running much farther ; the legumes are between ten and fourteen inches in length, and generally contain ten or eleven seeds. This species is distinguished by its large falcated legume and white seeds, with a saffroncoloured scar .- Native of Jamaica.

9. Dolichos Tetragonolobus. Legumes quadrangular, membranaceous; stem herbaceous, round, slender, scandent. long, branching; leaflets broad-lanceolate, smooth, pale green; stipules lauceolate, minute; flowers pale blue, on long, lateral, few-flowered pedancles; seeds about eight .--Native of the East Indies, China, and Cochin-china.

10. Dolichos Sesquipedalis; Long-podded Dolichos. Le-6 C

pale above, reddish within; legume more than a foot and a half in length, roundish, with a little obtuse gibbous hook at the end .- Native of the West Indies.

DOL

11. Dolichos Altissimus : Tall Dolichos, Legumes racemed, rough-haired, equal; seeds surrounded with a scar; leaves smooth on both sides. This climbs the highest trees. whence hang elegant wreaths of flowers in loose racemes. on peduucles frequently more than twelve feet in length; the proper pedicels are short, and in threes; the flowers void of scent, an inch and a half long, with a ferruginous calix, a violet blue standard and wings, and a vellowish keel; the whole of the stamina and pistilla rise surprisingly, and are inclosed within the convoluted standard .- Native of the island of Martinico.

12. Dolichos Pruriens ; Horse-eve Bean. Legumes in racemes ; valves somewhat keeled, rough-haired ; peduncles by threes; leaflets rough with hairs underneath; calix campanulate, five-toothed, the middle tooth shorter; banner very short, three times less than the other petals, ovate ; keel linear. acute, boat-shaped at the end; four alternate filamenta somewhat club-shaped, larger; legume compressed, inflex at the base, reflex at the tip .- Common in all parts of the West Indies, and rising to the top of the tallest trees, or spreading wide among lower bushes; flowers dark purple, in spikes at the axils of the ribs. A decoction of the roots is reckoned a powerful diuretic and cleanser of the kidneys; and a vinous infusion of the pods in beer. (twelve pods to a quart.) is said to be a certain remedy for the dropsy, and the dose is half a pint. In the Windward Islands they make a syrup of the pods, which is said to be very effectual against worms .- Native of Cochin-china. This and the next species are sometimes preserved in botanic gardens, especially the latter, whose pods are closely covered with stinging hairs, commonly known by the name of cow-itch, and often employed in the mischievous pranks of young people. Both these plants are too tender to thrive in the open air of our country, so that whoever desires to have them should sow their seeds in a hot-bed in March; and when the plants come up, they should be each planted in a separate pot, and plunged into the hotbed again, taking care to shade them until they have struck root; after which they must every day have fresh air admitted to them, in proportion to the warmth of the season; and when the plants are too tall to remain in the hot-bed. they should be removed into the bark-stove, where, if they be allowed room to run, they will flower and perfect their seeds.

13. Dolichos Urens; Cow-itch Dolichos. Legumes in racemes, with furrows transversely lanceolate; the seeds surrounded into a scar; stems round; leaves subovate, quite entire, acuminate, the upper surface smooth, the lower covered with a shining silvery down that is hardly perceptible; racemes simple, pendulous, scarcely ever longer than the leaves; proper peduncles one-flowered, in threes, placed closely at the end of the raceme, and hence forming a very elegant pendulous wreath of about eighteeu flowers, which are scentless, about two inches long, have a ferruginous calix, and a yellow corolla, with the lower edge of the wings red; the seeds, from their resemblance to an eye, are called by the French yeux bourrique, or ass's eye; and in the British West India islands, they are for the same reason named ox-eye bean. This plant climbs to the top of the tallest trees, throwing down its long slender flower-stalks to a moderate distance from the axils of the upper ribs, whence they generally rise, and are not above the thickness of a common packthread, but seldom under four or five feet in length, and bear

gume subcylindric, even, very long: standard of the flower the flowers in clusters at their extremities .- Native of the West Indies. For its propagation and culture, see the preceding species.

14. Dolichos Minimus; Small Dolichos. Legumes in racemes, compressed, with four seeds in them ; leaves rhomhshaped. This climbs three or four feet in height, and has uumerous branches; leaves glaucous; racemes stiff; wings of the corolla vellow ; standard brownish red, turning blue as it withers. Browne calls it small fetid dolichos ; and in Curacoa, it has the name of vrattekruut, or wart-herb, the leaves bruised with salt being reputed to cure warts .- Native of Jamaica.

15. Dolichos Lineatus. Legumes in racemes, oblong, three-keeled; stem subangular, smooth; leaflets smooth, ovate, obtuse, with a point, marked with lines, equal, an inch and half in length, the side ones short, the middle ones on a long petiole; stipules very small, bristle-form; legumes rounded in front, straight at the back, marked with three lines, the side ones larger than the middle line, acute, smooth. two inches long .- Native of Japan.

16. Dolichos Capensis. Pedancles with one or two flowers; legunes elliptic, compressed ; leaves smooth ; stem filiform, angular, even; stipules ovate, acute, striated, very small; leaves petioled; leaflets ovate-oblong, acuminate, veined; peduncles long; legumes acute at both ends, the back suture straight, smooth, containing usually two seeds .- Native of the Cape of Good Hope.

17. Dolichos Scarabæoides: Silveru-leaved Dolichos. Leaves ovate, tomentose : flowers solitary: seeds two-horned : stem scabrous; leaves petioled; leaflets obtuse, veined underneath, soft; flowers single, from the axils .- Native of the East Indies.

18. Dolichos Incurvus. Legumes solitary, incurved, threekeeled ; stem striated, smooth ; leaflets oblong, acute, entire, smooth, paler underneath, nerved, two inches broad, a hand in length, equal, the side ones on very short petioles, the middle leaflet on a longer ; flowers axillary, solitary, peduncled; peduncle round, bent round at the end, and smooth .--Native of Japan.

19. Dolichos Bulbosus: Bulbous Dolichos. Leaves smooth. many-angled, toothed ; stem perennial, suffruticose, long, round, smooth, branched, without any stipules; leaves roundish, angular, ternate, acuminate, petioled ; flowers terminating in long racemes : calix cup-shaped, four-cleft ; the upper segment shorter, emarginate; corolla pale violet, with an ovate, entire, converging standard; the root consists of roundish, tailed, juicy, white tubers, in bundles, they are eaten both raw and dressed, but the seeds are refused .- Native of both Indies.

20. Dolichos Trilobus. Lateral leaflets gibbous on the ontside, the middle one three-lobed ; stem perennial, suffruticose, round, very long, branched, twining, or creeping, when it lies on the ground, hirsute; leaves petioled, with two horned stipules; leaflets three-lobed, acuminate, pubescent; flowers purple, in long terminating and lateral spikes, with a large yellow spot on the middle of the standard; the root is composed of a few loug tubers in bundles, they are two feet long, subcylindric, fibrose, fleshy, of a pale colour, aud eat-able when boiled .--- Native of the East Indies, and cultivated in China and Cochin-china.

21. Dolichos Aristatus. Peduncles two-flowered, axillary; legumes linear, compressed, ending in a straight awn; stem round; leaflets even, ovate, oblong, acuminate; legumes straight and stiff, ending in a filiform, stiff, sharp awn, an inch in length .- Native of America.

22. Dolichos Filiformis; Cat's-claw Dolichos. Leaflets

This grows among bushes, but seldom stretches beyond three purgative ingredient in diet-drinks, and is said to answer well in dropsical cases .- Native of Jamaica, where it is called cat's-claws.

23. Dolichos Purpureus; Purple Dolichos. Stem smooth; petioles pubescent; wings of the corolla spreading; leaflets subcordate, smooth, netted underneath with purple veins; calices covered with two bractes; corolla bright purple; keel violet below the tip; the legnmes when young and fresh are sapid and salubrious; seeds compressed, ovate, surrounded with a scar .- Native of both Indies : cultivated in China and Cochin-china.

24. Dolichos Regularis. Leaves ovate, obtuse ; peduncles many-flowered ; petals equal in size and alike in form .--- Native of Virginia.

25. Dolichos Lignosus; Woody Dolichos. Stem perennial; peduncles forming a head; legumes stiff and straight, linear; root woody, perennial; leaves alternate, on long footstalks, ternate, or rather binate, with an odd leaflet; common footstalk roundish, channelled above, umbelling, and purplish at the base; partial ones very short, swollen, incurved ; leaflets rhombed, elongated, acute, entirc, obsoletely three-nerved, bright green and shining above, glaucous beneath ; racemes axillary, solitary, erect, having from three to six flowers in a little head ; flowers nodding a little, rosecoloured, with a purplish keel; seeds black .-- Native of the East Indies. It is easily propagated by seed, and produces abundance of flowers during summer in a stove.

26. Dolichos Polystachios. Stem perennial ; racemes very long; pedicels in pairs; legunes acuminate, compressed; leaves alternate, unequally pinnate, smooth; leaflets about six pairs, opposite, on very short petioles, ovate, acuminate, entire, smooth, pale underneath, an inch long, the odd lobe on a longer petiole; the flowers from the same bud with the leaves, in racemes often a foot in length; pedicels scattered, opposite, and alternate, short, one-flowered; it varies with white and with purple corollas, with larger hirsute, and with smaller smooth legumes .- Native of Japan, where it is frequently cultivated for arbours, and also of Virginia.

27. Dolichos Reticulatus; Netted-leaved Dolichos. Leaves ovate, acute, wrinkled, netted, villose; racemes fcw-flowered, shrubby .- A native of New South Wales.

28. Dolichos Luteus. Twining: flowers in a sort of spike; legumes subcylindric, smooth ; leaves roundish, rhombed, obtuse, entire, smooth .- Native of Jamaica.

29. Dolichos Montanus, Stem shrubby, climbing; leaflets ovate, rhombed; five filamenta with oblong anthera, and five alternate, roundish; roots subtuberous, hard, long, in bundles; stem long, branched; leaflets large, tomentose, entire; flowers wholly purple, in long lateral spikes; stamina five, longer, with oblong antheræ, five alternately shorter, with roundish antheræ; legume linear, straight, compressed separated between the seeds, which are compressed, and suborbiculate .- Native of the mountain woods of Cochinchina.

30. Dolichos Hastatus. Stem procumbent; leaves subhastate; peduncles many-flowered, erect; flowers vellow, axillary, on long striated peduncles; legume linear, straight, subcylindric; seeds ovate, pale, esculent .--- Native of Africa.

31. Dolichos Rotundifolius. Legumes racemed, compressed, somewhat hairy, sword-shaped; leaflets oval, roundish, smooth; stem smooth, woody, angular at top; leaflets oval, the end one roundish, entire, emarginate, veined ; pe-

linear, obtuse, nucronate, smooth, pubescent underneath. tiole a little longer than the leaflets, scarcely hairy: petiolules purple, hairy; racemes axillary, half a foot long; flowers or four feet in length; the pods are long and compressed; two or three at each tubercle, on very short pedicels; bractes the stigma or top of the style almost naked. It is used as two, roundish, caducous, at the base of the flower: calix bell-shaped, smooth; corolla large, purple .- Native country unknown.

** Erect.

33. Dolichos Ensiformis; Scymetar-podded Dolichos. Stem suberect ; legumes scymetar-shaped, three-keeled ; seeds arilled; leaflets acute, wrinkled, smooth; stipules bristleshaped, very small; flowers violet-coloured, on many-flowered axillary peduncles ; calix tubular, two-lipped, upper lip bifid, lower three-toothed, shorter. There is a variety with legumes twice as long, and flatter, with blunter leaves, and other minute differences .- Native of China and Cochin-china, where it is cultivated for arbours, but not for food.

33. Dolichos Soja. Stems flexuose; racemes axillary, erect; legumes pendulous, hispid, containing about two seeds ; leaves petioled, hirsute ; leaflets petioled, ovate, obtuse, with a point, entire, the middle leaves on a longer petiole, and larger, an inch in length ; petiole striated, hirsute, a finger's length; flowers in short, erect, hirsute racemes; subsessile, from three to five together; corollas purple, scarcely bigger than the calix .- Native of the East Indies, Ceylon, and Japan.

34. Dolichos Catiang. Legumes double, linear, somewhat erect; stem annual, a foot and a half high, roundish, rugged, branched; leaflets broad-lanceolate, smooth; common petiole long; stipules lanceolate, minute; flowers subterminating, two or three together, on a very long peduncle; seeds oblong, ovate, somewhat compressed, with a scar of a different colour. There are several varieties differing in the colour of the flower and seed, all of which are much cultivated for food in the East Indies.

35. Dolichos Biflorus ; Two-flowered Dolichos. Stem perennial, even; peduncles two-flowered; legumes erect; root an ovate brown tuber; leaves linear-lanceolate, quite entire, veined, pubescent on both sides, subsessile; flowers yellow, axillary .--- Native of China and India.

38. Dolichos Repens; Sea-side Dolichos. Stem creeping; leaves pubescent, ovate ; flowers racemed, in pairs ; legumes linear, columnar .- This is a common plant by the sea-side, in Jamaica: the root is a strong purgative.

37. Dolichos Roseus. Stem creeping, ascending; leaflets roundish, shining ; flowers in racemes ; legumes three-keeled at the back .- Native of Jamaica.

38. Dolichos Fabæformis. Stem erect, angular; leaves villose, glaucous ; legumes stiff and straight, subquadrangular; root annual; petioles three-sided, channelled; stipules linear. very acute, villose, erect, permanent; spikes axillary, solitary, erect, villose, shorter than the petioles; flowers subsessile, erect, purple; bracte awl-shaped, erect, under each flower .- Native of the East Indies. It may be propagated by its seeds, which will come to perfection in England.

Doliocarpus ; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix ; perianth fiveleaved; leaflets oblong, rounded, concave, unequal, coloured, permanent. Corolla : petals three, roundish, concave, plaited. Stamina : filamenta very many, inserted into the receptacle, capillary. Antheræ compressed, flat, subbifid. Pericarp: berry globular, one-celled, crowned with the style. Seeds: two, arilled, oblong, rounded, flat on one side, convex on the other. ESSENTIAL CHARACTER. Calix: five-leaved, Corolla : three-petalled, plaited. Stigma : subbifid. Berry : globular, crowned with the style, one-celled, two-seeded -The species are,

1. Doliocarpus Rolandri. Stem stiff and straight; leaves ovate-lanceolate, toothed; flowers terminating. This grows to a shrub.—Native country unknown. 2. Doliocarpus Major. Stem scandent; leaves ovate,

DON

 Doliocarpus Major. Stem scandent; leaves ovate, toothed; peduncles lateral, one-flowered; the flowers are aromatic, but rather nauseous, and the berries positively pernicious; stem slender and flexuose; branches at right angles; leaves spreading.

3. Dollocarpus Calnea. Stem scandent; leaves ovate, quite entire; flowers axillary, in bundles. This is a shrub with several knotty spreading twigs, scattering over the neighbouring trees; the branches are garnished with alternate, oral, shiming, green leaves, terminating in a point, the largest are four inches long; the flowers spring from the bosoms of the leaves, on the branches, and arranged alternately in little heaps; the corolla consists of three white petals, which are large and rounded.—Native of Guiana.

Dombeya; a genus of the class Diœcia, order Monadelphia .- GENERIC CHARACTER. Male. Calix : ament ovatecylindric, imbricate, with very many woody short scales, each terminated by a lanceolate, acute, coriaceous leaflet, concave at bottom, narrower and recurved at top; perianth none. Corolla: none. Stamina : filamenta none, except the amentaceous scales. Antheræ ten or twelve, heaped about each amentaceous scale, linear, grooved, the length of the scale, fastened to the top of it below the leaflet by the upper extremity, approximating and converging round the scale, separating by the lower extremity when the scale is broken. Female. Calix : ament large, roundish, ovate, closely imbricate, with very many germina, resembling scales; perianth none. Corolla: none. Pistil: germen each wedge-form, oblong, subcompressed, contracted at the base into a point, with a broad, thick, callous termination; style none; stigma bivalve, the valves unequal, the inner very small, obtuse, the outer very large, broad at the base, thick, curved inwards above the inner one, terminated by a linear, acute, slender, ascending strap, almost the length of the germen, beut in at a right angle above it. Pericarp : none. Seeds : very many, heaped into a roundish strobile, imbricate, each oblong, subcyliudric, towards the base obtusely four-cornered, with a short broad spatulate wing or strap at the top, thickened at the edge, incurved, ascending ; the shell coriaceous, coloured, valveless; the kernel oblong, subangular at the base. Receptacle : naked, villose, here and there alveolate. ESSEN-TIAL CHARACTER. Male. Calix: of the ameut scales, terminated by a leaflet. Corolla: none. Anthera: ten or twelve without filamenta. Female. Calix: ament with many germina. Corolla: none. Stigma: bivalve, unequal. Seeds: many, in a roundish strobile .---- The only species hitherto discovered is,

1: Dombeya Chilensis. Turbinate imbricate leaves, mucronated on one side; the branches quaternate and cruciate. This tree is very little known—It is a native of Chili, of a resinous nature, in some respect allied to proteat, and also to the pines, in some particulars of its fructification; the trusk is straight, and of considenable height; the wood white, solid, and clothed with a kind of double bark; the boughs are covered with very manerous leaves, sessile, oval, very pointed, crite, smooth, and coriaceous, a little concave inwards, and convex outwards, they have a sharp point, and are ranged on the branches in the manner of scales; it the flowers are made and finnale, forme ou different individuals, and languig in solitary catikus from the tops of the branches.

Donatia ; a genus of the class Tetrandria, order Trigynia. -GENERIC CHARACTER. Calix : perianth three-leaved ; leaflets awl-shaped, short, remote. Corolla : petals nine, or

eight to ten, linear, oblong, twice as long as the cair, spreading. Stamina: filamenta three, awi-slaped, the length of the calix. Antheræ tubglobular, twin. *Pistil:* germen inferori styles three, filform, a little longer than the stamina; stigmas blantish. ESSENTIAL CHARACTER. *Calix:* three leaved. *Petals:* nine, twice as long as the calix, linear, oblong. Antheræ subglobular, twin.——The only known species is,

 Donatia Fascicularis. This is a simple undivided plant, a finger's length, with imbricate leaves.—Native country unknown.

Dorean: a genus of the class Pentandria, order Monogynia-GENERER. Calkr. Perianth one-leafed, five-cleft, shorter than the corolla; divisions ovate, concave. Corolla: one-petalled, subcylindric, wheel-shaped; border five-cleft; segments ovate, obtuse, erect. Stamina: flamenta very short, so as to be scarcely any, inserted into the tube of the corolla. Anthere oblong, subquadrangular, included. Pistil: gemen conie, smooth, superior; style filform, the length of the corolla; stigma truncate, emarginate, Pericary: capsule ovate, acute, one-celled. Seeds: very many. ESSENTIAL CHARCTER. Corolla: five-cleft. Stigma: emarginate. Capsule: one-celled.——The only socies hitherto discovered is.

1. Dorzena Juponica. A tree about six feet high; branches alternate; round, ash-coloured, smooth, divaricate; leaves alternate, petioled, oblong, acuminate, remotely and obscurely serrate, perved, smooth, spreading, the length of a finger; petioles semicylindric, grouved on the upper part, smooth, half an inch in length, flowers in racenes, white, minute; racenes axillary, scarcely half an inch long; capsule the size of a pepper-corm.—Native of Japan.

Doronicum ; a genus of the class Syngenesia, order Polygamia Superflua, - GENERIC CHARACTER. Calix : common, with leaflets lance-subulate, about twenty in number, equal, upright, of a double series, length generally of the rays of the corolla. Corolla: compound, rayed; corollules hermaphrodite, tubular, numerous in the disk ; females ligulate, of the number of calicular leaves in the ray; proper of the hermaphrodite funnel form; border five-cleft, patulons; female ligulate, lanceolate, three-toothed. Stamina : in the hermaphrodites; filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: in the hermaphrodites, germen oblong; style filiform, length of the stamina; stigma emarginate: in the females, germen oblong; style filiform, length of the hermaphrodites; stigmas two, reflex. Pericarp: noue; calix slightly converging. Seeds: in the hermaphro-dite solitary, obovate, furrowed, a little compressed; down hairy: in the females solitary, obovate, furrowed, a little compressed ; down none. Receptacle : naked, flat. ESSEN-TIAL CHARACTER. Calix: scales in two rows, equal, longer than the disk. Seeds: of the ray naked, and destitute of down ; down to those of the disk simple. Receptacle: naked .---- The species are,

1. Doronicum Pardalianches: Great Leopard's Bank, Leaves cordate, obtuse, toolheited, those next the root petioled, on the stem embracing; roots thick, fleshy, divided into many knots, sending out strong fleshy fibres, which penetrate deep into the ground; root-leaves heart-shaped, hairy, petioled; among these arise the flower-stalks, which are channelled and hairy, nearly three feet high, putting out one or two snatler stalks from the side; these grow erect, and have one or two heart-shaped leaves closely embracing the stalk; this and each branch is terminated by one large yellow flower, which appears in May, and ripens seed in July.—Native of Fance, Switzerland, Germany, Austria, Carniola,

469

Hungary, and Savoy. It is always found near houses, and has been stigmatized as poisonous without much occasion, although it derives its name from this imaginary noxious quality. The famous Conrad Gesner, however, took two drachms of it without injury ; and some say that it is an antidote to poison, which is still farther from the truth. It is not used in the present practice ; and Dr. Stokes informs us, that two drachms occasioned a sense of inflation in the stomach, and also of general weakness, but that these symptoms were only of short duration ; he adds, that it has been recommended in vertigo, epilcpsy, and meustrual obstructions, but that these powers want the confirmation of a more accurate experiment. It multiplies very fast by its creeping roots, aud if the seeds be permitted to scatter, they will produce plants wherever they happen to fall, so that it becomes a weed where it is ouce established: it requires a moist soil and shady situation.

2. Doronicum Plantagineum ; Plantain-leaved Leopard's Bane. Leaves ovate, acute, somewhat toothed ; branches alternate; the stalks rise about two feet high, each is terminated by a large yellow flower, which have two or three alternate embracing leaves, not so hairy as those of the first species .- Native of Germany, France, Spain, and Portugal. This is equally hardy with the first, and multiplies abundantly.

3. Doronicum Bellidiastrum; Daisy-leaved Leopard's Bane. Stem naked, very simple, one-flowered. This, like the two preceding, has a perennial root; the leaves are like those of the common daisy, but longer, and not so broad; the flower grows on a naked stalk, nearly a foot long, and the root seldom sends out more than one stalk; the ray of the flower is white, very like that of the common daisy; disk yellow. Haller found it in the Lower Alps with a deep red flower .- Native of the Swiss, Tyrolese, and Italian Alps, and of Austria, Carniola, and Silesia. This species is propagated by parting the roots, for the seeds do not ripen well in England; it must have a shady situation, and a moist soil; the flowers do not make a much better appearance than those of the common daisy, only they stand on much taller stalks,

Dorstenia ; a genus of the class Tetrandria, order Monogynia.-GENERIC CHARACTER. Calix: receptacle common, one-leafed, flat, cornered, very large, covered by the receptacle, with very numerous floscules inhabiting the disk very small; perianth proper, four-cornered, concave, imbedded in the receptacle, and united with it. Corolla: none, Stamina : filamenta four, filiform, very short. Antheræ roundish. Pistil: germen roundish; style simple; stigma obtuse. Pericarp: none; receptacle common, becoming fleshy. Seeds : solitary, roundish, acuminate. ESSENTIAL CHARACTER. Receptacle: common, one-leafed, fleshy, in which solitary seeds nestle. It will be difficult to obtain these plants, because the seeds are seldom to be found good, nor will they grow, if they be kept long out of the ground ; so that the only sure method to obtain them, is to have the roots taken up at the time when their leaves begin to decay, and planted pretty closely in boxes of earth, which may be brought very safely to England, provided they be preserved from salt water, and are not too often supplied with fresh during their passage. As soon as they arrive, each of them should be transplanted into a separate pot, filled with fresh earth, and plunged into the bark-stove, which should be kept of a moderate heat: they must be frequently refreshed with water during the summer season, but in winter, when their leaves are decayed, it should be more sparingly given. These directions will enable any one who conforms to them, not only to maintain, but increase the plants, by parting their three quarters broad, having four acute corners; these have 40.

roots in the spring, before they put out their leaves .---- The species are.

1. Dorstenia Houstoni. Scapes rooted; leaves heart-shaped, angled, acute; receptacles quadrangular. It scuds out the leaves upon footstalks eight or nine inches in length, and very slender; the leaves are about three inches and a half long, and almost four broad at their base, the two ears having two or three angles which are acute, and the middle of the leaves are extended, and end in acute points like a halbert; they are smooth, and of a lucid green; the footstalk which sustains the placenta is nine inches long, and about half an inch square, and the upper surface closely set with small flowers. -Native of Campeachy, in South America.

2. Dorstenia Contraverva: Jamaica Contraverva. Scapes rooted ; leaves pinnatifid-palmate, serrate ; receptacles quadrangular. It sends out several leaves from the root, which are about four inches long, and as much in breadth; these are deeply laciniated into five or seven obtuse parts, standing upon footstalks nearly four inches long; they are smooth, and of a deep green ; the stalks arise from the root, and grow nearly four inches high, upon which the fleshy placenta is vertically placed, this is of an oval form, about one inch long, and three quarters broad; upon the upper surface of this the small flowers are closely situated, the fleshy part becoming an involucre to them; they are very small, and very indistinct at a distance, being of an herbaceous colour: the roots and seeds of this plant are excellent aromatics, and alexipliarinics or counter poisons, and cure the bites of serpents, and stings of scorpions, or black spiders. A decoction of the root in water, is also good in dropsies, and debilitations, or taken as a bitter in wine, with the addition of steel. The root, says Motherby, has a light aromatic smell, and a very pungent bitter taste; it promotes perspiration, resists putrefaction, and is an excellent medicine in malignant, low, and putrid fevers. Meyrick recommends it for strengthening the stomach and digestive faculties, dispersing wind, easing the colic, and is excellent in the decline of ardent fevers, and through the whole course of putrid ones. Hill remarks, that we use the roots ; he adds, our druggists keep them, and they are the principal ingredients in that famous powder, called, from its being rolled up into balls, lapis contrayerva. It is an excellent cordial and sudorific, good in fevers, and in nervous cases, and against indigestions, colics, and weaknesses of the stomach : it may be taken in powder, or in tincture, but it is better to give it alone than with that mixture of crab's claws, and other useless ingredients, which are compounded in the contrayerva-stone. In fevers and in nervous disorders, it is best to give it in powder; in weaknesses of the stomach it is best in tincture, and is also an excellent ingredient in bitter tinctures, so that it is wonderful that the present practice has not put it to that use. All the old prescribers of recipes for these things have put some warm root into them, but none is so proper as this, although the galangale is the most commonly used ; but that has a very disagreeable flavour in the tincture, while the contrayerva, with equal or superior virtues, is entirely free from that defect.

3. Dorstenia Drakena. Scapes rooted ; leaves pinnatifidpalmate, quite entire ; receptacle oval. This plant sends out leaves of different forms, some of the lower ones are heartshaped, having a few indeutures on their edges, and ending in acute points, but the larger leaves are deeply cut, like the fingers on a hand, into six or seven acute segments. These leaves are five inches long, and six broad in the middle, they are of a deep green, and stand upon long footstalks; the placenta is very thick and fleshy, an inch and a half long, and 6 D

a number of small flowers placed on the upper surface, like the other species.—Native of Vera Cruz, and Tobago; whence, Mr. Miller informs us, all the three species are brought over, indifferently to be used in medicine and in dyeing; and that it was not known what the plant was, the roots of which were imported, and had been long used in medicine, until Dr. Houston informed us.

DRA

4. Dorstenia Caulescens. Peduacles on a stem. This is a small plant, the leaves of which proceed irregularly from the stem, which is short; the leaves are ovate acute, and pretty strongly dentated at the edges; the male flowers are collected into little heads, and the females into a kind of sharply lobed or irregular flattish heads, they stand upon remarkably long footslatks.—Native contry unknown.

5. Dorstenia Lucida. Caulescent: leaves obliquely ovate, entire, even; peduncles in cymes, axillary.-Native of the Society Islands.

6. Dorstenia Pubescens. Caulescent: leaves obliquely ovate, serrate, pubescent; peduncles axillary, bearing heads. Native of the Society Islands.

7. Dorstenia Cordifolia. Scapes rooting ; leaves cordateovate, toothletted; veceptacles orbiculate; disk a little concave; male flowers in the disk, towards the ray; calices immersed in the receptacle, or four-toothed hole; filamenta two, three, or four, short, with twin anthera; flowers in the middle of the disk, female; germen ovate; style bifid; stigmas reflex,—Naitve of Jananica, and St, Domingo.

8. Dorstenia Chinensis. Peduncles cauline; petioles three of five-leaved; root fasiform, three inches long, white within and without, fleshy, aromatic; stem perennial, sub-rect, round, simple, whitis; leaves ternate or quinate, lancolate, quite entire, sunoth, on a long common petiole; receptacle of the dowers lateral, fleshy, suboval, with many florets put forth at the top; the calix is funnel-form, and three-toothed; the root is aromatic; and used in medicine.

Dove's foot Crane's-bill. See Geranium.

Douglassia ; a genus of the class Polyadelphia, order Polyandria,-GENERIC CHARACTER. Calix: perianth oneleafed, turbinate, half six-cleft, permanent; segments ovate, acute, coloured. Corolla : none ; nectaries six, ovate on the outside, with two oblong pits on the inside convex; anthera bearing, terminated by two glands, convex without, concave within, ending at bottom in a capillary pedicel, shorter than the calix, inserted at the base of the segments, with a villose gland on each side at the insertion of it. Stamina : filamenta none. Antheræ very many, minute, one-celled, with the valve opening at the base. Pistil: germen ovate, superior; style filiform, the length of the stamina; stigma six-cleft. Pericarp : berry ovate, acute, one-celled. Seed : single, with a brittle shell. ESSENTIAL CHARACTER. Calix: half sixcleft. Corolla: none. Nectaries : six ; filamenta none ; germen superior; stigma six-cleft; berry ovate, one-celled. Seed : one, with a brittle shell .---- The only known species of this genus is,

 Douglassia Guianensis; Guiana Douglassia. With alternate lanceolate leaves. This is a middling-sized shrub growing in Guiana; it is about five feet high, and branching at top, its diameter five or six inches; the wood white and compact; the branches are subdivided into smaller ones; and the flowers grow at their extremities in a kind of stragging clusters, they are small and yellowish.

⁵ Drade; a genus of the class Terindynamia, order siliculosa, obtained admittance. Lineus observes, that it hangs down —GENERIC CHARACTER. Calix; perinath four-leaved; the flowers in the night and in wet weather; that in Sonleaflets orate, concave, from erect spreading, deciduous, land they sow rge when this plant is in blossom, and that Corollar: four-petalled, cruciform; petals oblong, somewhat in dry soils whole fields are covered with the flowers early in spreading, with very small claws. Stamine; filamenta six, the spring. In England it is common upon walls, dry banks;

length of the calix, of these the four opposite ones somewhat longer, from creect spreading. Antherae simple. *Piciti*: germen ovate; style scarcely any; stigma headed, flat. *Pericarp*: silicle elliptic, oblong, compressed, entire, destitute of style, two-celled; disseptiment parallel with the valves; valves plano-concave. *Steds*: several, small, roundish. Es-SENTIAL CHARACTER. *Silicle*: entire, ovate, oblong; valves flattish, parallel to the disseptiment. *Style*: none.-If the seeds of any of these plants, except the first, second, third, or fifth, be sown in autumn in a shady border, the plants will come up in the spring; or where the seeds are permitted to scatter, the plants will rise without any trouble. Some of them are peculiarly adapted to adom rock-work, and they all prosper best in that situation -----The species are,

1. Draba Aizoides; Hairy-leaved Alpine Whitlow Grass. Scape naked, simple; leaves ensiform, keeled, ciliate; root perennial; stem three inches high; petals entire; silicle hairy, rough, ovate, sharp at both ends, ending in a long style, four lines in length, the cells having six to eight seeds, which are round and flatted : flowers in a sort of corymb, which becomes a raceme when the fruit is ripe ; petals yellow, usually entire. It is well adapted to rock-work, and is a pretty plant with a pleasant smell .- Native of the mountains of France, Switzerland, Savoy, Austria, Carniola, and Silesia. This, with the second, third, and fifth species, are easily propagated by parting the heads in autumn, for they shoot up to flower very early in the spring; they will thrive, and flower annually, in a moist soil and shady sitnation, and require no other culture but to be kept clean from weeds.

2. Draba Ciliaris. Stem almost maked; leaves linear, ciliate about the edge and along the keel; petals enlire; root pereminal; root-leaves forming a close tufi, imbritate, crowded, even, keeld, distinctly ciliate; peduncie naked, the length of the stem, fiftorm, for-lowered; flowers terminating, subsessile; leaf-lets of the calix erect, almost equal, hanceolate, obtuse, green on the outside, yellowite on the inside; greemen ovate, longer than the stamma.—Native of Provence, in dry rocky piaces. See the preceding species.

3. Draba Alpina. Scape naked, simple; leaves lancedate, quite entire; petals emarginate; perennal; all the root-leaves spreading, sprinkled with hairs on the upper surface, by no means imbricate, linear, ciliate or smooth on the upper surface; stem leafles, with a few hairs scattered about it, not one-leafled or smooth; petals slightly emarginate, not entire, -Native of the European Alps. See the first species.

4. Draba Verna; Common or Spring Whitlow Grass. Scapes naked; leaves somewhat serrate, often very entire; petals divided ; root annual ; stems about three inches high, one to five or more from the same root, in a rich soil, smooth after flowering, but hairy when young; peduncles alternate, bearing one flower only; leaflets of the calix obtuse, and somewhat hairy ; corolla petals white, twice the length of the calix, two-parted; filamenta bending forward, the four longer ones the height of the pistil; seeds ovate, brown, fixed to the edge of the partition, from three to six in a cell, according to Scopoli, but sometimes as many as twenty-four; by these it propagates itself with such amazing rapidity, that it is a weed which it is hardly possible to eradicate wherever it has obtained admittance. Linneus observes, that it hangs down the flowers in the night and in wet weather; that in Smoland they sow rye when this plant is in blossom, and that in dry soils whole fields are covered with the flowers early in fields, and pastures, flowering in March and April, or earlier | numerous, hoary ; silicles oblong, oblique, subsessile ; root if the weather be mild. In some countries abundance of this little plant is supposed to prognosticate dearness of corn, which may have some foundation, as a wet season produces a great crop of this little weed, which some say is much liked by the sheep. Gerarde calls it whiteblowe, or whitlowe-grasse, or naile woort. This small plant may serve as an index of the difference of climates: for in Sweden it flowers in the month of April ; in Germany a month earlier ; in England, Holland, and France, in February ; while in the genial air of Sicily it flowers throughout the winter.

5. Draba Pyrenaica. Scape naked ; leaves wedge-shaped, palmate, three-lobed. It is a perennial plant, seldom more than two inches high, with a shrubby stalk dividing into many small heads; leaves small, the lower ones have five short narrow lobes, the upper have but three; the flowers come out in clusters, sitting close to the leaves, they are of a bright purple colour, and appear early in the spring; root creeping, putting out erect branching shoots, which at the end bear thick, shining, stiffish, spreading leaves, half threelobed, narrowed at the base into a sort of half-embracing erect petiole, marked with three lines; the lobes spreading, oblong, sharpish, ciliate at the tip, and interruptedly on the edge .- Native of the mountains of Switzerland, in the canton of Appenzel, Provence, Carniola, Austria, and Piedmont; flowering in May. For its propagation and culture, see the first species.

6. Draba Muralis ; Wall Whitlow Grass. Stem branched ; leaves ovate, sessile, toothed ; root annual ; root-leaves entire at the base, toothed upwards; stem-leaves rather heart-shaped; fruit-bearing peduncles horizontal, longer than the silicles; corollas pale yellow, or white, with the petals slightly emarginate; silicles exactly elliptic, ending in a short blunt knob; seeds reddish brown. It rises with an upright branching stalk about ten inches high; leaves heart-shaped, indented, embracing; the stalks are terminated by loose spikes of white flowers, which appear in the beginning of May. The wood variety being sown in a garden, became so like it as not by any means to be distinguished, the yellow flowers becoming white .- Native of Sweden, Switzerland, Germany, the south of France, and of Italy, in the fissures of rocks. Mr. Ray found it near Montpellier, and between Lucca and Pisa, in hedges. In England, it is met with in Derbyshire, Yorkshire, and Westmoreland, and is common about Malham.

7. Draba Hirta, Scape one-leafed ; leaves subhirsute ; silicles oblique, pedicelled; petals white, emarginate, perennial; rootleaves elliptic, smooth, ciliate, tongue-shaped; stem-leaves sessile, ovate-acuminate, having only two teeth: it varies in the leaves, which are sometimes only smooth and ciliate, only about the edge, or bairy all over, and hoary, sometimes toothed, and at other times entire.-Native of Lapland, Denmark, Provence, Switzerland, Silesia, Austria, and Piedmont, in the fissures of the rocks, flowering in May.

8. Draba Fladnizensis. Scape two-leaved ; leaves smooth, ciliate ; silicles straight, pedicelled ; root fusiform, perennial ; root-leaves forming roses, lanceolate, bluntish, quite entire, flat, shining, smooth, firm, ciliate, with distant hairs; stems from the centre of the roses, erect, undivided, slender, an inch high, naked, they have one or two sessile, lanceolate, smooth, entire leaves on them, villose, ciliate on the edge; raceme terminating, few-flowered; flowers from five to eight, pedicelled; calicine leaflets naked, half the length of the petals, green; petals snow-white, slightly emarginate; filamenta awl-shaped, white, with ovate yellow antheræ; silicle naked: it has no scent .--- Native of Carinthia.

9. Draba Incana; Hoarn Whitlow Grass. Stem-leaves tive of the East Indies, and the Society Isles.

biennial; root-leaves very numerous, spreading like the flower of a rose, lanceolate, tomentose, and somewhat hairy, entire, acute; stem a hand in height, straight, and stiff, hoary, clothed with many leaves, frequently more than thirty, very like the root-leaves, but shorter, so that the uppermost are ovate, sessile, and have a few teeth, on the lower part of the stem they are more crowded; flowers in a small terminating corymb; petals white, obscurely emarginate; silicles in a raceme, erect, ovate-oblong, oblique, twisted in a direetion contrary to the sun's diurnal motion, compressed, naked ; peduncles hoary, three times shorter than the silicles, stiff, approaching to the stem .- Native of Lapland, Sweden, Denmark, Norway, Britain, as in Westmoreland, Yorkshire about Settle, and near the summit of Ingleborough, in the Scottish islands of Isla and Skye, and in Caernaryonshire, North Wales, It flowers in May and June.

Dracæna ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix : none. Corolla : petals six, oblong, somewhat upright, equal, cohering by the claws. Stamina : filamenta six, inserted into the claws, subulate, thicker in the middle, membranaceous at the base, length scarcely of the corolla. Antheræ oblong, incumbent. Pistil: germen ovate, six-striated ; style filiform, the length of the stamina; stigma three-cleft, obtuse. Pericarp: berry ovate, six-furrowed, three-celled. Seeds : solitary, ovateoblong, incurved at the tip. ESSENTIAL CHARACTER. Corolla : six-parted, erect; filamenta somewhat thicker iu the middle ; berry three-celled, one-seeded. For the propagation and culture of this species, see Palms. — The species are, 1. Dracæna Draco; Dragon Tree. Arboreous: leaves

somewhat fleshy, with a thorny eud. This rises with a thick trunk, nearly equal in size the whole length, the inner part very pithy, next to this a circle of strong fibres, and the outside soft, height twelve or fourteen feet; the trunk is marked with circular rings where the leaves are fallen off, and the top sustains a large head of leaves coming out singly all round it; they are shaped like those of the common iris, but are much longer, being often four or five feet in length, and an inch and a half broad at their base, where they embrace the trunk, they lessen gradually, and terminate in a point; these leaves are also pliable, hanging down, entire, of a deep green, smooth on both surfaces. It is called dragon's-tree, because the inspissated juice becomes a red powder, very like the Eastern dragon's blood. - Native of the East Indies.

2. Dracæna Ferrea ; Purple Dracæna, Arboreous ; leaves lanceolate, acute; stem shrubby, almost simple, eight feet high, erect, round, with close protuberant rings from the fallen leaves : these are quite entire, a foot and a half in length, erect, smooth, on stem-clasping petioles, and of a dusky red colour; flowers red purple, subterminating; spadix diffused; spathe long, awl-shaped, permanent; corolla bell-shaped, six-parted, inferior; segments oblong, obtuse, spreading; antheræ sagittate, sharp, and bifid at the end; style awl-shaped, thick, trifid, equal to the stamina; stigmas simple ; berry red .- The Chinese call it tat-sio or tsict-tsao. and, as well as the Cochin-chinese, plant it in their gardens. It flowers in March and April,

3. Dracæna Striata. Frutescent, caulescent, erect : leaves lanceolate, obliquely sickle-form, striated; stem flexuose,----Native of the Cape of Good Hope.

4. Dracæna Terminalis. Herbaceous, caulescent ; leaves lanceolate ; raceme terminating, composed of a few branches ; pedicels alternate, solitary, shorter than the flower, surrounded at the base by an obtuse glume. It is a hardy tree,-Na-

5. Dracæna Ensifolia: Sword-leaved Dracæna, Herbaceous, subcaulescent: leaves ensiform; root perennial, horizontal, creeping, somewhat woody, odoriferous, simple; rootleaves heaped, thick, striated, shiuing, reflex, a foot long; scape three feet high, leafy at bottom, naked at top, round, slender, declining; flowers terminating, subumbelled; corolla hell-shaped, spreading; petals lanceolate, blue on the outside, white within, small; filamenta spreading, dilated at the base ; berry roundish, blue, three-grooved, containing many minute seeds .- Native of the East Indies, and Cochin-china.

6. Dracæna Undulata. Herbaceous, caulescent, erect: leaves ovate, acute, many-nerved; flowers axillary, peduncled .- Native of the Cape of Good Hope.

7. Dracæna Medeoloides. Herbaceous, twining: leaves ovate, nerved .- Native of the Cape of Good Hope.

8. Dracæna Erecta. Herbaceous, caulescent, erect: leaves lanceolate, subulate, sessile,-Native of the Cape of Good Hope.

9. Dracæna Volubilis. Herbaceous, twining: leaves lanceolate .- Found at the Cape of Good Hope.

10. Dracæna Graminifolia, Herbaceous, stemless : leaves linear; scape scarcely longer than the leaves; four or five flowers at each tooth of the raceme, on pedicels shorter than the flower itself, coming out from a kind of obscure glume,---Native of Asia.

11. Dracæna Emarginata; Aloe-leared Dracæna. Shrubby: leaves tooth-spiny; racemes axillary; berries manyseeded .--- Native of the Isle of Bourbon.

12. Dracana Boyealis; Oral-leaved Dracana. Herbaceous, subcaulescent: leaves elliptic .- It flowers in June, and is a native of Newfoundland.

13. Dracæna Indivisa. Arboreous: leaves ensiform, acute; raceme compound ; trunk round, full of small chinks, undivided, leafy at top, from six to nine feet high; raceme apparently lateral, but perhaps this was owing to the next set of leaves destined for the ensuing year coming out; it is ovate, nodding, with the partial racemes digested into a cylindric thyrsoid form ; pedicels one-flowered, very short, horizontal ; bractes at the base of the pedicel, two, very small, lanceolate, acute, concave; petals subreflex; germen superior; style short; berry globular, blue, marked above with three hollow dots, mucronate, with the permanent style, having about seven seeds in each cell, involved in an aril or membrane. so ts to appear only one; they are black, smooth, semilunar, and three-sided; the berries of this species are eaten by the New Zealanders, they are ripe in May, that is, at the beginning of their winter; the young leaves, or rather the hybernacle concealed among them, is an excellent salad, which, together with the areca oleracea and sapida, apium graveolens, or smallage, tetragonia halimifolia, lepidium oleraceum and piscidium, and sonchus oleraceus, or sow-thistle, was found to be of great service to our navigators in resisting the putrid scurvy .- Native of New Zealand.

14. Dracæna Australis. Arboreous: leaves ensiform, acute; raceme terminating, crect, superdecompound .-- Native of New Zealand,

Dracocephalum; a genus of the class Didynamia, order Gymnospermia.-GENERIC CHARACTER. Calix : perianth one-leafed, tubular, permanent, very short. Corolla: onepetalled, ringent; tube length of the calix; throat very large, oblong, inflated, gaping, a little compressed at the back ; lip superior, straight, arched, complicated, obtuse; lip inferior, three cleft; lateral divisions upright, as it were the segments of the throat, the intermediate one hanging down, small, prominent, forwards at the base, roundish, emarginate. Stamina : filamenta four, subulate, hid beneath the upper lip are lanceolate, with bristly teeth, and are often red : corollas

of the corolla, of which two are a little shorter. Authera somewhat cordate. Pistil; genuen four-parted; style filiform, in the situation of the stamina ; stigma two-cleft, sharp, slender, reflex. Pericarp : none ; calix cherishing the seeds in its bosom. Seeds : four, ovate oblong, three-sided. Es-SENTIAL CHARACTER. Corolla: throat inflated, upper lip concave .---- The species are,

* In Snikes.

1. Dracocephalum Virginianum ; Virginian Dragon's Head. Flowers crowded; leaves linear-lanceolate, serrate, It rises with an upright stalk, nearly three feet high; leaves about three inches long, and half an inch broad, sessile: they are usually in pairs at each joint, but sometimes there are three together; the flowers are purple, in terminating spikes. and make a pretty variety among other hardy plants.-It is perennial, flowering from July to September, and a native of North America, in woods, and by the sides of rivers. It will live in the open air of our climate, but requires a moist soil in dry weather, otherwise the leaves will shrink, and the flowers make little appearance. It may be allowed a place in the shady borders of a garden, for it will not ramble nor take up much room, and may be propagated by parting its roots in autumn.

2. Dracocephalum Denticulatum ; Denticulated Dragon's Head. Flowers remote; leaves obovate-lanceolate, denticulate above. It is allied to the first species, but is inferior in point of beauty; it spreads more on the ground, and its flowering stems are broader, and the flowers in the spikes less numerous .- It flowers in August and September, and is a native of North America. Like the first, it is a hardy perennial, multiplying considerably by its roots, which creep in some degree : it requires a moist soil and a shady situation

3. Dracocephalum Canariense; Canary Dragon's Head, or Balm of Gilead. Leaves compound. This plant is perennial, rising with several stalks to the height of three feet or more, and becoming woody at the lower part; the flowers come out on short thick spikes at the top of the stalks, they are of a pale blue colour, and are produced from July to September; the corolla is flesh-coloured, or pale purple with white lines .- Native of the Canary Islands, whence it was imported into Europe, under the name of permento de tana: the old writers call it camphorosma, and cedronella; and the moderns, balm of Gilead, from its rich odour on being gently rubbed. It is usually kept in the green-house, but in mild winters the plants will live abroad in warm borders, and those which are kept in pots will thrive much better when sheltered under a frame, than in a green house, where the plants are apt to draw up weak, for they require as much free air as possible in mild weather, and must be sheltered from severe frost. This species may be propagated by seeds. which if sown in autumn will more certainly grow than those which are sown in the spring; but if these be sown in pots, they must be sheltered under a frame in winter, and if the plants do not come up in the same autumn, they will rise in the spring; but if the seeds are sown in the full ground, it should be in a warm border, and they should be defended from hard frosts, otherwise the young plants will be destroved. They may also be propagated by cuttings, which if planted in a shady border any time in summer, will very soon take root, and furnish plenty of rooted plants.

4. Dracocephalum Pinnatum. Leaves cordate, pinnate, sinuate; stems shrubby, decumbent; leaves transversely pinnatifid, obtuse, with remote lobes, on long petioles. The spike is like that of the melampyrum arvense. The bractes

472

katsch in Siberia. 5. Dracocephalum Peregrinum ; Prickly-leaved Dragon's Head. Flowers somewhat spiked ; stem-leaves ovate, oblong, gashed ; bractes linear, lanceolate, denticulate, spiny ; root perennial; stems several, a long span in length, with the joints an inch asunder; leaves like those of the common hyssop or rosemary, moderately hoary underneath : from the axils of these come out branches with similar leaves, but smaller, and flowers at the end, with rigid calices, and corollas of a very elegant blue purple colour; seeds oblong, angular, blackish .- Native of Siberia.

DRA

6. Dracocephalum Austriacum ; Austrian Dragon's Head. Leaves and bractes linear, parted, spiny; root perennial; stalks hairy, a foot and a half high, sending out several sidebranches; flowers terminating in short whorled spikes, with some very narrow leaves or bractes under each whorl. This, says Jacquin, is a beautiful plant, and grows in Austria, where it was first observed by Clusius. The stems, which vary in number according to the soil, are annual, squarish, and villose; the leaves opposite, hoary below, smooth, and green above, and are deeply lobed, or cut in a pinnatifid manner. The flowers are axillary ou the upper part of the plant, commonly in pairs, sometimes in threes, and are of a violet purple colour, paler without .- Native of Austria and Hungary. This, and the seventh and eighth species, will be best propagated by seed, which should be sown in the latter end of March, in a bed of fresh light earth, in an open exposure, and in about five or six weeks after, the plants will appear, when they should be carefully cleared from weeds; and, if the season should prove dry, they must be refreshed now and then with water, which will greatly promote their growth. When the plants are about two inches high, they should be carefully transplanted into a bed or border of fresh, light, undunged earth, observing to shade them from the sun until they have taken root, as also to refresh them with water until they are well established in this bed ; after which time, they will require no farther care, but to keep them constantly clear from weeds till Michaelmas, when they are to be removed into the places where they are finally to remain. When they are first removed from the seed-bed into the nursery-bed, they should be planted six inches asunder every way, which will be sufficient room for them the first season ; and this will admit of the hoe to come between the plants to destroy the weeds, which is safer than pulling them up by hand, as well as sooner performed : for as the hoe stirs the ground between the plants, it not only cuts down the weeds which were up and visible, but also destroys all those whose seeds were sprouted, and would soon after have appeared; so that one hoeing, if well performed, and in dry weather, will more effectually destroy the weeds, than two hand weedings would do, were they performed ever so carefully; besides, the stirring the ground is of great service to the plants. At Michaelmas, when they are transplanted for good, they should be carefully taken up with balls of earth to their roots. and planted in fresh light earth in the middle of the borders of the pleasure garden, where, when intermixed with other hardy plants of the same growth, they will make a pretty appearance when they are in flower, and will continue three or four years, and have been known to live six or seven years in stony soils, where, however, the spikes of flowers are neither so large nor so vigorous as those of younger plants. Hence, as these plants do not continue many years, it will be proper to raise a supply of young plants to succeed them, for the old plants will produce seed plentifully, which are ripe the latter end of August, or the beginning of Septem- survive two or three years in a dry soil. There is also a va-40.

small; styles twice as long as the flowers .- Native of Jer- | ber, when they should be gathered in dry weather, and kept in a warm dry room ready for use.

7. Dracocephalum Ruyschioma; Hyssop-leaved Dragon's Head. Leaves and bractes lanceolate, undivided, awnless; root perennial; stems about two feet high, with two smooth linear leaves at each joint, about an iuch long, and one eighth of au inch broad, with a deep furrow along the middle; at each joint, at the other sides of the stem, come out two or three very narrow small leaves of the same shape, The calices are cut into five segments at top, of which, four are narrow and acute, and the fifth, which is on the upper side of the flower, is broader, and rounded at the point. The tube of the corolla is longer than the calix, swelling, and large at the chaps; the upper lip broad, erect, and arched over the tube, the lower shorter, with two short, erect, side segments; but the middle segment is broad, rounded, and indented at the point, and reflex. The flowers appear in June, and are of a fine blue colour .- Native of Norway, Sweden, Switzerland, and Siberia. For its propagation and culture, see the sixth species.

** In Whorls.

8. Dracocephalum Sibiricum; Siberian Dragon's Head. Flowers subverticilled; peduncles bifid, pointing one way; leaves cordate, oblong, acuminate, naked. The stalks of this species do not grow erect, like the preceding, but spread nearer to an horizontal position; they divide into several branches, which have a pair of large leaves at each joint, and four smaller, two on each side; they are smooth, have sharp indentures on their edges, and stand erect. The flowers come out from the side of the stalks, at the base of the leaves. two or three together, on each side; calix purple, cut into five acute segments, three broad in the upper lip, two narrower in the lower; upper lip of the corolla broad, indented at the point, and erect, lower trifid, but the middle segment not so much reflexed as that of the preceding, and the whole of a paler blue. The chaps of the corolla are broad, and almost inflated; the upper lip is compressed and bifid, the lower toothletted, and villose in front; the two upper stamina are hirsute at the base .- Native of Siberia. For its propagation and culture, see the sixth species.

9. Dracocephalum Moldavica ; Moldavian Dragon's Head, or Balm. Leaves dotted underneath; bractes lanceolate, the serratures capillaceous. This is an annual plant, rising with branching stalks, a foot and a half high, with oblong leaves, deeply serrate on their edges. The flowers come out in whorls round the stalks at every joint, are blue, appear in July, and continue to the middle of August. The seeds ripen in September. It has a strong balsamic odour, which is very agreeable to some persons .- Native of Moldavia. This, with the tenth, eleventh, twelfth, thirteenth, and fourteenth species, may be propagated by seeds, sown either in the spring or autumn, in small patches upon the borders where they are to remain. When the plants come up, they should be thinned where they grow too near together, and kept clear from weeds

10. Dracocephalum Canescens; Hoary Dragon's Head. Bractes oblong, with spiny serratures; leaves subtomentose. The stalks are hoary, a foot and a half high, putting out two or three side-brauches, with hoary leaves, uearly two inches long, and half an inch broad, a little indented on their edges; they are placed just under the whorls of flowers which sit close to the stalk ; the corolla is large, of a fine blue colour, and makes a pretty appearance among the hoary leaves. It flowers and seeds about the same time as the foregoing sort, and is generally treated as an annual, although the roots will 6 E

riety with white flowers .- It was discovered by Tournefort in the Levant. For its propagation and culture, see the tenth species.

DRA

11. Dracocephalum Peltatum : Willow-leaved Dragon's Head. Bractes orbiculate, serrate-ciliate. This is an annual plant, about a foot high, sending out two small branches from the lower part ; leaves lanceolate, crenate, petioled ; flowers small, purplish .- Native of the Levant. For its propagation and culture, see the tenth species.

12. Dracocephalum Grandiflorum ; Great-flowered Dragon's Head. Leaves crenate; root-leaves cordate; stemleaves orbiculate, sessile; bractes acuminate, toothed; rootleaves like those of betony, petioled, obtuse, wrinkled, pubescent : stem-leaves almost wedge-shaped, rounded, very obtuse, crenate-toothed. The bractes and floral-leaves somewhat of a violet colour. The whorls have the flowers by threes on each side; calices subpeduncled, five-cleft; the three upper teeth less divided; corollas large, blue; the chaps much inflated, with a rising streak at the back on each side : upper lip bifid, lower trifid ; the middle segment larger, dark blue, reflex, bearded at the end; antheræ oblong .- Native of Siberia. For its propagation and culture, see the tenth species.

13. Dracocephalum Nutans; Nodding Dragon's Head. Bractes oblong, ovate, quite entire; corollas rather large, nodding. Annual; stalks weak, many, about nine inches high, having at bottom ovate-lanceolate leaves, about two inches long, and an inch and a quarter broad, crenate, and on pretty long footstalks. The upper part of the stalk has smaller leaves, sitting close at the joints, and from these come out the flowers in whorls ; they are of a deep blue colour, and hang down, appear at the same time with the preceding, and the seeds ripen in autumn .- Native of Siberia. For the propagation and culture, see the tenth species.

14. Dracocephalum Thymiflorum; Small-flowered Dragon's Head. Bractes oblong, quite entire ; corollas scarcely longer than the calix ; stalks a foot and a half high ; lower leaves very like those of betony, standing upon very long footstalks; the upper small, sitting close to the stalks; the flowers come out in whorls at every joint ; they are of a pale purple or blue colour, and being small, make little appearance; seeds small, ovate-oblong, slightly convex on one side, angular on the other, dark chesnut colour .- Native of Siberia. See the tenth species.

15. Dracocephalum Cochin-chinense. Flowers in spikes : bractes roundish, acute ; leaves ovate-lanceolate, quite entire ; stem herbaceous, ten inches high, erect, grooved, villose; leaves villose, few; flowers violet-coloured, in terminating spikes ; bractes many-flowered ; filamenta hairy .- Native of Cochin-china.

Dracontium : a genus of the class Gynandria, order Po-Ivandria .- GENERIC CHARACTER, Calix: spathe boatform, leathery, one-valved, very large. Spadix : extremely simple, cylindric, very short, coated on all sides with fructifications, disposed into a head, of each of which the perianth proper none, unless you call the corolla so. Corolla : proper, five-petalled, concave; petals ovate, obtuse, somewhat equal, coloured; stamina in each filamenta seven, linear, depressed, upright, equal, longer than the corolla; antheræ four-cornered, twin, oblong, obtuse, upright. Pistil: germen somewhat ovate ; style columnar, straight, length of the stamina; stigma obscure, three-sided. Pericarp : in each a roundish berry. Seeds: very many. ESSENTIAL CHARAC-TER. Spathe; boat-form. Spadix; covered. Calix: none. Petals: five. Berries : many-seeded .---- The species are,

prooted, torn; leaflets three-parted; divisions pinnatifid. It has a large, knobbed, irregular root, covered with a rugged brown skin. The stalk rises about a foot high, is smooth and of a purple colour, full of sharp proinberances of different colours, shining like the skin of a serpent; it is naked to the top, where it has a tuft of leaves, which are divided into many parts. The flower-stalk rises immediately from the root, and is seldom more than three inches high, having an oblong swelling hood or spathe at top, which opens lengthwise, showing the short, thick, pointed style within, upon which the flowers are closely ranged. Mr. Miller received the roots of it from Barbuda .- It grows naturally in several of the islands of America, also in Surinam and Japan, where they prepare a medicine from the acrid roots, which they call konjakf, and esteem as a great emmenagogue, which dissolute women take to procure abortion. In the Society Islands, it is cultivated for the sake of the roots, which are eaten in a scarcity of the breadfruit, notwithstanding their extreme acrimony. This and the second species are tender. and require a warm stove to preserve them in England. The roots must be planted in pots filled with light kitchen-garden earth, and plunged into the tan-bed in the stove, where they should constantly remain; in the winter, they must be watered very sparingly, but should be often refreshed in warm weather, when they are in vigour. Their roots do not increase in our climate.

2. Dracontium Spinosum. Leaves sagittate; peduncles and petioles prickly. The root is oblong, thick, and full of joints, from which arise several leaves, shaped like those of the common arum; but their footstalks are covered with rough protuberances. The stalk which supports the flower is short, and set with similar protuberances; at the top is a spathe, about four inches long, as thick as a man's finger, which opens longitudinally, and exposes the spadix, which is set with flowers .- It grows naturally in the island of Ceylon, and in several parts of India. For its propagation and culture, see the preceding species.

3. Dracontium Fætidum ; Fetid Dragon, or Scunkweed. Leaves roundish. The flowers of this plant appear first; after they arrive to a state of perfection, the leaves come out at a small distance, in a conic form, very closely rolled together. They are nearly ovate when expanded, and petioled. The plant has no stem. The globe of flowers is nearly the colour of the spathe, which is beautifully variegated with scarlet and yellow. The corolla has four erect, very thick, narrow, obtruncated petals. The stamina have four flattish filamenta, rising from the receptacle, longer than the corolla; style rather longer than the stamina; stigma bifid; seeds large, roundish, single, inclosed within the receptacle .- Native of North America, where it is found in swamps, and upon the borders of meadows, flowering in April and May, The vulear names of scunk-cabbage and scunkweed, are taken from its rank smell, nearly resembling that of a scunk or polecat. The roots, dried and powdered, are an excellent remedy in asthmatic cases. It may be given with safety to children, in doses of four, five, or six grains; and to adults, in doses of twenty grains and upwards. It appears to be antispasmodic, and bids fair to be useful in many disorders. In collecting the roots, particular care ought to be taken, that the white hellebore, or pake-root, which some call scunkweed, be not mistaken for this. There is this obvious difference ; white hellebore has a stalk, the real scunkweed has none. Cattle will not touch it during summer. The Swedes, settled in North America, call it byorn-blad, or byorn-retter, (bear'sleaf, or bear's-root,) because the bears, when they leave their 1. Dracontium Polyphyllum. Scape very short; petiole winter quarters in the spring, are very fond of it.

DRO

4. Dracontium Camschatcense. roots of this species resemble the common arum, and the leaves come out, each on a separate footstalk, immediately from the root, as in that plant. It has never flowered in England, and is a native of Siberia, requiring a shady situation, and being fully able to bear the greatest cold in our climate.

5. Dracontium Pertusum ; Perforate-leaved Dragon. Leaves perforated ; stem climbing. This species has slender jointed stalks, which put out roots at every joint, that fasten to the trunks of trees, walls, or any support which is near them, and thereby rise to the height of twenty-five or thirty fect. The leaves are placed alternately, standing upon long footstalks ; they are four or five inches long, and two and a half broad, having several holes in each; so that, on the first view, they appear as if eaten by insects. The flowers are produced at the top of the stalk, which always swells to a larger size in that part than in any other : these are covered with an oblong spathe or hood, of a whitish green colour, which opens longitudinally on one side, and shews the spadix closely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it seldom advances farther in height, so that these seldom are more than seven or eight feet high; but the leaves are much larger on these, than those of the plants which ramble much farther .- Native of the West Indies, and of the isle of Tanna in the South Seas. This plant is easily propagated by cuttings, which, if planted in pots filled with poor sandy earth, and plunged into a hot-bed, will soon put out roots, if they had none before ; but there are few of the joints which have not roots ; the plants being tender, will not endure the open air in England; and the pots should, on that account, be placed near the walls of the hot-house, against which the plants will climb, and fasten their roots into the wall, and thereby support the stalks. They should have but little water in the winter; but in warm weather, it must be given them three or four times a week ; and in the summer, the free air should be admitted to them in plenty. The plants have no particular season of flowering; for they sometimes flower in autumn, and sometimes in the spring, but never ripen their seed in our climate. These plants are preserved in the gardens of the curious, both in England and Holland, more for variety than for beauty. This species, however, may be suffered to have a place against the wall of the stove, over which it will spread, and cover the nakedness of the wail; and the leaves, which are so remarkably perforated, remaining all the year, make a singular appearance.

Dragon. See Arum and Dracontium. Dragon's Head. See Dracocephalum. Dragon Tree. See Dracana. Draining. See Land. Drilling. See Hoeing. Dropwort. See Spiræa. Dropwort Water. See Enanthe.

Drosera ; a genus of the class Pentandria, order Pentagynia .- GENERIC CHARACTER. Calix : periauth one-leafed, five-cleft, sharp, upright, permanent. Corolla: funnel-form. Petals: five, somewhat ovate, obtuse, rather larger than the calix, and alternate with it. Stamina : filamenta five, subulate, length of the calix, and alternate with the petals; antheræ small, growing to the filamenta. Pistil: germen superior, roundish; styles five, simple, length of the stamina; stigmas simple. Pericarp : capsule surrounded with the calix, somewhat ovate, one-celled, three, four, or five-valved at the tip. Seeds ; very many, very small, somewhat ovate. scabrous, fixed to a branching loose receptacle in the centre effect upon milk as the pinguicula vulgaris; and, like that

Leaves lanceolate. The | cleft, Petals: five. Capsule: one-celled, five, or threevalved at the tip. Seeds: very many .- These plants are not easily preserved in gardens. They must be taken from their native bogs, with a sufficient quantity of bog-earth and watermoss, and planted in pots, set in pairs, constantly supplied with water. They will also succeed better if defended from the sun, and well enveloped in moss kept constantly wet. These are herbs of a small size, and singular structure. The leaves, in most of the species, only next the root furnished with glandulous hairs on the upper surface, and fringed with them round the edge : these hairs have each a small globule of a pellucid liquor like dew, continuing even in the hottest part of the day, and in the fullest exposure to the sun; from which remarkable circumstance, their English name of sundew is derived .---- The species are,

1. Drosera Acaulis. Flower radical, without any scape, solitary; leaves oblong. This plant is singular for having a sessile flower in the bosom of the root-leaves .---- Native of the Cape of Good Hope.

2. Drosera Cuncifolia; Wedge-leaved Sundew. Scapes radicate: leaves wedge-form, rounded. It resembles the third species, but is larger, and has sessile leaves rounded at the summit, but gently attenuated towards the base .- Native of the Cape of Good Hope, where it was first observed by Thunberg.

3. Droscra Rotundifolia ; Round-leaved Sundew. Scapes radicate; leaves orbiculate; root perennial, black; root-leaves many, forming a tuft, two or three lines in length and breadth. set with red hairs about the edge and on the upper surface, the under surface smooth; the petioles red, and half an inch or eight lines in length, ciliate at the base ; scape erect, round, slender, simple, three or four inches in height; flowers in a kind of racemed spike, bent in at the top before floweringtime, they point one way, are alternate, erect, and from six to seven in number; the peduncles are half a line or a line in length; corolla white; calix smooth; stigmas obtuse, white; bractes none; flowers open from nine to twelve; the young leaves before they expand are rolled inwards, and at the same time bent in to the very peduncle .- In England it flowers in July and August, and is found on Hampstead Heath; at Battle's well near Harefield, and Iver heath; on Hinton and Teversham moors, and Gamlingay bogs, in Cambridgeshire; on Malvern chace; Birmingham heath; Selborne, in Hampshire; Ludgvan Lee, on the Barton and Moors, and Senan, in Torvorian commons, Cornwall : Halston, in Northamptonshire; near Mansfield and Oxton in Nottinghamshire, and frequently in various parts of Scotlaud. The variety mentioned by Ray, was found by Mr. Willisel in Devonshire. The whole of this plant is acrid, and sufficiently caustic to corrode the skin; some ladies, however, know how to mix the juice with milk, so as to make it an innocent and safe application to remove freckles and sunburn. The unmixed inice will destroy warts and corns, if a little of it be frequently put upon them. These effects, however, show its internal use to be dangerous, although some authors very gravely tell us, that a water distilled from this plant is highly cordial and restorative; for it is more than probable, that it never merited the character given of it for those virtues; since, if it be not productive of bad consequences when distilled for cordial waters along with other ingredients, it is merely because its peruicious qualities are not of a nature to rise in distillation ; while the leaves only, bruised and externally applied, will erode the skin, and bring on such inflammations as are not easily removed. This plant has the same at the bottom. ESSENTIAL CHARACTER. Calix: five- too, is supposed to occasion the rot in sheep. Is not, says

Withering, the sour coagulated milk of the Syrians called | dula, a tear; the leaves being surrounded with drops, as in leban, or leven, at first prepared with some plant of this kind? In Great Britain this plant is called generally sundew, youthwort ; in the north parts, red-rot ; and in Yorkshire, mooregrasse; in German, sonnenthau, tindau, lofflein kraut; in Dutch, zonnedaauw, or loopig kruid; in Danish, soeldug, or himmeldug ; in Swedish, marice sileshar ; in Smoland, dagport ; in Italian, rugiada del sole ; in Spanish, rociada, or rocio del sol; iu Portuguese, rossolina; in Russian, solneznaja trawa.

4. Drosera Longifolia; Long-leaved Sundew. Scapes radicate ; leaves ovate, oblong. Linneus is of opinion that this is scarcely specifically distinct from the preceding species, since they only differ in the form of their leaves. This seems not to be so common as the round leaved sort, although Mr. Woodward informs us that it is frequent in Norfolk; and Mr. Lightfoot, that it is so also in Scotland. On Brigstear moss, near Kendal, it grows thrice as large as any where about London: it is also found on Hinton Moor, near Cambridge: on Bagshot Heath, in Surry; and at Selborne, in Hants. Great sundew, which Mr. Hudson makes a distinct species because it is larger, has eight styles, and four valved capsules; it is common, as he informs us, in the northern counties, also in Devonshire, Hampshire, and Norfolk: three miles from Carlisle towards Scotland, where Mr. Dixon found it near Fort Augustus; near Ellesmere, and in Ireland. Another variety was found by Mr. Willisel, between Doncaster and Bautrey, in Yorkshire; and by Mr. J. Sherard on West-field down near Hastings. These plants have the same property with dionæa muscipula, of entrapping small insects with their folded leaves ; which was discovered by surgeon Whately, in August, 1780. On inspecting some of the contracted leaves, he observed a fly in close imprisonment; and on centrically pressing other leaves yet in their expanded form with a pin, he observed a sudden elastic spring of them. so as to become inverted unwards, and as it were encircling the pin : the same account occurs in a German author, in July 1779. An ant was placed on the middle of a leaf, the insect endeavoured to escape, but was held fast by the clammy juice at the point of the bairs : in some minutes the short hairs on the disk of the leaf began to bend, then the long hairs, and laid themselves upon the ant; after a while the leaf began to bend; and in some hours the end of the leaf was so bent inwards as to touch the base: the ant died in fifteen minutes.

5. Drosera Capensis; Cape Sundew. Scapes radicate; leaves lanceolate, scabrous underneath; root putting out spiral threads; flowers violet-coloured .- Native of the Cape of Good Hope.

6. Drosera Lusitanica : Portuguese Sundew. Scapes radicate; leaves subulate, convex underneath; flowers tenstamined; the stem has a few leaves on it, and from two to four peduncled flowers at the end; capsule twice as long as the calix .- Found in Portugal by Tournefort.

7. Drosera Cistiflora; Cistus-flowered Sundew. Stem simple, leafy ; leaves lanceolate ; stems a foot high, pubescent ; leaves alternate, with glutinous hairs; flowers terminating, one to three, large, on peduncles; the bottom of the corolla dark; stamina black, the length of the calix; autheræ yellow, cordate; pistil black; germen ovate, and round the top, but not on the top of it ; five black styles, the length of the corolla: stigmas several times dichotomous, even into hairs. -Native of the Cape of Good Hope.

8. Drosera Indica, Stem branched, leafy; leaves linear; peduncles axillary, with two or three flowers .--- Native of the Fast Indies. The Ceylonese call it kandulaessa, from kan- emarginate, deeply and bluntly serrate, or more properly cre-

our European species ; the stem is half a foot high, and very slender: the leaves are extremely fine, and come out alternately all over the stem and branches, and are bent unwards at the ends; the peduncles are the length of the leaves, or longer, and sustain three flowers or more, but the weaker only one

9. Drosera Umbellata, Scapes rooted: leaves ovate. flower umbelled; stem none; leaves next the ground, only on long petioles; scapes various, naked, five inches long, terminated by an umbellule of about five flowers, with corollas of five petals .-- Native of China.

Dryandra; a genus of the class Diœcia, order Monadelphia .- GENERIC CHARACTER. Male. Calix: perianth two-leaved; divisions ovate, acute, shorter than the corolla. Corolla: five-petalled; petals obovate, oblong, from reflex patulous, unguicular. Stamina: filamenta nine, united below into one body, unequal, shorter by half than the corolla. Antheræ minute. Pericarp: tricoccous, or tetracoccous, three-grooved, or four-grooved, wrinkled, fleshy. Seeds: so-litary, oblong. ESSENTIAL CHARACTER. Calix: twoleaved. Corolla : five-petalled ; or calix five-leaved, resembling a corolla, surrounded by a two or three-leaved calicle. Stamina ; nine ; fruit three or four-grained .---- The only known species is.

1. Dryandra Cordata. Stem arboreous, a fathom or more in height; branches round, with a wrinkled bark, dotted, smooth; leaves at the ends of the twigs approximate, alternate, petioled, cordate, acute, entire, five-nerved, the nerves branching, smooth, paler underneath, spreading, a hand in length and breadth; petioles almost the length of the leaf. round; flowers terminating in a panicle, the branches of which are dichotomous, or trichotomous, and patulous; petals yellow. From the seeds they express an oil for lamps and the table .- Probably a native of the Mauritius.

Dryas ; a genus of the class Icosandria, order Polygynia .--GENERIC CHARACTER. Calix : perianth one-leafed, eightparted; divisions spreading, linear, obtuse, equal, a little shorter than the corolla. Corolla: petals eight, oblong, emarginate, spreading, inserted into the calix, Stamina; filamenta numerous, capillary, short, inserted into the calix, Antheræ small, Pistil: germina many, crowded, small; styles capillary, inserted into the side of the germen; stigmas simple. Pericarp: none. Seeds: numerous, roundish, compressed, furnished with extremely long woolly styles .---- The species are,

1. Dryas Anemonoides. Five-petalled ; leaves pinnate, with all the pinnas distinct .- This very small plant is a native of Siberia; the radical leaves are commonly ternate, compound, consisting of a middle leaflet longer than the rest, and two lateral ones; all the leaflets are deeply-cut or divided, but vary much as to breadth and length, in different individual plants; sometimes the leaves have more than three divisions, they are of a bright green, and very smooth ; the footstalk is round; the stalk is terminated by a single flower, which is large in proportion; the calix is outwardly green, and inwardly lanuginous, and of a silvery appearance; the stamina are extremely numerous and short; the germina converge into a globe, and are coated with a thick white down.

2. Dryas Octopetala. Eight-petalled : leaves simple. This delicate evergreen plant, with its snow-white blossoms, is a great ornament to Alpine heights; the stalk and branches are woody and perennial, lying flat upon the ground, and spreading flat about the root in tufts; leaves evergreen, ovate, turned back at the edge, ending very obtusely, and sometimes

DUR

nate, hard and stiff, of a dark green wrinkled surface on the a stove to preserve them in England : they are propagated upper side, and hoary underneath, having woolly footstalks, and a large halbert-shaped stipule to each, embracing the stem; peduncles naked, downy, seattered with purple hairy glands, each bearing one flower, an inch in diameter, consisting generally of eight petals, but sometimes of ten or six, seldom of five ; seeds oblong, gibbous on one side, straightish on the other, somewhat villose, reddish brown, narrowing at bottom, ending at top in a feathered flexile tail, eight times the length of the seed; the corolla is frequently double .---Native of high mountains in Lapland, Denmark, Switzerland, where it was observed by Ray, on Thuiri, one of the highest points of mount Jura; the Grisons, Savoy, Austria, Carniola, Stiria, Carinthia, Germany, France, Italy, Siberia, Ireland, Scotland, and the north of England, as between Gort and Galloway, where it was found by Mr. Heaton; and near Sligo in Ireland : Breadalbane, Isle of Skye ; Ross-shire, Sutherland, and Argyleshire, in Scotland; Arncliff Clowder, in Kittendale, near Kilnsay; and near Settle in Yorkshire. It flowers in June; and no cattle will eat it. Dryas pentapetala, mentioned by Sibbald as growing in the den of Bethaick, four miles from Perth, is not now to be found there : possibly the potentilla argentea was mistaken for it.

Drupis; a genus of the class Pentaudria, order Trigynia. -GENERIC CHARACTER. Calix : perianth one-leafed, tubular, half five-cleft, permanent. Corolla : petals five ; claws length of the calix, narrow; border flat; plates two-parted; divisions linear, obtuse; throat crowned with the two toothlets of each petal. Stamina : filamenta five, length of the corolla. Antheræ simple, oblong, incumbent. Pistil: germen obovate, compressed; styles three, simple, patulous; stigmas simple. Pericarp : capsule roundish, covered by the calix, one-celled, small, clipped round. Seed : single, kidney-form, glossy. ESSENTIAL CHARACTER. Calix: five-toothed. Petals: five; capsule clipped, round, one-seeded.---The species are,

1. Drypis Spinosa. The first stems are procumbent, fourcornered, brachiate, the last dichotomous, and flower-bearing; fresh green brauches push forth in the spring from the dry ones of the former year, the extreme ones are dichotomous, and bear flowers ; leaves subulate, somewhat three-cornered, mucronate, those at the subdivisions of the stem are laneeolate, with three teeth on each side; peduneles shorter than the flower; ealix erect; corolla crowned, purple or white; petals narrow, spreading ; stamina erect ; biennial .- Native of Barbary, Italy, and Istria. This plant in its adult state becomes shrubby. Johnson and Gerarde call it sperage thistle; the Italians have named it erba ciuccia, or ass's herb, because that animal feeds freely on it.

Duck's Foot. See Podophyllum.

Duck's Meat. See Lemna.

Dung. See Manure.

Duranta ; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. Calix: one-leafed, tu-bular, somewhat truncated, five-eleft. Corolla: one-petalled; tube longer than the ealix, somewhat curved; border patulous, five-parted, nearly equal, rounded. Stamina : filamenta four, the two longer ones within the tube. Antheræ roundish. Pistil: germen inferior, roundish; style filiform, length of the stamina; stigma thickish. Pericarp: berry roundish, covered by the calix. Seed : kernels four, two-celled. Es-SENTIAL CHARACTER. Calix: five-eleft, superior; berry four-seeded. Seeds : two-celled, according to Gærtner. Calix: five-toothed. Corolla : funnel-shaped, five-cleft ; berry one-celled, containing four two-celled stones .- The plants of this genus being natives of warm countries, require SENTIAL CHARACTER. Calix: five-cleft, pitcher-shaped, 40.

by seeds, which should be sown in small pots, and plunged into a hot-bed of tanner's bark; and when the plants are fit to remove, they must be planted each into a separate potfilled with light earth, and plunged into the hot-bed, observing to shade them until they have taken new root, and afterwards treat them in the same manner as other plants from the same country. These are shrubs with quadrangular branches; the flowers are in loose spikes, either from the axils or at the ends of the branches; they generally have axillary spines, and they are so alike in their manner of flowering, as well as in the structure and colour of the flower, that it is doubtful, according to Jussieu, whether they may not be all varieties of one species .---- The species are,

1. Duranta Plumieri; Smooth Duranta, Fruiting calices twisted. It grows fifteen feet high, with alternate branches, erect, or reclining; spines awl-shaped, opposite, but very frequently wanting; leaves lanceolate, on short petioles, acute, bluntly and unequally servate above the middle, smooth, opposite, two inches long; racemes loose, wide, reclining, both axillary and terminating; flowers slightly sweetsmelling, very many, blue, on very short peduncles ; fruit yellow, the ealix also then becoming yellow, and like a berry, the whole being changed, and different from its former shape, -Native of South America, and the West Indies.

2. Duranta Ellisia. Fruiting calices erect. This shrub is a fathom in height or more, branched and even; branches long, reclining, quadrangular, subdivided, with axillary, onposite, ovate-lanceolate, acuminate, serrate, nerved, smooth on both sides; racemes compound, terminating, brachiate, many-flowered ; flowers on short peduncles, and blue. The specific character of this and the preceding, taken from the contortion of the calix above the fruit, is vague and insufficient. since the differences occur frequently in the same raceme ; they are therefore in all probability not specifically distinct. Jacquin also remarks, that it is extremely like the first species, except that the fruiting calix is not twisted in the upper part, but continues convergent and erect. Notwithstanding this approximation, Dr. Patrick Browne made it a distinct genus, under the name Ellisia, from Mr. Ellis, the ingenious author of a treatise on zoophites, or plant-like marine productions, of an animal nature : he says, that this shrub rises frequently to the height of six or seven feet; that the leaves are very like those of green tea; and that the branches, though sometimes beset with thorns, are often otherwise .-Native of the West Indies : in Jamaica it is frequently found in hedges between Kingston and San Jago de la Vega,

3. Duranta Mutisii. Leaves elliptic, quite entire. This differs from the two preceding species merely in the leaves .-- It is a native of South America, and was found there by Mutis,

Durio ; a genus of the class Polyadelphia, order Polyandria .- GENERIC CHARACTER. Calix: perianth one-leafed, pitcher-shaped, five-lobed; lobes rounded, deciduous. Corolla: petals five, added to the calix, and less than it, concave. Stamina : filamenta in five bodies, divided into seven. subulate, longer than the corolla. Antheræ twisted, or, according to Jussien, filamenta five, fat at the base, seven or eight-cleft at the top ; the divisions connate, subulate, bearing thirty-five to forty twisted antheræ. Pistil: germen roundish, stipitate; style bristle-form, length of the stamina, Pericarp : pome roundish, on all parts muricated with manysided dagger points, five celled, gaping open in five directions: cells one to five-seeded. Seeds : large, ovate, involved in a mucous pulp, in a membranaeeous aril. Observe. The character of this genus is to be amended by eve-witnesses. 6 F

in five bodies ; pome five-celled .---- The species are,

1. Duris Zibethinus. A lofty tree, with alternate flowers below the leaves; the leaves resemble those of the cherry, but are not dented at the edges, and on that account more resemble nutmeg leaves : the flowers are borne in loose heads. they are large, and of a pale yellow white colour; the fruit is of the size of a man's head, and round or oblong, resembling in some degree a rolled up hedge-hog, with a hard bark or rind : the fleshy part of the fruit is of a creamy substance. and of a delicate taste, but of an unpleasant heavy smell. something resembling that of rotten onions, and the smell of the breath of those who eat it is infected also in a high degree : but when once a person has accustomed himself to eat this fruit, he generally considers it preferable to all others.

Duroia ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth one-leafed, cylindric, truncate, contracted, very short, superior. Corolla: monopetalous : tube cylindric : border length of the tube, six-parted ; divisions ovate, spreading. Stamina : filamenta none. Antheræ six, oblong, within the tube. Pistil: germen inferior; style filiform, the length of the tube; stigmas Pericarp: pome globular, umbilicate, covered with two. erect hairs : seeds very many, nestling, oval, flat, very smooth, incumbent, in a double row. Observe. The flowers are frequently abortive, nay, there are some genuine male flowers without any germen; it should therefore be rather referred to the class Polygamia. ESSENTIAL CHARACTER. Calix: cylindric, truucate. Corolla: six-parted; filamenta noue; pome hispid .---- The only known species is,

1. Duroia Eriopila. A tree with thick unequal branches. hirsute at the end; leaves terminating, opposite, approximating, many, subpetioled, a span in length, obovate, quite entire, rather obtuse, ribbed, pubescent above, netted underneath; petioles very short, hirsute; flowers at the ends of the branches, sessile, heaped, many, several of them abortive; corollas white: fruit somewhat larger than a turkey's egg. spherical, covered very thick with erect brown hairs, umbilicate with the hollow calix .- It is well-flavoured, and much esteemed at Surinam, of which it is a native.

Dwale. See Atropa.

Dwarf Trees, were formerly in much greater request than they are at present, for though they have many advantages to recommend them, yet the disadvantages attending them greatly overbalance; and since the introduction of espaliers into the English gardens, dwarf-trees have been little in esteem for the following reasons: 1. The figure of a dwarftree is very often so much studied, that in order to render the shape beautiful, little care is taken to procure fruit, which is the principal design in planting these trees. 2. The branches being spread horizontally near the surface of the ground, renders it very difficult to dig or clear the ground under them. 3. They take up too much room in a garden, especially when grown to a considerable size, so that nothing can be sown or planted between them. 4. They spread their branches close to the ground, and continually shade the surface of the earth, so that neither the sun nor air can pass freely round their roots, to dissipate noxious vapours, with which the circumambient air will become very replete, and these crude rancid vapours being drawn in by the leaves and fruit, will render the juices of the latter crude and unwholesome, as well as ill-tasted. It is also very difficult to get to the middle of these dwarf-trees in the summer, when their or thirty feet asunder each way; which are managed in the leaves and fruit are on the branches, without beating off some same way as pears. Some persons also plant apricots and of the fruit, and breaking the young shoots; whereas the plums for dwarfs, but these seldom succeed well, as being

inferior. Corolla: five-petalled, small; style one. Stamina: side, to the up the new shoots, or remove all that are juxnriant, which would soon rob the trees of their nourishment if suffered to remain. Add to this, the fruit-buds of all sorts of pears and apples, and most sorts of plums and cherries, are first produced at the end of the former year's shoot, which must be shortened to keep the dwarfs to their proper figure. so that the fruit-buds are cut off, and a greater number of branches are obtained than can be permitted to stand, so that all those sorts of fruit-trees whose branches require to he trained up at their full length, are very improper to train up as dwarfs; and the peaches and nectarines which will bear amputation, are too tender to be trained so in this country, These evils being entirely remedied by training the tree to an espalier, has jointly gained them the preference ; however, if any one still feel disposed to have dwarf-trees, notwithstanding what has here been said, we shall lay down a few rules for their management: If you design to have dwarf pear-trees, bud or graft them on quince stocks; but as many sorts of pears will not thrive if they are immediately budded or grafted on quince stocks, so some of these sorts which will take freely, should be first budded on the quince stocks; and when these have shot, the sorts you intend to cultivate should be budded into these, for free stocks are apt to make them shoot so vigorously, as not to be kept within bounds: these grafts or buds should be put in four or six inches above the surface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four shoots, the ends of the shoots should be stopped, in order to force out lateral branches. Two years after budding, these trees will be fit to transplant where they are to remain; for though many people choose to plant trees of a greater age, yet they seldom succeed so well as young ones. The distance these trees should be planted is twenty-five or thirty feet asunder, for less will not do if the trees thrive well. The ground between them may be cultivated for kitchengarden herbs while the trees are young, but they ought not to be sown or planted too near the roots of these trees. In order to train the trees regularly, drive stakes into the ground round each tree, to which the branches should be fastened down with list in an horizontal position; for if they are suffered to grow perpendicularly while young, they cannot afterwards be reduced to any tolerable figure without great violence: the necessary directions to be afterwards followed. are, not to suffer any branches to cross each other, and always in shortening any shoots, to take care and leave the uppermost eye outwards, whereby the hollowness in the middle of the tree will be better preserved ; and be careful also to cut off every perpendicular shoot in the middle of the tree as soon as it appears. The other necessary rules will be found under the article Pruning. The sorts of pears which answer best in dwarfs, are summer and autumn fruits, for winter pears are not worth planting in dwarfs; they seldom bear well, and are always ill tasted, and generally stony, because they are commonly grafted on quince stocks. Apples are also planted in dwarfs, most of which are now budded or grafted on paradise stocks; but as these are for the most part of a short duration, they are not profitable, and are fit only for small gardens, as a matter of curiosity, producing fruit sooner and in greater plenty than when they are upon crab or apple stocks. The distance these trees should be planted if on paradise stocks, should be six or eight feet; and upon Dutch stocks, eighteen or twenty; but if on crab stocks, twenty-five trees on an espalier can at all times be approached on each of a tender constitution; and those which will produce fruit

on dwarfs, are much more likely to do so when trained on an espalier, where they can be better managed.—After what has been here said concerning dwarf-trees, we can hardly suppose that many persons will still continue to prefer them to espaliers ; and we refer those with whom the objections here

EARTH Nut. See Arachis. Earth Pea. See Lathyrus.

Earwort. Sec Hedyotis.

Ebenus ; a genus of the class Diadelphia, order Decandria. -GENERIC CHARACTER. Calix ; perianth one-leafed, bell-shaped, terminated by five filiform teeth, which are villose and nearly equal. Corolla : papilionaceous, length of the calix; standard roundish, straight, entire; rudiments of wings obscure, crescent-shaped, gibbous, ascending at the tin. Staming : filamenta diadelphous, all growing together into a sheath, with tips distinct. Antheræ roundish. Pistil: germen roundish, villose; style capillary; stigma terminal, acuminate. Pericarp : legume ovate. Seed : single, rough with hairs. ESSENTIAL CHARACTER. Calix ; with teeth, the length of the corolla; wings scarcely any. Seed: one, rough with hairs .- These plants are propagated by seeds. which should be sown in the autumn, for those which are sown in the spring often fail; they must be sown in pots, and placed under a frame in winter, where they may be protected from frost. In the spring the plants will come up; they should be kept clean from weeds, and now and then refreshed with water. When they have acquired strength enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a moderate hot-bed, just to promote their taking new root; then they should be gradually inured to bear the open air, into which they should be removed the latter end of May, placing them in a sheltered situation, where they may remain till autumn, when they must be removed into shelter, for these plants will not live in the open air through the winter, nor should they be too tenderly treated, lost they draw up weak. They succeed best when placed in an airy glass-case, without fire in the winter, where they will have more sun and air than in a green-house. During the winter season the plants must be sparingly watered, but they often require to be refreshed in the summer .---- The species are.

1. Ebenus Cretica; Creton Ebony. Leaves ternate, quinate, or pinnate, with two pairs of leaflets; pikkes terminating. It rises with a shrubby stalk three or four feet high, with sevenal side-branches; leaves at each joint, hoary, composed of five narrow lanceolate leaflets, which join at their tails to the footstalk, and spread out like the fingers of a hand; the branches are terminated by thick spikes of large purple fowers; the spikes are from two to three incluse long, and make a fine appearance. It flowers in June and July, and in warm seasons will sometimes perfect seeds in England.— It grows naturally in Crete, and some islands of the Archipelago.

2. Ebenus Pinnata; Pinnated Ebony. Leaves pinnate, with four pair of leaflets; spikes axillary, on very long peduncles. It flowers in July, is biennial, and a native of Barbary and the Levant.

Ebony. See Amerimnum, and Diospyros Ebenaster.

Echinophora; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. Calix: umbel universal, with very many rays, the intermediate ones shorter; partial

urged against the former have no weight, to the article Grafting, where they will find many corroborative proofs of the advantages arising from the latter, together with other useful bints upon the same subject.

DYE

Dyer's Weed. See Genista.

ЕСН

with very many sessile flowers, the central one sessile, receiving the germina between the pedicels; involucre universal, with some sharp rays; partial turbinate, one-leafed, six-cleft, acute, unequal; perianth proper, five-toothed, permanent, very small. Corolla: universal, difform, rayed; floseules male, abortive, the central one of the umbel female; proper five-petalled ; petals unequal, patulous. Stamina : filamenta five, simple. Antheræ roundish. Pistil: germen oblong, inferior, clothed with an involucel ; styles two, simple ; stigmas simple. Pericarp : none, in place of which is a hardened mucronate involucre, Seed : single, ovate-oblong. ESSENTIAL CHARACTER. Lateral flowers male, central hermaphrodite. Seed : one, immersed in an involucel .---These plants do not produce their seeds in our climate, but are increased by their creeping roots. Transplant them in the beginning of March, a little before they shoot. They require a warm situation, and a dry soil, or else you must cover them in winter, to prevent the frost from destroying them. -The species are,

1. Echinophora Spinosa; Prickly Sca Parsnep, Leadets subulate, spiny, quite entire; root premnial, creeping; stalks branching, five or six inches high, with short thick leaves, terminating in two or three sharp thorns, and opposite, in pairs; flowers in an umbel, on a maked pedunele, which arises from the side of the stalk; under the umbel an involucre composed of several leaves, terminating in sharp spines; corolla white.—It flowers in June, and is a native of the stack and the starts. It was found by Mr. Blackstone, between Feversham and Sca-aster in Kent.

2. Echinophora Tenuifolia; Fine-leared Sca Parsnep, Leaflets gashed, narmed; root perennial; stalk nearly a foot and a half high; whence come out two opposite side-branches a tevery joint. At the lower part of it are leaves finely divided, like those of the carrot; and the flowers grow is small umbels at the extremities of the branches, having a short prickly involuce.—It flowers in July, and is a native of the sea-coast of Apulia.

Echinops; a genus of the class Syngenesia, order Polygamia Segregata. - GENERIC CHARACTER. Calix: common. many-leaved, with scales, subulate, totally reflected, containing many flowers. Perianth : partial one-flowered, oblong, imbricate, cornered ; leaflets subulate, loose above, upright, permanent. Corolla : one-petalled, length of the calix, tubular; border five-cleft, reflex, spreading. Stamina : filamenta five, capillary, very short; antheræ cylindric, tubular, fivetoothed. Pistil : germen oblong ; style filiform, length of the corolla; stigma double, somewhat depressed, rolled back. Pericarp : none. Calix : unchanged, larger. Seed : single. ovate-oblong, narrower at the base, with obtuse tip; down obscure. Receptacle: common, globose, bristly. ESSEN-TIAL CHARACTER. Calix: one-flowered. Corolla: tubular, hermaphrodite. Receptacle: bristly; down obscure .---These plants are easily propagated by seeds, which, if permitted to scatter, the plants will come up in plenty, and a

479

few of them may be transplanted to the places where they are j designed to remain and flower; they require no other culture, but to keep them clean from weeds; the second year they will flower, and produce seeds, and the roots will continue two or three years after ; but if the seeds scatter, the plants will become troublesome weeds; to prevent which, the heads should be cut off as soon as the seeds are ripe. They will grow almost in any soil or situation.----The species are,

ECH

1. Echinops Sphærocephalus ; Great Globe Thistle, Heads globular; leaves sinuate, pubescent; root perennial; stalks many, four or five feet high ; leaves long and jagged, divided into many segments, almost to the mid-rib, the jags ending in spines ; they are of a dark green on their upper side, but woolly on the under. There are several globular heads of flowers on each stalk. The florets are commonly blue, but sometimes white : they come out in July, and ripen seed in August .- Native of France, Spain, Italy, the Valais, Austria, Carniola, and Germany.

2. Echinops Spinosus: Thornwheaded Globe Thistle. Heads interspersed with long spines. This plant is of the same stature with the preceding, but the stem and leaves are more tender; stem, in the green-house, becoming somewhat shrubby, without glandular bairs. The heads are like those of the first species; but the florets are white, and larger, with the jags reflex-hooked. Among the florets, every where come out spines, formed of unexpanded calicles, four times the length of the florets, which at length are cloven in two. -Perennial, and a native of Egypt and Arabia.

3. Echinops Ritro ; Small Globe Thistle. Head globular ; leaves pinnatifid, smooth above. This has a perennial creeping root, sending up several strong stalks, two feet high, and branching; leaves cut into many fine segments to the midrib; each branch is terminated by a globular head of flowers, smaller than those of the first species, and of a deeper blue, but sometimes white. They appear in July .- Native of the south of France, Italy, and Siberia.

4. Echinops Strigosus; Annual Globe Thistle. Heads in bundles, lateral; calices barren; leaves strigose above. It is an annual plant, with a stiff white stalk, two feet high; leaves divided, ending in many points, which have spines; their upper side green, covered with brown hairs, their under side white, and woolly; the stalk is terminated by one large head of pale blue flowers, appearing in July .- Native of Spaju and Portugal. The seeds should be sown in the spring, on a border of light earth, where the plants are designed to remain.

5. Echinops Gracus. Stem one-headed ; leaves spiny, all pinnatifid and villose; root creeping, and perennial; stalks about a foot high; leaves shorter, and much finer divided than the preceding sorts; they are hoary, and armed on every side with sharp thorns; the stalks are terminated by one middle-sized globular head of blue or white flowers, appearing at the end of June .- Native of Greece. It is easily propagated by its creeping roots, or from seeds ; it loves a dry soil, and a warm situation.

Echites ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth five-parted, sharp, small. Corolla: one-petalled, funnel-form; border five-cleft, flat, spreading very much; nectary of five glands, standing round the germen. Stamina : filamenta five, slender, erect; antheræ stiff, oblong, acuminate, converging. Pistil: germen two: style filiform, length of the stamina; stigma oblong-headed, two-lobed, attached by a gluten to the antheræ. Pericarp: follicles two, extremely long, onecelled, one-valved. Seeds : very many, imbricate, crowned with long down. ESSENTIAL CHARACTER. Contorted : white where the follicles are separated, which is easily done ;

follicles two, long, straight. Seeds : downy. Corolla : funnel-form, with the throat naked .- These plants have a singularity in their habit, by which they may be known at first sight. The leaves are opposite, petioled, quite entire, veined, and shining, the third species only having them frequently rugged; common peduncles seldom longer than the leaves, lateral, and alternate, except in the tenth species; flowers scentless. The nectareous glands and the downy seeds are in follicles, which is of great importance in determining the character ; while the corolla, which varies much in the different species, is of no consequence in this respect. The stigma in all is glued to the inside of the wall of the cone, formed by the antheræ, and which separates at the explosion of the pollen, whilst the outer wall of the cone continnes undissolved; the fecundation in the greater part being accomplished within the closed tube of the corolla, but in the rest within the cone, stretched beyond the tube. They have not been introduced into European cultivation. and being mostly inhabitants of the West Indies, they will require the protection of the bark-stove, and should be propagated and managed in the same way as the tender sorts of Apocynum, which scc .---- The species are.

1. Echites Biflora, Peduncles two-flowered. This is a branched shrub, full of milky juice, supporting itself by stems, partly erect, partly twining upon trees, and mounting them to the height of twenty feet; from which circumstance, it frequently acquires the air of a tree; leaves oblong, growing narrower to the base, obtuse at the end, with a small point, three inches long; peduncles sometimes, but rarely, three-flowered; flowers handsome, very white, with a yellow throat .- Native of most of the Caribbee islands in salt marshes.

2. Echites Quinquangularis. Peduncles racemed : leaves ovate, acute; stems twining, shrubby, somewhat scabrous; lcaves three inches long; racemes simple; flowers about sixteen, green, with a yellowish border; the edge of the tube white, and in the form of a pentagon .- It is not milky like the preceding : flowers in October, and is a native of Carthagena in South America.

3. Echites Suberecta; Oral-leaved Echites, or Savanna Flower. Peduncles racemed ; leaves subovate, obtuse, mucronate .- This shrub differs much from all others of this genus. It abounds in milky juice, grows among other shrubs to the height of ten feet, but is only three feet, and sometimes scarcely a foot high, in savannas; stems scarcely twining, and climbing. The leaves more or less ovate, either smooth on both sides, or scabrous at the back. The peduncles support a few large, handsome, yellow flowers, hirsute on the outside, and in the tube. The follicles are slender, and brown. The flowers being of a bright vellow, and large, make a fine appearance. It grows naturally in the savannas of the island of Jamaica, where it is chiefly known by the name of savanna-flower. It is also very common in the island of St. Domingo, flowering from September to March. Browne declares all parts of it to be extremely poisonous; and an intelligent traveller has lately informed us, that it operates as a slow or quick poison, according to the dose; and that fatal accidents have happened from stopping breakers of rum with grass, in which this noxious weed has been concealed. The antidote for this poison, is expressed arrow-root juice. See Maranta Arundinacea.

4. Echites Agglutinata. Peduncles racemed : leaves ovate. emarginate, with an acumen; stems twining, shrubby; lcaves four inches long; common peduncles the length of the leaves, often difform, sometimes bifid. The flowers are small, and

481

a drop of watery glutinous liquor, such as the whole plant abounds with, flows out at the two points by which they had cohered.—It flowers in December, and is found on the mountains, near Cape François in St. Domingo.

5. Echites Torulosa; Climbing Echites. Peduncles subracemed; leaves hancoolate, acuminate. This plant is so weakly, that it commonly sustains itself by the help of the neighbouring bushes, and frequently rises to a considerable height among them. The branches and follicles are extremely slender and delicate; stems twining, round, and shrubby; leaves two inches long. The common peduncles support about six small yellow flowers, and the whole plant abounds in a miky gluen.—It flowers in March, and is often found at the foot of the mountains of Liguanea in the island of Jamaica.

6. Echites Umbellata; Umbelled Echites. Peduncles umbelled ; leaves ovate, obtuse, mucronate ; stem twining .- It climbs to the height of fifteen feet, by means of its shrubby, twining, pliant stems, which are woody and tuberous at bottom, but round, green, and glossy above. The whole abounds in a clear glutinous juice; leaves roundish, ovate, subcordate at the base, three or four inches long. The common peduncle has from four to seven flowers at the end, in a kind of umbel, with some stipules serving the purpose of an involucre. The flowers are large and handsome ; the border white, and the tube green on the outside. Browne describes them to be of a pale yellow, with a longish slender tube. He remarks, that like other plants of the same natural class, it is rather deleterious, and that there is a variety of it found in the drier savannas, which has pointed leaves, and very slender stalks. It flowers from October to February, and is a native of Jamaica, Cuba, and St. Domingo.

7. Echites Trifida. Peduncles trifid, many-flowered; leaves orate, oblog, acuminate; stems twining, shrubby; leaves three inches in length; common peduncles short, with difform pedicels; flowers large, pretty; the tube purple, and the border green. It climbs trees to the height of twelve feet, and the whole plant is milky. It flowers in October, and is a native of South America, near Carthagena. 8. Echites Repens. Peduncles many-flowered, divided ;

8. Echites Repens. Peduncies many-flowered, divided ; leaves lanceolate, oblong. This is an elegant shrubby plant, not milky, with round, smooth, samentose stems; the older ones procumbent, and putting out roots; the younger subcreet, and thickened at the joints into discoid knots. The common pedunceles are usually blidd, bearing elegant, tender, red flowers, which appear from October till December.—Native of St. Domingo.

9. Echites Corymbosa. Racemes corymbed; stamina standing out; leaves lanceolate-ovate. This climbs up trees, with its twining shrubby stems, twenty feet in height, and the whole abounds with a white glutinous milk ; leaves ovate, oval, or obovate, acute, numerous, two inches long, entire, smooth, shining above, pale underneath, stiffish; racemes terminating, branched, spreading, red; flowers numerous, small, red or purple; teeth of the calix very minute, coloured; corolla cylindric, very short; border reflex, with sharp segments; nectareous glands connate; filamenta from the bottom of the tube, longer than the corolla; germen twin, pubescent; style with a very slight longitudinal groove on each side, by which it may be easily split in two; stigma within the cone of the anthera; follicles horizontal, reflex, roundish, obtuse, two-valved; seeds oblong, with a bristly down .- Native of the island of St. Domingo, where it flowers in November; and of the mountainous woods of Hispaniola, where it flowers in the spring. The French call it gras de galle.

10. Echites Spicata. Spikes axillary, short; stamina standing out; leaves anbovate. This plant abounds in a white milk, and climbs the trees to the height of sixty feet; stems round, wordy, plant, twining, an inch in diameter, with alternate branches, a foot and a half long, at different distances, and leafy their whole length; leaves oblong, vein-ed, smoothish, acuminate, distich, half a foot long; spikes opposite, close, an inch and a half long; solitary, spreading, sometimes but rarely divided in two; flowers numerous, switte, small, subsessite.—Native of Carthagena in New Spain, where it is found in thick lofty woods, flowering in July and August.

Î1. Echites Caudata. Corollas funnel-form, with very long linear tips. It is a tree, with lanceolate, elliptic, naked leaves. The flowers are axillary, peduncled, erect, the size of those of nerium or oleander, funnel-form; border erect, terminating in linear tips, longer than the whole corolla, a circumstance in which it differs from all other known plants. —Native of the East Indies.

12. Echites Scholaris. Leaves subverticilled, oblong; folicies filicitors, ever long; umbels compound. The branches of this tree are leafy only at the joints, where there are five or seven oval-lanceolate leaves, which are coriaceous, and transversely streaked. A few peduanceles are produced among the leaves, of the same length with them. The flowers are very small, and the folicies in pairs, a foot and a half long, and therefore longer than any others that are known.— Naitve of the East Indies.

13. Echites Annularis. Stem twining; corollas salver, form, with an elevated ring on the tube; leaves a foot long; racemes bifd, peduncled, axillary; calicine l-radlets oblong, erect, concave: tube of the corolla explication; longer than the calix; segments of the border roundish, emarginate; anthere countae, within the thrat; sigma obluse, surrounded by a sharp ring. The nectary covers the germen with five small ovate scales.—Native of Surinam.

14. Echites Siphilitica. Leaves ovate, subprioled, very smooth, ribbed ; panicles dichotomous; flowers in spikes.— This tree yields a milky jinke. The leaves are on short petioles, a long span and upwards in length, and sharr; peduncles axillary, divided into two branches, and these again into two shorter spikes, closely covered with flowers, and errect; corolla large, white, with a large flat border; follicles in divaricating pairs.—Native of Surinam, where a decoction of it is often used as a remedy in the venereal disease.

15. Echites Succulenta. Prickles in pairs, extrafoliaceous; leaves linear, tomentose underneath; corollas funnel-form,— Native of the Cape of Good Hope.

10. Echites Bispinosa. Prickles in pairs, extrafoliaceous; leaves lanceolate, smooth; corollas salver-form. This very strongly resembles the preceding, and both are very singular shrubs, succulent, miky, and two-spined.—Native of the Cape of Good Hope.

17. Echites Costata. Peduncles in cymes; leaves elliptic, lanceolate, acuminate.-Native of the Society Isles.

18. Echites Tomentosa. Leaves cordate-oblong, neuminate, both hey and the stem rough-haired; flowers in racemes, hairy; stem twining, round, as are also the petioles; the rib, nerves, and edges of the leaves, rough-haired; leaves three inches long, a little narrowed towards the base, bronder at top, cordate at the base; the sinus being closed by the incombent lobe; they are somewhat rugged, nerved, veined, hairing hairs presed close, and scattered over both surfaces, but more copiously, and of a greater length on the rhs and nerves, especially underneath; pedoncles axillary, shorter than the leaf, rough-haired; flowers approximating, alternate, 6 G

on short pedicels; segments of the calix lanceolate, attenuated, smooth; corolla two inches in diameter, or a little more, with ash-coloured hairs scattered over the outside, but very thick in the tube, where the filamenta are inserted ; style filiform, the length of the tube .- Found by Von Rohr in Cayenne.

ECH

19. Echites Domingensis. Peduncles racemed ; leaves cordate, ovate, somewhat rigid, of a different colour underneath; stem twining .- Native of the West Indies.

20. Echites Asperuginis. Peduncles racemed : follicles filiform ; leaves oblong, acute, rough above ; stem twining. -Native of the West Indies.

21. Echites Circinalis. Peduncles axillary, many-flowered. jointed ; segments of the corolla waved ; leaves elliptic ; stem twining .-- Native of the West Indies.

22. Echites Floribunda. Racemes corymbed; leaves ovate, acuminate; nerves parallel; branches almost erect.-Native of the West Indies.

Echium ; a genus of the class Pentandria, order Monogynia .--- GENERIC CHARACTER. Calix: perianth five-parted, upright, permanent; divisions subulate, upright. Corolla: one-petalled, bell-shaped; tube very short; border upright, gradually widened, five-cleft, obtuse; divisions generally unequal; the two superior ones longer; the inferior smaller, sharp, reflex ; throat pervious. Stamina : filamenta five, subulate, length of the corolla, declined, unequal; antheræ oblong, incumbent. Pistil: germina four; style filiform, length of the stamina; stigma obtuse, two-cleft. Pericarp: none; calix grown stiffer, guarding the seeds in its cavity. Seeds: four, roundish, obliquely acuminate. ESSENTIAL CHARACTER. Corolla: irregular, with the throat naked .--Most of these plants are berbaceous ; some, however, are suffrutescent. The flowers are in spikes, or spike panicled ; in the spikelets, the flowers all point one way .---- The species are,

1. Echium Fruticosum ; Shrubby Viper's Bugloss. Stem shrubby; leaves lanceolate, attenuated at the base, villose, strigose, without veins; calicine leaflets lanceolate-acute. It has a shrubby stalk, two or three feet high, dividing at top into several branches; leaves sessile, hairy, light green; stamina not longer than the corolla. The flowers are produced singly between the leaves, at the ends of the branches; they are of a purple colour, and in shape much like those of the Cretan sort. It flowers in May and June, but does not ripen seed in England .- Native of the Cape of Good Hope. This plant is propagated by seeds, when they can be obtained, which should be sown in pots, filled with light sandy earth, soon after they are received. These may be exposed to the open air till the beginning of October, when the pots should be placed under a frame, to guard them from frost; but in mild weather, they should have the free air, to prevent the seeds from vegetating till the winter is past; for if the plants come up at that season, their stems will be weak, and full of juice, and very liable to rot with damps; therefore, it is much better, if the plants do not come up till toward March, which is the usual time of their appearing, when the seeds are not forced by warmth. When the plants are fit to remove, they should be each planted into a small pot filled with light earth, and placed under a frame to forward their putting out new roots; then they should be gradually inured to bear the open air, and may be placed abroad in a sheltered situation, at the latter end of May, where they may remain till the beginning of October, at which time they must be removed into an airy glass-case, where they may enjoy the sun, and have free air in mild weather. During the winter season, these plants must be sparingly watered ; for as their stems are succulent, too much moisture will cause them to to October, is annual, and a native of Italy.

In the summer, they should be set abroad in a sheltered rot situation, and treated in the same way as other plants from the same country.

2. Echium Candicans; Hoary Tree Viper's Bugloss, Stem shrubby; leaves lanceolate, nerved; they and the branches birsute; calicine leaflets oblong, and lanceolate-acute; styles rough with hairs. This handsome shrub has woody stems, and branches which are somewhat tomentose, marked with linear transverse scars from fallen leaves; leaves a span long, approximating, lanceolate-subulate, attenuated at the base, to the insertion where it widens, marked with lines above, and veined underneath; veins very long, and simple; towards the panicle they are imbricate, and narrower at the base: flowers in a conical panicle, formed of many spikes at the ends of the branches; spikes pedicelled, simple, pointing one way, bending inwards; corollas small, subhirsute, blue. The whole plant is white, and as it were silvery, with a soft close sbagginess covering the whole, hardly excepting the corolla .- Native of the high rocks of Madeira.

3. Echinm Giganteum ; Gigantic Viper's Bugloss. Stem shrubby; leaves lanceolate, attenuated at the base, hairy; hairs very short ; bractes and calices strigose ; stamina longer than the corolla. It is a very lofty shrub, with woody, round, hoary, smooth branches; leaves a span long, and the breadth of a finger, scabrous, veined; flowers pointing one way, and forming a very large, pyramidal, terminating thyrse, consisting of long-spiked peduncles; corollas obtuse, nearly equal, white .- Found by Masson on the rocks of Teneriffe.

4. Echium Strictum; Upright Viper's Bugloss. Stem shrubby, stiff, branching; leaves oblong, lanceolate, hairy; corollas somewhat bell-shaped; stamina longer than the corolla. It is distinguished, as its English name imports, by the uprightness and stiffness of the stem, by its petioled oblong leaves, and by the hairs of the stem being turned downwards. peduncles axillary at the top of the stem, solitary, naked, with three-parted spikelets, contracted into a head at the tip, The corolla is small and blue, with the stamina standing out. -- It is biennial, and flowers most part of the year, and was found by Masson on the rocks of Teneriffe.

5. Echium Spicatum; Spiked Viper's Bugloss. Stems ascending, very simple; flowers in spikes; root-leaves very many, a hand in length, lanceolate-linear, very narrow : stems twice the length of the leaves, with a few smaller, alternate, hairy leaves; spike terminating, nearly of a finger's length, compact ; calices hoary ; stamina longer than the corolla,-Native of the Cape of Good Hope.

6. Echium Argenteum; Silvery Viper's Bugloss. Leaves linear, hirsute, and whitish, patulous at the tip; stem branched determinately; leaves scattered, acute, bent outwards at the tip, hoary, with white hairs .- Native of the Cape of Good Hope.

7. Echium Capitatum; Headed Viper's Bugloss. Stem hairy ; flowers head-corymbed, equal ; stamina longer than the corolla : leaves hispid : flowers crowned closely into terminating heads ; corollas regular, funnel-form ; stamina twice as long as the corolla; and style double the length of the stamina .- Native of the Cape of Good Hope.

8. Echium Plantagineum; Plantain-leaved Viper's Bugloss. Root-leaves ovate, marked with lines, petioled ; leaves above, hairy, soft, hispid; root-leaves like those of plantain, very entire, large; stem-leaves lanceolate, sessile; stems bairy, with soft, not strigose hairs; brown dots under the hairs, as in the rest, but minute; corollas violet-coloured; bractes between the flowers, half cordate, the length of the calix, not subulate, not longer than the calix .- It flowers from July
9. Echium Lavigatum; Smooth-stalked Viper's Bugloss, Stem even; leaves iancoolate, naked, scabrous about the edge and at the tip; corollas equal; the stems are also undershrubby, and about a foot in height; leaves smooth, except that they are scabrous with mucronate callous dots about the edge, along the keel, and at the tip above; racemes from the axils of the upper leaves, pointing one way, and smooth; calix smooth; corolla but slighty irregular; stamina deelined; seeds muricate.—Native of the Cape of Good Hope.

10. Echium Italicum; Wall Fiper's Digloss. Stem herbaccons, hairy: leaves linear-lauceolate, strigose, hirsute, the lower ones nerved; corollas nearly equal; stamina longer than the corolla; the statk is upright and hairy; the flowers are produced in short spikes on the side of the branches, they are small, and scarcely appear above the calices; some plants have white flowers, others purplish; the calices are very hairy, and cut into acute segments.

11. Echium Rubrum; Red Viper's Bugless. Flowers in a long spike made up of little short racemes; corollas nearly equal; leaves hispid; stem erect, about a fool high; radical leaves long and lanceolate, hairy, deepish green above, paler below, and with a strong back-nerve; stem-leaves smaller and narrower; stem rough, and covered with red points; spike of flowers about a fool long, consisting, as in the common echium, of a great many separate spikelets, or smaller flowering spikes, proceeding from the aloe of the small leaves, and at first coiled as usual; flowers rather small tana large, of a palish red, and with nearly equal and somewhat triangular segments; anthere pale blue.—It grows plentifully in Hungary, where it is a naive.

12. Echinum Vulgare ; Common Viper's Bugloss. Stem tubercled and hispid; stem-leaves lanceolate, hispid; flowers in lateral spikes. The whole plant is hispid ; the stem often, and the leaves in some instances, beautifully spotted with red; the hairs on the stem rise from glossy purplish black tubercles; root-leaves forming a tuft, nearly two feet long, petioled; stem-leaves sessile, four or five inches long, all lanceolate, quite entire, scabrous, and hairy on both sides; flowers numerous, in spikes, those of each spike pointing one way, and closely wedged together; corolla, before it expands, of a fine red, afterwards of a bright blue, which varies to pale red and white; if the colour be blue, the stems are bluish, the stamina purple, and the bulbs from which the hairs spring are blood-red ; but if the corolla be pale red, then the other parts of the flower are of the same colour, and the hair-bulbs are yellow; and if it be white, all the parts of the flower are of the same colour, and the hair-bulbs are green; the outside of the corolla is set with short hairs, and is marked with five rising ribs, extending from the middle of each segment down to the base; the upper and lateral segments are rounded, the lowest somewhat pointed ; the filamenta are red, and longer than the corolla, sometimes much longer, and sometimes very little longer, or barely equal to the upper segment; antheræ gray ; style very hairy ; germina embedded in a fleshy receptacle. It is a showy plant; and such is the absurdity of fashion, that if it were not common, it would assuredly obtain admittance into our gardens. It is biennial, and appears abundantly once in three years, in the corn-fields of Cambridgeshire, where it is known by the name of cat's tail. Bees are fond of the flowers; but, unfortunately for those useful and interesting insects, the strong hairs of the corolla and style often tear their wings. Hill informs us, that the leaves, especially those growing near to the root, make a good cordial by infusion, which operates by perspiration, and alleviates fevers, head aches, and all nervous complaints.

13. Echium Violaceum; Violet-flowered Viper's Bugloss.)

Corollas equal to the stamina; tube shorter than the calix; stem a foot high, branching at the top and the bairs are softer; and some of them rise from tobercles, these are hardly if at all discernible on the leaves, though they are on the stem, where they are intermixed with short hairs, not rising from tubercles; corolla deep blue, half as long again as the calix, at the bottom of the two upper segments, beset both within and without with hairs. Found near Norwich, in England.—Native of Austria and Germany. It flowers in July.

14. Echium Creticum; Cretan Viper's Bugloss. Stem procumbent; fruiting calices distant. It has trailing hairy stalks, about a foot long, putting out several side-branches; leaves lanceolate, hairy, about three inches long, and threequarters of an inch broad, sessile ; the flowers come out on slender spikes, upon long peduncles, from the axils ; they are stalks, a foot and a half long, declining towards the ground, and covered with stinging hairs; leaves four inches long, and not more than half an inch broad, pretty much warted, and hairy; the flowers grow in loose spikes from the sides of the stalks, and also at the ends of the branches, they are of a reddish purple colour, but not so large as those of the preceding; and the stamina are longer than the corolla. This plant is annual, and the most beautiful of the whole genus ; to propagate it, the seeds must be sown every year where they are designed to remain, and the plants require no other culture but to keep them clear from weeds, and to thin them where they grow too close; they flower in July, and their seeds ripen in five or six weeks after : the seeds of the other sorts being sown in the spring, will in the second summer after produce flowers and seeds, after which they seldom continue. They delight in a rubbishy, gravelly soil, and will grow upon the tops of old walls or buildings, where, when they have once established themselves, they will drop their seeds, and thereby maintain a succession of plants without any care; and on these places they will appear very beautiful.

15. Echium Orientale; Oriental Viper's Bugloss. Stem branched; stem-leaves ovate; flowers solitary, lateral; root above a foot long, and two inches thick, mucilaginous, and sweetish; stem about three feet high, an inch thick, pale green, hard, solid; lower leaves fifteen or sixteen inches long, and four or five inches wide, pointed, whitish green, satin-like above, and cottony underneath, with a strong midrib, they diminish considerably along the stem, not being above half a foot in length, they are also less cottony than the former, and much more pointed; branches about half a foot long, both they and the top of the stem are rough with strong hairs, accompanied by leaves about an inch and a half in length. All these branches are subdivided into smaller ones, bending like a scorpion's tail, and loaded with flowers an inch and a half in length, of a pale blue colour, with two red bands on three of the segments, on a bright purple ground ; calix almost as long as the corolla, rough with very large hairs; style almost as long as the corolla, slightly villose, and purple ; the flower has no smell .- Found by Tonrnefort in the Levant.

16. Echima Lusitanicum : Portugal Fiper's Bugloss. Corollas longer than the stamina; the lower leaves are more than a foot long, and two inches broad in the middle, gradually lessening to both ends, and covered with soft hairs; the stalks grow two feet high; the flowers are in short spikes from the sides of them.—Native of Spain and Portugal.

17. Echium Sericeum. Leaves linear, wedge-shaped; stem suffruticose, both hoary; stems several, diffused, woody at the base, simple, a palm or more in height, soft at bottom, somewhat rugged at top, hoary, with white hairs pressed | numerous, four-cleft, minute; of the ray very many, minute: close, and placed on minute tubercles, the lower ones longer, the upper ones more dispersed; the lower leaves from two to three inches long, crowded, linear, ciliate below, gradually widening towards the top, dilated at the base, embracing, obtuse, hoary on both sides, with close short hairs placed on minute dots, the upper ones an inch long and recurved ; spike terminating, pointing one way, hoary-haired ; Bractes ovate-lanceolate, obtuse; corolla villose on the outside : stamina longer than the corolla .- Native of Egypt.

18. Echium Setosum, Leaves linear-lanceolate; stem suffruticose, procumbent, both hispid and hoary; spike terminating, solitary; flowers at first crowded, but afterwards more remote; bractes ovate; corolla half an inch in diameter, hoary; stamina longer than the corolla; nuts small, ovate, acuminate, muricate.

19. Echium Glabrum. Leaves linear-lanceolate, smooth above, callous, dotted beneath on the outside; spikes alternate; branches scattered, a little compressed at top, purplish ash-coloured, with very slender appressed villose hairs ; leaves sessile, firm, an iach long, even; spikes from the upper axils, erect, few-flowered, two inches long; bractes ovate-lanceolate, the length of the calix; calices hairy, with lanceolate segments, the same length with the tube of the corolla; stamina longer than the corolla .- Native of the Cape of Good Hope.

20. Echium Rosmarinifolium. Leaves petioled, linearlanceolate, reflex at the edge, hairy underneath, and hoary; branches round, scarred, hoary with hairs; petiole very short; raceme terminating, short; leaflets of the calix linear, hairy; corolla almost regular, half as long again as the calix .- Native of the Cape of Good Hope.

21. Echium Sphærocephalum. Leaves linear-lanceolate, strigose ; heads solitary, terminating ; branches smooth ; heads globular, hairy, on short peduncles, with small flowers that are almost regular, and having stamina longer than the co- the South Seas. rolla .- Native of the Cape of Good Hope.

Eclipta; a genus of the class Syngenesia, order Polygamia Superflua .- GENERIC CHARACTER. Calix : common, many-leaved; leaflets lanceolate, nearly equal, in a double series. Corolla : compound rayed ; of the ray most plentiful, female; of the disk hermaphrodite; proper of the hermaphrodite tubular, four-cleft, upright, outwardly mealy; in the females very narrow, ligulate. Stamina : in the hermaphrodites ; filamenta four, very short. Antheræ cylindric. Pistil : in the hermaphrodites, germen oblong; style middling; stigma two-cleft, spreading, Pericarp; calix unchanged. Seed : in the hermaphrodites, oblong, compressed, notched, obtuse, unarmed; in the females three-sided, oblong, notched, obtuse, unarmed. Receptacle: flattish, chaffy; chaffs very narrow. ESSENTIAL CHARACTER. Receptacle: chaffy. Down: none; corollets of the disk four-cleft. -These plants are all propagated by seeds, sown upon a hot-bed in the spring; when they are fit to remove they should be transplanted into a fresh hot-bed to bring them forward; they must be shaded till they have taken new root, and then treated as other tender annuals, being careful not to draw them up too weak. In June they may be taken up with balls of earth, and being planted with pots, are to be set in a stove where they must remain, and be shaded and watered, or they will not flower well.— The species are, 1. Eclipta Erecta; Upright Eclipta. Stem erect; leaves

deflected at the base, and sessile; peduncles alternate, usually in pairs, longer than the leaves, one-flowered; flowers white; calix of five or six leaves; scales broad, lanceolate, two larger, somewhat hispid; flowers discoid; of the disk pletely answers the design as dwarf-box.

seeds angular, thickish, naked, without any down; receptacle naked, not chaffy .-- Native of the West Indies, and of the East Indies, Cochin-china, &c. Loureiro says, that in Cochin-china the leaves are not nerved, nor properly serrate. nor sessile ; and that the flowers are not in pairs : he adds, that the juice is used for dveing hair both of men and quadrupeds, whence the natives call it ink-plant. It flowers from July to September, and is an annual plant, although Linneus has marked it as biennial.

2. Eclipta Punctata : Dotted-stalked Eclipta. Stem erect. dotted ; leaves flat ; peduncles one-flowered, subterminating ; flowers whitish, having no smell; the whole plant produces a green watery sap, which becomes black when exposed to the air, may be used as ink, and if it could be fixed would make a very fine dye; the negroes are said to increase the blackness of their skin by rubbing it with this juice. This species resembles the first species, but the stem has white dots scattered over it. It is annual, and a native of St. Domingo and Martinico.

3. Eclipta Latifolia: Orate-leaved Eclipta. Stem erect: leaves ovate, petioled; root annual; flowers terminating, solitary, on very short white peduncles; calix close, and the length of the flower; ray of the corolla short, with subtrifid petals; in the disk four florets, which are five or six-cleft; antheræ black; stigmas recurved; seeds oblong, subtrigonal; receptacle the length of the seeds .- It flowers in September and October, and is a native of the East Indies,

4. Eclipta Prostrata; Trailing Eclipta. Stem prostrate; leaves somewhat waved and petioled. It is often found erect, like the first species, with subsessile flowers, or at least on very short peduncles; the flowers come out alternately in pairs; calix simple; antheræ brown; seeds awnless and muricate, in four rows. It is an annual plant .- Native of the East Indies, Japan, Cochin-china, and the isle of Tanna in

5. Eclipta Sessilis; Sessile-leaved Eclipta. Stem erect; leaves slightly embracing, ovate, toothed; flowers axillary, sessile, discoid .- This is an annual plant, and a native of Iamaica.

Edgings .- The best and most durable plant for edgings in a garden, is box ; which, if well planted and rightly managed, will continue in beauty for many years. The best season for planting it, is either in the autumn or very early in the spring, for if it be planted later, and the season happen to turn out hot and dry, it will be very subject to miscarry, unless great care be taken to supply it with water. The best sort for this purpose is the dwarf Dutch .- Box-edgings are only planted upon the sides of the borders next the walks, and not, as the fashion formerly was to plant the edgings of flower-beds, or the edges of fruit borders, in the middle of gardens, unless they have gravel walks between them, which makes it necessary to keep the walks clean, by keeping the earth of the borders from washing down into the walks during heavy raius. It was also the custom to plant edgings of divers sorts of aromatic herbs, such as thyme, savory, hyssop, lavender, rue, &c. but as these very soon grow woody, and therefore caunot be kept in due compass, and are also often killed in whole patches by hard winters, whereby the edgings are rendered incomplete; they are now seldom used for this purpose. Some persons make edgings of daisies, thrift, catchfly, and other flowering plants; but these also require to be transplanted every year, in order to have them handsome, for they soon grow out of form, and are subject to decay in patches, so that there is not any plant which so com-

Egg-plant. See Solanum.

Eglantine. See Rosa. Ehretia ; a genus of the class Pentandria, order Monaudria. -GENERIC CHARACTER. Calix: perianth one-leafed, hell-shaped, half five-cleft, obtuse, very small, permanent. Corolla: one-petalled ; tube longer than the calix ; border five-cleft ; divisions somewhat ovate, flat. Stamina : filamenta five, subulate, patulous, length of the corolla ; antheræ roundish, incumbent. Pistil: germen roundish; style filiform, thicker above, length of the stamina; stigma obtuse, emarginate. Pericarp: berry roundish, one-celled. Seeds: four, convex on one side, cornered on the other. ESSEN-TIAL CHARACTER. Berry: two-celled. Seeds: solitary, two-celled ; stigma emarginate. These plants are too tender to thrive abroad in England, where they require a moderately warm stove in the winter; but they may be placed in the open air during the heat of the summer; but it should be in a sheltered situation; and when the evenings grow cold in the autumn, they must be removed into shelter. They are propagated by seeds, when they can be obtained, which should be sown in small pots, and plunged into a hot-bed. They may also be increased by layers, but these are long before they put out roots .---- The species are,

1. Ehretia Tinifolia ; Tinus-leaved Ehretia. Leaves oblong, ovate, quite entire, smooth ; flowers panicled. It is an upright tree, from twenty to thirty feet high, with an oblong thick head; branches unarmed, roundish, subdivided; leaves alternate, veiued, blunt, about four inches long, on short pctioles; panicles terminating, oblong, large; flowers terminating, numerous, white, small; calix five-parted, with minute ovate segments; corolla a little larger than the calix, with acute segments, finally rolled back; filamenta longer than the corolla; style scarcely shorter than the stamina, awl-shaped, bifid; stigmas simple; berry spherical, at first yellow, then black; seeds two, hemispherical, two-celled .- It flowers in January and February, and is a native of Cuba and Jamaica, where it is pretty common in the lower lands, being known by the name of bastard cherry-tree. It generally rises to the height of sixteen or twenty feet ; and produces small berries, which seldom exceed the largest of our European currants in size, and serve to feed the poultry, and are even eaten by the poorer sort of people.

2. Ehretia Spinosa; Thorny Ehretia. Thorny. This tree has a trunk three or four inches in diameter, dividing almost close to the ground, usually in three parts, which run up twenty-five or thirty feet high : these having put out a few similar boughs in their progress, scarcely attain the length of ten feet before they are bowed back to the ground, and require support from the boughs of the neighbouring trees ; they have many very short lateral branches, scatteringly disposed ; their bark is ash-coloured and smooth, strong, woody, short, very thick, awl-shaped ; spines are scattered over the trunk, principal boughs, and secondary branches, the oldest of which frequently put forth from their middle a perpendicular leafy branchlet of the same length with themselves .- It flowers in August, bears fruit in October, and is a native of Carthagena in New Spain, where it is known by the name of cacara-cacara, but differs much in habit from the preceding description.

3. Ehretia Bourreria : Oval-leaved Ehretia. Leaves ovate. quite entire, smooth; flowers in a kind of corymb; calices smooth. This small inelegant tree has an adust habit, and is often found fifteen feet high in the island of Curacao, though in Martinico it seldom exceeds five ; trunk unequal, with a chinky bark; branches very many, irregular; leaves alternate, petioled, quite entire, various, obtuse, acute, or divided, smooth; peduncles crowded or solitary, simple or 41.

emarginate; on rocks smooth, elsewhere rugged, differing in size; racemes corymbed, terminating; flowers sweet; corollas white, with roundish segments; antheræ obloug; calix in the fruit cloven; berries shining, saffron or orange-coloured, pulpy, sweet, succulent, more quadrangular as they are larger, eaten by children and the natives .- Native of the West Indies, growing from the crevices of rocks, where there is no soil. According to Dr. Browne, it grows in the savannas of Jamaica, where it is called poison berries, and by the French bois cabril batard.

4. Ehretia Exsucca; Dry-fruited Ehretia. Leaves wedgeform, lanceolate, with the edge reflex. This small tree is fifteen feet in height, sometimes erect, and sometimes supporting itself on other trees; leaves ovate, acute, very smooth, alternate, petioled, two inches long; racenies branched, subcorymbed, subterminating; flowers having a slight degree of sweetness, much larger than in the preceding species; corollas white, with heart-shaped segments; antherae ovate, and large; berries green, four-cornered, slightly fourgrooved, ending in a blunt point, without any pulp, becoming finally of a reddish black colour, dividing into four parts, with the seeds sticking in them, and continuing a long time on the tree .- It is often found in the neighbourhood of Carthagena in New Spain, in mountain woods, where it flowers from May to August, and ripens seed in October.

5. Ehretia Virgata. Leaves oblong, entire, rugged on the upper surface; branches filiform; flowers terminating, scattered ; calices hirsute .- Native of Hispaniola.

Ehrharta: a genus of the class Hexandria, order Monogynia, or Digynia .- GENERIC CHARACTER. Glume oneflowered, two-valved, ovate, concave, shorter than the corolla, patulous, one-valved, a little larger than the other, and membrauaceous. Corolla: double; outer two-valved; valves oblong, complicate, keeled, retuse, transversely wrinkled, three times as long as the calix, villose on the outside at the base, inner a little shorter, keeled, with a smooth even surface; nectary two-leaved, very small; leaflets jagged and ciliate, involving the genitals. Stamina: filamenta six, capillary, very short; antheræ upright, linear, emarginate, shorter than the corolla. Pistil: germen ovate; style compressed, very short, smooth ; stigma simple, villose. Pericarp: none. Seed : single, ovate, smooth. ESSENTIAL CHARACTER. Calix : a two-valved, one-flowered glume. Corolla: double, each two-valved, the outer compressed, -The species are,

1. Ehrharta Cartilaginea. Culm undivided ; panicle simple ; outer corolla retuse, almost awnless ; edge of the leaves cartilaginous and curled. This is an extremely beautiful smooth glass; root fibrous, perennial; culm erect, jointed, from a foot and half to two feet high; joints above five; flowers drooping ; calicine glume coloured at the base ; outer corolline glume violet, inner becoming pale; bundles of villose hairs very white and shining; nectary and filamenta white; antheræ yellow .- First observed at the Cape of Good Hope by Thunberg.

2. Ehrharta Bulbosa. Culm undivided; panicle branched, many-flowered; outer corolla retuse, awned .--- Native of the Cape of Good Hope.

3. Ehrharta Longiflora. Culm simple; panicle branched. many-flowered; outer corolla mucronate, tubercled, and hispid ; flowers three-stamined ; root fibrous, whitish ; culms many, erect, jointed, leafy, round, streaked, very smooth: leaves sheathing, linear-lanceolate, acute, nerved, streaked, smooth, except about the edge, where it is scabrous; panicle terminating, erect; branches crowded, more or less sub-6 H

divided, capillary, straight, scabrons, thicker at the tip; ; flowers upright, large, hermaphrodite, three-stamined; corolla pale green; nectary none; filamenta very slender, equal; antherae ovate, blifd both at the tip and base, two-celled, as the germen increases they are torn from the filamenta, and raised on the styles to the top of the flower; germen oval, compressed, smooth; styles two, upright; stigmas crimite, whiths; seed oval, maked,—Native of the Cape of Good Hope.

4. Ebrharta Panica. Culm divided; panicle somewhat branched; flowers erect, two-styled; leaves sheathing, ensiform, streaked, naked, scabrous about the edge; peduucles capillary, straight, thickening at the end.—Native of the Cape of Good Hope.

5. Enhanta Calicina. Culm branched; panicle almost simple; calix coloured, equaliling the corolla; leaves sharp, very slightly pubescent underneath, subciliate about the edge; peduncies usually in fours, one-dowered, capillary, straight, thickening at the tip, mostly pointing one way; flowers the same size as in the fourth species, upright, monecous; filamenta equal; anthere much larger than in the fourth species, filing almost the whole cavity of the inner corolla, and at length standing forth.—Brought from the Cape of Good Hope by Sparmann.

Ekbergia; a genus of the class Decandria, order Monogonia.--GENREIC CHARACTER. Calir: periath oneleafed, bell-shaped, tomentose, four-parted; divisions oute, obtuse. Coralle; petals four, oblong, obtuse, tomentose on the ontside, a little longer than the calix; nectary a ring surrounding the base of the gennen. Stamina; filamenta ten, very short, pubescent; anthera ovate, acute, upright. Pisfil: germen superior; style cylindric, very short; stigma capitate. Pericarp a globular berry. Seeds: five, oblong. ESSENTAL CHARACTER. Calir: four-parted. Petals: four. Neetary: like a garland, surrounding the germe. Berry: containing five oblong seeds.----The only known species is,

 Ekebergia Capensis. A tree with abruptly or unequally pinnate leaves; the common petiole flatted; the flowers panicled, and axillary.

Elcagenus; a genus of the class Tetrandria, order Mongynia.-GENERIC CHARACTER. Calix: perinath oneleafed, four-cleft, superior, straight, bell-form, outwardly scabrous, invardly coloured, deciduous. Corolla: none. Stamina: filamenta four, very short, inserted into the calix below the divisions; anthere oblong, incambent. Pistil: germen roundish, inferior; style simple, a little shorter than the calix; sigma simple. Pericarp: A tompe ovate, obtuse, smooth, with a dotted tip. Seed: nut oblong, obtuse. Es-SENTAL CHARACTER. Corolla: none. Calix: iour-cleft, bell-form, superior; drupe below the calix.----The species are.

1. Elsagnus Angustiolia; Narrous-laced Okaster, Leaves Janceolate. A tree, branching from the bottom, growing sometimes to the height of three fathoms, with a trunk the incidences of a man's arm or thigh, ledguat in its appearance, especially from the silvery brightness of the laeves; bark smooth, brown; wood pale, prettily vertued with gray and brown, but not lard; branches and branchiets slender, frequent, alternate, smooth, unarmed, or having thorns, especially in young trees. The flowers come out at the middle leaves of the smaller branches, usually solitary, of two together, sometimes, but very seldom, three from each axil, mich they solitary, obligation, laving having solitary, obligation, and while when young.

thicker and vellowish when ripe, inclosing within a sweet pulp, or woody, gray, furrowed nut. In the deserts near the Volga, the fruit is hardly bigger than the berries of the barberry, whereas in the more southern parts it is of the size of the cornelian cherry. Mr. Miller specifically distinguishes the thorny from the unarmed narrow-leaved oleaster. The latter, he says, is that which is most commonly preserved in the English gardens. The leaves are more than four inches long, and not half an inch broad ; they are very soft, and have a shining appearance like satin. The flowers come out at the footstalks of the leaves singly, or two, and frequently three, at the same place; the outside of the calix is silvery and studded, the inside of a pale yellow ; it has a very strong scent. The flowers appear in July, and are sometimes succeeded by fruit. Mr. Miller conceives the thorny elæagnus to be the common sort, which grows naturally in Bohemia, aud of which he saw some trees in the curious garden of the famous Boerhaave, near Leyden. The leaves of this are not more than two inches long, and about three quarters of an inch broad in the middle; they are white, and have a soft cottony down on their surface ; at the footstalk of every leaf comes out a pretty long sharp thorn ; the leaves being alternate, the spines come out on each side of the branches. The flowers are small, and have a strong scent when fully open .----Native of the Levant. This species is extremely hardy, and sets the frost at defiance. It is not, however, of very long duration; young plants, therefore, should be raised, one in three or four years, by seeds or layers,

2. Elaaguius Orientalis; Oriental Oleaster. Leaves oblong, ovate, opake. This has the appearance of the foregoing species, but the leaves are twice as broad, ovate, oblongish, soft to the touch ou both sides, pale underneath, but ueither surface shining nor silvery. In its stature and manner of growth, this tree resembles an indile-sized willow, as it does also in the heariness of its leaves, and the division of its branches. This, and the spinosa of Linueus, do not sceem to differ, except as a garden-tree does from a wild one, or the thorny variety of the preceding species from the unarmed.—Native of the mountaius of Persia, from Caucasus to Derbent; found in abundance on the shores of the Caspian sea, and also in the Levant. This plant requires the protection of a greenhouse.

3. Elsaganus Latifolia; Broad-leared Oleaster. Leaves orate. This rises with a word stem to the height of eight or nine feet, dividing into many branches; leaves silvery, with several irregular dark-coloured spots; they are alternate, and continue all the year. Naive of the East Indies and China. This sort requires a warm stove to preserve it in this country; for it is too tender to live in the open air, except for a short time in the warmest part of summer. It may be raised from the seeds.

4. Elkagnus Crispa; Curled-laterd Oleaster. Leaves lancolate-oblong, obluse, wared; howrs solitary. This is an upright tree; branches and branchlets alternate, round, divaricate, upright, ash-coloured, scabrous with dots; the last trug's angular, and whitis); leaves alternate, petioled, entire, above naked, brownish, dotted, with a middle longitudinal furrow, silvery underneath; from erect patulous, an inch and a half in length; petiole furrowed above, scarcely a line long; flowers not in the asils, but scattered over the last twigs, solitary, and pedunoled; peduncle capillary, shorter than the flower—Native of Japan.

5. Elæagnus Multiflora; *Many flowered Oleaster*. Leaves obovate, obtuse; flowers axillary, aggregate; pedualese longer than the flower; stem shrubby, little brauched; brauches and branchlets alternate, few, round, ferruginous. bud, many, alternate, petioled, entire, upright, above half naked, with scaly silver dots, wholly covered with silvery scales underneath, unequal, about an inch in length ; petioles capillary, a line in length; flowers many, peduneled from a bud among the leaves; peduneles capillary, loose, silvery, about an inch long; calix club-shaped, oblong .--- Native of Japan.

6. Elæagnus Umbellata; Umbelled Oleaster. Leaves obovate, obtuse; flowers axillary, aggregate; pcduncles shorter than the flower; stem shrubby; branches and branchlets alternate, round, upright, ferruginous, brownish, scabrous with dots ; leaves from alternate buds, many, petioled, patulous, rather naked above, with silvery dots, underneath silvered all over, half an inch in length; petioles capillary, scarcely a line long; flowers many, from a bud among the leaves, in a kind of umbel, peduncled, drooping ; peduncles capillary, nodding, scarcely a line in length; calix ovate .--Native of Japan.

7. Elæagnus Glabra; Smooth-leared Oleaster. Leaves ovate-oblong, acuminate : flowers axillary, subsolitary ; stem arborescent; branches roundish, almost naked, brown; branchlets angular, reddish, ash-coloured, scabrous with dots, alternate, from erect patulous; leaves alternate, petioled, entire, from spreading erect, above green, smooth, underneath reddish, scaly, with ferruginous dots interspersed, an inch and a half in length; petioles semicylindric, chaunelled above, half an inch long; flowers axillary, solitary, and in pairs, peduncled, upright; peduncles shorter than the flower, capillary .--- Native of Japan.

8. Elæagnus Macrophylla; Silver-leaved Oleaster. Leaves rounded, ovate, silvery. This is an upright thornless tree; branches round, streaked, tubercled, with the deciduous branchlets ash-coloured, scabrous with dots, upright; branchlets angular, alternate, like the branches; leaves alternate, petioled, entire, from erect patulons, above smooth, green, beneath silvery, an inch in length; petioles semicylindric, above channelled, upright, half an inch long; flowers axillary, aggregate, peduncled, almost upright; peduncles four or more, the length of the flower.

9. Elæagnus Pungens. Branchlets becoming thorns; leaves oblong, waved ; flowers axillary, in pairs. This is an upright tree, a fathom in height, with a brown scabrous bark; branches round like the trunk, flexuose, leafless, spreading ; branchlets alternate like the branches, leafy, stiff, spinescent at the end, the extreme ones axillary, spinescent, very short, leafless; leaves alternate, petioled, somewhat obtuse, entire, above smooth, green, beneath silvery, with scales interspersed with ferruginous dots, from reflex spreading, an inch long, stiff; petiole half an inch in length; flowers in the axils of the leaves, about two, distinct, upright; pedicels shorter than the flower .--- Native of Japan.

Elæis; a genus of the class Diæcia, order Hexandria .---GENERIC CHARACTER. Male. Calix : perianth six-leaved ; leaflets concave, upright. Corolla: one-petalled, six-cleft, upright, sharp, length of the calix. Stamina : filamenta six, subulate, length of the corolla; antheræ oblongsharp. Female. Calix : as in the male, (according to Gærtner, nine leaves, with the inner leaflets longer.) Corolla: sixpetalled. Pistil: germen-ovate; style thickish; stigmas three, reflex. Pericarp: drupe fibrous, ovate, somewhat angulated, oily, (superior berried, one-celled, according to Gærtner.) Seed : nut ovate, obscurely three-sided, with three holes, three-valved, one-celled. ESSENTIAL CHARAC-TER. Male. Calix: six-leaved. Corolla: six-cleft. Stamina : six. Female. Calix : six-leaved. Corolla : six-petal- from reflex expanding, unequal. Pistil: germen, somewhat

brown, spreading, scabrous with dots; leaves from each led; stigmas three; drupe fibrous; nut one to three-valved. -The only species known and fully described is,

ELA

1. Elæis Guineensis. Leaflets long, narrower, and not so stiff as most of the palms. The forestalks of the leaves are broad at their base, where they embrace the stem, diminish gradually upwards, and are armed with strong, blunt, yellowish thorns, which are largest at their base. The flowers come out among the leaves at the top of the stem, some bunches having only male flowers, others only female, the latter of which are succeeded by oval berries, bigger than the largest Spanish olives, but of the same shape; they grow in very large clusters, and are of a yellowish colour when ripe. From this fruit, the inhabitants of the West India islands draw an oil, in the same manner as if it were extracted from olives. They also obtain a liquor from the body of the tree, which, when fermented, has a vinous quality, and will inebriate. The leaves are wrought by negroes into mats, on which they repose. The West Indians call this tree, the oily palm, and uegro's oil, the fruit having been first imported from Africa by the negroes. It grows in great plenty on the coast of Guinea, and also in the Cape de Verd Islands, but was not found in any of our American colonies, till carried there by the negroes, who now propagate it in great plenty. The French call it palmier. Gærtner mentions another elæis, which he names melanococca, from the blackness of the nuts. but thinks to be probably only a variety of the above. The shell, however, is much smaller, and not so much bellied, but rather oblong, and suddenly contracted at the tip into an oblique dagger-point; it is also thinner, and elegantly variegated on the outside with testaceous streaks irregularly confluent, and with alternate streaks like the others, but of a coal black; when broken, it appears of a sooty black colour, and the seed is ovate, oblong, and brown. Jacquin also describes another very thorny palm, which has somewhat of the same habit as the elæis Guineensis, and is called gigri in the island of Martinico. The fruit is eatable, of an acid flavour. globular, slightly depressed, acuminate by means of the style, scarlet, and shining. The pulp is small, red, soft, and not fibrous, surrounded by a very thin pellicle. Nut brown, with three obscure holes, from which run lines in a stellate order. like veins, over the whole surface ; kernel cartilaginous and hollow. A palm occurs also about Carthagena in New Spain. which the natives call corozo, and make both an oil and a butter of the fruit. The pericarp is shining, and yellow on the outside, supported by a three-leaved calix, and a threepetalled corolla, permanent, and shining. It is but little fibrose, not thick, and contains a pleasant oil. Its form is ovate, obscurely three-cornered. Nut black and shining, of the same form, with three obscure holes at the base; kernel roundish, cartilaginous, very hard, solid, with the fruit slightly cloven. To propagate the species first described, it must be kept constantly in the bark stove, otherwise it will make no progress. In about twenty years it will be too tall for most of our stoves. It is propagated by seeds; for the sowing and management of which, see Palms and Phænix.

Elæocarpus ; a genus of the class Polyandria, order Monogynia --- GENERIC CHARACTER. Calix: perianth one-leafed, spreading, permanent, five-parted; leaflets linearlanceolate, concave, sharp. Corolla : petals five, with claws, multifid, laciniate, the extreme jags capillary, equal, scarcely longer than the calix, inserted at the base of the nectary, Stamina : filamenta twenty to thirty, capillary, very slender, short, inserted into the nectary; antheræ shorter than the corolla, upright, linear, scabrous, two valved at the tip ; valves spreading, with about five ciliate hairs, very slender, globular, villose, sitting on the nectary; style filform, longer than the stamina; stigma sharp. Pericerery: drupe oblong of a smooth even surface. Seed: nut oblong, grooved, and tubercled; shell subtrivalvular; kernel subtrigonal. Ed-SENTIAL CHARACTER. Calix: five-leaved. Corollar fivepetalled, jugged. Anthera: two-valved at the tip. Drupe: with a curled shell.——The species are,

ELA

1. Elacoarpus Serratus. Leaves alternate, lanccolate, elliptic, serrate; raccentes axillary; branches round, warted, smooth; leaves petioled, three inches long, bluntly serrate, smooth, nerved, and veined; racenes axillary; flowers distant. Linneus observes, that they are simple, loose, solitary, the length of the leaves, which have a double gland at their base.—Native of several parts of the Last Indies.

2. Elacocarpus Dentatus. Leaves alternate oblong, toothserrate at top; racemes availary; flowers one-styled; branches round, dotted, smooth, with pubescent brauchlets; leaves petioled, two inches long, sharp at the base, smooth on both sides, except on the midrib, nerved above, somewhat veined underneath; petioles villose,—Native of the islands of the South Seas.

3. Elecocarpus Dicera. Leaves opposite, ovate, doubly serrate; racemes compound; flowers four-styled; branches round, a little compressed at top; leaves petioled; smooth, veined at top, two inches long; racemes three inches long, erect.—Native of the East Indies.

4. Elwocarpus Copalliérus. Leaves quite entire; paniel terminating; leaves large, ovate, coriaceous, very entire, with transverse nerves; flowers in panieles; calix superior; the divisions linear-oblong, obtuse, tomentose on both sides; petials longer than the calix, ovate, entire; stamina forty or more; anthere filiorm at the tip; germen cone, streaked, tomentose; style angular; fruit a conic, flesky, resinous, one-celled pome. The long linear anthere, terminated by cirthose threads, seem to furnish a better character than the torn petals. It yields the copal resin, of which there are nevertheless several sorts.—Native of the East Indies.

5. Elsocarpus Integerrimus. Leaves lanceolate, quite entire; flowers heaped, axillary. A middle-sized tree, with spreading branches; leaves smooth, petioled, alternate; flowers many, golden, sweet-smelling; calis five-leaved, with las leaf-les; petals lacerated, longer than the calix; germina ten, roundish, minute, placed round the base of the style; drups small, black, subovate, subacnuter, ripening singly, the rest of the germina proving abortive.—Native of Cochin-china, where it is also cultivated for the sweetness and beauty of the flowers.

6. Elacocarpus Oblongus. Drupe berried, superior, ovate-oblong, or subcylindric, smooth, covered with a soft fleshy bark; shell stony, oblong, muricate, and curled, with irregular tubercles, having three spurious sutures, never opening, one-celled, testaceous; seed oblong, attenanced to both ends, obscurely three-cornered, ferruginous.—Native of the East Indies.

Elaadendrum; a genus of the class Pentandria, order Moorgynia.-GENBERIC CHARACTES. Calk:: perianth fiveleaved; leaflets roundish, blunt, concave, spreading very much, small, permauent. Corolla: petals five, roundish, blunt, concave, spreading very much, twice as long as the calks. Stamina: filamenta five, subulate, bent back, arising from a gland beneath the geneme. Antherar roundish, erect. Pistil: germen roundish, conical, placed on a gland; style conical; sigma obuse, blid. Periarger drug ovate. Seed: nut ovate; shell thick and very hard, two-celled; kernels obloug; compressed. ESENTIAL CHARACTER. Corolla: five petalled; drupe ovate, with a two-celled nut.----The species are,

1. Elaodendrum Orientale. This is a moderate-sized viggy shrub or tree, a native of the Oriental regions; with the leaves ovate-lanceolate, smooth, sometimes slightly waved, and sometimes even a little inclined to a subserrated appearance on the upper parts of the shoots; flowers borne towards the ends of the branches, standing by twos and threes, of a pale green colour, supported on short pedicels, each of which approach on a somewhat longer common pedicel; the lower shoots, or those nearest the ground, appear to be somewhat procumbent, and have narrower and longer leaves in proportion than the upper ones; the nerves or midribs of these leaves are also of a pedice loour.

2. Elæodendrum Argan. Branches spiny ; leaves ovate. obtuse. It is a middle-sized tree, with short thickish spines at the ends of the branches; leaves solitary, and in bundles, an inch long, petioled, quite entire, coriaceous, others decrease towards the petiole, so as to be almost spatulate; flowers in the axils of the leaves and spines, heaped, sessile ; calix inferior ; leaflets a little unequal, hirsute, and brown on the outside, with the edges smooth and whitish; petals half ovate, entire, greenish with white edges; filamenta longer than the corolla, compressed, fastened to the base of the petals; antheræ ovate; drupe dry; nut very hard and smooth. pale brown, divided longitudinally by a white line, and having a single kernel in each cell; the calix and style abide after the petals are fallen, but are wanting in the fruit; one of the cells in the nut is generally abortive. It is called argan by the Moors, who express an oil from the fruit, which the Europeans employ in a variety of manufactures, and the Moors for the table.

Elate; a genus of the class Monecia, order Triandria,-GENERIC CHARACTER. Male Flowers. Calix: spathe two-valved; spadix branching. Corolla: petals three, roundish. Stamina: filamenta three, simple. Antheræ admate. Fænde Flowers: in the same spadix with the males. Calix: spathe common with the males. Corolla: petals three, roundish, permanent. Fristl: germen roundish: style subulate; stigma sharp. Pericarp: drupe ovate, acuminate. Sedi stiftere-toothed. Corolla: three-petalled; antheræ sink. Gis: three-toothed. Corolla: three-petalled; Antheræ sesile. Fenale. Calix: con-elated. Corolla: three petalled. Pistli: one; stigmas three. Drupe: one-seeded.—The species are.

1. Elate Sylvestris; Prickly-leaved Elate. Fronds pinnate; leaflets opposite. This palm grows to the height of about fourteen feet, the trunk being covered with an ashcoloured crust, closely united with a very hard whitish wood ; pinnate leaves break out from the top of the trunk only, in a decussated order, the old ones dropping off as the young ones break forth; the midribs are green, smooth, and shining, flat within, convex without, with long siff spines at bottom; leaflets opposite, on short petioles, numerous, oblong, rounded, acuminate, close, smooth, of a shining green, closed at the base towards the inside, finely streaked longitudinally; the flowers are concealed in stiff, green, coriaceous spathes, they are small, several on the same peduncle; petals whitish green; stamina whitish, lanuginous; they have no smell, but a rough taste; the fruit is oblong, round, small, like a wild plum, with a hard woody point at top, covered with the calix at bottom, first green, then red, but when ripe of a reddish brown, or blackish and shining, covered with a thin rind that is easily broken, and having a whitish, sweet, farinaceous pulp within; the nut or stone is oblong, rufous, marked longitudinally with a deep furrow, and containing a whitish bitter keruel; the fruits grow on green, smooth, shining branches, near a vard long, and two fingers broad, flat, stiff, and woody, whence

a clear austere liquor flows when they are cut or wounded. Iround, the thickness of a quill, at the lower joints thick set The poorer sort of people chew the nut in the same manner with roots hanging in the water, having at the rest whorled, with the areca nut, with the leaf of the betel and quick-lime. Sessile entire leaves, four to six in a whorl, at top only three. The elephant is very fond of the fruit-branches, which are very sweet; the leaves, find, cc. are very astringent, and or even capillaceous, bright green, reflex; flowers axillary, are looked upon as powerful in stopping fluxes.—Naive of two or three, sessile; calix very small, greenish; petals three the East Indies. For its propagation and culture, see *Palue*, or four, white, a little larger than the calix; istamina seven

Elaterium ; a genus of the class Monoccia, order Monandira, -GENERIC CLARA.CTR. Male Flowers. Cali: : none. Corolla: one-petalled, salver-shaped; tube eylindric; border five-cleft; divisions lanceolate, channelled on the back, the incisures furnished with a toothlet. Stamina: flamentum single, columant. Anthera linear. Female Flowers. Caliz: as in the male. Corolla: as in the male. Pistil: gemen inferior, echinate ; style columanr, thickening; stigma capitate. Pericarp: capsule inferior, echinate, leathery, filed with pulp, uniform, one-celled, two-valved, elastic. Seds: several. ESENTIAL CHARACTER. Male. Calis: none. Corolla: salver-shaped. Female. Calis: none. Corolla: salver-shaped. Capsule: inferior, one-celled, twovalled.--The species are,

1. Elaterium Carthaginense. Leaves cordate, angular; stems round, smooth, herbaceous, diffused, scandent, with tendrils bifid and lateral; leaves very finely serrate, smooth underneath, somewhat rugged above, petioled, alternate, numerous; peduncles of the male flowers axillary, solitary, many-flowered, spreading almost the length of the leaves, racemed or subumbelled; female peduncle from the same axil, solitary, one-flowered, short ; corolla white, without scent in the day, but smelling sweet at night; fruit green, an inch and a half long, having but little watery pulp, smelling like cucumber; when ripe it opens elastically with a very gentle touch, and disperses its seeds ; or when approaching to maturity, if it be held some time in the hand closed, it will do the same .- Native of Carthagena in New Spain, covering entire shrubs with its stalks, and flowering in October and November.

2. Elaterium Trifoliatum. Leaves ternate, gashed ; capsule kidney-shaped, rough with hairs, two-valved, opening with a a spring, and therefore of this genus.—Native of Virginia.

Elafine; a genus of the class Octandria, order Tetragynia. -GENERIC CHARACTER. Caliz: perianth four-leaved; leaflets roundish, flat, size of the corolla, permanent. Corolla: petals four, ovate, obtuse, sessille, spreading. Stamina: lill: germen orbicular, globose, depressed, large; siyles four, upright, parallel, length of the stamina; sigmas simple. Pericarp: capsule orbicular, globose, depressed, large, furciled, four-valved, flatted. This genus consists of low, spreading, annual, aquatic herbs; the flowers axillary, and very smail. — The species are,

1. Elatine Hydropipe: Opposite-icaeed Waterwort. Leaves opposite. This is a very small plant, being hardly as pan in length; stem very tender, creeping; the shoots erect and leafty; leaves orate-lanceolate, quite entire, sessile at the joints; flowers solitary, much smaller than in the second species, alternate, on very short peduncles, at the axils of the leaves on the branches, and close to them on the stem; peak white, purplish, or rosc-colourcd; styles none; stigmas very small; antheræ globular; capsules smaller than in the second. Native of Denmark, Sweden, Switzerhand, Silesia, and France, where it is found in ditches and other wet places, flowering in summer.

2. Elatine Alsinastrum; Whart-leared Waterwort. Leaves by seeds, which should be sown on a liot-bed in the spring; in whorls, stem decambent, creeping at bottom, then erect, and when the plants are come up, they must be transplanted pellucid, brittle, six or seven inches in length branched, into potsfilled with fresh lightentth, and plunged into a hot-bed 41.

round, the thickness of a quill, at the lower joints thick set with roots hanging in the water, having at the rest whorled, sessile entire leaves, four to six in a whorl, at top only three, the emersed leaves ovate-lanceolate, the immersed ones linear, or even capillaceous, bright green, reflex; flowers axillary, two or three, sessile; calit very small, greenish; petals three or four, white, a little larger than the calix; stamina seven or eight, very short; capsule a little flatted, the partitions growing to the axils, and opposite to the sutures of the valves; seeds numerous, very small, somewhat cylindric, marked with longitudinal streaks, and transverse ones much finer, in a beautiful kind of net-work, bent a little, and ash-coloured. It flowers in June and July.—Native of Abo, Leipisc, Sileiais, Switzerland, near Paris, and Montpellier; in England, in ditches, and also on the bogs of the common by the road from Eltham to Chiselhurst.

Elatine. See Antirrhinum.

Elder. See Sambucus.

Elder Marsh. See Viburnum.

Elecampane. See Inula.

Elegia; a genus of the class Direcia, order Triandria .--GENERIC CHARACTER. Male. Calix : spathes within spathes, remote, one-valved, coriaceous, lanceolate, deciduous; spadix filiform, jointed, with an ament at each joint; ament loose, with pedicelled florets, distinguished by a bracte : bracte bristle-shaped, membranaceous, flat, longer than the florets; perianth proper, of six bristle-shaped, chaffy, loose leaflets. Corolla: none. Stamina : filamenta three, very short. Antheræ incumbent, oval, larger than the perianth. Female on a distinct individual. Calix : spathe as in the male, but shorter. Spadix: as in the male; ament with a compound raceme; perianth proper six-leaved; valves the three outer lanceolate, channelled, petaloid, equal. Corolla: none. Pistil: germen somewhat oblong; styles three, filiform, the length of the perianth ; stigmas simple. Pericarp and Seed not described .---- The only known species is,

1. Elegia Juncea,—This plant is a native of the Cape of Good Hope, and has the habit of a rush; the stems are several, about a foot high, round, smooth, filled as if it were a rush, hard, strong, very simple, scarcely any leaves, but two or three leafy sheaths towards the root, imbricated over each other, and of a brown colour; there is also a rudiment of a similar sheath towards the middle of the stem; the spathe is reminal, and divided into toher interior ones, which are also compound; the parts of fructification are not very easily made out, but are most clear in the female flowers.

Elephantopus; a genus of the class Syngenesia, order Polygamia Segregata .- GENERIC CHARACTER. Calix: involucre of three broad sharp leaflets, many-flowered, large, permanent, without an umbel; perianth partial four-flowered, oblong, imbricate; scales lance-subulate, mucronate, upright, of which the four longer are equal. Corolla: compound, tubular; corollets hermaphrodite, five or four, equal, disposed in a single circle; proper one-petalled, tubular; border narrow, five-parted, nearly equal. Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: germen ovate, crowned; style filiform, length of the stamina; stigmas two, slender, spreading. Pericarp : none. Calix : unchanged. Seeds : solitary, compressed ; down bristle-form. Receptacle: naked. ESSENTIAL CHARACTER. Calix: four-flowered. Corolla : tubular, hermaphrodite ; receptacle naked. Down : bristle-form .- These plants are propagated by seeds, which should be sown on a hot-bed in the spring : and when the plants are come up, they must be transplanted 6 I

of tanner's bark, observing to water and shade them until they have taken root, when they must have a large share of fresh air admitted to them in warm weather, besides requiring to be frequently refreshed with water .---- The species are,

ELL

1. Elephantopus Scaber; Rough-leaved Elephant's Foot. Leaves oblong, scabrous. This from its perennial root sends out many oblong rough leaves, which spread near the ground ; between these in the spring arises a branching stalk, little more than a foot high; the side-branches are short, and generally terminated by two heads of flowers, each on a short peduncle; the florets are of a pale purple colour. According to Dr. Brown, in the East Indies it is accounted a good vulnerary, and is much used in consumptive cases : the leaves are frequently used instead of carduus benedictus, among the inhabitants of the French West India islands. If this plant he set in a pot, and sheltered in the winter from frosts, it may be preserved for several years, and will flower annually.

2. Elephantopus Tomentosus; Woolly-leaved Elephant's Foot. Leaves ovate, tomentose; root-leaves four inches long and three broad, having many transverse nerves; they spread flat on the ground, and from among them rises a stiff stalk about a foot high, dividing into several branches, and terminated by two flowers composed of several florets, inclosed in a four-leaved involucre, having two of the leaflets alternately larger than the two others; this involucre being longer than the florets, they do but just appear within the two larger leaves; and the flowers make little appearance .- Native of South Carolina.

3. Elephantopus Spicatus. Leaves ovate-lanceolate, serrate, scabrous; bundles of flowers sessile, lateral; stem branched. It generally rises to the height of fifteen or twenty inches, sometimes more; the common receptacles of the flowers rise singly from the axils of the upper leaves, and seem disposed in the form of a spike, but there are seldom more than four florets in each; the seeds are crowned with four little bristles .- Native of Jamaica, Hispaniola, and Guiana: biennial.

4. Elephantonus Angustifolius. Stem-leaves linear-lanceolate, entire, villose; flowers glomerate, in sessile and peduncled bundles; stem simple; root large, oblong, whence rises a single, round, striated, hollow stalk, about two feet high, having sessile leaves set on it alternately, the lower part whereby they are joined to the stalk having a membrane inclosing it; they are about five inches long, and half an inch broad near the top where broadest, and round, are of a pale green colour, and wrinkled; towards the top the flowers come out in a spike, they are sessile, inclosed in an involucre of a few dry brown membranes; these are followed by small channelled seeds, having much pappus on them .- Native of Jamaica.

Elephant's Foot. See Elephantopus.

Ellisia ; a genus of the class Pentandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth one-leaved, five-parted; divisions sharp, gaping. Corolla : one-petalled, funnel-form, smaller than the calix ; border five-cleft, Stamina : filamenta five, shorter than the tube. Antheræ roundish. Pistil: germen roundish; style filiform, short; stigma two-cleft, oblong. Pericarp: capsule bag-form, leathery, two-valved, two-celled; the calix then very large, flat, starform, Seeds ; in each cell two, globose, black, hollowdotted, but one seed over the other, scarcely separated by a transverse partition. ESSENTIAL CHARACTER. Corolla: funnel-form, narrow; berry dry, two-celled, two-valved. Seeds : two, dotted, one placed over the other .---- The species are.

stem herbaceous, brittle, dichotomous, very much branched. diffused, prostrate, round; leaves alternate, petioled, pinnatifid, during foliation imbricate backward; the divisions sharp, with a tooth on each side; peduncles opposite to the leaves, one flowered, spreading, elongated, pubescent ; flowers drooping; corolla white, with minute purple dots on the inside of the divisions; the position of the seeds is singular .---It flowers in July and August, and is a native of Virginia.

Elm. See Ulmus.

Elymus ; a genus of the class Triandria, order Digynia,-GENERIC CHARACTER. Calix: receptacle common, lengthened into a spike; glume four-leaved, two ranked, two subulate leaflets being placed under each spikelet. Corolla: two-valved ; valve exterior larger, acuminate, awned, interior, flat; nectary two-leaved; leaflets oblong, sharp, ciliate. Stamina: filamenta three, hair-form, very short. Anthera oblong, two-cleft at the base. Pistil : germen top-shaped ; styles two, divaricated, hairy, inflected ; stigmas simple. Pericarp: none; corolla involving the seed. Seed: single. linear, convex on one side, covered. ESSENTIAL CHARAC-TER. Calix: lateral, two-valved, aggregate, many-flowered. For the propagation and culture of plants of this genus, see Grass .---- The species are,

1. Elymus Arenarius; Sea Lyme Grass. Spike apright. close : calices tomentose, longer than the floret ; leaves reedy. glaucous or whitish, involute, and mucronate, channelled, and rigid; stem two or three feet high and more, strengthened by three or four joints; spike tomentose, linear, eight or nine inches long, as large, but less compact than a fullsized wheat-ear; spikelets two, straight, two-flowered, awnless. Like arundo arenaria, it prevents the sea sand from blowing about, by means of its matted roots. Dr. Withering conjectures, that it may possibly admit of being made into ropes, as the stipa tenacissima is in Spain .- It is perennial : flowers from June to August ; and is found on the sea-coast in many parts of Europe.

2. Elymus Sibiricus; Siberian Lyme Grass. Spike pendulous, close; spikelets in pairs, longer than the calix; stems tall, round, and smooth; leaves moderately broad, and commonly distinguished by a kind of glaucous powdery complexion on the under sides; spike pendulous, close or contracted with the spikelets by pairs, and longer than the calix; the awns are moderately long, and slightly flexuose. Flowering in June and July .- Perennial, and a native of Siberia.

3. Elymns Philadelphicus; Philadelphia Lyme Grass. Spike pendulous, patulous; spikelets six-flowered, the lower ones ternate. This strongly resembles the following species : perennial .- Native of Philadelphia.

4. Elymus Canadensis; Canadian Lyme Grass. Spike nodding, patulous, lower spikelets ternate, upper binate; the leaves of this species are bluish, especially underneath: the awns also of the corolla, when the seed is ripening, from spreading become reflex, which in the other species is not common .- It is perennial; flowers in July and August; and is a native of Canada and Virginia.

5. Elymus Caninus; Bearded or Dog's Lume Grass, or Wheat Grass. Spike nodding, close ; spikelets straight, without any involucre, the lowest double ; leaves bare of hairs underneath; sheaths smooth; spikelets five or six lines long; lowermost corolla four or five lines long ; the outer valve sending out from a bluntish point an awn from seven to nine lines long, an inner valve lanceolate, just sensibly longer than the outer, which is bare of hairs, with the edges at the point membranaceous. It is perennial, andflowers in June and July .---1. Ellisia Nyctelea; Cut-leaved Ellisia. Root annual; It is found in woods and hedges in the north of England, and

between Greenwich and Woolwich; near Croydon; Ripton | merson, who named it ixora. The common name is catus, woods, Huntingdonshire; and Stokenchurch woods, Oxfordshire.

6. Elymus Tener. Spike pendulous ; florets double ; culm two feet high, smooth and even, with red joints .-- Perennial : Native of Virginia.

7. Elymus Virginicus; Virginian Lyme Grass. Spike erect; spikelets three-flowered; involucre streaked. The spike is larger than that of a common ear of barley .-- Perennial, and a native of Virginia.

8. Elymus Europæus ; Wood Lyme Grass, or Barley Grass. Spike upright; spikelets two-flowered, equal to the involucre; culm upright, stout, two feet high and more, having four or five joints. The leaf at each of those is about a span in length, and a quarter of an inch or more in breadth, smooth to appearance, but roughish to the touch, especially round the edges; sheaths hairy .- Native of Germany, Switzerland, and found on calcareous soils in woods near Berkhamstead in Hertfordshire, Marlow and Hambledon in Buckinghamshire, Henley and Stokenchurch in Oxfordshire, Ripton woods in Huntingdonshire, on rocks opposite to Matlock Baths, and frequently in the north. It is a coarse grass, like most of those which grow in woods, and is sometimes, like them, drawn up to a great height. Perennial, and flowering in June.

9. Elymus Cuput Medusæ; Portugal Lyme Grass. Spikelets two-flowered; involucres bristle-form, spreading very much ; culm narrow, a foot high ; spike oblong ; partial involucres four-leaved, spreading very much, or reflex, the length of the florets with their awns; spikelets in pairs, twoflowered; both florets awned, but the inner one smaller in all its parts. Annual; flowering in July; and a native of the coasts of Spain and Portugal.

10. Elymus Hystrix ; Rough Lyme Grass. Spike upright ; spikelets without involucre, spreading. Annual : flowering in England in July and August .- Native of the Levant.

11. Elymus Giganteus. Spike erect, close ; spikelets in sixes, six-flowered, villose; calices awl-shaped, smooth, longer than the spikelets; culm the thickness of the middle finger ; leaves involute, strict .- Native country unknown.

Embothrium ; a genus of the class Tetrandria, order Monogynia,-GENERIC CHARACTER. Calix: none. Corolla: petals four, linear, oblique, with the tip broader, roundish, concave, staminiferous, after fecundation revolute. Stamina : filamenta four, very short, on each petal one or none; autheræ oblong, within the cavity of the petal largish. Pistil : germen linear, ascending, inflex; style none; stigma roundish, plain in front, behind concave, large. Pericarp: follicle round, one-celled. Seeds : four or five, ovate, compressed, with a winged membrane on one edge. ESSENTIAL CHARACTER. Corolla: four-petalled. Antheræ: sessile, sitting on the tips of the petals. Follicle : round .---- The species are,

1. Embothrium Umbellatum. Umbels axillary, very simple, peduncled; leaves veinless; antheræ sessile, This is a handsome shrub, with small red flowers in solitary umbels .----Native of New Calcdonia.

2. Embothrium Coccineum. Thyrses terminating, sessile : antheræ pedicelled; leaves obovate, veined, or oblong-ovate, ending in a cusp. The whole of this plant is smooth; stem shrubby; leaves scattered, having one nerve branching on both sides, on short petioles, dilated at the base, and reddish; buds red, with lanceolate reflex scales; flowers in spikes, terminating; corolla scarlet, tubular, incurved, with an anthera lying in the broad end of each of the four petals; seeds in the follicle imbricate, with a sharp wing .- Found in Terra del Fuego by Forster, and in the straits of Magellan by Com-

Several other species have been observed in Peru and Chili, -3. Embothrium Speciosissimum .- This magnificent shrub

EMP

is a native of New Holland; it grows to the height of eight or ten feet, with several simple, wandlike, round branches, clothed with numerous, large, alternate, bright green leaves, from four to six inches long, obovate, and blunt, but tipped with a small point; they are more or less serrated on the sides. The flowers grow in a very dense simple head on the top of each branch, and the head is surrounded at the base with numerous lanceolate leaves, or rather bractes, constituting the involucre, which, like the flowers themselves, are of a rich sanguine red.

4. Embothrium Silaifolium. The stems, which are several, grow three or four feet high, or more, are upright, and alternately branched, and have alternate leaves. The upper and lower leaves are, however, more simple; the flowers stand in a long, loose, terminal spike, and are white, with the tips of the petals revolute .- Native of New Holland.

Empetrum ; a genus of the class Direcia, order Triandria. -GENERIC CHARACTER. Male. Calix : perianth threeparted ; divisions ovate, permanent. Corolla: petals three. ovate-oblong, narrower at the base, larger than the calix, withering. Stamina: filamenta three, capillary, very long, hanging forwards ; antheræ upright, short, two-parted. Female, Calix : perianth as in the male. Pistil : germen superior, depressed; style scarcely any; stigmas nine, reflex, expanding. Pericarp: berry orbiculate, depressed, onecelled, larger than the calix. Seeds : nine, jointedly placed in a circle, on one side bulging, on the other cornered. Es-SENTIAL CHARACTER. Male. Calix: three-parted. Corolla: three-petalled. Stamina: long. Female. Calix: three-parted. Corolla: three-petalled. Styles: nine. Berry : nine-seeded .-- These little shrubs are seldom propagated in gardens, unless for variety sake ; but they may be culti-vated in shady places, and will thrive well in a stiff soil. The plants should be procured from places where they grow naturally, for the seeds remain a year in the ground before they vegetate, and are very slow in their growth. If they are planted on a moist boggy soil in autumn, they will get root in the winter, and will require no farther care than to clear them from the weeds : for these low shrubs commonly grow upon the tops of wild mountains, where the soil is peaty, and full of bogs .---- The species are,

1. Empetrum Album; White-berried Heath. Erect: berry guarded at the base by the calix, fleshy, white, shining; seeds two or three, seldom more, bony on one side, convex, and obscurely furrowed, on the other angular, flattish .- Native of Portugal.

2. Empetrum Nigrum; Black-berried Heath, Crow or Crake-berry. Procumbent. This is a small decumbent shrub. The outer bark is deciduous, and of a brown colour. the inner yellow; branches rough with the remains of the petioles. The terminating bud consists of five membranaceous leaflets, hairy at the edge; this puts forth five little branches, of which four are in a whorl. The leaves are in fours, they are somewhat three-cornered, with a white linear keel, and petioled; flowers axillary, sessile, solitary, surrounded by a bracte resembling an outward three-parted calix ; calix whitish ; petals purple ; filamenta very long, and purple, with brownish black antheræ. The female is like the male, but the stem is redder; the leaves deep green, in fives; pistil black; berries brownish black when ripe .- Native of the northern parts of Europe, generally in elevated situations, both on dry, barren, aud moorish or boggy soils. It is found in the moors, from the Baltic to the Eastern

Ocean, in Kamtschatka, and the American isles. The mountains of Lapland, and the mines of Fahlun in Sweden, also produce it; and in the latter, it has been known to survive, when every other plant had perished with cold. In Warwickshire. Staffordshire. Derbyshire, and the northern counties of England, it is common ; and the Scottish Highlanders, with their children, eat the berries, but they are no desirable fruit, and, if taken in large quantitics, are said to bring on a slight head-ache. The Russian peasants, however, eat them, and the Kamtschadales gather great quantities of them to boil with their fish, or to make a sort of pudding with the They are esteemed antiscorbutic, and bulbs of their lilies. Grouse and heath-cocks feed upon them, and dinretic. they give their excrement a tinge of purple. When boiled in alum-water, they afford a dark purple dye, and are said to be used in dyeing otter and sable skins black, when boiled with fat. Catile do not seem to browse on this shrub. Linneus says, it flowers in April with the elm; in England, it flowers in April and May.

Empleurum ; a genus of the class Monœcia, order Tetrandria .- GENERIC CHARACTER. Male Flowers. Calix: perianth one-leafed, bell-shaped, four-toothed, permanent. Corolla: none. Stamina: filamenta four, awl-shaped, longer than the calix, patulous; antheræ oblong, subquadrangular retuse. Female Flowers on the same plant; calix as in the male. Corolla : none. Pistil: germen superior, oblong, compressed, terminated by a leafy erect process; style none; stigma placed on the lateral toothlet of the germen, cylindric. deciduous. Pericarp : capsule oblong, compressed, crowned by a leafy process, one-celled, opening along the straighter margin. Seed : solitary, oblong, covered with a subcoriaceous bivalve aril. ESSENTIAL CHARACTER. Male. Calix: four-cleft, Corolla; none, Female, Calix : four-cleft, inferior. Corolla: none; stigma cylindric, placed on the lateral toothlet of the germen; capsule opening on the side. Seed : one, arilled .---- The only known species is,

1. Empleurum Serrulatum; Cape Empleurum. This is a shrub, with wandlike even branches; leaves like those of a willow, alternate, subnetioled, linear-lanceolate, even above, beneath longitudinally wrinkled, smooth, quite entire on the edge, but appearing to be servate by pellucid dots; peduncles few-flowered, lateral, much shorter than the leaves; flowers small, most of them male : capsules usually solitary, incurved with a beak of the same length .- Native of the Cape of Good Hope.

Enargea ; a genus of the class Hexandria, order Monogynia .-- GENERIC CHARACTER. Calix: none. Corolla: petals six, oblong, ovate, concave, acute; three outer and three inner all marked below the middle with two green spots. Stamina : filamenta six, half the length of the corolla, Pistil : germen roundish. Style : three-cornered, thick. Pericarp : berry subglobular, three-celled. Seeds : four or five, globular. ESSENTIAL CHARACTER. Calix: none. Petals: six, oblong-ovate, concave, acute ; three outer and three inner green-spotted ; berry three-celled, with four or five globular seeds .---- The only known species is,

1. Enargea Emarginata. The fruit is an elliptic-spheroidal berry, fleshy, the same consistence with those of vitis idea, red purple on one side, whitish on the other; in each of the three cells are four or five globular rufescent seeds .-- Native of Terra del Fuego.

Enchanter's Nightshade. See Circaa.

Endire. See Cichorium.

English Mercury. See Chenopodium.

Epacris; a genus of the class Pentandria, order Monogy-

equal, permanent : divisions lanccolate, Corolla : one-netalled, funnel-form ; tube gradually widening into a five-cleft border; divisions ovate, acute, villose above; nectary five obovate emarginate scales fastened to the germen, and pressed close; Stamina ; filamenta five, very short in the throat of the corolla; antheræ incumbent. Pistil; germen roundish. five-streaked ; style cylindric, short ; stigma capitate. Pericarp: capsule globular, flatted, five-celled, five-valved, gaping. Seeds : numerous, very small. ESSENTIAL CHARAC-TER. Corolla: funnel-form, villose. Nectary : scales fastened to the germen. Capsule: five-celled, five-valved .--The species are,

1. Epacris Longifolia. Arboreous : leaves subulate. sheathing ; racemes upright ; flowers opposite ; capsule superior, subturbinate, rounded, five-cornered ; partitions inserted in the middle of the valves, and corresponding with the depressed grooves on the outside of the capsule .- Native of New Zealand.

Arboreous: leaves scattered, 2. Epacris Juniperina. linear, acute, spreading, sessile; racemes drooping; flowers alternate. The fruit of this plant is a small, superior, juiceless, spherical berry, terminated by a short awl-shaped style; the rind is coriaceous, thin, and black ; the pulp fungous, rather solid, white, and five-celled .- Native of New Zealand,

3. Epacris Pumila. Herbaceous: leaves ovate-oblong. imbricate ; flowers sessile, subsolitary .- Native of New Zealand.

4. Epacris Rosmarinifolia. Shrubby : leaves linear, obtuse, rigid, sheathing ; flowers solitary, lateral .- Native of New Zealand.

Ephedra ; a genus of the class Diœcia, order Monadelphia. GENERIC CHARACTER. Male. Calix : ament compounded of one-flowered scales, few, roundish, concave, length of the perianth; perianth proper one-leafed, half twocleft, roundish, inflated, small, compressed; divisions obtusc. Corolla: none, Stamina: filamenta seven, coalescing into a subulate pillar, divided at the tip, longer than the calix; antheræ roundish, turned outwards, of which four are inferior. the other three superior. Female. Calix: perianth five-fold, one placed on another, with alternate divisions, in an ovate figure, each one-leafed, somewhat ovate, two-parted, the exterior ones smaller. Corolla : none. Pistil : germina two, ovate, size of the last perianth, on which they are placed ; styles simple, filiform, short; stigmas simple, Pericarn; none; calicine scales all thickened, succulent, constituting a divided berry. Seeds ; two, ovate, sharp, on one side convex, on the other flat, compressed by the calix covering them on every side. ESSENTIAL CHARACTER. Male. Calix: of the ament two-cleft. Corolla: none. Stamina: seven, Antheræ: four inferior, three superior. Female. Calix : two-parted, five fold. Corolla : none. Pistil : two. Seeds : two, covered with a berried calix .- These plants may be propagated by offsets, which they send forth in great plenty; for the roots creep under ground, and send forth suckers, which may be taken off to transplant in the spring. They love a pretty moist strong soil, aud will endure the cold of our ordinary winters very well in the open air. Some of these plants were formerly preserved in pots, and were housed in winter; but by later experience they are found to thrive better in the full ground.——The species are,

1. Ephedra Distachya; Great Shrubby Horse-tail, or Sea Grape. Peduncles opposite; aments in pairs. It is a shrub, says Pallas, varying wonderfully according to its station, sometimes a foot or eighteen inches high, sometimes only a finger's height, or even lower, prostrate or ascending; trunk nia .-- GENERIC CHARACTER. Calix : perianth five-parted, fibrous, woody, often thicker than a finger, with some

branches spreading on the ground, and others, which are short and woody, rising, and subdivided copiously into rushlike branchlets. The male plant is usually taller, with the aments of the upper joints commonly in pairs, opposite, on a peduncle issuing from one of the scales. The male aments are ovate, composed of three pair of scales, decussately imbricate, somewhat fleshy, concave, rounded, greenish; in the bosom of each scale is a two-valved corolla, somewhat membranaceous, putting forth a stamina, standing out beyond the scales, having seven or eight globular yellow antheræ in a kind of raceme. Female aments usually solitary, larger, ovate-acute, composed of four pair of scales, the upper ones gradually smaller. These scales, in a flourishing plant, when ripe become turgid, succulent, and of a beautiful scarlet colour, having two ovate-acute brownish gray seeds, between the upper and most swelling scales. In dry soils, the scales continue almost the same, juiceless, yellowish gray when ripe, with immature fruits, which have usually one seed only, and that barren. It is found in most of the southern parts of the vast Russian dominions, is common from the Volga to the Lena, and southward to Persia and India. The berries ripen in July and August; they are sweetish, mucouse, and leave a little heat in the throat. They are eaten by the Russian peasants, and by the wandering hordes of all Great Tartary : the Calmucs and other Tartars also use them medicinally, in catarrhs, rheumatisms, &c .- Native of Siberia.

2. Ephedra Monstacyha ; Small Shrubby Horse-tail. Peduncles several; aments solitary. It flowers from September to November, strongly resembles the preceding, and is a native of most parts of Europe.

Ephielis; a genus of the class Octandria, order Monogynia,-GENERIC CHARACTER. Calix : perianth one-leafed, five-parted, spreading; segments roundish, acute. Corolla: petals five, having claws, roundish, spreading, emarginate, with a point, the length of the calix ; nectary of ten scales, a pair to each petal fastened to the base, roundish, villose, smaller than the petals. Stamina : filamenta eight, bristleshaped, longer than the corolla, inserted into a gland; antheræ four-cornered, roundish. Pistil: germen ovate, surrounded by a gland; style none; stigma blunt. Pericarp: capsule oblong, compressed, grooved on both sides, onecelled, two-valved. Seeds: two, kidney-form, fastened to one of the valves in the middle, one above the other. Es-SENTIAL CHARACTER. Calix: five-parted, Petals: five. with claws, Nectary ; ten scales, two to each petal. Capsule: oblong, one-celled, two-valved, two-seeded .---- The species are,

This tree is fifty or sixty feet 1. Ephielis Guianensis. high, very much branched at top; the middle branches, or those in the centre, being the highest, and standing perpendicularly; the lower ones are more inclining and horizontal, and spread out to a great distance; they divide into many branchlets, furnished with alternate leaves, each of which is pinnated; the pinnules opposite, from four to six in number, entire, oval, pointed, of a smooth surface, and of a bright green; these pinnules or leaflets are sometimes eight inches in length. The flowers grow from the bosoms of the leaves, on long pedicels, divided at their extremities into several smaller ones: they are very small and white. The tree is a native of the forests of Guiana, and flowers in the month of October.

Epibaterium ; a genus of the class Monœcia, order Hexandria .- GENERIC CHARACTER. Male. Flowers. Perianth double, deciduous; outer six-leaved, very small, flat; inner three-leaved, three times the size of the other, with 42

inner calix, roundish; three outer interposed between the calicine leaflets ; three inner. Stamina : filamenta six, capillary, bowed inwards, the length of the pctals; antheræ roundish. Female Flowers : in the same plant, Calix and Corolla as in the male. Pistil: germina three, subglobular; styles three, bowed inwards, very small; stigmas compressed, spreading. Pericarp : drupes three, subglobular, mucronate with the permanent styles. Seed: nut kidney-form, compressed, slightly grooved. ESSENTIAL CHARACTER. Calix: double; outer six-leaved, small, inner three-leaved, large. Petals: six, three outer, between the calicine leaflets three inner; drupes three globular, mucronate with the permanent styles, inclosing a kidney-form nut .----- The only species known is,

EPI

1. Epibaterium Pendulum.

Epidendrum ; a genus of the class Gynandria, order Diandria .- GENERIC CHARACTER. Calix: spathes vague; spadix simple ; perianth none. Corolla : petals five, oblong, extremely long, very spreading ; nectary tubular at the base, top-shaped, placed downwards within the petals, with an oblique two-cleft mouth; the superior lip very short, three-cleft, the inferior lengthened into a point. Stamina : filamenta two, very short, sitting on the pistil; antheræ covered by the upper lip of the nectary. Pistil: germen slender, long, twisted, inferior; style very short, fastened to the upper lip of the nectary ; stigma obscure. Pericarp : silique extremely long, columnar, fleshy. Seeds: numerous, extremely small. ESSENTIAL CHARACTER. Nectary turbinate, obliquely reflex. Corolla: spreading. Spur: none.—Of the propa-gation of this genus of plants, Mr. Miller remarked, that by any art yet known they cannot be cultivated in the ground; but if that were possible, many of them would produce very fine flowers of uncommon forms. He informs us, that he had three species sent him from America, which hc carefully planted in pots, and placed in a stove, where they just displayed their flowers, and soon after perished. Since Mr. Miller's time, however, many species of this fine and very singular genus have been introduced into our gardens, and some of them cultivated with success, by the superior skill of modern practice, which despairs not of rearing and preserving any plants, where expense is not regarded. It, however, certainly requires great skill and attention, to overcome the united difficulties which attend the cultivation of plants, which are at the same time of the orchis tribe, and parasitical. Dr. Smith says, We have scarcely seen any one species of this genus, except in a dry state, before the year 1787. when the twenty-fourth species flowered for the first time in the stove at Kew; nor was it till October 1788, that the sixtythird species exhibited its fragrant and elegant bloom in the same rich collection. They are all cultivated in the stove, with very great heat : being mostly parasitical, they flourish best with fragments of half-rotten bark at their roots. They may be increased by parting their roots, or what are commonly called offsets, of which they have in general an abundance .---- The species are,

Climbing.

1. Epidendrum Vanilla; Vanilla, or Vanilloe. Leaves ovateoblong, nerved, sessile, cauline; tendrils spiral; stem trailing, somewhat like common ivy, but not so woody, fastening itself to whatever tree grows near it, by small fibres or roots, produced at every joint, by which it may receive nourishment, when cut or broken off from the root a considerable height above ground. The leaves are as large as those of the common laurel, but not quite so thick ; they are placed alternately at the joints, which are six or seven inches asunder, and of a ovate spreading leaflets. Corolla: petals six, less than the lively green colour above, but paler underneath. The stems 6 K

shoot into many branches, which also fasten themselves to

494

** Stem upright, leafy.

3. Epidendrum Tenuifolium. Leaves on the stem subu-The flowers are of late, channelled .- Native of Malabar in the East Indies.

4. Epidendrum Spatulatum. Leaves on the stem oblong, alternate, obtuse, veinless; lip of the nectary bifid and divaricate .- Native of the East Indies.

5. Epidendrum Furvum. Caulescent : leaves imbricate. lanceolate; racemes axillary .- Native of the East Indies.

6. Epidendrum Coccineum. Leaves on the stem ensiform. obtuse ; peduncles one-flowered, axillary, crowded. This is an elegant parasitical plant; roots round, numerous, fibrous, ash-coloured ; stem several, scarcely attaining to a foot in height; before these spring, the flowers come forth in the axils of the root-leaves; they also come out from the axils of the stem-leaves successively as the stems advance; flowers void of scent, the whole with the germen scarlet, agreeing in character with the eighth species, except that the petals are ovate, acuminate, and concave .- Native of Martinico. where it is found in moist woods, particularly by the side of torrents ; also in Jamaica, where, however, it is not common.

7. Epidendrum Secundum. Leaves on the stem oblong, emarginate ; stem compressed ; spike directed one way ; tube of the nectary length of the corolla, Parasitical: roots fibrous, white; stem round at bottom, gradually compressed, leafy, pendulous ; leaves sessile, sheathing, alternate, spreading in two rows; the outmost tip emarginate, veinless; flowers terminating, in form of a corymb, nodding one way, pale red or brown. It varies with a rounder and more compressed stem ; leaves broader, or more acuminate ; flowers terminating, or breaking out on the side; and tube of the nectary shorter or longer than the petals .- Native of the mountainous woods of Martinico and Jamaica.

8. Epidendrum Lineare. Leaves on the stem distich. linear, obtuse, emarginate ; stem simple ; flowers terminating in a sort of spike; lip entire. Parasitical: roots filiform, creeping, strict, white; stems simple, heaped, tufted, from one to two feet long, erect, filiform, leafy, compressed a little, smooth ; sheaths radical, withering, whence the stems appear to be jointed; leaves alternate, approximating, sessile, sheathing, slightly streaked, smooth on both sides; sheaths of the leaves compressed ; spike scarcely the length of the leaves ; flowers sessile, alternate, imbricate, from six to ten, small, and blood-red; spathes sheathing under the flowers, coloured; corolla three-cornered, gibbous at the back ; the three outer and the two inner petals almost equal. oblong, concave, blunt; the two outer in front vaulted, compressed at the tip ; nectary of the same shape with the inner petals, erect, embracing the column at the base, having two dark purple spots at the edge, concave, blunt at top, bloodred ; seeds extremely minute, dusty, and bristly ; and, according to Jacquin, irregularly shaped like saw-dust. It flowers in spring, and is a native of the woods in Martinico, and other of the West India Islands.

9. Epidendrum Punctatum, Leaves lanceolate, nerved : sheaths imbricate ; scape panicled, and corollas dotted. The sheaths of the leaves, the panicle, and the petals, are dotted; hence the name .--- Native of America.

10. Epidendrum Caudatum. Leaves lanceolate, nerved; scape panicled; petals spotted, tailed, two, very long .-- Native of America.

11. Epidendrnm Ovatum. Leaves on the stem ovate, acute, stem-clasping, nerved ; scapes panicled,-Native of the East Indies.

12. Epidendrum Ciliare. Leaves oblong, veinless ; lip of

the boughs of trees, and thus rise to the height of eighteen feet, spreading quite over smaller trees. a greenish yellow colour, mixed with white, and are succeeded by fruit, six or seven inches long. The pods grow in pairs, are generally the thickness of a child's finger, and about five or six inches in length; they are green at first. then vellowish, and turn of a brownish cast as they ripen. The stalk is moderately slender, and throws out a long winding tendril, opposite to each of the lower leaves, by which it sticks to the branches or bark of the tree ; but after it gains the top, these become useless, and the place of each is supplied by a yellow leaf. The manner of growth and flowering, the size of the flowers, fruit, and lens-shaped, dark shining seed, without any aril, distinguish this from the other species. When it turns of a vellowish colour, and begins to open, they sther it, and lay it in small heaps to ferment two or three days, in the same manner as is practised for the cocoa or chocolate pods; then they spread them in the sun to dry, and flat them with their hands, when they are about half dried ; and afterwards rub them over with the oil of Palma Christi, or of the cocoa; then they expose them to the sun again to dry, and afterwards they rub them over with oil a second time; then they put them in small bundles, covering them with the leaves of the Indian reed, to preserve them. These plauts produce but one crop of fruit in a year, which is commonly ripe in May, fit for gathering, for they do not let them remain on the plants to be perfectly mature, because then they are not so fit for use ; but when they are about half changed vellow, they esteem them better for keeping, than when they are changed to a dark brown colour, at which time the fruit splits, and shews a great quantity of small seeds, which are inclosed within it. While the fruit is green, it affords no remarkable scent; but as it ripens, emits a most grateful aromatic odour. When the fruit begins to open, the birds attack it, and devour all the seeds very greedily, but do not eat any other part of the fruit. Those which are brought to Europe are of a dark brown colour, about six inches long, and scarcely an inch broad; they are wrinkled on the outside, and full of a vast number of black seeds, like grains of sand, of a pleasant smell, like balsam of Peru. In England the vanilla fruit is only used as an ingredient in chocolate, to which it gives a pleasant flavour to some palates, but which to others is equally disagreeable. The Spanish-American physicians employ it in medicine, and esteem it grateful to the stomach and brain, for expelling wind, as a diuretic, an antidote against poison, or a cure for the bite of venomous animals. The Spaniards, French, and Italians, not only use the vanilla to give chocolate a delicate smell and agreeable flayour, but also to perfume snuffs and other substances. It vields a great quantity of oil and volatile salt. Mr. Miller has another species, which he calls vanilla axillaris, distinguished by its oblong, blunt, compressed, jointed leaves, and axillary flowers. It was sent him from Carthagena in New Spain, where it naturally grows. It has a climbing stalk, sending out roots from the joints like the other, and mounting to a great height. The leaves, which come out singly at each joint, are oblong, smooth, and jointed. The flowers come out from the side of the branches; they are shaped like those of the great bee-orchis, but are longer; the helmet is of a pale pink ; and the lip is purple. There are in all two or three varieties of the common vanilla, differing in the colour of the flowers, and length of the pods.

2. Epidendrum Flosæris. Stem columnar, somewhat branched; leaves lanceolate; petals linear, obtuse. This plant branched ; leaves lanceolate; petals linear, obtuse. This plant the nectary three-parted, ciliate ; the middle segment linear; is parasitical. The flowers resemble a spider.—Native of Java. stem two-leaved. This elegant plant is a foot and a half

high, and grows parasitically on the trunks of vast trees, from which it hangs down towards the ground; roots thick, fabrous, numerous; stem simple, smooth; leaves two, obtuse, quite entire, shinning, veinless, coriaceous, flat, alternate in two rows, haff a foot in length, erect like laarés ears, each arising from an oblong, thick, striated, spongy body, forming the base of the stem; spike loose, composed of about ten handsome white flowers, four incles in diameter, all pointing one way. —Native of Martinico.

13. Epidendrum. Nocturnum. Leaves oblong, veinless; inp of the nectar; three-parted, quite entire, the middle segment linear; stem many-leaved; roots round, thick, filiform, whitish; stem from one to two feet high, single, erect, round, leavy, smooth; leaves sheathing, alternate, subdistich, from two to three inches long, oblong, entire, thickish, veinless, shiming; flowers terminating, two or three, sessile, larze, whitish yellow; spathes a few, ovate, compressed; petals almost equal, lanceolate-linear, spreading, the two inner narrower and white; seeds resembling saw-dust.—It smells very sweet during the night; and is a native of the mountain woods in Martinico and Jamaica, but is not very common in the latter.

14. Epidendrum Cncullatum. Leaves subulate; scape one-flowered; lip of the nectary ovate, ciliate, acuminate; petals elongated.—Native of America.

15. Epidendrum Teres. Stem sheathed, decumbent; leaves columnar; roots several, filiform, flexuose, creeping; stem sheathed with the rudiments of leaves; leaves alternate, flexby, sharp, a finger's length.—Native of Japan.

*** Scape naked ; Leaves radical.

16. Epidendrum Nodosum. Leaf single, subradical; spa dix containing about four howers; roots thick, numerous, filiform, striet, whitiah, kance-jointed; stem one-leafed, thick, round, sheathed, a foot high, thickened towards the roots, knotled; sheaths closed, alternate, closely surrounding the stem, keeled, streaked, membranaceous, whitish; perlat shice outer, lanceolate-inear, long, spreading, two inner linear; germen very long, round, filiform; stigma moistened in front under the cavity of the authera; capsules an inch long, oblong, pendulous, siz-grooved, three-valved, many-seeded; seed, suty brithy—It flowers in the spring, and is a native of the West Indies, where it is usually found near the seaccost.

17. Epidendrum Carinatum. Leaves oblong, obtuse, compressed, jointed.—Native of the Philippine Islands, growing upon trees.

18. Epidendrum Aloifolium. Leaves oblong, obtuse, broader at the end; root thick, fungous, crinite, knobbed, parasitical; leaves several, from the kaob of the root, from two to three feet long, and two fingers' broads, smooth, shining, brownish green, thick; flowering-stems several, undivided, round, green, shining; three of the petals are narrow, oblong, a fine red colour within, with white edges, on the outside with reds, returns, site and green, in streaks, with a tunge of red; nectary sellow, with red. It grows on different trees.—Native of Malabar.

19. Epidendrum Guttatum. Leaves lauceolate, clanamled; petals wedge shaped, retuse. From a matted root this sends out several leaves three inches long, and not a quarter of an inch broad, almost triangular, and of a yellowish green colour; from the midst of these comes the flowering-stalk; each flower is made up of four little while petals, spotted with brown, and one large one with flewer spots, on which is a small yellow hood, and opposite to it one like it of a blue colour, on pedicels an inch long, round the top of the stalk. —Native of Jamaica, where it grows on the ebony trees.

20. Epidendrum Juncifolium. Leaves subulate, furrowed; scape and petals dotted; lips without dots, dilated.-Native of America.

21. Epidendrum Scriptum. Leaves ovate-oblong, threenerved; flowers racemed, spotted .- Native of the East Indies.

22. Epidendrum Retusum. Leaves linear, retuse at the end, in two rows; flowers racemed, spotted. It is three feet in height; root white, woody, bent in, curled, fixing itself into the bark of trees by its capillary hairy fibres; stem rising between two rows of leaves, simple, shining, smooth, marked with rings; the leaves, which come out from the top of the stem, which when dry constitute the stem itself, are oblong, narrow, equally thick and broad on every side, folded together, smooth, shining, without any visible veins or nerves: flowering-branches ten or twelve together, rising straight from among the leaves, green, rigid, accompanied at the base by abundance of very minute whitish buds, gradually enlarging, but not opening till they have acquired a considerable size; all the flowers opening together invert the stem, and resemble a fox's tail; they are on whitish peduncles, issuing from a small acute bracte, stiff, thick, oblong, irregular, whitish, spotted with red, blue, and lurid colours .- Native of Malabar, where it flowers in April and October, the flowers continuing two months; and a branch set in water will flower for a month.

23. Epidendrum Anabile. Leaves broad, lanceolate, vein-less; petals lateral, orbiculate; roots thick, like packthread; leaves like crinum or squills, fleshy, half a foot long; stem two feet high, naked, surrounded by a few acute very short scales; flowers snow-white, like those of orchis susanme, the size of narcisus flowers; leaves the two side petals are orbiculate, the three others are ovate; cowl three-leaved, the two side ones long, the middle hastate, hifd, with two awl-shaped, bristled. Osbeck observed it in the East Indies. Rumphing also saw it growing on the branches of trees on the coast of Java. The flowers are large and odorif-rous; when laid in a room, they do not wither for several days, and fill it with a most agreeable perfume. On the island of Ternate, none to prioresses are allowed to wear this precisions flower.

24. Epidendrum Cochleatum. Leaves oblong, double, smooth, streaked, growing on the bulb; scape many-flowered; nectary cordate; roots filform, strict, whitish; leaves broad-lanceolate, acuminate, keeled at the base, compressed, growing on an oblong, fleshy, smooth, fibrous, succulent, compressed bulb, involved in membranaceous sheaths; flowers pressed bulb, involved in grage, subscalle; petals linear, acuminate, reflex, yellowish; nectary lip heart-shaped, blant, concave, dark blood-red, streaked with white at the base, yellow at the tip.—It flowers here in January and February, and is a native of the monntainous parts of Januarica.

25. Epidendrum Tuberosum. Leaves broad-lanceolate, nerved, membranaceous, growing on the bulb; scape sheathed; nectary boat form, bifid. --Native of America.

26. Epidendrum Posillum. Leaves ensiform, somewhat fleshy scape few-flowerd; root fibrous; plants little more than an inch high; leaves even, acute, all ratical; scapes between each of the leaves solitary, the length of the leaves, with three or four minute leafets scattered over them; flowers terminating, one or two, from a three-valved glume, the three uppermost petals spreading, oblong, the uppermost very small, the two inner toothed; ip trifd, the side-lobes subcordate, the middle larger, bifd; or, according to Allamand; petals ovate-oblong, acute, upper lip of the nectary ampullaceous, tubular, emarginate, lower very large, simular, with four lobes on each side, opposite, equal; capsule spherical, six-keeled. Observed by Dahlberg in Surianan.

27. Epidendrum Ensifolium. Stem round, even; leaves ensiform : petals lanceolate : lip lanceolate, recurved, dotted : root perennial, consisting of a few thick fleshy fibres; leaves radical, several, equitant, erect, clothed with some brown permanent scales at the base, rigid, rather sharp-pointed, with a rough margin towards the top, channelled, nerved, smooth on both sides, when dry becoming longitudinally striated : stalk growing on the outside of the leaves, and not quite so long, erect, simple, brown, bearing from four to six flowers, and furnished with three or four alternate, sheathing, acute, striated, brown scales, and compressed towards the top: flowers alternate, sessile, a little drooping; bractes solitary, resembling the scales on the stalk, but smaller; the flowers have a sweet lemon-like odour, pungent, but not strong, most powerfully perceived at night, or on entering the hot-house in a morning; on account of this perfume the plant is much cultivated in China .- Native of China and Japan.

EPI

28. Epidendrum Moniliforme. Stem round, jointed, stenked, necklace-form, naked, quite simple; leaves linear, acute.—This is a parasitical plant with white flowers, observed at Misima in Japan, by Thunberg, during his travels through that country, who says it was tied up in bundles, and hung out before a house. It can live several years without water or other nourishment, and yet grow and flower all the while.

29. Epidendrum Ophioglossoides. Stem one-leafed ; flowers racemed, pointing one way.-Native of America.

30. Epidendrum Ruscifolium. Stem one-leafed; flowers from the sinus of the leaf, aggregate; roots numerous, filform, rigid, whitish; stems aggregate; roots numerous, filform, form, a foot high, erect, sheathed, smooth; leaf terminating, orate-lancelate, half the length of the plant, acuminate, entire, keeled, channelled at the base, compressed; smooth, thick, veined; sheaths of the stem long, acuminate, streaked, withering; peduncles short, two-flowered.—Native of the high mountains of Janaica, where it is found on the trunks of old trees, and in the thick woods of Martinico.

31. Epidendrum Graminifolium. Stem one-leafed ; flowers from the sinus of the leaves in pairs .- Native of America.

32. Epidendrum Capense. Scape naked; leaves imbricate, in two rows, linear, obtuse; flowers directed one way; horn very long; parasitical.—Native of the Cape of Good Hope.

32. Epidendrum Fuscatum : Brown Epidendrum. Siems simple; leaves oval; pedancie terminating, elongated, scaly; lip of the nectary five-lobed, the middle lobe minute; flowers stalk erect, very long, simple, compressed, with many knotly joints, smooth, green, but entirely covered with brown, membranaceous, sheating scales, which are alternate, sharpish, compressed, keeled, and ribbed; spike terminating, erect, forming a globose dense head of uany flowers; bractes solitary under each flower, lanceolate, concave, acute, purplish green, one-third the length of the germeu; flowers place green ish purple, with a faint herbaceous smell.—Native of Jamaica.

34. Epidendrum Tripterum; Triangular-fruited Epidendrum. Leaves from a bulb and from the root sword-shaped; stalks radical, sheathed, many-flowered; germen three-winged; lip equal to the petals; roots of a few thick, fleshy, long, and nearly simple fibres, slightly downy: bulbs above ground, numerous, ovate, but little compressed, smooth, green, somewhat glaucous, an inch long; stalks thrice as high as the bulbs, erect, thickly covered at the base with smaller, concave, blumitsh, reddish scales, imbricated in a two-fold order, in the upper part roundish, ending in a cluster of many flowers; flowers on footstalks, spreading, white, and scentless.—Native of Jamaica.

35. Epidendrum Barringtoniæ; Large flowered Epidendrum. Leaves broad-lanceolate, nerved, arising from a bulb : peduncles radical, mostly single-flowered; lip fringed; column with a cover; root consisting of numerous branched fleshy fibres, brown, downy, and divaricating; bulbs several above the surface, large, ovate, slightly compressed, smooth, green, with an nnequal and somewhat furrowed surface; flowerstalks three inches high, nearly erect, bearing one flower, rarely two, round, green, smooth, clothed with four or more sheathing alternate scales, which are ovate, concave, green, with a rusty-coloured powdery down ; flowers from the uppermost scale, a little drooping, and inodorous; petals lanceolate, obtuse, somewhat succulent, slightly spreading, greenish, towards the tips of an olive brown, the two innermost rather the smallest, the two lowermost lengthened out at the base, and united into a short blunt pouch ; lips of the nectary arising from the back part of the inside of this pouch, unconnected with every thing above, somewhat shorter than the petals, covered on its upper side with an oblong, yellowish, deeply-furrowed callosity, inversely heart-shaped in front; its margin is three-lobed, the lateral lobes small, acute, entire, erect, thin and transparent, terminating one very large, of a rusty brown, blunt, hollowed above, swelling below, pale, and beautifully fringed all round the margin; column of the fructification white, elongated at the base, connected by its back to the pouch of the corolla, and by its forepart at the bottom to the lip of the nectary, incurved, and blunt at the top, behind obtusely keeled, flat, and with two slight furrows before; cover pointed, obscurely three-celled within; stamina red, close together; antheræ red, two on each filamentum, obovate, yellow; stigma large, very much excavated ; germen somewhat longer than the pouch of the flower, green, nearly cylindrical, with six furrows. This is the most distinguished of the species hitherto introduced amoug us. not only on account of its size, but its singularity .-- Native of Jamaica.

36. Epidendrum Claviculatum. Stem climbing, round, branching; I eaves sessile, liml 5 stem-classing, acute, concare, recurred, rigid. This plant hangs down from the branches of trees, and creeps up others to the height of forty feet. Observe: The stem is jointed at the distance of five inches, and at every joint there are fibres three or four inches long; catching hold, by their broad visiel end, of any part of a tree they come near; it is about three quarters of an inch in diameter, very mooth, round, and deeg preen, solid, juicy, and sometimes branched; here and there, opposite to the tendril, comes out a thin menbranaceous leaf, from a broad beginning ending in a point.—Native of Jamaica and Hispaniola.

¹ 37. Epidendrum Ramosum. Stem very branching, suffratesont; leaves linear, emarginate; racemes terminating, compressed. This plant is a foot and a half high, leafy, parasitical; roots fibrous; branches compressed a little, smooth, ash-coloured; leaves oblong, obtuse, coriaceous, rigid, veinless, entire, shining, sheathing at the base, dirty green, alternater, an inch and a half long; greenaly four-flowered; howered; mover in high the shaft of the petals, of which it dowers have first in the heat of the petals, of which it dowers in heat in the rate outer hancedate, the two inner linear; lower in for the nectary oblong cordate, acuminate, concave, rigid, the length of the petals, of which it occupies the place of the third interior one; anthere roundish.—Native of Martinico and Jamaica.

38. Epidendrum Nutans. Stem simple; leaves ovatelanceolate, nerveless, stem-clasping; spike terminating, nodding; lip of the nectary three-lobed, the middle lobe threetoothed .- Native of Jamaica.

39. Epidendrum Umbellatum. Stem simple ; leaves ovate, emarginate, stem-clasping, veinless; flowers terminating, umbelled, parasitical, smooth, seldom a foot in height; roots round, fibrous, ash-coloured, numerous; stems round, leafy, commonly horizontal, or pendulous; leaves oblong, coriaceous, pale green, sheathing, clothing the whole stem, alternate; an inch or an inch and a half in length, mostly difform ; spadix very short, concealed within the sinus of the terminating leaf, with about five leaves; spathes very few; flowers somewhat fetid, greenish white, rigid .- Common in the vast woods of Martinico, and in Jamaica.

40. Epidendrum Anceps. Leaves cordate-lanceolate, stemclasping, horizontal; raceme terminating, compressed, ancipital, subflexuose; flowers distich, inner petals capillary, with a three-lobed lip .- Native of Jamaica.

41. Epidendrum Rigidum. Leaves oblong, obtuse, sheathing; raceme terminating, compressed, ancipital; flowers distich, larger than the spathes; lip entire, cordate ovate, acute; parasitical, a foot high; roots fibrons, ash-coloured, round, numerous; stems simple, round, leafy, ending in a very loose distich spike, four-flowcred .- Native of woods in Martinico and Jamaica.

42. Epidendrum Diffusum. Leaves oblong, stem-clasping; stem ancipital; panicle terminating, very much branched, diffused ; lip entire, acuminate .- Native of Jamaica.

43. Epidendrum Montanum. Leaves lanceolate, flat, recurved, spreading, submembranaceous; raceme terminating, simple; flowers pointing one way; lip trifid .- Native of Jamaica.

44. Epidendrum Serrulatum. Stems aggregate, subdiphyllous; leaves lanceolate, kccled, serrulate; raceme terminating; flowers distich .- Native of Jamaica,

45. Epidendrum Teretifolium. Leaves semicylindric; stem one-flowered ; lip three-sided at the tip .- Native of Jamaica.

46. Epidendrum Globosum. Leaves cylindric, channelled ; flowers terminating, subsolitary; lip ovate, acute; capsules globular; roots fibrous, round, ash-coloured, numerous, parasitical; stem cespitose, quite simple, two or three inches high, round, smooth, leafy, ending in a spadix, bearing one flower, seldom two, very seldom three, whence there are very few spathes; leaves awl shaped, acute, smooth, shining, somewhat rigid, sessile, alternate, an inch long; flowers small, scarcely coloured, erect .- Native of the woods of Martinico and Jamaica.

47. Epidendrum Sertularioides. Stem filiform, creeping, jointed; leaves lanccolate; peduncles one-flowered, from radical sheaths .- Native of Jamaica.

48. Epidendrum Testæfolium. Stem creeping; leaves incumbent, elliptic, concavo convex, keeled; flowers sessile under the leaves .- Native of Jamaica.

49. Epidendrum Undulatum. Leaves elliptic, acute; scape sarmentosc, very much branched; petals ovate, clawed, obtuse; lip dilated, charginate, waved. This is parasitical, and the largest of that kind ; roots large ; stalk round, tough, brown, crooked, six feet high, with joints at every eight or ninc inches' distance, where arc branches standing straight out, with several flowers on peduncles an inch long .- Native of Jamaica.

50. Epidendrum Variegatum. Leaves lanceolate, keeled, channelled, cartilaginous, servate on the edge; sheaths im-This is an elegant parasitical plant; roots round, Jamaica. two-lobed. ash-coloured, fibrous; leaves radical, awl-shaped, acuminate. 42.

keeled, somewhat rigid, coriaceous, obtusely angular on the back, with acute angular margins, pale green, sometimes rugged, with rust-coloured dots, sometimes without and quite smooth, from an inch and a half to six inches in length; scape round, slender, from a foot to two feet in length; flowers sweet swelling, elegantly variegated with purple, violet, yellow, and red : petals four .- Native of the woods in Jamaica and Hispaniola,

51. Epidendrum Utricularioides. Leaves lanceolate, marked with lines, flat ; scape panicled ; lip large, heart-shaped ; horn very short .- Native of Jamaica and Hispaniola.

52. Epidendrum Triquetrum. Leaves three-sided, cultrate, compressed at the tip, lanceolate, acute; scape simple; lip heart-shaped, ovate; sides emarginate .-- Native of Jamaica.

53. Epidendrum Sessile. Leaves compressed at the base, broader at the top, lanceolate, lanceolate-linear, obtuse, veinless; peduncles radical, very short, one-flowered .- Native of Jamaica.

54. Epidendrum Flatelliforme. Leaves compressed at the base, dilated at top, ovate-lanceolate, acute, flat, nerved ; peduncles one-flowered, elongated .- Native of Jamaica.

55. Epidendrum Subulatum. Leaves awl-shaped, grooved ; peduncles sheathed, radical, many-flowered .- Native of Jamaica.

56. Epidendrum Satyrioides. Leaves subulate, cylindric; scape few-flowered; corollas ventricose at the base in front. -Native of Hispaniola.

57. Epidendrum Tribuloides. Leaves pedicelled, lanceolate, obtuse, emarginate; peduncles very short; capsules globose, echinate .- Native of Jamaica.

58. Epidendrum Corniculatum. Leaves pedicelled, wedgeshaped, oblong; peduncles radical, one-flowered; corollas acuminate, curved .- Native of Jamaica.

59. Epidendrum Lanceolatum. Leaves pedicelled, lanceolate, acute; peduncles from radical sheaths, two-flowered. Native of Jamaica.

60. Epidendrum Angustifolium. Leaf lincar, growing upon the bulb; scape panicled .--- Native of Jamaica.

61. Epidendrum Palmifolium. Leaves broad lanceolate, nerved, membranaceous, growing on the bulb ; peduncles radical, sheathed, many-flowered; nectary boat shaped, entire, reflex .- Native of Jamaica.

62. Epidendrum Altissimum. Leaves lanceolate, growing on the bulbs; scape very much branched, sarmentose; petals oblong, lanceolate, acute; lip obcordate, shorter than the petals. This is an elegant parasitical plant; roots round, fibrous, ash-coloured, numerous ; leaves acute, ensiform, oblong, veinless, shining, quite entire, thickish, an inch wide, and half a foot long, keeled at the base, in other parts flat, each springing from a joint, or an ovate-compressed smooth tuber, sometimes as big as a goose egg, which is placed on the base of another root-leaf or two, like the others; between this and the joint arises a solitary, round, smooth scape, of a rust colour, slender, inclined, four feet high, racemed at top, clothed at the peduncles and joints with membranaceous, lanceolate, ash-coloured spathes ; peduncles two or three-flowered, alternate, in two rows: flowers without scent, yellow, with brown spots, numerous; petals oblong, distinct, acute at both ends, waved, nearly equal .- Native of the woods of Martinico.

63. Epidendrum Fragrans. Leaf broad-lanceolate, nerveless, growing in the bulb; scape many-flowered, abbreviated : bricate; scapes sheathing, with a simple raceme; lip cruciate, lip heart-shaped.-It flowers in October, and is a native of

64. Epidendrum Sanguineum. Leaves in pairs, oblong, 6 L

growing in the bulb; scape many-flowered, subflexuose; hip roundish, waved, emarginate; hor addrate. It has many thick white fibres, like those of leeks, or the tendrils of ivy, taking firm hold of the bark of trees, and matted together; these send out one thick, greenish, roundish, compressed, bulbons, or tuberous leaf, of an inch diameter, covered with some brown withered filamenta; from the top of this come two smooth, strated, hollow, hard, pale green leaves, three inches long and one broad, between which springs out a naked, brown, jointed, round, smooth stalk, about a foot high, near the top of which stand several long, reddish, purple flowers, very beautifild.—Native of Jamaica, where it is found in the savanna woods, growing upon the ebonies and other trees.

EPI

65. Epidendrum Labiatum. Leaves radical, oblong; middle bub solitary, one-leafed; scapes few-flowered; lip oblong, with a fleshy corpuscle, growing to it at top.—Native of Hispaniola.

66. Epidendrum Polybulbon. Stem creeping, bulb-bearing; bulbs two-leaved, one-flowered; flower peduncled; lip heart-shaped.-Native of Jamaica.

67. Epidendrum Proliferum. Caulescent: leaves distich, subimbricate, ovate; bulbs from the sheaths of the leaves two-leaved; flowers axillary, sessile.—Native of Jamaica.

68. Epidendrum Vestitum. Stem leafless, imbricate all round with sheaths, round.sh, bulb-bearing; bulbs growing on the leaf; flowers crowded from the sheaths of the stem.— Native of Jamaica.

69. Epidendrum Romiforme. Caulescent: leaves growing on the bulbs, ovate-acuminate, convex, channelled, threesided beneath; scapes from the bosom of the leaves.—Native of Jamaica.

70. Epidendrum Echinocarpon. Stem compressed, decumbent, one-folwered; leaves imbricate all round, distich, ovate; capsules muricate; roots small, branched, fibrons; stems pendent, simple; leaves alternate, numerous, small, reflex, quite entire, subtomentose, stem-clasping. From the axils of the leaves, flowers solirary, on very short peduncles; corolla of a coral red colour, the upper and the two lower petals of the same size and figure, the two lateral ones larger and wider; nectary small, three-lobed, the two ouper lobes rounded and concave, the lower emarginate; capsule red, ovate, warted.—Native of Guiana, where it is found on the trunks of old trees, which are sometimes found quite covered with it.

71. Epidendrum Trichocarpon. Stem compressed, round, rooting; leaves imbricate all round, distich, linear; capsules tomentose.—Native of Jamaica.

72. Epidendrum Glaucum. Stem compressed, almost up right, many-flowered; leaves imbricate all round, distich, broad lanceolate, very suooth, glaucous beneath; capsules naked.—Native of Jamaica.

73. Epidendrum Graminoides. Stem erect, compressed, many-flowered; leaves imbricate all round, distich, remote, linear; peduncles longer.—Native of Jamaica.

74. Épidendrum Micranthum. Stem one-leafed ; leaf broad lanceolate ; raceme very long, filiform ; flowers pointing one way, roundish, six-cornered.—Native of the West Indies.

75. Epidendrum Trigoniforum. Stem one-leafed; leaf oblong lanceolate; raceme the length of the leaves; flowers mostly pointing one way, three-cornered. This is a small parasitical plant, only about four inches high; roots filform, whitish, numerous; leaf catline, acute, quite entire, coriaceous, rigid, veinless, flat, shining, two or three inches long; flowers small, directed all to the same side, without scent, on

growing in the bulb; scape many-flowered, subflexuose; lip | short peduncles, of a dirty yellow colour.-Native of the roundish, waved, emarginate; horn adnate. It has many thick | mountain woods in Jamaica and Martinico.

76. Epidendrum Racemiflorum. Stem one-leafed; leaf ovate; raceme longer than the leaves; flowers pointing one way, inner petals ovate.—Native of Jamaica.

78. Epidendrum Laxum. Stem one-leafed; leaf oblong; raceme the length of the leaves, inner petals awl-shaped; lip ovate; capsules naked.—Native of Jamaica.

79. Epidendrum Ovale. Stem one-leafed; leaf ovate, acuminate; raceme pressed close, many-flowered; petals roundish, the inner ones remote in front at the base; capsules pedicelled,—Native of Jamaica.

80. Epidendrum Pulchellum. Stem one-leafed; leaf roundish, acute; raceme loose, few-flowered; petals acuminate, ciliate, the inner one crossed at the tip.—Native of Jamaica.

81. Epidendrum Tridentatum. Stem one-leafed; leaf ovate-acute, three-toothed at the tip; raceme many-flowered; flowers three-sided, acuminate; petals of the nectary erect, bowed inwards.—Native of Jamaica.

 Epidendrum Cochlearifolium. Stem one-leafed; leaf orbiculate, concavo-convex; raceme few-flowered.—Native of Jamaica.

83. Epidendrum Funale. Leafless, filiform, rooting: peduncle two-flowered; lip two-lobed; horn very long, awlshaped.—Native of Jamaica.

84. Epidendrum Filiforme. Leafless, filiform, rooting: peduncles subtriflorous; lip ovate; horn very short, headed at tip.—Native of Hispaniola.

15. Epidendrum Concretum. Leaves radical, lanceolateacute; netary concrete with the petals. This plantis parasitical, and only a foot high; roots fibrons, whitish, thick, round, long; leaves radical; two, three, or four, lanceolateacute, coriaceous, flat, stiffish, quite entire; scape simple, compressed, cret, ten-flowered, or thereabouts; common peduncles few, lateral, few-flowered; flowers small, sessile.— Native of Martinico.

86. Epidendrum Cebolleta. Leaf radical, single, awishaped; knot rooted; raceme compound. It is a parasitical plant; roots round, fibrous, numerous.—Native of Carthagena, especially in woods on the coast, where the natives call it *ecolotics cibauls*, or little bulls, and make use of the tubercles, triturated with salt, in violent contusions, fractures, &c. It is entirely void of smell.

87. Epidendrum Spathulatum. Leaves bifarious, alternate, approximating, pravmorse, with a double tip, coriaceous, scarcely a foot long; peduncles axillary, almost erect, sometimes pendulous, round, smooth, jointed, woody at the joints, bracted, undivided half way, a foot and a half long, within the raceme angular; pedicels spreading very much, scattered, bracted at the base, round, smooth, white, the length of the flowers; bractes oblong, pressed close, acute, rust-colonred; petals united at the base to the nectary, flat; two lateral, spreading very nuch, orate, broad, acute, larger; three inferior obovate, the middle one largest, all snow-white, with a large rose-coloured one at the end.— Native of the East Indies.

88. Epidendrum Variegatum. Leaves alternate, spreading, sheathing, ovate-acute, three-nerved, wared, smooth, varie-gated; stem none; scape erect, a palm high, solitary, seldom two, angular, striated, smooth, coloured, terminated by an oblong raceme; peduncles simple, subalternate, spreading very much, roundish, club-shaped, striated, coloured, scarcely the length of the flowers.—Naive of the East Indies.

89. Epidendrum Calceolaria. Leaves bifarious, alternate,

roots capillaceons, numerous, flexuose, whitish ; stems many, crowded, roundish, fiexuose, jointed, perennial, scarcely a span high; racemes terminating, simple; flowers remote .--Native of the East Indies.

90. Epidendrum Hexandrum. Leaves bifarious, alternate, spreading, a little sessile, ending in sheaths, somewhat removed, lanceolate, emarginate, with a point, rigid ; root capillaceous, flexuose, white, parasitical; stems several, round, naked, a little way above the root, the rest covered with oblong, tubular, acute, striated, rigid, whitish scales. The whole plant is scarcely a foot high; the leaves are smooth, and the flowers white .- Native of the East Indies.

91. Epidendrum Ophrydis. Leaves alternate, sheathing, from erect spreading, ovate, acute, quite entire, nerved, smooth, a little bulbed on the surface, membranaceous, shorter than the scape, ending in tubular, keeled, smooth sheaths; roots fibrous, filiform, hirsute, white, fixed in the ground ; scape erect, clothed with sheaths and leaves, round, grooved, acute, red, with recurved, linear, acute, smooth, green, long stipules, scattered over it, a foot high or more ; spike erect, cylindrical, closely set with blood-red flowers, a palm and a half in length, the thickness of the middle finger. -Native of the East Indies.

92. Epidendrum Supplex. Leaves crowded, sword-shaped, sheathing, compressed, quite entire, acute, smooth, fleshy, This plant grows upon trees by capillaceous fibres, a little compressed ; stcm none ; spikes terminating, naked at the base, filiform, longer than the leaves, scarlet .--- Native of the East Indies.

93. Epidendrum Orchideum. Leaves bifarious, alternate, sessile, spreading, lanceolate, quite entire, acute, smooth, fleshy, rigid. This plant is parasitical by means of filiform, branched, smooth, green fibres; stems simple, pendulous, jointed, leafy, flexuose, sheathed thicker than the roots, two feet long or rather more, and a little more slender at the base; flowers above the leaves usually solitary; spathes heartshaped, small, somewhat fleshy, yellow, caducous; petals lanceolate, yellow, with large darker spots; the two upper ones ascending, the middle one spreading from the lower petals, the two lateral ones larger, more reflexed towards the back, narrower, all concavo-convex,

94. Epidendrum Pusillum. Shoots in bundles, appressed, a span long; racemes solitary, simple, upright, compressed, naked at bottom, toothletted towards the tin ; roots canillaceous, few, white, parasitical shoots, in bundles, pressed close to the bark, little branched, sometimes jointed, unequal, a span long, hoary, green; racemes half an inch long, green, rust-colour; flowers alternate, spreading; petals fastened to the nectary, erect, linear-lanceolate, acute, a little longer than the nectary, equal, yellow; nectary truncated at the base .--- Native of the East Indies.

95. Epideudrum Complanatum. Leaves alternate, sessile, spreading, linear, moon-shaped, retuse, smooth; upper surface concave; lower keeled, fleshy; roots filiform, very long, whitish green, parasitical; stem, with the long roots, commonly pendulous, roundish, sheathed with leaves, simple, short; leaves scarcely a span in length; petals linear, acute, pendulous, smooth, narrow, yellow .- Native of the East Indies.

96. Epideudrum Clavatum, Leaves alternate, sessile, spreading, a little linear, club-shaped, with two unequal teeth at the end, smooth, flat, having a large uerve, depressed above, permanent beneath ; roots filiform, white, parasitical ; stems at the threads of the roots pendulous, round, sheathed with leaves, short; leaves bright green; spikes short, oppo-

remote, spreading very much, awl-shaped, thick, smooth ; | site to the leaves, spreading very much, peduncled, clubshaped; peduncles roundish, smooth, with a few coloured dots, woody, scarcely the length of the leaves ; bractes solitary, pressed close, heart-shaped, smooth, rigid towards the middle of it; corolla six-petalled, or more properly onepetalled; five segments spreading, linear-lanceolate, nearly equal, yellow, long .- Native of the East Indies.

97. Epidendrum Subulatum. Leaves alternate, erect, sessile, awl-shaped, cylindric, smooth, acute; sheaths obtuse, margined, smooth, with minute dark purple dots, short; roots filiform, smooth, white, parasitical; stems simple, erect, round, smooth, sheathed, short; leaves a span long; nectary in the disk of the flower, surrounded by the lower petals, semicvlindric, obtuse, smooth, snow-white, with the edge of the blunt apex of a most elegant carmine colour; antheræ two, sessile on the truncated concave body, inclosed in the scalelet, yellow; silique filiform, smooth, roundish .--- Native of the East Indies.

98. Epidendrum Nudum. Stem none ; peduncles simple, one-flowered, with two or three smooth membranaceous tubular sheaths, investing the younger peduncles with an oblique mouth, caducous; roots filiform, branched, smooth, green, parasitical; peduncles several, round, woody, sheathed, jointed ; corolla monopetalous, irregular ; tube erect, capillaceous, with hairs scattered over it, snow-white, long; border double ; lower four-parted .--- Native of the East Indies.

99. Epidendrum Tomentosum. Leaves from the bulbs usually four, seldont two or three, alternate, almost erect, bifarious at the base, half sheathing the bulb, oblong, quite entire, acute, concave, recurved at the tip, smooth, eightnerved, fleshy; roots parasitical, filiform, round, clothed with scales, flexuose, from one bulb to another, the thickness of a goose-quill, putting out bristle-shaped thickish fibres, especially helow the bulbs, of a chestnut colour; bulbs above the root almost erect, sessile, obovate, compressed, wrinkled, terminated by leaves, scarcely the size of a hen's egg; flowers racemed, distich, subalternate, peduncled; peduncles spreading, round, covered with a chestnut nap, shorter than the spathes; corolla irregular, consisting of double petals; the outer monopetalous, navicular, ascending .- Native of the East Indies

100. Epidendrum Bidentatum. Leaves sheathing each other, three or four, seldom five, sword-shaped, bifarious, sessile, quite entire, with two sharp toothlets at the tip, smooth on both sides, keeled at the back : roots filiform. slightly complicated, a little flexuose, smooth, whitish green, very long; stem scarcely any; corolla six-petalled, fastened to the germen below the nectary; the two lateral ones are obliquely ovate, erect, smooth, yellow, three surrounding the back of the nectary, erect, of these the two more lateral ones are lanceolate, the third outer one is broader and ovate; filamentum single, fastened to the truncated body, flat, membranaceous, white, short ; silique oblong, angular .- Native of the East Indies.

101. Epidendrum Bycopodioides. Stems crowded at the roots, pendulous, simple, compressed; leaves alternate, bifarious, sheathing one another at the base, pressed close above the sheaths, lanceolate, acute, a little margined, smooth, fleshy; roots simple, filiform, slender, flexuose, scariose, hoary green, fastened to the bark of the mangostan-tree: stems three or more, sometimes but seldom above a foot long : spikes terminating, solitary, peduncled, cylindric, acute, resembling spikes of wolf's claw moss, (lycopodium,) but not so thick, and two inches long; flowers sessile, closely approximating, covered with heart-shaped, ciliate, appressed. membranaceous, pale green, caducous spathes; corolla six,

499

petalled, unequal, fastened to a coloured germen, the uppermost petal spreading very much, pressed close to the spike ovate, sometimes obcordate, concave; the two upper lateral ones reflex towards the back of the upper one, ovate, smaller, the two lower lateral ones more spreading, incumbent on the lower, ovate, acute, very small, a little thicker, and more eoloured; the lower petal flat, heart-shaped, a little less than the uppermost; the whole corolla orange-coloured; filamenta none; germen club-shaped; silique ovate .- Observed by Kœnig at Malacca, growing upon the tamarind.

EPI

102. Epidendrum Longiflorum. Leaves growing to the bulbs, solitary, subpetioled, erect, lanceolate, retuse; margin quite entire, recurved, smooth, fleshy, rigid, brittle; roots in bundles, filiform, flexuose, parasitical; stems creeping, filiform, unequal, with a whitish bark ; leaves more than a palm in length, and two-thirds of an inch in breadth; bulbs sessile, incumbent, straightish, solitary, ovate, grooved, wrinkled, scarcely more than half an inch in length, vellowish green ; seapes solitary by the side of the bulbs, simple, erect, round, smooth, jointed, scaly, shorter than the leaves; petals unequal, the two upper ones approximating, linear, oblong, curved at the base, and spreading, a little concave, ciliate at the edge, nerved, having very small hairs scattered over them, the tips very long, sometimes two inches, pendulous, very narrow, straw-coloured; the two side ones upright, oblong, obliquely sharpish, flat, membranaceous, concolor, small, scareely longer than the truncated nectary. In the morning the flowers are spread out, and hence two petals are long, straight, and upright; in the afternoon they are pendulous .- Native of the East Indies.

103. Epidendrum Flabellum. Leaves solitary, one from each bulb, petioled, lanceolate, oblong, quite entire, emarginate, a little recurved, obscurely nerved, smooth, fleshy, rigid ; roots filiform, flexuose, simple, parasitical ; stem none ; buibs above the roots closely crowded, ovate, quadrangular, wrinkled, the size of sparrow's eggs; leaves a palm long, and two-thirds of an inch broad ; petioles semicylindric, channelled, a little twisted, short ; peduncle at the base of the bulb pressed close by a sheath, and another sheath above the base, the rest naked, ending in an umbel in an erect flat semicircle, with from six to nine flowers in a row ; pedicels erect, but spreading towards the end, a little curved to one side, round, smooth, coloured; corolla four-petalled, unequal; the upper petal erect, linear-lanceolate, with two teeth at the tip, and a large ovate hole at the base, where it appears to be tubular on account of the edges being bent back ; it is white, with a purple base, and more than an inch long, the two sidepetals are erect, obliquely lanceolate, a little incurved at the tips, the edges yellow, recurved, and ciliate, with golden hairs; they are longer than the nectary, and of a blood-red colour; the lower petal spreading, ovate, acute, inflated, striated, ciliate, membranaceous, scarcely so long as the side ones, of a yellow red colour; antheræ double, subglobular, vellow, small .- Native of the East Indies.

104. Epidendrum Saaronicum. Leaves alternate, subbifarious, sessile, spreading, lanceolate, flattish above, even, streaked slightly, and having five more evident nerves beneath, smooth, with a small groove along the mid-rib, but no streaks, emarginate, fleshy, rigid; roots filiform in bundles below the bulbs on the stems, parasitieal, flexuose, smooth, woody, whitish green, shining; stems subscandent, variously branched, compressed a little, smooth, jointed, sometimes sheathed, ferruginous, green, long; bulbs at the base of the branches; raeemes terminating, simple, sometimes, though rarely, a foot and a half in length ; flowers nodding ; sheaths solitary, sessile, with scalelets between; corolla boat-shaped, one toothlet opposite to the leaf, a little shorter than the

five-petalled, snow-white. It flowers in the morning, shutting after noon, during several days .- Native of the East Indies.

105. Epidendrum Plantaginifolium. Leaves bifarious. sheathing each other, erect, linear, three-sided, slightly channelled, sharpish, smooth, fleshy, narrow at the base next the sheaths; roots fibrous, flexuose, parasitical; stem none; sheaths membranaceous, striated, margined, smooth, the breadth of the leaves, short; spike axillary, simple, peduncled, bifarious, creet, longer than the leaves ; peduncle ereet, smooth, compressed, a little jointed in the middle. having a large, oblong, acute, membranaceons, cadueous bracte; the upper one has two or three alternate smaller bractes; flowers on very short alternate pedicels, having involueres at the base, which are lanceolate-ovate, acute, solitary, appressed, membranaeeous, whitish, much longer than the pedicels; corolla six-petalled, three outer larger, all spreading a little, concave, membranaceous, whitish ; nectary a truneate body, very small, covered by an inflated semiglobular membrane; antheræ two, twin, fastened to a single filamentum, oblique, ovate-oblong, obseurely angular, smooth; seeds very numerous, white, thrown out to a considerable distance by very slender elastic threads or hairs .- Observed by Kænig in a wood near Malacca, upon the upper boughs of very lofty trees.

106. Epidendrum Sessile. Leaves scattered from sessile bulbs, spreading, subpetioled, retuse above, smooth, a little channelled, beneath convex, fleshy; stems seandent, branched, round, filiform, scaly; flowers among the scales in pairs, seldom solitary, approximating to the stem, small. Instead of a calix, an ovate, acute, keeled scalelet, fastened to the germen, inflated, membranaeeous, white, short ; corolla sixpetalled; three outer almost crect, ovate at the base, with lengthened tips, slightly awned, equal, whitish, stiffish; two inner lateral, fastened to the side of the nectary, erect, ovate, oblong, quite entire, rounded at the tip, flat, membranaceous, white, subtransparent, much shorter than the outer ones; the sixth or third inner petal is fastened to the upper tip of the nectary, ascending, lanceolate, recurved, a little channelled, longer than the two other interior ones, callous, yellowish; style none,-Native of the East Indies,

107. Epidendrum Lilifolium. Leaves from the bulbs subpetioled, erect at the base, more spreading at the tip, linearlanceolate, sharpish, smooth, keeled at the back, membranaceous, scarcely rigid ; roots filiform, flexuose, white, parasitical; bulbs crowded, ovate, angular, grooved, pale green, terminated by two, or seldom three leaves, the size of a lark's egg; leaves dark green, scarcely a palm and a half long, and four lines wide ; flowers from eighteen to thirty, pedicelled, remote, the lower ones more so, alternate; petals, the four outer spreading very much, the lower and upper linear, acute, a little incurved at the tip, coneave, the side ones broader. rounded at the tips, concave, more coloured purple, all equal in length, somewhat fleshy, purple at the tips, the rest white. -Native of the East Indies.

108. Epidendrum Calceolariæ Terrestre, Leaves spreading, bifarious, sessile, ending in sheaths, oblong, lanceolate, quite entire, slightly and obliquely emarginate, above even, shining beneath, smooth, with from nine to fourteen nerves. rigid; the lower ones short, broader; the upper longer, and scarcely an inch broad; roots creeping in the ground; stem simple, erect, round, sheathed, compressed, a little smooth, jointed; the interstices shorter than half the length of the leaf, from three to four feet long, and half the size of a goosequill; sheaths at the joints closely involving the stem, mem-branaceous, striated, two-keeled, blunt at the mouth, having

internodes; shealts radical, and below the middle of the stem, semivate at the mouth, keeded on the back; fowers terminating on two or three alternate compressed spathes, toothletted in two rows on the edge, flexuose, naked; germen cylindric, less than half the length of the flowers, which are larger than those of the white narcissus.—Found in the swampy parts of thick woods near Malacca.

109. Epidendrum Floseris. Leaves from bulbs ovateohlong, acute, flat, fleshy. This climbs variously on trees; flowers subspiked, solitary, alternate, somewhat remote, sessile on the germen, spathaceous, boat-shaped. This is suspeated to be the same as the second species, and is therefore named after it.—Native of the East Indies.

110. Epidendrum Triste. Leaves cylindric; empty sheaths fistulose; peduncles opposite to the leaves, corymbed, perforating the sheath; lip of the nectary entire, spatulate, heart-shaped.—Native of New Caledonia.

111. Épidendrum Crispatum. Leaves cauline, round, filiform, subincurved, empty, sessile; raceme quite simple; lip of the nectary with the niddle segment revolute, waved, crenate.—Native of the Society Islands in the South Seas.

112. Epidendrum Equitans. Leaves equitant, ensiform, compressed, keeled, acuminate; scape naked; raceme spiked, nodding, filiform.--Native of the Society Isles.

113. Epidendrum Myosuruse Leaves sheathing at the base, obliquely divaricate, linear, obtuse, channelled; scape naked; raceme spiked, nodding, filiform.—Native of the Society Islands.

114. Epidendrum Biflorum. Leaves distich, linearlanceolate, acute; peduncles two-flowered, solitary, perforating the sheaths of the leaves; lip of the nectary trifid, acuminate.—Native of the Society Islands.

115. Epidendrum Autumnale. Leaves cauline, lanceolate, nerved, crowded, sheathing; peduncles terminating, sealy, panicled; lip of the nectary erect, retuse.—Native of New Zealand.

116. Epidendrum Fasciola. Leaves rooting, parasitical, bundled, linear, waved; scapes several, racemed; lip of the nectary slipper-shaped, with a spur.—Native of the Society Islands,

117. Epidendrum Umbellatum. Runners creeping; leaves oval, fleshy, petioled; petioles fixed into ovate, angular, keeled apophyses; scape rooted; umbel simple, one-sided, lowest petals elongated.—Native of the Society Islands.

118. Epidendrum Resupinatum. Leaves cauline, petioled, ovate, acuminate, quite entire, plaited, keeled, five-nerved; raceme simple, spiked; flowers inverted; lower lip of the nectary toothed.—Native of the Society Islands.

119. Epidendrum Clypeolum. Leaf radical, roundith, cordate, cowled at the base, reflex, and sharp at the tip; scape almost erect, racemed; the lower lip of the nectary orbiculate, emarginate, very large.—Native of the Society Islands.

120. Epidendrum Nervosun. Scape angular; leaves ovate, nerved; lip entire, reflex; flowers at the top of the scape in spikes, alternate, drooping, purple; spike sharp, angled, erect, smooth, about a span long. A very short, ovate, purple bracte undre each flower; upper petal of the corolla ovate, reflex in the middle, grooved, emarginate, forming a helmet twice as broad as the others—Native of Japan, where it is found between Osacco and Jedo, flowering in May and June.

121. Epidendrum Striatum. Scape angular, smooth; leaves sword-shaped, nerved; petals lanceolate; lip oblong, flat; flowers on the top of the scape in racemes, several, drooping; bractes like the leaves, gradually diminishing. 42. The two upper petals equal, ovate, the length of the calix, yellow, with a purple line, concave.—It flowers in June, and is a native of Japan.

EPI

122. Epidendrum Tesselatum. Roots simple or branched, thick, smooth, long, contorted; if thre issuing from the lower naked part of the stem, and from among the lower leaves, adhering frmuly to the bark of the tree; stem perennial, simple, one or two feet long, as thick as the little finger, crooked, the upper part covered with leaves, the lower naked, withering away at the lower extremity; flowers on axillary racemes, from five to ten in number, remote, facing two ways, beautifully wared, and striated, with various shades of a greenish yellow; petals oral, spreading, equal, scolloped; nectary length of the petals; about the middle its sides approach, forming a tube, the apex is somewhat pointed. This plant is a very beautiful paraste, found flowering during the wet season upon trees among the Circar mountains.

123. Epidendrum Przenorsum. Leaves remote, alternate, facing two ways, linear, channelled, smooth, very firm, and bitten, jointed just above their sheaths-like base, about six inches long, and one inch broad; spike before the leaf, or leaf opposed, short, straight, thick, many-flowered; flowers surround every part of the spike, small, variegated with red and yellow.—Native of the East Indies.

124. Epidendrum Pendulum. The root consists of many feshy fibres like the two last, but issuing from one head ; stem none; leaves radical, three to five, alternate, facing two ways, from one and a half to three feet long, three or four inches at bottom, involved in chafty sheaths, the rest forming the raceme, pendulous, many-flowered ; petals lanceolate, spreading, equal, striated with rose-colour, and yellow ; nectary red, the lower lip three-parted.—Native of the East Indies.

Epigæa : a genus of the class Decandria, order Monogynia .--- GENERIC CHARACTER. Calix: perianth double, approximating, permanent. Exterior Perianth : three-leaved ; leaflets ovate, lanceolate, acuminate, the exterior large. Interior Perianth : five-parted, upright, a little longer than the exterior ; leaflets lanceolate, acuminate, Corolla : one-petalled, salver form; tube cylindric, as long as the calix or longer, hirsute within; border spreading, five-parted; lobes ovate-oblong. Stamina: filamenta ten, filiform, length of the tube, affixed to the base of the corolla; antheræ oblong, sharp. Pistil: germen globose, villose; style filiform, length of the stamina; stigma obtuse, subquinquefid. Pericarp: capsule subglobose, depressed, five-cornered, five-celled, fivevalved. Seeds: very many, roundish; receptacle large, fiveparted. ESSENTIAL CHARACTER. Calix: outer threeleaved, inner five-parted. Corolla: salver-form; capsule five-celled .---- The species are,

1. Epigea Repens; Creeping Epigeae, or Trailing Arburs. Leaves cordate-oate, entire, flat, sharp; corollas cylindric. This is a low plant, with a trailing shrahby stalk, which puts out roots at the joints, and, when in a proper soil and situation, multiplies very fast. The stalks are garnihed with oblong rough leaves, which are waved on their edges. The flowers are produced at the end of these branches, in loose bunches; they are which are waved on their edges. The flowers in July, but does not produce finit in England.— Native of Virginia and Canada. This plant is easily propared by his trailing stalks, which put out roots at the joints, and may be cut off from the old plant, and placed in a shady that the plants may be well rooted before the spring. If the winter should prove very severe, it will be proper to by a few 6 M.

dried leaves, or some light covering, over them, which will fur, has been manufactured into stockings, and other articles defend them from the injuries of the frost ; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

EPI

2. Epigaa Cordifolia ; Heart-leaved Epigaa. Leaves heart-shaped, roundish, serrate, convex, hispid, rigid; corollas ovate .- Native of Guadaloupe.

Epilobium; a genus of the class Octandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth one-leafed, four-parted, superior; divisions oblong, acuminate, coloured, decidnous. Corolla : petals four, roundish, outwardly wider, emarginate, expanding, inserted into the divisions of the calix. Stamina: filamenta cight, subulate, the alternate ones shorter; antheræ oval, compressed, obtuse. Pistil: germen cylindric, extremely long, inferior; style filiform; stigma four-cleft, thick, obtuse, rolled back. Pericarp: capsule extremely long, cylindric, streaked, four-celled, four-valved. Seeds : numerous, oblong, crowned with down ; receptacle extremely loug, four cornered, free, exile, coloured. Observe. In some the stamina and pistil are upright, in others bent downwards to the lower side. ESSENTIAL CHARAC-Calix : four-cleft. Petals : four. Capsule: oblong. TER. inferior. Seeds: downy. This genus consists of hardy perennials, which, though not destitute of beauty, are in general only considered as weeds, and, excepting the first species, seldom find admission into gardens. They propagate spontaneously both by seeds and runners, and require to be restrained, rather than increased by the hand of art, but may be advantageously admitted to fill up remote shady corners, or decorate rock-work .-----The species are,

* Stamina bent down.

1. Epilobium Angustifolium ; Narrow-leaved, or Rosebay Willow-herb, Leaves scattered, linear-lanceolate, quite entire, veined : flowers unequal ; root creeping ; stem upright, from three to six fect high, branched at top, round, and pubescent; branches alternate; flowers purple, showy, growing in a kind of long spike on purple peduncles, the length of the germen, bending down before the flowers open, but afterwards erect, seldom more than four or five blown together on the same spike; the two lowermost petals somewhat remote from each other. From the similitude of the leaves of this species to those of the willow, this plant obtained the name of willow-herb, or French willow. It was formerly much planted in gardens; but as it overruns all the neighbouring plants by means of its creeping roots, it has generally been cast out ; however, in low moist places, or in great shade, this plant will make a good appearance while it is in flower, which will continue nearly a month, unless the season be very hot. - It is a native of most parts of Europe, from Lapland to Italy, but is not common in Great Britain, though it may be found on Maize Hill beyond Greenwich, and in other places near London. Mr. Miller found it wild in great plenty near Alton in Hampshire, in Charlton forest, and several other woods in Sussex, also about Berkhamstead in Hertfordshire, in several parts of Yorkshire, and at many places in Scotland. Gerarde informs us, that he had plants of this species from Yorkshire, and that they grew in his garden, and were very goodly to behold, for the decking up of houses and gardens. The young shoots are said to be eatable, although an infusion of the plant produces a stupifying effect. The pith, when dried, is boiled, and becoming sweet, is by a proper process made into ale, and this into vinegar, by the Kamtschadales; it is also added to the cow parsnep, to enrich the spirit that is prepared from that plant. As fodder, goats and sheep are said to be extremely fond of it, and cows and sheep most underneath. The bottom-leaves are often of a bright to eat of it: the down of the sceds, mixed with cotton or red colour; calicine leaflets four, lanceolate, with a conspi-

of clothing.

2. Epilobium Angustissimum ; Linear-leaved Willow-herb. Leaves scattered, linear, obscurely toothletted, veinless; petals equal, quite entire. This has been confounded with the preceding species. It differs in its woody stem, its very nar-now leaves with salient glands on their edges, the much more lively colour of the flower, shorter siliques, and has an entirely different air. Haller says, that the stem is only a foot or eighteen inches high, with a branch from almost every axil; the flowers almost the same with the foregoing. Villars informs us, that the flowers do not come in a spike, like those of the preceding, but terminate the stem, and are fewer in number. It is an Alpine plant, but is common low down in the beds of the Alpine torrents, as in the Vevaise and the Grande Eau, near Aigle .- It is also found in Provence, and flowers in July and August.

3. Epilobium Latifolium ; Broad-leaved Willow-herb. Leaves alternate, lanceolate-ovate ; flowers unequal. This differs from the first species, in having flowers twice the size; the leaves broader, regularly alternate, not scattered, very smoothly tomentose on both sides. The stem is round, erect, and from eighteen inches to two feet in height .- Native of Denmark, Silesia, and Siberia.

** Stamina upright, cegular; Petals bifid.

4. Epilobium Hirsutum: Large-flowered Willow-herb. Leaves ovate-lanceolate, half stem-clasping, hirsute : stem branching very much; root creeping; roots full of shoots, with numerous fibres, sending out from the upper part runners of a considerable thickness, which creeping under the surface, spread widely, and propagate the plant; flowers large, showy, purple, or flesh-coloured, somewhat bell-shaped, and hanging down a little on peduncles, solitary, alternate .--Native of most parts of Europe by the sides of ditches, ponds, lakes, and rivers, flowering in July and August. The leaves, and particularly the top shoots, when slightly bruised, have a delicate cool fragrance, resembling scalded codlings, whence its name of codlings and cream ; but this fragrance is very soon lost after the plant is gathered. It is also called great hairy-codded loosestrife. Horses, sheep, and goats eat it; and, if it were found to be an acceptable fodder, it might be advantageously cultivated in wet situations. It varies with white flowers, and also with variegated leaves, in which state it is sometimes sold by the gardeners; but having a creeping root, it is very liable to increase too much.

5. Epilobium Villosum ; Hoary Willow-herb. Leaves oblong, lanceolate, toothed, pubescent ; stem columnar, villose. This species invariably differs from the foregoing in its corolia, root, and pubescence. The corolla is in general not more than one-third of the size; the root does not creep ; and both stem and leaves are covered with numerous soft hairs, which give the whole plant a hoary appearance. It is also smaller, and less branched, than the preceding species, but grows in the same places, and flowers at the same time.

6. Epilobium Montanum ; Mountain or Wood Willow-herb. Leaves opposite, ovate, toothed. The root has, on its upper part, little buds of a bright red colour; stem from one to three feet high, upright, red, cylindric ; down scarcely perceptible, sometimes branched at top, but often single ; leaves opposite, except the uppermost, on very short petioles uniting at the base, sharp at the end, finely servate, with unequal teeth, somewhat booked, smooth on the upper side, on the under paler, and very slightly hairy; the downiness is just perceptible on both surfaces, according to Withering, but

502

EPI

cuous mid-rib, slightly hairy on the outside, and at the edges; petals obcordate, deeply emarginate, pale purple, veined with deeper purple lines. It flowers from June to August, is a native of Europe, found in woods and hedges, sometimes in moist meadows, but oftener in dry gravelly soils, in courts, neglected walks, upon walls, and also upon old trees, particularly willows.

7. Epilobium Tetragonum ; Square-stalked Willow Herb. Leaves lanceolate, toothletted, the bottom ones opposite; stem four-cornered. One of the most striking characters of this is the apparent squareness of the stalk, which arises from projecting lines running from the leaves down to it; to this we may add the narrowness of its leaves, the uncommon length of its pods, and its undivided stigma, which was first noticed by Ray .- It flowers in July and August, is a native of Europe, the East Indies, China, and Cochin-china. It is not uncommon in Great Britain, being generally found in marshes, and by the sides of rivulets and ditches, as in the lane from Newington to Hornscy wood ; near Bungay, in Suffolk ; and at Alconbury in Huntingdonshire.

8. Epilobium Palustre; Marsh Willow Herb. Leaves opposite, lanceolate, quite entire; petals emarginate; stem erect : calix a little hairy on the outside ; petals reddish, or pale purple, emarginate, not cloven in the middle; the antheræ, when they are shedding their pollen, adhere firmly to the stigma, so as hardly to be separated without violence, but before and after that time they do not touch it; stigma thick, club-shaped, yellowish white, slightly cloven at top into four parts; siliques peduncled .- Native of Europe, on marshes, bogs, and by the side of lakes.

9. Epilobium Alpinum ; Alpine Willow Herb. Leaves opposite, ovate-lanceolate, quite entire; siliques sessile; stem creeping. This plant is hardly a span high, decumbent at bottom, then upright, and bears one or two flowers at the top .- Native of the mountains of Lapland, Denmark, Switzerland, Silesia, Savoy, Dauphiny: and in Britain, on Cheviot hills, near Settle; about Buckbarrow well, and in many parts of Scotland, by the sides of rivulets, and in sandy places.

10. Epilobium Fruticosum. Stem shrubby, very much branched; leaves quite entire, alternate, hirsutc; peduncles one-flowered ; flowers superior, yellow ; capsule columnar, eight-cornered, crowned with the permanent calix; seeds not pappous .- Native of Cochin-china.

11. Epilobium Glabellum. Leaves oblong, toothed, obtuse, the bottom ones opposite; stcm roundish, erect .- Native of New Zealand.

12. Epilobium Rotundifolium. Leaves opposite, roundish, toothletted .-- Native of New Zealand.

13. Epilobium Parviflorum. Leaves opposite, lanceolateserrate, sessile, both they and the stem villose .-- Native of Germany.

14. Epilobium Alsinefolium. Stem creeping; leaves ovate, acute, toothed ; siliques the length of the stem. This is very nearly allied to the ninth species in its size, habit, disposition of the leaves, flowers, and siliques : the flowers are bright red. a little emarginate, middle-sized; the siliques arc few, small, at an obtuse angle in the first, square, very long, and straight in the second. Both this and the ninth species grow upon the summits of the highest mountains, near the snow, and have their siliques often as long as their stems.

Epimedium ; a genus of the class Tetrandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth fourleaved; leaflets ovate, obtuse, concave, expanding, small, placed directly below the petals, caducons, according to Jus-

tals four, ovate, obtuse, concave, expanding : nectaries four, cup form, with obtuse bottoms, of the size of the petals, and leaning on them, affixed by the edge of the mouth to the receptacle. Stamina : filamenta four, subulate, pressing on the style. Antheræ oblong, erect, two-celled, two-valved, gaping from the base towards the tip, with a free dissepiment. Pistil : germen oblong ; style shorter than the germen, length of the stamina; stigma simple. Pericarp: silique oblong, acuminate, one-celled, two-valved. Seeds : very many, oblong. ESSENTIAL CHARACTER. Nectary: four, cupform, leaning ou the petals. Corolla: four-petalled. Calix: very caducous; fruit a silique .---- The only known species is,

1. Epimedium Alpinum; Alpine Barrenwort. It has a creeping root, from which arise many stiff smooth stalks about nine inches high, cylindric, simple, near the root surrounded with scales, at top trichotomous; leaves once and twice ternate, pendulous, heart-shaped, ending in a point, serrate, the serratures ending in a hair, pale green on the upper side, gray on the under.-Native of the Alps and Apennines, also of Japan. It flowers in April and May, and even later in shady places: it is common in English gardens. The inhabitants of the northern parts of Europe give a decoction of the herb, in milk, to the females of domestic animals when going after the male ; and they say that it effectually quenches those desires which nature excites at that season. If this be true, what an excellent antidote against fornication and bastardy has nature here presented us with, if those, whose warm constitutions are habitually prone to illicit practices, could only be prevailed upon to use it. Hill says, that a strong decoction of the roots, given to women of robust habits, have been often known to succeed, even in cases which have baffled all the efforts of regular practice. It may be increased by the roots, and succeeds best in the shade, where it must every year be reduced, otherwise it will spread its roots so as to interfere with the neighbouring plants. Although it is by no means showy, it deserves to be admitted into gardens on account of its beauty and singularity.

Equisetum ; a genus of the class Cryptogamia, order Filices.-GENERIC CHARACTER. Fructifications disposed into a long ovate-oblong spike; each orbiculate, gaping at the base, with several valves, connected by a flat shield-shaped top .- Though the genus of the horse tails be inhabitants of the water, or at least flourish best where they can lodge their perennial creeping roots in a wet soil, or strong clay which holds the wet, yet they will grow in a garden, especially near water, under a north wall, or in the shade ; they only require to be kept within bounds, as they run much at the root : hence it is better to plant them in pots plunged into the earth than in the open ground. It is very difficult to extirpate them from cultivated lands. Haller says, that he tried in vain to accomplish it by ploughing, dunging, and other methods; and that any one who published the secret of detroying these unpropitious weeds, so injurious to cattle, would merit a considerable reward. Draining the lands infested with it, seems most likely to remove the evil .---- The species are.

1. Equisetum Sylvaticum; Wood Horse-Tail, Stems spiked; fronds compound. It grows to the height of a foot or eighteen inches, and sometimes reaches to three or four feet; stem slender, scabrous, angular; the angles edged with short spinnles, scarcely visible without a microscope; the whorls are hardly an inch asunder; there are twelve or more branchlets, or leaves as some call them, in a whorl, these are very slender, about five inches long, quadrangular, and beset sieu, with a single bracte at the base of them. Corolla ; pe- with several other secondary whorls, having five to seven

ERA

branchlets on each, so that the whole resembles a pine-tree in minitature; the flowering-spike is at the end of the frond. —Native of most parts of Europe, in woods and shady places, flowering in April and May. Linneus informs us, that it is a principal food for horses in some parts of Sweden. Scopoli affirms that it is noxious to cows, making them shed their teeth, and bringing on them a diarrhoa. The whole plant may be usefully employed, either fresh or dry, though it is most effecacious when fresh gathered. A strong decoction of it is an excellent medicine in immoderate discharges of the menses, and in fluxes of the belly attended with griping pains and bloody stools. Externally applied, it stops the bleeding of wounds, and quickly heals them. It is a very cooling astingent therb, and, taken either in powder, decoction, or juice, is of considerable efficacy, in spitting of blood, bloody urine, and for ulcers in the urinary passages.

EQU

2. Equisetum Arvense; Corn Horse-Tail. Fruit-bearing scape naked, barren, leafy; the naked flowering-stems appear early in the spring, and soon decay, they are the thickness of a large wheat straw, a hand's-breadth or more in height, upright, yellowish, with from two to five joints, covered with membranaceous ribbed sheaths, divided at top into numerous segments or teeth ; spike terminating, oblong, swelling about an inch in length, throwing out a greenish powder when ripe, which moves as if it were alive, especially if it be breathed upon; every particle has three or four, rarely five, fine pellucid threads, club-shaped at the end, which occasion the motion, by extending and curling themselves up. It is a troublesome weed, and difficult to extirpate, is reputed noxious to cattle, especially cows, which it afflicts with a diarrheea, but they are not very ready to meddle with it. The country people call it horse-pipe and snake-pipe. It is supposed to indicate subterraneous flowing waters or springs. -It flowers in March, April, and May, is found in cornfields and wet meadows, and is a native of most parts of Europe, the Levant, Japan, and North America.

3. Equisetum Palusire; Marsh Horse-Tail, Stem angular; fonds simple. The stem is a foot or eighteen inches high, nearly smooth, channelled, with five or six deep furrow; ; the sheaths are divided into seven or eight acute black dents with white edges, from these, at a flowering time, come out sixteen forrowed, smooth, simple, short branchlets, becoming afterwards longer; spike terminating, and turning black before it disperses the seed, which is very lively when fresh from the spike.—Found in marshes and diches, flowerring in June. There is a variety of it with smaller fronds, almost all the spikelets having a branch at the end, but that at the end of the stem twice as large as the rest. Haller declares, that this is also injurious to cattle. In Scotland they call it paddock-pipe.

4. Equisetum Fluviatile; River Horse-Tail. Stem streaked; fronds almost simple. This is the largest of all the European species : the stem is three or four feet high, the thickness of a finger, and sometimes nearly an iuch in diameter, streaked, not furrowed, smooth, soft, of a pale or whitish colour at first, but blackish in decay; joints numerous; the spikes grow distinct from the fronds on scapes, but from the same root, these come out earlier, are a foot or eighteen inches in height, and the spikes are replete with a bluish powder. Haller tells us, that this species was eaten by the common people among the Romans; and Linneus says, that the rein deer, who refuse hay, will however eat this; that it is cut as fodder for cows, with a view to increase their milk, but that it is not acceptable to horses .-- Native of Europe, flowering in May and June, and found upon the banks of rivers, lakes, ponds, and ditches.

5. Equisetum Lincosum; Smooth Horse-Tail. Sten almost maked. It grows three or four feet ligh, and is often quite destitute of leaves, but sometimes produces a few straggling ones; the stem is smooth, channelled with twelve or more furrows, and terminated with a black oval spike; the dents of the sinet have acute and black, and of the same number with the furrows.—It flowers in May and June, and is found in watery places, lakes, ponds, and diches.

6. Equesetum Hyemale : Royal Horse-Tail, Stem naked, scabrous, subracemed at the base; the sheaths are black at the base and edge, and obscurely indented with as many short obscure teeth as the stein has furrows: the flowering spike terminates the stem; and the sheath, which immediately subtends it, is pale at the base, but black at the edge, distinctly and acutcly toothed. This is the best species for polishing wood and metal, being the hardest and roughest; hence our old writers called it shave-grass. It is much used by the white-smiths and cabinet makers, under the name of Dutch rushes. The Northumberland dairy-maids scour their milk-pails with it. Gerarde says, that the women scour their pewter and wooden things of the kitchen therewith, and thence call it pewterwort ; and that the fletchers and combmakers rubbed and polished their work with it. Linneus informs us, that it is salutary for horses, noxious to cows, who lose their teeth by feeding on it, and that sheep avoid it; but it is nevertheless certain, that the pasture must be very bad. where any cattle are compelled to eat such food .- It flowers in July and August, and is a native of Europe and of Japan. where it grows in wet marshy places in woods.

Eranthenum; a genus of the class Diandria, order Monogynia.--GENERIC GHARACTER. Calir: perianth fix-ecleft, tubular, very narrow, upright, short, acuminate, permanent. Corolla: one-petalled, funnel-form; tube filiform, extremely log; border five-parted, flat; divisions obvate. Stamina: filamenta two, very short, in the mouth of the corolla. Anthere subvate, compressed, beyond the tube. Pistif: germen ovate, very small; style filiform, length of the stamina; sigma simple. Pericary and Seeds not described, recommended to the attention of the intelligent botanist. ESSEN-TIAL CHARATER. Corolla: five-cleft, with filiform tube; anthere beyond the tube; sigma simple; fruit also undescribed.---The species are,

 Eranthemum Capense. Leaves lanceolate-ovate, petioled; stems long, terminated by one or three spikes, from lanceolate, green, imbricate bractes, within each of which is a long purple flower.—Native of the Cape of Good Hope.

2. Eranihemum Angustifolium. Leaves linear, remote, patulous; stem erect, branched; racemes simple, very long, erect; tube of the corolla very long, with a small obtuse border; antiteræ incumbent, linear.—Native of the Cape of Good Hope.

3. Eranthemum Parviflorum. Leaves ovate-linear, imbricate; bractes ovate.-Native of the Cape of Good Hope.

6. Eranthemum Salsoloides. Leaves fleshy, nearly columnar, linear, very smooth; racemes axillary, they and the calces pubscent; tube bent back. This shrub resembles salsola, but with axillary pubscent racemes at the ends of the branches; pedicels reflex, and at the origin of each three subniate brates; calix five-parted, with subulate pubscent divisions; tube of the corolla longer than the calis, bent back in the middle; divisions of the border ovate-acuminate. Native of the Cape of Good Hope.

5. Eranthemum Spinosum. Leaves ovate, opposite; stipules

R.R.ICA.

spiny; flower solitary; stem suffruticose, a foot high, cespitose, erect, with short rising branches, spiny stipules and bractes; flower pale violet, solitary, lateral; peduncled; calix two-leaved, with acuminate erect leaflets; tube of the corolla curved at the base .- Native of Africa, in the suburbs of Mosambique.

Erica; a genus of the class Octandria, order Monogynia. -GENERIC CHARACTER. Calix: perianth four-leaved; leaflets ovate-oblong, permanent. Corolla: one-petalled, bell form, four-cleft, often bellied. Stamina : filamenta eight, capillary, inserted into the receptacle. Antheræ two-cleft at the tip. Pistil: germen roundish, superior ; style filiform, upright, longer than the stamina; stigma crowned, fourcornered, four-cleft. Pericarp: capsule roundish, smaller than the calix, covered, four-celled, four-valved; partitions meeting with the sutures, or, according to Gærtner, opposite to the sutures. Seeds: numerous, very small. Observe: There are some species with a double calix; the figure of the corolla, as to ovate and oblong, differs in the different species ; the antheræ in some are emarginate, in others two-horned, or awned, included or standing out; the stamina in some are longer, and in others shorter than the corolla; the stigma is also different in different species. ESSENTIAL CHARAC-TER. Calix: four-leaved. Corolla: four-cleft. Filamenta: inserted into the receptacle; antheræ cloven; capsule fourcelled. This genus has, within the compass of a few years, risen from neglect to splendour. Mr. Pope marks it with contempt, at the same time that he celebrates the colour of the flowers, "E'en the wild heath displays its purple dycs."

In some of the species the antheræ are awned, in others they are crested, and in others awnless; in some they are included within the corolla, in others they are projected, or stand out beyond the corolla. Hence this unwieldy genus is commodiously divided into four sections, and these sections are again subdivided according to the disposition of the leaves ; the inclusion or projection of the style also affords another division of the species; the calix in some is double; and lastly, the form of the corolla assists us much in distinguishing the numerous species; the campanulate and ovate forms, with their several modifications, are the predominating sorts. All this may be best understood by the following table, which is of great use to exhibit these material differences at one view.

Antheræ awned, from species No. 1 to 29.

- _____ crested, 30 to 43.
- awnless, 44 to 82. 84.
- --- included. 1 to 69, 84,
- standing out, 70 to 80.
- Leares in pairs, opposite, 1. 2. 44. 45.
- in threes, 3 to 19; from 30 to 33; from 46 to 55; from 70 to 75; 83.
- in fours, 20 to 28; from 39 to 43; from 56 to 57; from 76 to 78; from 81 to 84.
- more than four, 29. 68. 69. 79. 80. 82.
- Style included 2 to 7; from 9 to 14; 20 to 21; 23 to 25; 29 to 35; 39; 44 56 to 58; 60 to 66; 83.
- ----- middling, 42. 43.
- ----- standing out, 1; from 15 to 19; 22; 26 to 28; 36 to 38; 45; 47 to 52; 55, 59, 70, 71; 73 to 82.84
- Corolla bell-shaped, 1; 9 to 18; 21, 22, 37, 45, 47, 55, 62, 64; 74 to 77; 80.
 - bell salver-shaped, 49.
- pitcher bell-shaped, 43.
- .43.

Corolla globular bell-shaped, 30. 31.

- globular, 20, 48, 64. - subglobular, 6, 50,
- roundish, 53.
- ovate, 2 to 4; 23, 24, 27; 32 to 36; 39 to 41, 46. 54. 81.
- ovate bell shaped, 51.
- ----- ovate-conical, 7, 8.
- ------ ovate-oblong, 42. 66.
- ------ ovate fig-shaped, 52.
- ----- ovate funnel-shaped, 63.
- ----- funnel-shaped, 84.
- ----- oblong, 5. 28, 78.
- ----- cylindric, 19, 38, 59, 68, 70, 71, 72, 79, 82.
- cylindric fig-shaped, 69.
- ----- fig-shaped, (this seems to be the only sense in which the word grossus can be applied,) 25. 26 29
- ------ club fig-shaped, 56, 57, 58, 60.
- ----- salver-shaped, 61.
- tubular, 67.
- four-cornered, 83.----The species are,

1. Erica Vulgaris; Common Heath. Corollas bell-shaped. almost equal; calices double; the inner longer than the corolla; leaves sagittate, imbricate in four rows. Common heath is a foot or two in height, or more; the stems brown and woody, very much branched; the branches in opposite pairs, mostly upright, round, downy, and reddish; the branchlets square ; flowers solitary, on peduacles the length of the leaves, from the sides of the branches, slightly nodding, opposite, but generally pointing one way, giving the branches the appearance of long bunches, but leafy shoots will be always found at the end. The inner or proper calix consists also of four oval-oblong coneave leaflets, slightly adhering at the base, alternating with the segments of the corolla, of the same colour, and nearly of the same texture with them, five times as long as the outer calix, open, but after flowering approaching with the points bent in. We may here observe a curious instance of the gradual transition from the green herbaccous leaves of the stem, to the more delicate texture of the corolla, which is of a pale purplish rose-colour, whitish to-wards the base, divided two-thirds of the way down into four, sometimes five, ovate, blunt, equal, open segments; filamenta awl-shaped, double, to and fro towards the point, white, or tinged with purple, springing from small glands at the base of the germen. It varies with white flowers, and with hoary leaves, and is common on Bagshot Heath, Enville Common in Staffordshire, Birmingham Heath, and, as Ray says, not only about Windsor, where Clusius observed it, but all over England. This plant, which is little regarded in warmer climates, is made to serve a great variety of purposes in the bleak and barren Highlands of Scotland, and other northern countries. The poorer inhabitants cover their cabins with it instead of thatch, or else twist it into ropes, with which they bind down the thatch in a kind of lattice work. They also form walls with alternate layers of heath, and a sort of cement made of black earth and straw, and these hardy people have even been known to make their beds of it. In most of the Western Isles they dye their yarn of a yellow colour, by boiling it in water with the green tops and flowers of this plant : and woollen cloth boiled in alum-water, and afterwards in a strong decoction of the tops, comes out a fine orange colour; and in some of those islands they tan their leather with a strong decoction of it. Formerly the young tops are said to have been used alone to brew a kind of ale; and Boethius relates that this liquor was much used by the Picts; and in 6 N

505

several of the isles it is said that they still brew ale with one part malt, and two parts of the young tops of heath, some-times adding hops. In many parts of Great Britain, besoms are made of it, and the turf, with heath growing upon it, is cut up, and dried for the fuel of the cottager, heating ovens, covering under-ground drains, &c. Sheep and goats will sometimes eat the tender shoots, but are not fond of them, Cattle not accustomed to browse on heath give bloody milk, but are soon cured by drinking plentifully of water. The branches of heath afford shelter, and the seeds a principal part of the food of many birds, especially those of the grouse kind ; and for this purpose the seed-vessel is formed and protected in such a manner, that the seeds are preserved a whole year, or even longer. Bees collect largely from the flowers, and honey made from them was anciently supposed to be of a bad quality, but in fact it is only of a darker colour. The foliage affords nourishment to the phalænaquercus, or great egger moth. Dodder frequently entwines itself about this plant, and gives it a singular appearance. Meyrick says, that a water distilled from the flowers is a good application to inflamed eves ; and an oil made from them is reported to be of great efficacy in curing the shingles, and other cutaneous eruptions. Almost every part of Europe abounds with heath, especially the northern countries, it is also common in all the temperate parts of the vast Russian dominions: it is called ling in some parts of England ; grig, in Shropshire ; and ha ther in Scotland; though it is remarkable that Shakspeare enumerates heath and ling as quite different plants ; the former of these names is derived from the German heide, and the latter from the German lyng. The Swedes call it liung ; the Italians, erica; the Spaniards, brego; the Portuguese, urze, erice, torga, or estorga; and the Russiaus, weresk. Common heath, which overruns immense tracts, especially in the elevated parts of northern countries, can only be effectually extirpated by paring and burning. In some lands deep and cross ploughings, getting up roots with heavy harrows, burning the whole, and spreading the ashes, may be sufficient. Dr. Anderson affirms, that wherever heath abounds, there is generated, by the rooting of the plant, a peculiar black earth, that is not only sterile of itself, but has a powerful tendency to make any other soil unproductive, so that in improving heathy grounds, the top soil should be buried by trenching or deep ploughing. Notwithstanding the commonness of our British heaths, they deserve a place in small quarters of humble flowering shrubs, where, by the beauty and long continuance of their flowers, together with the diversity of their leaves, they make an agreeable variety. The first, twenty-third, thirty-sixth, and eightieth species, may be taken up with a ball of earth growing to their roots, from the natural places of their growth, in autumn; the soil should not be dunged, and the less the ground is dug, the better they will thrive, for they commonly shoot their roots near the surface. They may also be propagated by seeds, but this is a tedious method.

2. Erica Lutea; Yellow Heath. Corollas ovate-acuminate; flowers heaped; leaves linear. The whole is smooth, with a rufescent upright stem, two feet high; branches scattered, flinform, very frequent, wand-like; branchlets also scattered, flinform, very frequent, wand-like, short; leaves opposite, blund, grooved underneath, a line in leagh; flowers on the extreme branchlets, one, two, or three logether, upright; brates linear, obtuse, concave, pale; calicine leaftest ovate-acuminate, keeled below the tip; it varies with the corolla; calix and bractes yellow or white. The whole plant being covered with its shining golden or silvery flowers, is very beautiful_Nativer of the Cape of Good Hope. This species,

together with all the others of this genus which are natives of the Cape of Good Hope, or the more interior parts of Africa leading to that famous promontory, must be preserved in the divystore, green-house, or gluss-case. These may be increased either from cuttings of from layers; there are few but what may be increased by cuttings, provided good young shoots can be procured, especially if they be put under bel-glasses, and the pots are set where they can be shaded, and have a moderate heat. The third, threaty-ninth, and a few other species, have on yet been struck from cuttings, and must therefore be propagated from layers, which, however, will not always strike the first year. These plants should have a light and rather poor soil to grow in; a composition of bog earth and light loam will suit them well.

* Leaves in threes.

3. Erica Halieacaba; Purple-stalked Heath. Corollas orta, inflatel; style included; flowers solitary; stem smooth, rugged, brown, flexuose, decumbent, strict, a span high; branches alternate, divaricate, like life stem; leaves in threes, lanceolate, acute, smooth, flat above, convex beneath, with a slender groove, spreading; peduncles tomestose, reflex; bractes ovate, acute, approximating, many times smaller than the caiux; calcine leaflets ovate, acute, keeled, entire, pale flesh-colour; the segments straight, acute, converging, alt one site largest plant of the genus, and a native of the Cape of Good Hope. For its propagation and culture, see the preceding species.

4. Erica Regerminans. Carollas ovinte; style included; calices acute; flowers racemed; style shrubby, determinately branched; branches rushy; leaves linear, subulate, acuminate, even, patulous; racemes pointing one way, nodding, on pedundes the length of the flower, fleshcolaured; brates remote, minute, coloured; calix red, lanceolate, very small; corolla ovate-globular, red, with a blunt mouth; anthere a little shorter than the corolla; style included, the length of species.

5. Erica Monsoniana : Bladder-flowered Heath. Flowers at the ends of obtuse branchlets; calix calicled; corolla oblong, inflated : style included ; the stem is erect, pubescent, leafless, two feet high; branches scattered, frequent, spreading, covered with leaves, very short, simple; leaves in threes, ovate, obtuse, convex beneath, with a longitudinal groove, flat above, entire, imbricate, smooth, scarcely a line in length; flowers solitary, nodding, on pubescent reflex peduncles; bractes ovate, keeled, acute, white, a little shorter than the calix, on the middle of the peduncle; calicine leaflets ovate acute, concave, keeled, white, smooth, almost three times shorter than the corolla, which is almost an inch long, divided at the mouth into four very short blunt segments. It resembles the third species, but has ovate not linear leaves, smaller, less inflated, and deeply divided corollas; the flowers more copious, and the stem erect. This plant is one of the most beautiful of this very beautiful genus, and has large white flowers. Thunberg found it in the interior of Africa. See the second species.

6. Erica Mucosa: Mucosa Hath. Corollas subglobular, mucous; style included; stem frutescent, determinately branched, with white awt-shaped decurrent lines under the scars of the leaves, which are linear, even, pressed close; scarcely longer than the intersifies; flowers terminating, subumbelled, on pedancles the length of the flowers; bractes linear, minute, remote; calk scarbose, mucous, a little shorter

ERI

short; style short, cylindrical; stigma naked .- Native of the Cape of Good Hope. See the second species.

7. Erica Urceolaris; Hairy-flowered Heath. Flowers umbelled; calices lanceolate; corollas ovate-conical, villose; style included ; stem flexnose, erect, ash-coloured, two feet high; brauches opposite, or in threes, cinereous-villose, wandlike; branchlets filiform, scattered, frequent, wandlike; leaves in threes, linear lanceolate, beneath grooved from the revolute margins, tomentose, whitish, from erect spreading, curved a little; peduacle, calix, and corolla hirsute; calix shorter by half than the corolla, which is flesh-coloured, oblong, subcampanulate, and a line in length ; it varies with flowers very hirsute and hairy, red and whitish flesh-colour. It flowers in May and June .- Native of the Cape of Good Hope. For its propagation and culture, see the second species.

8. Erica Marifolia; Marum-leaved Heath. Leaves ovate, pubescent, whitish underneath; corollas ovate-conical; style of a middling length. It flowers in May and June .- Native of the Cape of Good Hope. Sec the second species.

9. Erica Bergiana. Calices reflex; corollas bell-shaped; style included. This shrub is about two feet high, and pubescent; leaves linear, subciliate, erect; flowers at the ends of the branchlets, subsolitary, on very short peduncles; calix lanceolate, acute, one-third of the length of the corolla, spreading, or reflex; corolla shaped like that of the lily-of-the-vallev, purple, blunt; stamina shorter than the corolla; pistil the length of the corolla; stigma subcapitate: it is covered with beautiful flowers .- Found by Bergius at the Cape of Good Hope. For its propagation and culture, see the second species.

10. Erica Depressa. Stem depressed ; flowers few; corollas bell-shaped; style included; stems procumbent, copious, a palm in length; leaves lanceolate, bluntish, even, keeled; flowers scattered, solitary; calix scariose, lanceolate, acute, shorter by half than the corolla, which is obtuse, red, and even; antheræ very short; stigma blunt .-- Native of the Cape of Good Hope. See the second species.

11. Erica Pilulifera. Flowers umbelled; corollas bellshaped : style included. The whole shrub is smooth, purple, erect, a foot high or more; branches and branchlets trichotomous, from erect spreading, subfastigiate; leaves in fours, obliquely whorled, three equal in situation, the fourth lower, linear, obtuse, flat above, beneath convex, with a deep longitudinal groove, the lower smooth, the uppermost very finely ciliate, attenuated into paler petioles, imbricate; flowers terminating, four to ten drooping; peduncles blood-red, longer than the leaves; calicine leaflets boat-shaped, acute, pale blood-red, smooth, ciliate at the tip, pressed close, a little shorter than the corolla, which is blood-red and smooth. The above is Thunberg's description .- Native of the Cape of Good Hope. For its propagation and culture, see the second species.

12. Erica Viridi Purpurea. Flowers scattered; corollas bell-shaped; style included; leaves lanceolate, smooth; flowers in racenies, directed all the same way; corolla purple. It varies with the leaves in fours .- Native of Portugal. This, and the sixteenth, seventeenth, thirty-eighth, fiftysecond, seventy-fifth, sixth, seventh, eighth, ninth, and eighty-first species, which are natives of the southern countries of Europe, will bear the open air in England, when placed in a dry soil, and a warm situation. They may be propagated and treated in the same manner as our British heaths, and may also be increased by layers and cuttings.

13. Erica Pentaphylla, Flowers pubescent; corollas bell-

than the corolla, ovate, acute; corolla blunt; antheræ ovate, | shaped; style included .- Native of the Cape of Good Hope. For its propagation and culture, see the second species.

14. Érica Nigrita. Calices imbricate, three-flowered, sessile; corollas bell-shaped; style included; stem brown, upright, a foot high and more; branches and branchlets scattered, aud whorled, flexuose, erect, wandlike, ash-coloured, tomentose; leaves linear-ovate, obtuse, very finely rugged about the edge, flat above, convex beneath, with a slender longitudinal groove, shining, pressed close at the base, spreading, and recurved from the middle, a line in length; flowers terminating in threes, peduncled, erect; bractes oblong, acute, keeled, white, approximating to the calix, im-bricate, shaped like the calicine leaflets, which are ovate, acute, keeled, very finely rugged about the edge, white, smooth, nearly equal to the corolla .-- Native of the Cape of Good Hope. For its propagation and culture, see the second species.

15. Erica Planifolia. Leaves spreading very much; corollas bell-shaped; style standing out; branches filiform, creeping; flowers violet-coloured; leaves ovate, acute, ciliate .- Native of the Cape of Good Hope. See the second species.

16. Erica Scoparia; Small Green-flowered or Brush Heath. Corollas bell-shaped ; stigma standing out, peltate. This is a shrub, growing to the height of seven feet. The leaves soon fall off, and the branches are made into besoms, from which circumstance it has derived its trivial name. It flowers in April and May, is common in the south of Europe. For its propagation and culture, see the twelfth species.

17. Erica Arborca; Tree Heath. Branchlets hoary : corollas bell-shaped ; style standing out. This is an upright shrub, growing to the height of six feet, with upright branches, covered with a white nap ; leaves very abundant, upright, smooth, almost awl-shaped, covering the branches, wrinkled when dry; flowers very numerous on the middle of the branches, so that the later leaves are above them; they are on branching peduncles, forming a panicle; calix single, short, with lanceolate leaflets; corolla white, short, broad, four-cleft two-thirds of the way. It flowers from February to May .- Native of the south of Europe, and the island of Madeira. See the twelfth species.

18. Erica Vespertina. Corollas bell-shaped ; style standing out. This is an upright shrub, with the branches growing by threes ; leaves triquetrous, even, pressed close ; flowers in a panicle, nodding, alternate, white, on white pubescent peduncles, with ovate, alternate, white bractes : leaflets of the calix ovate, keeled, sharpish, the length of the tube ; corolla double the length of the calix, broad, sharp; antheræ black, two-parted above the throat; style purpurascent, rather longer than the corolla; stigma blunt .- Found by Thunberg at the Cape of Good Hope. See the second species.

19. Erica Cruenta; Bloody-flowered Heath. Leaves smooth ; bractes remote ; calices awl-shaped, dilated at the base; corollas cylindrical, incurved; style standing out; branches round, smooth; branchlets pubescent; lcaves linear, awl-shaped, grooved, spreading, half an inch long, on appressed petioles, scarcely half a line in length; flowers axillary; peduncles hardly half an inch long, sometimes bifid or trifid; bractes three, awl-shaped, three-sided; leaflets of the calix keeled, smooth, two lines in length ; corolla deep crimson, an inch long, a little bent in, smooth, subpellucid, a little swelling at top, with a four-cleft mouth; segments sharpish, broad, suberect ; filamenta whitish ; antheræ included, oblong, brown, bifid; awns subulate, capillary, the length of the antheræ; style a little longer than the corolla, red; stigma standing out, incrassated, very dark purple. It flowers at various seasons.—Native of the Cape of Good Hope. See the second species.

* Leaves in fours.

20. Erica Ramentacea; Stender-branched Heath. Leaves bristle-shaped; corollas globular; style included; stigma doubled; branches filiform, ramentaceous, long, ferruginous; leaves very narrow, upright, pressed close; flowers umbelled; calix shorter than the corolla, green; corolla purple; anthere with two cilitate horns, inwardly mucronate, opening in an ovate form on the sides; style purple; stigma double, the upper roundish, the lower quadrifid. It flowers in July.— Native of the Cape of Good Hope. For its culture and propagation, see the second specifies.

² 21. Erica Persoluta; Elush-flowered Heath. Calies ciliate; corollas bell-shaped; sile included; stem shrubby, smoothish, with pubescent branches; leaves linear, obtuse, erect, channelled underneath, the length of the joints, hispid, or subscabrous; flowers numbelled, dispersed on the upper twigs.—It flowers from February to May, and is a native of the Cape of Good Hope. See the second species.

22. Erica Strigosa: Dwarf Doumy Heath. Leaves puberent, eilate; corollas bell-shaped, smooth; style standing out; branches somewhat villose; leaves linear, acute, spreading, somewhat villose, ciliate, with a few long hairs; glanduous at the tip, three lines long, on petioles half a line in length; flowers axillary on the extreme twigs, on pedundes a line and a half long; corolla pale red, almost twice as long as the eaks. It flowers in March and April.—Native of the Cape of Good Hope. See the second spreies.

23. Erica Tetralix; Cross-leaved Heath. Leaves ciliate : flowers in heads; corollas ovate; style included; stems shrubby, from nine to twelve inches high, branched, brown, somewhat rugged from the remains of the leaves which have fallen off; branches woolly; leaves commonly in fours, but sometimes in fives, ovate, linear, spreading near the flower, pressed close to the stem, the edges turned in, and ciliated, each hair terminating in a small round gland, the upper surface is flat, the lower concave and white; flowers hanging down one over another all one way, forming a little head; peduncles downy, about the length of the flowers ; bractes three at the base of each flower on the upper side, of the same shape as the leaves of the calix, the lowermost the largest, inserted about a line below the calix : the two others, one on each side, rising from the base of the calix; calicine leaflets from four to six, linear, three times shorter than the corolla, woolly, fringed with long hairs tipt with brownish red globules ; corolla pale purple or flesh colour, varying to white, divided into four very shallow segments, which turn back ; antheræ sagittate, purple, with two white horns at the base, and two little apertures for the discharge of the pollen ; germen woolly, glandular at the base ; capsule villose, truncate. It flowers twice in the year, though some say only in July and August, and is a native of the northern parts of Europe, on moist heaths, and moorish grounds. This species is not inferior to many of the foreign heaths in the delicacy and beauty of its flowers. It is distinguished from the other British heaths, not only by the flowers growing in a pendulous cluster on the tops of the stalks, but by the leaves growiug in fours, and forming a sort of cross, whence the trivial and English names. Our old writers call it low death-heath, or besom-heath .-- For its propagation and culture, see the first species.

24. Erica Pubescens. Leaves rugged; flowers sessile, cles, with alternate, remote, flesh-coloured bractes; calix lateral; corollas ovate; style included; stem ash-coloured, flesh-coloured, lanceolate, the length of the corolla, keeled,

hispid, decuose, erect, two feet high and more; branches scattered, seldom in whords like the stem; branchlets fillform and capillary, short, wandlike; leaves in threes or fours, frequently four on the branches, and three on the branchlets, seldom all in fours, linear, obluse, rugged, villose, incurred, grooved beueath, spreading a line in length; flowers at the end of the branchlets, unbelled, two, three, or more together, abundant, blood-red, hirsute.—Native of the Cape of Good Hope. See the second species.

25. Dried Abieina; Fir Heath. Flowers sessile; corollas fig-shaped; style included; stem abs-coloured, ragged, erect, a foot high and more; branches and branchlets in a sort of wholt, from erect spreading; leaves in fours, lanceolate, subulte, grooved underneath, smooth, imbricate; flowers at the ends of the branches in racenes, nodding; peduneles blood-red, villose, the length of the leaves; brates blood-ted, pale. It flowers in June and July—Native of the Cape of Good Hope. See the second species.

26. Erica Mammosa. Corollas fig-shaped; style standing out; sten sonewhat rigid, with white awl-shaped decurrent lines from the scars left by the fallen leaves; leaves awl-shaped, crowded, somewhat rugged on the edge; flowers in a sort of head, on very short purple pedincles, with very small remote bractes; ealix blood-red, ovate, very short; corolla ovate, cylindric, blood-red, very long, with a blunt mouth.—Native of the Cape of Good Hope. See the second species.

27. Erica Caffra. Leaves pubescent; flowers heaped; corollas ovate; style standing out.—Native of the Cape of Good Hope. See the second species.

20. Érica Sessilifora. Flowers in a spike, sessile, bent down, oblong; corollas club-shaped; styles standing out. This is a bown rugged shrub, determinately branched, somewhat rigid; leaves crowded very much together, linear, acute, deep greet; spike terminating, surrounded by sessile, imbricate, broadish flowers.—Native of the Cape of Good Hope. Sec the second species.

Leaves scattered.

29. Erica Fascicularis. Leaves several, linear, truncatel ; flowers in bundles ; corollas fig-shaped ; style included ; stem shruby, upright, compound, two feet high ; leaves crowded, scattered, almost filform, an inch long, even, capillery at the base, from erect spreading a little, glandular near the tip; flowers terminating, fastigiate.—Native of the Cape of Good Hope. See the second species.

** Antheræ crested ; Leaves in threes.

30. Erica Triflora. Flowers terminating : corollas globus lar, bell'shaped; style included; stem brown, smooth below, hispid at top, erect, a foot high; branches dichotomous, brown at bottom, and smooth above, ash-coloured, hirsute; crect, fastignet; branchets scattered all over the brauches, fillform, frequent, hairy, rough, wandlike; leaves linear; sublatke, entire, smooth, fat above, convex beneath, with a very slender groove, incurved, from erect spreading; flowers solitary, or two or three together, on very short drooping peduncles, ash-coloured, tomentose.—Native of the Cape of Good Hope. See the second species.

31. Erica Baccans; Arbatus Jouverd Hrath. Leaves imbriate; corollas globular, bell-shaped, overed; style included; stem erect, branched; flowers terminating in threes or thereabourds, nodding, the size of a pac, on purple peduncles, with alternate, remote, flesh coloured bractes; calit (esb-coloured, hancolate, the length of the corolla, keeled, bent in; corolla obtuse, red; antheræ awnless, very short, yellowish. It flowers in April and May.—Native of the Cape of Good Hope. See the second species.

32. Erica Craphaloides. Corollas ovate, covered; style included; stigma four-parted. It is a small shrub, smooth all over, of a cinereous brown colour, erect, a span high; branches and branchlets dichotomous and trichotomous, fuiform, from erect spreading, fastigate; flowers terminating, about three together, purple,—Native of the Cape of Good Hore. See the second species.

33. Erica Corifolia; Skender-twigged Heath. Flowers unbelled; calics turbinate; corollas ovarle; style included; atem shrubby, compound; calix spreading, with ovate, purple leaftes; corollas purple; sigma headed.—It flowers in August, and is a native of the Cape of Good Hope. See the second species.

34. Erica Articularis. Corollas ovate, acuminate; style included, longer than the calix; flowers racemed, peduncled; corolla bell-shaped, white; style dark purple.—Native of the Cape of Good Hope. See the second species.

55. Erica Calicia. Calices spreading very much, wheelshaped; corollas ovate; style included; calix and bracte white; corolla yellow; leaves three-sided; bractes alternate. --Native of the Cape of Good Hope. See the second species.

36. Erica Cinerea ; Fine-leaved Heath. Corollas ovate ; style a little standing out; stigma capitate; root perennial, woody; stems shrubby, about a foot high, with opposite branches; the bark ash-coloured; leaves linear, fleshy, spreading, above smooth and shining, transversely wrinkled towards the end, beset with a few scattered hairlike points: beneath having a longitudinal furrow, which is white from a woolliness apparent to the magnifier; the edge somewhat membranaceous, and, when viewed with the microscope, appearing serrulate; the leaves when young have three flat sides, but when full grown are nearly flat; flowers in long, clustered, whorled, terminating spikes, sonorous when struck; they come out from the sides of the young shoots; those from the ends of the shoots are near cach other, but scattered and bare; those from the small lateral branches generally in pairs; peduncles shorter than the flowers, purplish brown, somewhat downy, the lower nodding, the upper upright, with a bracte about the middle; corolla three times as long as the calix, bluish purple, shrivelling, and turning of a fawn colour; the clefts very shallow. It flowers from June to August, and is a native of all parts of Europe, except the extreme southern and northern regions, and is also found in the Levant. It may be applied to the same purposes as the common heath, and the flowers are much more showy. For its propagation and culture, see the first species.

37. Erica Paniculata; Panicled Heath. Flowers minute; corollas bell-shaped; styles standing out. This is a shrub, with linear upright leaves, almost even; flowers purple, very small, as are also the calices and peduncles; they are so abundant as to cover the whole plant. It flowers from February to April.—Native of the Cape of Good Hope. See the second species.

38. Erica Australis ; Spanish Heath. Leaves spreading ; corollas cylindric; style standing out. This is an upright rigid shrub, with an ash coloured hark; leaves in threes or fours, linear, obtuse, somewhat rugged on the edge; howen terminating, two or three subsessle; calis rude, acute, keeled, inbritant bratest; corolla scarcely club-shaped, obtuse, three times as long as the calix; the segment becoming hoary. It flowers in April and May,—Native of Spain and Portugal. See the twelith species. 43.

ERI

39. Erica Physodes. Flowers subsolitary; corollas ovale, inflated; style included; leaves patulous, broad-lineer, keeled; calix ovate, smooth, coloured, one-third of the length of the corolla, which is the size of a pea, and visid. The flowers are at the ends of the brauches in a sort of umbel.—Mative of the Cape of Good Hope. See the second species.

40. Erica Empetrifolia; Crowberry-lowed Heath. Flowers essile, lateral; corollas ovalte; stem brown, rugged, a foot high; branches in whords like the stem, flexuose, erect; branchlets trichotomous and dichotomous like the branches; fidwers aggregate, in whorls in the middle and at the ends of the branchlets; calicine leaflets lanceolate, ciliate, blood-red; corolla ovale, bell-shaped, hairy, rongla the bottom, blood-red; style purple, curved, twice as long as the corolla, with the headed stigma standing out. It flowers in April and May, and is a native of the Cape of Good Hope. See the second species.

41. Erica Cernua. Flowers ovate, capitate; calices cilicate; anthere included. The whole plant is smooth, brown, erect, a foot in height; branches scattered in threes, filiform, flexuose, erect; leaves ovate, obtuse, ciliate, flat above, convex beneath, grooved, imbricate; flowers terminaing, drooping.—Native of the Cape of Good Hope. See the second species.

42. Erica Retorta. Leaves recurved; corollas ovate, ob-long; style of a middling length; stem fritescent, somewhat rugged, determinately branched; leaves ovate-oblong, terminated by a little bristle, convex above, snooth, shining; flowers terminating, corymbed, subsessile; calix red, lanceolate, with an awn at the end; corolla long, inflated, viscid, with a globalar throat, and a four-parted, accumbate, short border; filamenta linear, membranaccous.—Native of the Cape of Good Hone, See the second species.

43. Erica Margaritacea; P-àrt/fourered Heath. Corola pitcher bel'shaped; style of a middling length; fowers terminating, four or eight from the uppermost axils; peduncies filiform, shorter than the leaves; bractes linear, three in number; corola white; tube pitcher-shaped, a little longer than the calix; segments of the border obluse, pathous; filamenta white, shorter than the tube, ben in at the tip; anthera ovate, compressed, brown, two-partel; laminas oblong; acute, gash-serate without, white, the length of the anthera; germen red, having eight little knobs at top; style the length of the corola, whitish; stigma headed, fild beneath, coavex above, commonly four-lobed.—Native of the Cape of Good Hope. See the second species.

*** Antheræ awnless included ; Leaves opposite.

44. Erica Tenuifolia. Corolla and calix blood-red. The whole stem is smooth, erect, a span high; branches and branchlets filform and capillary, erect; leaves opposite, lancolate, smooth, couves beneath, with a slender groose, pressed close; flowers terminating, nucleid, in threas; calicine leadles equalling the corolla, keeled; flowers bloodred; style included.—Native of the Cape of Good Hope. See the second species.

45. Erica Passerine. Corollas bell-shaped; style standing out, (according to Thunberg, included); flowers solitary, terminating, peduncled; peduncles white, tomentose, generally longer than the flowers; calix bell-shaped, bluntish, fourparted, with ovate leadlets; filamenta the shortest of any; germen white, tomentose; sigma subcapitate. This has the erb of passerina ericoides has entirely the herb of an 6 O erica with the flowers of passerina. This is an instance of the intermixture of genera, which is not uncommon in the Cape plants.—Native of the Cape of Good Hope. See the second species.

Leaves in threes.

46. Erica Albens. Racemes pointing one way: corollas vorte-oblong, acute; stem futescent, with determinate wand-like branches; leaves linear, three-sided, crect, even, longer than the internodes, sharpish; flowers in a sort of spike, white, with lanceolate white bractes on the peduncle; calix scariose, which, ovate, acuminate, half the length of the co-rolla, which is white, with the belly hyaline, and the border four-parted, narrowed, acute, funnel-form; anthera blifd, obtuse, short; style shorter than the corolla.—Native of the Cape of Good Hope. See the second species.

47. Erice Spunosa; Siz-angled Heath. Corollas in threes, covered by a common calix; style standing. A small shrub, with marrow brancillets; leaves ovate-oblong, threesided, channelled; flowers terminating, nodding, sessile; calices globular, waved, inbritaete, with roundish scales, keeled, and bent in at the tip, blood red.—Native of the Cape of Good Hope. See the second species.

49. Erice Capitals; Wouly Heath. Flowers sessile: co-rollas covered with a woolly calix; anthere middling; stem seldom erect, commonly decumbent, smooth, flexnose, fliform; brancles filform, fexuose, villose; branchlets capilary, frequent, tomentose; leaves ovate, spreading, rough with long hairs; flowers at the end of the extreme branchlets, peduncled, one, two, or three together; the whole calices covered close with a white wood; anthere protruded, pupe. It flowers in April, and continues till July.—Native of the Cupe of Good Hope. See the second species. 40. Error laboration of the Cupe of Laboration of the Cuples of Honghamed, longer than 40. Erics Meanthera. Corollas bell-shaped, longer than a second species.

40. Erica Melanthera. Corollas bell-shaped, longer than the coloured calix; anthera middling; style standing out; strm shrubby, flexile; leaves linear, obtuse, even, patulous; flowers terminating, subumbled, scattered in close parcels, nodding a little; peduucles the length of the corolla, purplish; bractes lauccolate, alternate, coloured; calix bloodred, obovate, more in breadth than length, keeled, with a dagger-point at the tip; corolla bell salver-shaped, bloodred; tube the length of the calix; b order spreading, generally longer than the tube; the segments roundish, orate; anthera dark-coloured, blifd, the length of the border. —Native of the Cape of Good Hope See the second species.

50. Erica Thunbergii. Corollas flat, with a globular tube; antheræ midding si tyle standing out ; stem rufescent, round, seldom branched; : leaves linear, even, sessile, acute, generally pressed close; flowers terminating, peduncled; : bractes two, alternate, scariose, lanccolate.—Native of the Cape of Good Hope. See the second species.

51. Erica Absynthoides. Corollas ovate, bell-slaped; style standing out; stigma funnel-ahaped. This shrub is panicled, and grows to the same height as wormwood; stem rufous; branches in threes; leaves linear; gibbous on the outside, subhirsue; flowers at the ends of the branchlets; corollas pale; antheræ very dark purple, bifd within the mouth of the corolla; stigma purple, four-cleft. Thumber; informs us, that this species has four varieties.—Native of the Cape of Good Hope. See the second species.

52. Erica Ciliaris; Ciliated Heath. Racemes pointed one way; corollas ovate, fig-shaped; style standing out. This plant is safiruticose, two feet high; leaves spreading very much, sessile, ovate, acute, reflex, and ciliate on the edge; raceme terminating, whorled by threes; style alimost twice as

long as the corolla. It flowers from July to September.-Native of Spain and Portugal. See the twelfth species.

53. Erica Hispidula. Stem hispid; leaves about three, ovate, acute, ciliate; corollas roundish; stems decumbent, half a foot high, strigose or hairy; leaves subsessile, horizontal, patulous, even; flowers small, bell-shaped, bent towards the ground, scattered thinly; style longer than the corolla,— Native of the Cape of Good Hope. See the second species.

54. Erica Petiolata; Rosemary-leaned Heath. Leaves ablong, petioled; corollas in three, ovate, the length of the calix; antheræ standing out a little; style standing out; stem round, flexuose, decumbent, rigid, smooth; branches scaltered, opposite, or by threes, almost erect, bent in, flexuose, tomentose at top; flowers terminating, umbelled, on very short tomentose peduncies; bracts lanceolate towards the base of the calix; calicine leaflets ovate, acute, entire, smooth, concave, keeled below the tip, pressed close. It flowers from March to June.—Native of the Cape of Good Hope. See the second species.

55. Erica Leucanthera. Flowers in threes; calix white; corolla bell-shaped; anthrew and style standing out; stem erect, smooth, a foot high and more; branches commonly in threes, publescent, erect, wandlike; branchlets scattered, very frequent, filform and capillary, publescent, erect, leasy; leaves three-cornered, obtuse, pressed close, smooth, with a very slendte groove underneath; flowers on very short peduncles, erect. This is distinguished by its white corolla, and awnless, projected, white anthreme.—Native of the Cape of Good Hope. See the second species.

Leaves in fours, or more.

56. Erics Tubifors : Tube-flowered Heath. Leaves subclinte ; corollas club fig-shaped ; antheræ and style ineluded; leaves linear, even, the upper ones clinite ; flowers terminating, solitary, sessile ; corollas purple, acuminate, pubesent, several times longer than the calix; the segments lanceolate; style scarcely projected,—Native of the Cape of Good Hope. See the second species.

57. Erica Curviflora; *Curve-flowered Heath*. Leaves smooth; corollas club fig-shaped; antheræ and style included.— Native of the Cape of Good Hope. See the second species.

58. Erica Coccinea. Calices hirsute; corollas club figshaped; antheræ subincluded; style included; flowers copious; corollas pubescent.—Native of the Cape of Good Hope. See the second species.

59. Erica Conspicua; Long-tubed Yellow Heath. Leaves smooth; corollas cylindric, curved, very long, hairy, with a revolute border; anthere subincluded; style standing out. It flowers from May to August.—Native of the Cape of Good Hope. See the second species.

60, Erice Cerinthoides; Honeynort flowered Hurth. Corollas club fig-shaped; stigma included, cruciate; branchet compound; leaves oblong, convex, even, grooved underneath ciliate, with spinules; flowers large, heaped on the side inte a sort of head, sessile, publecent; calix rough with whith hairs, as it were doubled; corolla bright blood-red, rough also with white hairs, having the mouth obscurely four-cleft It flowers most part of the year.—Native of the Cape o Good Hope. See the second species.

61, Erica Pastigiata. Corollas salver-shaped, in bundles style included. This is a small shrub with even branches streaked, in four rows; leaves linear, acuminate, three sided even, rugged about the edge, erect, the length of the inter nodes, but the upper ones longer; flowers erect, fastigiate terminating; calix similar to the leaves; corolla with a cylin drie patholas tube, a little longer than the leaves; borde

ERI

date; stamina shorter than the corolla; antheræ scarcely emarginate .- Native of the Cape of Good Hope. See the second species.

62. Erica Cubica. Calices four-cornered; corollas bellshaped, acute; style included; stem shrubby, determinately branched; leaves spreading, linear, acute, longer than the internodes, slightly incurved, on white petioles; flowers terminating, corymbed, on subtomentose peduncles, having bristle-shaped bractes in the middle; calix scariose, with the leaflets obcordate, complicate, keeled, bent in, and rude at the tip : corolla half four cleft, purple, with a pale base, twice as long as the calix; stigma obtuse .- Native of the Cape of Good Hope.

63. Erica Denticulata. Calices toothletted ; corollas ovate. funnel-shaped; style included; stem distorted as in common heath ; leaves crowded together, spreading a little, subcylindric, even; flowers in terminating bundles; calix doubled; tube of the corolla long, ovate; the segments ovate, obtuse, spreading; antheræ not longer than the corolla, almost included; stigma obtuse .- Native of the Cape of Good Hope. See the second species.

64. Erica Viscaria; Clammy-flowered Heath. Flowers in racemes; corollas bell-shaped, glutinous; style included; stem determinately branched; leaves linear, erect, acute, longer than the internodes, rugged at the edge; bractes calicine, rude, approximating ; calix rude, awl-shaped, half the length of the corolla, which is purplish, with the segments erect and acute; antheræ bifid, with a cavity on the outside, and very short; style shorter than the corolla, but twice as long as the stamina, purple ; stigma headed, four-lobed. It flowers in March, and is a native of the Cape of Good Hope. See the second species.

65. Erica Granulata. Calices subimbricate; corollas globular; style included; leaves linear, erect; flowers terminating, few, peduncled ; calix scariose, very short ; colour of the corollas red; antheræ rugged, bifid at the tip, as it were two-horned; stigma headed.-Native of the Cape of Good Hope. See the second species. 66. Erica Comosa ; Tufted flowered Heath.

Flowers heaped; corollas ovate-oblong; style included; branches heaped above the flowers; leaves linear, bluntish, erect; flowers heaped, lateral, below the top of the stalk; stigma headed .- Native of the Cape of Good Hope. See the second species.

67. Erica Sparmanni. Leaves imbricate, ciliate; heads four-flowered ; corollas tubular, strigose-hispid ; antheræ subincluded. This species is remarkable for having the flowering heads always divided into four flowers, before these are elongated the head appears globular and echinate, as in achyranthes, from the very spreading yellow bristles of the leaves of the involucre and calix ; corollas extremely hirsute. with a four-cleft mouth, the segments very short. Observed by Sparmann far inland from the Cape of Good Hope. See the second species.

68. Erica Concinna; Flesh-coloured Heath. Leaves in sixes or thereabouts, smooth ; flowers terminating, umbelled ; corollas cylindric, attenuated at the base; branches smooth; leaves on the branches in sixes, on the branchlets in fours, petioled, erect, acerose, four lines in length; petioles smooth, scarcely half a line long; flowers from three to six in an umbel; peduncles filiform, somewhat hairy, two lines in length; corolla flesh-coloured, somewhat villose on the outside, scarcely an inch long, the thickness of a fowl's quill; filamenta smooth, a little shorter than the tube of the corolla ; anthera oblong, acuminate at the base, two-parted at top, as shaped; style standing out; leaves in threes or fours, but on

flat, red above, white underneath, the four segments subcor- | far as the middle, where they are fixed to the filamenta, they are awnless, and of a brown colour; germen turbinate, concave above, crenulate on the edge; style red, the length of the stamina; stigma subcapitate, very dark red. It flowers in September and October .-- Native of the Cape of Good Hope. See the second species.

69. Erica Massoni ; Tall Downy Heath. Leaves in eight rows, imbricate, pubescent; flowers capitate; corollas cylindric, fig-shaped; stems shrubby, filiform, covered all round with leaves; leaves in fonrs, imbricate, in eight rows, very short, elliptic, crowded, obtuse, ciliate, so that they appear villose; flowers in a terminating sessile head .- Native of the Cape of Good Hope. See the second species.

**** Antheræ awnless, standing out : Leaves in threes.

70. Erica Plunkenetii; Smooth-twigged Pencil-flowered Heath. Calices simple; corollas cylindric; antheræ very long; style standing out; leaves linear, crowded; flowers peduncled, nodding; calix shorter by half than the corolla, awl-shaped, keeled; corolla long, with the mouth obscurely four cleft: stamina almost membranaceous, linear, obtuse, twice as long as the corolla .- Native of the Cape of Good Hope. See the second species.

71. Erica Petiveri; Downy-twigged Pencil-flowered Heath. Calices imbricate; corollas acute; antheræ very long ; style standing out. This is a brown shrub ; branches covered with branchlets in threes, crowded, very short, pubescent, clothed with squarrose leaves, which are also crowded, awl-shaped, subtrigonal, somewhat rugged at the edge, patulous, or standing out at the tip; flowers solitary at the end of the branchlets, drooping, on a short pubescent peduncle ; calix subcartilaginous, angular, imbricate, with similar but shorter bractes in threes; corolla cylindric, three times as long as the leaves, with a four-cleft, acute, yellow mouth. It flowers from January to March .- Native of the Cape of Good Hope. See the second species.

72. Erica Nudiflora. Branches tomentose; corollas cylindric, scattered : stem shrubby, determinately branched, round, twisted; bark covered with a white nap, chinky, deciduous; brauchlets very many, erect, leafy, many-flowered, very closely tomentose; flowers numerous, axillary, peduncled, nodding a little; peduncles the length of the leaves, capil-lary, pubescent; bractes none; corolla bell-cylindric, half the length of the peduncles, almost four times as long as the calix, smooth, four-cleft at the edge; segments small, blunt, upright; filamenta erect, parallel, capillary, smooth; stigma headed, blunt,-Native of the Cape of Good Hope. See the second species.

73. Erica Bruniades. Flowers scattered ; corollas covered by a woolly calix; style standing out; leaves linear, remote, patulous, with a few hairs scattered over them; the calices, clothed with a white wool, cover the whole subtruncate corolla .-- Native of the Cape of Good Hope. See the second species.

74. Erica Imbricata. Corollas bell-shaped, covered with the imbricate calix ; style standing out ; flowers lateral, white ; corolla covered with the white calix .- Native of the Cape of Good Hope. See the second species.

75. Erica Umbeilata. Leaves acerose; corollas bell-shaped; style standing out. This little shrub has the habit of common heath; leaves short, smooth, with a white line underneath; umbellets naked, without an involucre ; calix compound ; corolla pale blue, angular; anthera gibbous, tailed at the base, -Native of Portugal. See the twelfth species.

76. Erica Purpurascens. Flowers scattered; corollas bell-

the upper branchlets in fives, according to Seguier; calix | awl-shaped : corollas evlindric .- Native of the south of Europe. See the twelfth species.

ERI

77. Erica Vagans; Wandering Heath. Flowers solitary; corollas bell-shaped; style standing out; stem like that of empetrum, shrubby, somewhat rugged, the extreme branches whitish and divaricating; leaves in fours, seldom in fives, linear, bluntish, sometimes smoothish, sometimes a little rugged, beneath convex and channelled, shortish, crowded; flowers on the sides of the branchlets, scattered, peduncled; calix coloured, erect, concave, very short; corolla blunt; antheræ without any tail, two-parted; stigma simple. Native of Africa. See the twelfth species.

78. Erica Herbacea : Early-flowering Dwarf Heath. Flowers directed all one way; corollas oblong; style standing out. This is a small shrub, from a foot to eighteen inches in height, decumbent at bottom, then upright, branched, flexible: leaves almost covering the whole stem, deciduous, resembling those of the fir, thickish, having a prominent nerve, narrow, very sharp, smooth; flowers at the tops of the branchlets, on short peduncles, alternate, among the leaves. They come out in autumn, continue closed in winter, and are then green; in May, the year following, the flowers are unfolded; the antheræ which were inclosed are protruded; the calix and corolla opening are both changed into a pale purple or flesh-colour .- Native of Anstria, Switzerland, and Silesia. See the twelfth species.

79. Erica Multiflora; Many flowered Heath. Leaves in fives; flowers scattered; corollas cylindric; style standing out; stem the height of a man; leaves in fours or fives, spreading, obtuse, gibbous at the base ; flowers purplish. It flowers from June to November .- Native of the south of Europe.

80. Erica Didyina; Double-anthered Heath. Leaves in fives; peduncles scattered, longer than the flower; corollas bell-shaped; antheræ twin; style standing out; stems twisted, trailing; branches between scored and angular, light reddish brown, the more slender shoots ash-coloured, all lateral, to seven or more rising from the same point in the manner of an umbel; flowers roundish, on long slender peduncles from the sides of the branches, beginning from below the middle, and extending to the ends, continuing on, at least in the cultivated plants, till the next season ; corolla truly bell-shaped, pointed at the base, cloven near half way down; segments broad, soon coming to a bluntish point, spreading, generally of a pale flesh-colour, approaching to white, but sometimes with a deep tinge of purple ; filamenta capillary, somewhat flatted, white, as long as the corolla,-Found on heaths; as on Goonhilly-downs, going from Helston to the Lizard Point, in Cornwall. It flowers from June to August. See the first species.

81. Erica Mediterranea; Mediterranean Heath. Leaves spreading; flowers scattered; corollas ovate; style standing out; branches whitish, angular; leaves in fours, seldom in fives, even; flowers lateral; calix simple, coloured, lanceolate, acute, shorter by half than the corolla; style twice as long as the corolla; stigma entirely simple. It flowers from March till May .- Native of the south of Europe. See the twelfth species.

82. Erica Grandiflora; Great flowered Heath. Leaves in sixes, or thereabouts, acerose, smooth; flowers axillary, peduncled; corollas cylindric, subincurved, smooth; style elongated. It flowers from May to July .- Native of the Cape of Good Hope. See the second species.

83. Erica Tetragona. Leaves in threes; flowers in racemes, pointing all the same way; calix linear; corolla four- lanceolate-linear, hairy, viscid; peduncles one-flowered; root

cornered, oblong; style included; flowers yellow .- Native of the Cape of Good Hope. See the second species.

84. Erica Pyramidalis : Puramidal Heath. Antheræ awnless, included ; corollas funnel-shaped, in fours ; style a little protruded ; leaves in fours, pubescent .- Native of the Cape of Good Hope. See the second species.

Erigeron; a genus of the class Syngenesia, order Polygamia Superflua.-GENERIC CHARACTER. Calix: common. oblong, cylindric, imbricate; scales subulate, upright, gradually longer, nearly equal. Corolla: compound, raved; corollets hermaphrodite, tubular in the disk ; females ligulate in the ray; proper of the hermaphrodite funnel-form ; border five-cleft; of the female ligulate, linear, subulate, upright, commonly quite entire; stamina in the hermaphrodites; filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: in the hermaphrodites; germen very small, crowned with a down longer than its corollet; style filiform, length of the down; stigmas two, very slender. Pericarp: none; calix converging. Seeds: in the hermaphrodites oblong, small; down long, hairy; of the females extremely like the hermaphrodites. Receptacle: naked, flat. ESSENTIAL CHARAC-TER. Receptacle : naked. Down : hairy. Corolla : of the ray linear, and very narrow .---- The species are,

1. Erigeron Viscosum; Clammy Erigeron. Peduncles one-flowered, lateral; leaves lanceolate, toothletted in the middle, reflex at the base; calices squarrose; corollas radi-ate; stem upright, stiff, striated, hairy, viscid, branched from the very bottom; leaves stem-clasping, thick, rough with hairs, having glands between them, exuding a clammy juice, strong-scented, rounded, and stem-clasping; on the branches linear, entire; flowers single, on pretty long footstalks, some from the side, others from the end of the stalk; they are yellow, have an agreeable odour, and appear in July. -Native of the south of France, Italy, Sicily, Portugal, and Spain, by way-sides, and on the borders of vineyards. It is used to drive away fleas and gnats, the strong scent, as some suppose, being disagreeable to those insects; but it is probable they are caught by the clammy juice of the leaves and The old name of this plant is great sweet fleabane, or stalks. great fleawort. It is propagated by seeds, which, if sown in autumn, will more certainly succeed than those which are sown in the spring. When the plants come up, they should be thinned, if they are too close, and kept clean from weeds till autumn, when they should be transplanted where they are to remain. They delight in a dry soil and a sunuy exposure. The second year the plants will flower and perfect their seeds, but the roots will continue several years, and annually produce their flowers and seeds.

2. Erigeron Graveolens : Strong-smelling Erigeron. Leaves sublinear, quite entire; branches lateral, manyflowered; root annual; stcms upright, purplish, hairy, and viscid, from eight or ten to eighteen inches in height, striated, branched the whole length; branches patulous, at bottom longer, alternate, simple, crowded, all flowering; leaves sessile, narrow, lanceolate, quite entire, a little scabrous, with very small hairs, viscid, at the end scattered over them, strongsmelling, of a russet dusky colour; corolla vellow, small, with a minute upright ray of five or six florets, purplish undemeath. In gardens the stalks are stiff, and about three feet high ; the flowers are produced in close bunches, from the side of the stalk towards the tip: they appear in July, and in warm seasons the seeds ripen in England. It was formerly called small true fleabane .- It is a native of the south of France and Italy, and very common near Madrid.

3. Erigeron Glutinosum; Glutinous Erigeron. Leaves

perennial; stems a long span in height, slender; leaves quite entire, narrow and sharp, villose and glutinous; peduncles alternate, one-flowered, few in number ; semiflorets twenty and more in a flower, purple .- Native of the south of France and Spain, on mountains near the sea coast. It flowers in August.

4. Erigeron Siculum ; Red-stalked Erigeron. Lower calicine scales loose, longer than the flower ; peduncles leafy : annual: stems rcd; flowers without any ray, small; peduncles covered with linear, recurved, minute leaves .-- Found in Sicily, and about Montpellier, in marshes. It flowers in August and September.

5. Erigerou Carolinianum ; Carolina Erigeron. Stem panicled; flowers subsolitary, terminating; leaves linear, quite entire; stems three feet high and more, straight, round, streaked, the thickness of the little finger at bottom, where they are red, growing gradually more slender upwards; the leaves from top to bottom are frequent, very narrow, and somewhat hairy; towards the top the stem puts forth branches, forming in the whole a sort of pyramid, these are covered with leaves, like those of the stem, only shorter and narrower, each of these bears one small flower, sometimes more; the root-leaves are like those on the stem, only shorter and blunt. -It is a native of North America, and hardy enough to flower in the open ground, in July and August.

6. Erigeron Canadense : Canadian Erigeron. Flowers in panicles, hairy, rough; leaves lanceolate, ciliate; root annual; stem firm, hairy, sometimes three or four feet high, frequently crooked, much branched towards the top, and even from the middle; the branches gradually shorter, and forming a long cone; flowering-heads numerous, or simple, on branched slender peduncles; florets very small .-- It came originally from North America, but now has the appearance of being indigenous in many parts of Europe; it is not uncommon about London on cultivated grounds, and on rubbish. It flowers in August. Petivers calls it white golden rod. This, with the seventh, thirteenth, and fourteenth species, are preserved in botanic gardens for the sake of variety, but are seldom admitted into gardens for pleasure.

7. Erigeron Bonariense: Buck's horn Erigeron. Leaves rolled back at the base; root annual; stem angular, firm, hirsute, branched at top; leaves alternate, lanceolate, hirsute, and soft, sessile, the lower ones tooth-gashed, the upper entire, narrower, and almost linear, towards the base waved, the midrib more prominent and hirsute; flowers on the top of the stem, and at the extremities of the branches -- It flowers in July and August, and is a native of Buenos Ayres, in South America. It is an annual plant ; and, like the thirteenth species, when once admitted into a garden, and suffered to scatter its seed, will become a very troublesome weed, although it is very serviceable to cover rubbish or rock-work.

8. Erigeron Jamaicense; Jamaica Erigeron. Stem fewflowered, subvillosc; leaves wedge-form, lanceolate, with two serratures on each side; root almost single, but sometimes subdivided, descending; stems erect, or ascending, often a span high, filiform, pubescent, almost single; flowers subsolitary, terminating, peduncled, whitish; those on the top of the stem resemble groundsel flowers, composed of many small yellow florets set close together, encircled by many whitish, long, narrow semiflorets .- Native of Jamaica.

9. Erigeron Philadelphicum ; Spreading Erigeron. Stem many-flowered; leaves lanceolate, subservate, those on the stem half stem-clasping; floscules of the ray capillaceous, the length of the disk : perennial .- It flowers from June to August, and is a native of North America, where it was observed, as well as in Canada, by Kalm. 43.

10. Erigeron Purpureum; Purple Erigeron. Stemmanyflowered, hairy; leaves oblong, somewhat toothed, stemclasping; corollas of the ray capillaceous, longer than the disk; root perennial; stem herbaceous, branched, a foot or more in height; flowers panicled; corollets of the ray very numerous, purple, of the disk yellow .--- It flowers in July and August, and is a native of Hudson's Bay.

11. Erigeron Ægyptiacum; Egyptian Erigeron. Leaves half stem-clasping, spatulate, toothed; flowers globular; root annual; stem simple, upright, a foot and half high, somewhat streaked, ash-coloured, pubescent, and somewhat viscid; flowers panicled, terminating, four or five, peduncled, round ish, on purplish peduncles; corolla florets minute, those in the ray naked and abundant; style cloven, yellow, capillary, quickly disappearing .- Native of Sicily and Egypt.

12. Erigeron Gouani; Cluster-flowered Erigeron. Flowers heaped; calices scariose; leaves lanceolate, somewhat toothed, scabrous about the edge; root annual, bitter; stem upright, round, a foot high, simple, with a few upright hairs; flowers panicled; calix roundish, imbricate; scales lanceolate, naked, convex, close, scariose about the edge, bluntish, not patulous, with a subulate tip. It flowers in July and August .--- Native of the Canary Islands.

13. Erigeron Acre ; Blue Erigeron. Peduncles alternate. one-flowered ; root perennial, or, according to some, biennial. fibrous, acrid; stems from six to eighteen inches high, upright, somewhat angular, hairy, often purple, in some scarce branched at all, in other plants very much so. The upper part of the stem is divided into alternate branches, each bearing a single flower, which never expands, and is externally purple, but internally yellow, with a cavity in the middle .--It is often found in dry lofty pastures, especially in sandy and calcareous soils, and upon old walls. It has been found growing at the Block-house at Gravesend, and near Charlton wood, but is not often seen near London. It flowers from July to September. Cows and goats refuse to eat it, but the Germans take a decoction of it to attenuate viscid phlegm, English botanists have named it blue-flowered or nurnle flea bane, which name is also applied to several others of this genus, and tends very much to confound it with the genus Conyza, to which the intelligent reader is referred.

14. Erigeron Alpinum; Alpine Erigeron. This so strongly resembles the preceding species, that Haller suspects it to be only a variety. It has frequently a higher stem, but the height varies much in both; the flowers are larger, the semiflorets more numerous, the leaves longer, the feather dense and whitish .- Native of Alpine pastures. Found on Ben Lawers in Scotland. Perennial; flowering in July and August. It may be propagated by seeds, in a shady situation and moist soil. See the first species.

15. Erigeron Uniflorum; Dwarf Erigeron. Stem oneflowered ; calix hairy ; root perennial ; stems a finger's length ; leaves few, lanceolate, almost smooth on the upper surface, but with spreading hairs scattered over the lower; the stemleaves often sublinear, the root-leaves oblong. The flower is as large as in the foregoing species, thick ; the scales covered with a white nap, lanceolate, broader; all the semiflorets ligulate, with no imperfect ones, sometimes purple; all the varieties with one and many flowers, with a smooth and hairy calix, with blue and white flowers .- It flowers in August and September, and is a native of the European mountains, from Lapland to Italy.

16. Erigeron Gramineum; Grass-leaved Erigeron. Stem one-flowered ; leaves linear, ciliate, scabrous. This is a small perennial plant, guarded with fading dry leaves .--- Native of Siberia.

6 P

17. Erigeron Camphoratum. Leaves lanceolate-ovate, villose; serratures cartilaginous at the tip.—This plant is annual, and a native of Virginia.

ERI

18. Erigeron Japonicum. Leaves sessile, obovate, serrate, villose; flowers panicled. Annual: stem simple, filform, hairy, upright, a foot high; leaves attennated to the petioles, half stem-clasping, obtuse, upright, an inch in length; flowers terminating; feather simple, ferroginous.—Native of Japan, where it flowers in June.

10. Erigeron Scandens; Climbing Erigeron. Leaves ovate, scrate, villose; dowers axillary; stem climbing; stem filform, branched, purplish, smooth; leaves from each bud three or four; subsessile, skarp, with selaceous teeth, villose on both sides, half an inch in length; flowers among the leaves, axillary, solitary.—Native of the Cape of Good Hope.

20. Erigeron Tuberosun; Tuberons-routed Erigeron. Leaves linear; branches one-flowered; stem suffruticose; root perennial, bitten; stem short, woody; branches simple, one-flowered; flowers yellow, terminating, sessile; feather gray.—Native of the south of France, and Svria.

21. Erigeron Foetidum; Stinking Erigeron. Leaves lanceolate-linear, retuse; flowers corymbed; root perennial, thick, fibrous, from which arise several upright hairy stalks, near four feet high, putting out several side-branches; the stem is terminated by several large corymbs of goldencoloured flowers, which appear late in the autumn, continue in beauty during great part of the winter, fade in the spring, and are sometimes succeeded by oval seeds, which ripen in England: the stems generally decay the second year, and are then supplied by new ones from the same root ; the old ones, with their green hairy leaves, remaining in vigour until the young ones are grown to a considerable height. It has been long cultivated in the gardens of curious Europeans. It is too tender to thrive in the open air in this country, so the nlants should be kept in pots ; and if in the winter they are placed in a common frame, where they may have a large share of free air in mild weather, and screened from hard frosts, they will thrive better than with tender treatment. It is easily propagated by cuttings, which, if placed in May, will readily put out roots, and the young plants will flower the autumn following.

22. Erigeron Ohliquum; Oblique-laured Erigeron. Very much branched; leaves ovate, oblique. Annual: stem berbaccous, a hand high, round, ereet, hairy, braaching very much; branches from all the axils, the lower ones gradually longer, diffused at top, dictonomos, opposite; flowers solitary, the length of the peduacle, one-flowered, copious; calix cylindric, pubescent, with numerous, equal, subalate, approximating leaflets; corollas yellow; stigmas of the disk erect, of the ray patholos.—Naitve of the fast Indies.

23. Briggron Tricuncatum; Wedge-kaued Eriggron. Somewhat shrubby: leaves wedged, three-lobed. A small shrub, very much branched or panieled, leafy: flowers terminating, sessile, several heaped together, the length of the leaf; calix the size of a lentil-seed..-Native of Mexico.

24. Erigerum Pinnatum. Leaves pinnatifid, toothed; stem herbaceous, upright, a foot bigh, somewhat hispid, simple; flowers terminating, subglomerate, yellow; feather white. —Native of the Cape of Good Hope.

25. Erigeron Sumatrense. Tomentose: flowers racemepanicled; leaves lanceolate, subserrate; stem three feet bigh and more, round, streaked, tomentose, red; peduncles long, raceme-panicled, with one or two narrow lanceolate leaves on them, generally entire. - Native of Somatra.

26. Erigeron Sericeum; Silky-leaved Erigeron. Flowers panicled; leaves ovate-lanceolate, tomentose, silky, entire,

and serrate, appendicled at the base; stem upright, simple; tomentose; panicle diffused .-- Native of Java.

27. Erigeron Hirsutun. Stem hispid; leaves linearlanceolate, subserrate, very hairy on boih sides; stems herbaceous, two feet high, erect, round; flowers few, in a terminating erect paniele; florets in the disk yellow, in the ray stift, quite entire, blue, maw.--Native of China near Canton.

28. Erigeron Rivulare. Leaves wedge-shaped, acute, rough with hairs, toothed on both sides at the tip, ciliate on the edge, those on the stem sessile; stem almost simple, erect, few-flowered. Annual; native of Jamaica and Elispaniola.

22. Erigeron Decurrens. Leaves decurrent, linear, tonemiose; flowers panicled; stem crect, striatel, pubescent, tomentose at top; branches woody; pedicels capillary, with a pair of minute leaflest towards he tip; calitece sullose; scales bristle-shaped, shorter than the down; corollas of the ray maked.—Native of Arabia.

30. Erigeron Iucanum. Leaves linear, tomentose, toohed a little; flowers corymbol; stem shrubby. This is a shrub with tomeutose branches; corymbs terminating, nany-flower-ci; caix subvillose; with linear leaflets; corollets of the ray makel; down ferruginous, longer than the calix.—Native of Arabia Felix.

Eringo. See Eryngium.

Erian; a genus of the class Didynamia, order Angiospermia. – GR-REINC CHARACTER. Colirs perianth free-leaved; leaves hanceolate, upright, nearly equal, permaneta. Corolles, one-petalled, unequal; tude o vate-cylindric, length of the calix, bent back; border flat, five-parted; divisions equal, obcordate. Simmias: filamenta foru, very short, within the tube of the corolla, of which the two opposite ones are a little longer. Amthere small. Pitkit? germe somewhat ovate; style very short; stigma headed. Pericorp; capaule ovate, rolled up in the calix, two-celled, agoing two ways. Seeds: numerous, small. ESSENTIAL CHARACTER. Calits: five-leaved. Corolls: border five-celf, equal, with the lobes emarginate, upper lip very short, reflex. Capsule: two-celled. — The species are.

1. Erinus Aloinus : Alnine Erinus, Flowers racemed : leaves spatulate : root perennial : the root-leaves form a thick tuft close to the ground, they are all linear, spatulate, pubescent, with a few serratures at the end on both sides; stems many, very simple, a hand high, round, pubescent, upright, the side ones barren and decumbent; flowers alternate, separated by leaves like those on the stem, but smaller, and forming an upright simple raceme : corolla funnel-shaped : the leaves are about half an inch long, and one-eighth of an inch broad, of a dark green ; the flower-stalk is scarcely two inches high; the flowers are in a loose raceme, and purple; they appear in May, or earlier, and sometimes are succeeded by ripe seeds in July. This is a desirable little plant for the decoration of rock-work, growing in close tufts, and producing its numerous lively purple flowers during most of the summer months .- Native of Germany, of the Swiss Alps, of the Pyrenees, and the south of France. This is propagated by parting the roots in autumn.

2. Erinus Africanus. Flowers lateral, sessile; leaves lanceolate, somewhat toothed; stem herbaceous, branched, a span long, declined; flowers solitary, in the axils of the leaves, purple, slender,—Native of Africa. It must be kept in the dry-stove.

3. Erinus Capensis, Flowers splitcd; leaves linear, toothed; perennial; stem erect, round, pubescent, two feet high; splike terminating, oblong, imbricate, with broader, ovate-lanceolate, toothed bractes; corolla yellow, smelling very sweet; tube filform, three times as long as the calix; style filform, the

length of the tube .-- Native of the Cape of Good Hope. It | manent. Corolla : universal, uniform, convex : proper threerequires the protection of the dry-stove.

4. Erinus Fragrans. Leaves lanceolate, oblong, toothed ; divisions of the border entire; stem simple; corollas tomentose on the outside, of a dark colour, fragrant at night .- Native of the Cape of Good Hope. It must be placed in a glasscase, or in the dry-stove.

5. Erinus Peruvianus. Leaves lanceolate-ovate, serrate .--Native of Peru; said also to be found at the Cape of Good Hone. It must be placed in the dry-stove, or in a glass-case.

6, Erinus Maritimus. Leaves lanceolate, quite entire, smooth ; divisions of the border cloven half way .--- Native of the Cane of Good Hope.

7. Erinus Tristis. Leaves oblong, gashed, toothed; divisions of the border emarginate. The flowers are sweet, but of a dull colour .- Native of the Cape of Good Hope.

8. Erinus Laciniatus. Leaves laciniate. See Buchnera Americana, and Verbena Anbletia. This, together with the ninth, tenth, eleventh, twelfth, and thirteenth species, must be placed in the bark-stove. The eleventh, being a shrubby plant, will continue several years, but the others are annual. They are propagated by seeds sown in pots filled with light earth, and plunged into a moderate hot-bed, where sometimes they will come up in five or six weeks; but they frequently do not vegetate till the following spring, especially when the seeds have been kept long. When the plants are fit to remove, they should be each planted in a separate small pot filled with light earth, not too rich with dung, and then plunged into the bark-pit. When they have taken new root, treat them as other plants from the same countries, by admitting proper air when the weather is warm, and frequently refreshing them with water ; with this management, the annual sorts will flower in July and August, and often ripen their seeds in autumn, if brought forward early in the spring.

9. Erinus Tomentosus. Tomentose: stems procumbent; flowers sessile, axillary; stems trailing, about six inches long. At the joints, just above the leaves, come out the flowers. sitting very close to the stems; they are white, and are succeeded by round capsules. At a distance, this plant bears a great resemblance to sea cudweed .-- Native of Vera Cruz in New Spain. See the preceding species.

10. Erinus Americanus. Stem erect ; leaves lanceolate. opposite; flowers loosely spiked, terminating; stem upright, two feet high towards the top, two smaller branches opposite and erect; these and the middle stalk are terminated by loose spikes of purple flowers .--- Native of Vera Cruz. See the eighth species.

11. Erinus Frutescens. Stem upright, shrubby; leaves ovate-lanceolate, serrate, alternate; flowers axillary; flowers single, or two and three at a joint, sessile, white, succeeded by round capsules. The shrubby sort must also frequently be refreshed with water in winter, but not in large quantities, nor in very cold weather. The plants will flower and perfect their seeds in the second year.

12. Erinus Verticillatus. Stem branching, trailing : leaves ovate, serrate, smooth, opposite; flowers in whorls; flowers sessile, white, making but little appearance, and succeeded by round capsules.-Native of Vera Cruz. See the eighth species.

13. Erinns Procumbens. Stems procumbent; leaves ovate, smooth ; flowers solitary, axillary ; peduncles longer ; flowers bright yellow, on long slender peduncles, succeeded by oval capsules .- Native of Hispaniola.

Eriocaulon ; a genus of the class Triandria, order Trigyuia .- GENERIC CHARACTER. Calix: perianth common,

petalled : petals equal, lanceolate, obtuse, villose at the tip, attenuated at the base, and connected into a style-shaped pedicel, which is hairy. Stamina: filamenta three, capillary, sitting on the germen; antheræ oblong, versatile, Pistil; germen slender, superior under the stamina; styles three, capillary, very short; stigmas simple. Pericarp: none; calix unchanged. Seeds: solitary, crowned with the corolla. Receptacle: chaffs of the size and figure of the calicine seales, one-flowered. ESSENTIAL CHARACTER. Calix: common, an imbricate head. Petals: three, equal. Stamina : upon --- The species are, the germen .----

ERI

1. Eriocaulon Triangulare. Culm triangular ; leaves ensiform ; heads ovate .- Native of Brazil.

2. Eriocaulon Quinquangulare. Culm quinquangular; leaves ensiform .- Native of the East Indies.

3. Eriocaulon Sexangulare. Culm hexangular; leaves ensiform. The leaflets surrounding the head, instead of an universal calix .- Native of the East Indies.

4. Eriocaulon Sctaceum. Culm hexangular : leaves setaceous. This is a small annual herb, tufted, and bent back in a ring; heads terminating, small, oblong, subacute; flowers aggregate, male and female in the same common, globular, chaffy receptacle; calix none. The male flowers have three petals to the corolla, somewhat hirsute on the outside, and six stamina; the females have six petals, and resemble the males; they have a roundish three cornered germen, and three styles. The roots are dispersed in the water .- Native of the East Indies, and of Cochin-china.

5. Eriocaulon Decangulare. Culm decangular ; leaves ensiform; flowers in a head; males in the disk, and females in the circumference .- Native of the swamps of North America.

6. Eriocaulon Quadrangulare. Culm quadrangular ; leaves ensiform; head of flowers globular, truncate at the base. This is an annual herb, with an upright, naked, fourcornered culm, eight inches high; head of flowers whitish. flattish at the base, with roundish scales, attenuated at bottom, one-flowered, closed ; petals two, subconcave, blunt at the tip, toothed ; seeds three, ovate,-Common in every part of Cochin-china.

Eriocephalus; a genus of the class Syngenesia, order Polygamia Necessaria.-GENERIC CHARACTER. Calix: common, upright; scales ten, ovate, equal, converging, of which the five exterior are kceled, the interior flat. Corolla: compound, rayed ; corollules hermaphrodite, twice as many in the disk; females five in the ray; proper of the hermaphrodite funnel-form ; border five-cleft, patulous. Of the ray ligulate, obcordate, with three-lobed equal tips. Stamina : in the hermaphrodites ; filamenta five, capillary, very short ; antheræ cylindric, tubular. Pistil : in the hermaphrodites ; germen very small, naked; style simple; stigma two-cleft, sharp. In the females, germen ovate, naked; style simple; stigma acuminate, inflex. Pericarp : nonc; calix scarcely changed; seed to the hermaphrodites none; females solitary, obovate, naked. Receptacle: naked, flat, or else a down of the calix in a double row is interspersed both between the hermaphrodite and female floscules. Observe. A compressed corpuscle adheres to the base of each calicine scale. Essen-TIAL CHARACTER. Receptacle: subvillose. Down: none. Calix : ten-leaved, equal. In the ray five floscules .---- The species are.

1. Eriocephalus Africanus; Cluster-leaved Eriocephalus. Leaves entire and divided ; flowers corymbed. This plant has a shrubby stalk, from four to six feet high, putting out many side-branches the whole length. The leaves are globose, depressed, imbricate; scales lanceolate, equal, per- woolly, coming out in clusters, some taper and entire, others divided into three or five parts, which spread open like a hand; when bruised, they emit a strong smell, approaching to that of lavender cotton, but not quite so rank. The flowers are produced in small clusters at the ends of the branches, and stand erect. They appear in autumn, but do not produce seeds in this country. It flowers from January to March, and is a native of the Cape of Good Hope. This plant is propagated by cuttings, which may be planted any time from May to the middle of August, for if they be planted later in the season, there will not be sufficient time for them to get good root before the winter: these cuttings should be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun till they have taken root : they must also be refreshed with water twice or thrice a week, but they should not have too much at each time, for much moisture is very hurtful to these plants. As soon as the cuttings have taken root, they should be gradually inured to the open air, to prevent their shoots from being drawn up weak : afterwards they should be removed into the open air, and placed in a sheltered situation, where they may remain till October, when they must be placed in an airy glass-case, that they may have as much sun as possible, and enjoy the free air in mild weather, but be at the same time secured from frost and damp air, either of which will soon destroy them. During the winter, they must be sparingly watered, for the reason before given; but in the summer, when the plants are placed in the open air, they will require frequent refreshment with water in hot weather. Both this and the next species retain their leaves all the year, and are therefore a valuable addition to the variety of exotics in the winter season.

2. Eriocephalus Racemosus; Siltery-leared Eriocephalus, Leaves linear, undivided; flowers racemed. It has the stature and appearance of the preceding species, but all the leaves are undivided; flowers on pedicels shorter than the calks; outer scales of the calks four, orace, subtomentose, with a very soft wool from the bosom of them.—Native of the Cape of Good Hope.

Eriophorum; a genus of the class Triandria, order Monogynia .- GENERIC CHARACTER. Calix : spikes on all sides imbricate; scales ovate-oblong, flat, inflected, membranaceons, loose, sharp-pointed, separating the flowers. Corolla: none. Stamina : filamenta three, capillary : antheræ upright, oblong. Pistil : germen very small ; style filiform, length of the calicine scales; stigmas three, longer than the style, bent backwards. Pericarp: noue. Seed : three-sided, acuminate, furnished with villose hairs, longer than the spike. Observe. Some species are polygamous. ESSENTIAL CHA-RACTER. Glumes chaffy, imbricate every way. Corolla: none. Seed ; one, surrounded with a very long wool. This genus consists of bog plants, and are seldom preserved in gardens. They may, however, be planted in pots filled with bog earth, set in pans wherein water is constantly kept ; or by the side of ponds, or other waters. The species are, I. Eriophorum Vaginatum; Mountain or Single-spiked

1. Eriophorum Vaginatum; Mountain or Single-spiked Catton Grass. Clams sheathed, round; spike scariose; root-leaves obscarely three-cornered, sharp, streaked on two sides; convex on one side, flat on two sides; scape twice as long as the leaves, flattish on one side, streaked; stem-leaves awa-leas, sheathing; sheath swelling a little; the uppermost pupel at the base. Ray calls this plant hare's *icid* rusd, and in Westmoreland it is named *moss-crops*, which is also applied to the third species, as they do not distinguish between them. Sheep are very foul of both, from which they derive this common name—Native of bogs in cold barren situations, in various parts of Europe. It is not very general in England,

but is found on Shirley common near Croydon, near Lynn, on Birmingham heath, and is often met with in all the northern counties, upon Elsemere meers in Shropshire, and on Pillin moss in Lancashire.

ERI

2. Eriophorum Polystachion; Many-spiked Cotton Grass. Culms columnar; leaves flat; spikes peduncled.—Native of the Cape of Good Hope.

3. Eriophorum Angustifolium : Narrow-leaved Catton Grass. Culms columnar; leaves channelled, three-sided. spiked, peduncled ; stem from nine inches to a foot or more in height, upright, smooth, with two joints projecting a little, covered throughout its whole length with the sheaths of the leaves. Those next the root are of a chestnut colour, short, lanceolate, streaked, marked with transverse lines, which give them a reticulated appearance; floral-leaves three or four, of unequal lengths, forming sheaths at bottom, terminate the stalk. from the axils of which, the spikelets proceed, In Germany, and the more northern parts of Europe, the down of this plant has been mauufactured into various articles of dress, paper, and wicks for candles. In some parts of Sweden, the peasants stuff their pillows with it, whence it is called poor man's pillow. It becomes brittle when quite dry. Early in the spring, cattle crop the leaves before the grasses are sufficiently grown. It is common on moors and boggy ground ; insomuch that they are often white all over with it. in June aud July, when it is in seed .- It flowers in April and May

4. Eriophorum Virginicum. Culms leafy, columnar; leaves flat; spikes upright, compact, leafy, large, brown, or goldcoloured.—Native of Virginia.

5. Eriophorum Cyperinum. Culms columnar, leafy; panicle superdecompound, proliferous; spicules mostly in threes.—Native of North America.

6. Eriophorum Alpinum, Culms naked, three cornered; pikke shorter than the down; thick tufts of culms and leaves rise from the root; spikelets erect, having no sheaths: the least of all the species, swelling only one or two lines iu length, pale, yellowish brown, with white hairs much longer than the spikelet, which is made up of lanceolate, acaminate, imbricate glumes, the lowest longer and broader than the spikelet, which is made up of lanceolate, additional spikelet, spikelet, spikelet, and is catended into a point; seed very small, yellowish—Native of the mountains of Laphand, Sweiten, Demark, Slesia, Carniola, Switzerland. It flowers in June and July—It was found in a moss, about three niles east of Forfar, Angueshire, Scotland.

Erithalis; a genus of the class Pentandria, order Monogymin-GENERIC CHARACER. Collis: perianth one leafed, superior, pitcher-form, five-toothed, permanent. Corolla: conceptalled, five-partel; tube very short; divisions lanceshaped, long, bent back. Stamina: filamenta five, subaltet, patulous, scarcely the length of the corolla; a nithere oblong, linear, erect. Pistli: germen inferior, roundisi; stigma sharp. Pericarp: berry globose, crowned, tencelled. Seed: small. Esservita.CURACTER. Corolla: five-parted, with the divisions bent back. Calix: pitchers haped. Berry: tencelled, inferior.— The species are,

1. Erithalis Truticosa. Leaves opposite; corymbs compound. This is an upright elegant branching tree, fifteen leet in height; racemes compound, corymbed, axillary, opposite; flowers numerous, caducous, will white petals, mostly six-stamined, with a six-cleft calix and corolla, smelling exactly like the common syringa—Native of Jamaica and Martinico. Jacquin describes another plant, which is a native of Curaçao, and probably only a variety of this species, anising from its growing in the clefts of rocks, where there is in the result.

ERI

516

no earth. It is a shrub two feet high, with procumbent diffused branches; the leaves are thicker, and numerous; the berry and flowers smaller; the former entirely void of scent, the latter whitish, or very seldom purple.

2. Erithalis Polygama. Leaves obovate ; flowers axillary, males cymed; hermaphrodites solitary.—Native of the Society Isles. It has a variety with narrower leaves.

Ernodra ; a genus of the class Tetrandria, order Monogyna.—GENERIC CHARACTER. Caliz: perianth four-parted, small, superior; segments erect, acute, equal, permanet. Corolla: one-petialled, salver-shaped; tube four-cornered, elongated; border four-parted; segments lanceolate, revolue. Stamins: fikamenta four, inserted in the nuddle of the tabe, awishaped, longer than the corolla; anthera erect, sequinate. Pisitl: germen four-cornered, inferior; style filform, longer than the stamina; stigma obtuse, emarginate. Pericarp: berry roundish, crowned by the calix, twogrooved, two-celled. Szeds: solitary, hemispherical, striated, one-petalled, salver-shaped; berry two-celled. Szeds: solitary.—The only species hitterto discovered is.

1. Ernodea Littoralis. Branches four-cornered, wandlike, jointed, ash-coloured, leafless; branches alternate, two inches long; leaves on the branchlets opposite, sessile, an inch and a half long, hanceolate, attenuated to both ends, verinless, obscurely three-nerved or five nerved, very smooth on both surrounding the branch, truncate, ciliate; flowers axillary, opposite, sessile. It varies with broader and narrower leaves. Browne has named this plant knazia, probably from Knox, who resided namy years in the island of Ceylon, and publish ed an account of it.— Native of Januare, frequently found near the shore in the parish of St. George, running three of four fect or more along the royand.

Erodium ; a genus of the class Monadelphia, order Pentandria .- GENERIC CHARACTER, Calix ; perianth five-leaved ; leaflets ovate, acute, concave, permanent. Corolla: petals five, obcordate or ovate, spreading larger; nectary five scales, alternate, with the filamenta and milliferous glands placed at the base of the stamina. Stamina: filamenta five, awl-shaped, connected at the base with the scales into the shape of a pitcher, but spreading at top, shorter than the corolla; antheræ oblong, versatile. Pistil: germen five-cornered, beaked; style awl-shaped, longer than the stamina, permanent; stigmas five, reflex. Pericarp: capsule five-grained, beaked, the cells opening inwards, each having a long tail fixed to it, which becomes spiral, and is hairy or bearded on the inside. Seeds: solitary, (seldom two together.) ovateoblong. ESSENTIAL CHARACTER. Calix: five-leaved. Corolla : five-petalled. Nectary : five scales, alternate, with the filamenta and glands at the base of the stamina. Fruit : five-grained, with a spiral beak, bearded on the inside,-For the propagation and culture of this genus, see Geranium.---The species are,

* Leaves compound, or pinnatifid.

 Erodium Absynthoides; Wormwood-leaved Crane's-bill, Caulescent: peduncles four-flowered, or thereabouts; leaves interruptedly bipinnate laciniate; seguents linear.—Found in Armenia by Tournefort, and on Mount Olympus by Dr. Sibthorp.

 Erodium Chrysanthemum; Golden flowered Crane's-bill. Almost stemless; peduncles four flowered; leaves decompoundedly pinnate lacinate, silky. This species is very distinguishable by its yellow flowers.—Found on Mount Parnasus,

3. Erodium Trichomanifolium; Meidenhair-leared Urane's bill. Stemless: scapes leadless, four-flowered; leaves bipinnatifid, hirsute. This differs from the preceding species, in having the flowers fields-coloured, marked with lines; the leaves smaller, and less cut; the scapes leafless and radical. -It was discovered by Billardiere on Mount Libanus.

4. Erodium Pulverulentum : Hoary-teared Creare's-bill. Caulescent : peduncles many-flowered : leaves decompoundedly lacinaite, mealy hoary. The whole of this plant is covered with frequent, short, villose hairs, whence it has the appearance of being dusty.—Found in the kingdom of Tunis in Africa.

5. Erodium Crassifolium; Upright Crane's-bill. Umbels many-flowered; leaves pinnatifid, laciniate, thick; segments linear.—Native of the island of Cyprus. It flowers in April and May.

6. Eradium Fætidum; Stinking Crane's-bill. Almost stemless : seapes radical, many-flowered; Laves interruptedly bipinnatifid; petals roundish. All the leaves are heaped about the root, they are heary with hairs, the whole forming a triangle; calices large, striated, very hirstie ; leaflets blunt, membranaceous at the edge, ending in a short awn; corolla large, blue, purple, or red. Lobel reports this plant to be insufferably feitid; others say, it is singular in having a very strong nauseous smell; and Gouan asserts, that its smell is strong, but neither nauseous uor musky.—Native of the country about Montpellier.

 Érodium Macredemum. Subcaulescent: scapes radical, uany-flowered; leaves interruptedly bipinnatifid; petals ovate. The herb of this plant exactly corresponds with that of the preceding species.—Native of Spain.

8. Érodium Supracanım; Silky-leaved Crane's-bill. Almost stenless: scapes radical, two-flowered or thereabouts; leaves interruptedly bipinnatifid, thickish, silky hoary on the upper surface.—Found in Montserrat and Catalonia.

 Erodium Petroselinum; Parsley-leaved Crane's-bill. Peduncles two-flowered; leaves pinnate; leaflets pinnatifid; segments linear.—It is found upon the sandy coasts of Barbary.

10. Evolum Alpinum; Alpine Crané-sbill. Pednacles many-flowered; leaves interruptedly pinnatifid, laciniate; root perennial, running very deep into the ground; lower leaves smooth, and on very long footstalks; siem a foot and a half high, with leaves of the same form, but smaller, and opposite; flowers purple, many together, on very long peduacles.—Native of Italy. It flowers with us in June, but will not ripen its seed in England.

11. Erodium Romanum; *Homan Cremésbill*. Stemless: scapes radical, many-flowered; leaves pinnate; leadels pinnatifid. It has a rather thick tuberous root; stems irregular, branching, diffused, somewhat woody, and having swelling joins, at each of these is one leaf, opposite to which comes out the peduncle; the peduncles on the lower part of the stem are very long and naked, but those which terminate the branches are shorter, and lave one or two small leaves at theses; the flowers are in small bunches, and continue in succession most parts of the summer.—Native of Italy, where it is found about Rome; also of the Pyrenees and of Provence.

12. Erodium Cicutarium; Heimkok-kaerd Creaz-sbill, Peduncles many-flowered; leaves pinuate; leadets sessile, pinuatifid; root annual; stem several, thickish, round, hirsute, procumbent, and branched; pinuas of the leaves slightly hairy pinuales sharply indented; flowers in an unbel, from three to six, of a rose-colont. This species varies extremely, from nearly smooth to very hairy, and from very large and branched; with a many-flowerd unbel, to small 6.0 and nearly simple, with few flowers. The common sort is found all over Europe, in Africa, Asia, North America, and the island of Madeira. Dilleuius mentions another remarkable variety, in which the petals are irregular, the two upper shorter, rounder, and marked with a greenish spot at the base. This has been found in England, near Hackney, and in several parts of Suffolk.

ERO

13. Erodium Moschatum ; Musk Crant's-bill. Peduncles many-flowered [leaves pinate: leaflets shupefielded, unequally gashed. This strongly resembles the preceding, but has an ambroxial or musky scent; the whole plant is covered with hairs, which are glutinous, particularly those of the calix. All the parts are larger; the stem is swollen, and crooked at the joint; corollar ed or purple. Annual.—Native of France, Switzerland, the Cape of Good Hope, Syria, Barbary, Peru, and Great Britian, where it is found about Battersea, Streathem, Ace. near London, near Bristol, Stourbridge, and in Westmoreland and Yorkshire.

14. Erodium Tordylioides. Peduncles many-flowered; leaves bipinnatifid, unequally serrate, the outmost lobes confluent.—Found on the rocks near Algiers.

15. Erodium Gruinum; *Strad-Leared Annual Cranet-bill*. Peduncles many-flowered; leaves ternate, crenate-toolhed, the outmost pinnatifid-lobed. This is an annual plant, with very broad leaves, cut on their sides regularly and erenate; flowers on long axillary peduncles; petals entire, and blue; beaks of the fruit remarkably large—Native of Spain, Sicily, Candia, Cyprus, and Syria.

16, Erodham Ciconum; Long-beaked Crane's-bill. This is also an annual plant, which has several prostrate stems, nearly a foot long; peduncles axillary, three inches long; flowers palle blue; beaks of the fruit very long, but by no means so long as those of the preceding.—Native of the south of Europe, Barbary, Syria, Cyprus, and Madeira. There is a variety, the whole plant of which is rough with hairs. It is a native of the sandy coasts of Spain, Portugal, and Italy.

17. Erodium Lacerum. Peduncles many-flowered; leaves doubly pinnatifid; segments very remote, linear, quite entire; stem grooved, branched, more than a foot high; leaves opposite, longer than the petioles, divided almost to the petiole into three pinnated segments; the pinnules linear, with a point; corolla very pak-blue colour, with equal petals.—Native of Portugal.

16. Erodům Dipbyllum. Peduncks many-flowered ; involucers tvo-laved, roundish ; lower leaves three-lobed, upper pinnatifid, laciuiate, gashed. The involucre is composed of two opposite, membranaceous, largish bractes, that are very conspicuous, and give it the significant trivial name. It is annual, and a native of Portugal, Gibraltar, Algiers, Tunis, Candia, and Cyprus.

19. Erodium Muticum. Peduncles many-flowered; leaves ternatifid, gashed, toothed; calices awnless.—Found in the kingdom of Tunis in Africa.

20. Erodium Hymenoides. Peduncles many-flowered; leaves ternate, or ternatifid; segments roundish, lobed. The stem is scaly at the base, with membranaceous stipules, larger thau in any other species.—Found by Des Fontaines on the rocks of Barbary.

21. Erodium Incatinutum; *Plash coloured Crame'sbill*. Peduncles few-flowered; leaves three-parted, or ternate, trifid, rugged; stem somewhat shrubby, slender, smooth, and hard. The leaves are on very long petioles, heartshaped, roundish, undivided, small; stipules kancedate, very sharp; flowers red, fesh-coloured, or scarlet, with a paler dias.--Nature ot the Cape of Good Hope.

** Leaves lobed, or undivided.

22. Erodium Malacoides; Mallow-leared Cranel-shill, Peduncles may-flowcred; leaves heart-shaped, three-lobed; lobes lobed, obtuse, obsoletely toothed. This is an annual plant, with the lower leaves heart-shaped, and three-lobed; branches inclining to the ground, and spreading a foot and a half each way. The peduncels are placed on the side of these, and sustain many bright red flowers. The fruits have long beaks—Native of the south of Europe, Madeira, Barbary, Syria, the islands of the Archipelago, and of Peru, There is a variety of this species, called the warious-leaved crane's-bill, which is a native of the isle of Chio in the Mediterranean.

23. Erodium Populifolium. Peduncles many-flowered; leaves heart-shaped, sublobed, obtuse, toothed; stamina hirsute.—Found in Barbary.

24. Erodium Nervulosum. Peduncles many-flowered; leaves heart-shaped, almost undivided, toothed, thick, nerved, -Native of Sicily.

25. Erodium Glaucophyllum; Glaucous Cranet-sbill. Peduncies many-flowered; leaves oblong, obsoletely crenate, glaucous; beaks feathered. Annual: stem extremely simple, very short; peduncles from three to five:flowered; corolla purple or pale blue, with a dark trifid line at the base. It is easily known by the gray or glaucous colour of the leaves, and the very long feathered beaks to the fruit.—Native of Equypt.

26. Erodium Guttatum. Peduncles three-flowered; leaves heart-shaped, obsoletely lobed, tooth-serrate, ash-coloured, the centre of a different colour. The flowers are violetcoloured, with a very dark violet disk, and are extremely sweet-scented.—Found by Shaw and Des Fontaines in Barbary.

27. Erodium Maritinum; Sea Crame's-bill. Pedunelics: three-flowered, or thereaboutts: leaves heart-shaped, gashedcreuate, rugged; stems depressed, branched, lying close to the ground; root-leaves on long petioles, spreading in a circle on the ground, hairy, variously cut and jagged, sometimes nearly lobed; stem-leaves similar; peduneles, shorter than the leaves; flowers one to three, pale red, small; beaks of the fruit very small, not exceeding half an inch in length,...Native of the English and Dutch coasts. Found in Norfolk and Cornwall, and also on the sandy commons in Worcestershire;

28. Erodium Chamedryoides; Dwarf Crane's bill. Amost stemless: peduncles one-flowered; leaves heart-shaped, obtuse, crenate; leaves radical, on very long petioles, namerous, orbicolate, heart-shaped, shining, much shorter than the petioles; scapes a little longer than the petioles, with opposite bractes; petals white, quite entire, oblong, with viloge claws, between which are green fleshy obcordate glands.— Native of the islands of Minorea and Corsica.

Eroteum ; a genus of the class Polyandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth five-leaved : leaflets ovate, concave, incumbent, permanent. Corolla: petals five, ovate, roundish, concave, entire, spreading, Stamina: filamenta numerous, (thirty,) shorter than the petals, erect, filiform, placed on the receptacle ; antheræ roundish, minute. Pistil : germen ovate, pubescent, superior; style erect, generally longer than the stamina, awl-shaped, trifid at the tip, permanent; stigmas obtuse, simple, reflex. Pericarp : berry roundish, juiceless, acuminate, with the permanent style, smooth, three-celied. Seeds: in threes or fours, oblong, compressed a little. Observe. It has the inflorescence, flower, and habit of Thea, but the fruit is of a different kind, ESSENTIAL CHARACTER, Calix: five-leaved. Corolla : five-petalled. Style : trifid. Berry ; juiceless, three-celled, many-seeded .---- The species are,

ERV

1. Eroteum Thæoides. Leaves ovate-lanceolate, serratetoothed ; flowers axillary, solitary.--Native of Jamaica.

2. Eroteum Undulation. Leaves elliptic, lanceolate, acuminate, serrate; flowers convedei, axillary: branches flexuose at top, hairy, tomentose, expecially towards the tip; leaves alternate, two or three inches long, coriaceous, broad lanceolate, acute at both ends, smooth, paler underneath, thicker at the edge; the younger ones nerved, and hairy underneath; patioles very short; peducles four or five, but sometimes solitary, one-flowered, the same length with the petioles; exists ovate, very finely cilitact, obluse. It varies with smooth branches—Native of Jamaica, St. Kitt's, Monserrat, and Guadoloupe.

Erram: a genus of the class Diadelphia, order Decandria. GENERIC CARACTER. Calk:: perianth five-parted, length of the corolla; divisions linear, acuminate, nearly qual. Corolla; papilonaccous; standard fat, slightly refice, roundish, larger; wings obtuse, shorter by lialf than the standard; keel shorter than the wings, acuminate. Stamina: filamenta diadelphous, (simple, and nime-cleft), rising; rising. Stigma: obtuse, beardless. Pericarp: legume oblong, obtuse, columnar, knotty with the protuberant seeds. Seeds: four, usually roundish. Observe. This genus differs from Vicia in the stigma alone. ESENETAL CHARCTER. Caliz: five-parted, the length of the corolla.— The species are.

1. Ervum Lens; Flat-seeded Tare, or Common Lentil. About two flowers on a peduncle: seeds compressed, convex, It is an annual plant, and the least of the kind that is cultivated. It rises with weak stalks, a foot and a half high, having pinnate leaves at each joint, composed of several pairs of narrow leaflets, terminated by a tendril, which supports it by fastening about some other plant. The flowers come out of short peduncles from the sides of the branches; they are small, of a pale purple colour, and three or four together; legumes short and flat, containing two or three flat round seeds, a little round in the middle. The flowers appear in May, and the seeds ripen in July. It grows spontaneously in the corn-fields of France and Germany, the pastures of Carniola, and the vineyards of the Valais. The lentil has not been long cultivated in England, and is now propagated, either as food for cattle, or for the seeds, which are used in soups. They are commonly eaten by the poorer inhabitants of some islands of the Archipelago, and other warm countries, although they are held in little estimation. Hill says, that when ground into powder, they make poultices for swellings, but are not much regarded. The seeds of lentils are commonly sown in March, where the land is dry, but April is the best time in moist ground. The usual quantity of seed allowed to an acre is, from a bushel and a half to two bushels. If these be sown in drills in the same manner as peas, they will succeed better than when they are sown broadcast ; the drills should be a foot and a half asunder, to allow room for the hoe to clean the ground between them, for, if weeds be permitted to grow, they will overtop and starve the lentils. The seeds will ripen in July, when the plants should be cut and dried, and the seeds afterwards threshed out for use. There is another sort, or rather variety, which is cultivated by the name of French lentil. It is the Lens Major of Caspar Bauhin, and is much more worthy of cultivation than the common sort, which is preferred before it. This pulse is frequently called Tills in some parts of England.

2. Ervour Tetraspermum; Smooth Tare. About two flowers on a peduncle: seeds globular, four in a legume; ing three or four round see root annual; stems, in open places, slender, weak, and much where each seed is lodged.

branched, but among corn supporting themselves by tendrils to a foot or more in height, two-edged, and inclining to fourcornered ; stipules in pairs, the lower semisagittate, the upper entirely or nearly so; flowers on slender capillary peduncles, as often single as in pairs ; calix somewhat hairy ; the lower segments longest; corolla violet, often blood-coloured. This is easily distinguished from the third species, for in that the pods are hairy, and contain only two seeds; in this they are smooth, and contain four; in that the flowers grow in a kind of cluster, in this seldom more than two grow together. It is exceedingly fertile, one plant, casually pulled up, having two hundred and twenty pods on it. It is found in most corn-fields, clinging to the corn, and, if the season favours its growth, sometimes quite overcoming it. Both this and the next species are small annual tares, which flourish among wheat and rye in many parts of England, and are not admitted into gardens. They may be easily destroyed in fields, if only cut up when they begin to flower.

3. Ervum Hirsutum ; Hairy Tare. Peduncles many-flowered; seeds globular, two in a legume. Annual: stems weak, much branched, climbing, quadrangular, streaked, from one to two feet high; lower stipules with two, three, or four awl-shaped teeth; the upper ones awl-shaped or entire; leaflets mostly linear, sometimes lanceolate, eight to twelve pairs, somewhat alternate, terminated by a branched tendril. It is easily distinguished from the foregoing, the leaves not being pointed as in that, but truncate; the stipules divided into many more segments; the flowers, and consequently the legumes, growing in a kind of cluster, being rough, and containing two sceds. It grows among corn, and is more destructive to it, being stronger and more prolific than the other species. In wet seasons whole crops are overpowered by this plant. All sorts of cattle eat it .- These two are called tine tare; that with smooth pods, and this with rough pods. They are common in Japan and Cochin-china. See the preceding species.

4. Ervum Soloniense; Spring Ture. About two dowers on a peduncle, awned; petiodies zuminate, and the solution of the soluti

5. Ervum Monanthos; Ome-flowered Tare, or Lentil. Peaknets one-flowered, larger than the common lentil, climbing by means of bifd and trifd tendrils; petioles horizontal; leaftet sixteen to eighteen, linear, retuse, with a point; stipules two, alternately larger, different in form; pedande one-flowered; calix three tunes shorter than the corolla, with the toothlets nearly equal; standard compressed, whitain, with viole views; lequen larger, somewhat nodding, containing two or three seeds, the size of peas, compressed, with an obtuse nargin. Annual: Novering from May to July.—Native of Russia; found also among lentils at Herborn in Gereis.

5. Ervum Ervilia; Officinal Tare. Germinia naked and plaited; leaves unequally pinnate. This is an annual plant, rising with angular weak stakks a foot and a lalf high, having at each joint one pinnate leaf, composed of fourteen or fifteen pairs of leaflest, like those of the vetch, but narrower. The flowers come out from the sides of the stalk, on peduncles an inch long, each sustaining two pale-coloured flowers, which are succeeded by short pods a little compressed, each containing three or four round seeds; the pods swell at the place where each seed is lodged. The seeds ground to flour are feeding cattle in some countries, but the plant is not worth cultivating for that purpose in England.

ERY

Erungium; a genus of the class Pentandria, order Digynia. GENERIC CHARACTER. Calix: recentacle common.conic: chaffs separating the sessile floscules. Involucre: of the receptacle many-leaved, flat, exceeding the floscules ; perianth proper, five leaved, upright, sharp, exceeding the corolla, seated on the germen. Corolla : universal, uniform, roundish ; floscules all fertile; proper five-petalled; petals oblong, the tips bent inwards to the base, straitened longitudinally by a line. Stamina: filamenta five, capillary, straight, exceeding the floscules. Antheræ oblong. Pistil: germen hispid, inferior; styles two, filiform, straight, length of the stamina: stigmas simple, Pericary; fruit ovate, divisible in two directions. Seeds : oblong, columnar. Observe : On some species the seeds are deposited from the crust of the pericarp, in others they remain included in it. ESSENTIAL CHARAC-TER. Flowers : in a head ; receptacle chaffy .-- These plants have somewhat the appearance of thistles; the leaves are often spinous, as are also the involucres; the umbellets in some are inclosed in an involucre, which is often irregular and branched, in others they are dispersed .---- The species are.

1. Eryngium Fætidum; Stinking Eringo. Root-leaves lanceolate-serrate; floral-leaves multifid; stem dichotomous; root annual, or biennial; root-leaves bluntish, the serratures terminating in harmless spines; stem a foot high or more. green, somewhat angular, dichotomons, spreading, with the extreme branches flexuose. The whole plant has a penetrating, strong, though not very unsavoury smell; the flowers are produced in small sessile heads, coming out at every division of the stalks, and at the ends of the branches; they are of a dull white colour, and make little appearance: they appear in June and July, and the seeds ripen in autumn .- It is a native of the West Indies, Mexico, Surinam, and Virginia. All parts of this plant are reckoned very powerful antihysterics, and much used by the negroes and poorer whites, on all occasions of that nature, from whence they name it fit-weed ; it is chiefly administered in decoctions or infusions. As this plant is a native of hot countries, it will not thrive in England but in a warm stove. It is propagated by seeds, which, if sown in pots, and plunged into a moderate hot-bed, will come up much sooner than those which are sown in a hot bed ; and when the plants are fit to remove, they should be each planted in a small pot, and plunged into the bark-bed, and afterwards treated like other tender plants from the same country; the second year they will produce

flowers and seeds, soon after which they commonly decay. 2. Eryngium Aquaticum; Marsh Eringo. Leaves gladiate-servate, spiny; floral-leaves undivided. This plant has a perennial root, from which rise several long leaves, disposed round the root, like those of the aloe or yucca; they are of a gray colour, a foot long or more, and one inch and a half broad, stiff, and ending in spines; the stem is strong, two feet high, and divides at top into several peduncles, each terminated by an oval head of flowers, which are white, with a little cast of pale blue. They come out in July, but unless the season be very warm, the seeds will not ripen in England. -It grows naturally in Virginia and Carolina, where it is called rattlesnake weed, from its use in curing the bite of that venomous creature. This sort is propagated by seeds, which, if sown in pots, and plunged into a moderate hot-bed. will come up much sooner than those which are sown in the full ground, whereby they will be much stronger before the winter. When the plants are fit to remove, they should be

sometimes used in medicine abroad, and the green herb for | each planted in a separate small pot filled with light earth : and if they are plunged into a moderate hot bed, it will forward their taking root; then they must be gradually inured to bear the open air, into which they may be removed at the latter end of May, and placed among other hardy exotic plants. When the plants have filled these pots with their roots, some of them may be shaken out, and placed in a warm border ; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be exposed to free air in mild weather, but sheltered from severe frost; the following spring these may be turned out of the pots, and planted in a warm situation, where they will endure the cold of our ordinary winters very well; and if in severe frost hey be covered with straw, pease haulm, or any similar light covering, it will secure them from injury.

3. Eryngium Planum; Flat-leaved Eringo. Root-leaves oval-flat, crenate; heads peduncled; root perennial; stem upright, round, furrowed or streaked, whitish, about a foot and half in height, bluish at top, where it divides into three parts, each of which is terminated by a peduncled axillary flower; flowers in terminating heads, fenced with a six-leaved involucre, spreading, and reflex ; the leaflets long-lanceolate. mncronate, as long as the flowers. It makes a pretty appearance when in flower, which is in July, especially that with blue stalks and flowers, for there is a variety in which they are white, with the leaves of a lighter green. As it does not spread at the root, it ought to be allowed a place in the pleasure ground.—Native of Austria, Silesia, Poland, and Russia. It is propagated by seeds, which if sown in the autumn, will more certainly succeed than when sown in the spring, for the latter commonly remain in the ground a year before they vegetate; and if the seeds are sown where the plants are to remain, they will flower stronger than those which are transplanted; for as they have long downright roots, so they are commonly broken in taking out of the ground, which greatly weakens them. The culture they require is, to thin them where they are too near, keep them clean from weeds, and dig the ground about them every spring before they shoot.

4. Eryngium Pusillum; Dwarf Eringo. Root-leaves oblong, gashed; stem dichotomous; heads sessile. This plant puts out oblong plain leaves from the root, which are cut on their edges; the stalks rise about a foot high, and branch out into many forked divisions, which are regular, and have a small head of flowers in each, sitting very close between the branches. It flowers from June to August .- Native of Spain.

5. Eryngium Tricuspidatum; Trifid Eringo. Root-leaves cordate; stem-leaves palmate, with ears bent back; chaffs three-cusped; root biennial, tuberous, approaching to the shape of the radish; stem a foot high, with spiny heads at the top, and in the axils with purple florets in them; involucres of long, narrow, hard, prickly leaflets, much longer than in the common sort .- Native of Spain, Sicily, and the Levant.

6. Eryngium Maritimum; Sea Eringo, or Sea Holly. Root-leaves roundish, plaited, spiny; heads peduncled; chaffs three-cusped; root creeping, and running deep into the ground ; leaves roundish, stiff, gray, set with sharp spines on the edges; stems a foot high, branched, smooth, having at each joint leaves of the same form with the lower ones, but smaller; the flowers come out at the ends of the branches in roundish prickly heads, and are of a whitish blue colour; under each head is a range of narrow, stiff, prickly leaves, spreading like the rays of a star. The flowers appear in July. The young flowering-shoots, eaten like asparagus, are very grateful and nourishing; the leaves are sweetish, with a

slight aromatic warmth and pungency; the roots are supposed | to have the same aphrodisiac virtues as the orchis tribe: they are kept in the shops candied, and are still regarded by the Arabs as an excellent restorative. Boerhaave says, a decoction of the roots drank freely, increases the urinary discharge, and is serviccable in scorbutic complaints. Blackwell also informs us, that the roots are good in obstructions of the liver, and in the jaundice; they operate as a diuretic, and are a good restorative in those consumptions that are brought on by venereal excesses. The candied root, according to Hill, is a good medicine in coughs, and other disorders of the breast and lungs. A decoction of it while fresh forms a good diuretic, which is serviceable in the jaundice, and other disorders which arise from obstructions of the viscera: when resorted to for these complaints, the fresh root should be preferred. Old English writers call this plant sea-holly, sea-holme, and sea-hulver. It grows in great abundance on the sandy and gravelly shores of many parts of Great Britain, and other countries of Europe. This species will grow in a garden, if the roots be planted in a gravely soil, and produce flowers annually; but the roots will not grow near so large or fleshy as those which are found upon the sea-shore, where they are overflowed with salt water. The best time to transplant the roots is in autumn, when the leaves decay; the young roots are much better to remove than the old, because being furnished with fibres, they will readily take root, and when fixed in the ground should remain unremoved, and require no farther culture except to be kept clean from weeds.

7. Eryngium Campestre; Field Eringo. Root-leaves stem-clasping, pinnate-lanceclote; root perennial and strong. The whole plant is very stiff, and of a pale green colour; corolla blue, sometimes white or yellowish, appearing in July and August—Native of most parts of Europe. In Great Britain it is found upon the coast near the ferry from Plymouth into Cornwall; near Newcastle upon Tyne; below Melling, in Yorkshire, and opposite Brock-hall; near Daventry, in Northamptonshire. Gerarde cultivated this species in his garden. It is a very troublesome weed, for the roots run deep into the ground, and are not easily destroyed by the plough; they spread and multiply greatly in the ground, to the prejudice of whatever is sown or planted on the land, and are therefore not admitted into gardens.

8. Eryngium Amethystinum: Amethystine Eringo. Root-leaves triid, subpinante at the base; the lower leaves are divided, like the fingers of a land, into five or six segments, which are very much cut at their extremities into many parts, and have small spines; stem about two feet high, with smaller and more divided leaves; the upper part of the stem, and also the heads of flowers, are of the finest amethystine colour, so that they make a very beautiful appearance. There is a variety with smaller leaves, the involucer of which has trifd folioles. It flowers in July, and when the autumn proves dry, the seeds will ripe in Englaud. It may be propagated in the same way as the third species, to which the reader is referred.—Mattive of the mountains of Strina.

9. Eryngium Triquetrum. Root-leaves trifd; stem very much branched; pedmeles three-sided; involuerse three-leaved, keeled; stem ereet, rigid, a span or a foot in height, very much branched; round, suooth, amethystine, as are also the branches and flowers; branches alternate, divaricate, abdichtononos, three-sided; stem-leaves three-parted, half stem-chasping; segments lauceolate, rigid, apiny, with a spiny tooth on each side at the base—Native of Tunis in Africa.

10. Eryngium Alpinum; *Alpine Eringo*. Root-leaves heart-shaped; stem-leaves tcrnate, gashed; involucres spiny, 44.

pinnate, ciliate; root perennial; the leaves are cordate, and toothed, the lower on long perioles, the upper stem-clasping; the lower leaves resemble those of cacalia, but are more sauroand the teeth end in a soft spine; a methystine leaves surround the oblong head of flowers, some of them bristeform and reflex, others pinnatified and lanecolate; corolla white; antileræ green. It is a plant, says Villars, curious to see, on account of the beauty of the involueres, which are of a vinous zoure blue, mixed with green and white, scarcely prickly; the heads of flowers are much elongated, cylindric in the lower, and suddenly rounded in the upper part.—Native of the mountains of Switzerland, Dauphuy, and Italy. It is cultivated in the same way as the third species.

11. Eryngium Bourgati; Ćut-læred Eringo. Root and stem-læves alternate, and three-parted, twice trifdt; involucres awl-shaped, many-leaved, somewhat spiny, height from eight inches to a foot; stems thick, white, strong, and branched from the bottom. Mr. Miller, who cultivated this plant, says, that the stalks rise about two feet high, that the flowers are of a light blue colour, in very large heads, appearing in June and July, and ripening seed in autumn.—Native of the south of France.

Erysimum; a genus of the class Tetradynamia, order Siliquosa .- GENERIC CHARACTER. Calix: perianth fourleaved; leaflets ovate-oblong, parallel, converging, coloured, decidnous. Corolla: four-petalled, cruciform ; petals oblong, flat, extremely obtuse at the tip; claws length of the calix, upright; gland nectariferous, double, within the shorter filamentum. Stamina : filamenta six, length of the calix, those of the two opposite shorter. Antheræ simple. Pistil: germen linear, four-cornered, length of the stamina : style very short; stigma headed, permanent, small. Pericarp; silique long, linear, strict, exactly four-cornered, two-valved, twocelled. Seeds: very many, small, roundish. ESSENTIAL CHARACTER. Silique columnar, with four equal sides. Calix: closed. These plants are seldom introduced, except into botanic gardens; most of them perish soon after they have ripened their seeds, but the fifth sort will abide several years in a dry lean soil, or on a wall; in a rich land it soon decays. They may all be propagated by sowing their seeds in the autumn, where they are to remain, and afterwards require no farther culture, except thinning and weeding.----The species are,

1. Erysimum Officinale; Common Hedge Mustard. Siliques pressed close to the spike ; leaves runcinate ; root annual; stem from one to two feet high, upright, ronud, finely grooved, beset with numerous short rough hairs, branched, and for the most part purplish, particularly at the angles of the branches, which spread very much; racemes of flowers terminating, roundish; of fruits filiform, elongated, naked, pubescent; petals of a dull yellow, wedge-shaped, veined. Viewed as it comes into blossom, and when its floweringbranches shoot out horizontally to a great length, it scarcely seems to be the same plant .- It is common on dry banks, under walls, pales, aud in waste places, from May or June to September. Linneus informs us, that it is excellent in asthmas, hoarseness, and other complaints of the breast. Rondeletius cured a hoarseness brought on by loud speaking in a few days with this herb, the juice of which is the most excellent of all remedies for diseases of the throat, especially in ulcerated sore throats, which it has been found to cure when all the advice of physicians and surgeons proved ineffectual. The above assertion is grounded on a manuscript note, found by the late celebrated Dr. Withering, in a copy of Parkinson's Herbal, which formerly belonged to Mr. Saunders, surgcon, of Stourbridge. Hill informs us, that the 6 R.

to be preferred. A strong infusion is a good attenuater and dissolver of tough phlegm, and is excellent in asthmas, hoarseness, and other complaints of the breast : this simple infusion, made into a syrup with honey, also answers the same purposes, and keeps all the year round. This, and some others of the class, are apt to spring up among the ashes where charcoal has been made, or where there has been any considerable fire, Besides its common name of hedge mustard, it has those of bank cresses, and scrambling rocket : Turner calls it winter cresses; the Germans name it der hederich, wegesenf, wilder senf, falscher wassersenf, das gelbe eisenkraut, das weibchen des eisenkrauts, kreuzkraut ; the Danes, vild senep, veysenep; the Swedes, vagghrassa; the French, le velar, la sortelle, l'herbe au chantre ; the Italians, erisamo ; the Spaniards, jaramago, hierba de san Alberto, irion ; the Portuguese, erisimo ; and the Russians, gorczyca polna, or pszonak ziele. It is warm and acrid to the taste, and, when cultivated, is used as a spring pot-herb. Birds are fond of the seeds; sheep and goats eat it; cows, horses, and swine, refuse it.

2. Erysimum Barbarea: Winter Hedge Mustard, or Cress. Leaves lyrate, the outmost lobe roundish; root perennial: stem a foot or eighteen inches high, smooth, round, deeply furrowed, much branched; flowers in racemes, or thick spikes, at the ends of the stem and branches ; peduncles compressed, quadrangular; calix green, caducous; two of the leaflets larger, with a liclmet-shaped hollow at the top; petals yellow, much longer than the calix. There are several varieties of winter cress; one, mentioned by Linneus and Tournefort, is distinguished by Ray as having smaller leaves, more frequently sinuated, the pods thicker, and the seeds larger, pale brown, inclining to white. Petiver figures it under the name of early winter cress, and says, that it flowers in April. A variety with double flowers is common in the gardens, under the name of yellow rocket. The common people in Sweden use the leaves in salads early in the spring, and late in the autumn ; they also boil them as kale. Some persons in England also cultivate it for spring salad, under the name of French or American cress, but it has to most people a bitter unpleasant taste. It is found on the banks of ditches and streams, in watery places, and even on walls, flowering from May to July. It is called winter rocket as well as winter cress, and herb de St. Barbara; the Germans name it die winter kresse, barbenkraut, barbelkraut, rapunzel, senskraut, schnodesens, habichtskraut, gelber beyfuss, falsche bumon ; the Danes call it vinterkars ; the Swedes, vinterkrasse ; the French, la Barberée, l' herbe sainte Barbe. l'herbe aux charpentiers, la Julienne jaune, roquette; the Italians, Barbarea, erba di santa Barbara, ruchetta; the Spaniards, hierba de santa Barbara, raqueta; the Portuguese, herva de santa Barbara.

3. Erysimum Alliaria; Stinking, or Garlie Hedge Mustard. Leaves cordate; root biennial; stem upright, from two to three feet high, round, smooth, somewhat striated, at bottom purple, and slightly hairy, at top branched; the branches are few, alternate, and upright; flowers in a corymb, terminating, upright, on peduncles the length of the flowers; leaflets of the calix pale green, obtuse, deciduous, hollow at the tip; corolla white; petals obovate; border spreading, marked with a few veins; the leaves are recommended to be taken internally, as sudorifies and deobstruents, of the nature of garlic, but much milder; externally as antiseptic, in gangrenes and cancerous ulcers; the seeds excite speezing. According to Linneus's observation, horses, sheep, and swine refuse it, but cows and goats eat it; if eaten by

whole plaut is used, but that an infusion of it when fresh is | cows, it gives a very strong disagreeable taste to the milk-When it grows in poultry yards, the fowls eat it, and it gives an intolerable rank taste to their flesh. The whole plant has a strong smell and taste of garlic, and is therefore used by the country people in sauces, with bread and butter, salted meat, and with lettuce in salads, from which it has acquired another name, that of sauce alone. The fresh leaves, plentifully eaten, says Meyrick, or the juice of them, taken, either by itself or boiled into a syrup with honey, operate powerfully by urine, and are found serviceable in dropsies. The syrup is likewise good to cut and attenuate tough viscid phlegm, and for coughs and hoarsenesses. The seeds snuffed up the nose excite sneezing, and a discharge of watery humours from the head; and the herb, when eaten as a salad, warms the stomach, and strengthens the digestive faculties .----It is commonly found by hedge-sides, on banks, and in shady places, and thence derived another vulgar name, that of Jackbu-the-hedge. It flowers in April and May. The Germans call it dus knoblauch kraut, der knoblauch hederich, lauchel, waldknoblauch, ramfen, rampen, ramschelwurzel, gernsel. salsekraut, saskraut ; the Danes name it huidlog furt, gaflekaal; the Swedes, hvitloksort; the French, l'alliare, cherbe des aux, l'herbe aux aillets ; the Italians, Spaniards, and Portuguese, alliaria.

4. Erysimum Repandum ; Small flowered Hedge Mustard. Leaves lanceolate, toothed ; racemes opposite to the leaves ; siliques racemed, subsessile; corollas minute; stem upright, augular; flowers small, pale; stigmas very slightly emarginate .- Annual: flowering in May and June, and a native of Spain, Bohemia, Silesia, Anstria, and Italy.

5. Erysinum Cheiranthoides; Treacle Hedge Mustard, or Worm Seed. Leaves lanceolate, quite entire, sometimes toothed; siliques patulous; root annual; stem from one to two cubits in height, upright, stiff, streaked, rough, usually simple, sometimes branched a little, others say very much branched; corollas small, yellow; silique an inch long; rhomb quadrangular, obscurely knobbed where the seeds lie; partition membranaceous, contrary to the valves, or certainly narrower than the silique; valves keeled on the outside, at an acute angle; receptacle between the valves, filiform, ending in the very short style, with a blunt stigma : seeds about eighteen in each cell, ovate, a little turgid, beaked, of a yellowish brown colour. They are as intensely bitter as wormseed, or coloquintida, but are, according to the united testimony of Withering and Meyrick, undoubtedly excellent for destroying worms in the stomach and intestines. for which purpose they are much used by the inhabitants of the places where the plant is found, who therefore call it wormseed, or treacle wormseed. The seeds are also given in obstructions of the viscera, and in the rhenmatism and jaundice, with success: they operate moderately by urine, when taken in small doses; in larger, they purge briskly; and in still greater quantities, occasion vomiting-they should on this account be given with caution, and then they will answer all the purposes of mercurial worm medicines, which are frequently attended with danger, especially amongst those who have not skill to manage such medicines properly. All kinds of cattle will eat it .- It flowers from May to August, and is a native of most parts of Europe, though not very common in England: it is found, however, on the osier-holts near Elv, and on the banks of the river between the bridge and that city; also in the corn-fields about Elden; among turnips, near Bungay in Suffolk ; and near Ashburne in Derbyshire.

6. Erysimum Hieracifolium. Leaves lanceolate-serrate; root biennial; stems upright, stiff, sometimes branched, manyangled, smooth; flowers in racemes, yellow, smelling faintly; calix greenish yellow, brown at the end; petals almost linear, | ternate, smooth; stem arboreous, prickly; calices campanutruncate; a small gland at the shorter stamina. -Native of Sweden, Denmark, France, Germany, Austria, and Italy.

7. Erysimum Perfoliatum. Leaves cordate, stem-clasping, smooth .-- Native of Germany, and of the Levant. Linneus has not this plant, which he seems to have confounded with brassica campestris, from which it differs in having a more diffused habit, a white flower, a longer silique, entirely quadrangular, whereas that has the silique cylindric, loose, dry, wrinkled, and veined, ending in a soft fistular horn. Annual : See Brassica Orientalis.

8. Erysimum Bicorne; Horned Hedge Mustard. Leaves lanceolate, hairy; siliques two-horned at the tip. Annual: flowers small and yellow, they appear in August and September .- Native of the Canary Islands. It requires the protection of a green-house.

Erythrina ; a genus of the class Diadelphia, order Decandria .- GENERIC CHARACTER. Calix: perianth oneleafed, entire, tubular; mouth emarginate above, bencath furnished with a melliferous pore. Corolla: papilionaceous, five-petalled; standard lanceolate, with sides bent back, ascending very long; wings somewhat ovate, scarce longer than the calix, scarcely projecting beyond the tube of the stan-dard, very small; keel straight, length of the wings, twopetalled, emarginate. Stamina : filamenta ten, conjoined at the lower part, but little bent in, the length of half the standard, unequal. Antheræ ten, sagittate. Pistil: germen pedicelled, subulate, attenuated with a subulate style, the length of the stamina; stigma terminal, simple. Pericarp: legume extremely long, protuberating at the seeds, terminated by a point, one-celled. Seeds : kidney-form .- This genus of plants is best propagated by seeds procured from the countries where they naturally grow, for they do not produce any here: sow them in small pots, and plunge them into a moderate hot-bed, where, if the seeds be good, the plants will come up in a month or five weeks. When they are two inches high, shake them carefully out of the pots, and replant each in a separate small pot, filled with light earth, plunging them into a moderate hot-bed of tanner's bark, shading them from the sun until they have taken new root, and admitting a large share of air to them when the weather is warm, to prevent their being drawn up weak, taking care to give them a larger portion of air as they increase their strength, and to water them moderately, for too much moisture will rot the fibres of their roots. Remove them into the stove in antumn, where for the two or three first winters they will need a greater degree of heat than will be necessary when they are grown stronger. They should be watered twice or thrice a week when the leaves are in vigour; but when the leaves are fallen, moisture is very injurious. They may also be increased by cuttings, planted in pots during the summer months, and plunged into a hot-bed ; but seedling plants are best.----The species are,

4. Erythrina Herbacea; Herbaceous Coral Tree. Leaves ternate; stems entirely simple, shrubby: annual. It has a large woody root, producing fresh shoots every spring, and growing to the height of about two feet ; they seldom throw out branches, and are sometimes perennial; the petioles are usually prickly underneath, there is commonly a prickle or two-scattered about the stem; leaflets hastate, deep green; the upper part of the stalks are terminated by a long bunch or spike of scarlet flowers -This species flowers, but never produces seeds in England, and is a native of South Carolina. It may survive the winter when placed in a warm green-house, but rarely flowers in that situation.

late, truncate. The seeds are of a bright scarlet colour, only half the size of the next species. The branches are very closely armed with crooked greenish spines, as are also the ribs and footstalks of the leaves. The flowers grow in very long close spikes, and are of a beautiful scarlet colour .- Native of the Cape of Good Hope. It is frequently plauted in the gardens hear Lisbon, where it flowers annually, and ripens seed; but neither this, nor any other species of the genus, will often flower in England, with any treatment we can give them.

ERY

3. Erythrina Corallodendron: Smooth-leaved Coral Tree. Leaves ternate, unarmed; stem arboreous, prickly; calices truncate, five-toothed. It has a thick woody stem, which rises about ten or twelve feet high in this country, but grows to twice that height where it is a native, sending out many strong irregular branches, which are covered with a brown The flowers come out at the ends of the branches, in bark. short, thick, close spikes; they are of a deep scarlet colour, and make a fine appearance, being commonly in beauty in May and June; but are not succeeded by pods here. In America, they produce thick, swelling, crooked pods, containing large seeds of a reddish purple colour. The leaves fall off in spring, and in autumn new leaves put forth, which continue green all the winter. The flowers do not appear till the leaves drop. Dr. Browne thinks it is not a native of Jamaica, but that it was introduced by the Spaniards, who planted it among their cacao-trees, where the walks were most exposed to the weather, in order to break the force of winds, whence it acquired the appellation of mader di cocco among them. In Jamaica it is called the coral or red bean-tree. There is some difference between the Western and Eastern plant; the prickles in the latter are blackish, but the difference seems scarcely sufficient to constitute them distinct species. The leaves sleep about noon, by conniving or clapping together. It is a native of the Society Isles, and of the southern part of China and Cochin-china.

4. Erythrina Picta ; Prickly-leaved Coral Tree. Leaves ternate, prickly; stem arboreous, prickly. This plant has shrubby branched stalks, seldom above eight or nine feet high, armed in every part with strong, crooked, black spines, The leaves are smaller than those of the preceding, and have a nearer resemblance to the first; the footstalks are armed with the same sort of spines, and the mid-rib has also some which are smaller, and not so black ; the flowers are of a paler scarlet, and grow in looser spikes. The secds are as large as those of the third sort, but of a dark purple colour. -This tree is generally planted in the East Indies, for a support to the pepper plants.

5. Erythrina Cristo Galli ; Cock's-comb Coral Tree. Leaves ternate; petioles somewhat prickly, glandular; stem arboreous, unarmed. This is a very lofty tree, without any prickles on the trunk. The branches are stiff ; the leaflets ovate, oblong, and quite entire. The petioles elongated, having frequently one or two recurved prickles underneath; on this petiole, at the base of the pedicels on each side, is a gland, and there are also two glands on the middle of the intermediate pedicel; flowers two or three, axillary, purple, on separate peduncles, resupinate ; calix belly-shaped, two-lipped ; the lower lip dagger-pointed; germen oblong, villose; style subulate; stigma with a minute dot .- Native of Brazil.

6. Erythrina Planisiliqua. Leaves simple, oblong .-- Native of South America.

7. Erythrina Fuscar. Leaves ternate, unarmed, lanceolate; banner of the corolla convolute; stem arboreous, eight 2. Erythrina Carnea ; Flesh-coloured Coral Tree. Leaves feet high, with a brown bark like that of hemp, and many 524

scattered, petioled; leaflets quite entire, smooth; flowers of a brown red colour, in a terminating raceme; seeds oblong. -Native of Cochin-china, where it is found on the banks of rivers. Mr. Bruce affirms, that the seeds of one species of erythrina are called carats, and are used in weighing gold and precious stones. Mr. Miller mentions several other sorts or varieties of this fine genus. One he names erythrina inermis, the pods of which are longer, and not more than half so thick as those of the third species ; the seeds of a bright scarlet, longer and slenderer than those of the other sorts ; the leaves small and acute-pointed; the stalks smooth, and without spines. It does not grow very large, but shoots out into branches at a little distance from the ground ; and these grow erect, so as to form a bushy shrub. The flowers come out at the ends of the branches in short spikes. The wings of the corolla are longer than in the other sorts, and the whole flower is more closed. It is a native of the West India islands. A second sort, Mr. Miller raised from small seeds of a bright scarlet colour, which were sent him from the Cape of Good Hope. The plants had no spines ; the leaves were much larger than the other sorts; their stems were strong, and they had the appearance of growing to large trees. He raised a variety of the second sort, with paler flowers and seeds, and the plants less thorny. Also a variety of the third sort, which he received from the island of Barbuda, with the flowers and pods very short ; the stamina much longer than the petals; the pods very short and crooked, but rather thicker than those of the third species ; the leaves, stems, and branches armed with spines.

Erythronium ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix: none. Corolla : petals six, oblong-lanceolate, acuminate, alternately incumbent towards the base, gradually more spreading from the middle, bent backwards. Nectaries : tubercles two, obtuse, callous, growing to each alternate and interior petal near the base. Stamina: filamenta six, subulate, very short; antheræ oblong. Pistil: germen turbinate; style simple, shorter than the corolla, straight : stigma triple, spreading, obtuse, Pericarp : capsule somewhat globose, narrower at the base, three-celled, three-valved. Seeds: very many, ovate, acuminate. ESSENTIAL CHARACTER. Corolla: six-petalled, bell-shaped. Nectary: tubercles two, fastened to the base of the alternate petals.

1. Erythronium Dens Canis; Dog-tooth Violet. Mr. Miller makes two distinct species. The first with two ovate leaves joined at their base, three inches long, and one inch and a half broad in the middle, gradually lessening towards the ends': these at first embrace each other, inclosing the flower, but afterwards they spread flat upon the ground, they are spotted with purple and white all over their surface. Between them rises a single, smooth, purple, naked stalk, about four inches high, sustaining one flower which hangs down; the petals are reflex, and spread open to their base; their colour is commonly purple, but sometimes white; stamina purple, standing close about the style, which is longer than them. The roots are white, oblong, and fleshy, shaped like a tooth, whence this plant has the name of dog's tooth in English. The same idea has governed the name in all the European languages; the Germans call it hundszalm; the Swedes and Danes, hundetand ; the French, le dent de chien ; the Italians, dente di cane ; the Spaniards, diente de perro ; the Portuguese, dente de cao; aud the Russians, kandik. The second differs in the shape of the leaves, which are longer and narrower; and the flowers are a little larger, but not so well coloured. There is also a variety, in which the leaves

short scattered prickles. The branches are diffused ; leaves (are of a darker green, and the flower of a pale vellow colour Ray observed the first, with a purple flower, near Turin, in the way to Asti, in April; and with a white flower, between Novi and Genoa. Clusins found the variety near Gratz in Stiria : and John Bauhin, at La Bâtie near Geneva, flowering in March. They grow naturally in the south of France, Italy, Savoy, Switzerland, Austria, Friuli, and Siberia. It is increased by offsets from the roots, which they do not send out very plentifully. It is not therefore so common in gardens as most other flowers of the spring season, and it loves a shady situation in a light loamy soil. It may be transplanted any time after the beginning of June, when the leaves will be quite decayed, till the middle of September; but the roots should not be too often removed, nor should they be kept out of the ground too long, which will cause them to shrink, and frequently to rot. They should not be planted scatteringly in the borders of the flower-garden, but in patches ; and thus disposed, they will make a good appearance.

Erythroxylon ; a genns of the class Decandria, order Trigynia .- GENERIC CHARACTER. Calix : perianth oneleafed, five-cleft, turbinate ; divisions ovate, sharp, very small, withering. Corolla: petals five, ovate, concave, expanding; nectary of five scales, emarginate, upright, coloured, inserted into the base of the petals, Stamina : filamenta ten, length of the corolla, at the base connected by a truncated membrane ; antheræ heart-shaped. Pistil ; germen ovate ; styles three, filiform, distant, length of the stamina : stigmas obtuse, thickish. Pericarp: drupe ovate, onecelled. Seed : nut oblong, obtusely quadrangular. ESSEN-TIAL CHARACTER. Calix : turbinate. Corolla: having a small, emarginate, nectareous scale at the base of the petals. Stamina : connected at the base ; drupe one-celled .---- The species are.

1. Erythroxylon Areolatum. Leaves obovate, mucronate : branchlets short, floriferous, scaly. Browne describes it as a small beautiful tree ; the leaves of an oval form, and marked with two slender longitudinal lines upon the back, which were the utmost limits of that part of the leaf which was exposed, while it lay in a folded state. The flowers grow in little clusters, and are very thick upon the branches. The inward bark is of a flesh colour, and the wood of a reddish brown. It is reckoned an excellent timber wood, for the size of the tree, which seldom exceeds sixteen or eighteen feet in height, and five or six inches in diameter .- Native of dry coppices in the West Indies. Dr. Browne has another species, which he calls small round-leafed erythroxylon, or redwood, with very slender branches. This tree, he says, differs much from the foregoing, both in shape and manner of growth. It grows in the low lands of Jamaica, like the other, and rises commonly to the height of eighteen or twenty feet; the leaves are roundish and small, and the branches very slender.

Leaves elliptic ; flowers 2. Erythroxylon Havanense. axillary. This is a shrub three feet in height, having altogether the habit of the preceding, but the leaves ovate, obtuse, quite entire, without any lines underneath ; fruit orangecoloured .- Native of the Havanna, on rocks near the coast.

3. Erythroxylon Hypericifolium. Leaves obovate, emarginate ; branches floriferous ; peduncles axillary, solitary. The branches are covered with a brownish, wrinkled, dotted bark, compressed at top, and toothletted from the fallen leaves; scales on the branchlets awl-shaped, and deciduous; leaves petioled, glaucous underneath; peduncles capillary, nearly the same length with the leaves .- Native of the West Indies.

4. Erythroxylon Squamatum. Leaves elliptic, lanceolate, acuminate, obtuse; branchlets scaly, floriferous; branches

3

smooth, covered with an ash-coloured bark, round below, but compressed at top among the leaves, having ovate, halfembracing, short, acute, keeled scales, with a longitudinal groove on the back, at the base of which is inserted an awn, the length of the scale .-- Native of the West Indies. Observed by Rohr in Cayenne,

5. Erythroxylon Macrophyllum. Leaves elliptic, acute ; flowers axillary and lateral, aggregate; branches round at bottom, compressed at top, smooth, covered with a gray bark at bottom among the leaves, having approximating scales of an ovate lanceolate form, half-embracing, keeled, striated, purplish, acute; near the base on the outside, is a broad awl-shaped awn, the length of the scale, concealed within the dorsal groove of the scales .- It was observed in Cavenne by Rohr.

Escallonia ; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: one-leafed, fivecleft, superior, permanent; divisions spreading, keeled, sharp. Corolla: petals five, tongue-shaped, distant, longer than the calix. Stamina : filamenta five, smooth, opposite to the divisions of the calix, alternate with the petals, and shorter than them; antheræ incumbent, fastened by the back to the filamenta, emarginate, two-celled. Pistil: germen half inferior, an oblate spheroid; style upright; stigma capitate. Pericarp : berry roundish, surrounded with the calix, terminated by the permanent style, two-celled. Seeds: numerous, small, nestling. ESSENTIAL CHARACTER. Calix : surrounding the fruit ; stigma capitate. Berry : twocelled, containing many seeds .---- The species are,

1. Escallonia Myrtilloides. Leaves serrulate, ending in a small dagger-point, veiny underneath. This is a branching leafy shrub ; branches wandlike, obscurely angular, covered with a smooth, chinky, deciduous bark ; branchlets alternate, spreading, angular, closely leaved, one-flowered; flowers terminating, solitary, peduncled, upright .-- Native of New Granada

2. Escallonia Serrata. Leaves serrate, subretuse, veinless underneath. This is a low shrub, very much branched, leafy, smooth ; branches alternate, angular, somewhat flexuose, with a smooth pale bark; branchlets alternate, straightish, leafy, one flowered, green ; flowers terminating, solitary, peduncled, upright, very handsome, milk-white, with a violet-coloured germen; peduncles short, round, thickening at the tip, bent in, smooth; divisions of the calix spreading, deltoid, somewhat fleshy, smooth, pale underneath, coloured; petals spreading, obtuse, three times the length of the calix; filamenta broader at the base .- It was found in the straits of Magellan, and in Terra del Fuego.

Eschalot, or Eschalotte, so named from Ascalon in Palestine, about which place it grows, from whence it has also derived the names of Cepa Ascalonica, or Ascalon onion, and Ascaloutides. The old English name was barren onions, because it seldom puts up auy flowering-stem. See Allium.

Espaliers are either rows of trees planted to enclose a whole garden or plantation, or in hedges, so as to enclose quarters or separate parts of a garden; they are trained up flat in a close edge, for the defence of tender plants against the violence and injury of wind and weather. The most commonly received notion of espaliers are hedges of fruittrees, which are trained up regularly to a lattice of woodwork, formed either of ash-poles, or square long timbers, cut out of fir; and it is of this sort of espalier that we intend to treat in this place. Espaliers of fruit-trees are commonly planted to surround the quarters of a kitchen-garden, for which purpose they are extremely useful, as well as highly 44.

larly, which are bounded on each side by these hedges, when they are handsomely managed, they have a wonderful effect in sheltering the kitchen plants in their quarters, and also screening them from the sight of those who frequent the walks; so that a kitchen-garden laid out in this manner, and properly managed, will be equal to the finest regular parterre for beauty. The trees chiefly planted for espaliers, are apples, pears, and some plums, but the two former are mostly used. Some plant espaliers of apples grafted upon paradise stocks : but these being of humble growth, and a short duration, are not so proper for the purpose, except for very small gardens. We should rather advise the having them upon crab stocks, or, if in smaller gardens, where the trees cannot be allowed to grow so high, upon what the gardeners call the Dutch stock ; which will cause them to bear sooner, and prevent their growing too luxuriantly, beside securing their vigour for many years. In clusing the trees for an espalier, endeavour as nearly as possible to plant the several sorts which are nearly of the same growth in one line, that the espalier may be more ready, and of an even height, which greatly adds to their beauty; for if you plant trees which shoot very unequally in the same line, it will be impossible to make the espalier regular: besides, the distance of the trees must be in proportion to their growth; for instance, some trees of a larger growth should be planted thirty or thirty-five feet asunder, whereas the smaller ones need not be placed at above twenty-five feet from each other. 'The width of the walks and borders between these espaliers should, (in a large garden,) be at least fourteen or sixteen feet, and, if it be intended to carry the trees up pretty high, the distance should be greater, that each side may receive the advantage of the sun and air, which is absolutely necessary, if you would have the fruit well tasted. And if your ground be so situated as to leave you at full liberty which way to make the espaliers, Mr. Miller advises the placing the lines from the east, a little inclining to the south, and towards the west, a little inclining to the north, that the sun may shine between the rows in the morning and evening, when it is low; for in the middle of the day, when the sun is advanced far above the horizon, it will shine over the tops of the espaliers, and reach the surface of the earth about their roots, which is a matter of more consequence than many people are aware of. The sorts of apples proper for espaliers, are the golden pippin, nonpareil, rennette, grise, aromatic pippin, French pippin, Wheeler's russet, and Pile's russet, with some others. The season for planting, and the method of pruning and training these trees, will be found under the articles Pruning and Pyrus. The sorts of pears proper for an espalier, are chiefly the summer and autumn fruits; for some of the winter pears seldom succeed well in an espalier. These trees, if designed for a strong moist soil, should be upon quince stocks; but if for a dry soil, upon free stocks. Their distance of planting must also be regulated by the growth of the trees, which are more unequal in pears than apples, and should therefore be more carefully examined before they are planted. As for the pears upon free stocks, the distance should never be less than thirty feet for moderate-growing trees; but for those that shoot vigorously, the space of forty feet is not too much, especially if the soil be strong, in which case they should be planted at a greater distance. The particular sorts of pear, which Mr. Miller recommends for an espalier, are the jargonelle, blanquette, poiresans, peau, summer boncretien, Hamden's bergamot, autumn bergamot, L'ambrette, Gros Rousselet, Chaumontelle, Beurre du Roy, le Marquis Cressane, with some others of less note; always ornamental; for by laying out the walks of this garden regu-6 S

ESP

dom ripen well on an espalier; as also that many sorts of pears will ripen well on an espalier in a warm soil and situation, which require a wall in other places; you should also be careful of the stocks these are grafted on, for if the breaking pears are grafted upon quince stocks, the fruit will be stony, but the melting pears will be improved by them. For the method of planting them, the reader is again referred to the genus Purus; and for the pruning and management, to the article Pruning. In order to form the espalier to which the trees are to be trained. Mr. Miller gives the following directions .--- The espalier should not be made until the third year after the trees are planted ; for while they are young, it will be sufficient to drive a few short stakes into the ground on each side of the trees, in a straight line, to which the branches should be fastened in an horizontal position, as they are produced, in order to train them properly for the espalier, which stakes may be placed nearer, or at a farther distance, according as the shoots produced may require, and these will be sufficient for the three first years; for should you frame the espalier the first year the trees are planted, many of the stakes would rot before the espalier is covered. The cheapest method of making espaliers, is with ash-poles, of which two sorts should be provided ; one of the largest size, which contains thirteen poles in a bundle, and the other size, those of half a hundred. The first, or largest sized pole, should be cut about seven feet and a half long, which are intended for upright stakes, and must be sharpened at the largest end, that they may with more ease be driven into the ground ; and if their bottoms are burred or rubbed over with a proper composition, they may be preserved a long time sound: these should be placed at a foot distance from each other in a direct line, and of an equal height, about six feet above ground; then you should nail a row of straight slender poles along upon the tops of the upright stakes, which will keep them exactly even, and continue to cross the stakes with the smaller poles, and also with the tops which were cut off from the larger stakes, at about nine inches' distance row from row, from the top to the bottom of the stakes. These rows of poles should be fastened with wire to the stakes, which, if made of fir, and painted over, will last a long time: and the largest eud of the poles should be cut flat, and nailed to the upright stakes, which will secure the espalier almost as long as the poles will endure ; whereas, if your fastening is not strong, the poles will be continually displaced with every strong wind. When the espalier is thus framed, the branches of the trees must be fastened thereto, either with small osier twigs, rope-varn, or some such binding, observing to train them in a horizontal position, and at equal distances, being careful not to cross any of the branches, nor to lay them in too thick. The distance which should be allowed for the branches of pears and apples, must be proportioned according to the size of their fruit : those which produce large fruit, as the summer boncretien, Monsieur John, and Beurre du Roy pears, and the Rennet Grise, Holland pippin, French pippin, and other large apples, should have their branches six or eight inches' distance at least; and those of lesser growth, four or five inches will be sufficient. But for farther directions, see the article Pruning, where these particulars are sufficiently explained. Besides this sort of espalier, made with ash-poles, there is another sort that is by many people preferred, which is framed with square timbers, cut to a proper size, according to the strength thereof, or the expense the owner is willing to go to. These, though more sightly, when well fixed and painted, are not more lasting than the former loose, somewhat leafy.--Native of China. sort, provided it be well made, and have upright poles of 5. Ethulia Bidentis. Racemules directed one way; calices

will do better in espalier than the breaking pears, which sel- sufficient strength; nor will they answer the purpose better. though they are much more expensive. The greatest beauty of an espalier, consists in disposing the branches of the trees, which, especially in summer, when the leaves abound, entirely hide the frame. All expense therefore, farther than what is necessary to secure the branches in regular order, is needless, Fruit-trees thus planted, and well managed, are much preferable to those trained up in any other figure ; first, because they take up very little room in a garden, and are not injurious to the crops in the quarters ; secondly, because the fruit is better tasted, the sun and air having free access to every part of the tree, and the dampness of the ground being quickly dissipated ; thirdly, because the trees being kept low, and the branches fastened to the espalier, the fruit will not be so exposed, and likely to be blown down by high winds.

Ethiopian Sour Gourd. See Adansonia.

Ethulia ; a genus of the class Syngenesia, order Polygamia Equalis .- GENERIC CHARACTER. Calix : common, manyleaved, rounded, simple; leaflets linear, nearly equal, spreading. Corolla: compound, tubular; corollets hermaphrodite, uniform, distant by a space; proper funnel-form; border five-cleft, upright. Stamina : filamenta five, very short, capillary; antheræ cylindric, tubular. Pistil : germen prismatic ; style filiform, length of the stamina ; stigmas two, recurved. Pericarp : none; calix unchanged. Seeds: solitary. truncated, turbinate, five-cornered, five-furrowed : down none, but a little projecting margin : receptacle naked, convex, excavacated with points. ESSENTIAL CHARACTER. Receptacle ; naked. Down ; none. Most of the plants of this genus, being annual, must be propagated by seeds; and coming from the East Indies, must be kept in the stove .--The species are,

1. Ethulia Conyzoides; Panicled Ethulia. Flowers panicled; root annual; stem herbaceous, the thickness of a finger, four feet in height, upright, round, but angular at top, pubescent, hollow; branches alternate, axillary, short, somewhat erect; flowers small, containing above twenty florets, of a pale blue colour. It is a large plant, remarkable for having the florets distant, and in putting forth roots from the base of the stem, which is seldom the case in annual plants. The leaves smell very sweet .- It flowers in July and August, and is a native of the East Indies.

 Ethulia Spargnophora. Flowers sessile, lateral; calix subglobular, imbricate, with unequal scales, recurved, and patulous at the tip; receptacle flat, with raised dots on it; seeds small, uniform, ovate, narrower at bottom; rhomb compressed, with angles at the sides, and one on the back ; the rib white, but the interstices and the ventral plane of a pale testaceous colour .- Native of the East Indies.

3. Ethulia Divaricata. Leaves linear, toothed, decurrent ; peduncles opposite to the leaves, one-flowered ; stem divaricate. This is an annual plant, a hand in height; stem upright, corymbed, smooth at bottom, pubescent at top, and branched; the primary branches shorter, sharply quadrangular; calix subglobular, subsquarrose; scales oblong, patulous, or recurved at the tip ; florets difform ; those of the disk funnel-shaped, five-cleft, and rogynous, barren, fewer; in the ray awl-shaped, without teeth : female fertile, very numerous ; receptacle flat, large, hollow, dotted .- Observed by Konig in the fields of Malabar.

4. Ethulia Tomentosa. Undershrubby : leaves linear. quite entire, tomentose; stems streaked, branched; leaves alternate, sessile, lanceolate-linear, hoary, or very finely tomentose, like those of lavender; calices terminating, sessile,

containing about five flowers ; leaves lanceolate, opposite ;] stem herbaceons, upright, hexagonal, brachiate ; leaves threenerved, subpetioled, serrate, smooth; racemes two or four at the ends of the stem and branches, brachiate, on the upper side of which are sessile, narrow, yellow flowers, about five together, alternate, and supported by a subulate bracte; seeds oblong, even, with a few streaks .- Native of the East Indies.

6. Ethulia Struchium. Flowers axillary, sessile, all trifid. This plant generally rises to the height of two feet and a half or more; leaves alternate, oblong, entire; flower-bunches interspersed with a few smaller ones, that rise between the common cups, as they stand compacted together at the axils of the leaves; corollets nearly equal, the marginal trifid, the central four-parted; germen oblong, angular, crowned with its proper calix, which has about four little notches; style longer than the corolla; stigmas oblong, revolute .- Native of Jamaica.

Eucalyptus ; a genus of the class Icosandria, order Monogynia .- GENERIC CHARACTER. Calix : perianth superior, permanent, truncate, covered with a hemispherical decidnous lid before flowering-time. Corolla : none. Stamina : filamenta very numerous, inserted into the calix. Pistil: gcrmen inferior, turbinate; style single. Pericarp : capsule four-celled, gaping only at the tip. Seeds : very many, an-ESSENTIAL CHARACTER. Calix: superior or gular. permanent, truncate, before flowering-time covered with a hemispherical deciduous lid. Corolla : none. Capsule: four-celled, opening at the top, inclosing many seeds .--The species are,

1. Eucalyptus Obliqua ; Oblique-leaved Eucalyptus. This is a very tall tree, growing to the height of more than a hundred feet, and above thirty in circumference; the bark is smooth like that of the poplar, and the young branches are long and slender, angulated near the top, but as they grow older the angles disappear. The leaves are alternate, lanceolate, pointed ; ray entire, smooth on both sides, and remarkably unequal or oblique at their base; the veins are alternate, and not very conspicuous. The whole surface of both sides of the leaves is marked with numerous minute resinous spots, in which an essential oil resides. The footstalks are about half an inch in length, round on the under side, angular above, quite smooth. The flowers have not been fully examined, but the capsules are supposed to grow in clusters, from six to eight each, sessile, and conglomerated ; each is about the size of a hawthorn berry, globular, but as it were cut off at the top, and of a dark brown colour ; the seeds numerous, small, and angular.-Native of Botany Bay. 2. Eucalyptus Resinifera; Red Gum Tree. This tree is

much larger than the English oak; the wood is brittle, and contains a large quantity of resinous gum; the flowers grow in little clusters, or rather unbels, about ten in each, and every flower has its proper partial footstalk, about a quarter of an inch in length, besides the general one; the general footstalk is remarkably compressed, and the partial ones in some degree; the flowers are vellowish, and of a singular structure; the calix is hemispherical, perfectly entire on the margin, and afterwards becomes the capsule : on the top of the calix, rather within the margin, stands a conical pointed calyptra, which is of the same colour as the calix, and about as long as that and the calix taken together : this calyptra constitutes the essential mark of the genns. The antheræ are small and red, and in the centre is a single style, terminated by a blunt stigma; the stamina are very resinous and aromatic; the germen appears, when cut across, to be divided into three cells, each containing the rudiments of one or greenish colour, appearing in April : the leaves decay in June.

more seeds. On making incisions into the trunk of this tree. large quantities of red resinous juice are obtained, sometimes more than sixty gallons from a single tree. When dried, this juice becomes a powerful astringent gum-resin, much resembling that known in the shops by the name of kino, and full as efficacious for all medical purposes. Mr. White, the chief surgeon to our settlement at Botany Bay, administered it to a great number of patients in the dysentery, and found it eminently serviceable, never failing' in a single instance. This guin-resin dissolves almost entirely in spirit of wine, to which it gives a blood-red tincture; water dissolves about a sixth part only, and the watery solution is of a bright red ; and both solutions are powerfully astringent.

Euclea ; a genus of the class Direcia, order Dodecandria or Polygamia,-GENERIC CHARACTER. Male. Calix : perianth one-leafed, many times shorter than the corolla, subangular, smooth, five-toothed; teeth very short, upright. Corolla: one-petalled, five-parted; segments ovate, obtuse, concave, patulous. Stamina: filamenta thirteen, very short, eight in the circumference, five in the centre. Antheræ four-cornered, subulate, grooved, erect, perforated at the tip on both sides. Female. Calix, perianth one-leafed, four-toothed, (more scidom five-toothed,) permanent; segments erect, three times shorter than the corolla. Corolla : one-petalled, four-cleft ; segments ovate, obtuse, concave, erect. Pistil: germen ovate, subvillose, superior ; styles two, thickish, the length of the corolla; stigmas emarginate, bifid, obtuse. Pericarp: berry globular, unbilicate, with a dot, smooth, fleshy, according to L'Heritier, a berried capsule, three-horned, threecelled, three-valved; Linncus says two-celled. Seed: single, globular, smooth; according to L'Heritier, roundish, arilled, one or two abortive. ESSENTIAL CHARACTER. Male. Calix : four or five-toothed. Corolla : four or five-parted, Stamina: twelve to fifteen, Female. Calix and Corolla: as in the male. Germen: superior; styles two. Berry : twocelled .---- The only known species is,

1. Euclea Racemosa; Round-leaved Euclea. This is a branching tree: leaves alternate, subpetioled, obovate, quite entire, obtuse, smooth, perennial; racemes of flowers from the axils of the upper leaves, simple, nodding, hardly the length of the leaves .- It flowers in November and December, and is a native of the Cape of Good Hope.

Eucomis ; a genus of the class Hexandria, order Monogynia .- GENERIC CHARACTER. Calix : none. Corolla : inferior, six parted, permanent, spreading, Stamina; filamenta subulate, dilated at the base, and united there into a concave nectary, fastened to the bottom of the corolla. Pistil: germen suferior; stigma simple. Pericarp: capsule three-celled. Sceds ; many. ESSENTIAL CHARACTER. Corolla: inferior, six-parted, permanent, spreading. Filamenta : united at the base into a nectary growing to the corolla. The plants of this genus require the same management as other Cape bulbs .---- The species are,

1. Eucomis Nana : Dwarf Eucomis. Scape club shaped : leaves broad-lanceolate, acute .- It flowers in May, and is a native of the Cape of Good Hope.

2. Eucomis Regia; Tongue-leaved Eucomis, or Fritillary. Scape cylindric ; leaves tongue shaped, obtuse, close to the ground; root tuberous, from which arise in the autumn six or eight obtuse leaves, nearly five inches long, and two broad towards the top, growing narrower at their base, crenated on their borders, lying flat on the ground, and continuing all the winter. In the spring arises the flower-stalk, in the centre of the leaves, about six inches high, naked at the bottom, but the upper part is surrounded by bell-shaped flowers of a

There is a variety of this species, the flower-stalks of which | rise higher than it, and the flowers are of the same shape and colour, but seldom appear till August .- They are both natives of the Cape of Good Hope.

3. Encomis Undulata : Wave-leaved Eucomis or Fritillary Scape cylindric ; leaves ovate-oblong, waved, spreading ; the leaves of the coma almost as long as the raceme : this is the largest species .- It flowers in July, and is a native of the Cape of Good Hone.

Evergreen Thorn. See Mespilus Pyracantha.

Eugenia; (so named in honour of the illustrious prince Eugene of Savoy, the friend of the great duke of Marlborough.) a genus of the class I cosandria, order Monogynia.-GENERIC CHARACTER. Calix: perianth one-leafed, superior, elevated in the middle into a subvillose little ball, four-parted; divisions oblong, obtuse, concave, permanent. Corolla: petals four, twice as large as the calix, oblong, obtuse, concave. Stamina: filamenta very many, inserted into the bell of the calix, length of the corolla. Antheræ small. Pistil: germen turbinate, inferior; style simple, length of the stamina; stigma simple. Pericarp: drupe four-cornered, crowned, onecelled. Seed: nut roundish, smooth. Swartz observes, that this genus is not easily distinguished from that of murtus. except in the habit; the first, second, sixth, and seventh species, are the most distinct, but the third, fourth, and fifth, approach nearer to myrtus. ESSENTIAL CHARACTER. Calix: four-parted, superior. Petals: four; drupe oneseeded, four-cornered. To propagate this genus, set the stones fresh from their places of natural growth, in small pots filled with light earth; plunge them in a hot-bed, observing to keep the earth moist, but not wet. In about six weeks the plants will appear ; when about four inches high, separate them carefully, plant each in a small pot, plunge them in the hot-bed again, and carefully shade them till they have taken new root. Treat them in the same way as other tender plants from the same countries, keeping them plunged in the tan-bed, and watering them sparingly in winter .---- The species are.

1. Eugenia Malaccensis ; Broad-leaved Eugenia, Leaves quite entire; peduncles branched, lateral. It rises with a tree-like stem from twenty to thirty feet high, covered with a brown bark, and sending out many branches; leaves oblong, ending in acute points, opposite, when young of a bright purple colour, but as they grow older becoming of a light green; the flowers are produced on the sides of the branches; every peduncle branching into three or four others, each of which supports one flower; fruit succulent, irregularly shaped, and inclosing a single nut. Loureiro calls it a berry; it is of a roundish form, commonly obtusely quadrangular, sometimes it is ovate, in size it is an inch and a half in diameter, fleshy, very sweet, smelling like the rose, not very juicy, covered with a thin, shining, yellowish skin, and containing commonly one seed, which is large, roundish, soft-ish, not bony or horny; the fruit is very agreeable to the taste, smell, and sight, and is esteemed wholesome. Forster describes it as whitish, tinged with rose-colour, pear-shaped, and sometimes as big as the first, but usually much smaller .-It is very common in most of the islands in the South Sea, and is cultivated almost every where between the tropics.

2. Eugenia Jambos ; Narrow-leaved Eugenia. Leaves quite entire; peduncles branched, terminating. This rises to the same height as the preceding species, but the leaves are longer and nariower; flowers mostly terminating, but some

much esteemed .- It flowers from May to July, and is a native of the East Indies, and Cochin-china

3. Eugenia Pseudo-Psidium. Leaves quite entire; peduncles one-flowered, several lateral and terminating. This resembles a pear-tree, is upright, and about twenty feet in height; leaves lanceolate-ovate, acuminate, and sickle-shaped at the end, bright green, shining, from three to four inches long, opposite, on short petioles; calix deeply four-parted; petals white; fruit globular, at first green, then passing through the different shades of yellow as it ripens, till at length it becomes scarlet, it is scarcely half an inch in diameter, the skin thin, and the pulp soft, sweet, and red : the seed is large and globular .- Native of Martinico, where it is called goyavier bastard. It flowers in October, and bears fruit in December and January.

4. Eugenia Uniflora. Leaves quite entire, cordate-lanceolate; pednucles one-flowered, lateral, solitary; flowers white; fruit bright red, soft, slightly grooved, with a sweet smell,-Native of Goa in the East Indies.

5. Eugenia Cotinifolia. Leaves ovate, obtuse, quite entire; peduncles one flowered; the younger branches are angular; the leaves are numerous, opposite, subpetioled, glittering, leathery, sometimes but seldom emarginate; fruit globular, succulent, inclosing a single shining, membranaceous nut, having one seed in it .- Native of Cavenne, where the French call it cerisier de Cayenne.

6. Eugenia Acutangula. Leaves crenate; peduncles terminating; fruits oblong acute-angled pomes; raceme simple. very long; flowers small, with longish stamina and pistils, Loureiro describes it as a large tree with spreading branches. -Native of the East Indies, and of Cochin-china.

7. Eugenia Racemosa, Leaves crenate; racemes very long; pomes ovate, quadrangular; peduncles simple, longer than the leaves, pendulous; pomes rounded, without any sharp angles .- Native not only of India, but of New Caledonia, in the South Seas.

8. Eugenia Sessiliflora. Flowers lateral, sessile : leaves oblong, quite entire, shining, dotted underneath; branches round, smooth, covered with an ash-coloured bark, leafy at top, warted below ; fruit the size of a plum, globular, dotted, Observed by West in the island of Santa Cruz.

9. Eugenia Punctata. Leaves oblong, dotted on both sides : peduncles opposite, three-flowered, the length of the leaves ; branches round, alternate, ash-coloured at bottom, purplish at top, having raised dots scattered over them; the two lateral flowers pedicelled, the middle one sessile; there are two bristle-shaped bractes at the base of the lateral ones ; segments of the calix five, round, dotted ; petals, when magnified, appearing to be very finely ciliate .- Native of Santa Cruz.

10. Eugenia Nervosa. Leaves quite entire; flowers heaped, terminating; berries globular, nerved. This is a large tree with spreading branches; calix large; petals roundish, small, quickly deciduous; filamenta linear, more than a hundred, three times as long as the petals, spreading out wide into a globular head, with small nodding antheræ.-Native of the woods of Cochin-china

11. Eugenia Corticosa. Leaves ovate-acuminate, racemed, corymbed; filamenta very short. This also is a large tree with spreading branches, covered with a thick cloven bark, having something of an aromatic flavour; flowers reddish white, small, numerous, subterminating ; calix goblet-shaped, subtruncate; petals small, roundish, closed; filamenta twenty, awl-shaped, shorter than the corolla, placed near the edge of the calix ; antheræ roundish, very small ; berry only a quarter come out from the sides; fruit smaller, rounder, and not so of an inch in diameter, subturbinate, smooth, blackish, in-

EUO

Cochin-china.

Evolvulus ; a genus of the class Pentandria, order Tetraynia .- GENERIC CHARACTER. Calix : perianth fiveleaved ; leaflets lanceolate, sharp, permanent. Corolla : onepetalled, rotate, five-cleft. Stamina : filamenta five, capillary, spreading, almost the length of the corolla. Antheræ a little oblong. Pistil: germen somewhat globose; styles four, capillary, diverging, length of the stamina; stigmas simple. Pericarp : cap-ule somewhat globose, four-celled, four-valved. Seeds : solitary, roundish, cornered on one side. This genus entirely consists of stove plants, to be cultivated and treated as the tender sorts of convolvulus from the same countries. -The species are,

1. Evolvulus Nummularius. Leaves roundish; stem creeping; flowers subsessile; from a small, stringy, fibrous, annual root spring long trailing stalks, taking root here and there where they touch the ground, and putting forth alternately, at small unequal distances, leaves almost round, three quarters of an inch long, and an inch broad, having a small notch at the end, and on petioles a quarter of an inch in length. and of a brown colour; flowers axillary, on short peduncles, of a light blue colour .- Native of Jamaica and Barbadoes; common also in the dry plains of other islands in the West Indies.

2. Evolvulus Gangeticus. Leaves cordate, obtuse, mucronate, villose, petioled; stem diffuse; peduncles one-flowered. -Native of the East Indies.

3. Evolvulus Alsinoides; Chickweed-leaved Evolvulus. Leaves obcordate, obtuse, hairy, petioled ; stem diffuse ; peduncles three-flowered. It is a little annual plant, with a creeping root; the stems, leaves, petioles, and peduncles, are covered with rufous hairs; leaves alternate, roundish, on a short petiole; flowers axillary, on long peduncles; corolla blue, large in proportion to the plant. The Ceylonese call it wisnugarandi, from the Malabar idol wisnu, and garandi, which signifies the dysentery, for which disorder it is reputed to be a sovereign remedy. It flowers in June and July .---Native of the East Indies.

4. Evolvulus Emarginatus. Leaves kidney-form, repand. Annual: stems filiform, creeping; flowers axillary, solitary, small; peduncles the length of the petioles .- Native of the East Indies.

5. Evolvulus Linifolius: Flax-leaved Evolvulus. Leaves lanceolate, villose, sessile; stem upright, peduncied, threeflowered, long. The whole of this plant has the appearance of a very fine sort of flax. It seldom rises above ten or fourteen inches high; the stalk is generally simple, or but very little divided, slender, and upright; the leaves are narrow and few, they throw out a long and delicate peduncle from their axils, furnished with a very small exterior two-leaved cup about the middle; the styles are two, and bifid; the capsules are divided into two or four cells, and contain many seeds .-- In the low lands of Jamaica it is frequently met with: annual, flowering in August and September.

6. Evolvulus Tridentatus, Leaves linear, wedge-form, three-cusped, dilated at the base, and toothed; peduncles one-flowered; stem twining .- Native of the East Indies.

7. Evolvulus Sericeus. Leaves lanceolate, sessile, silky underneath; pedancles short, one-flowered; the flower-stalks are very short; the cups single, and every flower furnished with four styles .- Native of the low lands of Jamaica.

Euonymus; a genus of the class Pentandria, order Monogynia .- GENERIC CHARACTER. Calix: perianth oneleafed, five-parted, flat; divisions roundish, concave. Co-45.

closing one roundish softish seed .- Native of the woods of lix. Stamina : filamenta five, subulate, upright, shorter than the corolla, placed on the germen, as it were on a receptacle. Antheræ twin. Pistil: germen acuminate; style short, simple; stigma acute. Pericarp: capsule succulent, coloured, five-sided, five-cornered, five-celled, five-valved. Seeds: solitary, ovate, involved in a berried aril. Observe: The fructification in some individuals or species takes away a fifth part of the number. In some there are no filamenta, except the points of the receptacle. ESSENTIAL CHARACTER. Corolla: five-petalled. Capsule: five-sided, five-celled, fivevalved, coloured, Seeds ; calvptred, or veiled, ---- The species are.

1. Euonymus Europæus; Common Spindle Tree. Flowers mostly four-stamined; peduncles compressed, many-flowered; stigmas awl-shaped; leaves smooth, bluntly servate; angles of the capsules blunt. The common spindle-tree, when growing in hedges, is seldom seen of any considerable size, but is a shrub; if planted single, however, and properly trained, it will have a strong woody stem, and rise more than twenty feet high, dividing into many branches; leaves lanceolate, about three inches long, and au inch and a quarter broad in the middle, opposite, entire, of a deep green colour. The flowers come out at the end of May or in the beginning of June, in small bunches from the side of the stalks, on slender peduncles; the petals are whitish, and spread in the form of a cross; the seeds are pale flesh, or rose-coloured; the fruit ripens in October, at which time the seed-vessels spread open and expose the seeds, which being of a beautiful red colour, these shrubs then make a good appearance. The wood is said to be used by the musical instrument makers, for skewers and tooth picks; the branches should be cut when the shrub is in blossom. for it is then tough, and not easily broken ; in that state it is also used by watchmakers for cleaning watches. No animal but the goat browses upon it; the berries are said to be fatal to sheep; they vomit and purge violently; when powdered and sprinkled upon the hair, they destroy lice. From its uses for skewers it has the name of prickwood; Gerarde calls it prick-timber; it is also called house berry, dogwood, and gatteridge-tree, by which latter names it is confounded with cornus sanguinea; the Germans call it spindlebaum; the Swedes, alster; the Dancs, beenved; the Italians, fusaggine; the Spaniards, bonetero, bonete de clerigo; the Portuguese, barrete de clerigo; and the Russians, mereskletiana, keslianka, swida, sedlini, beresdren. This, with the second, third, and fourth species, may be propagated either by seeds or lavers : if by seeds, they should be sown in autumn soon after they are ripe, then the plants will come up in the spring following ; but if the seeds are not sown till spring, the plants will not appear till the spring following, whereby a whole year is lost. The seeds should be sown upon a shady border, where they will succeed better than when they are more exposed to the sun, and when the plants appear, they will only require to be weeded till the following autumn, when as soon as the leaves decay, the plants should be taken up, and transplanted into a nursery, in rows two feet distant, and the plants one foot asunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain. When they are propagated by layers, the young shoots should be laid down in autumn, and if the joint which is laid deepest in the ground be slit, as is practised for carnations, it will cause them to put out roots much sooner than they otherwise would do; these layers will be sufficiently rooted in one year to bear transplanting, when they should be taken from the old plants, and treated in the same way as the seedlings ; the cuttings of these sorts, planted rolla : petals five, ovate, flat, spreading, longer than the ca- in a shady border, will take root, but they should be planted 6 T

in autumn, as soon as their leaves begin to fall; they should reture, entire; stem shrubby, uprighr; leaflets branched, be the shoots of the same year, with a knot of the former scarce a fathom in height; branches alternate, round, upright, year at bottom.

EUO

2. Euonymus Latifolius; Broad-leaved Spindle Tree. Most of the flowers five-stamined, bark smooth ; peduncles filiform, cylindric, many-flowered; (leaves sharply serrate; angles of of the capsules sharp.) This species rises with a stronger stem than the first species, and grows to a larger size; the leaves are ovate-lanceolate, about four inches long, and two broad in the middle, opposite, entire, light green, on short footstalks : the flowers come out from the side of the branches upon very slender peduncles, two inches and a half long, branching out into a loose bunch, and the flowers on separate pedicels; petals five, at first white, but changing to nurple: the same number predominates in the other parts of the fructification: the fruit is much larger than that of the common sort, and the peduncles being weak, it always hangs down. This plant was seldom seen in England, until Mr. Miller procured it from France, and it is now become very common in the nurseries .- Native of Austria, Hungary, and most of the southern parts of Europe. See the first species.

3. Enonymus Verrucosus ; Worked Spindle Tree. Flowers four-stanioted; bark warted; pednacles filtform, cylindric, with about three flowers. This species differs from the two first, in having the stem and branches warted, the upper surface of the petals covered with a pile consisting of very small teats; the antheræ rounded, and placed upon their pyrminidal fiburenta, like the cap of a mustroom. It flowers in May and Jane,-Native of Austria and Carniola. See the first species.

4. Euonymus Attopurpnerus; Purple-flowered Spindle Tree. Flowers fon-stammed; peduncles compressed, manyflowered; stigmas four-sided, truncate. This shrub is about six feet high, with an ash-coloured bark, smooth, and free from tubercles; the branches are round, and-a little compressed at their extremities: the leaves are oblong-lanceolate, smooth on both sides, veiny on the back, and stand opposite, they are very fuely serated on the edges, where they are of a purple tinge, as are also the footstalks; the common peduncles are bidroons, slender, and branchy, the proper ones red.—Native of the northern parts of Asia. See the first species.

5. Euonymus Americanus; Evergreen Spindle Tree. All the flowers five-cleft; leaves sessile. It rises with a shrubby stalk to the height of eight or ten feet, dividing into many branches, which come out opposite from the joints of the stem; leaves lanceolate, two inches long, and about three quarters of an inch broad in the middle, ending in acute points, they are opposite, and continue green all the year; the flowers are produced at the ends of the branches, and also from the sides, in small clusters, and are succeeded by round capsules, which are closely armed with rough protuberances. It flowers in July, but seldom produces ripe fruit in England. There is a variety in the nurseries with variegated leaves. As they are evergreen shrubs, they deserve a place in every curious garden, and particularly in all plantations .- It is a native of North America, and is so hardy, that it rarely suffers by the cold of our winters, provided it be not very much exposed. It may be propagated by laying down the young branches in the autumn, observing to tongue them in the same manner as is practised in laying of carnations; these will have made good roots in one year, when they may be cut from the old plants, and planted for two years in a nursery, in order to acquire strength, after which they should be planted where they are designed to remain.

6. Euonymus Tobira. Flowers five-cleft; leaves oblong,

retuse, entire; stem shrubby, upright; leaffets branched, scarce a faithon in beight; branches alternate, round, upright, leaffest; branchlets alternate, upright, green, smooth, leafy; lowers at the ends of the branchlets aggregate, in a kind of umbel, upright; petals five, seldom six, white, smelling like orange-flowers, oblong-owste, blunt, entire, patulous; stamina seldom six: the whole plant is rather milky.—Native of Japan.

7. Enonymus Japonicus. Flowers four-cleft; leaves ovate, obluse, sortate; siem shrubby, ercet, strict, ash-coloured, naked, a fathom in height; branches opposite, from upright spreading, green, but little leafy; branchlets decusate, leafy, sort, green; fowers axillary, panicle1; panicle trichoto-mous, decompound, divaricate, subfasigiate; peduncle anglecicels angular, smooth, compressed; corolla four-petalled, white, patulous; petals rounded, concave, entire, a line in length; stamin four. It varies with leaves spotted with white; the flowers appear in June and July, and the frait prens in November and December-Matixe of Japan.

8. Euonymus Chinensis, Stem scandent; leaves threelobed; peduneles many-flowered; stem herbaceous, long, climbing by tendrils; flowers white; calix five-cleft, spreading; petals five, oblong-ovate, spreading, longer than the calix.—Native of China, where it is found near the suburbs of Canton.

Euparce ; a genus of the class Pentandria, order Monogynia.-GENERER. Calit: perianth fice-leaved; leaftet lanceolate, acute. Corolla: petals five or twelve, oblong, natrow, spreading, longer than the calit. Stamina: filamenta five. Antheræ not described. Pisfdl: germen roundish, superior; sivle bristle-shaped, long; stigma simple. Pericarp: betry juiceless, globular, crowned with the permanent siyle, one-celled. Sæds: very many, roundish, snall, adhering to ag iobular, finogous, free; receptalce in the middle of the berry. ESENTIAL CHARACTER. Calix: fiveleaved. Corolla: five or twelve-petalled. Berry: superior, one-celled. Sæds: very many, adhering to a free receptacle. ---The only species hitherto known is.

1. Expare: Amena: which is a procumbent annual plant, having the appearance of nummularia, but being only one-fourth of the size; the flowers have the colour of those of anagalits planticea, or pimperael, but are many-petalled; the first, which Geartner in one place calls a capsule, and in another a jukeless berry, however it be pressed, will not open with regular valves, and is therefore nearly allied to triantalis; the seeds have a navel in the belly opposite to the embryo.— Native of New Holland, and Terra del Fuego.

Eupatorium; a genus of the class Syngenesia, order Polygamia Æqualis. - GENERIC CHARACTER. Calix: common, oblong, imbricate; scales linear-lanceolate, upright, unequal. Corolla: componed, uniform, tubular: corollets hermaphrodite, equal : proper funnel form ; border five-cleft, spreading, Stamina : filamenta five, capillary, very short. Antheræ cylindric, tubular. Pistil: germen very small; style filiform, very long, two-cleft almost to the germina, straight : stigmas slender. Pericarp ; none ; calix unchanged. Seeds ; oblong ; down plumose, long, (according to Gærtner, pilose,) only toothletted or ciliare. Receptacle; naked. ESSENTIAL CHA-RACTER. Calia : imbricate, oblong ; style cloven half-way, long. Down : plamose. Receptacle : naked. This genus consists principally of tall-growing, perennial, herbaceous plants; the greater part of the old sorts are natives of North America; many, however, of South America, and the West indies, whence come most of the new sorts. Several are found wild in the East Indies, and one on Ely in Europe. The two first, and a few other species, are shrubby. Some

* Calices four-flowered.

1. Eupatorium Dalea; Shrubby Hemp Agrimony. Leaves lanceolate, veined, obscurely serrate, smooth ; stem shrubby. This species rises to the height of nine or ten feet or more : it has a moderately thick woody stem, and throws out its branches in a pretty open position. It flowers with us in August, and is frequently met with on the lower hills of Liguanea in Jamaica. This plant is remarkable for the very pleasant odour which it emits from every part, which continues for many years, even when dried. This, with the first, second, fifth, sixth, seventh, eighth, ninth, fifteenth, seventeenth, eighteenth, nineteenth, twenty-second, twenty-fifth, twenty sixth, twenty-seventh, twenty-ninth, thirtieth, thirtyfirst, second, third, fourth, fifth, and thirty-ninth, forty-first, second, third, fourth, fifth, sixth, seventh, eighth, and fortyninth species, being tender, should be planted in pots, and kept constantly plunged into the tan-bed in the stove, where they will thrive and flower. These may be propagated by cutting off some of their young shoots, about the middle of June, when they have strength, planting them in pots filled with light earth, and plunging them into a moderate hot-bed, where, if they be shaded from the sun, and gently watered as they may require it, they will put out roots in six weeks, and may then be transplanted into separate pots, and treated like old plants. When the seeds of these tender sorts can be procured from their native countries, the plants raised from them are much preferable to those which are obtained by any other method, and will flower much stronger; but as these seeds seldom grow the first year, few persons have patience enough to wait for the plants coming up. When any of these seeds are brought over, they should be sown as soon as they arrive, in pots, that they may be removed at any time : the pots should be plunged into a moderate hot-bed, and the earth kept tolerably moist ; the glasses should also be shaded in the heat of the day, to prevent the earth from drying. In this hot bed the pots may remain till autumn, when, if the plants are not up, they should be plunged between those in the bark-stove, and removed in the spring to a gentle hotbed, which will bring up the plants soon after. When they are fit to remove, they ought to be planted in separate small pots, and plunged into the hot-bed again, shading them from the sun till they have taken new root; then they should have a large share of free air admitted to them in warm weather, and frequently refreshed with water. In the winter these plants should be more sparingly watered, especially those, the stalks of which decay. In the summer they require a large portion of free air, with which they will thrive and flower.

2. Equatorium Parviflorum. Shrnbby: leaves ovateharceolete, serrate, smooth; corymbs spreading: calces three flowered. This strongly resembles the preceding species, but the leaves are oblong, the flowers smaller, the calces constantly three flowered, and the whole plant almost wide of scent.-Native of Jamaica, where it is much more common than the first species, growing in the same situations. For its progragation and culture, see the first species.

3. Eupatorium Hyssopifolium; Hyssop-leaved Hemp Agri mony. Leaves lanceolate, hnear, three-nerved, almost entire. This species rises with an upright round stalk, to the height of three feet, sending out several branches towards the top,

which come out regularly by pairs. The flowers stand upon long peduncles at the ends of the branches, some sustaining one, some two, and others three or four flowers, which are white, and appear late in autumn .-- Native of Carolina, Virginia, and Maryland; and found also in Japan. This, together with the fourth, tenth, eleventh, fourteenth, sixteenth, twenticth, twenty-fourth, twenty-eighth, thirty-sixth, thirtyseventh, thirty-eighth, and fortieth species, are hardy plants, and are propagated by sowing the seed in the full ground ; but there must be care taken in the sowing to keep the sorts separate; for, as the seeds of these plants have a light down adhering to them, they are easily displaced by the least wind ; so that the best way will be to sow them in drills, which should be shallow, for when the seeds are buried too deep, they will not grow. The bed in which these are sown should not be too much exposed to the sun, but rather have an eastern aspect, where the morning sun only reaches them; but when more exposed, they must be shaded with mats in the heat of the day, and the ground should be kept pretty moist; for, as they generally grow in moist shady situations in their native countries, they will of course succeed better where they have a soil and situation somewhat like that; though, as we want their heat in summer, the plants will thrive here when exposed to the sun, provided they have a moist soil, or are supplied with water in dry weather. When the young plants come up, they must be kept clean from weeds, and where they are too close, some of them should be drawn out, to give room for the others to grow, and if these be wanted, they may be planted in another bed, where they are shaded and watered, and they will soon take root; after which, they will require no farther care, but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are intended to remain. As the roots of these plants spread out to a considerable distance, they should not be allowed less than three feet distance from any other plants, and some of the largest growing should be allowed four feet. If the soil in which they are planted is a soft gentle loam, they will thrive much better, and flower stronger than in light dry ground, in which, if they are not duly watered in dry summers, their leaves will shrink, and their stalks will not grow to half their usual height. All the species above enumerated have perennial roots, by which they may be propagated; and as some of them do not perfect their seeds in England, that is the only way of increasing the plants here : some of the sorts have creeping roots, sending out offsets in great plenty, so these arc easily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing which, great care should be taken not to injure the old plants, or cut them too much, which would cause them to flower weak in the succeeding year. The best time to remove these plants is in autumn, as soon as they have done growing, that they may get fresh roots before the frost comes on; but if the frost should commence soon after their removal, if the surface of the ground is covered with tan or dried leaves to keep out the frost, it will effectually secure them ; and if this be done to the old plants in very severe winters, it will always preserve them; however, it may not be infudicious to practise this on the young seedling plants, which have not so good roots, nor are so well established in the ground : the future culture will be only to dig the ground about them every spring, and keep them clean.

4. Eupatorium Scandens; Climbing Hemp Agrimony. Stem twining; leaves cordate, ovae, attenuated, crenatetoothed; lobes divaricate; branches smooth; stems annual, twisting about any neighbouring support, to the height of five or six feet. At each joint two small side-branches come out, I terminated by clusters of white flowers, so that the stalks seem covered with them most part of their length; but as these come out late in the season, unless the summer prove warm, this plant does not flower well in England .- Native of Virginia and Carolina; and also, it is supposed, of the East Indies. This species is sometimes killed by severe weather in our climate, when left uncovered. When the stalks therefore decay in autumn, the ground should be covered with some old tanner's bark. It multiplies very fast by its creeping roots, which may be parted every other year. For further particulars respecting its propagation and culture, see the third species.

5. Eupatorium Volubile. Leaves cordate-ovate, crenate. acute; lobes parallel; stem twining; branches and petioles villose. This differs from the preceding, in having the branches, petioles, nerves of the leaves underneath, and peduncles, villose, the leaves less attenuated, with the lobes not divaricated, but parallel, the egret purplish, but not hoary. There is another eupatorium from Madagascar, exactly like this, except that it is entirely smooth .--- Native of the East Indies. See the first species.

6. Enpatorium Denticulatum. Leaves cordate, rugged. minutely toothletted : branches angular ; stem climbing ; the branches have five acute angles, standing; leaves petioled, two inches long, bluntish, paler underneath, very finely and thinly haired, sometimes not toothed; corymbs terminating the branches and branchlets; pedicels umbelled, filiform, rugged, angular; calix four-leaved; leaflets linear, equal, shorter than the egret, which is purple,-Native of Surinam. See the first species.

7. Eupatorium Amarum. Leaves cordate-ovate, acuminate, quite entire, subtomentose underneath; flowers corymbed ; stem climbing ; branches the thickness of a swan's-quill, smooth, striated; branchlets axillary, a hand in length, flower-bearing ; leaves petioled, three inches in length and breadth, smooth, and nerved above, beneath slightly tomentose, with stellate hairs, visible only with a magnifier, and having veins standing out; the leaves on the branchlets are an inch long, and become gradually smaller towards the top; corymbs from the extreme axils of the leaves on the branchlets, and from the end; seeds four, angular; egret longer than the calix, purplish .- Found in the Caribbee islands by Martfelt, and in Surinam by Rolander. See the first species.

8. Eupatorium Houstoni ; Houston's Hemp Agrimony. Stem twining ; leaves ovate, quite entire ; stalks slender, twining, eight or ten feet high, sending out small opposite branches at most of the upper joints ; lower leaves heart-shaped, ending in acute points; upper almost triangular, smooth, and of a lucid green. The upper part of the stalks has long branching stalks of white flowers, which are small and sessile .- Imported from Jamaica. See the first species. ** Calices five-flowered.

9. Eupatorium Zeylanicum; Ceylon Hemp Agrimony. Leaves ovate, hastate, petioled, toothed; leaves alternate, narrower at the base, with small rounded ears bent in, green, and smooth on the upper surface, tomentose, and veined on the lower lip like sage. The corymbs of flowers resemble those of the eupatoriums : the fructifications, however, want to be examined more critically .- Native of Ceylon. See the first species.

10. Eupatorium Sessilifolium ; Sessile-leaved Hemp Agrimony. Leaves sessile, stem-clasping, distinct, lanceola'e; stems slender, round, smooth; leaves in two pairs, at two inches' distance, sessile, two inches long, mucronate, resembling those of mint, slightly toothed on the edge; flowers minute; style longer. The flowers smell like those of caca-

terminating, corymbed, in many little heads, white, slender, It flowers in September and October .- Native of Virginia. See the third species.

11. Eupatorium Album ; White Hemp Agrimony. Leaves lanceolate-serrate; leaflets of the calix lanceolate, scariose at the end, and coloured; stem erect, streaked, scarcely pubescent; leaves opposite, subsessile, almost naked; corynib terminating, composed of alternate subdivided branchlets, fastigiate, and white; down simple .- Found in Penusylvania by Bartramand, and by Thunberg in Japan. See the first species.

12. Eupatorium Chinense : Chinese Hemp Agrimony. Leaves ovate, petioled, serrate; stem somewhat angular, flexuose, erect, smooth, but little branched, a foot high or more : leaves opposite, sharp, entire at the base, pale underneath, nerved, smooth, spreading, an inch and more in length: flowers in a fastigiate and roundish panicle .- Native of China and Japan.

13. Eupatorium Japonicum; Japonese Hemp Agrimony. Leaves undivided, and three-lobed, servate: stem scabrous: stem round, streaked, erect, branched two feet and upwards in height; branches alternate, panicled, from erect patulous like the stem; leaves opposite, petioled, the lower threelobed, the upper undivided, ovate, sharp, unequally serrate, sometimes entire, paler underneath, nerved, scabrous, a finger's length, the upper ones gradually less; petioles half an inch in length; flowers on the branches and branchlets terminating, in ovate panicles, on very short peduncles .- Native of Japan.

14. Eupatorium Rotundifolium ; Round-leaved Hemp Agrimony. Leaves sessile, distinct, roundish, cordate. It rises with upright stalks about a foot high; the joints are near each other, and at every joint is a pair of leaves, of a light green colour, and serrate. The flowers are produced in small loose panicles at the tops of the stalks, they are white, and have two small leaves immediately under them. The flowers appear at the end of June, but the seeds seldom ripen in England .- Native of New England and Virginia. See the third species.

15. Eupatorium Stipulaceum. Leaves hastate, acute at both ends, three-nerved, stipuled ; flowers corymbed ; stem climbing ; stem very smooth, and very finely streaked ; leaves an inch and a half or more in length, mucronate, acuminate at the base, veined, very smooth above, beneath appearing very slightly villose with a magnifier; lobes ovate, acute, oblique behind, having frequently one or two minute teeth. -Native of Brazil. For the propagation and culture, see the first species.

16. Eupatorium Altissimum : Tall Hemp Agrimony. Leaves lanceolate, perved, the lower ones a little serrate on the outmost part; stem undershrubby. This rises with a single, upright, green stalk, about four feet high; at each joint are four leaves in whorls, they are six inches long, and two inches broad in the middle, lessening to both ends, terminating in acute points, rough, serrate, and on short footstalks ; stem terminated by a close corymb of purple flowers, appearing in July, and continuing till September .- Native of North America. See the third species.

17. Eupatorium Hastatum ; Hastate-leared Hemp Agrimony. Leaves cordate-hastate, somewhat toothed, naked; stem twining; flowers in spikes; stem shrubby, branched, striated, pubescent; leaves petioled, opposite; petioles also puhescent ; racemes axillary, opposite ; flowers spiked in whorls, four in a whorl, white; calix four-leaved; leaflets lanceolate ovate, convex; corollets four; stamina extremely

lia suaveolens, and the taste of the whole herb is bitter. | the road to Eltham, and Mr. Woodward has since observed bouring bushes .- It is frequent about St. Thomas's, in the see the first species.

East, and Manganeel in Jamaica. See the first species. 18. Eupatorium Syriacum ; Syrian Hemp Agrimony. Leaves opposite, subsessile, ternate; stems straight, round, four or five feet high, purplish, striated ; branchlets come out at a right angle almost over the whole stem ; flowers in erect compound corymbs. It flowers in October: the flavour is unpleasant, and bitterish .- Native of the West Indies. See the first species.

19. Eupatorium Trifidum. Leaves three-parted, the floral ones undivided; stem climbing; corymbs from the upper axils, and at the top, on long peduncles, compound; partial peduncles and pedicels subpubescent; calix smooth, fiveflowered ; leaflets smooth, about ten, linear, the five outer ones very short .- Native of the Caribbee Islands. See the first species.

20. Eupatorium Trifoliatum ; Three-leaved Hemp Agrimony. Leaves in threes ; stem slender, cylindric, rigid, hairy on the upper part ; flowers very small, as in the other species, but they have not the calices so long, nor are they so exactly disposed in umbels, but rather like the common red valerian .- Gronorius found it in Virginia; Vernon brought it from Maryland; Miller says that it grows in Pennsylvania; Krocker, that it is found in Silesia, and that it is like our common European sort, except in having leaves in threes, and white flowers. See the third species.

21. Eupatorium Cannabinum; Common Hemp Agrimony. Leaves digitate: stems three or four, and even six feet high, hairy, reddish, branched; leaflets three or five, lanceolate, sharply serrate on the sides, entire at the base and top, slightly hairy, the middle one much larger than the others; scales of the calix few, not more than ten, unequal, linear, red on the edge, a little hairy; flowers in thick umbels or corymbs at the top of the stem or branches; florets five, and sometimes six together, of a pale red or purple colour; seeds black, streaked, smooth, little more than a line in length; egret sessile, with simple rays, not three lines long; the rays, when viewed with a glass, are finely toothed, or shortly ciliate. The stem has a pleasant aromatic smell when cut. The flowers have a strong smell, and the whole plant has a very bitter taste : a handful of it vomits and purges smartly. An ounce of the root in decoction is a full dose, and is sometimes taken in the jaundice and dropsy; but it is a rough medicine, and ought to be used with caution. Boerhaave gave an infusion of this plant to foment ulcers and putrid sores ; and Tournefort informs us, that the Turks cure the scurvy with it. Withering says, that an infusion of about a handful of the leaves vomits and purges briskly; and adds, that the Dutch peasants make use of it in smaller doses, as an alterative or purifier of the blood, and against the scurvy. Meyrick affirms, that the fresh-gathered root boiled in ale purges briskly, but without producing any bad effects; and there are, says he, many instances of its having cured the dropsy. It is also a good wound-herb, whether bruised and applied to the parts, or made into an ointment with hog's lard. Goats are the only cattle that appear to eat this plant. On the banks both of running and stagnant waters, frequently in most parts of Europe, flowering in July and August. In Johnson's edition of Gerarde, it is named common Dutch agrimony. There is a variety which is the seedling, and has oval-lanceolate leaves : it sometimes flowers in that state, but not often : the second year it bears leaves in threes. Professor Martyn found this variety with simple leaves, but forgot the place. Dillenius met with it afterwards, before you come to Lee, in linear leaflets, of a brown ferruginous colour, and at the 45.

It is a climber, and stretches a great way among the neigh- it near Bungay in Suffolk. For the propagation and culture,

*** Calices eight-flowered.

22. Eupatorium Coriaceum.' Leaves elliptic, coriaceous, smooth, toothed on the outside; petioles an inch long, dilated at the base; corymbs terminating, superdecompound; common peduncle pubescent; pedicels having minute scales scattered on them towards the base; calix seven-flowered; the outer scales ovate, shorter; the inner longer, linear; egret purplish, twice as long as the calix, almost simple, supposed to be a native of South America. See the first species,

23. Eupatorium Cinereum. Calices seven-flowered; leaves opposite, lanceolate, tomentose. This very much resembles an athanasia in its flowers and woody rigid stem. Thunberg found it at the Cape of Good Hope.

24. Eupatorium Purpureum; Purple Hemp Agrimony. Leaves in fours, scabrous, lanceolate ovate, unequally serrate, petioled, wrinkled; stem cylindric, green, but purplish at the base of the petioles; corymb terminating; calices fleshcoloured ; corollas whitish ; antheræ purple ; style very long, It grows to the height of three feet or more, with a suffruticose, upright, striated stem, but little branched. The leaves are subsessile, and of a very dark green. The corymb of flowers is fastigiate. The calix has about eight flowers. The receptacle is narrow, convex, scrobiculate, smooth. The seeds are small, four-cornered, columnar, acuminate at the base, with the streaks and angles rugged with dots, and whitish, the interstices smooth and livid; egret capillary, very minutely toothletted .- Native of North America and Cochin-china. See the third species.

25. Eupatorium Diffusum. Leaves ovate, serrate, threenerved; panicle very much branched and diffused. The whole plant is smooth; panicle terminating, large, a foot long; the last pedicels capillary; at all the ramifications opposite narrow leaves, becoming gradually smaller; calicine leaflets lanceolate, the outer ones shorter; corollets eight; egret white, the length of the calix .-- Native of South America. See the first species.

26. Eupatorium Nervosum. Leaves elliptic-lanceolate. attenuated, toothed, triple-nerved, smooth on both sides; calices many-flowered .- Native of Jamaica. See the first species.

27. Eupatorium Rigidum. Leaves petioled, ovate, acute, serrate-toothed, rigid, rugged underneath; stem subherbaceous .--- Native of Jamaica. See the first species,

28. Eupatorium Maculatum; Spotted Hemp Agrimony. Leaves in fives, somewhat tomentose, lanceolate, equally serrate, veined, petioled; stem annual, about two feet and a half high, purple, with many dark spots upon it; leaves rough, placed by threes towards the bottom of the stalk, but near the top by pairs at each joint ; flowers purple, terminating in a sort of corymb, appearing in July and August, and in warm seasons, ripening the seeds in autumn ; egret simple or capillary .- Native of North America. See the third species.

29. Eupatorium Auriculatum. Leaves ovate, toothletted. tomentose underneath ; petioles eared ; stem climbing ; flowers in spikes : stem woody ; branches striated, tomentose, hoary, becoming bald with age; petioles tomentose, half an inch in length, with a half-ovate tomentose earlet at the base on each side; the flat floral-leaves having only a rudiment of these; spike compound, flexuose, axillary, and terminating ; spikelets alternate; flowers usually in pairs, distant; in the axils of the branches of the spike single ; calix smooth, with eight

6 U

base a few minute tomentose scales; corollets seven; style longer by half than the corollet; egret a little longer than the calix, white, when magnified serrate. Annual.—Native of Brazil, Guiana, Jamaica, &c. See the first species.

EUP

30. Eupatorium Molle. Leaves petioled, cordate, acute, subserrate, pubescent; stem herbaceous, tomentose.—Native of Jamaica. See the first species.

31. Expatorium Villosum. Leaves opposite, decussated, ovate, subsertale, beneath villose, tomenose; calices eight to fifteen-flowered; stem shrubby; branches softly villose; corymbs terminating, decompound; peduncles and pedicels single, tomentose; at the ramifications short, bristle-shaped leaves; calicine leaflets linear, pubescent; corolles small, as far as sixteen; seeds the length of the calix, with a dirty-coloured egret, longer than the calix.—Native of Jamaica and Domingo. See the first species.

32. Eupatorium Cordifolium. Leaves cordate, serrate, tomentose, hirsute underneath; petioles very short; corymbs subsessile; calices squarrose; stem shrubby.—Natives of Jamaica. See the first species.

33. Eupatorium Montanum. Leaves cordate, acute, toothletted, petioled, rugged, hirsute underneath; corymbs much spreading; stem shrubby.—Natives of Jamaica. See the first species.

34. Eupatorium Canescens. Hoary: leaves ovate, sub-lobed and entire, underneath very soft and three-nerred; corymbs simple. This is a branching shrub; the branches spreading, hoary, and very soft, as are also the tops of the branches; corymbs from the ends of the branches; corymbs from the ends of the branches and branchitts, few-dowerd; calix cylindrical, subvillose; leaf-lets linear, obtuse, with pale streaks, the outer ones shorter; forets ten; seed black, when magnified appearing angular, with minute villose hairs scattered over it.—Observed in the first species.

35. Expantorium Scabrum. Villose: leaves opposite, petioled, ovatc, mostly entire, wrinkled, scabrous on the upper surface. The stem scems to be undershrubby; it is uprght, branched, roundish, streaked, villose, scabrous, leafy, manyflowered; branchets opposite, angular, bearing flowers at the end. No stipules; panicles terminating, uprght, rough with hairs, many-flowered, contracted; peduncles opposite; pedicels mostly alternate; bractes lanceolate, rough with lairs; flowers uprght); calità cylindric, smooth; scales oblong, obtuse, three-nerved, somewhat callous at the tip; the outer ones shorter and brader; florets seven or eight, scarcely longer than the calix, five-sided; seeds black, with a down, scarcely the length of the corola, serrate, hardly feathered, spreading.—Gathered by Mutis in New Granada. See the first species.

**** Calices with fifteen or more Floscules.

36. Expatorium Perfoliatium; Perfoliate Henp Agrimony, Leaves counate, perfoliate, tomentoie; stems annual, from two to three feet high, hairy. The upper part of the stalk divides into many slender pedluncles, each sustaining a close closter of white flowers, coming out in July. The seeds will sometimes ripen in England.—Native of North America. See the third species.

37. Eupatorium Celestinum; Blue-flowered Hemp Agrimony. Leaves cordate-ovate, obtusely serrate, petioled; calices many-flowered. This has a creeping root, which spreads and multiplies very fast. The stalks rise about two feet high. The flowers are produced at the top of the stalks in a sort of corymb, and are of a fine blue colour,—Native o Maryland. See the third species.

38. Eupatorium Aromaticum ; Aromatic Hemp Agrimony.

Leaves ovate, obtunely serrate, petioled, three-nerved; calices simple; stem round, four feet high, strict, brachinte, having the appearance of scutellaria; leaves somewhat wrinkled; racemes terminating; flowers twice the length of the calix, snow-white, containing from eighteen to twenty-eight florets; the styles scarcely longer than the floret: in this eircumstance it differs from the other species, and in having the calix not imbricate, but the leaflets almost equal.—Native of Virginia. See the third species.

39. Eupatorium Macrophyllum. Leaves heart-shaped, three-nerved, serrate undernealth, pubeccent; stem also pubescent; stem the thickness of a swar's-quill, striated, pubecent; petioles from two to three inches in length; corymba terminating, and axillary, pedancied, decompound, close; calix loosely imbirate; the leafters lanceolate, pale green, very finely streaked,—Native of the Caribbee islands. See the first species.

40. Eupatorium Ageratoides; Nettle-leaved Hemp Agrimony. Leaves ovaries, serrate, petioled; stem smooth, annual, five or six feet ligh, towards the top putting out sidebranches. At the ends of the shoots the flowers are produced in large tufts, and are of a pure white; they appear in October.—Native of North America. See the third species.

41. Eupatorium Conyzoides. Leaves orate, attenuated, sharply seriet, three-nerved, smooth above; calices closely imbricate; branches straited, pubescent; corymb terminating almost simple, few-flowered; partial peduncies three-flowered; pedicels one-flowered.—Supposed to be a native of South America. See the first species.

42. Eupatorium Odoratum; Sweet-scented Heup Agrimory. Leaves deltoid, toolked at bottom, fomentose underneath; calices unary-dowered; stem a fathom in height, shrubby, branched, even; if hovers terminating, subcorymbed, white; seeds linear, slightly compressed with a capillary egret. This weakly shrubby plant is generally observed to grow among other bushes, where it frequently casts its long, slender, flexile, opposite branches to a underate distance. The flowers are sometimes imperfectly resembling that of the European meadow-sweet.—It flowers in August and September, and is very common in the island of Jamaica. See the first species.

43. Expatorium Triplinere. Leaves lanceolate, triplenerved, quite entire, smooth; stem round, smooth, very finely streaked, branching, spreading, flower-bearing; panicle terminating, subtrichotomous; partial peduncies escarely pabescent; the last pedicels an inch long, filform, with a minute leaf at the base of each; calix many-leaved; leaflets linear, nearly qual, acute, villose, and purplish at the tip; the outmost shorter; florets more than twenty, purple at the top.—Sent from the island of Santa Cruz.

44. Eupatorium Ivarfolium. Leaves narrow, lanceolate, Inter-enerved, subscrate; calices squarrose, many-flowered; stem subherbaceous, two feet high, erect, strict, branched, hispid; branches simple, elongated; peduncles terminating and in the axis of the upper leaves opposite, filtiorm, mostly trichotomous, but the last one-flowered; flowers small, blue. —Common in Jamaica. See the first species.

45. Eupatorium Urticzfolium ; Nettle-leared Henp Agrimony. Hispid: leaves perioled, cordate, gash-serrate; panicle terminating; calices many-flowered, awl-shaped, somewhat purgent. This plant appears very much like a nettle at first sight, but the leaves are three-nerved at the base; stem upright, brunched, round, streaked, hairy, leafy; pelioles scarcely the length of the leaves, angular, equal. No stipules; panicle like a cyme, upright, hairy; pedicles late or crowded; bracks limear, few; flowers upright, pale purple; calix subcylindric, patulous, pubescent; scales keeled, three-nerved, attenuated at the edge, the outer ones smaller; floscuels little longer than the calix; sceds black; in early two feet high, having towards the bottom larevs of a link down shorter than the corolla; viewed with a glass, appearing to be minutely serrate.—Native of New Granada. See the first species.

46. Eupatorium Stoechadifolium. Tomentose : leaves petioled, linear, crenate, hoary underneath; panicle terminating; stem upright, roundish, covered with a soft, thick, white down. No stipules : panicles upright, somewhat like corymbs, conglomerate; peduncles opposite, variously divided, woolly; bractes none, except a pair of leaves, smaller than the rest at the base of each panicle; flowers purple; calix cylindric, woolly at the base; scales sharp, with a green line along them, membranaceous and ciliate about the edge, the inner ones somewhat tongue-shaped, the outer lanceolate and smaller; floscules very numerous, the length of the calix, a little swelling, five-sided; segments from erect spreading, sharpish, quite entire, scarcely pubescent; antheræ included; style scarcely half cleft; down shorter than the corolla, yellowish, scabrous .- Native of New Granada. See the first species.

47. Eupatorium Microphyllum. Leaves triangular, ovate, with nine notches, tomentose and veined underneath; panicle conglomerate, terminating ; peduncle elongated ; stem undershrubby, woody, ascending, a little branched, leafy, round, subhirsute; petioles the length of the leaves, hairy; no stipules; panicle on a long peduncle, resembling a corymb; pedicels variously divided, rough, haired; bractes two at the first ramification of the panicle, usually lanceolate, but sometimes of the same form with the leaves ; flowers purple, fewer than in the foregoing; calix subcylindric, scarcely pubescent at the base; all the scales lanceolate, sharp, nerved, attenuated and ciliate at the edge, the outer ones smaller and thicker: floscules scarcely the length of the calix, swelling at top, not angular; segments from erect spreading, bluntish, entire, closely pubescent on the outside; antheræ included; style scarcely half cleft; seeds brown; egret almost the length of the corolla, hardly rugged when viewed through a glass : the flowers resemble those of the preceding in structure, but differ in several characters .- Native of New Granada, See the first species.

40. Eupatorium Squarrosum. Leaves subcordate, ovatecate, seriate; calices squarrose; stems a futhom in height, round, subtomentose, with opposite branches; flowers in racemes, on axillary three-flowerde peduncles; calix cylindric, with nary lanceolate-acute striated leaflets, the outer ones reflex at the tip, and containing about twenty-four florets; corolla twice as long as the calix; if oreits greenisil yellow, with short, orate-acute, pathlous segments; seeds small, obong, striated, with very small hairs; egret sessile, obscurely feathered, shorter than the corolla. Native of Mexico. See the first species.

49. Euplatorium Sinuatum. Leaves ovate, sinuate, hairy, alternate; calies eight-flowered, or thereabouts; stem suffutitiose, three feet high, erect, hispid; leaves toothletted; flowers purplish, in terminating panicels; receptatel concave. —Native of the island of Mozambique, on the constol of Africa. Besides the species above caumerated, Mr. Miller describes five sorts which were sent to him from Vera Cruz by Dr. Houston, viz. 1. Enpatorium Fruitcosum, with oblong corfade leaves; flowers in panicles; stem shrubby, climbing, It rises to the height of ten or twelve feet; the leaves are opsite, and about three inclues long and n inclu and a half broad, of a lucid green; the panicles are long and branching, and proceed from the side of the statks; the flowers white.

smooth leaves, and simple calices. It rises with an upright stem nearly two feet high, having towards the bottom leaves of a thick substance; from the upper part, which is naked, the flowers come out in a thick panicle, they are of a blue colour, and appear late in autumn ; the root is biennial. 3. Eupatorium Morifolium, with heart-shaped servate leaves, and an upright tree-like stem. It rises twelve or fourteen feet high, sending out many channelled branches, covered with a brown bark; leaves as large as those of the mulberry-tree, of a light green colour, opposite, on petioles near two inches long; branches terminated by four or five peduncles, which come out opposite from the joints, there is also an odd one at the end, these sustain branching panicles of white flowers, forming a long, loose, pyramidal thyrse, without any leaves intermixed, and making a fine appearance, 4. Eupatorium Punctatum, with ovate-petioled entire leaves; stem shrubby, branching; calices simple; stems near five feet high, dividing into many slender branches, the joints of which are three or four inches asunder, at each of these is a pair of leaves about three quarters of an inch long and half an inch broad, baving several black spots on their surface, and upon long slender footstalks. the branches are horizontal, terminated by small bunches of white flowers; the calices are composed of seven narrow lanceolate leaflets, divided to the bottom. 5. Eupatorium Paniculatum, with heart-shaped, wrinkled, crenate leaves, and a panicled stem. It rises with an upright branching stem three feet high, sending out two side-branches from the joint, almost the length, these are terminated by loose spikes of red flowers, as is also the principal stem ; the leaves are rough, sessile, of a light green, and a little hoary. 6. Eupatorium Convzoides may probably be the same with kuhnia conyzoides of Linneus.

Euphorbia; a genus of the class Dodecandria, order Trigynia .- GENERIC CHARACTER. Calix: periauth one-leafed. inflated, somewhat coloured, four-toothed at the mouth, and in some few five-toothed, permanent. Corolla : petals four. in some few five, turbinate, gibbous, thick, truncate, unequal in situation, alternate with the teeth of the calix, with their claws placed on the margin of the calix, permanent. Stamina: filamenta several, twelve or more, filiform, jointed, inserted into the receptacle, longer than the corolla, breaking forth at different times. Autheræ twin, roundish, Pistil : germen roundish, three-sided, pedicelled; styles three, twocleft; stigmas obtuse. Pericarp : capsule roundish, tricoccous, three-celled, starting open elastically. Seeds : solitary. roundish. ESSENTIAL CHARACTER. Corolla: four or fivepetalled, placed on the calis. Calix: one-leafed, bellying; capsule tricoccous .- This genus consists of milky plants, which are mostly herbaceous, several however are shrubby, upright, for the most part very few of them creeping, some leafless, but most of them leafy; stems angular, or tubercled, or more frequently cylindric or columnar, unarmed, or in the angular sorts resembling the upright cactuses, and armed with prickles, which are either solitary or in pairs, placed in a single row on the top of the ridges; such as have leaves have them simple, most frequently alternate and naked ; in some sorts, however, they are opposite, and are then commonly attended with stipules, and in a few they are placed by threes in whorls ; peduncles in the leafless sorts naked, bearing from one to three flowers, in the leafy ones axillary, but more frequently from two to five or more, in a terminating umbel, each sometimes in a many-flowered head, but more frequently dichotomous, trichotomous, or even tetrachotomous, with single flowers between the divisions, at the base and in the forkings having bractes, in number the same with the

536

neduncles, forming a sort of involucre. Jussieu doubts whether each stamen being jointed and accompanied with chaffs, and breaking forth at different times, may not, as in box, be considered as so many one-stamined male flowers, encircling one female flower in a common calix or involucre : if so, the flowers of euphorbia should be regarded as compound, and the plants as belonging to the class Monœcia.----The species are.

* Shrubby, prickly.

1. Euphorbia Antiquorum; Triangular Spurge, Almost naked, triangular, jointed; branches spreading; stem triangular, compressed, succulent, rising to the height of eight or ten feet, and sending out many irregular spreading twisting branches, for the most part three-cornered, but having some two and others four angles; at their extremities are a few short roundish leaves, which soon fall off, and near these come out now and then a few flowers, which have five thick whitish petals, with a large three-cornered germen in the centre, they soon drop off without producing seeds. It grows naturally in the East Indics, whence the plants were brought to the gardens in Holland, and thence communicated to most of the curious gardens in Europe. This has generally been mistaken for the true euphorbium, and consequently directed to be used in medicine; but it is from the second sort that the drug now imported under that name in England is taken. Linneus supposes the seventh to be the sort which should be used; but as they are all nearly of the same quality, it may be indifferent from which this drug, which is the inspissated juice of the plant, is taken. There is a variety with a naked, three-cornered, compressed stalk, sending out a great number of erect branches, which are also generally three-cornered, but sometimes four-cornered; they are armed with short crooked spines, but have no leaves, not have the plants produced here. It is also a native of India. The plants included from the first to the twenty-fifth species. and which form the two first divisions of this vast genus, are in general known by the name of euphorbium ; the others, before Linneus appeared, were mostly known by the name of *trithamylus* or *spurge*. These plants are introduced into the gardens of the curious, principally on account of the oddness of their structure, which is entirely different from that of any European production : they are all full of a milky acrid juice, which will soon raise blisters, and flows out of the plant when wounded in any part. This juice will burn linen almost as much as aqua fortis, the plants ought therefore to be handled with great caution, nor should the ends of their branches be ever bruised or injured, for if they be, it frequently causes them to rot down to the next joint, and will sometimes destroy the whole plant, if those injured branches be not cut off in time; so that whenever the branches appear to have been injured, the sooner they are cut off from the plants, the less danger there will be of their suffering from it, nor should any of the branches be cut between the joints, for the same reason. The Dutch imported most of these plants into Europe: that people, it must be confessed, have been very curious to introduce great numbers of plants from India, and also from the Cape of Good Hope : from the last-mentioned place a great variety of valuable plants have been recently brought, many of which produce very elegant flowers, and are the greatest ornaments of the conservatory in the winter and spring seasons. These have been brought over in seeds; but most of the different sorts of euphorbia came over in plants or cuttings, which may be easily transported to any distance, if either of them be secured in boxes, with any soft dry package to prevent their being bruised, or their spines from wounding each other, and defended from Canary Islands, this grows to the height of twenty feet or

wet and cold, for they will live thus six months out of the ground, and if carefully replanted take new root, and thrive as well as if they had been just cut off from the old plants, or taken out of the ground, which is a much more expeditious method of obtaining the plants, than from seeds, when they can be procured. The greatest part of these succulent plants grow naturally upon barren rocky places, or in dry sandy soils, where few other plants will thrive, therefore they should never be planted in rich or loamy earth in our climate, nor suffered to receive much wet, which will soon rot them. The best mixture of earth for these plants is, about a fourth part of screened lime-rubbish, a fourth part of seasand, and half of light fresh earth from a common ; these should be mixed well together, and frequently turned over before the mixture is used, that the parts may be incorporated, and the compost sweetened by being exposed to the air. If this mixture be prepared a whole year before it is wanted, it will be the better, that it may have the benefit of the winter's frost and the summer's heat to mellow it : and the oftener it is turned over, and the smaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for use. These plants are easily propagated by cuttings, which should be taken from the old plants in June ; these must be cut off at a joint, otherwise they will rot. When the cuttings are taken off, it will cause the milky juice of the old plants to flow out in plenty, therefore there should be some dry earth or sand applied to the wounded part, which will harden and stop the sap; and the wounded part of the cuttings should also be rubbed in sand, or dry earth applied upon the wounded part, for the same purpose; the cuttings should then be laid in a dry part of the stove for ten days or a fortnight; and some of those whose branches are large and very succulent, may lie three weeks or more before they are planted, that their wounds may be healed and hard-ened, to avoid the rot. The cuttings should be each planted in small halfpenny pots, laying stones or rubbish at the bottom, and filling them with the mixture before directed, then plunge the pots into a moderate hot-bed, aud if the weather be very hot, the glasses of the hot-bed should be shaded in the middle of the day, and the cuttings gently watered once or twice a week, according as the earth may dry; in about six weeks or two months the cuttings will have put out roots, so if the bed is not very warm the plants may continue there, provided they have free air admitted to them every day; otherwise it will be better to remove them into the stove. where they may be hardened before the winter, for if they are too much drawn in summer, they are very apt to decay in winter, unless very carefully managed. During summer these plants require gentle waterings two or three times a week, according to the warmth of the season, but in winter they must be sparingly watered, and only once a week, especially if the stove is not warm. This first species will require more warmth in the winter than any of the other, and also less water, and if well managed, will grow seven or eight feet high; but the plants must constantly remain in the stove. receiving a large share of air in warm weather, and in winter a temperate degree of warmth. The annual sorts should have their seeds sown in the autumn; they will come up in the spring, and require no farther culture. The perennial sorts may be propagated either by sowing the seeds, or parting the roots, or by cuttings. They are most of them hardy enough to endure the greatest cold of this country, especially if they be planted in a dry soil.

2. Euphorbia Canariensis; Canary Spurge. Naked, subquadrangular; prickles in pairs .- In its native country, the more, but in England it is rarely seen more than six or seven; the stem is very thick, green, and succulent, and has four or five large angles, closely armed with black crooked spines, which come out by pairs at every indenture; it sends out from every side large succulent branches of the same form, which extend to the distance of two or three feet, and then turn their ends upwards, so that when the plants are well grown they have some resemblance to a chandelier, thry have no leaves, but are closely armed with black spines like the stem; at the ends of the branches come out the flowers in March and April. For its culture and propagation, see the first species.

3. Euphorbia Edulis; Fire-angled Spurge. Prickly, leaty, fore-angled, peduncles many-fowered, lerminating; flowers apetalnous; stem six feet bigh, with prickles in pairs, and ascending branches; leaves many, scattered, almost wedge-shaped, rounded at the tip, three inches long, quite entire, fleshy, smooth; corolla none; calix fleshy, ventricose, red within, green without; stamina short, about forty.—Native of Cochin-china, where the leaves are eaten boiled with other berbs. For the culture and propagation, see the first species.

4. Euphorbia Heptagona; Seven-angled Spurge. Naked, seven angled; spines solitary, subulate, flower-bearing; stem roundish, upright, succulent, about three feet high, putting out several branches on the side, of the same form ; the angles are armed with long, single, black spines; at the ends of the branches come out small flowers, which are sometimes succeeded by small fruit .- Native of the Cape of Good Hope, This species is at present exceedingly rare in England; those procured from Holland have been most of them destroyed by placing them in stoves, where by the heat they have in one day turned black, and rotted immediately after. It will however thrive well, if placed in a dry airy case, with other succulent plants, where they may have free air in mild weather, and be protected from frost; in summer the plants may be exposed in the open air, in a warm situation, but should be screened from much wet ; with this treatment the plants will thrive much better than when they are more tenderly nursed. For further particulars, see the first species.

5. Euphorbia Mammilairis; Warty-angled Spurge. Naked: angles tubered, with spines between. This differs from the preceding, in having the angles doubled, and swelling a little, and the spines single between the tubercles, which are placed longitudinally.—It flowers in July and August, and is a native of the Cape of Good Hope. This species, which are good glass-case without fire in winter, provided the frost be entirely excluded. In summer they may be placed abroad in a warm situation, and as they are very succulent plants, they should be they were were succulent plants, they should be they were, where they may enjoy the free air, and be screened from the rain, otherwise by receiving too much wer, they whill soon begin to rot, especially in winter. For further particulars respecting its propagation and culture, see the first species.

6. Euphorbia Cereiformis ; Noked Sparge. Naked, manyungled; spines solitary, subvalute. This sort has stalks and branches very like those of the next sort, but much more lender; the spines of this are single, and those of the others foulde, and the ends of the branches in this are closely set with flowers on every angle. It flowers in June and July, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species. 45. 7. Exphorbia Officinarum; Officinal Spurge. Naked, many-angled prickles doubled. This puts out many stalks just above the surface, which are thick, succulent, and round-ish, having eight or ten angles whilst they are young, but as they grow old they lose their angles and become round; the branches grow distorted and irregular, first horizontal, but afterwards turning upwards; the angles are armed with small crocked spines, and on the upper part of the branches, in June and July, come out the flowers; they are small, and of a greenish while—Native of Africa. For its propagation and culture, see the first species. Gerarde calls it the poison seg sum thisle.

8: Euphorbia Triaculeata; Three-prickled Spurge. Prickly, maked : stem round, grooved; prickles in threes. This is a shrub of a cubit high, spreading, and branchy; branches about the thickness of a finger, subtated longitudinally; in the interjacent channels are inserted three prickles, of which the exterior are very slort, and bent downwards, the middle one about an inch long, subulate, spreading, and curring downwards; the flowers spring by threes from the bosoms of the prickles, and are sessile; the stainina is in number, two in each angle of the flowers.—Native of Arabia. For its propagation and culture, see the first species.

9. Euphorbia Nerificial: Olemader-leated Spurge. Angles obliquely tubercled; stem upright, strong, five or six iect high, with irregular angles, and protuberances oblique to the angles, the lower part is naked, and the upper part is branching; the branches are armed with crooked spines; at every protuberance, and at the top, are oblong leaves of a lucid green, very smooth, entire, and rounded at the end, these fall off in spring, and the plants remain maked for some months, and then in June and July the flowers come out; the ysit close to the branches, and are of a greenish white colour; the leaves come out in the autumn.—Native of the least Indies and Cochin-china, where it is much used for hedges, on account of its strong thorns. For its propagation and culture, see the first species.

** Shrubby, unarmed; Stem neither dichotomous nor umbelliferous.

10. Euphorbia Melofornis; Melon Spurge. Subglobase, many-anglei trunk fielsly, Intere inches in diameter, smooth; ridges eight, ten, or more, broad at the base, and keeled; keels flower-bearing, marked with scars of the peduncles and with glands alternately; peduncles cylindric, the thickness of a pigeon's quill, jointed, with very slort villose hairs scattered over them, usually first trichotomous, then dichotomous, seldom simple.—It flowers from May to Sptember, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

11. Euphorbia Caput Meduse; Medusa's Head Spurge-Imbricate tubercles, furnished with a linear leaf; howers subpeduneled; petals palmate. It has thick, roundish, succulent stalks, which are scally, they send out many branches from their sides of the same form, which are twisted, and run over one another, so as to appear like a parcel of serpents, which gave it the name of Medusa's head; at the end of these are narrow, thick, succulent leaves, which drop off, and round the upper part of them the flowers come out, these are write, and of the same form with those of the other sorts, but larger, and are frequently succeeded by first. There are several varieties of this species; that called little Medusa's head; has a the fashert stalk, sellow more hum they of sheet mixing in branches, about a foot in length, intermixing and having the same appearance with the other, but smaller, and much G X shorter; the ends are beset with narrow leaves, between which the while flowers come out.—It is a native of Africa. This species will require to be supported, to prevent the weight of the branches from drawing them upon the pots, and by training the stems up to stakes, they will grow four or five feet high, and a great number of side-branches will be produced. For further particulars respecting its propagation and culture, see the first and fifth species.

EUP

12. Euphorbia Clava; Club Spurge, 'Imbricate: tubercles furnished with a lauceotale leaf; flowers peduncled; petals quite entire. This is a perfectly smooth species, abounding with a miky joice, which seems to be but slightly acrid; stem and branches erect, and round, gradually thickening upwards, till they arrive at the diameter of an inch; leaves sessile, spatule-shaped, and elongated, very entire, and about four inches long, with a prominent back-rub; peduncles oneflowered, axillary, solitary, coated with lanceolate bractes.— It flowers from January to August, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

13. Euphorbia Anacantha; Scaly Spurge, Imbricate: Inbercles furnished with a roundish leadt; fowers terminating, solitary, sessile; pictals palmate. This is one of the smaller shrubby species, and has a scaly and tuberous branched stem; lite petials are each three-toolked; the leaves are extremely small, few, and are chiefly produced lowards the top of the branches; the flowers are large in proportion to the plant, and spring to the number of three or four, from the top of some of the upper branches, which in this species are covered over with prominent tubercles, and thick scales. If dowers in September and October.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

14. Euphorbia Mauritanica; Barbary Spurge. Halfmaked, shrubby, fillform, faccid: leaves alternate; stems many, taper, succulent, about four feet high, and requiring support; they have a light green bark, and their lower parts are naked, but their upper parts have oblong, smooth, entire leaves, placed alternately on every side; flowers in small clusters at the ends of the branches, of a yellowish green colour, and sometimes succeeded by smooth round frait, but the seeds rarely ripen in England. It grows naturally on the African shore of the Mediterranean. For its culture and propagation, see the first and the fifth species.

¹5. Euphorbia Piscatoria; Sanoth Spran-Leaved Spurge, Shrubby, strict: umbels five-cleft, terminating; involucels oblong; leaves linear, even.—Native of Madeira, and the Canaries. For its propagation and culture, see the first species.

16. Explorbia Glabrata; Smooth Spurge. Unarmed, shrubb, branched: leaves opposite, overleacute, smooth, quite entire. The whole of this plant is smooth; stem erect, urarmed, jointed, purplish; branches dichotomous, covered with leaves at bottom; flowers at the ends of the branchlets, axillary, and at the divisions solitary, small, peduncled; capsule nearly the size of a coriander seed, smooth, and quite even.— Native of the Caribbee islands. For its propagation and culture, see the second species.

17. Euphorbia Linitólia; *Plaz-leared Spurge*. Stem saffruitose; leaves opposite and alterate, linear-lanceolate; peduncies from the top of the stem and branches, in fives or thereabouts, unbelled; calix smooth, as is also the throat; petals obvate, truncate, yellowish green; capsules smooth, quite even, the size of a small pea.—Native of the island of Dominica. For its culture and propagation, see the first species.

18. Euphorbia Cuneata. Shrubby: leaves oborate; peduncles lateral, three-flowered; stem unarmed; branches round, smooth, with an ash-coloured bark; leaves petioled, several from the tubercles of the branches, unequal, smooth, veinless, quite entire.—Native of Arabia Felix. For its propagation and culture, see the first species.

EHP

19. Euphorbia Balsamifera; Balsam Spurge. Shrubby, strict: head terminating; leaves lanceolate, even, glaucous, --Native of the Canary Islands. For its propagation and culture, see the first species.

20. Explorbia Timealli; Judian Sparge Tree, Half-naked, shrubby, filtorm, erect: branches patulous, crowded in an orderly manner; stem taper, succulent, eighteen or twenty feet high, sending out many branches of the same form, subdividing into many smaller, they are jointed, but at great distance, smooth, and of a deep green colorn, having a few small leaves at their extremities, which soon fall off. As the plants grow older, their stalks become stronger and less succulent, especially towards the bottom, where they turn to a brow colour, and become a filter wordy. It does not produce any flowers here.—Naive of the East Indies, For its promacation and culture, see the first species.

21. Euphorbia Tithymaloides. Shrubby : leaves in double rows, alternate, ovate. This is a wandlike suberect plant, six feet high, the whole of it abounding in a white, bitterish, milky juice; stems numerons, round, smooth, weak, very pliant, branched, the thickness of a finger or of the thumb, the older ones ash-coloured, the younger green; peduncles one-flowered, short, aggregate about the extremities of the branchlets, coming out principally when the plant is without leaves; flowers void of scent, of a beautiful scarlet colour, and on account of their singular structure, perhaps rightly claiming to form a distinct genus, although possest of the same characters with the other euphorbia. Mr. Miller makes two species of this, under the names tithymalus myrtofolius, aud lauro cerasifolius, or myrtle-leaved and laurel-leaved The first grows naturally near Carthagena in spurge. S. America, whence Mr. Robert Millar, surgeon, sent the branches, which were planted here, and succeeded, rising into shrubby succulent stalks to the height of twelve or fourteen fect; but though often as large in circumference as a man's finger, they were too weak to sustain the weight of their succulent leaves, which bore down the unsupported branches. The leaves are oval, and terminate in acute points. they are two inches and a half long, and one inch and a half long near their base, about the thickness of bay-leaves, and are ranged alternately on two sides of the branches, to which they sit close. The flowers are produced at the end of the branches, three or four together; they are of a scarlet colour, monopetalous, and shaped like a slipper. The South Americans give a strong decoction of this plant, particularly of the stalks, in venereal cases, and in suppressions of the menses. -It is a native of the Caribbee islands, and of the neighbouring continent. The langel-leaved spurge grows naturally in Barbadoes, and most of the other islands in the West Indies, where the English inhabitants know it by the title of poisonbush : this has thick, shrubby, succulent stalks, which will grow to the height of ten or twelve feet: these are larger than those of the former sort, and are garnished with oblong oval leaves, ending with blunt points; they are above three inches long, and an inch aud a half broad in the middle, of a very thick consistence, and of a dark green colour, ranged alteruately on two sides of the stalk. The flowers grow at the end of the branches, and are of a deep red colour, slippershaped like the other variety. This variety abounds with an acrid milky juice, which will draw blisters wherever it is apinformed, becomes a deadly poison, when mixed with the blood, so that if the points of arrows, or the edges of swords, he rubbed with this juice, it ensures the death of any animal wounded by those weapons. For the propagation and culture of this species and its varieties, see the first species.

22. Euphorbia Heterophylla: Various-leaved Spurge. Leaves serrate, petioled, difform, ovate, panduriform or dichotomous, with a bifid umbel. This is an annual plant, Some of the leaves are narrow, from two to three feet high. and entire, others ovate, and divided in the middle almost to the midrib, in shape of a fiddle; they also vary in colour, some being inclinable to purple, others of a light green, and their footstalks are short. The flowers are produced in small umbels at the ends of the branches; they are of a greenish white, and are succeeded by small round capsules.—It grows naturally at La Vera Cruz. For its propagation and culture, see the first species. Morison speaks with admiration of the heterogeneous leaves in this plant, a circumstance which is since found not to be uncommon, particularly in plants from the South Seas. He speaks of this species of spurge as attaining the height of a man, even in this country, with a trunk an inch or more in thickness, spreading out into straight, loug, pliant branches, having some leaves three or four inches long, and narrow, resembling those of the narrow-leaved willows, others on the same branch soft, like those of an atriplex or orach, tending to a sea-green colour, sinuated, and from an inch to two inches in breadth. Varieties are observed in this plant, some having a reddish, and somewhat wrinkled bark, whilst in others it is green and smooth ; the leaves also being subject to vary much. This being shrubby, and so large a plant, cannot be the annual species first described. and is introduced here for the sole sake of the curious and intelligent botanist.

23. Euphorbia Cotinifolia ; Venice Sumach-leaved Spurge. Leaves opposite, subcordate, petioled, emarginate, quite entire ; stem shrubby. This is an annual plant, rising with an upright stalk, about a foot high, and dividing into a great number of branches, which spread very wide on every side. The flowers come out singly from the divisions of the stalks ; they are small, of an herbaceous colour, and are succeeded by small round capsules. - Native of Vera Cruz in South America. For its propagation and culture, see the first species.

24. Euphorbia Ocymoidea ; Basil-leaved Spurge. Herbaceous, branching : leaves subcordate, quite entire, shorter than the petiole; flowers solitary. This is an annual plant, rising with an upright stalk, about a foot high, and dividing into a great number of branches, which spread very wide on every side; leaves roundish, heart-shaped, on pretty long footstalks. The flowers come out singly from the divisions of the stalk; they are small, of an herbaceous colour, and are succeeded by small round capsules .- Native of South America. This, with the twenty-fifth, and eighth, thirtieth, thirtysecond, third, fourth, fifth, and sixth, and the forty-sixth, are annual, and must have their seeds sown upon a hot-bed in the spring, and when the plants are fit to remove, they should he planted separately in small pots filled with light earth, and plunged into the hot-bed again; they must afterwards be treated in the same manner as other tender annual plants from hot countries.

25. Euphorbia Lævigata. Shrabby, branched : leaves opposite, oblong, obtuse, smooth, quite entire. The whole of this plant is smooth; stem unarmed; branches dichotomous at the end, three and four times divided ; leaves on short pe-

plied to the flesh ; and, says Mr. Miller, I have been credibly one side of the base, terminated by a minute dagger-point, even, veinless, glaucous, green ; peduncles at top, from the forks of the branchlets, solitary; flowers small; capsule smooth, even, the size of a coriander-seed .- Native of the East Indies. For its propagation and culture, see the preceding species.

3. Dichotomous .- With a bifid umbel, or none.

26. Euphorbia Origanoides; Marjoram Spurge. Leaves serrulate, ovate, obtuse, three-nerved ; panicle terminating ; stems simple. This plant cannot at first sight be distinguished from marjoram .- It is a native of the island of Ascension, and the Friendly Isles.

27. Euphorbia Atoto. Dichotomous: leaves ovate, quite entire; umbel terminating .- This is an annual plant, and a native of the Friendly Islands.

28. Euphorbia Hypericifolia; St. John's - Wort - leaved Spurge. Leaves serrate, oval-oblong, smooth ; corymbs terminating ; branches divaricate. It rises about two feet high, with a branching stalk; peduncles axillary, alternate, erect, dichotomous, commonly longer than the leaves, with the flowers crowded together ; calix very minute. This is a weed found in most of the cultivated grounds in the West Indies; every part of it is poisonous to some .- For its propagation and culture, see the twenty-fourth species,

29. Euphorbia Mellifera ; Honey-bearing Spurge. Leaves scattered, lanceolate-acute, even ; peduncles dichotomous ; capsules muricated. It flowers in April and May .-- Native of Madeira.

30. Euphorbia Prostrata ; Trailing Red Spurge, Leaves oval, obscurely serrate ; peduncles axillary, with about three flowers; stems diffused, smooth; flowers on short pedicels, often in threes, but sometimes solitary; petals purple .- Native of the West Indies. For its culture and propagation, see the twenty-fourth species.

31. Euphorbia Maculata; Spotted Spurge. Leaves serrate, oblong, hairy; flowers axillary, solitary; branches patulous. This is an annual, acrid, and milky plant, flowering in gardens in the open air, and readily springing from seed. The stems are very numerous, spreading closely on the ground .- Native of Jamaica.

32. Euphorbia Hirta; Creeping Hairy Spurge. Leaves serrulate, ovate, acuminate; peduncles in axillary heads; stems hairy; flowers crowded together, pedicelled, minute; calix blood-red .--- It is a native of both Indics, and recom-mended by Browne as a powerful resolutive and deobstruent, operating by promoting perspiration, and the urinary discharge, For its propagation and culture, see the twenty-fourth species.

33. Euphorbia Pilulifera, Leaves serrate, oval-oblong; peduncles in two axillary heads; stem upright .- Native of India. See the twenty-fourth species.

34. Euphorbia Hyssopifolia; Hyssop-leaved Spurge. Leaves subcrenate, linear ; flowers fascicled terminating ; stem upright,-It flowers in August and September, is annual. and a native of the West Indies. Browne extols a decoction of this plant as an active warm medicine, after a passage is procured, in the dry belly ache, by bathing in warm water, or on any occasion where resolutive medicines are required. See the twenty-fourth species.

35. Euptorbia Thymifolia ; Thyme-leaved Spurge. Leaves serrate, oval-obloug; heads axillary, glomerate, subsessile; stems procumbent. The whole plant resembles thyme, is annual, and a native of India. For its propagation and culture, sec the twenty-fourth species.

36. Euphorbia Parviflora. Leaves scrrate, oblong, tioles, longer than the internodes, shorter and narrower on smooth; flowers solitary; stem erectish, alternately branched ; peduncle axillary, an iuch long, alternate, sustaiuing a leaves. The involucer is of the same form with the leaves ; few very small flowers. The leaves have frequently a brown but the involucels are obliquely cordate.—Found in Savoy, spot; calices purple; petals white. Annual, and a native of and about Montpellier. India. See the twenty-fourth species.

EUP

37. Euphorbia Canescens. Leaves entire, roundish, hairy ; flowers solitary, axillary; stems procumbent. Annual, and a native of Spain, particularly in the province of La Mancha.

38. Euphorbia Chamæsyce ; Crenated Annual Spurge, Leaves crenulate, roundish, smooth ; flowers solitary, axillary ; stems procumbent ; seeds roundish, angular, black .--Native of the south of Europe, especially of the kingdom of Valencia in Spain, also of Siberia and Mesopotamia, and by the way-sides, and in barren fields in the West Indies.

39. Euphorbia Rubra. Leaves wedge-shaped, emarginate, imbricate; umbels bifid; corollas five-petalled; root annual; seeds whitish, with red grooves .- Native of Spain, near Aranjuez, flowering in April and May.

40. Euphorbia Granulata. Dichotomous : leaves opposite. oblong, quite entire ; flowers solitary, axillary, procumbent. -Native country unknown.

41. Euphorbia Peplis; Purple Spurge. Leaves quite eutire, semicordate ; flowers solitary, axillary ; stems procumbent; root long, slender, fibrous; seeds smooth, tipped with It is annual, and flowers in July and August. purple. Gerarde calls it Isope spurge .- Native of the south of France, Spain, Carniola, and found also on the sea-coast of England, between Penzance and Market-Jew in Cornwall, and near Exmouth in Devonshire.

42. Euphorbia Polygonifolia; Knotgrass-leaved Spurge. Leaves opposite, quite entire, lanceolate, obtuse; flowers solitary, axillary; stems procumbent. Annual .-- Native of Maryland and Virginia.

43. Euphorbia Graminea. Leaves lanceolate, elliptic, petioled, quite entire; stem upright; peduncles dichotomous; calix bell-shaped, hirsute within; petals two, roundish, quite entire, white : capsules shining, smooth, small,-Native of wet grassy places near Carthagena in New Spain.

44. Euphorbia Ipecacuanhæ. Leaves quite entire, lanceolate ; peduncles axillary, one-flowered, equalling the leaves ; stem upright; root creeping; calix thick .--- Native of Virginia and Canada.

45. Euphorbia Portulacoides ; Purslain leaved Spurge. Leaves quite entire, oval, retuse; peduncles axillary, oneflowered, equalling the leaves; stem upright .- Native of Philadelphia

46. Euphorbia Myrtifolia ; Myrtle-leaved Spurge. Leaves quite entire, roundish, emarginate, hoary underneath; flowers solitary; stem upright .-- Native of the cooler mountains of Jamaica. See the twenty-fourth species,

47. Euphorbia Imbricata. Umbel dichotomous, bifid ; involucels roundish, mucronate; leaves obovate, imbricate, serrulate; stem fruticulose. This is a small shrub, a little more than a hand in height, branched at the base; branches simple, round, covered with leaves, toothletted where the leaves fall, smooth, as is the whole plant ; petals quite entire ; stamina numerous; filamenta whitish .-- Native of Portugal.

4. Umbel trifid.

48. Euphorbia Peplus; Petty Spurge. Umbel dichotomous; involucels ovate; leaves quite entire, obovate, petioled; root annual; stem upright, nine inches high, round, smooth, and branched; at bottom harder, more slender, and of a reddish colour, leafy, and milky; branches few, not growing in any regular order, the lower ones longest. It is a native of most parts of Europe, in kitchen-gardens, and other rich cultivated soil. It flowers in July and August. There is a variety of this species, which has ovate-lanceolate sharp

49. Euphorbia Falcata. Umbel dichotomous ; involucels subcordate, mucronate; leaves lanceolate, bluntish .- Native of the south of France, Switzerland, Germany, and Austria.

50. Euphorbia Exigna ; Dwarf Spurge, Umbel dichotomous; involucels lanceolate; leaves linear; root annual; stem upright, branched, very leafy, about six inches high; branches from the lower part of the stem; leaves pressed to the stem, ending very sharp ; umbel trifid, quadrifid, seldom quinquifid, dichotomous. This small and delicate species is found in corn-fields in many parts of Europe, flowering from July to September. There is a variety, which Linneus affirms to be sharp-leaved, on hills, and retuse in meadows. Cavanilles, on the contrary, says, that he has found the latter on sandy hills, and the former in corn-fields; and Krocker observed both in corn-fields.

51. Enphorbia Obliterata. Leaves oblong, trapezoid, serrate, pubescent, obliterated on one side of the base : stems hirsute .- Native of Carthagena in New Spain, found also on the sandy coast of Jamaica.

52. Euphorbia Tuberosa. Involucre four-leaved ; stem naked ; leaves oblong, emarginate ; root tuberous ; leaves nearly an inch and a half in length, and almost half an inch in breadth, on petioles two or three inches long, springing from the root; they are blunt at the end, and sometimes emarginate. The stems are scarcely a hand and a half inheight, naked, dividing at top into two peduncles, each sustaining two flowers; there are two leaves at the division; capsules large, hairy .-- Native of Africa.

53. Euphorbia Divaricata. Umbel trifid or quadrifid; stem shrubby, trichotomous. This is a smooth lactescent species, with round shrubby brauches; the older ones ashcoloured, the younger reddish brown, marked by the cicatrices of the fallen leaves ; leaves very narrow, and lanceolate, obtuse, entire, with very short footstalks, and very numerous : the terminating umbels are generally trifid, with dichotomous rays; the leaves forming the smaller umbels are roundish; petals four, sometimes five, dull yellow, roundish, flat, and obtuse; perianth hairy; antheræ yellow, green; germen pale green ; capsule smooth .--- Native country unknown.

5. Umbel quadrifid.

54. Euphorbia Lathyris; Caper Spurge. Umbel dichotomous; leaves opposite, quite entire; stem upright, succulent, from three to four feet high, with oblong, smooth, sessile leaves; the upper part dichotomous, and an umbel comes out from each division; that in the first division being the largest. and those in the upper the smallest. The flowers are of a greenish yellow colour, appear in June and July, and the fruit follows soon after. It was common in our English gardens in the time of Gerarde, and is a native of France and Italy .-- This plant is vulgarly called the caper bush, and will become a weed in gardens where it is allowed to scatter its seeds; and when once introduced, requires no care, but to keep the young plants clean from weeds.

55. Euphorbia Terracina. Umbel dichotomous; leaves alternate, lanceolate, retuse, mucronate; root annual; stem herbaceous, more than half a foot in height, round; involucre consisting of about four leaves, which are oblong, ovate, blunt, broader than the leaves, scarcely serrate; involucels ovate-truncate at the base; petals yellowish, with two or three teeth; capsules smooth. From the lower axils of the leaves proceed barren branches .- Native of Spain and the south of France.

56. Euphorbia Diffusa: Spreading Spurge, Umbel fonr

or free-cleft, dichotomous; stem very much diffusci; leaves wedge-form, quite entire, alternate; root annual, of a slender fusiform figure; umbels four-cleft or five-cleft, with the rays several times dichotomous; the branches are sometimes divided into a similar umbel, and are sometimes very dichotomous; hence the plant when grow nu phecomes so spreading, and has such an abundance of branchlets and rays, as to give it an appearance quite different from what it had when young; flowers all fertile, solitary, in the divisions small, sessite; calis smooth, pale; petals four, yellow, two broader; gemen smooth; seeds brown, much wrinkled.—Found near Vienna, flowering from July to September.

57. Euphorbia Apios; Pear-roited Spurge. Umbel fourcleft, biid; involucels kidney-form; the first obcordate. It has a knobbed pear-shaped root, from which arise two or three stalks, about a foot and a half high; leaves oblong, hairy, alternate on every side of the stalk, "all high; leaves oblong, hairy, alternate on every side of the stalk, "and," genenish yellow, addom producing seeds here.—Native of the island of Candia. It may be increased by offsets from the main root: these may be taken off in autumn, and planted in a shady situation, where they will thrive better than in the full sun.

58. Euphorbia Læta; Mezereon-leaved Spurge. Umbel quadrifid or quinquefid, twice dichotomous ; first involucels oblong, upper ones rhomb-roundish ; leaves linear, lanceolate, subemarginate, quite entire. The whole plant is smooth; stem shrubby, round; leaves scattered, sessile, an inch and a half in length. The universal involucres resemble the leaves; involucels of the first division oval, oblong, somewhat emarginate, half the length of the leaves; those of the second division, and the floral ones, elliptic, roundish, emarginate. It flowers in June and July.-Native place unknown. This species, with the following, together with the seventy eighth, ninety-second, and ninety-fifth, may be propagated by cuttings during any of the summer months, and all require protection from frost in winter. The other perennials may be increased by parting the roots, or sowing the secds in autumn. They are most of them hardy enough to endure the greatest cold of this country, especially if they be planted in a dry soil.

6. Umbel quinquefid.

50: Euphorbia Genistoides; Broom-like Spurge. Unbel guique(ch, bifd; involuees) orate; leaves linear, erect; stem becoming shrubby. This is an upright shrub, with branches alternate, strict, very simple, short, bearing flowers at the very tip; involuere four-leaved; leaflets lanceolate, the length of the unbel; petals in form of a crescent; capsules smooth.—Native of the Cape of Good Hope. See the preceding species.

60. Exphorbia Spinosa; Prickly Spurge. Umbel subquiaquefid, simple; involucels ovate, the primary ones three leaved; leaves oblong, quite entire; stem shrubby. The branches, as they grow old, dry away, and continue on the pint, so that in appears as if it had thoras. The flowers are usually solitary; petals round; capsules warted.—Native of the Levant.

61. Euphorbia Epithymoides. Umbel quinquefid, bifid; involucels ovate; leaves lanceolate, obtuse, villose underneath.—Native of Italy and Austria.

62. Euphorbia Niceenensis. Umbel quinquefid, bifd ; involucels cordate, roundish, quite entire; leaves lanceolate, mucronate, subcoriaceous; root perennial; stems several, smooth, farm, somewhat woody, green, or reddish, either simple, or a little branched near the umbel, but without any involucer on the branches; rays of the umbel twice dichotomous, the last division two-flowered; in the axil ouc-flower; 46.

on the extreme branches two flowers, one yellow, with horned petals, and naked, the other green supported with two bracets, and abortive; capsules smooth, not grooved, large; universal involuere ovate, terminating in a prickle. It abounds in milk.—Native of the county of Nice, found also by Vahl about Pampeluna.

EUP

63. Euphorbia Dulcis: Steert Spurge. Umbel quinquefid, bitid, involucels subvate; leaves lanceolate, obtuse, quite entire; petals cuttre; fruit red, muricate. It varies with villose leaves; root consisting of little scaly bulbs; stem smooth, upright, simple, a foot high, red at bottom; involacres five-leaved, but sometimes four, three, and even two-leaved; flowers sessile; petals red, crescent-shaped, two horned; stamina two to five; caspane villose, warde below the middle. The milk of this plant is mild.—Native of the south of Europe.

64. Exphorbia Carniolica. Tays of the umbel nodding: involuces, and leaves lanceolate. The peculiarities of this species are, that the leaves are quite entire, spreading, sessile, acuminate, with the edges pellucid and red, that the leaves and rays of the umbels are very lax, that the colour is yellowish, that the flowers are all pedunded, and most of them barren, except those at the endy it was not of the part. The milk is mild. It flowers after the end of April.— Native of the shady meadows of Idria, about Friuli.

65. Euphorbia Tithynsas; Janiper-kancel Spurge. Umbel quinquefd, blifd; involuces ovate, mucroante; leaves lancolate, the lowest rolled in, imbireate backwards; stems shrubby, simple, many, vilose, a foot high. The dowers from the first division of the rays fertile, peduaded; petals reddish brown, lemispherical; capsules the size of a pea, echinated with soft reddish prickles.—It flowers in June and July, and is a native of the south of Europe.

66. Euphorbia Portlandica; Portland Spurge, Umbel dichotomous; involucels subcordate, concave; leaves linear. lanceolate, smooth, spreading; stems rather shrubby, a handbreadth or more high, smooth, cylindric, red, especially during the winter; branchlets lateral, those from the lower axils barren, at length growing up so as to overshadow the stem; flowers subsessile, yellow; the first and second male, having very blunt petals, without horns, the rest hermaphrodite, with horned petals. In the central flowers, the calix has five sides, and five blunt corners, with five slight clefts, and the segments are more or less toothed at the end : the petals are bairy within; the filamenta in number eight or nine; the germen subsessile on the lateral flowers; the segments of the calix are four; the petals four; the stamina fourteen or more; the filamenta surrounded at top with a ring. In all, at the base of the flower, are several flat, slender, shining, woolly substances, cloven at the end ; fruit smooth, with the angles muricate. It flowers from May till September, is marked as a shrub by Linnens, as perennial in the Kew catalogue, and as annual by Hudson and Withering. It abides two or three years in gardens, and was first found upon the narrow neck of land which joins Portland to Devonshire, and since near Exmouth in the same county, and in abundance upon the Cornish coast, and near Caernaryon in North Wales,

67. Empherbia Sasatilis; Rock Spurge. Umblel quinquefid, bitiq; involuces and involucels cordate; leaves oblong, smooth; stems five or six inches long, procumbent, and but very few in number, smaller, or secondary branches more numerous, each terminated by a rose of leaves, while the older or lower leaves fall away in succession, so as to leave numerous scars; branch-leaves lanceolate; top and flower-G Y

541

the plant is glaucous, except the bractes or round leaves, supporting the flowers .- Native of Austria.

EUP

68. Euphorbia Paralias; Sea Spurge. Umbel subquinquefid, bifid ; involucels cordate, reniform ; leaves imbricate upwards ; root perennial ; stems upright or ascending, numerous, generally red at bottom, thickly imbricated, with smooth fleshy leaves pointing upwards when wild, but open when cultivated, gradually increasing in size from the lower part of the stem upwards, the lower ones linear, linear-lanceolate, or oblong, sessile, the upper ones oval, lanceolate, half stemclasping ; involucre of five heart-shaped leaves ; petals entire ; capsules very large, smooth, according to Dr. Withering, rough, though all others say 'smooth, The juice of sea spurge is highly acrid, and, according to Gerarde, the most so of any species. He relates, that putting a single drop into his mouth his throat inflamed so, that he hardly escaped with his life by riding to the next farm-house, and drinking milk .- It is found on the sandy shores of Europe, and in Great Britain on the coasts of Essex and Kent, and between Southwold and Dulwich in Suffolk, and also in Cornwall,

69. Euphorbia Juncea; Linear-leaved Spurge. Umbel dichotomous ; leaves and involucres linear-lanceolate, acute ; involucels ovate-oblong, acuminate. It is nerennial, flowers in July, and is a native of the island of Porto Santo near Madeira.

70. Euphorbia Aleppica. Umbel dichotomons; involucels ovate-lanceolate, mucronate; lower leaves bristle-form; stems a foot and a half high ; flowers in large umbels, from the divisions of the stem, yellow, appearing in June, but rarely producing seeds in this country .- Native of Aleppo, and other parts of the Levant. The roots should be confined in pots; for when planted in the full ground, they creep to a great distance.

71. Enphorbia Pinea. Umbel dichotomous; involucels cordate : leaves linear, acuminate, crowded : cansules smoothish .- Native country unknown.

72. Euphorbia Segetalis; Corn Spurge. Umbel dichotomous; involucels cordate, acute; leaves linear-lanceolate. the upper ones broader; root annual; petals crescent-shaped; fruit smooth, except that it is scabrous at the corners. Villars describes it as from six to ten inches high ; the lower stem-leaves fall very soon, and sometimes barren branches spring from the bottom of it .- Native of Barbary and Russia, of the south of France, Austria, Silesia, and the county of Nice.

73. Euphorbia Taurinensis. Umbel quinquefid, bifid; involucre four-leaved, hanging down; leaves linear-lanceolate; stem branched; root annual; stems eight or ten inches ligh, erect, smooth, round, red at bottom; the terminating umbel has generally four rays, three or four inches in length, naked, and dividing again into pairs; where these divide, a single flower sits on a peduncle, about an inch in length; petals crescentshaped; the fruit is smooth, except at the angles .- It flowers from the beginning of April to the end of June, and is a native of Dauphiny,

74. Euphorbia Helioscopia: Sun Spurge, or Wartwort. Umbel quinquefid, trifid, dichotomous; involucels obovate; leaves wedge-form, serrate, smooth; capsules even; root annual; stem upright, from six to nine inches high, round, slightly hairy, having opposite branches at bottom ; involucre of five leaves like the other leaves; calix greenish vellow, with four or five yellow segments; pctals or necturies four, eutire, roundish, or oval, yellowish green; filamenta four- Jamaica, and produced in England. teen, two, three, or more, visible at a time; capsule smooth.

leaves round-cordate, all sessile; flowers smallish and vellow; flowering from July, through the autumn. The country neople call it wart-wort, churnstaff, and cat's-milk. 'The inice is very acrimonious, and hence is often applied to warts for the purpose of destroying them. It should be cautiously used where the parts are tender, particularly near the eyes, as it will inflame the face to a great degree. Linneus informs us, that when sheep eat it, they are purged by it, and their flesh acquires a bad taste, but that this is not the case with 0.018.9

> 75. Euphorbia Pubescens. Umbel quinquefid, trichotomous; involucels semicordate; leaves wedge-shaped, hairy, seriulate; capsules muricate; root annual. The top of the stem, the leaves, peduncles, and pedicels, are villose, and the capsules muricated, with small tubercles .- Found in cultivated grounds about Tunis.

> 76. Euphorbia Serrata : Narrow Notch-leaved Spurge. Umbel quinquefid, trifid, dichotomous ; involucels twolcaved, kidney-form; leaves stem-clasping, cordate, serrate, This is a foot high, and easily known by its oblong leaves, with frequent and sharp servatures. The leaves, however, vary very much, being sometimes cordate on the flowering stems, and linear on the branches and barren stems, and sometimes linear on all. The umbels are also sometimes three-rayed and bifid, with the involucres and involucels cordate-attenuate .- Native of the south of Europe.

> 77. Euphorbia Verrucosa; Warty-fruited Spurge. Umbel quinquefid, subtrifid, bifid; involucels ovate; leaves lanceolate, serrate, villose; capsules warted; root biennial; stems from eight inches to a foot in height, simple, cylindric, decumbent ; flowers of the first, second, and third rank abortive; petals four, entire, yellow; capsule very much warted. —It flowers in July, and is a native of corn-fields in the south of Europe, and the Levant. In Englaud it is found in Essex, near Gransden Lodge in Cambridgeshire, and also near York.

> 78. Euphorbia Punicea : Scarlet-flowered Spurge. Umbel quinquefid, trifid; involucels oval, acuminate, coloured; capsules smooth; leaves obovate, lanceolate. This most splendid plant, by far the most beautiful of the genus, is the height of a man; the stem shrubby, rather fieshy, full of milky juice, round, abruptly branched; the branches curved upwards, three together; the smaller branches sometimes four or five together; bark smooth, whitish, marked with spots or scars, where former leaves have grown ; leaves on the summits of the smaller branches crowded together, almost sessile, spreading in every direction, bluntish, ending in a small point, smooth, opaque, dark green, glaucous underneath; the younger ones turned inwards, and those nearest the umbels coloured; principal nerve of all the leaves dull yellow, and in the younger ones near the umbels it is besides stained with red ; umbels terminating, erect, having five, six, or seven rays ; peduncles club-shaped, smooth, dichotomous; involucels two or three together under each flower, of a most vivid searlet : flowers solitary, turbinate, vellowish, soon turning reddish; calix five-toothed; petals five, divaricated, vellow, full of very sweet pellucid honey; stamina fifteen or twenty, fertile, many, abortive; germen reflex; styles reflex, red; receptacle occupied by chaffy branched filamenta; capsule smooth .- It flowers in January, and was discovered in Jamaica, where it is not easily procured. It must be kept in the hot-house, and being so eminently beautiful, it is to be lamented that it is yet confined to the most choice collections, which is the more remarkable, as it not only may be increased by cuttings, but also grows readily from seeds, both sent from

79. Emphorbia Corollata. Umbel quinquefid, trifid, -Native of most parts of Europe, in cultivated grounds, dichotomous; involucels and leaves oblong, obtuse; petals membranaceous, erect; stem-leaves lanceolate, very obtuse; petals snow-white, spread out flat in fives, not shaped like a petal, but very slender.---Native of Virginia and Canada.

30. Explorbia Coralloides; Coral-stalked Spurge. Umbel quinquefid, triffa, dichtomous; involucels ovate; leaves lanceolate; capsules woolly; stems quite simple, annual, rush-like, upright; petals four, entire; capsules glabular, scarcely grooved, covered with a thin long white wool. —Native of Sicily, Barbary, and the Leavant.

81. Explorible Pilosa; *Hairy Spurge*. Umbel quinquefid, triffu, Hind; i woldcels ovarte; petals entire; leaves lanceolate, somewhat hairy, sernilate at the tip; root perennic]; the umbels are so confounded with the lateral numbelies, that the primary one is distinguished with difficulty; the petals and involucies are yellow; the primary flowers are male and forse-petalled, the rest hermaphrolite, and four-petalled; the petals are transversely oval; capsules warted, with very fine white hair scattered over them; there are barren branches from the lower axils of the leaves.—It flowers from May to August, and is a native of Siberia.

82. Euphorbia Orientalis: Willow-laved Spurge. Umbel quinquefi, quadrifid, dichotomous; involucels roundish, acute; leaves lanceolate; root perennial; stems many, succulent, three feet high, covered with a purple bark; the upper part of the stalks divides, and in the fork is situated an umbel of flowers of a greenish yellow colour, appearing in June, and ripening seed in Angust.--Native of the Levant.

83. Exphorbin Platyphyllos, Broad Natch-leaved Sporge, Umbel quinquefd, trifd, dichotomous; involucels hair; along the keef; leaves serrate, lanceolate; capaules warted; root annual; stem upright, from a foot to two or three feet high, smooth; petals entire, suborbiculate, yellow; germina obseurely warter [: a trifd unabelle grows from the axils of the leaves. The upper part of the plant is of a greenish yellow. -Native of Eugland, France, Gernamy, Switzerland, Aastria, Carniola, and Piedmont, in corn-fields. It has been found in England, at Black Notley in Easer between Harefield common and Battle's well; near Northheet; at Ripton in Huntingdomshire; and in the Isle of Wight.

84. Euphorbia Glauca. Umbel subquinquefid; involucres and involucels ovatc; leaves scattered, oblong-lanceolate, quite entire; stem frutescent. Native of New Zealand.

7. Umbel multifid.

13. Euphorbia Esula; Grommell-lawed Spurge, Umbel multifd, bird; involucels subcordate; petals obscurely two-horned; leaves on the barren and fertile branches the same, Perennial: stem a foot, eighteen incles, or two feet in height, upright, round, smooth, sea-green, much branched, leafy, All the flowers fertile, according to Linneus; but Scopolis, says, that those on the first divisions are male; petals four, yellowish, obscurely horned; capsules smooth, somewhat warted on the prominent parts: the milk is very acrid.— Native of France, Holland, Germany, Switzerland, Carniola, and Savoy.

36. Euphorbia Seguierii, Umbel multifd, bifd, dichormons; involucels kidney from, acuminate; petuls moond; capsules smooth; leaves lanceolate, acuminate; the lateral umbels so crowded together at the top of the stalk, as hardly to be distinguished from the primary one; the rays laft a foot long, angular, twice bifd; flowers between the branches barren and deciduous, the rest fertile and pedanciel; petais foor, red; capsule without warts or laivs, but romewhat wrinkled on the back of each lobe,—Native of lstria, Verona, and Piedmont.

87. Euphorbia Gerardiana. Umbel dichotomous; involucels roundish; petals quite entire; branches none; leaves all of one form. Perennial: stems procumbent, a foot in length; peduacles from the upper axils simple, fertile; flowers sessile, in threes; petals four, broad, blunt, truncated; capsnles smooth.—Native of Provence and Austria.-

88. Euphorbia Cyparissias ; Cypress Spurge. Umbel dichotomous; involucels subcordate; branches barren with setaceous, fertile with lanceolate leaves. This bears a great resemblance to the eighty-fifth species, and in the spring the umbels are very much alike; this however differs in being larger, in having leaves not all alike, but the upper ones, or those of the branches, bristle-shaped or linear, the lower or those of the stem lanceolate; the involucre consisting of about twenty leaves, which are broader ; the involucels twoleaved, ovate-cordate, yellowish or reddish; the petals crescent-shaped, yellow; capsules smooth according to some, and warted according to others. As the unbel withers, la-teral branches with very narrow fillform leaves grow up, resembling the pine,...-It is a native of the south of France, Germany, Austria, Carniola; Switzerland, and Piedmont, where it is found on hills by road-sides, and in dry barren places. It flowers from May to September in England ; and Parkinson informs us, that it was often found in the country gardens of poor folks, who knew it by the name of welcometo-our-house; from which we may presume it was a favourite plant, and probably then much used as a purgative. The spurges were at that time also much in request, not only for taking away warts, but for curing the leprosy, and other cutaneous disorders.

80. Explorbin Myrsinites; Glancows Spurge, Umbel with about eight bifid rays; involuceds subwate; leaves spatulate, spreading, fleshy, mucroante, scobrous at the edge; root prennial; stems many, a foot long, trailing, with scars at bottom from the fallen flexues; these are alternate, succulent, concave, seagreen, sessile, the upper ones reflex; flowers within the primary and secondary involuceis male, the rest hermaphrofite; calices serate about the edge; petals low; relus, horne attin tranul tips, siming; capsules smooth. It flowers from April to June.—Native of the south of France, Spain, and Taty.

90. Euphorbia 'Valustris', Marsh Sparge. Umbel multifid, subtrifid, bifd; involucels ovate; leaves lanceolate; branches barren; root perennial; stem three, four, or five feet ligh, rooml, smooth, with branches towards the top, which are alternate; and shorter than the stem; the primary flowers mule, five-petalled; abortive, the secondary hermaphrodite, four-petalled; calix very pale yellow; petals entire, yellow, blunt, not horned; capsales warded.—Native of Sweden, Denmark, Germany, Holland, Switzerland, France, and Piedmont. It flowers from May to August.

91. Euphorbia Hibernica; Irish Spurge, Umbel multifid, bifid; involucels ovate; leaves oblong, emarginate, somewhat villose underneath; stem simple; capsules warted, ramentaceous; root perennial; stems several, a foot or more in height, upright, unbranched, round, smooth, very light green, with red blotches here and there. The number of rays in the umbel is usually five, but sometimes on the middle and stronger stems another ray or two branches out, with a leaf or two under each somewhat bigger than the rest; of the two flowers on each ray one only usually comes to maturity; the flower has usually five petals, but sometimes only four. Mr. Ray relates the case of a boy who was killed by a dose of the juice of this plant .- Native of Ireland, in the mountains of Munster, where it is known by the name of makinbon, It flowers in May and June, and is said to have been found near Otterspool, over against Richmond, and between Fevershain and Sittingbourne in Kent.

92. Euphorbia Dendroides; European Tree Spurge. Umbel dichotomous; involucels subcordate, the primary ones three-leaved : stem arboreous. It rises to the height of four feet, with an upright branching stem: the leaves are oblong, pointed, and alternate; flowers in umbels from the forks, they are small and yellow, and rarely produce seeds in Eng-land .--- Native of Italy, Sicily, and Candia. See the fiftyeighth species.

93. Euphorbia Amygdaloides ; Wood Spurge, Umbel dichotomous; involucels perfoliate, orbiculate; leaves obtuse; root perennial; stem herbaceous, not woody, slightly downy, purple, two or three feet high; the flowcring part, during the time of flowering, grows to more than twice its original length ; lateral flowering-branches numerous, twice bifid, and forming a sort of long spike. It is common in woods and hedges in a clayey soil, and flowers in May, and sometimes before, and continues to July. This, with the two following species, being inhabitants of woods, require a shady situation. They will come up from scattered seeds, and may be increased by the roots.

94. Euphorbia Sylvatica. Umbel quinquefid, bifid; involucels perfoliate, subcordate; leaves lanceolate, quite entire; stems shrubby, proliferous, thick; petals crescent-shaped, erose, or gnawn, whereas those of the next species are entire. Scopoli says, the leaves are very finely serrate at the tip; the flowers between the rays and the branches male and sessile, with most of the stamina imperfect, and five petals; the other flowers fertile, and four-petalled; germen neither villose nor warted .- Native of woods in the southern countries of Europe. See the preceding species.

95. Euphorbia Characias; Red Spurge. Umbel multifid, bifid ; involucels perfoliate, emarginate ; lcaves quite entire ; stem becoming shrubby; flowers small, those within the first involucels male, the rest perfect; petals four, purple; styles scarcely cloven; gcrmen villose. The whole plant is very downy .- Native of France, Spain, Italy, and Germany, in woods and hedges. It flowers in June, and is seldom seen in England. See the ninety-third species.

96. Euphorbia Cretica. Umbel multifid, bifid ; involucels orbiculate: leaves linear-lanceolate, villose. This rises with a shrubby purple stem nearly three feet high; umbels terminating, and forming a sort of spike; the flowers appear in May, and the seeds ripen in July. It may be propagated from seeds or from cuttings, and will live abroad, if planted in a dry rubbishy soil and warm situation, otherwise the plants are frequently killed by severe frost. The young plants raised from seed are generally very fruitful; but the old ones, and those raised from cuttings, are barren.

97. Euphorbia Linearis. Dichotomous: peduncles solitary : leaves opposite, linear, quite entire ; stem round, naked, jointed; petals entire; capsules seem to be smooth .- Native of the island of Santa Cruz.

98. Euphorbia Rosea. Dichotomous: leaves obovate, oblique at the base, toothletted at the tip; stem depressed, diffused; root almost simple, a span in length, going straight down, a little writhed; flowers heaped at the ends of the branches, males mixed with hermaphrodites; the petals of a beautiful rose-colour; capsules smooth .- Native of the East Indies, in driving sand.

Euphrasia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. Calix: perianth onc-leafed, cylindric, four cleft, unequal, permanent. Corolla: one-petalled, ringent; tube length of the calix; lip superior, concave, emarginate ; lip inferior, expanding, three-parted ; divisions equal, obtuse. Stamina: filamenta four, filiform, inclined under the upper lip. Antherae two-lobed, of which cornered; branches opposite; flowers in long leafy spikes,

the inferior are sharpened into a little spine on the lower lobe. Pistil: germen ovate; style filiform, of the situation and figure of the stamina ; stigma obtuse, entire. Pericarp : capsule ovate-oblong, compressed, two-celled. Seeds : numerous. very small, roundish. ESSENTIAL CHARACTER. Calix: four-cleft, cylindric, Capsule: two-celled, ovate-oblong, Lower Antheræ: have a little thorn at the base of one of the lobes. The plants of this genus are all annuals, and can only be propagated from seed, sown soon after they are ripe, or in the spring, in the borders of the gardens. All, except the second and fourth species, are natives of the sonthern countries of Europe, and are not easily preserved in gardens. -The species are,

1. Euphrasia Latifolia ; Broad-leaved Evebright, Leaves tooth-palmate; flowers in a kind of head; root annual; stem a handbreadth high, or less, square, reddish, slightly hairy, simple, or dividing at bottom into two small branches, not more; corolla purple, sometimes white; bractes palmate, subhirsute.-Found about Montpellier. It spreads a purple carpct on many of the hilly pastures of Italy; it is found in Montserrat, the county of Nice, and near Turin; Verona; on Monte Testacceo, near Rome; in Apulia; and in the Spanish kingdom of Castille, particularly near the palace of the Escurial.

2. Euphrasia Officinalis : Common Euchright. Leaves ovate, marked with lines, sharply toothed ; root annual ; stem from two to four inches high or more, upright, round, hoary, purple, for the most part branched in opposite pairs : flowers from the axils of the leaves, on short peduncles, opposite, forming a spike or raceme at the tops of the branches and stem; corolla-tube rather crooked, a little hairy, white, stained with vellow at the mouth ; border bluish white, with purple streaks; germen bearded, or a little hairy at the top; style pubescent on the upper part; stigma fringed, with very minute glands round the edge; it varies much in size, and in the colour of the corolla, which changes to quite white and vellow: it is more or less branching, and sometimes wholly unbranched. This plant is common on heaths, and other dry pastures, especially on a chalky soil, flowering from July to September. It seems to have been unnoticed by the ancients, but the Arabians mention it under the name of adhil. Mattheus Sylvaticus, a physician of Mantua, who lived about the year 1320, recommended this plant in disorders of the eyes. It is still in use, particularly as an ingredient in British herb tobacco; and Mr. Lightfoot informs us, that the Highlanders iu Scotland make an infusion of it in milk, and anoint the patient's eyes with a feather dipped in it. It is, however, neglected by the faculty, and even thought by some to be injurious, at least in inflammations of the eyes. Meyrick, however, assures us, that it is famous for curing disorders of the eyes, and the common method of using it is, to apply the recently expressed juice, by way of collyrium, twice or three times a day; but where the disorder is bad, or of long standing, the whole herb, dried and reduced to powder, should be taken for a long time together, in the quantity of half a drachm twice or thrice daily. It also promotes evacuation by urine. This species will not grow in a garden, unless it has grass or some other herbs to protect it.

3. Euphrasia Tricuspidata. Leaves linear, three-toothed; corolla like that in the preceding species .- Annual, and a native of Italy.

4. Euphrasia Odontites ; Red Eyebright. Leaves linear, all serrate ; root annual. The whole plant is commonly of a brownish red; stem upright, stiff, very much branched, from six inches to a foot or more in height, hispid, obtusely fourpointing one way, nodding a hitle at top, in pairs, or single on short peducies; calis hairy on the outside; the teeth equal and sharp; corolla dusky red or purple, sometimes varying to white, hairy, very differently formed from the preceding, the upper Inp being compressed, and scarcely emarignate, the three lobes of the lower Inp shorter than the upper, equal, truncate, crenulate; all the lobes of the antheræ are throny at the tip, and bearded at the base; at the back, where the finamenta is inserted, are several small club-shaped threads or appendages; seeds ovate, very white, with a membranaceous margin on one side, elegantly latticed, with loor gludual ridges, and similar transverse streaks. It is common both in corn-fields and pastures, especially those that

5. Euphrasia Lutea; Yellow Exploright. Leaves linear, serrate, the upper ones quite entire. This resembles the fourth species, but differs from it in laving yellow flowers; the upper lip bearded or villose within and without, and emarginate ; the lower lip concave, trifid, with the segments equal; stem one, seldom more, rough, lard, woody, upright, wandlike, dusky red; syley yellow; sigma simple, both permanent; anthere beardless; capsule smooth, and green at bottom, at toy villose, blackish red; seeds brown, oblong.—Naive of Switzerland, Savoy, Austria, Fridi, Silesia, the Palatinate, Piedmont, Tuscany, and the south of France.

6. Euphrasia Linifolia; Flaz-leared Eyebright. Leaves linear, all quite entire; calices smooth. This is a little stiff, narrower, finer, but frequently higher than the common sort; the leaves are entire; the flowers yellow.—Native of France and Italy.

7. Enghrasia Viscosa; Clammy Eychright. Leaveslinear; calices guitous, hispid. This plant is described by Gouan to be only three inches high, and simple, or a foot high and branched, smooth and villose; all the leaves are broader at the base, thence gradually attenuated, and rough with hairs, most frequently quite entire, but sometimes toothed, the lower ones are opposite, the rest alternate, whence the branches themselves are seldom opposite; flowers on a very short peducel, alternate, each within a single bracte.—Na tige of Provence, Dauphiny, Switzerland, Savoy, Piedmont, and the county of Nice.

8. Euphrasia Cuneata; Wedge-leaved Eyebright. Leaves somewhat wedge-shaped, gashed.—Native of New Zealand.

9. Emphansia Longillorit, Long-flowered Eyebright. Puscent, viscil : leaves linear, quite entire; tube of the corolla filiform, three times as long as the calix. Cavanilles describes the sterm as a foot high, of a dark red colour; the branches decussated and four-concred; flowers axillary, in pikes; calix cut half way; tube of the corolla half an inch long, lower lip broader, with rounded segments; filamenta short, fastened to the upper part of the tube, within the upper lip; and there ovale, twin, two-award at the base, and perforated; style red, the length of the corolla; taigma club-langed; longitudinally streaked—It flowers in September; in Spain, where it is a mative, having been found there, near Espesa, Rivas, and in the kingtion of Arragon.

Europe ; a genus of the class Dodecandria, order Monogymin-GENREIC CLARACTER. Calit: perianth five-leaved; leaflets ovate, concave, obtuse, smooth, surrounded at the size of the calis. Covola: petals five, roundish, ovate, concave, the size of the calis; neetals five, roundish, ovate, concave, the size of the calis; scatter, dots or a purple rim, at the base of the filamenta. Sctamia: filamenta thirteen, very short, so as to be scarcely any. Antherre upright, four-sided, almost the leagth of the corolla. Pistfit: germen superior, convex, smooth; style subulate, shorter than the anthera; 46.

stigmas three, reflex. *Pericarp*: capsule globular, with the style permanent, sharp, smooth, five-celled, five-valved. *Seeds*: somewhat three-cornered, dotted, very many. *Observe*: The flowers seem very frequently to be directus, *ESENTIAL CHARACTER. Colit:* five-leaved, calided. *Corolla:* five-petalled. *Stamina:* thirteen. *Capsule:* fivecelled.——The only known species is,

1. Eurya Japonica. All parts of the plant are smooth: stem shrubby; branches and twigs alternate, lax, from upright bent in, ash-coloured; leaves on the twigs alternate, frequent, petioled, elliptic or oblong, drawn to a point at both ends, serrate, a little turned back at the edge, entire at the base, very smooth, thickish, evergreen, in two rows, upright, with an emarginate point, nerved, the upper surface green, but underneath yellowish, an inch or more in length; flowers axillary, in pairs, peduncled, drooping, seldom either single or in threes; preduncled; florom, one-flowered, scarcely longer than the petioles.—It flowers in September and October, and is a native of Japan.

Euryandra: a genus of the class Polyandria, order Trigyma-CERSENE CUARACTER. Calir: perianth five leaved; lendets roundish, concave, longer than the calix. Stamina: filmenta very many, capillay, very much dilated at the tip. Antheræ twin, with the cells disjointed. Piotif: german three, ovate; styles three, very short; stigmas two, slightly divided. Pericarp: foliteles three, ovate, divaricate, opening longitudinally on the inner side. Scate, issue. ESENTAL CHARACTER. Calix: five-leaved. Corolla: htree, petaled. Filameta: much dilated at the tip, with twin disjointed antheræ; follieles three.—The only known species is,

 Enryandra Scandens; which is a climbing plant, and a native of New Caledonia.

Exacum : a genus of the class Tetrandria, order Monogyna.—GENERIC CHARACTER. Colis: perioath four-leaved; leaflets ovate, obtuse, from erect spreading, permanent. Corolle : one-petilled, permanent : tube globose, length of the calix; border four-patted; divisions roundish, spreading. Stamina: filamenta lour, filiform, sitting on the tube, length of the border. Antleren roundish. Pissil : germen roundish, filing the tube; style filiform, upright, length of the border; stigma headed. Periorp: capsule roundish, compressed, two-furrowed, two-celled, length of the calix. Seeds: unmerous; receptacle filling up the capsule. ESENTIAL CHARACTER. Coliz: four leaved. Corolla: salver-shaped, with an inflated tube; capsule two-furrowed, two-celled, many-seeded, bursting at the top. For the propagation and culture of this genus, see Genitiona.—The species are;

1. Exacum Albeirs, Leaves subdecarrent; stamina protruded; root annual; stem a handbreadth high, dichotomous, hetbaceous, four-sided, smooth, fastigiate; corolla salver-shaped, white; tube cylindric, longer than the caix, border the length of the tube; filamenta very short; antheræ oblong; stigmas two, thickish.—Native of the Cape of Good Hope.

2. Exacum Pedmentatum. Flowers four-cleft, terminating: calcine leadies ovate: leaves lanceoinet, three-nerved, undotted; root annual; stem upright, a palm in height, fourcornered, with acute angles, branched, very smooth, as is the whole plant; branches few, simple, opposite, slorter than the stem; pedmetes from the top of the stem and branches, solitary, one flowered, short; calix four-parted, four-cornered; the parts ovate-acuminate, memioranaceous at the edge; corolla subcampanulate, violet coloured, larger than in the other sorts, permanent; tube the length of the 6Z calix : segments of the border lanceolate-obtuse. Antherae linear, a little shorter than the border; style the length of the corolla: stigma thickened .- Native of the East Indies.

EXA

8. Exacum Aureum. Leaves sessile ; stamina protruded ; root annual; stem a handbreadth high, dichotomous, slightly four-cornered, smooth, brachiate; pednucles from the divisions one-flowered, the length of the flower; calix five-leaved; corolla yellow, salver-shaped, four-cleft; segments lanceolate, sharp; filamenta bristle-form; antheræ oblong .- Native of the Cape of Good Hope.

4. Exacum Sessile. Flowers four cleft, lateral, and terminating; capsules nodding; leaves heart-shaped; stem erect, a spanhigh, four-cornered, even, simple, dichotomous; flowers from the divisions of the stem, solitary, sessile, larger than the leaves .- Native of the East Indies.

5. Exacum Cordatum, Flowers five-cleft : calicine leaflets heart-shaped, striated; corolla yellow, salver-shaped; tube cylindric, longer than the calix ; border five-parted, obovate ; filamenta short, in the throat of the corolla ; antheræ oblong ; style length of the stamina.—Native of the Cape of Good Hope. 6. Exacum Guianense. Corollas four-cleft; calices mem-

branaceous, keeled, even : leaves lanceolate. This plant is often scarcely a finger's height, with a stem either quite simple or very little branched, and quite smooth, upright, and sharply four-cornered; leaves opposite, attenuated, the lower ones shorter and sharp; peduncles terminating, or from the upper axils, solitary, one-flowered, very short, angular .- Native of Cavenne.

7. Exacum Spicatum. Flowers spiked, in whorls of threes : leaves lanceolate; stem simple; stem herbaceous, two feet high, erect, quite simple, except that sometimes there are two flowering branches from the last axils, obscurely fourcornered, without decurrent lines, smooth, the whole plant also is very smooth; spike terminating, erect, pyramidal, almost a span long, with abundance of flowers; corolla twice the length of the calix, with a cyliudrical tube; border, before it is unfolded, four-cornered, attenualed, rolled up spirally at the top ; divisions lanceolate, the length of the tube; antheræ sagittate .- Native of Cayenne.

8. Exacum Ramosum. Flowers subspiked, opposite; leaves lanceolate; stem branched. The whole plant is smooth; flowers distant, on very short pedicels, with two bristleshaped appressed bractes at the base of the calix, which is one-leafed, oblong, four-cleft; the clefts lanceolate, attenuated, membranaceous at the edge; segments of the corolla ovate-acute .- Native of Guiana.

9. Exacum Punctatum. Leaves on very short petioles, oblong, three-nerved, dotted; stamina protruded. This is larger than the other species; corolla bluish; stamina vellow. -Native of the East Indies.

10. Exacum Viscosum. Leaves oblong, nerved, embrac-ing; flowers five-cleft; bractes heart-shaped, perfoliate, longer than the calix; root perennial; stem somewhat shrubby, erect, foundish; branches opposite, erect, slightly quadrangular, green, leafy, many-flowered; flowers of an elegant golden-colour, inodorous, slightly droopiug .-- Native of the Canary Islands.

Excoecaria ; a genus of the class Direcia, order Triandria. -GENERIC CHARACTER. Male. Calix: ament cylindric. covered with floscules. Corolla: none. Stamina: filamenta three, filiform. Antheræ roundish. Female. Calix ; ament as in the male, Corolla: none. Pistil: germen roundish. slightly three-sided; styles three; stigmas simple. Pericarp: berry tricoccous, smooth; divisions marked out by a furrow. Seeds: solitary, smooth. ESSENTIAL CHARAC-TER. Ament: naked. Calix and Corolla; none; styles three; capsules tricoccous .--- The species are.

1. Excoecaria Agallocha. Causule small, the size of a juniper berry, subglobular, three-grooved, smooth, black, three-celled, of a papery substance, not divided within mto three distinct grains, but merely opening when pressed by three valves; seeds one in each cell, subglobular, acuminate at top, convex on one side, very bluntly angular on the other. Native of Amboyna and Tongataboo.

2. Excoecaria Cochin-chinensis, Leaves two-coloured. shining; scales of the ament many-flowered. This species is an arboreous shrub about eight feet high, with the stem and branches irregular, spreading, reclining; the female flowers have three long, awl-shaped, reflex stigmas; capsule three-lobed, somewhat fleshy, red, small, three-celled; seeds ovate, smooth and even. It has au astringent agglutinating quality; the whole plant abounds in a glutinous milky juice, which has not the reputation of destroying the sight, nor is the agallochum, even of a bastard sort, found in it .- Native both of China and Cochin-china, where it is cultivated for the beauty of its red leaves.

Exoacantha ; a genus of the class Pentandria, order Digynia.-GENERIC CHARACTER. Calix: umbel universal, manifold, spreading, the inner rays gradually smaller, the inmost very short; partial manifold; involucre universal, with rays, usually twelve, channelled, spiny at the end ; partial halved, with the middle ray very long, similar to the rays of the involucre ; perianth proper scarcely observable. Corolla: universal, uniform; proper five-petalled; petals inflex, heartshaped, equal. Stamina: filamenta five, capillary, longer than the corolla. Antheræ roundish. Pistil: germen inferior, ovate; styles two, shorter, straight; stigmas two, simple, Pericarp : fruit subovate, striated, bipartile. Seeds : two, ovate, convex, and striated on one side, flat ou the other. Observe : This genus is allied to echinophora, but with uncalicled flowers, all hermaphrodite, equal petals, and naked seeds. ESSENTIAL CHARACTER. Involucre: spiny; involucels halved with unequal rays; flowers all hermaphrodite, with equal inflex heart-shaped petals. Seeds : ovate, striated .---- The only known species is,

1. Exoacantha Heterophylla. Leaves pinnate ; root leaflets ovate, toothed, gashed ; stem-leaves lanceolate, acute; root simple, thickish, biennial; stem two feet high or more, striated, subflexuose, smooth; stem-leaves usually entire, with the middle leaflet very long; the two umbels have about forty rays; those of the umbellule nearly equal; antheræ yellowish .- Found near Nazareth, in Judea.

Eyebright, See Euphrasia.

FAG

nogynia .- GENERIC CHARACTER. Calix: perianth four- sules globular, one-celled, or two-celled, according to Gærtcleft, very small; leaflets concave, permanent. Corolla : pe- ner, and two-valved. Seed : single, round, bright. ESSENtals four, oblongish, concave, spreading. Stamina : filamenta TIAL CHARACTER. Calix : four-cleft. Corolla : four-pefour, or from three to eight, longer than the corolla. An- talled. Capsule : two-valved, with one seed. These are there ovate. Pistil: germen ovate; style filiform, length | tender plants, and must be kept constantly in the bark-stove.

FAG

FAGARA; a genus of the class Tetrandria, order Mo- of the corolla; stigma two-lobed, obtusish. Pericarp: cap-

They may be increased by seeds, and also by cuttings properly managed.——The species are,

1. Fagara Euodia; Seert-scented Fagara. Leaves simple, Ianceolate, clongated, oppositie; raceness branched, asvilary, solitary. Forster made a new genus of this species, under the ittle of Euodias, from its fine sanell. But it has no dis finet marks, except that the stigma is four-eleft, whereas in fagara it is two cleft; and that it has four capsules, whereas fagara has but one.—Native of the Friendly Isles, and the New Hebrides.

2. Fagara Trifoliata; *Three-leaved Fagara*. Leaves ternate; leaves obovate, subemarginate, entire, shining, dotted underneath.—This is a native of the island of Dominica.

3. Fagara Pteroia; Lentineus-leaved Fagera, or Baslard For-wood. Leadets emarginate. It rises, by a branched and somewhat prickly stalk, frequently to the height of eight or ten feet; the wood is very hard, and the branches are abundantly furnished with little leaves, and small white fowers, that ruise on double spikes from the axils of the ribs. It has a very goatish smell, and is extremely common in thower land sof Jannica. It flowers in August and Stember.

4. Fagara Piperita; Ash-leared Fagara. Leadiets create; stem scarcely a faition in height; branches round, prickly, purple; prickles scattered, horizontal; leaves many from the ends of the twigs, unequally puimate, with about six pairs of leadlets; these are alternate, and opposite, subsexile, ovare, emarginate, smooth, half an inch in kneuth; flowers among the leaves terminating, panicled, small, white; capsule wrinkled, once-theig one smooth black seed. The bark, leaves, and fruit being aromatic, are frequently used in soups instand of spice. The bruised leaves, made into a cataplasm with meal of rice, are hid upon the parts affleavor, is warm, diaphoretic, and emmenagogue, and is much estemed in intermittent fevers, theumatism, ac —Native of China, Cochin-clima, and Japan.

5. Fagara Horrida. Leaves pinnate; pinnas ovate-cre nate; spine of the branches armed with spinules. This is a small upright tree, smooth in all its parts; branches alterate, striated, flexuose, upright, from ash-coloured purplish, elongated, almost simple.—Native of Japan, where the natives call it distaf.

6. Fagara Tragodes; Prickly-kared Fagara. Joints of the piumas prickly underneath. A shrub, branching, almost erect, five feet in height; prickles in pairs, subulate, recurved, strong, subaxillary, brown, shiming: there is one similar, but smaller on the back of each joint of the leaves; flowers small, axillary, aggregate.—It flowers in February, and is a native of St. Domingo.

7. Fagara Emarginata. Leaves pinnate; leaflets ovate, emarginate, veined; racemes terminating, compound; flowers three stamined. The trunk of this tree is the size of the human leg, sometimes beste with many short prickles. It rises twenty feel high, and its branches are inclined towards the ground. The wood is white, solid, and odoriferous, with a pretty large pith; flowers white, small, like those of elder, three-petallet; fruit round, the size of black pepper; seed back, smelling somewhat like bay-berries. The smole of this wood, while buming, probably occasioned the fine seent; which Columbus perceived near the south-slowed for bands.

8. Fagara Spinosa. Leaves pinnate, sessile, ovate, acuminate; both they and the branches spiny underneath; flowers three-stamined.—Native of Jamaica.

9. Fagara Acuminata. Leaves pinnate; leaflets entire, elliptic, acuminate, shining, coriaceous; flowers in cymes, three-stamined.—Native of Jamaica.

FAG

10. Fagara Octandra. Leaflets tomentose; branches thick, few, long, irregular; leaves pinnate, tomentose on both sides, winged, deciduous, coming out from the ends of the smaller branches, with the flowers, or a little after them ; racemes many, simple, an inch, or an inch and a half long ; flowers very small, with white calices, and yellowish corollas; fruits green, the size of peas : when broken the valves distil drops of balsam. It is an inelegant tree, frequently more than twenty feet in height, abounding in a balsamic glutinous juice, much like that of burseria in its qualities. The wood is very white, and light. The natives of some of the West India islands make saddles of one piece of it, they have no pad, and only a sheep's-skin thrown over them when they ride. Jacquin calls it elaphrium, from the lightness of the wood .- Native of Curação, and the adjacent islands, where it flowers in July and August.

Fagonia ; a genus of the class Decandria, order Monogynia .--- GENERIC CHARACTER. Calix : periauth five-leaved ; leaflets lanceolate, erect, patulous, very small, deciduous. Corolla: petals five, heart-shaped, spreading; claws long, slender, inserted into the calix. Stamina : filamenta ten, subulate, erect, longer than the calix; antheræ roundish, Pistil: germen five-cornered, superior; style awl-shaped; stigma simple. Pericarp : capsule round, acuminate, (fivecornered, according to Gærtner,) five-celled, five-lobed, tenvalved, the cells compressed. Seeds: solitary, roundish. ESSENTIAL CHARACTER. Calix: five-leaved. Petals: five, cordate. Capsule: five-celled, ten-valved, with one seed in each cell .- This genus consists of herbaceous plants, with a woody base. The leaves are either simple or ternate ; the stipules in the two first species become thorns. The flowers are solitary and axillary. In order to propagate them, sow the seeds upon a warm border of fresh light earth in autumn, where they are designed to remain, for they do not bear transplanting well : in frosty weather shelter the plants with mats, or some other covering, thin them out to the distance of ten inches or a foot, and keep them clean from weeds. It is, however, a better plan to sow them in pots, and place them under a frame in winter; in the following spring, shake them out of the pots, and place them in a warm border, thus they will flower early, and ripe seeds may be obtained .----- The species are,

 Fagonia Cretica; Cretan Fagonia. Thorny: leaftest lanceolate, fait, even. This is a low plant, spreading its branches close to the ground, a foot or more every way. If flowers in July and August, but indies the season proces warm, does not ripen seeds in England.—Native of the island of Candia.

2. Fagonia Arabica; Arabian Fagonia. Thorny: leaftest linear, convex. This is a low plant, with a shrubby stalk, from which come out several weak branches, armed with long thorns; the leaves are thick, narrow, and convex on their under side; the flowers come out as in the first sort. This and the following species seldom flower in the first species during the two first winters.—It was discovered in Arabia ku Dr. Shaw.

3. Fagonia Hispanica; Spanish Fagonia, or Fagonia without Spines. Without thorns. This differs from the first species in being smooth, the branches having no thorns, it will also live two years, whereas that is annual.—Native of Spain.

Fagrae ; a genus of the class Pentandria, order Monogynia-GENERIC CHARACTER, Calix: perianth one-

FAG

leafed, bell-shaped, five-parted; i divisions obtase, incumbent, membranaccous at the end. *Corolla*; one-petalled, funnelshaped; tube round, gradually widening to the top, long; border twisted, five-parted; i divisions oblong, obluqe, obtase, entire, patulous, *Slamina*; filamenta five, filiöran, equal, inserted into the tube, slorter than the corolla; anthere ovate, twin, vertical, convex outwards, four-farrowed, flat on the inner side, easily bipartile. *Pitsili*; germen superior; style filiform, the length of the corolla; singua pelate; opticulate, flat. *Pericency:* herry ovate, fleshy, covered with an epidermis, two-celled. *Seeds*: orbiculate, smooth, funnel-shaped; herry two-celled, fieshy. *Seeds*: globular, *Sizems*: pelate.—The outly known species is,

1. Fagrica Zeylanica. Stein becoming shrubby, erect, somewhaf four-cornered, a finger in thickness, and two feet high; leaves fastigately opposite, petioled, frequent, ob-vate-oblog, very obtuse, entire, coraceous, a hand broad, and a span long; petioles semicolumnar, an inch in length; bidfowers terminating, subumbelled, peduneted. The umbel has about three flowers; peduneles one flowered, bracked, half an inch in length; brackets opposite, ovate, obtuse.— It is a native of Ceylon, where it flowers in December and January.

Fagus ; a genus of the class Monœcia, order Polyandria. -GENERIC CHARACTER. Male. Flowers: fixed to a common amentaceous receptacle. Calix : perianth oneleafed, bell-shaped, five-cleft. Corolla : none. Stamina: filamenta many, the length of the calix, setaceous; antheræ oblong, Female, Flowers: in a bud of the same plant. Calix : perianth one-leafed, four toothed, erect, acute. Corolla : none. Pistil: germen, covered with the calix ; styles three, subulate; stigmas simple, reflex. Pericarp: capsule (which was the calix) roundish, very large, covered with soft spines, one-celled, two or four-valved. Seeds : nuts one or two, ovate, three-cornered, three-valved, acuminate. Observe. In the third species, or beech, the male-flowers are in a ball, in chestnut they are in a cylinder. ESSENTIAL CHARACTER. Male. Calix: five-cleft, bell-shaped. Corolla : none. Stamina : twelve. Female. Calix : fourtoothed. Corolla: none; styles three. Capsule : which was the calix, muricate, four-valved. Seeds: two .---The species are,

1. Fagus Castanea : Common Chestnut Tree. Leaves lanceolate, with acuminate serratures, naked underneath. This tree will grow to a very great size, and spread its branches finely on every side where it has room, but planted closely, will shoot up straight to a great height. The leaves, which are large, and of a lucid green, end in a very long taper point, and the serratures terminate in a tender kind of prickle; they are about four or five inches long, and two wide, somewhat wrinkled, having several transverse veins, prominent on the under surface, and proceeding from a strong midrib. The aments or catkins of male flowers are pendulous at the ends of the branches, very long, and resemble those of walnut. They have a strong sperinatic smell; and the flowers, which are sessile, are collected in remote little balls. The proportion of male flowers to the females is prodigious. The stamina are about nine in number, some say from five to eightcen. In the female flowers, the number of styles varies from four to seven, but six is the most common. The calix becomes an echinate capsule of four valves, of a silky smoothness on the inside, and containing two nuts, sometimes three or only one .- This tree has long been naturalized in the southern countries of Europe, and is said to have been brought by the Roman emperor, Tiberius Cæsar,

from Sardis in Lydia to Italy, whence it was transplanted into France, and latterly into England. It is judigenous in many parts of Asia, in China, Cochin-china, and Japan. The chestnut abounds in the mountainous parts of Italy, in the south of France, Switzerland, the Valuis, and many parts of the Alps towards Italy, in Corsica and Sicily, where it grows half way up the side of Mount Ætna, as well as in Carniola, some parts of Germany, Portugal, and Spain. Mr. Miller supposes it formerly to have been more plentiful than at present in England, but it is probable that the timber in various old buildings in London, which he supposed to be chestnut. was nothing but oak of a different grain, and inferior quality. Evelyn makes little doubt that the chestnut-tree is a native of Great Britain; and Dr. Ducarel, who is of the same opinion, among other ancient records to which he appeals, produces a deed of gift from King Henry II, to Flexley Abbey, of the tithe of all his chestnuts in the forest of Dean. The Hon, Dames Barrington, on the contrary, thinks that it is not a native. It certainly is not in the woods north of the Trent; and, though it has been long in the southern parts, yet, says Hunter, there is no appearance of its being indigenous. This tree seems to be very long lived, and grows to a very great size. The famous castagno de cento cavalli, or chestnut of a hundred horses, on Mount Ætna, as measured by Mr. Brydone in 1770, was 204 feet in circumference; but some maintain that it is not one tree, and even Brydone himself confesses that it had the appearance of five distinct trees, but that he was assured the space was once filled with solid timber, and that no bark could be discovered on the inner parts. Kircher, who wrote a century before, declares that a whole flock of sheep might be commodiously inclosed within it, as in a fold. In the same neighbon hood is another tree, called il castagno del galea, which is undoubtedly single, and measured at the same time seventy-six feet round, at two feet from the ground; but it should not be forgotten, that both these monstrous trees grow upon a deep rich soil, formed from the ashes of the volcano. The most remarkable of these trees in England, is that at Tortworth, the seat of Lord Ducie, in Gloncestershire. Even in the year 1150, says Bradley. it was styled the great or old chestnut-tree of Tortworth; and in all probability is at least one thousand years old. It fixes the boundary of the manor; and in the year 1720, gitted fifty one feet, at a man's height from the ground. It divided at the crown into three limbs, one of which then measured twenty-eight feet and a half in circumference, five fect above the crown. The soil in which this tree grows is a soft, and somewhat loamy clay, and its situation on the north-west side of a hill. Lord Ducie has a beautiful painting of this ancient tree, from which an etching was made in the year 1772, under which is the following inscription, "The east view of the ancient chestnut-tree at Tortworth, in the county of Gloncester, which measures nineteen yards in circumference, and is mentioned by Sir Robert Atkyns, in his history of that country, as a famous tree in King John's time; and by Mr. Evelyn, in his Sylva, to have been so remarkable for its magnitude, in the reign of King Stephen, as then to be called the great chestnut of Tortworth, from which it may reasonably be presumed to have been standing before the conquest." When the above-mentioned etching was made, it was barely included within the garden-wall, which bore hard upon it; but the present Lord Ducie removed the incumbrance, and applied fresh earth to the roots, which seems to have enlivened it. So late as the year 1788, it produced great quantities of fruit, which, though small, were sweet, and well-flavoured. Mr. Lysons, however, who measured this famous tree in 1791, says, that

it measured only forty-four feet four inches round in the thickest part; and adds, that there does not seem to be any authority, to shew at what period it became remarkable for its size, except a very vague tradition ; and it could never have been a boundary of a manor, for it stands in the centre of it. There are some fine chestnut-trees on the banks of the river Tamar in Cornwall, at an old house belonging to the Edgecumbe family, and at Beechworth Castle in Surry : there are not fewer than seventy or eighty trees, measuring from twelve to eighteen or twenty feet in girth. At Wimley, near Hitchin Priory in Hertfordshire, a chestnut-tree, in 1789, girted somewhat more than fourteen yards, at five feet above the ground ; its trunk was hollow, and in part open, but its vegetation was vigorous. In the park adjoining to the garden, at Great Canford in Dorsetshire, are four large chestnut-trees, oue of them measuring thirty-seven feet round, still bearing fruit plentifully, though much shivered and decayed by age. There was an old decayed tree at Fraiting in Essex, whose very stump yielded thirty sizeable loads of logs. Another, in Gloucestershire, contained within its bowels a pretty wainscotted room, enlightened with windows, and furnished with seats. Ben Jonson, in his poem on Penshurst, makes mention of a chestnut, planted at the birth of the celebrated Sir Philip Sydney. There have been, and still are, many fine chestnut-trees in Ireland, as an avenue at Dunganstown, cut down in 1793, where one of the trees measured fourteen feet three inches, another fifteen feet, and a third sixteen feet six inches round ; the length of one was twenty-four feet, and of another thirty-six. The chestnut, says Mr. Gilpin, in maturity and perfection, is a noble tree, and grows not unlike the oak. Its ramification is more straggling, but it is easy, and its foliage loose. This is the tree which graces the landscapes of Salvator Rosa, who painted in the mountains of Calabria, where it flourishes. This tree deserves our care as much as any of the trees which are propagated in this country, either for use or beauty, being the best sorts of timber, and affording a goodly shade. The leaves continue late in the autumn, turning then to a golden colour, and are not so liable to be devoured by insects, as those of the oak, which renders that tree very unsightly during a great part of the summer. On this account, the chestnut is more valuable, as an ornament for parks and plantations; and there can be no better food for deer, and many other animals, than their nuts, which most of them prefer to acorns; but yet there should not be many of these trees planted too near dwelling-houses, because, when in flower, they emit an odour which is very offensive to most people. The shade of the chestnut, like that of the ash, is injurious to other plants; it should, therefore, be planted in thickets, or in detached plantations. Or, if these trees he planted in large wilderness quarters, next the walks, or in the woods by the side of the ridings, and left untrimmed, as they ought to be, they will feather to the bottom, and hide the naked and crooked stems of other trees. To recommend the restoration of this noble and useful tree, which has unaccountably lost ground among us, we must observe, that it may be cultivated in Eugland so as to afford an equal profit with any other sort of timber-tree; since the wood is equal in value to the best oak, and for many purposes far exceeding it, particularly for casks, for which it is much used in Italy, and for pipes to convey water under ground. In Italy it is planted as coppice-wood, to make stakes for their vines, It must therefore be very which will continue seven years. proper for stakes in espaliers and dead hedges, for hop-poles, and hurdles. The timber was formerly used for all the same purposes as oak, in building, mill-work, and household fur-40.

niture ; and lately, some of it that was finely variegated, has been successfully employed for doors, and the balustrades of a stair-case : a colour being given to it, by rubbing it over with alum-water, then laying on with a brush a decoction of logwood chips, and lastly a decoction of Brazil-wood, which process has produced a strong resemblance to mahogany. Some persons assert, that the timber of chestnut is brittle, and decays at heart ; whilst, according to others, it will last longer than oak, is not subject to cracks or flaws, and is never attacked by spiders or other insects. Old chestnut is certainly brittle, and liable to crack, and therefore should never stand longer than whilst it is in a growing state. If cut when it squares only six inches, it will be as durable as oak of six times its size and age, having very little sap in proportion to other trees. The durability of it, when exposed to the weather, has been sufficiently ascertained, from its use for gate-posts at Wellington in Somersetshire, of which the following is an authentic account. In or about the year 1763, some gate-posts of oak, and others of chestnut, were to be repaired ; they had the appearance of being put in at the same time, but the latter were much more sound, insomuch that some of them were adjudged good enough to remain as gate-posts, and were still to be seen there in 1788. Such as were too small were taken up, and set as posts to fix rails to. At the same time some new posts of oak were put in, there not being a sufficient quantity of the old chestnut posts ; which twenty-five years afterwards were found to be sounder than the oaken posts, which were then new. One side of the chestnut posts was the outside of the tree ; but the timber was as sound there as in any other part, which would not have been the case with oak, the sap of which next the bark soon decays. These chestnut gate-posts had been put down many years before 1745, and have, therefore, probably resisted the weather for above half a century. Another account says, that a chestnut-branch, about thirteen inches square, which, in the year 1726, was put down as a hangingpost for a gate, and carried the gate fifty-two years, when taken up appeared perfectly sound, and was put down for a clapping post in another place. In 1743, a large barn, built of chestnut timber, was sound in every part in 1792. At the former period, also, several posts and rails were put down, which, after standing thirty or forty years, appeared to be so sound, as in general to allow of being set up in some other place. In 1772, a fence was made of posts and rails converted from young oaks and chestnuts of the same age and scantling. In 1791, this fence was removed, and the chestnut-posts were found as sound as when first put down, but the oaken ones were so much wasted just below the surface of the ground, that they could not be used again without a spur. The nuts are the usual, and, in some places, almost the only food of the common people in the Apennine mountains of Italy, and in Savoy, some parts of the south of France, and in Portugal. They are not only boiled and roasted, but made into puddings, cakes, and bread. They are reckoned a very flatulent and indigestive diet, although in Italy there are instances of men's living to the age of eighty, and even an hundred years, who have fed wholly upon chestnuts. They are brought even to fashionable tables in desserts. Mr. Ray observes, that the Italians eat them with orange or lemon-juice, and sugar, and that they are there sold commonly about the streets, roasted upon a portable furnace, by which we may infer, that this luxury was unknown at London in the last century. These nuts are also used for whitening linen-cloth, and for making starch, and are excellent for feeding hogs. The leaves likewise make useful litter, and, when mixed with the dung of the cattle.

form a good manure. It is hoped that the above interesting account will have some tendency to encourage the growth of this noble, though neglected tree. Mr. Peter Collinson, who thought it a native of this country, assigned the great profit arising from chestnuts, when cut for hop poles, as the reason why large trees are so rarely met with in our woods. Let us hope, however, that it will once more be suffered to rear its head as a timber-tree amongst us. An arret of the council of Paris was published in May, 1720, ordering that all the great roads in France should be planted with chestnut, or other such fruit or forest trees as are suitable to the nature of the ground, at thirty feet distance from each other, and within six feet of the top of the ditch. The principal plantations, which have been made of late years in Great Britain, are in the northern parts of the island. The Earl of Fife has planted above 60,000 trees in the county of Murray ; George Ross, Esg. 4000 in Cromarty. In England Mr. Windham's plantations, at Felbrigg in Norfolk, planted in 1676, are well known, Mr. Joseph Mace has planted six acres, seventeen perches, with above 3000 trees, at Ashford in Biddenden. Kent. John Sneyd, Esq. 8000, at Belmont in Staffordshire, from 1784 to 1786; and Mr. Joseph Cowlishaw, six acres in Carlton forest, with above 1800 of these trees, mixed with larch, ash, &c .- There are several varieties of the chestnut, which have accidentally arisen from seeds; but the difference is chiefly in the size of the fruit and leaves. One sort, however, which has variegated leaves, is admitted into the nurseries as a curiosity. The striped chestnut is among the most beautiful of the variegated trecs, the blotches being of a rich shining gold colour, strongly marked. The dwarf branching chestnut is no more than a variety of the common sort. The chestnut-tree is propagated by planting the nuts in February, in beds of fresh undunged earth. The best nuts for sowing, are such as are brought from Portugal and Spain, and are commonly sold in the winter for eating, provided they are not kiln-dried, which is generally the case of most of those brought from abroad, which is done to prevent their sprouting or shooting in the passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of English growth, which are full as valuable. either for timber or ornament, as any of the foreign nuts, notwithstanding their fruit is much smaller: these should be preserved until the season for sowing, which is the beginning of March, in sand, where mice or other vermin cannot come at them, for they will soon destroy them. Before you plant them, it will be proper to put them into water to try their goodness, which is known by their weight; those that swim upon the surface of the water should be rejected as good for nothing ; but such as sink to the bottom you may be sure are good. In setting these seeds or nuts, the best method is to form a drill with a hoe, as is commonly practised in setting kidney-beans, about four inches deep, in which you should place the nuts at about four or six inches' distance. with their eye uppermost, then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for the conveniency of clearing the beds. When you have finished your plantation, set traps to destroy the mice and other ma rauders, or else they will infallibly destroy your work. In April these nuts will appear above ground ; observe therefore to keep them clear from weeds, especially while young; in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees, is either in October, or

distance these should have in the nursery, is three feet row from row, and one foot or eighteen inches in the rows; he careful, when about to transplant them, to take them up without injuring the roots, nor should they remain long out of the ground ; but if they have a downright tap-root, it should be cut off, especially if they are designed to be again removed : this will cause them to put out lateral roots, and render them less subject to miscarry, when they are removed for good. The time generally allowed for them to remain in this nursery, is three or four years, according to their growth : but the younger they are transplanted, if designed for timber, the better they will succeed : during this time be careful to keep them clear from weeds, prune off lateral branches. which would retard their upright growth; and where you find any that are disposed to grow crooked, either by their upper bud being hurt, or from any other accident, you may, the year after planting, in March, cut them down to the lowermost eye next the surface of the ground, which will cause them to make one strong upright shoot, and may be afterwards trained into good straight trees ; but this should not be done, unless the plants have absolutely lost their leading shoot; for although the stems of the trees should be very crooked, as is generally the case with them when young, vet when they are transplanted out, and have room to grow as they increase in bulk they will grow more upright, and their stems will become straight, as has been frequently observed where there have been great plantations made of them. But in doing this, care must be taken not to disturb or break their roots, which might probably destroy them. They require no other manure than their own leaves, which should be suffered to rot upon the ground; and in the spring of the year, the ground should have a slight digging, when these should be buried between the roots, yet not too close to the trees, which might be injurious to their young fibres. After remaining three or four years in the nursery, they will be fit for transplanting, either in rows to grow for timber, or in quarters for wilderness plantations, avenues, clumps, or the orchard ; but if you intend them for timber, it is by far the best method to sow them in furrows, as is practised for oaks, and let them remain unremoved ; for these trees are apt to have a downright tap-root, which being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, like the oak, walnut, &c. Let it be observed, however, that where the fruit is more sought after, then it is certainly the better way to transplant them; for as transplanting is a check to the luxuriant growth of trees, so it is a promoter of their fructification, as may be proved by observing low shrubby oaks, walnuts, &c. which generally have a greater plenty of fruit than any of the larger and more vigorous trees; and the fruit of such trees is much superior in taste, though the seeds of vigorous trees are vastly preferable for plantations of timber; for it is a constant observation, that, by saving seeds from dwarf trees or plants, from time to time, they may be rendered much lower in their growth than in their natural size ; but where the fruit is most desired, then they should be taken from such trees as produce the largest and sweetest nuts, which are commonly found upon such trees as spread the most, and have horizontal roots; for the weaker trees being less capable of furnishing a supply of nourishment, and having a greater quantity of fruit upon them, to which this must be distributed, together with their roots near the surface of the ground, by which means the juices are better prepared by sun, air, &c. before it enters their vessels, it is certain that their juices are better digested, and their fruit better matuat the end of February, but October is the best season : the rated, than those can possibly be which grow upon strong

vigorous trees, which have long tap-roots running several feet deep into the earth, and consequently take in vast quantities of crude unprepared juice, which is buoyed up to the extreme parts of the tree; and these seldom have many lateral branches to digest and prepare their juice, by perspiring and throwing off the crude part before it enters the fruits. This remark will, in all probability, extend to all sorts of fruit-trees, and is often the occasion of the good and bad qualities of the same sorts of fruits growing on the same soil. What leas been related about grafting this tree into the walnut to promote its bearing, or render the fruit fairer, or inoculating cherries into the chestnut for later fruit, is very whimsical and silly, since neither the chestnut nor the walunt will receive its own kind in any other way than by inoculating or inarching, and it is the latter only by which the walnut can be propagated ; nor was it ever known that any two trees of a different genus would take upon each other so as to produce either a good tree or good fruit; therefore we may justly explode all those different graftings of various trees upon each other, so much talked of by the ancients, at least we may suppose those trees are not known by the same names now that they are mentioned by in their writings; for, says Mr. Miller, " I have made many trials upon them, which, though performed with the utmost care, and in different seasons, have very seldom succeeded." But to return : if you design a large plantation of these trees for timber, after having two or three times ploughed the ground, the better to destroy the roots of weeds, make your furrows about six feet distance from each other, and lay the nuts in them ten inches apart, covering them with earth about three inches deep; and when they come up you must carefully clean them from weeds : the distance allowed between each row is for the use of the horse-hoeing plough, which will dispatch a great deal of this work in a short time ; but it should be very carefully done, so as not to injure the young plants, therefore the middle of the spaces only should be cleaned with this instrument, and a hand-hoe must be used to clean between the plants in the rows, and also on each side, where it will be unsafe for the plough to be drawn; and in handhoeing there must be great care taken not to cut the tender rind of the plants. If in the following spring the spaces are carefully stirred with the plough, it will not only make the ground clean, but also loosen it, so as that the sun and moisture may more easily penetrate the same, which will greatly promote the growth of the plants; and the offener these ploughings are repeated, the cleaner will be the ground, and the greater the progress of the plants, which cannot be kept too clean while they are young. When these have remained three or four years, if the nuts succeed well, you will have many of these trees to remove, which should be done at the seasons before directed, leaving the trees about three feet distance in the rows, at which distance they may remain for three or four years more, when you should remove every other tree to make room for the remaining, which will reduce the whole plantation to six feet square, a distance sufficient for them to remain in until they are large enough for poles, when you may cut down every alternate tree, selecting the most unpromising, within one foot of the ground, in order to make stools for poles, which in eight or ten years' time will be strong enough to lop for hoops, hop-poles, &c. for which purposes they are preferable to most other trees, so that every tenth year there will be a fresh crop, which will pay the rent of the ground, and all other incumbent charges, and at the same time a full crop of growing timber left upon the ground; but as the larger trees increase in bulk, their dis-

they have grown to a size for small boards, you should fell every other tree, which will reduce them to squares of twenty-four feet, which is a proper distance for them to remain for good ; this will give air to the underwood, which by this time would be too much overhung by the closeness of the large trees, by which means that will be greatly encouraged, and the small timber thus felled will pay sufficient interest for the money at first laid out in planting, together with the principal also; so that all the remaining trees are clear profit, for the underwood still continuing will pay the rent of the ground, and all other expenses; and how fine an estate the succeeding generations will find in the course of fourscore years, when the timber-trees shall have arrived at maturity, every one may easily conceive. In making a plantation of chesnut-trees for the fruit, the ground should have three or four ploughings the preceding summer and winter; and if one good digging be added a little before planting, it will be a great improvement. Plant your trees in rows six feet distance every way, dig the ground annually, and when the branches begin to meet, take up every second row and every second plant, which will leave all the trees at twelve feet distance, while the wood of those that are taken up will be found of great use for many purposes. Having dug or halftrenched the land, if it be of good quality it may for some years be cultivated with potatoes, cabbages, and turnips. When the branches begin again to meet, they must be reduced as before, and left twenty-four feet asunder, at which distance they may remain. The wood of this last felling will saw into small boards, and being about twenty years old, must be rooted out, for the chestnut shoots vigorously from stools. The remaining trees having produced fruit for several years, will now bear vast quantities, and make great returns of profit. In raising chestnut woods for timber, Mr. Boutcher advises for the first two years to take a line of beaus between the drills; and at the end of two years, carly in the spring, to remove every second plant in the rows, which will leave them about two feet and a half asunder, at which distance they may remain for three years. Then remove every second row, and every sscond tree in the remaining rows, which will leave them at the distance of eight feet by five; these plants will be useful for stakes and poles. The ground may now be levelled, and dug for any kitchengarden crops; in the February following cut them down, reserving only the straightest and most vigorous, at the distance of twenty-five or thirty feet. Dwarf crops may be taken between the rows for two years more, after which the trees will soon cover the ground. Both Mr. Boutcher and Dr. Hunter prefer February to Octoher for transplanting. Mr. Marshall advises the nuts to be set by the dibble, six inches asunder, in a quincunx order; because drills serve as conductors to the field mouse. Mr. Hanbury contends for planting a chestnut wood from the nursery; he advises to plant out the trees when they are five feet high, because they will not be so large as to require staking, nor so small as to be within the reach of hares, rabbits, &c. the distance to be two yards, which is far enough asunder for poles; when they are large enough for this use, they should be cut down, leaving a sufficient number of the most thriving trees for timber, this will be in fourteen years; if they are cut within a foot of the ground, there will be stools for another crop in ten years more. If the plantation be large, the first fall of poles may be begun so early, and the latter deferred so late, that the year after the last fall, the stools of the first-cut poles shall have sent forth others ready for a second cutting. Thus the proprietor will enjoy the benefit of an annual sale, tance of twelve feet square will be too small, therefore when and the country will not be glutted with too great a quantity,

Mr. Hanbury prefers this method, because when the tree is raised from nuts, it is subject to a tan-root, which strikes beyond the reach of nourishment, and grows slower in consequence : and because while they are in the nursery a vast quantity will stand in a small space; whereas when they are raised from the nuts, the whole wood must be kept clear of weeds till the plants are grown of a sufficient size to need no further weeding. The chestnut will thrive on almost any soils, and in all situations, if there be no standing water ; it succeeds best in a rich loamy land, aud will flourish very well on gravel, clay, or sand. All mixed soils suit it, as well as exposed places, and the declivities of hills. In foreign countries, where the chestnut is cultivated for the fruit, they graft cions from trees bearing the largest and fairest fruit, upon stocks raised from the nut. These grafted trees are, however, unfit for timber, and are called maroniers by the French. The varieties with striped or blotched leaves are maintained by budding, and in arching upon common chest-nut stocks. The chestnut-tree has its name *castanea*, from a town of that name in Thessaly, about which this tree grew in great abundance: it has the same appellation in all the European languages: the Germans call it castanienbaum : the Swedes and Danes, castanientræ ; the French, chataignier ; the Italians, castagno ; the Spanish, castano ; the Portuguese, castanheiro ; the Russians, keschtan.

2. Fagus Pumila; Dwarf Chestnut Tree, or Chinqua Pine. Leaves lanceolate-ovate, acutely serrate, tomentose under-neath; aments filiform, knotty. This seldom grows above twelve or fourteen feet high, but produces abundance of nuts, which are generally single in each capsule. This tree is very hardy, and will resist the severest of our winters in the open ground, but is very apt to decay in summer, especially in a dry soil. But although it delights in moisture, yet if the wet continues long upon the ground in winter, it frequently destroys the trees. It is very common in the woods of Ame-rica, but rare in England. The nuts of the chinqua pine, or dwarf Virginian chestnut, should be put up in sand as soon as they are ripe, and shipped off immediately, otherwise they will lose their vegetating quality. When the nuts arrive in England, they should be put into the ground as soon as possible, and if the winter should prove severe, cover the ground with leaves, tan, or pease-haulm, to prevent the frost from penetrating to the nuts.

3. Fagus Sylvatica; The Common Beech Tree. Leaves ovate, obscurely serrate. This tree will grow to a very large size, lofty, and spreading, the trunk straight, and covered with a whitish bark; the leaves are smooth and glossy, waved on the edges, rather than servate, or slightly sinuatetoothed, three inches and more in length, and two or upwards in breadth; the petioles reddish, slightly grooved above, four or five lines in length, pubescent, as is also the midrib of the leaf; stipules reddish-brown, shining, lanceolate, conspicuous; it retains the old leaves through the winter; the male catkins come out in bunches from the ends of the small branches, they are roundish, obtuse, half an inch long, and almost as broad, on peduncles from half an inch to fourteen lines in length, pendulous, round, aud pubescent; calix cut half way into six, sharp, villose, yellowish segments; stamina uncertain, four, six, eight, nine, eleven, and twelve, from the bottom of the calix; the female aments come out from the same place, a little above the others, they are erect. and on round, whitish, villose peduncles, four lines or upwards in length, the common involucre has two flowers, is four-cleft, and covered with soft spines ; calix superior, six-

one-cleft ; stigmas awl-shaped, aud slightly hooked, yellowish and smooth ; at the top of the germen there are also six whitish villose segments, shorter than the styles; the fruit is composed of two nuts joined at the base, covered with an almost globular four-valved involucre, with soft spines on the outside, but within very smooth and silky : the nuts, when ripe, are one-celled and triangular, and contain one or two angular seeds. The beech is very well adapted to form lofty hedges, to surround plantations, or large wilderness quarters, or for screens, where there is not room for trees to extend their branches naturally. Although the timber of this tree is not so valuable as that of many others, yet as it grows very fast in chalky or stony ground of little value, with a clear smooth bark and straight trunk, and as it will thrive on such soils and in such situations as better trees will scarcely grow on, and as it will resist winds on the declivities of hills better than most other trees; the planting of it should be encouraged, especially as it affords an agreeable shade, and the leaves both make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees, when they turn brown or orange, and frequently hold on all the winter. In parks, therefore, and other plautations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it. But though the wood of the beech be brittle, and decays soon in the air, yet it will endure long under water, and scrves for a great variety of uses, as will appear from the following account: It is of great use to turners for making trenchers, dishes, travs, buckets, &c.; to the joiner, for stools, bedsteads, and other furniture : to the wheel and millwright ; it makes shovels and spade-graffs for the husbandman, and is useful to the bellowsmender: floats for fishermen's nets, instead of corks, are made of its bark. It is good for fuel, billet, bavin, and coals, though one of the least lasting; and the very shavings are excellent for fining of wine. When the timber lies altogether under water, it is scarcely inferior to elm. Baskets for strawberries are made of the bark ; of the thin lamina or scale of the wood, scabbards for swords, band boxes, hat-cases, &c. The leaves are used abroad, on account of their elastic quality, instead of straw, for the paillasse, to lay under their mattrasses. To the above enumeration of its uses by Mr. Evelyn, we may add many other. It is now in much repute among the cabinet-makers, for chairs, both plain and painted, for bedstcads, with the posts frequently stained the colour of mahogany. In the country it is much used for rafters, in building. Much of it is cut out iuto quarters and planks for various purposes, and barn-floors are frequently laid with it. The millwright uses it for cogs, &c. and the wheelwright for spokes and fellies: it goes to the dock-yards for wedges, and may be used in ships' bottoms from the keel to the floorheads; and is known in the coal mines under the name of Newcastle railing. Being of an even grain, and without knots, it makes beautiful benches and railing for public rooms, and many sorts of inside work in houses. It is formed into gun-stocks, tool-handles, mallets, carpenters' planes, heel-pieces, pegs for heels, and into sounding-boards for harpsichords, by the musical instrument makers. The soapcask coopers cut it into staves for dry goods, for which purpose a considerable quantity is imported as ballast from Bremen and Dantzic, in slabs and clapboards about five feet in length. It is said that these coopers consume from twenty to thirty thousand of these clapboards yearly, except in time of war, when the importation is stopped. It is excellent leaved, tomentose; germen three-celled, with two rudiments fuel, and in burning affords a large quantity of potash. of seeds in each cell; style three, or, according to Gærtner, Much of it is sent to the metropolis, under the name of London billet, for the use of the bakers, glasshouses, &c.

The stackwood which is made up of the branches, is burnt chiefly into charcoal; the nuts or mast, as they are commonly called, fatten swine, but the fat is not firm; and they are greedily devoured by mice, squirrels, and birds : they are said to occasion giddiness and head-ache, but when dried and powdered, to make wholesome bread; they are sometimes roasted as a substitute for coffee, and the poor people in Silesia use the expressed oil instead of butter. At the beginning of the last century, Aaron Hill had a project for paying off the national debt with the oil of beech nuts, but they seem to yield so little oil in northern countries, that Linneus informs us, that scarcely any oil can be expressed from them. If the soil be tolerably good, beech will become fit to be felled in twenty-five years; the woods are then drawn, as it is called, that is, the trees fit for firewood or billet, poles, timber, &c. are taken down, and no crooked trees are suffered to remain. Formerly it was the custom to leave the old stools to produce new trees, but as these seldom grow well and handsome, now during the winter the old stools are grubbed up, and the plants which spring spontaneously from the mast are encouraged, to supply the places of the trees which are taken down. Once in six or seven years this operation of drawing the woods may be repeated, and thus there is a constant and regular succession of trees fit to cut. The price which firewood or billet fetches in Buckinghamshire, is nearly fourpence the foot solid measure; the poles and better stuff, for gun-stocks, wedges, &c. sell for fivepence the foot; and the largest trees, for millwrights, sell for sixpence or sevenpence; stackwood is fifteen or sixteen shillings per load, and faggots fifteen or sixteen shillings the hundred. Cesar's assertion, that the fagus was not in Britain when he visited the island, can hardly be controverted by supposing that his fagus is not the beech. But whatever may have been the case in Cesar's time, the beech is now no uncommon tree in many considerable tracts of Great Britain, particularly on that large ridge of chalk hills which runs from Dorsetshire, through Wiltshire, Hampshire, Surry, Sussex, and Kent, branching out into Berkshire, Buckinghamshire, and Hertfordshire; on the declivities of the Cuts wold and Strondwater hills of Gloucestershire, and on the bleak banks of the Wye, in the counties of Hereford and Monmouth; and it is, in short, to be found in almost every county of England. Some plantations of it have been lately made by the earl of Fife, in the county of Murray, where his lordship has planted nearly two hundred thousand of these trees. George Ross, Esq. has also set 13,000 of them in Cromarty. In England, John Sneyd, Esqr. has planted above 14,000 at Belmont in Staffordshire, between the years 1784 and 1786; and in 1788 the bishop of Landaff planted 2000 at Ambleside. The beech is a native of the greater part of Europe, and the southern provinces of the vast Russian empire; but it is not foud of very high and cold situations, being seldom found in the northern provinces of Sweden. Mr. Lightfoot doubts whether it be indigenous in Scotland; and Mr. Marshall thinks it not a native of the northern counties of England. It prospers in a chalky and rocky soil, but not in light lands, and thrives prodigiously in sheltered bottoms, but seldom flourishes in a western exposure. In some parts of Herefordshire, where the soil is a strong clay full of flints, this tree grows to a great size, and is extremely beautiful. Beech, says the late Mr. White, is one of the most grand and lovely of all the forest-trees, whether we consider its stately trunk, its smooth silvery rind. its glossy foliage, or graceful spreading pendulous boughs. 47.

ing singly in parks or ornamental grounds, as it throws out its branches very regularly, and feathers almost to the ground: in woods or groves it grows clear of branches to a great height. Mr. Gilpin is not inclined to rank the beech much higher in picturesque beauty than utility. Its trunk. he allows, is often highly picturesque, being studded with bold knobs and projections, and having sometimes a sort of irregular fluting, which is very characteristic; the bark too wears often a pleasant lue; it is naturally of a dingy olive, but is overspread in patches with a variety of mosses and lichens; its smoothness also contrasts agreeably with these rougher appendages. This is all the merit Mr. Gilpin allots to the beech ; for, says he, we rarely see it well ramified, and in full leaf it has the appearance of an overgrown bush. Virgil indeed was right in choosing it for its shade, for no tree forms so complete a roof, although its bushiness gives it great heaviness. The beech, therefore, is most pleasing in its young state, it is then light and airy, with spiry branches often hanging in the most easy and beautiful forms, and some of the finest oppositions of tint arise in the autumn from the union of this tree with the oak. Although this tree is supposed not to be a native of Ireland, several fine beeches are mentioned in that country; as at Tiny park, the seat of sir Skeffington Smyth, three noble trees together, the smallest fourteen feet round, the next fifteen feet six inches at the butt, and fourteen feet eight inches at seven feet from the ground, the third is sixteen feet three inches round, and continues nearly of the same girth for thirty-six feet. The celebrated Arthur Young, in his Travels in France, speaks of a beech at Chantilly as the finest he ever saw, straight as an arrow, and not less than eighty or ninety fect high, forty fect to the first branch, and four yards in diameter at five feet from the ground .- The beech derives its Latin name fagus from a Greek word which signifies to eat, either because mankind lived on beech mast before the use of corn. or because it was the food of the common people: the appeliation is the same in all the northern languages, and in all the dialects of the Sclavonian : in German, buche, buke, or boke; in Danish, bog; in Swedish, bok; in Russian and Polish, buk; the French hetre, is from the German hester, which signifies a young beech; the Italians call it faggio, from the Latin, which the Portuguese have softened into faya, and the Spaniards into haya, although they sometimes call it fagos. There are some planters who suppose that there are two species of this tree, the mountain beech and the wild beech, the first of which has a whiter wood than the second; but this difference arises only from the soil. There are also seeds of a beech brought from North America, by the name of broad-leaved beech, but the plants raised from them proved to be the common sort. There are two varieties in the nurseries, one with yellow, and the other with white stripes. In Germany they have another variety, with dark red leaves, which is called the purple brech. There are also some trees in our woods with a rougher bark, which the woodmen call hay beech : this tree is propagated by sowing the mast, the season for which is any time from October to February, only observing to secure the seeds from vermin when early sowed; if this be carefully done, the sooner they are sown the better. Since beech-mast, however, keeps very well, and is greatly relished by field mice and other vernin, many planters prefer spring sowing, in which case the seeds should be spread on a mat in an airy place for a few days to dry, and then put up in bags. A small spot of ground will be sufficient for raising a great number of these trees from seed: they must be kept clean No tree, says another writer, is more beautiful, when stand- from weeds, and if they come up very thick, drawing the

7 B

strongest the autumn following, and thus if a seed-bed be husbanded carefully, it will afford a three years' draught to young plants, which should be planted in a nursery; and if designed for timber-trees, at three feet distance row from row, and eighteen inches asunder in the rows: but if designed for hedges. two feet row from row, and one foot in the rows, will be sufficient. In this nursery they may remain two or three years. observing to clear them from weeds, and to dig up the ground between the rows at least once a year ; but be careful not to cut or bruise the roots, and never to dig the ground in summer. when it is hot and dry. The beech will prosper on stony barren soils, but then the nursery for the young plants ought to be upon the same soil, for if they be raised in a good soil and a warm exposure, and afterwards are transplanted into a bleak barren situation, they will seldom thrive. See Nursery. For hedges, the beech may be kept in a regular figure, if sheared twice a year at least, when it shoots strong; in which case, if the hedges be neglected but a season or two, it will be difficult to reduce them again. The varieties with striped leaves may be continued by budding or grafting upon the common beech, observing not to plant them in too good a soil, which will frequently cause the leaves to become plain. The above directions being in some respects imperfect, we subjoin the following from Mr. Boutcher: Being provided with mast from the straightest and freshest trees in September, as soon as the husks are quite dry, mix them with sand, and lay them under an old frame or other covering, to protect them from frost and wet. The beginning of March, sow them in beds four feet wide, in shallow drills eighteen inches asunder, covering them one inch deep ; if the season be dry, give them frequent but moderate waterings, from the time of their appearance above ground, until the middle of August. In March, next season, with a spade made very sharp, undermine the roots, and cut them over between four and five inches under ground, In the following autumn or spring, either raise the whole, or give them another cutting under ground, when gently raising such as are too thick, leave the remainder at proper distances to stand another season: plant such as you have raised, after smoothing the bruised and broken roots, and cutting away some of the small hairy fibres, in lines two feet asunder, and nine or ten inches in the line; here they may remain two, or, if the land be poor, three years. Next autumn or spring treat the rest in like manner; trim off only cross ill-placed branches, and those sparingly. From this nursery they must be removed to another, and planted in rows three feet and a half asunder, and eighteen inches in the row; here they may remain three years, in poor land four, observing always to prune moderately at removal, and to leave abundance of small branches. These plants will now be fit for common and extensive plantations; but such as are designed for removal when large trees, must again be transplanted in rows five feet asunder, and two feet distance in the rows, to remain in good ground three, in poor ground four years. From this remove them again into rows eight feet asunder, and six feet in the row, to remain four years : if required of a still larger size, plant them ten feet asunder every way. Mr. Young informs us, in his Irish Tour, that Mr. Mahon made a plantation of all sorts of forest trees in his park, in order to see how far the deer would let them escape ; they devoured every tree except the beech, not one of which they touched, either in leaf, branch, or bark : many of these beeches, of not more than thirty years' growth, were three or four feet in girth, and from thirty to forty feet high.

4. Fagus Ferruginea; American Beech Tree. Leaves ovate-oblong, remotely and acutely serrate, acuminate, tomentose underneath.-Native of North America.

5. Fagus Cochin-chinensis. Leaves ovate, crowded; capsules three-celled, three-valved. This is a small tree, about five feet high, with branches ascending a little; leaves obscurely serrate, smooth, petioled; made flowers in terminating aments, with a five-cleft calix and corolla, and twelve stamina; female flowers below on the same branch, with a five-cleft calix, and no corolla; capsule muricated, threecelled, three valved, one-seeted. The seeds are of the same form and colour with the common sort, but very small. The corols of the male flowers being very thin and membranacous, may be considered as a neetary. There appears to be some doubt whether this be a distinct species from the common beech.—Native of Coehin-china.

Fair Maids of Kent. See Ranunculus.

Falkia ; a genus of the class Pentandria, order Digynia .--GENERIC CHARACTER. Calix: perianth one-leafed, somewhat inflated, five-cornered, shorter by half than the corolla, five-parted; angles widened in the middle, compressed, standing out ; divisions ovate, acute. Corolla : one-petalled. bell-shaped, crenate, ten-parted; border spreading. Stamina : filamenta five, filiform, inserted into the tube of the corolla, erect, unequal, shorter than the corolla; antheræ ovate, compressed. Pistil: germina four, superior, smooth: styles two, capillary, divaricate, the length of the corolla; stigmas capitate, obtuse, simple, orbiculate, peltate. Pericarp : none. Seeds : four, globular, arilled at the bottom of Observe. This genus is allied to convolvulus, the calix. having the flower of the same structure, but differing in the seed. ESSENTIAL CHARACTER. Culix: bell-shaped, five-cleft. Corolla : bell-shaped ; stigmas orbicular, peltate. Seeds : four, arilled .--- The only discovered species is.

 Falkia Repens; Creeping Falkia. A perennial plant, flowering from May to June, and a native of the Cape of Good Hope. It is generally increased by parting the roots, planting in loamy earth, and watering freely in summer, Fan Palm. See Chamarrons.

Feather, Prince's. See Amaranthus. Feather d Columbine. See Thalictrum. Feather Grass. See Stipa. Felwort. See Gentiana. Fermale Fern. See Pteris.

Fences .- In hotter climates than England, where walls are not wanted to ripen fruit, the gardens lie open, where they can have water, fence, or prospects, or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing to the sight than a dead wall ; but in colder countries, and in England, we are obliged to have walls to shelter and ripen our fruit, although they deprive us of the pleasant prospect of the garden. Since, therefore, we are under the necessity of having walls to secure our gardens from the injury of winds, as well as for the conveniency of partitions or inclosures, and also to ripen our fruit, brick walls are accounted the warmest and best for this purpose; and these walls being built in the shape of pannels, with pillars at equal distances, will save a great deal of expense, because they may be built thinner than when built plain without these pannels; for then it would be necessary to build them thicker every where; and it must be allowed that the pannels are an ornament to the wall. Stone walls are preferred by some persons, and especially those of square hewn stones; but where they are designed for fruit, they should be faced with brick. Those that are made of rough stones, though they are very dry and warm, yet by reason of their unevenness are inconvenient to nail up trees to, except pieces of timber be laid in them here and there, to fasten a trellis to them. But in large gardens, it is better

554

should be surrounded with a fosse, that from the garden the adjacent country may be viewed; but this must depend on the situation of the place, for if the prospect from the garden be not good, it had better be excluded by a wall, or any other fence, than remain exposed to view. And where a garden lies near a populous town, and the adjoining grounds are open to the inhabitants, if the garden be open, there will be no walking there in good weather, without being exposed to the passers by, which is very disagreeable. Where fosses surrouud a garden situated in a park, they are extremely proper, because hereby the prospect of the park will be enjoyed in the garden, which will thus be rendered much more agreeable than those which are confined. There have been numberless inventions for making these fosses, but there are none in all respects preferable to those which have an upright wall next the garden, which, where the soil will admit of a deep trench, should be six or seven feet, high, so as to be above the reach of boys : and from the foot of this wall, the slope on the outside should rise with a gradual easy slope, to the distance of eighteen or twenty feet; and where it can be allowed, if it slopes much farther, it will be easier, and less perceptible as a ditch to the eye, when viewed at a distance. But if the ground be naturally wet, so as not to admit of a deep fosse, then, in order to make a fence against cattle, if the wall be four feet high, and slight posts of three feet and a half high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it, therefore it will be a secure fence against them; and if painted of a dark lead colour, they will not be discerned at a distance; at the same time that the chain will secure persons walking in the garden from tumbling over; and if another chain be carried through the posts at one foot from the ground, it will more effectually prevent cattle from creeping under. In places where no good prospects can be obtained from a garden, it is common to make the inclosure of park-paling, which, if well performed, will last many years, and has a much better appearance than a wall: this pale may be concealed by plantations of shrubs and evergreens within, or else by a quick hedge, which may be trained up so as to be an excellent fence by the time the pales begin to decay. There are some persons who make stockade fences round their gardens to keep out cattle, which, when well made, will answer the purpose of a fence; but these being very expensive in the making, and not very lasting, has prevented them from being brought into common use. As to park fences, they are generally of paling, which, if well made of winter-fallen oak, will last many years; but a principal thing to be observed in making these pales is not to make them too heavy, for when they are so, their own weight will cause them to decay; therefore the pale should be cleft thin, and the rails should be cut triangularly, to prevent the wet from lodging upon them; and the posts ought to be good, not placed too far asunder, burning that part of them which goes into the ground. If these directions be observed, the pales will last upwards of forty years in good order. The common way of making such fences, is to have every other pale nine or ten inches above the intermediate ones, so that the fence may be six feet and a half high, which is enough for fallow deer; but where there are red deer, the fence should be one foot higher, otherwise they will leap over. Some enclose their parks with brick walls; and in countries where stone is cheap, the walls are built with this material, some with, and others without mortar. A kitchen-garden, if rightly contrived, will contain

to have the prospect open to the pleasure garden, which the assistance of a wall for any family; and this garden being situated on one side, and quite out of sight of the house, may be surrounded with walls, to screen these persons in the kitchen-garden from the sight of those in the pleasuregarden ; and being locked up, the fruit will be much better preserved than it can be in the public garden; and the having too great a quantity of walling is often the reason why so many defective trees are frequently seen in large gardens, where there is not due care observed in their management. The borders of pleasure-gardens are also, in general, too narrow for the roots of fruit-trees, which it is therefore useless to plant there. The height of garden walls should be from ten to twelve feet high, which is a moderate proportion; and if the soil be good, it may in time be furnished with bearing wood in every part, especially those parts planted with pears, notwithstanding the branches being trained horizontally from the bottom of the walls. The white thorn, the holly, the black thorn, and the crab, are separately recommended for outward fences to a good ground, but it is said to be injudicious to intermix them. The white thorn is the best to plant, because it is the most common, and may be clipped so as to render it the closest and hardiest fence of any other tree, and being very durable, is preferred to all others for outward fences, or for the division of fields, where they are exposed to cattle. The black thorn and crab make very good fences, and are to be raised like the white thorn; but if the kernels of apples or crabs be sown, it is the best to sow the pummace with them, and they will come up the sooner, that is, in the first year, if sown in the autumn soon after the fruit becomes ripe. If crab-stocks be planted while young, in the same manner as the quick, they soon make excellent hedges; and so will some sorts of plums, especially such as are thorny. The black thorn is not so much esteemed for fences as the white thorn, because it is apt to run more into the ground, and is not certain as to the growing, especially when the plants are not set while very young; but then, on the other hand, the bushes are by much the better, and are also more lasting than the white thorn, or any other, for dead hedges, or to mend gaps: nor are they subject to be cropt by cattle as the others are. The richer the mould is, the better they will prosper, but yet they will grow on the same sort of soil that the white thorn does. The holly will make an excellent fence, and is preferable to all the rest, except that at first it grows slowly; but when once it does grow, it makes amends by its height, strength, and thickness. It is raised of young seedling plants or berries, as the white thorn is, and the berries will lie as long in the ground before they come up. It delights most in strong grounds, but will grow upon the driest gravel among rocks and stones. French furze will often do well upon dry saudy banks, where few other plants will grow; but they must be kept very clean at the bottom, and cut thin, and never suffered to grow too high, nor should they be cut in dry weather, or late in autumn, nor early in the spring; the doing either of which, is likely to make it die in patches, which is irrecoverable : it will never break out from old wood if cut close in, after it has been suffered long to grow out. Fences may likewise be made of elder; if the soil be tolerably good, you may put sticks of elder, or truncheons ten or twelve feet long, slopeways in your banks, so as to make a chequerwork ; and they will make a fence for a garden the quickest of any thing, and be a good shelter. But these fences are improper for a fine garden, because they shoot very irregularly, and are ungovernable: the roots of these trees also spread very far, and draw away all the heart of the ground, walling enough to afford a supply of such fruits as require so as to starve whatever plants grow near them : add to this the scattering of the berries, which will fill the ground near them with young plants, and if not weeded out in time, will spoil every thing about them, so that this sort of fence is seldom planted where a hedge of white thorn can be had. Elder planted on a bank, the side of which is washed with a river or stream, will make an extraordinary fence, and will preserve the bank from being undermined by the water, because it is continually sending snekers from the roots and lower branches, which is of great advantage where the stream washes away the bank. For middle fences in a garden, the yew is the most governable and durable plant. For surrounding wilderness quarters, elm, lime, hornbeam, and beech, are very proper. For farther particulars, see the article Hedges.
