The Coorgs make some attempts at bee culture and practise the industry to a small extent in their own homes; the bees are domesticated, and the hives, which are of a very primitive description, made merely of the hollowed out trunks of trees, are placed near the houses. The Coorgs have, however, no notion of collecting the surplus honey by any of the contrivances, such as bell-glasses, supers, etc., in use in England in the different apiaries.

In Cuddapah wild honey is collected also from the cliffs and ravines of the district. The process adopted is both perilous and exciting, and the Yanadies alone are able to climb into the difficult and apparently inaccessible places over perpendicular cliffs, in some places from 100 to 200 feet in height. They do this by the aid of a plaited rope, made of young bamboos tied together. This rope sometimes gives way, the result being a terrible accident. It is a very nervous sight to watch the men climbing up these frail supports, and it reminds one of the egg-collecting process in northern latitudes. The men, from below, look like little babies hanging midway, the rope being fastened on the top of the cliff above, by means of a peg driven into the ground, or to the trunk of a tree, the man swinging midway with 100 feet or so above and below him, and armed with a stick and a leather basket. The Yanady first burns some grass or brushwood under the hive, by which the bees are driven out; he then swings the rope until it brings him close to the hive, which he pokes with his stick, holding out his basket at the same time to catch the detached portions of comb. When the basket is full, he shakes the rope, at which signal his comrades above draw him up. The bamboo ropes are left to hang, often for years, until they rot away, for a rope of this kind is never used twice, a fresh one being made on each occasion and at each place.

South Canara is also a great honey district. The honey and wax have, however, but little local value, a maund, about 25 lbs., only fetching R2 and R16. It is thought that much might be done to open up the industry by exporting the honey and wax to England, the latter being a valuable product and one for which there is always a demand. The trade at present in Indian honey is almost entirely confined to wild honey; but as the keeping of bees is an industry requiring little or no capital, it is especially adapted to the people of India.

* From the *Times.*

Should the returns obtained from the inquiries now made and set on foot by Mr. Douglas show that it is worth while to introduce this industry in a practical form, then Mr. Buck—the whole subject having been placed under his department—may possibly see his way to making a decided effort to interest the people in systematic bee culture with a view to the trade in honey and wax becoming ultimately a profitable one to the country.

ANTISEPTIC PROPERTIES OF CARBONIC ACID.*

BY PROFESSOR H. KOLBE.

Since 1874, when the author published his first experiments on the antiseptic action of salicylic acid, it has been his constant endeavour to find out a suitable method of its employment for preserving meat. Innumerable experiments, repeated under varied conditions, have convinced him that although meat impregnated with carbonic acid is, in fact, protected from decay, it acquires an unpleasant flavour after a few days, and when boiled or roasted it disseminates a disagreeable (but not putrid) odour. In spots where any decomposition was noticed, the meat no longer reacted acid, but alkaline.

This experience led to the conjecture that meat could be protected from spoiling by the acids in general, as well as by their gases, if it is thereby protected from the liberation of ammonia which accompanies decomposition, in the same manner as by putting it in vinegar.

The first experiment in this direction, made by putting a piece of beef on a plate under a glass bell jar of carbonic acid, was unsatisfactory. Before the end of the week, a putrid odour was perceptible, and the parts in contact with the plate, where no carbonic acid could reach them, showed an alkaline reaction.

The results were better when the meat was suspended so as to hang freely in a vessel filled with carbonic acid.

The experiment was repeated in apparatus of various sizes. The meat to be preserved was hung on a tinned iron hook that moved along a horizontal iron rod in a cylinder made of sheet tin. On the bottom of the cylinder was a porcelain dish to catch the dropping liquid from the meat, and in the side of the cylinder, just above the dish, a tubulus was soldered on air tight, and through it passed a short glass tube connected with a rubber tube for introducing the carbonic acid gas. The rubber tube could be closed quickly and tightly by means of a pinchcock. The cylinder also had a gutter around the top, into which the lid fitted, and which was half full of glycerine. A tubulus was also soldered into the top of the metallic cover, and provided with a glass tube like the lower one.

The glycerine acted like a water seal, and when the vessel was closed, carbonic acid from a Kipp's constant apparatus was passed in by the lower tubulus and expelled the air through the upper one, which was left open. When nearly all the air may be supposed to have been displaced by carbonic acid, the two rubber tubes are securely clamped.

The first series of experiments were made in winter, the second in the hot months of summer. The cylinder containing the meat stood in the warmest room of my laboratory, which, being on the south side, was exposed to the sun's rays for the greater part of the day, and at noon the temperature rose to 32° C. (90° F.). Pieces of freshly killed beef weighing from 2 to 5 kilos (4½ to 11 lb.), including bone and fat, were used.

A week after the beef had been put in the cylinder of carbonic acid, it could not be distinguished by appearance, colour, or odour from fresh meat. It reacted slightly but distinctly acid everywhere.

After being carefully washed off it was boiled in water. The broth made from it smelled and tasted just like that from fresh meat, and the meat itself, if not boiled too long, was soft and tender, not stringy.

Meat suspended in carbonic acid for two weeks had the same qualities as the other, except that it looked greyer, but within it was red and juicy. The broth made from it, as well as the meat itself, had a pleasant flavour, and only a very sensitive palate could distinguish a slight difference in the taste of this broth and that from fresh meat. In a few cases the meat as well as the soup had a slightly acid taste, which was completely removed by putting in a very small quantity of carbonate of potash. Meat kept in carbonic acid for three weeks was as good as that left there for two weeks, but was softer than fresh meat, and required less time to cook it, or to obtain good broth.

After being kept in carbonic acid for four or five weeks, the meat was still free from putrid smells, but the broth made from it did not taste as good as fresh *bouillon*. The experiments were not continued any longer.

From this it will be seen that *carbonic acid is an excellent preservative for beef*, which will retain its flavour in it for several weeks.

It is worthy of note that mutton acts quite differently, and after being kept in carbonic acid gas for a week it begins to have a putrid smell.

Veal does not keep as long as beef. No experiments have been made with game or fowls.

Fish, oysters and fruit only keep a short time.

This property of carbonic acid to preserve beef a long time will scarcely become of any great practical importance, but may find use where carbonic acid is given out in abundance from the earth. At the Nauheim baths there are dry wells in which almost unlimited quantities of carbonic acid stream forth and are pumped out to be used for making soda water, and for other purposes. It would be worth while to try how long beef could be kept fresh by hanging it on a rope in such a well.

The experiments described give rise to many other queries, such as whether light has any effect on the preservative power of carbonic acid.

The author does not propose to extend his experiments any further, and leaves the field free for others who wish to study the chemical and physiological changes and reactions.

NEGRO COFFEE.*

The following extract from a letter from Dr. Nicholls, of Dominica, shows that the use of the seeds of *Cassia occidentalis* as a coffee substitute is well known amongst the negro inhabitants of that island:—

"*Cassia occidentalis* is, I find, an excellent coffee substitute; it is called in Dominica by the following names, 'l'herbe puante,' 'café marron,' and 'wild coffee.' I have often heard of the negroes using the seeds of a native plant as coffee, but it is only lately that I have inquired into the subject. I collected some seeds and directed my cook to roast and grind them, so that I might taste the 'coffee.' Other matters engaging my attention I forgot the circumstance until several days afterwards, when one evening my wife inquired how I liked my after-dinner cup of coffee. I turned to her inquiringly, when she laughingly said, 'that is your wild coffee.' I was indeed surprised, for the coffee was undistinguishable from that made of the best Arabian beans, and we in Dominica are celebrated for our good coffee. Afterwards some of the seeds roasted and ground were brought to me, and the aroma was equal to that of the coffee ordinarily used in the island.

"The plant itself is used by the native 'doctors' medicinally in the form of a decoction, and it has the reputation of being a good diaphoretic. The weed is very common, so if it turns out to be valuable it can be obtained in large quantities."

The Pharmaceutical Journal.

SATURDAY, JANUARY 13, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MISUSE OF POISONS IN INDIA.

THE annual report of the work done in the Department of the Chemical Examiner to the Indian Government in Calcutta, a copy of which has been placed at our disposal by Dr. WARDEN, contains a considerable amount of information respecting the use and abuse of poisons in India. That country has long had an unfavourable reputation in respect to the use of poisons for criminal purposes, and the department was originally established in order to prevent irresponsible persons from interfering in toxicological investigations. The need for such a department is evidenced by the fact that out of 1900 analyses performed during the year, no less than 1157 were in connection with medico-legal cases. The number of human viscera examined was 225 and poison was detected in 93 cases. Opium and arsenic were the poisons most frequently found and aconite was detected in a few cases. Cattle-poisoning also seems to be on the increase, but for this purpose arsenic is the poison most used, and, indeed, it is the only one that was detected during the year. It is known, however, that other poisons are employed by the natives for the purpose, though at present they have not been sufficiently investigated to allow of their detection with certainty.

Besides the analyses in connection with cases where the death of men or animals was supposed to have resulted from poisoning, 652 suspected articles of food were examined and more than half of them were found to contain poison, the poisons most frequently occurring being arsenic, opium, datura, aconite and copper. Enormous quantities of arsenic were sometimes found in the parcels of suspected cattle poison sent for examination; in one case as much as one pound of white arsenic was found in two packets. Further, in consequence of the existence of rumours to the effect that the spirits manufactured in the country were sophisticated with nux vomica, datura, etc., a large number of samples were examined, but no poisonous vegetable adulterant was in any case detected.

The use of poison for criminal purposes has naturally commanded the attention of the Indian Government for some time past, and the advisability of imposing restrictions has been discussed. Three years ago the chemical examiner recommended that some restriction should be placed on the sale of strychnine on the grounds of its strong resemblance to santonin, and because these substances, which are largely used throughout the country, are sometimes mistaken for one another. As, however, not more than four deaths from strychnine were reported in 1878–79, and five in the following year, and only four of the nine were due to it being mistaken for santonin, the Lieutenant-Governor was of opinion that the number of accidents was too small to justify any such restriction as that proposed. It was, however, directed that a recommendation should be made to the medical store-keeper to colour strychnine with a view to the prevention of such mistakes. Last year the attention of the Lieutenant-Governor was again turned to the subject, as the improper use of strychnine, aconite, morphia, and mercury was becoming more common, whilst the returns of cases of poisoning by arsenic remained constant. After consideration, however, a similar conclusion was arrived at, that it was not desirable at that time to lay down stringent regulations for the sale of poisons, or to define the class of persons who should be permitted to sell poisonous drugs. In the present report Dr. WARDEN has once more referred to the subject, and suggests that if it be impracticable to restrict the sale of all poisons, the indiscriminate vending of arsenic at least might be diminished by levying on it a prohibitory tax which would place it beyond the reach of the masses.

Another description of valuable work done in the department has been the examination of potable waters, and in this report, together with a table showing results of analyses, Dr. WARDEN gives a short and interesting account of the quality of some of the kinds of Indian waters which he has analysed. Dr. WARDEN also draws attention to the prevailing neglect of simple precautions against the pollution of tanks, and makes some useful suggestions as to the best method of insuring the purity of the water contained in them. The report further refers to the work done by Dr. WARDEN in the chemical examination of indigenous drugs with a view to their substitution for imported drugs, some of the results of which have already been reported in this Journal. Amongst other things, reference is made to a solution of daturine, intended for ophthalmic purposes, which it is stated could be prepared on the large scale at about one shilling a pint. This solution has been submitted for medical trial, and although it is not considered strong enough and has been found occasionally to cause pain and irritation, it is spoken of as a very useful remedy which in certain cases of eye disease might be employed instead of atropine, with the advantage that it is far less costly. It may be hoped that, notwithstanding the multifarious labours which fall to this department, some time will be found to continue the work of chemical investigation in so promising a field as the native plants of India.

PHARMACY IN THE FRENCH ACADEMIES.

A visitor to the new School of Pharmacy in Paris will readily perceive that French pharmacists are by no means disposed to forget the past history of their art. Good reason have they indeed to be proud of the parts played in the world of science by their predecessors, and M. Lefort needs no justification for taking the opportunity afforded by a recent meeting of the Paris Pharmaceutical Society to call attention specially to the extent to which pharmacy has been represented in the scientific academies of France.

The first Academy of Sciences in France was founded in the year 1666, by Louis XIV., at the instigation of his famous finance minister, Colbert. It was intended to be devoted to practical science rather than to the reading of papers, and with this object laboratories were maintained at the royal expense at the place of meeting, in which experiments and observations were made and the results obtained were discussed by the members in common. Animal and vegetable products, minerals, and especially mineral waters, were submitted to such analysis as was then possible, and it was only natural that after a few years pharmacists should be called to take part in the work. The first pharmacist admitted into the Academy of Sciences, in 1686, was Moses Charras, the author of a 'Pharmacopée galénique et chimique,' and next, in 1699, came Nicolas Lémery, the author of the 'Cours de Chimie." Then followed Boulduc, Geoffroy, Rouelle and Cadet de Gassicourt. But the revolutionary wave that swept away men did not spare institutions, and a few months before Lavoisier was sent to the guillotine the academies in France were suppressed as useless. In 1795, however, the Convention established a new "Institut des Sciences et des Arts," which included all the academies as they now exist. In the new Academy of Sciences, as in the old, pharmacists have taken an honourable place, as will be seen from the following roll of names:—Bayen, the two Pelletiers, Vauquelin, Parmentier, Baumé, Deyeux, Proust, Serullas, Robiquet, Lesson, Gaudichaud, Balard, Bussy, Gerhardt, Lecoq, Planchon, Berthelot, Chatin, Girardin, and Milne-Edwards. Each of these men was a legally qualified pharmacist; but there have been others also who commenced their scientific career in a pharmacy, among whom may be mentioned, Dumas, Frémy, and Trecul.

The Academy of Medicine was founded in the year 1820, by a decree of Louis XVIII., and one of its duties was to be to reply to questions of the Government on all subjects affecting the public health, and particularly in respect to new and secret remedies, and natural and artificial mineral waters. Originally the Academy was divided into three sections, medicine, surgery and pharmacy, and the first nine nominations to the pharmacy section were —Boullay, Deyeux, Fabre, Henri, Laugier, Pelletier, Planche, Robiquet and Vauquelin. Amongst the earlier elections by the Academy itself were—Boudet, Derome, Caventou, Guibourt, Labarraque, Bussy, Chevallier, Derosne, Frémy and Serullas. Since the year 1829 the Academy of Medicine has been divided into sections, of which that devoted to pharmacy is the eleventh, but pharmacists frequently figure in other sections. The list, given by M. Lefort, of eminent pharmacists who have been connected with this Academy as members, associates or correspondents, is too long for quotation here, and this is the less necessary since it includes many names that have already been mentioned. At present there is only the one class of members, limited to one hundred, and amongst them are included many whose names have frequently appeared at the head of articles published in these pages.

THE RELATIONS BETWEEN MEDICINE AND PHARMACY.

A correspondent writing to the *British Medical Journal* last week sketches some clauses regulating the relations between medicine and pharmacy which he submits should be inserted in the proposed new Medical Bill. The first clause suggested would be a restriction upon medical practitioners, prohibiting them from supplying or dispensing medicines between 8 a.m. and 9 p.m., except in cases of emergency, if a pharmaceutical chemist were resident within half a mile or a mile. The second would most affect prescribers and patients, since it would provide that a prescription should not be dispensed more than once, unless ordered to the contrary, until it has been redated and resigned by a medical practitioner. The next would be restrictive upon chemists and patent medicine proprietors, for it would impose stringent regulations to prevent counter prescribing, prohibit the recommendation of proprietary preparations and patent medicines, and provide that the only statements on the wrappers and labels of patent medicines should be as to the ingredients and proportions of which they are composed, without any reference to their medical uses or effects. Although in the presence of actual facts these suggestions as a whole must certainly be looked upon as impracticable and chimerical, there is running through them a healthy recognition of the necessity for a more distinct separation of medicine and pharmacy, which is welcome. The writer also goes on to say that in consideration of the increased business which non-dispensing by medical men would give to pharmacists they would probably be induced to charge less for dispensing prescriptions, and be satisfied with 25 to 50 per cent. profit on the retail price of the drugs used. Although the charges for medicines are not likely ever to be regulated in this crude fashion, we think this question may be left to right itself, for pharmacy is not yet such a close preserve as to be free from the competition which in all other businesses influences so largely the rates of charge.

The Seventeenth Chemists' Ball, held at Willis's Rooms on Wednesday last, was attended by upwards of three hundred persons. The chair was taken by Mr. R. B. Warrick, who in proposing the single toast of "Success to the Chemists' Ball" referred to the increasing favour shown towards these annual gatherings, which he was well able to illustrate from his own experience as one of the earliest promoters of them. Great praise is due to the Honorary Secretary, Mr. J. F. Savory, for the admirable way in which the arrangements were carried out and the success of the Ball thus secured.

* * * *

The new edition of the United States Pharmacopœia is to be the subject of a communication which will be brought before the North British Branch of the Pharmaceutical Society, by Mr. William Gilmour, at the Evening Meeting on Wednesday next. A "Note on Pungent Tincture of Iodine" is also to be read at the same meeting by Mr. P. MacEwan.

* * * *

The Twelfth Annual Soirée of the Midland Counties Chemists' Association is to be held on Monday, the 22nd inst., in the Town Hall, Birmingham. Mr. Stokes Dewson is the Honorary Secretary.

* * * *

The Second Junior Pharmacy Ball is to take place at Willis's Rooms, on Wednesday the 24th inst. This year the Ball is under the patronage of Mr. Michael Carteighe, and Mr. W. H. Kerr is the Honorary Secretary.

* * * *

On another page will be found a paper on "Genius, Talent and Industry, and their Relation to Pharmaceutical Research," which Mr. R. W. Giles read before the School of Pharmacy Students' Association last week. The Association may be considered fortunate in receiving at the opening of a new session the stimulus of two papers relating to pharmaceutical research from such eminent men as Mr. Holmes and Mr. Giles, but it may be hoped that the potential investigators in the Association will not conceive the idea that because the reference to pharmaceutical research *per se* by the authors is somewhat limited the field is a small one.

* * * *

At the meeting of the School of Pharmacy Students' Association on Thursday next, a "Note on the Detection of Strontium" is to be read by Mr. F. Ransom; and Mr. W. Elborne, as Reporter on Materia Medica, will read a report upon "New Remedies."

* * * *

On Thursday, also, the Chemical Society holds its next meeting, when a paper will be read on "A New Method of Estimating the Halogens in Volatile Organic Compounds," by R. P. Plimpton, Ph.D., and E. E. Graves.

* * * *

With a view to collecting professional opinion as to the communicability of phthisis the Collective Investigation Committee of the British Medical Association has had enclosed in each copy of the *British Medical Journal* for last week a form, with a request that it should be torn out by the medical man receiving it and returned with a statement whether he has ever observed any case in which pulmonary phthisis appeared to be communicated from one person to another and other particulars.

* * * *

Commenting upon the medical treatment of M. Gambetta last week, the *Lancet* refers to the likelihood that the very means employed for his recovery retarded the object in view. Being a prominent man it was thought desirable to multiply the number of physicians and surgeons and to enjoin absolute rest, whilst if he had been a more obscure person, he would have been out in the garden in a week with his arm in a sling. The constipation resulting from the rest in bed is considered not improbably to have been the determining cause of the inflammation, but the *Lancet* thinks it "strange that amongst so many eminent members of the profession in attendance there was no one able to detect the irreparable mischief going on."

* * * *

According to some statistics recently presented by M. Pasteur to the French Academy, the mortality from charbon among eighty thousand vaccinated sheep in the department of Eure-et-Loire, where the average mortality of the previous ten years had been 9·01 per cent., fell last year to 0·65 per cent.

* * * *

The number of visitors to Kew Gardens during the year just completed is announced to have been 1,244,167, or 407,491 in excess of the number in 1881 as recently quoted in these columns.

* * * *

According to a statistical abstract of failures in the United Kingdom during the year 1882, which has appeared in *Kemp's Mercantile Gazette*, the total number of chemists and druggists who failed last year was 87, whilst in 1881 it was 168. There was also a falling off in the number of bills of sale registered from 351 in 1881 to 223 in 1882. The entire number of failures in Great Britain last year was 10,707, and in the previous year, 11,632.

* * * *

A correspondent in the Isle of Wight has forwarded us a cutting from the *Hampshire Independent*, in reference to the recent case of poisoning by chloral, from which it appears that the implied reflection upon the chemists who supplied the chloral hydrate syrup, conveyed by the remark of a juror at the inquest, had not any foundation in fact. We are informed that the bottle was duly labelled "poison," but that the purchaser afterwards removed this label. We are glad to be enabled to point out this fact, as showing that proper attention is paid to the provisions of the law, at least by those upon whom rests the responsible duty of supplying poisons to the public.

* * * *

An engraving of the medal recently presented to M. Dumas to celebrate the completion of the fiftieth anniversary of his election to the Academy of Sciences is given in *Nature* for the 4th inst. On the obverse is figured the head of the recipient, with the inscription, 'J. B. A. DUMAS SECRETAIRE PERPETUEL DE L'ACADEMIE DES SCIENCES." On the reverse are the words: "A. J. B. A. DUMAS: SES CONFRERES: SES ELEVES: SES AMIS: SES ADMIRATEURS: 1832–1882.

* * * *

Professor Bunsen, of Heidelberg, has been elected a Foreign Associate of the French Academy of Sciences, to fill the place rendered vacant by the death of the late Professor Wohler.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, January 3, at the College of Physicians, Kildare Street, Dublin, at 3 o'clock.

The President, Professor Charles Tichborne, in the chair.

The other members of the Council present were Messrs. Allen, Bennett, Brunker, Dr. Collins, Messrs. Doran, Draper, Grindley, Hayes, Hodgson, McIlwaine, Dr. Montgomery, Messrs. Payne, Pring, Simpson, Wells, and Dr. Whitaker.

Mr. Fennell, the Registrar, read a letter from Dr. John William Moore, stating that in his opinion it would be advisable for the Council to eliminate from the curriculum of the Society's Preliminary examination the subjects of chemistry and botany. His experience as an examiner of the Society for the past three years had led him to think that those subjects ought to be relegated to the final examination, first, because candidates were always fully examined in them; secondly, because the subjects could only be studied usefully in a practical manner; thirdly, because his experience of the answering at the Preliminary examination convinced him that the candidate in almost every instance learned off by heart as much of the text-books as would enable him to obtain a passing mark; and fourthly, because such a mode of study was, in his opinion, worse than useless and calculated to create a dislike in the mind of the student to the subsequent practical study of those sciences. He thought a thorough testing of the students in English, Latin, arithmetic, and weights and measures, would better fulfil the purposes of the Preliminary examination.

Mr. Brunker said the Council could not at present take such a step as that suggested. It would involve the rescinding of bye-laws.

Mr. Draper dissented from the recommendation of the letter. The sooner a student began to endeavour to acquire a knowledge of such important subjects as chemistry and botany the better. If he had merely learned by rote the examiner would see that. The argument that the student got a dislike to the subjects should not weigh for a moment.

Dr. Collins: In what other way can the student learn botany and chemistry at first save by rote?

Dr. Whitaker said no doubt they should attach some weight to Dr. Moore's letter, but in almost all the public schools botany and chemistry were now taught; botany certainly was. There was not one of his children who did not know the difference between the stamen and the pistil of a plant, and in fact the rest of the rudiments of botany, although they were all very young. The great thing was to instil the first principles as soon as possible. He therefore thought the examiners would exercise a wiser discretion in recommending even book knowledge of the elements of those sciences. His experience was quite the reverse of that of Dr. Moore.

The President said it was on his recommendation that botany and chemistry were introduced into the Preliminary examination; and he confessed he did not see anything in Dr. Moore's letter to induce him to change his opinion as regarded the desirability of including the rudiments of these subjects. They were introduced into the Preliminary examination in order that it might lead to their being taught in public schools. The Pharmaceutical Society was the first licensing body that took the step in question, and he thought it was a move in the right direction. No doubt it would lead to other licensing bodies adopting the same course. At the same time their examiners were aware that they did not think these sciences should be made an important point at the Preliminary examinations as the candidates were afterwards examined more fully.

Mr. Draper said that next to mathematics there was no better subject for training the mind than chemistry.

Mr. Grindley: Does Dr. Moore get sufficient time?

The President: There is no restriction in that respect. He can have as long as he likes.

Mr. Brunker said he believed the knowledge of botany possessed even by those who came up for the licence was very often little better than book cram.

The President maintained that it was a good basis of knowledge for the student to have a knowledge of the contents of two text-books on chemistry and botany.

Dr. Montgomery: At what period are we to commence instilling a knowledge of chemistry and botany if not at the Preliminary examination? If we were to remove those subjects from the Preliminary examination they might be totally neglected.

Mr. Payne said the candidate for the Preliminary examination must be sixteen years of age and he should know the rudiments of the sciences in question before that.

Mr. Draper: If he does not he will never know them.

Dr. Collins remarked that several members of the Royal Medical Commission were of opinion that botany and chemistry should be in the Preliminary examination, but that there should be only the one examination.

Mr. Brunker moved—

"That the Council do not see any practical disadvantage arising from the including of the rudiments of botany and chemistry in the Preliminary examination."

Mr. Bennett seconded the resolution, which was carried, *nem. con.*

The President: A letter should accompany the resolution to Dr. Moore in order to explain the views of the Council.

A letter was received from Mr. John P. Middleton, enclosing a declaration which he desired the Council to accept, instead of the usual certificate, as evidence of a competent knowledge of compounding. It stated that on June 1, 1877, he became the apprentice of Messrs. Brooks and Grindley, who were then partners, and served for five years, during which period he performed the usual duties of an apprentice to a pharmaceutical chemist, making most of the preparations in the Pharmacopœia. On October 10, 1882, the partnership was dissolved and Mr. Brooks ceased to practise as a pharmacist. Before Mr. Grindley left, he (Mr. Middleton) applied to him for a certificate, but he declined to give it on the ground that it would be rejected by the Council. Mr. Middleton stated that he believed Mr. Grindley gave a certificate to Mr. George Lane McCormack, in 1881, and also that the Council accepted a declaration from a Mr. Boyd, who was in a similar position to that which he occupied. He (Mr. Middleton) passed the Preliminary examination in October, 1879.

The President said the most desirable course would be to refer the application to the Certificate Committee.

Dr. Whitaker was of a similar opinion.

Mr. Hodgson, Mr. Allen and Mr. Brunker thought it would be better to discuss the matter now.

Mr. Grindley said he gave the certificate to Mr. McCormack before the new regulation relegating such matters to a certificate committee was adopted. He understood at the time that any such certificate given afterwards would not be accepted by the Council. He had no personal feeling whatever against Mr. Middleton.

Dr. Montgomery: If he served five years we have no authority to ask the gentleman whom he served. Was his time fully occupied in compounding?

The President (To Mr. Grindley): Was there any difference between the position of Mr. McCormack, to whom you gave the certificate, and that of this gentleman, as regards pharmacy?

Mr. Grindley: No, certainly not.

Dr. Whitaker moved—

"That the application be referred to the Certificate Committee, with a request to report upon it to the next meeting of the Council."

Mr. McIlwaine seconded the resolution.

Mr. Brunker remarked that the other gentleman mentioned by Mr. Middleton, namely, Mr. Boyd, worked with a gentleman who died; and that was why he could not get a certificate.

Mr. Grindley: I am prepared to give Mr. Middleton a certificate to-morrow, and then let him come with it to the Council.

The motion of Dr. Whitaker was put and carried.

A letter was read from Mr. James H. Haslett, of Belfast, asking whether candidates who passed their Preliminary examination on November 1, 1882, would come under the resolution requiring all candidates for the Final examination to have served four years.

As the answer to this letter depended upon the course taken with respect to subsequent resolutions, it was merely marked "Read."

A letter, dated December 1, 1882, was read from Dr. Kaye, Q.C., Secretary to the Privy Council, enclosing the resolution of the Council of November 1, in the form as amended by the law officers of the Crown. The original resolution was in the following terms:—

"That all candidates for the licence be required to produce a certificate signed by a pharmaceutical chemist or apothecary keeping open shop, stating that he has served a *bonâ fide* engagement with him as either apprentice or assistant in his sole employment for a term of four years. To come into force on January 1, 1884."

The resolution as amended was as follows:—

"That every candidate for the licence shall be required to produce a certificate signed by a pharmaceutical chemist or apothecary keeping open shop, stating that such candidate has served a *bonâ fide* engagement as apprentice or assistant with and in the sole employment of such pharmaceutical chemist or apothecary, or the firm of which he is a member, for a term of four years. To come into force on January 1, 1884."

Mr. Payne withdrew a resolution of which he had given notice on the subject, on his attention being called by the President to the fact that it differed only verbally with one of which Mr. Allen had given notice.

Mr. Allen moved—

"That every candidate for the licence who has not passed the Preliminary examination previous to January 3, 1883, shall be required to produce a certificate signed by a pharmaceutical chemist or apothecary keeping open shop, stating that such candidate has served a *bonâ fide* engagement for a term of four years as apprentice or assistant, with, and in the sole employment of, such pharmaceutical chemist or apothecary, or of a firm of legally qualified pharmaceutical chemists or apothecaries, of which aforesaid pharmaceutical chemist or apothecary is a member."

His object was to avoid the great injustice which would be done to candidates who had passed their Preliminary examination under the supposition that they had only two years to serve if the resolution prescribing the new term were brought into operation at an earlier date than January 3.

Mr. Pring seconded the motion.

Mr. Doran: Suppose a candidate is accidentally prevented from finishing the four years?

The President: If his employer died he would have to commence again.

Dr. Whitaker: That is not what is intended. The resolution is very well worded in other respects; but you might add a proviso to meet the case of death, or other exceptional cases.

Mr. Draper said it would be idle for him to repeat the views which he had already expressed on this subject, and which were absolutely unaltered. He saw no reason whatever for converting the period of two years prescribed in the 'Calendar,' at page 56, into what was virtually an apprenticeship for four years. He thought the step a retrogressive one. He was unable to see what was to be gained by four years instead of two. He moved by way of amendment—

"That the regulation as regards practical pharmacy remain as at present stated at page 56 of the 'Calendar.'"

Mr. Pring: I do not think that can be received as an amendment to the motion. The principle of having a period of four years has already passed the Privy Council.

The President said he was not an advocate for reopening the question, but the remark last made did not come with good taste from a Belfast member, who came and reversed a decision previously arrived at by the Council. He (the President) told them at the time that they were making a very bad precedent. The resolution under consideration had been merely sent back for amendment by the Privy Council; it was not yet sanctioned by that body. He would appeal to Mr. Draper to recognize in any amendment that he proposed the views arrived at by the majority of the Council.

Mr. Hodgson said he had great pleasure in seconding Mr. Draper's amendment. He had the strongest possible objection to altering the regulation contained in the 'Calendar.' It was quite understood at the time of the formation of the Pharmaceutical Society that the principle of apprenticeship was abolished, and that the period of service was to be two years, spent in practical pharmacy, the qualifications of the candidate to be afterwards ascertained by an examiner in pharmacy.

Mr. Draper said it was quite evident that the law officers of the Crown had not a very strong opinion as to the value of the Preliminary examination.

Mr. Brunker moved—

"That the resolution be amended by the insertion after the words 'Preliminary examination' of the following words:—'Of this Society, or such examination as is accepted as equivalent to same.'"

Dr. Whitaker seconded the amendment.

Mr. Payne said he entirely approved of making the resolution take effect from the 3rd of January in this year, and he had very much pleasure in supporting the motion.

Dr. Whitaker remarked that there was now no reopening of the question. It was settled. Mr. Pring and himself were the earliest reformers in pharmaceutical matters; and they were satisfied that no amount of teaching by lectures or otherwise could give the practical knowledge that a pharmacist should have. Five years' service from the age of sixteen was a very small hardship, and a young man could not be a pharmacist until after he was twenty-one. They only wished to uphold the honour and prestige of the Society and make it not second to the sister Society in England. He knew that it was very easy to fluke examinations, and that the best examiners were sometimes deceived.

The President: Does Mr. Draper press his amendment?

Mr. Draper said if he had the faintest chance of carrying it he would. He felt very strongly on the subject of the attempt to substitute an apprenticeship for the examination test. He held that the examination standard was far too low; and that a young man should not be withdrawn from study to an enforced apprenticeship of four years. The English Society had not yet found it advantageous to substitute four years for two.

The President: He is right. No apprenticeship is required.

Mr. Draper: Not the drudgery of an apprenticeship.

The President said it had been stated two or three times there that the Pharmaceutical Society of England insisted on a three years' apprenticeship. He had made inquiries and had found that that was not so. The test they used was employment for a given time in pharmacy.

Mr. Payne: For three years.

Dr. Montgomery was of opinion that the only way a young man could learn his business was behind the counter of a respectable pharmacist. If they wanted him to know his business, he should be kept to it.

The President put the amendment of Mr. Draper, which was negatived on the suggestion of the President.

Mr. Brunker moved another amendment in the following terms:—

"Such term may be made up of shorter terms, amounting in all to four years, in the sole employment of a duly qualified pharmaceutical chemist or apothecary keeping open shop."

Mr. Doran seconded the amendment.

The President said that in his opinion it would be better that the date from which the resolution was to take effect should be January, 1884. A great many young men had made their arrangements for this year, and it would not be fair to take them short.

Mr. Brunker maintained that if the arrangement was for the benefit of the members of the Society, the sooner it came into operation the better. The Council were not under obligations to any young man outside the Society until he had passed the Preliminary examination.

The President: You are, to a certain extent, making it retrospective if you do not give every young man who is apprenticed an opportunity of coming up for his Preliminary. I propose that the date be altered to January 3, 1884.

Mr. Draper said he had much pleasure in seconding the amendment of the President.

The amendment on being put was negatived.

The two amendments of Mr. Brunker were agreed to; and the motion, as amended by them, was then put and carried.

The following new members were elected:—Mr. Joseph Edmondson, Peafield, Blackrock; Mr. John McMurray, M.D., M.Ch., Warrenpoint; Mr. John James Gamble, Balieborough.

A report was received from the Examiners, stating that the following gentlemen had passed the examination for the licence as pharmaceutical chemist held on that day:—Mr. James Finlay, Nairview; Mr. William James Hunter, Castleblaney; Mr. William Pratt, Belfast; Mr. James North Hardy, Dublin; and Mr. Henry Forewell, Dublin.

On the motion of Mr. Payne the Examiners' report was adopted.

A report from the Law Committee was considered and adopted.

Mr. Hodgson observed that the expense of prosecutions was a very serious item, and, unless the members of the Society subscribed to recroup them, he did not see how they could be carried on.

The President thought the advisability might be considered of sending out a circular to the members of the Society, informing them that a considerable amount of illegal compounding was going on, and that funds were required in order to enable the Council to carry out prosecutions to stop it.

Some formal business having been isposed of, the Council adjourned.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, Jan. 4, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. R. W. Giles read the following paper upon—

Genius, Talent and Industry, and their Relation to Pharmaceutical Research.

BY RICHARD W. GILES.

The words "genius" and "talent" denote qualities which differ not in degree but in kind; yet are they often used as though they expressed the same thing. This confusion of thought is not only to be met with in the deliberations of inferior institutions, such as social science congresses and legislative assemblies; it has even, once at least, intruded itself (doubtless by a slip of the tongue rather than by misconception of the brain) into the more classic sphere of this Association; and as this happened to be upon the last occasion of our meeting, to hear Mr. Holmes's paper upon 'Pharmaceutical Research,' it seems opportune in point of time to treat of it this evening, and fitting in point of method to consider it in connection with a third quality, viz., industry, and the relation of the three to pharmaceutical research.

In the first place let us see whether the dictionaries throw any light upon the true meaning of the words "genius" and "talent." For as to the word "industry" we all know the meaning of that. Happy are we if we "also practise what we know." Dr. Johnson in 1784, defined "genius" as—"1. The protecting or ruling power of men, places or things. 2. A man endowed with superior faculties. 3. The mental power or faculties. 4. A disposition of nature by which any one is qualified for some peculiar employment. 5. Nature or disposition."

I would have you notice that a hundred years ago the premier meaning assigned to the word "genius" was personal—a *divinity*, or a highly endowed *man*. It appears to have been only secondarily used to denote the *qualities* with which men are endowed. It will be interesting to observe how this order had become reversed seventy-five years later, and how "genius" in the sense of a divinity or a demon had become speciated from genius in the sense of a quality of the mind.

Thus Webster in 1858 defines "genius" (which he derives from γεννάω to beget, to produce, to create) as—

"1. The peculiar structure of mind which is given by nature to an individual, or that disposition or bent of mind which is peculiar to every man and which qualifies him for a particular study or course of life, as a genius for history, for poetry, for painting. 2. Strength of mind, uncommon powers of intellect, particularly the power of invention. In this sense we say 'Homer was a man of genius' and hence: 3. A man endowed with uncommon vigour of mind; a man of superior intellectual faculties, thus, 'Shakspeare was a rare genius.'"

Then follows:—

"Genius, pl. Genii, a spirit or demon; a tutelary deity."

"Genius loci, the presiding divinity of a place; hence the pervading spirit of a place or institution."

In this sense we might speak of the "genius loci" of this school; and having called him up for our convenience, we will wish him a happy new year and dismiss him to rejoin the company of the infernal gods; for we can scarcely suppose that the presiding genius of the laboratory is permitted to pollute with his odours the Asphodel meadows of the celestials.

We may venture to ignore our venerable friend Dr. Johnson, who contributes nothing to our knowledge of the matter in hand beyond the means of instituting the comparison already adverted to between the past and present meaning of the word, always an interesting point in philological inquiry, and we will proceed to extract what we can out of Webster.

First, then, Webster directs us to that most important element in ascertaining the true meaning of words, its derivation, which he ascribes to the Greek verb γεννάω to beget. It may be open to doubt whether "genius" is related to its root in its active sense as a thing which begets or creates, or in its passive sense as a thing begotten or created. I think the first is the most natural and most likely relation, and it agrees with that signification of the word "genius" for which I mean to contend, viz., that it is essentially a quality which creates, or as Webster put it, "particularly the power of invention." This is its distinctive characteristic, by which it differs from talent or cleverness, from industry or perseverance, almost from humanity, and approaches the divine; for, strictly speaking, creative power is the attribute of God alone, and it is only by some elasticity of language that we can say of "genius" that it creates. "There is nothing new under the sun," said the wise man of old, and even a new idea or new invention is but the grasping of some suggestion too subtle to be perceived by minds of ordinary mould.

The next thing to be noted in Webster's definition is the quality of *speciality*. Every illustration is characterized by the adjectives "peculiar," or "particular," or "uncommon."

Again, it is worthy of remark that the two examples of illustrious genius cited by Webster are respectively the greatest *poet* of antiquity and the greatest *poet* of modern times—Homer and Shakspeare. I need not remind you that our word "poet" (ποιητής of the Greeks) is derived from the Greek word ποιέω to make, and its primitive signification is "one who makes—a creator;" nor need I tell you that poetry has always been held to be the highest manifestation of the imaginative or creative faculty; but I may fairly deduce from the similar source of the word "genius" (from γεννάω) a similarity of meaning; and I do claim, on the ground of derivation and analogy, that genius always implies a special creative faculty, which is totally different from any amount of cleverness which may be properly designated as talent. The genius possesses another characteristic in common with the poet. It may be said of both with equal truth, "Nascitur non fit." In fact we may make use of our familiarity with the character and quality of the poet to rectify our conception of the word "genius," and we shall have a pretty good idea of its right meaning if we say that the poetical faculty is but one phase of a variety of faculties which are comprehended in the generic term "genius."

Webster suggests another thought when he says "Shakspere was a *rare* genius,"—genius is always *rare*. Nature cannot afford to be prodigal of geniuses; and it would be ill for the world and its everyday duties and necessities if she were. The speciality of genius has an obvious tendency to unfit its possessor for careers which may be open to him, and which offer better opportunities of personal advantage and even greater happiness than the strait and narrow path which he is compelled to tread by an impulse more powerful than self-interest. For it by no means follows that genius is a blessing to the possessor; it is often eccentric, Bohemian, not always moral; its domestic relations are not seldom infelicitous. As the fondest of mothers said of poor, crabbed, splenetic, unhappy Carlyle, "he was gay ill to live wi'." Shakspeare, whether the deer-stealing scandal be apocryphal or not, was certainly not conventional in other respects, and his marriage was an ill-assorted one. Goethe, who was undoubtedly a genius, a poet and something more than a poet, lived a life which set social laws at defiance, and blighted the happiness of many pure-minded women, at last marrying one who was in every way unworthy of his reputation, and not to be compared with those whose pure affection he had won and basely deserted. But at least he bore his degradation philosophically, and has left to the world the following recipe for securing domestic peace under matrimonial difficulties:—

"Use the woman tenderly, tenderly;
From a crooked rib God made her slenderly;
Straight and strong he could not make her,
So if you try to bend you'll break her;
But let her alone and have her own way,
She'll grow more crooked every day;
What's to be done with her, Adam, my boy?
Use her tenderly, that's what I say,
To break your own rib will bring you small joy."

It seems as if the genius which soars above the level of common humanity in intellectual exaltation could not brook the restraint of those social laws and conventionalities to which ordinary men yield a willing obedience, and hence those frequent eccentricities which have given rise to the line "Genius is to madness much allied."

Genius is a mighty trust given to one man for the good of all mankind; it is not a light which may be or which can be hidden under a bushel. No wonder then that genius is rare; and you, my friends, if you do not happen to possess this rare gift, be not discouraged, but bear your easier lot with Christian fortitude.

It will not be inappropriate at this place to read to you an extract from the address given by Mr. Ince at the beginning of the session, and which I hope you have not yet forgotten and will not soon forget. The speaker made a short and as it were parenthetical allusion to genius, and I claim his remarks as being altogether in harmony with the foregoing observations. He said:—"We read of genius—and in truth there is a species of divine intuition vouchsafed to a few. A street boy takes a piece of chalk and with it traces lines which command the admiration of the world; a rude miner in the bowels of the earth solves problems in mathematics; and an untaught lad makes music out of pots and pans—music destined to be the delight of after ages. For this there is no law—but next to genius there is something which marvellously simulates its effects, and that is uninterrupted perseverance. So great is its power that some have even mistaken its identity and declared that genius itself was but the faculty of unremitted application." Carlyle, whom I just now inadvertently grouped as a genius, which is by no means my real opinion, made this mistake when he said that "genius was only an infinite capacity for taking trouble," a faculty which he possessed to an extraordinary degree, but he could hardly have found more appropriate words to express what genius is *not*.

Parents sometimes unwisely complain that their boys show no inclination for any particular vocation in life, and will not assist them in the choice of a profession. It is because they have not that *peculiar bent of mind qualifying them for a particular course of life*, which is Webster's definition of genius. But they have what is better for the world at large and for their fathers in particular. They have (if they are good for anything) the *adaptability*, which is alien to genius, but which enables them to turn their hands and apply their minds to anything that comes in their way, and to fill with credit "that station in life to which it has pleased God to call them," with greater or less success, according to the talent with which they are endowed. It is rare that in their early years boys have a pronounced preference for any one pursuit. If they have they are dangerous, and likely to turn out sham geniuses (such counterfeits being more common than the genuine article) and to become a perplexity and trouble and ultimate disappointment to their friends. But if there be real genius, it may be safely left to work out its own deliverance, for it will not be controlled; it will "out," as sure as murder. I have known two instances of mechanical genius forcing its way through obstacles, in my own circle of acquaintance. The first was the son of a prosperous merchant who had every prudent reason for wishing his boy to succeed him, but it was hopeless; and the father at last reluctantly took him to a firm of engineers, where he introduced him thus, "Here is my boy; he *will* be an engineer, and I can't stop him." The boy justified his obstinacy by great success. Amongst other things he invented the oscillating steam engine. The other had similar tastes to which his friends would *not* yield. They apprenticed him twice or more to different trades, from which he always ran away at the end of about a fortnight, and after a time, I forget by what chance, he became a farmer, and pursued his mechanical hobby in the horse pond. There he matured the construction of the screw propeller, which revolutionized marine locomotion.

But for one such as these there are a dozen make-believes who, having neither genius, talent, nor industry, have a plentiful and impartial dislike to all kinds of honest work, for whom I recommend the fag end of Solomon's proverb, "A whip for the horse, a bridle for the ass and a rod for the fool's back."

Before passing from "genius" to "talent" I must make one observation which has the appearance of ungallantry, but is really not incompatible with the profoundest respect and admiration for the not inferior though dissimilar qualities of the gentler sex. It is an undeniable fact that "genius" in its highest manifestations has never been attained to by a woman. At first sight it may seem strange that the imaginative faculty, which seems to be closely allied to that emotional susceptibility which is undoubtedly most pronounced in women, has not developed a female *poet* of the highest order, though the sex are by no means deficient in facility of versification; still more remarkable that there has been no single example of a woman attaining to eminence as a musical composer. The fact is singularly at variance with the sentiment which has delighted to personify the Muses as a divine sisterhood, but it is a fact notwithstanding. If I may hazard an explanation I would suggest that the creative faculty which we call "genius," being the nearest approach which human intellect can make to divine intelligence, can only be produced by the highest development of the highest nature. We recognize something like this idea by the accepted phrase a "masculine intellect," which has become an accepted phrase because that which it denotes is common to men and exceptional in women, and that which is general in the one sex and exceptional in the other will naturally find its highest development in the first. But we do not mean to say that "genius" has no degrees, or that it is only to be found in such illustrious types as Shakspeare and his peers, if, indeed, he has any peers. It would not be easy to draw the line between "genius" and "talent," though we adhere to the dictum in our first sentence that the difference *is in* kind and not in degree. Certainly we do not mean to deny the possession of genius, and genius of a high order, to such remarkable women as the late Mrs. Cross (better known by her significantly selected *nom de plume* of George Eliot). As Mrs. Lewes she is understood to have been greatly indebted to Mr. George Henry Lewes for advice and assistance in the authorship of her best works. He probably had more learning, wider experience, more of all that can be acquired by study: but she had the *genius*, which no amount of study can give and no amount of teaching can convey.

And now we will deal much more briefly with talent, again having recourse to our dictionaries as a starting point.

Johnson here favours us with a derivation, which he says is from the Latin "talentum," a weight. This reminds one of the City gent, who said that "the word 'omnibus' was derived from the French 'omnibus,' signifying a public conveyance to accommodate twelve inside."

Johnson further defines "talent" thus—

"1. A talent signified so much weight, or a sum of money, the value differing according to the different ages and countries.

"2. Faculty, power, gift of nature. A metaphor borrowed from the talents in the holy writ. It is used sometimes seriously and sometimes lightly.

"3. Quality, disposition. An improper and mistaken use."

Webster, adverting to an earlier source, derives talent from the Greek ταλάω to bear, and adds that it originally signified a balance.

He says further that it was—

"1. A weight and denomination of money amongst the ancient Greeks, also amongst the Hebrews.

"2. Faculty, natural gift or endowment. A metaphorical use of the word derived from the parable of the talents."

There is not much to be got out of either of these definitions. They do not enter into philosophical or philological analyses; but one thing is in marked contrast with the definitions of genius previously quoted. There is here a total absence of reference to "speciality," "peculiarity," "particularity," "rarity," or even to "superiority." Nor is there any hint of a connection with inventive, imaginative, or creative powers.

For all that the dictionaries say "talent" may be (and no doubt *is* in greater or less degree) the common gift of all mankind. Here then we have a good broad distinction, which should suffice to prevent the two words "genius" and "talent" from being used synonymously or as though the difference between them was only one of degree. Let us follow out the thought and see if we cannot discover some other differences which will still further distinguish the two words and point to their relation with the quality of industry.

"Talent" is a quality which enables its possessor to acquire knowledge by learning from others and by unassisted study.

"Genius" on the other hand is characterized by a great independence of instruction: it takes its own course and originates new ideas and inventions never thought of before. It may of course enlarge its sphere of knowledge by reading, by observation, and by experiment; but it is by no means characteristic of genius to be apt to be taught; on the contrary embryo geniuses are often dull fellows at school and idle to boot. It rather dislikes to follow in the track of others, and rises superior to obstacles of circumstances and deficiencies of education. Genius may safely be left to hew a path for itself. Talent is greedy of instruction. Hence the two have very different relations to education, a subject upon which I should much like to dilate, but the length into which I have been unintentionally betrayed warns me to avoid the temptation.

Arkwright perfected his invention of the spinning frame in the uncongenial atmosphere of a barber's shop, in the teeth of a scolding wife who more than once broke up his models on the eve of completion, and who habitually upbraided him for neglecting the profitable occupation of "an easy shave for a penny," with the elegant apostrophe "Cuss the cheenery." I believe she lived to to be Lady Arkwright. Let us hope that she learnt to moderate the rancour of her tongue.

George Stephenson, inventor of the locomotive and the father of railways, developed his extraordinary engineering genius in the obscurity, physical and metaphorical, of a coal pit; eking out his slender earnings by mending the boots of his fellow workmen and occasionally a watch or clock.

Sir Humphrey Davy, who was described as an "idle and incorrigible schoolboy" was apprenticed to an obscure apothecary at Penzance; he afterwards became assistant in the laboratory of Dr. Beddoes, of the Hotwells, Bristol, well known to my father, who was then serving his apprenticeship at the same place, but I cannot discover that he knew anything of the doctor's more illustrious subordinate.

Faraday's father was a Yorkshire blacksmith, who migrated to London, presumably in search of work, and Faraday himself was apprenticed to a bookbinder. A chance attendance upon four lectures by Sir Humphrey Davy was the immediate cause of his directing his attention to science, and he was some time after introduced to the Laboratory of the Royal Institution through Davy's instrumentality.

Benjamin Franklin made his first entry into Philadelphia, a poor lad with all his possessions upon his back and a dollar in his pocket. As Mark Twain depreciatingly remarks "Anybody might have done that; the only difficulty is to have the dollar." But how few out of the millions who have begun life with a dollar or even with less, have arrived to be Franklins!

On the other hand it seems absolutely immaterial with what seemingly insuperable disadvantages genius may be oppressed; it *will* make its way to the surface and triumph over all.

Can industry then supply the place of genius? Emphatically, No! Industry may compensate for paucity of talent; for talent, as we have said, is a common heritage, and its presence or absence is a matter of degree, and whatever results are attributed to talent are the joint product of talent multiplied by industry.

Thus if T = talent and I = industry the following equation will correctly represent the results accomplished by two persons whose talent and whose industry differ in inverse ratios:—

$$T \times 10I = 10T \times I = 10TI.$$

If, therefore, any of you is conscious of an excess of talent,—say = 10 T,—let him glory in his good fortune, and in the assurance of the great results he may attain by multiplying his gift by a similarly high power of industry. For $10T \times 10I = 100TI$!!

If, on the other hand, there is anyone here who diffidently estimates his talent at something below par, let him not be disheartened; he has but to increase his industry and the results cannot fail to be respectable. Thus the zealous servants in the parable improved the talents committed to their charge, whether many or few, and received their reward; while he who hid his solitary talent in a napkin was visited with his lord's displeasure —not because it was but *one*, but because he slothfully neglected to turn that one to good account.

As for genius—whether you have it or not is no concern of mine—nor need it concern anyone, yourself included. It may safely be left to follow its bent, and to assert itself in due time; when the time has come it will ride you whither you know not, as remorselessly as ever witch rode 'to her Sabbath on a broomstick. In the meantime, and until it declares itself, it will be safer to assume that you have it not.

And now, just a few words upon the relation of these three qualities, genius, talent and industry, to pharmaceutical research. There can be no question of the absolute necessity of industry in order to acquire the knowledge upon which the higher qualities must work. There is as little doubt of the great advantage of talent, both to facilitate the acquisition of knowledge and to apply it judiciously under new circumstances from which discovery must be sought. Is there any room for genius? Yes! there is room, and much need for that inventive originality which is the chief characteristic of genius and which enables one man to read indications which are meaningless to another; but it will scarcely soar so high within the limited domain of pharmacy as to win the laurel crown of genius.

If in the prosecution of pharmaceutical research you or your contemporaries should be led to discoveries so striking as to merit that distinction, it is to be expected that they will belong to and be claimed by a wider field of science than pharmacy embraces; but pharmacy will look on and applaud your success and take an honest pride in the source from which it sprung.

In conclusion, I will try to illustrate in a somewhat allegorical form the respective characteristics of genius, talent and industry.

"Genius" is a living organism, instinct with its own life, performing its appointed functions spontaneously, as of necessity.

"Talent" is an elaborate engine, skilfully devised to move many wheels and to perform divers works, but wanting the motive power.

"Industry" is the motive power.

A discussion followed the reading of the paper, in which the Chairman, Secretary, Messrs. Alcock, Elworthy, Howard and Parker took part.

A hearty vote of thanks was passed to Mr. Giles for his interesting paper.

Mr. R. J. MacDermott then read some notes on "Practical Photography." The paper was illustrated by experiments and apparatus.

A discussion followed in which the Chairman, Secretary, Messrs. Alcock, Elworthy, Giles and Parker took part.

A vote of thanks was passed to Mr. MacDermott for the trouble he had taken in bringing the subject before the Association.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Subnitrate of Bismuth.*

BY F. HARRIS ALCOCK.

(*Concluded from page* 539.)

PHYSICAL AND CHEMICAL CHARACTERS.

U.S.P. (1872).—A heavy white powder of a somewhat satiny appearance. Faintly acid odour and taste, and when moistened with litmus paper a decidedly acid reaction. Entirely soluble without effervescence in nitric acid, and the solution yields no precipitate with dilute sulphuric acid. Upon being heated to redness it loses 20 per cent. of its weight. When mixed with dilute sulphuric acid in excess, and subjected to Marsh's test, it yields no arsenic, or merely a trace. But in 1882 the following description is given:—"A heavy white powder, permanent in the air, odourless and almost tasteless, showing a slightly acid reaction, when moistened, on litmus paper, and insoluble in water or alcohol. When heated to redness the salt gives off moisture, and afterwards nitrous vapours, leaving a yellow residue which is soluble in nitric or in hydrochloric acid, and is blackened by hydrosulphuric acid. On dissolving 1 part of the salt in 5 parts of warm nitric acid (specific gravity 1·200) no effervescence should occur (absence of carbonate) and no residue should be left (absence of insoluble foreign salts). The reactions, for purity, of this solution, as well as those of the original salt, should be the same as those mentioned under "bismuthi carbonas." [These may be added, and consist of the following:—Solution in HNO_3, as above, poured into 50 parts of water, a white precipitate is produced, and on filtering and concentrating the filtrate to 6 parts, a portion of this, mixed with five times its volume of diluted sulphuric acid, should not become cloudy (absence of lead). If another portion be precipitated with an excess of water of ammonia, the supernatant liquid should not exhibit a blue tint (copper). On diluting a third portion with 5 volumes of distilled water, the filtrate should not be affected by test solution of nitrate of silver (chloride), or of nitrate of barium (sulphate); nor by hydrochloric acid (silver). If the salt be boiled with acetic acid diluted with an equal volume of water and the cold filtrate freed from bismuth by hydrosulphuric acid, the new filtrate should leave no fixed residue on evaporation (alkalies and alkaline earths). On boiling 1 gram of the salt with 10 c.c. of solution of soda (specific gravity 1·260) and holding a glass rod dipped in acetic acid over the test-tube, not more than a faint white cloud, but no heavy white fumes should appear (only traces of ammonia). If the preceding mixture after thorough boiling be diluted with water to 50 c.c. and filtered, the filtrate, when supersaturated with hydrochloric acid and treated with hydrosulphuric acid should not deposit more than a trace of a precipitate, which should not have a yellow or orange colour (only traces of antimony, arsenic and tin). On boiling 1 gram of the salt with 10 c.c. of strong solution of soda, decanting the liquid from

---

* Read at a Meeting of the Association, November 8, 1882.

the precipitated oxide of bismuth into a long test-tube, and adding about 0·5 gram of aluminium wire cut into small pieces (a loose plug of cotton being pushed a short distance down the tube), the generated gas should not impart any colour or tint to paper wet with test solution of nitrate of silver and kept over the mouth of the test-tube for half an hour (absence of more than traces of arsenic)]."

Codex.—Of a fine pearl-white appearance; when pure, not affected by the light, but is soon coloured when it comes in contact with certain organic substances. To be preserved from all sulphurous vapours, which colour it brown.

German (1882).—A white powder, crystalline under microscope, of an acid reaction. At 120° C. 100 parts lose from 3 to 5 parts of water; and when heated stronger red vapours are emitted, and from 100 parts 79 to 82 parts of bismuth oxide are obtained. Half a gram dissolved in 25 c.c. diluted sulphuric acid (1 of acid in 6, and specific gravity 1·110 to 1·114) does not evolve carbonic acid, and remains clear. Some of this solution mixed with solution of ammonic hydrate in excess, when filtered is without colour, and when sulphuretted hydrogen water is added does not give any reaction (coloration). Another part diluted with a little more than an equal volume of distilled water, produces at once a precipitate when sulphuretted hydrogen is passed through, and if the precipitate be removed by filtration the clear supernatant liquid on evaporation should leave no residue. Subnitrate of bismuth dissolves in nitric acid with production of a clear liquid, which solution is neither rendered turbid by solution of nitrate of silver (17·0 grams to 1 litre) nor by solution of nitrate of barium (1 in 50). When warmed with an excess of solution of caustic soda, bismuth subnitrate evolves no odour of ammonia, and the clear liquid filtered, and placed in a test-tube with a few small pieces of bright iron wire and a small quantity of zinc filings, and heated; the gas evolved does not stain within an hour a piece of paper moistened with solution of nitrate of silver (1 in 2).

German (1872).—"Very white, crystalline powder; moistened with water turns blue litmus paper red; with nitric or hydrochloric acid a clear solution is formed without effervescence; a nitric acid solution diluted with a little water does not give turbidity with nitrate of silver, nor with dilute sulphuric acid. A solution obtained by boiling with ten times its weight of dilute acetic acid and precipitated by sulphuretted hydrogen and filtered does not on evaporation leave any residue. Solution of potash added in excess does not, when warmed, cause evolution of ammonia, and this solution diluted and filtered from insoluble residue is not rendered turbid by sulphuretted hydrogen. To see if free from arsenious acid heat with an equal quantity of sulphuric acid until nitric fumes cease to come off; mix with six times its weight of water and place in hydrogen apparatus, arresting sulphur compounds by means of cotton wool saturated with solution of acetate of lead placed as usual and holding over mouth of exit tube a piece of white filter paper, moistened with solution of nitrate of silver. To be preserved in well-closed bottles."

The appearance of bismuth subnitrate both ordinarily and microscopically varies very much. It is easily examined by means of the microscope, using a moderate power ($\frac{4}{10}$ inch). The crystals are generally small, prismatic, uniform, colourless, transparent, but may be acicular, triclinic, hexagonal, octagonal, and apparently in double oblique rhombic prisms, terminated by several planes. Pereira's description would not pass a sample which might answer U.S. tests in Pharmacopœia of 1880 and even 1882, for he says it is a dull white *inodorous, tasteless*, pulveriform substance, which with a magnifying lens is seen to consist of very fine silky acicular crystals. This appearance depends on mode of production, for if precipitated from very acid solution with little water the crystals are acicular and of a silky lustre. Clammy varieties of a dark grey colour may be looked upon with suspicion.

The formula for this substance, like its crystalline form, has been variously stated. Chemists have not agreed upon whether it shall be—

$$BiNO_4.H_2O;\ BiONO_3,H_2O;\ 4BiONO_3.BiH_3O_3.3H_2O;$$
$$5BiONO_3.BiH_3O_33H_2O;\ 3BiONO_3.BiH_3O_3.3H_2O;$$
$$3BiONO_3.2BiH_3O_3.H_2O:Bi_2O_3.N_2O_52H_2O;$$
$$Bi'''(NO_3)_3Bi_2O_3.3H_2O, \text{ or } BiO(NO_3)_2(HO)_2.$$

"It is difficult to prove whether or not the water in the subnitrate or hydrous oxynitrate of bismuth is an integral part of the salt (*vide infra* Gladstone's method). If it is the compound is simply the hydrato-nitrate ($BiNO_32HO$) of bismuth" (Attfield). One thing is certain and it is that commercial samples do not contain as much Bi_2O_3 as theory would require (being 79·28–82·37). Suppose $BiONO_32H_2O$ (molecular weight=306) to be the true formula, then we should require 100 parts to yield of Bi_2O_3, 76·477; N_2O_5, 17·64; water, 5·88 (see also Gladstone 'Chem. Mem.,' vol. iii.). Mr. Edwards in 1850 called attention to the variable amount of water present in this compound, his figures being:—

	Per cent.					
Bi_2O_3 . .	77·23	79·4	87·46	87·1	73·4	80·08
N_2O_5 . .	16·2	13·8	2·32	10·0	16·38	18·5
H_2O . .	6·0	6·6	10·1	1·6	9·5	1·3
	99·43	99·8	99·88	99·7	99·28	99·88

Again Pereira mentions five more authorities as under:

	Herberger.	Duflos.	Grouvelle.	Phillips.	Menigaud (at 212° F.).
Bi_2O_3 . .	79·70	80·00	81·37	81·92	85·33
N_2O_5 . .	14·44	13·58	13·97	18·36	14·67
H_2O . .	5·86	6·42	4·66	0·00*	0·00*
	100	100	100	100·68	100

To these may be added—

Gmelin.	Gladstone.
80·67	79·23
16·41	18·49
2·92	3·22 (mean of four experiments).
100·00*	100·94

Phillips and Menigaud supposed that all H_2O was removed by drying at 212° F., but Gmelin by repeated experiments showed that H_2O enters into the constitution of the compound. Gladstone's method consisted in ignition of the compound and determination of the water by passing the aqueous vapour, first over ignited metallic copper and then into a tube containing $CaCl_2$. Nitrogen was estimated by the absolute method used in organic analysis, and Bi as oxide by ignition of the salt in a platinum crucible.

It is sparingly soluble in water; decomposed by alkalies as in B.P. process for production of Bi_2O_3. Ammonia dissolves it to a small degree, due perhaps to formation of Bi_2O_3 and nitrate of ammonium which would retain some in solution. As above stated by gentle heat it becomes Bi_2O_3. It may be formed by heating ternitrate at 300° F. for several hours (Gladstone). With stannous chloride it assumes an orange-yellow colour which after some days, or immediately on boiling, changes first to brown and then to black. By repeated boiling with water it is said that all the acid can be removed and Bi_2O_3 alone will remain, but another writer says 1 per cent. HNO_3 is always left behind. The speedy effect of H_2S on this compound may be beautifully shown thus:—Take a book of one hundred pages, such as those in which silver leaf has been kept, and on the first page paint with a brush characters with this bismuth preparation and on last page put a little alkaline sulphide, the vapour of latter coming into contact with the bismuth by passing through the pores of the

* After drying on water-bath and placing under desiccator for some weeks.

paper produces a deep brown colour (brun foncé). M. Monge proved that air carries the vapour of the sulphide, since he found that on collecting the leaves one by one no coloration had taken place on them. Iodide of potassium in weak and *faintly* acid solution lets fall a brick-red precipitate of iodide of bismuth, and on this Thresh has endeavoured to form a quantitative method for estimation of alkaloids. With regard to the acidity of this preparation it is a question whether it ought to be very acid; the U.S. and German Pharmacopœias allow of a little, but some time ago a specimen was examined which was very acid, and on reference to such works as B.P., Professor Attfield's 'Manual,' Pereira's 'Materia Medica' (Bentley and Redwood), Macnamara's 'Neligan's Medicines,' Royle, Garrod, Griffiths, Scoresby Jackson, no direct mention is made of this. Phillips, however, on the authority of Martindale says "that it is sometimes so acid as to effervesce with carbonates," and Ekin in *Pharm. Journ.*, [3], iii., 381 says, "that manufacturers have told him that after some months it becomes acid." Roscoe, too, says "it has acid reaction." The B.P. preparation of the lozenge probably means that it should not be acid, for carbonates are there mixed with it. It would be interesting to know if the lozenges do alter in composition after keeping. Prepared exactly according to the B.P. when fresh it does not redden blue litmus when cold water is used to moisten it with, but when warmed, acid is soon liberated, and quickly reddens the test paper. There is another point which leads one to suppose that it should not be acid, and that is its use as a dusting powder and cosmetic; it would be unsuited for this purpose if very acid, and would in all probability do more harm than good in such cases as it is then used for; and, as has been said before, Pereira states that it is *inodorous* and *tasteless*, which is an indirect inference that free acid should be absent. Also Professor Gubler says it is a reliable *antacid*. It blackens the fæces of patients who take it. Here it may be mentioned that patients have sometimes complained that bismuth blackens the tongue and an explanation by Mr. Hamilton was mentioned in "The Month" of *Pharm. Journ.* (February, 1880-81), who said that it is probably due to the reduction of finely divided metallic bismuth upon the tongue by the sugar formed in the saliva after eating starchy matters. He found that the saliva, taken after fasting several hours and added to a heated alkaline solution of bismuth, caused no blackening, but that after eating bread and then adding the saliva to the bismuth solution, a blackening of the mixture readily occurred. In the case of a lady who had been taking bismuth for some months, she was suddenly alarmed one morning by finding that her mouth and tongue were quite black and came at once to ask her chemist the reason. It was found that she usually preceded her bismuth dose by one of Friedrichshall water which (as this did) sometimes contains sulphide of calcium, which is due to the action of organic matter on the sulphate of calcium present in this water, and hence had resulted in the production of black sulphide of bismuth.

IMPURITIES.

Very soon after this preparation became known to the world it was looked upon as a very uncertain and unsatisfactory one, because being extensively used, and closely allied to compounds of other metals it laid itself open to adulteration. On its acceptance by the medical faculty of the various colleges as a drug worthy of a place in their official pharmacopœias a test was subjoined which should indicate it to be free from lead, etc. Even now it is found impure, accidentally often, and intentionally much less frequently.

There are four sources of accidental impurity, viz., firstly, that arising from the metal itself; secondly, from the nitric acid; thirdly, washing water, and lastly manipulation. With regard to the metal, the method by which it is obtained, its source and geological associations, and firmness with which it sticks to its friends whose acquaintance it made at its source, would lead us to expect that we should find them many and formidable. We will not enter into the question of how these may be removed, but it will be well perhaps to have a glance at what may be and what have been found associated with the metal:—Gangue (this is understood by metallurgists to be a complex mixture of substances, such as stones or earthy matter in which or with which some metals such as gold, silver, bismuth, and iron are found): lead, antimony, arsenic, tellurium, selenium, iron, copper, gold, silver, zinc, cobalt, nickel, thallium (*Pharm. Journ.*, [2], iv., 302), vanadium, platinum, palladium, rhodium (?), tin, tungsten, sulphur, silica (quartz).

2nd. In the acid may exist solid matter, including chlorides and HCl; sulphates and H_2SO_4.

3rd. Distilled water, being the purest water, alone ensures the absence of traces of a multitude of things, such as compounds of calcium, magnesium, and the alkalies, especially chlorides and sulphates, resulting in the production of oxychloride and precipitation along with the silver if present, the precipitate retaining these often in a tenacious manner when they are present (*Vide* Riche, 'Year-Book of Pharmacy,' 1879).

4th. Amongst impurities due to this may be mentioned those which nitric acid solution of bismuth might dissolve from the vessels used, especially porcelain and enamelled ware; iron; particles of copper carried away mechanically from mortars made of iron or bell-metal when bismuth is powdered in them; ammonia from use of acid of different strength to the one ordered, viz., 1·420, and not using the proper addition of distilled water to dilute the acid; a parallel case is seen in the case of zinc and copper (*Pharm. Journ.* [3], ix., 849). If strong HNO_3 be used with the bismuth in powder even nitrogen is produced, and sometimes vivid flashes of light are seen. Pouring the whole nitric solution into water without separation from insoluble residue which may be present, as used to be directed in early editions of London Pharmacopœia. In this case, for probable contaminations see Dr. Letts's paper on "Bismuth Residues" (*Pharm. Journ.*, 1879). Too much or too little water used in washing, former causing it to be too basic, *the latter leaves free acid in.* Too high a temperature used for drying: this, as was said before, being a constant cause of variation.

Of other occasional impurities may be mentioned other compounds of bismuth, as hydrated oxide, phosphate, oxychloride, or oxysulphate, silica, sulphate of calcium, nitrate of alkalies (their hydrates or carbonates being used to saturate acid in supernatant liquors in order to obtain a greater yield). Particularly with reference to ammonia has this been noticed by a friend, who uses very large quantities of this preparation in combination with bicarbonate of sodium, the impurity being present sometimes to such an extent as to evolve very strongly the odour of ammonia gas, when the alkaline bicarbonate and the subnitrate were rubbed together in a mortar. Tichborne (*Pharm. Journ.*, 1860) asserts that manufacturers used chloride of sodium in the production of this preparation, which might account for the amount of oxychloride found in some commercial samples examined by Ekin (*Pharm. Journ.*, [3], iii., 381), and also the presence of silver which would be precipitated as chloride.

Of the above list of impurities the following were sought for in five different samples obtained from as many different manufacturers. The methods employed are given with other methods and also a tabulated list of results:—arsenic, tellurium, silver, lead, copper, iron, sulphur (which would occur as sulphate), ammonia, calcium chloride, phosphate, and carbonate.

1st, *Arsenic.*—It is well known that the B.P. process (Quesneville's) for the purification of the metal does not effectually remove this element. It is found in variable quantities, generally traces only, and in fact Parrish states that physicians believe that its presence has some bearing upon its therapeutic action and perhaps adds to its efficacy. M. Lassaigne detected one-sixth of 1 per cent. by Marsh's test. M. Glenard recommends heating strongly with acetate of potassium, and noticing if the odour of cacodyl is evolved. Another method is to treat with HCl, and collect vapours of $AsCl_3$; pass sulphuretted hydrogen gas into it and weigh as As_2S_3. The comparative method of Otto was used for the results subjoined, viz., Marsh's apparatus to which a $CaCl_2$ tube is attached to arrest moisture and the gas passed through combustion tubing drawn out in bulbs one inch long, these bulbs being strongly heated. The deposit of As, collected beyond this bulb, is noticed and amount compared with the deposit obtained from chemicals alone, as sulphuric acid and pure zinc are not absolutely free from arsenic. Before placing the bismuth subnitrate in the flask, it is evaporated to dryness in a fume chamber with some sulphuric acid, by which means the nitrate radical is eliminated. The hydrogen apparatus is allowed to go on uninterrupted for thirty minutes in each experiment.

Tellurium.—In this experiment advantage is taken of the reducing action of SO_2 on this element. A hydrochloric solution is prepared from the sample to be tested by evaporation to dryness with HCl two or three times, this repeated operation eventually leaves little HNO_3 in the solution to interfere with the action. To this solution thus prepared sulphite of sodium is added, and the whole warmed. If only traces are present a reddish coloration is produced, but if much be present, then after a time a dark coloured deposit of tellurium takes place. It is advisable to operate on a couple of drachms or so. This impurity makes itself evident by the peculiar fœtid odour of garlic which it communicates to the breath of patients who take bismuth for any length of time.

Silver.—Turach says that small quantities of silver cannot be detected by means of the usual reaction with hydrochloric acid or chlorides. The method adopted turned on the fact that bismuth when subjected to cupellation behaves in the same manner as lead, that is, becomes oxidized, and the Br_2O_3 formed is absorbed by the small cup-like moulds made of calcic phosphate or bone ash and designated cupels, leaving the silver as a shining bead behind. The bismuth subnitrate is ignited, and the resulting bismuth oxide gradually thrown into a heated porcelain crucible containing cyanide of potassium in a liquid state; this yields the metal, which settles at the bottom as a bright shining metallic mass, and may be seen very easily through the clear liquid cyanide and cyanate after a few minutes' heating. The whole is quickly poured into a crucible lined in cone-like fashion with asbestos, taking care that all the metal is transferred in one bead, and allowed to cool. Warming the mass in a beaker removes adhering cyanides and asbestos and a clear round metal bead is obtained, and this is proceeded with in the usual way prescribed for cupellation of metallic beads of lead and bismuth.

Copper.—Wood detects Cu by precipitation of the nitric acid solution (evaporated until a pellicle forms on the solution) by means of solution of ammonic chloride, the copper being left in the supernatant liquid; after some hours' repose, filter, add AmHO in excess and proceed in usual way (*Pharm. Journ.*, p. 317, [2], vol. x.). Ekin examined for Cu by addition of AmHo in excess to nitric acid solution, and treating the clear supernatant liquid with excess of acetic acid; on addition of ferrocyanide of potassium a red-brown precipitate is obtained. The latter test was used.

Iron.—The sample, gently ignited to remove all nitric radical, was dissolved in hydrochloric acid and diluted with water until turbidity began to show itself, sulphuretted hydrogen passed through until bismuth was completely precipitated, filtered, and to the filtrate, evaporated to remove as much acid as possible and then diluted with water, ferrocyanide of potassium was added. Care must be taken in this experiment that the hydrochloric acid is not present in such a quantity as to cause a *green* coloration with the reagent, which might be mistaken for traces of iron.

Lead.—The Pharmacopœia reagent used in testing for this impurity sometimes may give a precipitate when lead is absent. A. Riche (*Journ. Chem. Soc.*, page 841, 1878) states that the precipitate is very complex and may consist of sand, gelatinous silica, silicates, bismuth, silver, iron and especially lime in the state of sulphate. Carnot (*Journ. Chem. Soc.*, page 473, 1878) examined some specimens and found in seven samples ·011, ·016, ·023, ·032, ·038, ·065, ·098, grm. respectively, in the quantity operated upon, viz., 10 grms., and adds that these results should serve as a caution to those engaged in preparing and dispensing this drug. The B.P. method was used (rendered more sensitive by addition of a little spirit), and also one by Chapuis and Linnoissier (*Comptes Rendus*, 87, pp. 169–171), which was used qualitatively. The latter process consists in boiling the subnitrate with caustic soda and a small quantity of potassium chromate, the residue, after boiling, being separated by filtration. To clear the filtered liquid, acetic acid is added until slightly acid, when a yellow precipitate or cloudiness will be produced according to the quantity of lead present. Calcium phosphate containing silica and alumina, if present, and also impure soda, if it contains alumina and silica, of course, interfere with the latter reaction.

Chlorides.—Usual method, care being taken to begin with clear bismuth solution, formed with as little nitric acid as possible, for fear the acid solution might retain traces. Probably the removal of chloride by ebullition with pure fixed alkali would be better, adding excess of HNO_3 to filtrate and then reagent.

Carbonates.—No effervescence with acids.

Sulphates.—These might arise from wash water or oxidation of sulphur in the metal by HNO_3. The usual method, using as much water as possible to dilute the acid solution and $BaCl_2$ if in too acid solution, causes a precipitate which might be mistaken for $BaSO_4$; this, however, is insoluble on addition of more water. Nitrate of barium solution gives a precipitate which might be taken for sulphate. This, however, is insoluble on addition of more water.

Ammonia.—Ebullition with solution of fixed alkali and placing a piece of moistened red litmus in the neck of the flask in such a way as to prevent the alkali spirts coming in contact with the test paper.

Silica.—Through the courtesy of a friend, a specimen containing 3–5 per cent. of this substance was examined. Suspicion was aroused on account of the low price it was offered at in the market. Its insolubility readily reveals its presence.

Phosphate of Calcium.—As this has occurred in commercial samples on several occasions a method is given in some text-books for its detection. One originally devised by Monsieur Roussin (*Pharm. Journ.*, [2], x., p. 88), and modified by Messrs. Howard (*ib.*, p. 165), was shown to be liable to error (*ib.*, p. 347) by Mr. G. G. Hornsby. The method suggested by Dr. Tilden (*Pharm. Journ.*, [3], i., 504) is better, and was the one used, viz.:—A dilute nitric acid solution is taken and completely precipitated by means of sulphuretted hydrogen, filter and expel excess of H_2S by boiling; test a small portion of filtrate so treated for phosphoric acid by the molybdate of ammonium test, which gives a yellow colour if present. Another portion is tested for lime by neutralizing with ammonia, then adding acetic acid in excess, and lastly, oxalate of ammonium. A white precipitate of oxalate of calcium will be formed.

Other salts of bismuth may be examined as above for phosphate, oxychloride and sulphate.

The oxychloride has a soapy feel, and is amorphous; the same character also distinguishes the oxyhydrate when viewed under the microscope, after being moistened with a little water and a thin piece of glass placed over in the usual way.

TABLE OF RESULTS.

Microcharacter.	Arsenic.	Tellurium.	Ag.	Cu.	Fe.	Pb.	Ca.	Am.	Cl.	SO_4.	H_3PO_4.	Insoluble (Silica, etc.).	CO_2.

PHARMACY.

We frequently hear of explosions in pharmacies, but some it is a pleasure to find are not attended with any serious loss of life or property. Amongst this class may be mentioned mixtures which are very frequently prescribed by medical men, containing *ex. gratiâ*:—

℞ Bismuthi subnitratis
Magnesiæ carbonatis
Sodæ bicarbonatis
Aquæ menthæ piperitæ.

One operator might mix this and find nothing remarkable in his result; another, while checking such a mixture, finds after he has neatly finished it off, that the bottle bursts in his hands; a third is annoyed by the porter coming back again in a great hurry with the startling news that "a bottle has bursted" in his basket and marred the neatness of the packages; and lastly the patient sometimes experiences a species of fright when he or she observes such a phenomenon, and often wonders if the contents were a liquid explosive, or some other dreadful thing. Friend after friend has been asked "What would be the result of mixing this?" (the above prescription), and the opinions are astonishingly different. On this subject Mr. J. W. Yeats offers an explanation, and sends a copy of prescription (*vide* Dispensing Memoranda, *Pharm. Journ.*, [3], vii., 1055). He found the bismuth acid, and that double decomposition took place between the bismuth and carbonated alkalies thus:—$4BiONO_3 + 4NaHCO_3 = 2Bi_2O_2CO_3 + 4NaNO_3 + 2H_2O + 2CO_2$, the evolved CO_2 causing the mischief. A week later "An Assistant" states that he has made up similar mixtures, and has never met with such an occurrence. In vol. viii. of same series, page 66–67, the suggestion is made that the sample of bismuth should be examined, and it is said that decomposition is not a necessary result of such a combination; however, in such cases the writer of the prescription should be seen, and bismuth carbonate suggested to him as a good substitute. Reference may be made to Mr. Green's paper in *Pharm. Journ.*, [3], vol. ix., p. 505, in which experiments are described to show that decomposition does really take place, with effervescence and evolution of CO_2. This may be obviated, he says, by using neutral carbonates, which simply produce bismuth carbonate without evolution of CO_2. He recommends trituration of the two salts with hot water, and letting the the mixture cool before putting it in the bottle with the other ingredients. Probably such reactions are due in a great measure to variability of the bismuth. Some time ago a peculiar specimen was examined which was very acid indeed, so much so as to be easily tasted and smelt. It had been rejected by a medical man and effervesced strongly with alkaline carbonates. Rightly prepared this preparation should be very slightly, if at all, acid to litmus; when it becomes very acid it should be washed with a little water, and dried at the B.P. temperature and well preserved. That washing does make it more basic was proved by boiling ½ ounce in much water, pouring on to a filter, and washing very frequently with boiling water for two days, then drying at 150° F. until it ceased to lose weight:—1 gram gently ignited gave (mean of two results)—before washing 80·72 per cent. Bi_2O_3; after, 87·940 per cent. Bi_2O_3.

* A specimen was suspended in water, and the clear supernatant liquid being afterwards filtered was found to be acid to litmus and to contain bismuth in solution. The precipitate cleared by filtration and once washed, and dried at 150 F., effervesced slightly with acids, and solution after removal of bismuth with H_2S gave, after boiling and addition of ammonia, a rather large trace of calcium when oxalate of ammonium was added. It was examined by the spectroscope which immediately showed the peculiar light green band of calcium strongly.

In the first four instances, the per cent. of Bi_2O_3 in each (mean of two results) was found to be respectively 80·73 per cent.; 79·80 per cent.; 80·50 per cent.; 79·80 per cent. Unfortunately, the process adopted for the estimation of the nitric radical was not found to be trustworthy.

Parliamentary and Law Proceedings.

SUPPOSED POISONING AT WEST MALLING.

On Wednesday a Coroner's inquiry into the circumstances attending the death of Sarah Ann Wright, aged 16, daughter of a labourer at West Malling, was resumed before Mr. Joseph Rogers, county coroner.

The deceased, it appeared, had been ill for some time, and a few days before December 14, she was visited by the Rev. J. H. Timins, the vicar, who prescribed some medicine for her. On December 16, the rev. gentleman again saw her, and he then, after obtaining a glass and a spoon from the deceased's mother, gave her something from a bottle he produced from his pocket. No sooner had the poor girl swallowed this than she called out three times "Oh, Mr. Timins," then vomited more than once, and in about an hour and a quarter she died. Medical aid was at once procured, and two days afterwards the coroner held a preliminary inquiry into the matter. The same day a *post-mortem* examination was made by two local practitioners and as a result of their investigation they stated that the cause of death was poisoning by prussic acid. Various portions of the body were subsequently analysed by Professors Heaton and Tuson of London, and they reported that prussic acid had been found in the vomit and contents of the stomach, the amount discovered being about a-hundredth part of a grain, and essential oil of almonds was also found and separated. Death undoubtedly arose from a nerve poison, which in this case was prussic acid. The manner in which the poison came to be given to the deceased appeared from the evidence of Mr. Timins, who was duly cautioned by the coroner, and of Mr. Stedman, a chemist at Malling. The rev. gentleman's son had broken his arm and when he had recovered somewhat his father sent for some oil of almonds to reduce a nettle rash that appeared, and it was used externally with success. The bottle was put on a shelf with other poisons, but when Mr. Timins wanted some harmless expressed oil to give to the deceased he took a bottle from among others from a shelf where he did not keep any poisons, without noticing particularly which of the phials he took. He mistook it for another oil which was not dangerous. Mr. Timins further stated that he was under the strong impression that he was administering a harmless medicine to the deceased, and that when he saw the effect it had on her he himself swallowed a teaspoonful without any serious inconvenience. The chemist was positive that the bottle he sent to Mr. Timins was marked "poison," and the contents properly described. When he received the order he sent to inquire whether a mistake had not been made, and the rev. gentleman replied that he required the oil for outward application. The inquiry was adjourned for a fortnight.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 30th of December, 1882, Mr. William Kemp, Pharmaceutical Chemist, High Street, Horncastle. Aged 54 years. Mr. Kemp had been a Member of the Pharmaceutical Society since 1848.

On the 3rd of January, 1883, Mr. John Roberts, Chemist and Druggist, Pye Bank, Sheffield. Aged 79 years.

BOOKS RECEIVED.

Jahresbericht über die Fortschritte der Chemie und verwandter Theile anderer Wissenschaften. Fur 1881. Zweites Heft. Giessen: J. Ricker. 1882. From the Publisher.

Sur l'Extraction des Matières Colorantes des Urines Bleues (Indigotine et Indirubine). Par le Dr. C. Méhu. Paris: 1882. From the Author.

The Preliminary Examination.

Sir,—Perusing the Journal of January 6, I was considerably surprised to read the letter of your correspondent A. W. S., who, in my opinion, is too far outside the pharmaceutical world to broach such a subject as the Preliminary examination.

I contend that the examination in question is sufficiently strict and that to add more subjects will tend to discourage the younger members of the profession. If Cæsar, Book I., is so familiar, then select another author. The fact of a boy passing the examination is not, I admit, a proof of his proper education any more than the Major qualification is a guarantee that the possessor of it is incapable of making a mistake in his after career; the test is put and from the reply given to his question the examiner infers what the candidate knows and what he does not know, and from the inference drawn either passes or plucks him. Should the examination be made more harsh when so many fail in their attempt to pass even as it is now? The answers that are required from candidates in the Preliminary are perfectly sufficient to test any boy's elementary knowledge. I speak from experience, having both failed and passed not twenty years ago. A chemist is so seldom called upon to analyse English grammar that his pupils may well be excused examination in analysis.

Are there so many qualified assistants that it is necessary to place obstacles in the way of those wishing to enter the ranks? I think not. Are the advantages in this age of competition, both home and foreign, so great in our profession, that the trainers should be so heavily handicapped? Does the qualified man get such short hours and such a heavy salary to compensate him for the trials he had to undergo when being coached or reading for his examinations? Ask the assistants of London who, after having got through their apprenticeship, are working one hundred hours per week, exclusive of night work, which is generally very considerable, and for these—shall I say privileges?—are paid, with but few exceptions, a most miserable and paltry sum.

Possibly there exists in the imagination of A. W. S. a model college where, by an examination hitherto unknown, the defective may be sifted from those who have received a proper education. Many schemes, good perhaps in theory, are failures in practice, and to increase the severity of the Preliminary is unnecessary, and would, I feel confident, have a very injurious effect.

In conclusion, kindly permit me to ask a question, Why should candidates for the Major and Minor, when they fail to satisfy one examiner be examined again in the subjects in which they have previously been successful? I believe such is not the case in the medical examinations.

A. E. H. B.

Permanganate of Potash Pills.

Sir,—In the *Lancet* of January 6 permanganate of potash pills, containing 1 or 2 grains of the salt, are recommended by Drs. Ringer and Murrell for amenorrhœa. Having, during the last few days heard of cases of their spontaneous combustion, which is probable will occur if the common excipient containing glycerine, now generally used by dispensers, be used to mass them. I wish to point out that any readily oxidized excipient should not be used. Having prepared a quantity of the pills I found the following basis to answer best:—Vaseline, 2 parts; paraffin wax, 1 part; melt, stir till cold, and add kaolin, 3 parts; mix well. This binds the powdered permanganate together, and with a little dexterity the pills may be rolled out without much difficulty, and dusted over with kaolin. They may be coated with sandarach, dissolved in absolute alcohol, and rendered tasteless. Cacao butter may be used as an excipient, but it in time reduces the permanganate and it is troublesome to manipulate. In solution a dose of permanganate is very nauseous. In a tasteless pill, it dissolves slowly, and yet can be easily disintegrated; it is, besides, more agreeable to the stomach than in solution.

10, *New Cavendish Street.* Wm. Martindale.

The Manufacture and Sale of Patent Medicines.

Sir,—If the indiscriminate sale of potent remedies, covered by the patent stamp, is still to be allowed by unqualified traders, cannot some provision be made that the compounders possess at least the qualification of a vendor of oxalic acid, if not that of Pharmaceutical Chemist or M.R.C.S.?

Castle Cary. F. S. Moore.

W. M. A.—Probably the last mentioned labels would not involve the necessity for using a stamp, provided that the preparations are not advertised in any way for the relief of disease or claimed to be a specialty. But you are recommended to submit the question to the Inland Revenue authorities who alone are competent to answer it satisfactorily.

Sanitas.—We know nothing of the work. You should apply to the person under whose name it is advertised.

S. G.—Probably fermentation is set up.

Lime Juice.—We do not think it is possible to produce a preparation of the kind that "will not ferment;" the fermentation, however, may be retarded by proper precautions or by the addition of an antiferment.

Communications, Letters, etc., have been received from Messrs. Errington, Walker, Veritas, Independent, Norfolk, F.S.S., T.A.P.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 563.)

Balsamum Copaivæ, P.G.; Copaiba, U.S.P.—The botanical source of this oleoresin is now stated in the U.S.P. to be *C. Langsdorffii*, but in the P.G. it is attributed to *Copaifera officinalis* and *C. Guianensis*, instead of *C. multijuga*, as in the last edition of those works. Since, according to Mr. R. Cross's statement (*Pharm. Journ.*, [3], ix., 89), copaiba is collected indiscriminately from various species, its reference to any particular species is not of much importance. As copaiba does, however, vary considerably in proportion of volatile oil and resin, some limit in this direction might be easily imposed. Tests for the presence of gurjun balsam are now given in both Pharmacopœias, and for turpentine and fixed oils in the U.S.P. The latter adopts a specific gravity of 0·940–0·993, while the P.G. gives 0·96–0·99.

Balsamum Peruvianum, U.S.P. and P.G.—In the P.G. it is attributed to *Toluifera Pereiræ* (*Myroxylon Pereiræ*) instead of *M. Sonsonatense*, Klotsch., and in the U.S.P. to *Myroxylon Pereiræ*, Klotsch., instead of *Myrospermum peruiferum*, De Candolle. The tests for the purity of this substance differ in the two Pharmacopœias as follows:—The P.G. has altered the specific gravity from 1·15–1·16 to 1·137–1·145, while the U.S.P. gives specific gravity 1·135–1·150 (*Pharmaceutical Journal*, [3], xiii., p. 321). According to the latter the balsam is soluble in 5 parts of alcohol (specific gravity 0·820), and should show the absence of fixed oils and alcohol by not diminishing in volume when shaken with an equal weight of benzine or water. The bisulphide of carbon test is exactly that given in 'Pharmacographia,' p. 182, except that about 40 per cent. (instead of 38) of resin is said to be precipitated. In the P.G. the balsam is said to be miscible with an equal weight of spirit, specific gravity 0·830–0·834; 8 instead of 3 parts of bisulphide of carbon are to be added to precipitate the resin. This appears to be a waste of the bisulphide. According to the statement in 'Pharmacographia,' any further addition to the mixture of 1 part of balsam with 3 of bisulphide of carbon will precipitate the resin. The presence of turpentine, storax and balsam of copaiba are detected by heating the residue left by spontaneous evaporation of a mixture of 1 part of balsam with 5 parts of petroleum benzin previously well shaken together. Colophony is detected by shaking 5 drops of the balsam with 3 c.c. of liquor ammoniæ, when very little froth should be produced and a gelatinous mass should not be formed after twenty-four hours if the balsam be pure. Dr. C. Grote's test for 20 per cent. of resin or upwards is adopted ('Year-Book of Pharmacy,' 1881, p. 219), while Professor Flückiger's lime test is not given. It is not stated in the U.S.P. what admixture the distillation of the balsam with 200 parts of water is intended to detect. Peckolt states (*Pharm. Journ.*, [3], xi., 819) that balsam of Peru yields volatile oil when distilled with water, while that of *M. peruiferum* does not. It is probably intended, however, to detect oils of copaiba and turpentine.

Balsamum Nucistæ, P.G.—It is rather remarkable to find in a Pharmacopœia which so carefully distinguishes between rhizomes, roots and tubers, such an inconsistency as giving the name of "balsamum nucistæ" to an ointment containing yellow wax, olive oil and expressed oil of nutmeg.

Balsamum Tolutanum, U.S.P.—The name for the balsam of tolu tree now adopted is *Myroxylon toluifera*, Kunth., instead of *Myrospermum Toluiferum*, De Candolle. The test given for freedom from other resins is that bisulphide of carbon should dissolve out scarcely anything but cinnamic and benzoic acids. The simple test for the presence of cinnamic acid by warming a little between two pieces of glass and examining under the microscope for crystals of the acid is not given (*Pharm. Journ.*, [3], viii., 624.

Belladonnæ Folia, U.S.P. and P.G.—The U.S.P. gives the length of the leaves, but omits the breadth. The P.G. gives their length as two decimetres long by one broad, and remarks that the leaves are on both surfaces, "*albis punctis distincta*," a feature much more easy to observe on the upper than the under surface, and one which does not appear to be present in the leaves of stramonium. The dose is given as 0·2 gram or 0·6 *pro die*. In neither Pharmacopœia are any directions given as to the age of the plant from which the leaves should be collected, nor the time of year at which they should be gathered. The leaf is now the only part of the plant official in the P.G.

Belladonnæ Radix, U.S.P.—A preference for starchy roots is shown by directing the use of those breaking with a nearly smooth and mealy fracture (*Pharm. Journ.*, [3], xiii., 86), those which are tough and woody and break with a splintery fracture being disallowed. These directions, while providing against the admixture of such roots as *Medicago sativa* or marshmallow, are scarcely sufficient to exclude the root of *Scopolia japonica*, unless special attention is paid to the mealy fracture. The readiness with which the thin brown epidermis is scraped off by the nail, exposing the white starchy surface beneath, forms a feature which readily distinguishes young and good belladonna root from others of similar size and appearance. It is so difficult to obtain good samples of the root in commerce, that it is not surprising to find it omitted from the P.G.

Benzoin, U.S.P.; Benzoe, P.G.—The warning against the use of Penang and Sumatra benzoin in the last P.G. is now omitted, but the description still applies to Siam benzoin. The description in the U.S.P. also seems to be intended for Siam benzoin. As cinnamic acid is said to have been detected ('Pharmacographia,' 1st ed., p. 365) in Sumatra and Penang benzoin, as well as in some samples of Siam, the test for the absence of that acid is therefore probably intended to secure a suitable material for the preparation of benzoic acid. There is no proof that Siam benzoin is obtained from *Styrax Benzoin*, while the storax odour of the Penang variety and the vanilla scent of the Siam kind indicate that they are in all probability the produce of a different tree from that which yields Sumatra benzoin.

Brayera, U.S.P.; Flores Koso, P.G.—In the U.S.P. brayera (koosso) is now limited to the female inflorescence, and is attributed to *Brayera anthelmintica*, Kunth. The word *anthelmintica* is often erroneously spelt thus, its derivation from the Greek ἑλμινθος necessitating the use of "th" instead of "t." In the P.G. the female inflorescence is alone official; the name adopted for the koso plant is *Hagenia Abyssinica*, and the description now gives more botanical details, even going so far as to state that the fibre wound round the koosso consists of the stem of *Cyperus articulatus*.

Bryonia, U.S.P.—The roots, both of *Bryonia alba* and of *B. dioica*, L., are official. This is altogether a new addition, the drug not occurring previously in the secondary list. According to homœopaths the roots of the two species differ very much in strength and properties, that of *B. alba* being always preferred to *B. dioica*. The accuracy of this statement might perhaps be worthy of more attention than it has hitherto received now that the drug is introduced into the Pharmacopœia.

Buchu, U.S.P.—In the last edition the leaves of *B. crenata* "and other species" were official. The "other species" are now limited to *B. betulina*, Bark., *B. crenulata*, Hook., and *B. serratifolia*, Willd.

Calamus, U.S.P.; Rhizoma Calami, P.G.—This is another drug which probably finds a place in the U.S.P. owing to its use among the German portion of the population as an aromatic tonic in dyspepsia, etc. The description in the U.S.P. is not well worded, for the rhizome is described as showing numerous oil cells and *scattered* wood-bundles, the latter *crowded* within the subcircular nucleus sheath. In the P.G., 1872, the rhizome was directed to be collected in autumn and to be used only in the decorticated state. The root in its natural state is now official in both Pharmacopœias, and no directions are given as to the time of collection.

Calendula, U.S.P.—This, like bryonia, would seem to have been introduced to supply a formula for an extensively used homœopathic remedy, since it does not appear in the P.G. or in the previous edition of the U.S.P. A brief description of the flower-head is given, but no characters by which it might be distinguished from those of *Tagetes erecta*, L., and *Tagetes patula*, L., the plants commonly known as African and French marigolds, and the heads of which, according to Maisch, have been largely sold as calendula in the United States (*Amer. Pharm. Journ.*, 1867, p. 386). The achenes in these species are flattish, slender, and crowned with a few chaffy scales; the phyllaries of the involucre are united to form a tube, the receptacles are naked, and the ligulate florets are broader than in *Calendula*.

Calumba, U.S.P.—Radix Colombo, P.G.—The U.S.P. now adopts the name of *Jateorrhiza Calumba*, Miers, only, and the two Pharmacopœias consequently agree in this point.

Cambogia, U.S.P.—This is now attributed to *Garcinia Hanburii*, Hook. f. A description of the drug, and a test for its freedom from starch are given, but the proper percentage of resin is not mentioned.

Camphora, U.S.P. and P.G.—The name *Cinnamomum Camphora* is now adopted for the camphor plant. The characters given in the U.S.P., that camphor should be entirely soluble in alcohol and chloroform, and sublime without residue, are necessary since the introduction of the Japanese drug, in the manufacture of which mucilage is said to be used.

Cannabis Indica, U.S.P.; Herba Cannabis Indicæ, P.G.—The P.G. directs that the flowering tops should be more green than brown, while the U.S.P. states that the drug has a brownish colour. If it is usually met with in Germany of a greenish colour, it is not surprising that Dr. Fronmuller remarks that the extract is now four times as strong as it was thirty years ago. The P.G. is in error in giving the name of "bhang" to the flowering tops; these being known in India as "gunjah," or in the London market as "guaza." The object of retaining *Cannabis americana* in the Pharmacopœia is not evident.

Cantharis, U.S.P.; Cantharides, P.G.—The U.S.P. still retains the name *Cantharis vesicatoria* for the insect and the P.G. that of *Lytta vesicatoria*. In the U.S.P. a description and measurements are given, the latter being less than those of the P.G., which also directs that the ash left after incineration should not exceed 8 per cent. In the P.G. the maximum dose is now given as 0·05 gram, or 0·15 per day. The directions as to time of collection are now omitted. The U.S.P. orders a little camphor to be placed in a well-closed vessel with the insects; but no test as to percentage of cantharidin, or for the presence of euphorbium in powdered cantharides, is given in either Pharmacopœia.

Capsicum, U.S.P.; Fructus Capsici, P.G.—The fruits of *Capsicum fastigiatum* are official in the U.S.P., and those of *C. annuum* and *C. longum* in the P.G. The description of the dimensions in the latter is not so accurately worded as is usually the case in that work, since it admits of the construction that a conical fruit of capsicum might be 5 centimetres long and 4 broad in the lowest part, a shape which is by no means typical of commercial capsicum.

Caryophyllus, U.S.P.; Caryophylli, P.G.—In both Pharmacopœias the botanical name is altered to *Eugenia caryophyllata*, Thunb. According to the P.G. the flower-buds should be 10–15 millimetres long (12 mm. U.S.P.) and should exhibit volatile oil when scratched with the nail (U.S.P.) or split longitudinally and pressed between blotting paper. It is necessary to try this test on several specimens, as the exhausted cloves are often mixed with those in good condition, the exhausted specimens being usually moist and without petals.

Castoreum, P.G.—American (Canadian) castoreum is now official, the Siberian, which has long been almost impossible to obtain, being excluded. The powder should not melt at a temperature of 100° C., which precludes the presence of resin, with which spurious castor sacs are sometimes filled.

Cardamomum, U.S.P.; Fructus Cardamomi, P.G.—The dimensions given in both Pharmacopœias indicate that the Madras as well as the Malabar cardamoms are intended, since 2 centimetres long and 1 broad is rather an unusual size for Malabar cardamoms. The long cardamoms so frequently contain badly developed seed, that directions to use seed freed from the husk would give a more uniform result.

Cardui benedicti, Herba, P.G.—A more minute botanical description is now given.

Carum, U.S.P.; Fructus Carvi, P.G.—The U.S.P. gives the length of the fruit as about 4 millimetres, a measurement which applies to Dutch caraways, while the P.G. now requires the length to be 5 millimetres, which is characteristic of English caraways.

Cascarilla, U.S.P.; Cortex Cascarillæ, P.G.—The P.G. forbids the use of copalchi bark (*Croton niveus*), which it describes as occurring in larger quills, with a more strongly radiate fracture, rather more acrid taste and greater thickness. As there are several barks to which the name "copalchi" is applied it is well that the description is given, since it does not apply to the bark commonly known as "copalchi" in this country. By an oversight the length of copalchi quills is given in the old measure (1 foot) instead of in decimetres.

CASSIA FISTULA, U.S.P.—The description now given is sufficient to distinguish the pods from those of *Cassia moschata*.

CASTANEA, U.S.P.—A botanical description of the leaves is now given and it is directed that they should be gathered in September or October while still green. The drug is probably retained from the secondary list on account of its value in whooping cough. No allusion is made to the shape of the base of the leaf, which in the nearly allied species *C. americana* is rather acute.

(*To be continued.*)

NOTE ON THE ORIGIN OF CASSIA LIGNEA.*

BY W. T. THISELTON DYER, M.A., F.R.S.,

Assistant Director, Royal Gardens, Kew.

The spice now known in pharmaceutical literature under the name of *Cassia lignea* has, from time immemorial, been an article of trade from South China. Flückiger and Hanbury are indeed of opinion that it was the cinnamon of the ancients, what now bears the name being peculiar to Ceylon and unnoticed as a product of the island till the thirteenth century.† Cinnamon and cassia are, however, enumerated amongst the products of the East from the earliest periods; and the former was known to the Arabians and Persians as *Darchini* (*dar*, wood or bark, and *chini*, Chinese). It seems in ancient times to have been carried by Chinese traders to the Malabar coast, where it passed into the commerce of the Red Sea. In this way the statements of Dioscorides, Ptolemy, and others, are accounted for, who speak of cinnamon as a product of Arabia and Eastern Africa, countries in which there is no reason to suppose it ever grew. At the present day it is still an important item in Chinese commerce. I find, from the Statistical Returns of the Chinese Imperial Customs (for copies of which Kew is indebted to Sir Robert Hart), that the export from China for the last two years stands as follows‡:—

		Quantity.	Value.
1880	. .	38,784 piculs,	225,692 Haikwan taels.
1881	. .	57,456 „	300,303 „

1 picul = 133⅓ lbs.; 1 Haikwan tael = 5*s.* 6½*d.*

With regard to the botanical source of Cassia lignea, it is remarkable, considering its ancient history and its present importance in trade, that up to the present time nothing certain has been ascertained. Flückiger and Hanbury remark:—"Although it is customary to refer it without hesitation to a tree named *Cinnamomum Cassia*, we find no warrant for such reference; no competent observer has visited and described the cassia-yielding districts of China proper, and brought therefrom the specimens requisite for ascertaining the botanical origin of the bark."§

Bentley and Trimen also remark, in their 'Medicinal Plants,'|| "Though it is probable that this species (*Cinnamomum Cassia*) affords Chinese cassia, the fact has never been proved."

In the face of the uncertainty felt by these authorities, it appeared to be desirable to have the point, if possible, cleared up. The attention of the Colonial Office was accordingly drawn to the matter, November 18, 1881; and it was suggested that Mr. Charles Ford, Superintendent of the Botanical and Afforestation Department, Hong Kong, might be allowed, with the consent of his Government, to proceed to the cassia plantations on the West River for the purpose of reporting on the cultivation and collection of Cassia lignea, as well as of bringing back for distribution from the Hong Kong Botanic Garden living and dried botanical specimens of the authentic plant. Lord Kimberley was so good as to approve of the proposal; and in the month of May last Mr. Ford accordingly started for the cassia districts of the West River, the Sai Kong. He completely succeeded in the object of the expedition, and described his journey and its results in a Report to the Hong Kong Government, August 9. This Report has been printed as a Government Notification (No. 339); but as in that form its circulation will necessarily be very limited, I think the facts deserve the wider circulation which will be afforded by the Society's Journal.

Mr. Ford's journey was timed so that he might be in the districts at the season when the trees were flowering. This enabled him to obtain authentic specimens for their botanical identification, and also to witness the operation of obtaining and preparing the bark.

Mr. Ford gives the following account of the geographical position and extent of the cassia districts:—

"There are three chief districts where the cassia is cultivated, viz.:—Taiwu, in lat. 23° 34′ N., and long. 110° 18′ E. in the Kwangsi province; Lukpo, in lat. 23° 6′ N., and long. 112° 24′ E.; and Loting, in lat. 22° 52′ N., and long. 111° 8′ E., both in the Kwangtung province. These are the market towns of the district; but the cassia is cultivated over a large area of country stretching to considerable distances from the towns, the extent of which could not be ascertained owing to the unreliable accounts given by the different people questioned, who either had very vague notions of area, or were disinclined, as they usually are, to give information to foreigners.

"Taiwu is about four or five miles from the West River, and is reached by a pleasant walk leading over a plain; but the nearest cassia plantations are situated twenty-five or thirty miles further in a southern or south-westerly direction, to which there is no communication by river. Taiwu is about one hundred and eighty miles west of Canton. The Taiwu people said that the area of cultivation was not increasing.*

"The next most important, if not the *most* important (or at least tending in that direction) district is the Loting one, commencing at about eight or ten miles distant from the city of Loting. After leaving the West River about eighty miles of the Loting River—the Nam Kong—has to be traversed before reaching the city, and from there the distance to the plantations has to be accomplished overland. One of the largest cultivators said that in this district there were about 1,000,000 *maus* (about 52,600 English acres) under cultivation, and that the area was greatly extending every year. The cultivation of cassia has been carried on here for only about twenty-five years, *i.e.*, since the Tai-Ping rebellion, at which time, for the preservation of the plants and protection of them from destruction by the rebels, they were transferred from a district further south, at which it is reported the cultivation of cassia was abandoned when it was commenced at Loting.

"The next district is that of Lukpo, which is much less important than the other two. The city of Lukpo is situated on the northern bank of the West River; and the plantations are situated at about fifteen miles between the nearest one and the city.

"In addition to these places there are several small localities near the West River at intermediate places, where small patches of cassia are grown; and as the quantities of bark obtained are too small to send to market towns, it is brought off by small boats and sold to larger boats which carry produce down the river.

"About six miles south-west of the small town of To Shing, which is situated on the southern bank of the

* From the *Journal of the Linnean Society*, December 18, 1882.

§ 'Pharmacographia,' p. 528.

|| Vol. iii., *sub tab.* 223.

* "Near the town of Taiwu, according to Mr. Moss ('Narrative of an Exploration of the West River,' 1870), the best cassia bark is produced" (Bretschneider, 'Early European Researches into the Flora of China,' p. 13).

river, about twenty-five miles above the confluence of the Loting and West rivers, there are some plantations, from which, however, no bark has been obtained for two years and no new plantations made for ten, because the low prices which can now be obtained for the bark do not leave any profit to the producers. This was the only instance which came to my knowledge of the decrease of the trade in the cassia production, although it is said that the Java cassia trade, in consequence of the lower prices at which the cassia can there be produced, is cutting out and crippling the China trade."

From each of the districts of Taiwu, Lukpo and Loting, Mr. Ford obtained and sent to Kew copious and excellent specimens. These have been examined by my colleague, Professor Oliver, who informs me that they certainly all belong to the same species, and that this is undoubtedly *Cinnamomum Cassia*, Blume. Mr. Ford took great pains to ascertain if this was the exclusive source of Cassia lignea. He reports:—

"This is the *only* tree from which cassia bark, 'buds,' or leaves of commerce in China, so far as could be ascertained from personal inspection and reports, are obtained. All the trees seen in the districts of Taiwu, Loting and Lukpo, and intermediate localities where cassia was grown in smaller quantities, were of this species, nor were there, apparently, distinct varieties of the species in cultivation. The cultivators and other natives were much interrogated as to whether they knew or had heard of any other tree which yielded the products under notice, and the invariable reply was that there was no other kind. There is, therefore, I think, no doubt but writers who have named other kinds as cassia-yielding trees of China have been mistaken or misinformed on the subject. One writer alludes to a tree in terms which partly correspond to the description of *Machilus velutina*, Champ., another tree belonging to Lauraceæ, and indigenous to South China. It is quite possible that this tree may have been supposed by a casual observer to yield cassia bark, because it is sometimes grown in plantations intermixed with those of *Cinnamomum Cassia*. The trees are reared, planted, and treated in precisely the same manner as the cassia trees; but the bark is required for a very different use, viz., to supply a glutinous extract which is used to stick together powdered cassia bark and sandal wood (*Santalum album*) to form the joss-sticks used for incense. *Cinnamomum Burmanni*, Bl., which it has been supposed may probably yield 'in part the cassia bark of the Canton market,' does not, I feel sure, supply cassia bark to any extent. I did not see it anywhere cultivated; nor was it seen growing wild in any but very small quantities, and these wild trees bore no signs of having been cut as had the cassia trees: many natives were asked if it was ever used; but, with one exception, all denied that it afforded any cassia bark. The one exception was an old woman, who was cultivating a field of Indian corn close to a few small trees of *Cinnamomum Burmanni*, and who said that its bark was sometimes, but rarely, used to adulterate the true cassia bark."

Mr. Ford on his return journey paid a visit to the well-known Chinese botanist, Dr. Hance, H.M. Vice-Consul at Whampoa, who identified the specimens of the Cassia lignea tree collected by Mr. Ford as belonging to *Cinnamomum Cassia*. There is, in fact, in the Kew Herbarium a specimen of the same species collected by Dr. Hance in 1876; but I have searched in vain to see if Dr. Hance has published any thing about it, and the specimen bears no note that it is the source of Cassia lignea. This specimen is the material upon which the plate given by Bentley and Trimen is based, and represents no doubt the true plant.

Cinnamomum Cassia was first described by Blume, in 1825.* The species was apparently founded on cultivated specimens from Java, where Blume states it was "ex China introductum."

The Kew Herbarium possesses a cultivated Java specimen contributed by the Leyden Herbarium. This is no doubt an authentic type of the plant described by Blume; and Professor Oliver finds that it agrees precisely with the plant collected by Mr. Ford on the West River. It may be, therefore, considered finally settled on the one hand, that the Chinese Cassia lignea plant is really the *Cinnamomum Cassia*, Blume, and, on the other hand, that the plant cultivated in Java is identical with that now known to be the source of the spice in China.

It is remarkable that though the cultivation of the Cassia lignea tree has apparently been carried on in Southern China from time immemorial, it does not appear to be indigenous there.* In Cochin-China, however, there appears to be some probability of its being really wild. *Cinnamomum Cassia* is, botanically, very closely allied to *C. obtusifolium*, Nees, one of the species from which a similar product is obtained on the Khasia hills.

It only remains to give Mr. Ford's account of the mode of collecting and preparing the bark. He obtained and sent to this country a set of the implements, which are deposited in the Kew Museum.

"*Bark.*—When the trees are about six years old, the first cut of bark is obtained. The season for barking commences in March and continues until the end of May, after which the natives say the bark loses it aroma, and is therefore not removed from the trees. The branches, which are about an inch thick, being cut to within a few inches of the ground, are carried to houses or sheds in the vicinity of the plantations. All the small twigs and leaves being cleared off, a large-bladed knife, with the cutting-edge something like the end of a budding knife, is used to make two longitudinal slits and three or four incisions, at sixteen inches apart, round the circumference through the bark; the bark is then loosened by passing underneath it a kind of slightly curved horn knife with the two edges slightly sharpened. Pieces of bark sixteen inches long and half the circumference are thus obtained.

"The bark, after its removal and while it is still moist with sap, is then laid with the concave side downwards, and a small plane passed over it, and the epidermis removed. After this operation the bark is left to dry for about twenty-four hours, and then tied up in bundles about eighteen inches in diameter, and sent into the merchants' houses in the market towns.

"*Leaves.*—The leaves which are cleared from the branches that are barked are carefully preserved and dried, and afford by distillation cassia oil. A large number of leaves are sent to Canton, where I was told the operation of distilling is performed.

"*Twigs.*—These are removed from the cut branches at the same time as when the leaves are obtained. They are a marketable commodity for native uses.

"*Buds.*—Cassia-buds are the immature fruits. They are gathered when about one-eighth grown. Buds, and the seeds which are annually required for sowing, are obtained from the trees ten years and upwards of age that are left standing at about fifty and a hundred feet apart amongst the trees which are cut down every six years for their bark. These seed-bearing trees are not cut unless there is a demand for the very thick bark on their trunks, when some of the trees which can be conveniently spared are sacrificed."

TURPENTINE: ITS NATURE AND ADULTERATIONS.†

BY PROFESSOR HENRY E. ARMSTRONG, PH.D., F.R.S.

In the course of investigations on the terpenes, camphor and allied compounds, in which I have been engaged during several years past, the opportunity has occurred

* 'Bijdragen Fl. Nederl. Indië,' ii., p. 570.

* The earliest printed notice in works professing to give botanical information about China appears to be in Martini's 'Atlas Sinensis' (1655). See Bretschneider's 'Early European Researches into the Flora of China,' p. 13.

† From the *Journal of the Society of Chemical Industry*, December 29, 1882.

of gradually collecting a number of data which probably are of sufficient technical value to find a place in the *Journal of the Society of Chemical Industry.*

Thanks to the kindness of my friend, Mr. E. Phillips, of Messrs. Ingall, Phillips and Co., I was enabled to examine average samples of most of the cargoes of turpentine landed by his firm during the years 1877 to 1880, and thus to obtain a clear insight into the character of the commercial article. The high price of turpentine during the past few seasons has undoubtedly led dealers here to adulterate it, and it was to be feared that shippers might not uniformly resist temptation; therefore, at the request of the above-mentioned firm, since the beginning of last year, I have regularly tested all cargoes landed at their wharves.

The crude resinous exudation, formerly known as "turpentine," is no longer an article of commerce in this country, the obviously rational course being nowadays adopted of separating it into its constituents, "spirit of turpentine," or "turpentine oil" and rosin. On this account the name "turpentine"—*vulgare* "turps"—is now commonly employed as synonymous with the longer appellation, spirits or oil of turpentine, and it is in this sense that the term is employed in the paper.

The commercial varieties of turpentine mainly consist of hydrocarbons of the formula $C_{10}H_{16}$, of which certainly *three* distinct classes may be distinguished, viz., *terpenes, citrenes,* and a third of which *sylvestrene*, the characteristic constituent of Russian turpentine, is the type. Under *terpenes,* I include those varieties which boil at about 156° C.; under *citrenes,* those which boil at about 176° to 178°, such as are the chief constituents of the oils derived from various species of *citrus.*

French Turpentine.—It is generally stated that French turpentine is the produce of a single species of conifer, *Pinus maritima.* It certainly is of remarkably uniform quality, judging from the almost constant rotatory power of samples which I have had occasion to examine at various times, and probably the properties of the terpene of which the French oil mainly consists are not very different from those of the commercial article. Using any form of polarimeter which admits of the observation being made in monochromatic light—it is, perhaps, well to note that the Soleil form cannot be employed for the examination of turpentine—and operating with a 200 mm. column, the value of α_D is on the average about $-60°$ to $-61°$.

American Turpentine.—American turpentine is said by Hanbury and Flückiger ('Pharmacographia,' 1st ed.) to be chiefly the produce of the swamp pine (*Pinus Australis*), this and the loblolly pine (*Pinus tæda*) being, they say, the most important sources of turpentine.

The following particulars regarding the separation of the hydrocarbon from the crude resinous exudation will probably be of interest. I am indebted for them to Dr. Thomas F. Wood, of Wilmington, N.C.; they were written at the request of Mr. Charles Rice, American editor of the 'Pharmacographia':—

"Turpentine is distilled in copper stills now. Formerly iron stills were used. All crude turpentine is distilled with water. A fifteen-barrel still (barrel weighs 280 lbs.) is charged early in the morning. Gentle heat is first applied until the mass is liquefied, and a coarse wire skimmer is used to remove the chips, bark, leaves and such other foreign substances as rise to the surface, the temperature meanwhile rising until 316° F. is reached. All the accidental water (that contained in the crude turpentine as it comes from the forest) having been distilled off, a small stream of cold water is now let in, so that the heat is kept at or below 316° F., the boiling point of oil of turpentine. The oil of turpentine and water now come over, and the mixture is caught in a wooden tub. The distiller tests the quality of the flow from time to time in a proof-glass, and the distillation is continued until the proportion of water coming over is 9 of water to 1 of oil of turpentine. At this stage the heat is withdrawn, the still-cap is taken off, and the hot rosin is drawn off by a valvular cock at the side of the still near the bottom. This rosin passes through a strainer before it reaches the vat, to rid it of foreign substances which may not have been previously removed by the skimmer. The yield of oil of turpentine from 'virgin dip' (the first exudation from a newly-boxed tree) is about 5 gallons to the barrel, about 20 per cent. being left in the rosin,* since the removal of a larger proportion would darken the colour, and consequently depreciate its value. The yield from 'yellow dip' (the runnings of the second and subsequent years) is about 4 gallons to a barrel. The yield from 'scrapings' (the inspissated gum from the tree facings) is about 2 to 3½ gallons according to age, and also to the proportion of trash which it contains."

The separation of turpentine, by what is practically a steam distillation process, serves to explain the fact which, until I received the above information, had often surprised me, that the commercial article is uniformly free from products of the decomposition of rosin by heat.

Some idea of the importance of the turpentine industry will be gathered by inspection of the following table, representing the number of barrels imported into London since 1872:—

1873	44,495	1878	56,221
1874	57,720	1879	42,960
1875	57,093	1880	39,649
1876	57,371	1881	63,724
1877	49,500	1882	57,489

Probably about two-thirds of the entire quantity sent to this country is landed in London.

In so far as general properties are concerned, there is no practically distinguishable difference, other than in colour, I believe, between various samples of the commercial article, but tested by the polarimeter they vary considerably.

The chief port of shipment is Wilmington, and most of the turpentine from this port, like that from Bordeaux, is of remarkably uniform quality. Thus out of thirty-five samples, representing in all cases bulks of several hundred barrels, and in a number of cases bulks of from 1000 to 2000 or more barrels, no less than twenty-eight samples varied in rotatory power (value of α_D per 200 mm.), only within the very narrow limits of 27° 6′ to 28° 35′; four samples had an inferior rotatory power of 24° 29′ to 26° 40′, and only three had a superior rotatory power of respectively 29° 31′, 31° 21′, and 32° 38′.

That shipped from Savannah, on the other hand, is, as a rule, characterized by a relatively low rotatory power, *e.g.*:—

Ex. 1569	brls.	$\alpha = 22° 21'$	Ex. 1696	brls.	$\alpha_D = 19°$
Ex. 1000	,,	$\alpha_D = 24° 9'$	Ex. 1870	,,	$\alpha_D = 20° 33'$
Ex. 1383	,,	$\alpha_D = 20° 22'$	Ex. 1200	,,	$\alpha_D = 21° 21'$
Ex. 1571	,,	$\alpha_D = 19° 39'$	Ex. 1595	,,	$\alpha_D = 19° 12'$

In the case of the last of these shipments, I had the opportunity of taking five samples, each representing about one-sixth of the bulk, which gave the following values:—21° 4′, 21° 19′, 18° 13′, 17° 38′, and 20° 6′. I have not been able to ascertain whether the turpentine shipped from Savannah is the produce of a different tree, or whether the difference in climate between the two districts, of which Wilmington and Savannah are "centres," is the cause of the marked variation from what may be termed the Wilmington type. I trust that the publication of this paper may, as one result, lead to my being favoured with information on this point.

Judging from the opportunities which have presented themselves for examining turpentine shipped from Charleston, the deliveries from this port would appear

* The fact that the whole of the hydrocarbon is not removed accounts for the statement sometimes made, that "rosin spirit" is optically active, that made from pure rosin, according to my experiments, being inactive.

to comprise turpentine of somewhat high rotatory power, as well as those of the Wilmington and Savannah types:—

Ex. 1000	brls.	$\alpha_D = 30° 24'$	Ex. ——	brls.	$\alpha_D = 19°$
——	„	$\alpha_D = 30° 38'$	Ex. 1874	„	$\alpha_D = 26° 42'$
Ex. 250	„	$\alpha_D = 33° 33'$	Ex. 1886	„	$\alpha_D = 29° 39'$
Ex. 1689	„	$\alpha_D = 28° 15'$	Ex. 200	„	$\alpha_D = 24°$
Ex. 2179	„	$\alpha_D = 24° 15'$			

Other parts also furnish a somewhat irregular product; the values, however, always lie within those already given, and in the majority of cases belong to the Wilmington type, Brunswick alone exhibiting a marked tendency to furnish a product of the Savannah type.

Commercially, I believe, no distinction is made between the turpentine shipped from various American ports; nor indeed is French turpentine, which is now a comparative rarity in the English market, regarded as having distinctive qualities. My observations on the whole justify this practice: French turpentine is slightly less readily oxidized, absorbing oxygen somewhat less rapidly than American turpentine, but the difference is probably insufficient to make itself felt in practice.

Russian Turpentine.—Commercially this variety is of no importance, as it cannot well be used in paint or varnish making, both on account of its unpleasant odour and of the extreme readiness in comparison with French or American turpentine with which it absorbs oxygen, forming a viscid oil; its vapour appears also to produce far more marked physiological effects than either of the ordinary oils, inciting violent headache in many individuals. It is the produce of *Pinus sylvestris*, but I have not been able to ascertain whether the turpentine is specially collected, or is a mere bye-product. According to one account which I have received, the waste timber is piled into heaps and a fire lighted; the resinous matter which drains away is then collected and the turpentine extracted from it by distillation.

Different samples are remarkably different in their optical character, as the following numbers show:—

α_D(per 200 mm.) =	36° 29′	44° 11′	40° 42′
	36° 7′	41° 0′	46° 45′
	34° 18′	35° 28′	36° 4′
	38° 58′	30° 42′	37° 5′
	32° 27′	35° 20′	42° 10′
	31° 20′	38° 6′	39° 52′
	34° 8′	45° 10′	30° 10′
	39° 58′	38° 4′	

Excepting the first four, all these samples were drawn from single barrels, and were obligingly furnished to me by Mr. Kingzett.

Russian turpentine has been shown by Tilden (*Chem. Soc. Trans.*, 1878–80) to consist of a peculiar $C_{10}H_{16}$ hydrocarbon, the so-called *Sylvestrene* of Atterberg (*Ber.*, 10, 1202), and of an isomeride possessing the character of American turpentine. Sylvestrene, according to these authors, has a *specific* rotatory power of $(\alpha_D) = 19{\cdot}5°$ (Atterberg), 19·6° (Tilden), that of the associated hydrocarbon being 36·3° (Atterberg). In confirmation of the assumption that one of the constituents of Russian turpentine is probably identical with the main constituent of American turpentine, I may mention that I have separated from the latter by fractional distillation a portion having a rotatory power per 200 mm. of no less than 49° 34′, and that on several occasions, by submitting American turpentine to air oxidation, and afterwards distilling off the unaltered hydrocarbon by steam, I have obtained products of considerably higher rotatory power than the original oils. I have also examined several samples received from Mr. Kingzett of the hydrocarbon carried over by the air current during the air oxidation of Russian turpentine. In most cases these have been almost free from sylvestrene, and have exhibited a higher rotatory power than the original crude turpentine from which they were derived.

The numbers above given fluctuate within wide limits, and are of interest as indicating that the proportions in which the two recognized constituents of Russian turpentine are present probably vary considerably, and also that other perhaps isomeric hydrocarbons are mixed with them; they serve to confirm the idea that American turpentine is also a mixture of isomeric hydrocarbons. I may add that certain observations even lead me to think it not unlikely that the low dextrorotatory power of American turpentine is due to the presence of a lævorotatory terpene; this would serve to explain the difference in optical character of products from different localities. The comparative study of American turpentine—and indeed generally of oils containing $C_{10}H_{16}$ hydrocarbons—from this point of view, I think deserves attention; variations in climatic and other conditions may have led to a gradual differentiation both in botanical and physiological character of a single parent stock.

Method of Analysis.—The terms "petroleum spirit" and "petroleum oil" as commercially used do not admit of very precise definition; for the purpose of this paper, I would therefore define petroleum spirit as being that portion of crude petroleum which may be volatilized by means of steam from water boiling at atmospheric pressure, and petroleum oil as being the non-volatile portion. Judged of by this definition, commercial spirit and oil are, as a rule, more or less mixtures; the amount of spirit in the best burning oils is, however, small.

The presence of petroleum oil in turpentine is readily detected and the amount estimated by steam distilling. Unless it has been freely exposed to the air for a long time, but a mere trace of viscid matter remains on steam-distilling turpentine; on one or two occasions only have I met with samples containing a small amount of rosin, which was left as a solid on distilling off the turpentine by a steam current. Should more than a few tenths of a per cent. of non-volatile matter remain, it is probable that petroleum is present. This usually betrays itself by the more or less marked blue fluorescence of the residue; but should this criterion fail, the behaviour of petroleum and of the non-volatile product of the air oxidation of turpentine on digestion with dilute nitric acid will serve to differentiate them. The latter is readily oxidized and dissolved; the former does not alter much in bulk, but apparently undergoes more or less complete nitration. I have never yet met with a sample containing rosin oil, but it would not be difficult to detect it, as it is oxidized by nitric acid, and behaves in a most characteristic manner when triturated with a paste of slaked lime, forming the well-known grease.

The detection and estimation of petroleum spirit is less readily effected. The method which I employ is based on the different behaviour of turpentine and paraffins with sulphuric acid. The paraffins, it is well known, are almost unaffected, whereas turpentine is polymerized and for the most part converted into substances of high boiling point which do not volatilize in a current of steam. I say for the most part, because, as I have elsewhere stated, a certain amount of cymene and of a paraffinoid hydrocarbon is always produced. Inasmuch as the amount of cymene so produced varies with the strength of the acid and the temperature, being larger the more concentrated the acid and the higher the temperature, it is important always to work under uniform conditions, at as low a temperature as convenient, and to use diluted acid. I employ two strengths of acid, a mixture of 2 vols. acid and 1 vol. water (2:1 acid) and a mixture of 4 vols. acid and 1 vol. water (4:1 acid). The turpentine—500 c.c. is a convenient quantity—is placed with about one-fourth to one-third of its bulk of 2:1 acid in a well-stoppered bottle, and the mixture is somewhat cautiously agitated. It soon becomes more or less heated, and as it is important to effect the polymerization at a temperature not much above the ordinary atmospheric temperature, the bottle is placed in cold water for a short time. After repeated agitation with the acid, the turpentine is converted into a viscid oil, and when this is the case and no more heat is developed on continued agitation, the contents of the bottle is transferred to a separating funnel, the acid layer is run off and the oil poured into a flask; the latter having been connected with a condenser and a steam-pot—an ordinary tin can answers admirably—all that is volatile is distilled off. The distillate is mixed with about half its bulk of 4:1 acid, and treated in a precisely similar manner.

The product from this second operation should only consist of a mixture of cymene and the paraffinoid hydrocarbon; in bulk it should not be more than 4 to 5 per cent. of the original hydrocarbon. This is the result of a very large number of estimations; as little as 3 per cent., however, has been obtained in experiments conducted with special care. If much more than about 5 per cent. be obtained, it is desirable to repeat the treatment with 4:1 acid.

If, from the result of this treatment, it appears probable that petroleum spirit is present, the product is placed in a well-stoppered bottle, together with several times its volume of concentrated sulphuric acid, heated to 50° to 60°, with which it is violently agitated. This treatment is repeated if desirable (weak Nordhausen acid being with advantage substituted for the concentrated sulphuric acid), and the residual hydrocarbon is separated, steam distilled, and then measured. The amount thus obtained should not exceed from ½ to 1 per cent. of the original bulk of turpentine. This treatment with concentrated acid affords a check on the previous determination.

If American petroleum spirit be thus treated it suffers comparatively little loss, so that the amount of hydrocarbon above 1 per cent. represents the *minimum* amount of petroleum spirit in the turpentine. The spirit from Scotch petroleum contains a very much higher proportion of hydrocarbons alterable by sulphuric acid, and therefore cannot be satisfactorily estimated.

To confirm the presence of petroleum spirit, the turpentine should be distilled. Petroleum spirit commences to distil at a temperature which may be above or below that at which turpentine boils, according to its quality, but always distils within comparatively wide limits of temperature; turpentine commences to boil near 160°, and almost entirely passes over below 180°.

The presence of rosin spirit also affects the boiling point in a similar manner. Evidence of the presence of this adulterant is also afforded by the increased yield of hydrocarbons on treatment both with 4:1 and concentrated sulphuric acid, as rosin spirit also yields a cymene and paraffinoid hydrocarbon on treatment with 4:1 acid. The cymene from rosin spirit being isomeric with that from turpentine, proof of the presence of rosin spirit can be obtained by the detection of its cymene, but this is a somewhat delicate operation.

Addendum.—The method above described is also available for the analysis of solvent naphtha from coal tar and similar products; it is, in fact, the only method which is capable of affording results which approach exactness. The problem is by no means so simple, however, as the coal tar product itself contains, besides benzene and its homologues, basic bodies, hydrocarbons alterable by diluted sulphuric acid, and paraffins. Until, therefore, a considerable number of genuine samples have been examined, the method is chiefly of value as a qualitative test.

THE FIG TREE.*

During a lengthened stay in Naples and attendance at the Zoological station of that city, Count H. zu Solms-Laubach, assisted by Dr. P. Mayer, one of the staff of the institute, and by Baron Valiante, made a special study of the origin, domestication and cultivation of the fig-tree (*Ficus carica*, L.), the result of which he has published in the form of a pamphlet, 'Die Herkunft, Domestikation, und Verbreitung des gewöhnlichen Feigenbaum, Von H. Grafen zu Solms-Laubach. Göttingen, 1882.' The work is especially devoted to the study of the history of the fig-tree, and the operation of caprification, which, as is known, consists of hanging the fruit of the wild fig upon the cultivated tree, receives considerable attention. Perhaps it will be as well to mention here, for the benefit of some less acquainted with the subject, that the fruit of the wild fig is hung upon the cultivated tree by gardeners, in order that the insect which lives in the wild may enter the cultivated fruit, which they think results in preventing the figs from falling off, hastens their maturity, and improves their taste. Count Solms-Laubach begins by mentioning that already in ancient times two distinct varieties of fig-trees were clearly distinguished, the fruit of the first of which is sweet, succulent and eatable, that of the other remaining hard and milky until it attains a very imperfect maturity, without the least formation of sugar, and then quickly dries up. Count Solms-Laubach distinguishes the first species by the name of fig-tree, the other by the name of caprificus, or as it is called in the Neapolitan dialect, "profico." The caprificus (or wild fig-tree) usually bears fruit thrice, the cultivated fig-tree twice a year. The caprificus in the interior of its figs has both male and female flowers; the fig-tree usually only female. It is the female flowers of the caprificus fig which contain the insects that serve for the operation of caprification. Both the caprificus and the fig-tree are obtained from sowing the seed of the cultivated fig; but as the quality in such cases is generally very bad, propagation is exclusively carried on by shoots. The curious insects developed in the caprificus flowers, and called *Cynips Psenes* by Linnæus, but now named *Blastophaga grossorum*, were already known to the ancients as a means of caprification. These insects belong to the order of Hymenoptera. The females are winged, the males wingless. In Naples, where the author made the greater part of his studies, the wild figs produced at different seasons of the year are respectively named "mamme," "profichi," and "mammoni;" and it is from the first of these, the so-called mamme (which are the earliest harvest of the caprificus and ripen in April), that the insects which have wintered therein issue in spring in order to lay their eggs in the fruit of the second harvest, the so-called profichi, which ripen in June. When this has taken place—a very few insects, thanks to their great productiveness, are able to fill numerous flowers with their eggs—the mother insects die; in May the larvæ, and in June the perfect insects are formed, and meanwhile the fruit of the third harvest, the so-called mammoni, which ripen in August and September, are ready to receive the female Blastophagæ. From these mammoni, finally, the brood wanders into the mamme in order to winter, and thus the chain of events is completed, and in the following spring the laying of eggs in profichi is recommenced. Let us now see what happens when the female Blastophagæ, instead of entering the figs of the caprificus, lay their eggs in those of the cultivated fig-tree. The insects, indeed, perform the operation, but are unable to lay their eggs in the proper place (for reasons shown in the pamphlet, but too detailed to be mentioned here), and the progeny, therefore, never develops. Nevertheless the entrance of the insects has a most important influence; they carry with them into the fig with exclusively female flowers the pollen of the male caprificus flowers, and thus cause the formation of seed. Our author describes the Blastophaga as a small black insect issuing between the scales of the ripe fruit in June. Having arrived outside, it suns and dries its wings, and cleans its hairy body with its feet to rid itself of the pollen which adheres to it so thickly that it looks as if powdered. If one opens a wild fig at the proper time, a large number of these insects are seen running about, evidently seeking to escape. The wingless and

* From the *Daily News*.

helpless males are distinguished by a bright amber colour. When the insects pentrate the figs of the young profichi to lay their eggs, they frequently lose their wings, so great is the effort needed. Count Solms-Laubach often found whole bunches of torn-off wings, where many females had entered the same figs. They generally die after laying their eggs, while seeking their way out. Opinions are divided as to the efficacy of caprification. By some it is considered advantageous, while others regard it as injurious. Count Solms-Laubach gives his verdict as follows:—"Caprification is an operation, traditionally preserved from generation to generation in the same form, which, once necessary, is now scarcely useful, but the scientific importance of which as a means of determining the changes experienced by our cultivated plants in the course of years, cannot be too highly valued."

After deciding the geographical extent of the cultivation of the fig-tree, the author calls attention to the curious fact that caprification is not always practised where the insect is found. In Greece and its islands, in Sicily and Naples, in Southern Spain and Portugal, in North Africa and Syria, and Asia Minor, it is generally introduced; but is not practised in middle and North Italy, the Tyrol, Sardinia, Corsica, the South of France, Northern Spain, the Canaries and Azores, nor in Egypt. Fossil remains prove that the *Ficus carica* was spread over the whole Western portion of our present civilized world in pre-historic times, and that it existed also in Greece and in Asia Minor cannot be doubted, in spite of insufficient proof. In France the quaternary district in which it existed exceeded in extent the present district of cultivation. The author believes, with Lloyd, that the fig-tree had died out in the whole of the Western world, and was only reintroduced in the progress of civilization. He finds the different species so similar that a common origin cannot be doubted. Western Asia and North Africa are named as the fatherland of this origin, but without sufficient proof. The author comes to the conclusion that the fig-tree had an equatorial fatherland, in contrast to the circumpolar fatherland of the vine, and finds the most favourable conditions for such an origin in the Punjaub, Beluchistan, and South Persia, as well as in the border terraces of Abyssinia. From the circumstance that probably the invention of caprification will have gone hand-in-hand with the domestication of the fig-tree, and that the former operation is carried on now exactly as it was in ancient times, and also because the nation which invented caprification must have been tolerably far advanced in civilization, the author believes that the cultivation of the fig-tree commenced at a single point, and thence spread to the rest of the world. To which nation, then, do we owe it? It is proved by ancient authors that the domestication of the fig-tree was known in Greece in the ninth century, B.C. The Bible, and especially the Semitic name of "ti'n," a word belonging to the dialect of the Bahrâ race, leads us to Arabia as the mother-land of domestication and thence probably it spread to the Semitic peoples of Syria. These commercial nations having once possessed the tree, it was natural that its cultivation should spread. The Greeks will have received it from the Phœnicians, as probably also will North Africa, Southern Portugal and Spain, Sicily and Malta; and many facts speak for such a direct introduction. In Italy we find the curious circumstance that caprification is practised in the south, but not in the north. The contrast was so great that even in the eighteenth century the North Italians were not aware that their southern countrymen made use of caprification. Count Solms-Laubach comes to the very interesting conclusion that the Romans received the fig-tree direct from the Phœnicians (of which the name *Ficus* is cited as a proof), but only the tree and not the practice of caprification was known to the Semitic races; while caprification was independently introduced into South Italy by the colonizing Greeks.

The last chapter of the pamphlet is devoted to a short study on the sycamore (*Sycamorus antiquorum*, Miq.), to which the author's attention was drawn by the many analogies between that tree (in the fruit of which similar insects are found) and the fig-tree.

VEGETABLE SUBSTITUTE FOR RENNET.*

BY SIR J. D. HOOKER.

Mr. Stormont, Superintendent of the Government Farm, Khandesh, reported, May 10, 1880:—"Cheese-making is a branch of agricultural industry altogether unknown in this district, and but imperfectly understood in any part of India; yet there seems no reason why it should not be successfully practised."

Commissioner E. P. Robertson, minuted upon this, June 10, "Cheese to be saleable amongst the natives of this country should be made with some vegetable rennet. Natives would not touch cheese made with ordinary rennet, and I am convinced that good cheese cannot be made without the use of some rennet. If a good vegetable rennet could be procured the curd cheeses could be made; they would be cheap, and ryots would soon find a ready sale for them."

These facts having attracted my attention I consulted Mr. A. H. Church, formerly Professor of Chemistry in the Royal Agricultural College, Cirencester, but who has taken up his residence at Kew, and is now Professor of Chemistry to the Royal Academy. This gentleman very kindly made some experiments on curdling milk, with calcium chloride and with vegetable acids. He arrived at the conclusion, however, that though in the laboratory good results could be obtained they depended too closely on careful attention to the conditions of the process to afford a workable method for everyday use in India. Meanwhile, I had turned my attention to some suitable vegetable "rennet." Surgeon-Major Aitchison, while engaged at Kew, in working up his Afghan collections, under instructions from the Government of India, suggested a well-known North-West Indian plant (*Puneeria coagulans*), as possessing the desired qualities.

The plant in question is one of the best-known plants in Scinde, Beluchistan and Afghanistan. "It bears the name of Puneer-bund (cheese-maker), from its being used by the Beloochies and Afghans in making cheese (puneer) as a substitute for rennet."

I communicated this information to the India Office. As will be seen from the following extract from Mr. Stormont's report for 1881, the suggestion was immediately acted upon with very gratifying success.

"During the year a good deal of attention has been devoted to dairy experiments, especially the making of cheese after the practice of Italy and Switzerland. The Commissioner, C. D., pointed out that, before cheese-making can ever become an industry of the ryots, some vegetable substance must necessarily be found to take the place of the animal rennet used in European countries.

"In connection with this difficulty, Surgeon-Major Aitchison brought to the notice of the authorities at Kew that the fruit of *Puneeria coagulans*, a shrub common in Afghanistan and Northern India, possesses the property of coagulating milk.

"A quantity of the dried capsules of this plant was accordingly obtained, and part of it tried here, and found to be most suitable for the purpose. Being a member of the poisonous nightshade family, its safety was in the first place carefully and gradually tested. It has been ascertained that an ounce of the pounded capsules in a quart of water is a very suitable strength for use; a tablespoonful of this decoction coagulates a gallon of warm milk in about half an hour. Seeds of the plant sown have germinated freely, and their further progress will be specially reported upon."

* From the 'Report on the Royal Gardens at Kew.'

The anxiety as to the botanical position of *Puneeria* amongst the *Solanaceæ* has, I think, no solid foundation. The genus *Puneeria* is now reduced by botanists to *Withania*. This is a member of the tribe *Solaneæ*, which appears to be generally free from the poisonous principles so characteristic of *Atropeæ* and *Hyoscyameæ*. It abounds, in fact, in plants producing fruits which daily experience shows to be innocuous, such as the tomato, aubergine, capsicum, *Cyphomandra* and cape gooseberry.

THE DILUTION AND MIXTURE OF ACIDS, ALCOHOL, SOLUTIONS OF SALTS, ETC.*

BY TH. J. WRAMPELMEIER, PH.C.

There have appeared, at different times, rules and formulæ for the dilution of alcohol and acids. Some of them are very simple for particular cases, but are either not applicable to the more complicated cases, or, in their application, involve more or less tedious algebraic operations. I do not remember having seen any rule that is so simple or of so nearly universal application as the one I have used for some time, and which I will give below.

I started with the following consideration. It is evident that, if we mix 100 grams of 75 per cent. (by weight) alcohol with 100 grams of 25 per cent. (by weight) alcohol, the product will be 200 grams of 50 per cent. alcohol, because the first 100 grams contain 75 grams absolute alcohol, and the second 100 grams contain 25 grams—total 100 grams in the mixture whose weight is 200 grams, *i.e.*, 50 per cent. Now the 100 grams 75 per cent. alcohol contain 25 grams more absolute alcohol than is necessary to make it a 50 per cent. alcohol, whereas the 100 grams 25 per cent. alcohol *lack* 25 grams absolute alcohol of being the strength 50 per cent. Suppose we are to make 50 per cent. alcohol out of both the 75 per cent. and 25 per cent. alcohols, we add enough of the 75 per cent. alcohol to the 25 per cent. alcohol, so that the excess over 50 per cent. of the former is just sufficient to make up the deficiency below 50 per cent. of the latter, or *vice versâ*. Accordingly, in mixing two alcohols of different per cent. strength to make one of intermediate strength, the *excess* of absolute alcohol in the one (over what is necessary to make it the desired strength) must be equal to the *deficiency* of absolute alcohol in the other. Let

P = per cent. strength (by weight) of the stronger.
p = per cent. strength (by weight) of the weaker.
W = weight of stronger.
w = weight of weaker.

Then $P \times W$ = amount of absolute alcohol in the stronger alcohol, and $(P - p')\,W$ = excess of absolute alcohol above what is required to make it strength p'. Similarly $(p' - p)\,w$ = deficiency of absolute alcohol in the weaker alcohol (below what is necessary to make it strength p'). To make the mixture strength p', we must mix them, so that $(P - p')\,W = (p' - p)w$, from which we get the proportion—

$$(P = p') : (p' - p) : : w : W,$$

and our rule which is as follows:—

Having two solutions of the same substance and different per cent. strength (by weight) to make a solution of intermediate strength, mix them in the inverse proportion of the differences between their percentage strength and the percentage strength of the required mixture.

Or, having two solutions strength P (for the stronger) and p (for the weaker) to make one of intermediate strength, p′, mix them in the proportion of p′ - p of the stronger to P - p′ of the weaker.

When, instead of the weaker solution, water is to be used, as in the dilution of alcohol or acids, p becomes zero, and the proportion becomes p' of the solution to $P - p'$ of water. The following cases may arise:—

* From *New Remedies*, January, 1883.

(1) Given the weight of the stronger, how much of the weaker will be required to make the mixture of the required intermediate strength? The proportion is—
$p' = p : P - p' : : W : x$ = weight required, or if, instead of the weaker solution, water is to be used,

$$p' : P - p' : : W : x = \text{weight of water required.}$$

Example.—Having 100 kilos nitric acid, strength 70 per cent., how much nitric acid, strength 10 per cent., must be added to this to make an acid strength 50 per cent.?

$$(50 - 10) : (70 - 50) : : 100 : x.$$

$x = 50$ kilos = weight of 10 per cent. acid required.

If water is to be used instead of the 10 per cent. acid,

$$50 : (70 - 50) : : 100 : x.$$

$x = 40$ kilos = weight of water required.

(2) Given the weight of the weaker, how much of the stronger will be required? The proportion is—

$$(P - p') : (p' - p) : : w : x.$$

x = weight of stronger required.

Example.—Having 100 lbs. alcohol, strength 23 per cent. (by weight) to make 45 per cent. alcohol, how much 93 per cent. alcohol will be required?

$$(93 - 45) : (45 - 23) : : 100 : x.$$

$x = 45{\cdot}8$ lbs. = weight of 93 per cent. alcohol required.

(3) It is desired to make a certain quantity of the solution of intermediate strength, how much of each the stronger and the weaker will be required?

Let a = weight of alcohol (strength p') to be made,
and x = weight of stronger alcohol (strength P) rerequired,
then $a - x$ = weight of weaker alcohol (strength p) required.

We have $(P - p') : (p' - p) : : a - x : x$;
from which $(P - p) : (p' - p) : : a : x$.
x = weight of stronger solution required.
$a - x$ = weight of weaker solution required.

Example.—To make 10 kilos of alcohol, strength 85 per cent. (by weight), how much of each 91 per cent. and 45·5 por cent. alcohol is required?

$$(91 - 45{\cdot}5) : (82 - 45{\cdot}5) : : 10 : x.$$

$x = 8{\cdot}7$ kilos = weight of 91 per cent. alcohol required.
$10 - 8{\cdot}7 = 1{\cdot}3$ kilos = weight of 45·5 per cent. alcohol required.

If water is to be used instead of the 45·5 per cent. alcohol, p becomes zero, and we have—

$91 : 85 : : 10 : x = 9{\cdot}34$ kilos 91 per cent. alcohol.
$10 - 9{\cdot}34 = 0{\cdot}66$ kilos water required.

(4) Again, we may have three or more solutions which we desire to mix, in order to obtain a solution of certain strength, as, for instance, it may be desirable to use up several lots of recovered alcohol in the preparation of an alcohol of certain strength. It is evident that a sufficient quantity of the strongest alcohol or alcohols must be used, so that the excess of absolute alcohol above the required per cent. will equal the sum of the deficiencies of absolute alcohol of the weaker alcohols.

Let P = per cent. strength of strongest alcohol.
W = its weight.
p' = per cent. of required alcohol.
p'' = per cent. of a weaker alcohol.
w = its weight.
p = per cent. of the weakest alcohol.
w' = its weight

Then $(P - p')\,W = (p' - p'')\,w + (p' - p)\,w'$.

Example.—(*a*) You have 10 kilos alcohol strength 10 per cent. (by weight) which you desire to bring up to 50 per cent., using therefore 2 kilos of 25 per cent. alcohol and a sufficient quantity of 90 per cent. alcohol. How much of the last will be required? Substituting $P = 90$, $W = x$, $p' = 50$, $p'' = 25$, $w = 2$, $p = 10$, $w' = 10$, and

$$(90 - 50)\,x = (50 - 25)\,2 + (50 - 10)\,10.$$

$x = 11{\cdot}25$ kilos 90 per cent. alcohol required.

(*b*) You desire to make 10 kilos diluted alcohol, U.S.P. (45·5 per cent. by weight), using 2 kilos 40 per cent. alcohol. How much 91 per cent. alcohol and how much water will be required?

$$P = 91$$
$$p' = 45{\cdot}5$$
$$p'' = 40$$
$$p = 0$$
$$w = 2 \text{ kilos}$$
$$W = x,$$

then $w' = 10$ (amount to be made) $- 2$ (weight of w) $- x$ (amount of W)

$$(91 - 45{\cdot}5)\,x = (45{\cdot}5 - 40)\;2 + 45\;(10 - 2 - x)$$

and $x = 4{\cdot}1$ = weight of 91 per cent. alcohol required.

$10 - (2 + 4{\cdot}1) = 3{\cdot}9$ = weight of water required.

Other and different cases might be presented, but the above will show the general application of the rule, not only to the dilution of alcohols, acids, etc., but also to the bringing up of the strength of solutions, as, for instance, when it is necessary to fortify a wine.

THE ADULTERATION OF COCHINEAL.*

BY DR. JULIUS LOEWE.

Commercial cochineal appears in two forms, according to the method used in killing the insects, namely either as dull grains covered with a white dust, or as shining, blackish-brown grains, free from dust.

The whitish variety has long been known to have been subject to adulteration, by being weighed with 10 to 12 per cent. of mineral substances—such as sulphate of barium, carbonate or sulphate of lead, chloride of lead, talcum, etc.,—mostly all such substances as combine a high specific gravity with small bulk. The amount of such impurities may generally be detected by estimation of the ash of the cochineal: the unadulterated drug yielded not much over 0·5 per cent. of ash.

On account of the frequent adulteration of the white variety, purchasers fell into the habit of demanding the dark, undusted kind, which appeared to offer a better guarantee of purity. But even this has, of late years, been frequently found adulterated with various substances, as binoxide of manganese, sulphide of lead, ferric oxide, etc.

The method of adulteration, in this case, is generally so perfect that even a good judge will often be unable to detect it by mere inspection. It was, therefore, of interest to ascertain by what means this adulteration is so skilfully performed, and a series of experiments soon led to the discovery of the method.

To moisten cochineal with a cold adhesive liquid, such as solution of gum, etc., and then to add the weighing material, does not lead to the desired result, since the accompanying water extracts colouring matter from the cochineal, which imparts a red colour to the added mineral matters, and thereby detracts from the appearance of the article. Besides, the foreign substance does not penetrate sufficiently into the ridges of the insect, and only adheres to it very superficially, so that it may be easily recognized.

By the following method, however, the weighting may be done perfectly, and it is this method which is used, on a large scale, by the adulterators.

Cochineal is cautiously exposed to an atmosphere of steam, great care being taken that it does not come in contact with any water of condensation, but be merely enveloped in steam. The grains thereby swell up to several times their volume, and from their ridges exudes a very small amount of strongly adhesive red juice which serves as a glue for the weighting material to be added. As soon as the grains cease to increase in bulk, they are removed from the atmosphere of steam, and transferred in a suitable vessel—flask, drum, etc.—when the mineral substance is added (up to 10 or 12 per cent.), and the vessel is set in rotary motion until the material is completely taken up by the adhesive juice adhering to the insects. The grains are then removed and dried in a current of warm air, when they contract to their previous volume, and retain the weighing material concealed within their folds and ridges. By this method white mineral substance afterwards added remains uncoloured, and the dark substances previously incorporated remain undetected.

It appears, therefore, to be, under all circumstances, advisable to purchase only such cochineal as has been found pure, on estimating the ash. It is true, that this might also be made nugatory, if organic substances were used as adulterants, for instance, flour as "white substance," and asphaltum as "dark substance." Yet, if this were done, the real purpose of adulteration would not be attained, since these substances have but a small specific gravity compared with their volume, and would, therefore, not likely be chosen.

EFFECTS OF IRON ON DIGESTION.*

In an inaugural dissertation published at Berlin, Dr. A. Düsterhoff records the results of some experiments bearing on this subject. One gram of fibrin was added to 20 c.c. of artificial gastric juice, and during digestion equivalent quantities of various preparations of iron were also added. At the end of the process the undigested fibrin was dried and weighed, and the quantity of soluble syntonin in the solution was also estimated. The time of digestion was in one case three hours, ten minutes, in another it was seven hours and a half. In the first series 0·0614 gram of metallic iron was in each case added, in the form of pyrophosphate, perchloride and protolactate respectively. In the second series, various other preparations were used, the amount of metallic iron being in each case equivalent to 0·0077 gram. Other experiments were made with white of egg; the amount of albumen precipitated by boiling after digestion being estimated. The outcome of the experiment is—that the organic salts of iron seriously hinder and check peptic digestion. Probably the hydrochloric acid of the gastric juice displaces the organic acids from the iron salts and so is used up; while the free organic acids in the digestive fluids are far less powerful digestive agents than the hydrochloric acid. But this cannot be the only cause at work, for perchloride and phosphate also tend to hinder digestion. Even reduced iron has a similar effect, for it partially dissolves in the juices, forming chlorides. Its solubility, like that of the phosphate, is however not very great. Ferrous salts seem to interfere less with digestion than ferric salts.

EXTRACT OF MALT WITH QUININE.

Extract of malt	195 parts.
Hydrochlorate of quinine	1 part.
Glycerin	4 parts.

Dissolve the hydrochlorate of quinine in the glycerin, and mix it with the extract of malt.

This preparation should be freshly made when wanted for use.—*New Remedies.*

EXTRACT OF MALT WITH IODIDE OF IRON.

Extract of malt	96 parts.
Solution of iodide of iron	4 parts.

Mix them.

The solution of iodide of iron is prepared by bringing together 3 parts of iron with 8 parts of iodine, and enough water to make 40 parts, when the reaction is completed and the liquid filtered. Twenty parts of this solution contain 5 parts of ferrous iodide.

This preparation should be freshly made when wanted for use.—*New Remedies.*

The Pharmaceutical Journal.

SATURDAY, JANUARY 20, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ALKALI INDUSTRY.

THE history of the manufacture of soda and potash salts has been marked by some very unexpected results, which have not always been profitable to those most closely connected with the industry. When nearly a century ago the French pharmacist, LEBLANC, was engaged in working out the process for manufacturing soda crystals ever since associated with his name, he little anticipated that whilst his labours would bring little more than an almshouse and a pauper's funeral to himself, they would lay the foundation of a most important industry, which, during a long series of years was fated to be carried on principally in a country which was then the greatest rival of his own. So, too, another French pharmacist, BALARD, after many years of patient investigation and experiment, had only just succeeded in elaborating remunerative processes for obtaining potash salts from the salt marshes of his native district, when all prospect of monetary profit from them was dispelled by the announcement of the discovery of enormous saltine deposits in North Germany. On the other hand, when at various times a due regard to the public health and convenience has imposed upon the soda industry conditions which at first seemed to be unbearable, the real outcome has been fresh "leaps and bounds" of prosperity, continually giving new force to the adage that "Necessity is the mother of invention." It has been understood, however, for some time past, that an ebb in the tide of prosperity has become manifest; manufacturers are said to have been carrying on operations without profit, or even at a loss, whilst, this notwithstanding, the Board of Trade returns just issued for 1882 once more show a decrease in the export of alkali from the United Kingdom. Under such circumstances any observations upon the subject from so experienced a manufacturer and chemist as Mr. WALTER WELDON would have been sure to have attracted attention; but it may be truly said that a paper on the present condition of the soda industry, read by him a few evenings since before the London Section of the Society of Chemical Science, of which he is the President, is one of the most interesting and surprising contributions to the history of applied science that has yet been made.

Mr. WELDON commenced with a gloomy picture of the condition of the LEBLANC soda industry in this country at the present time. On the Tyne, out of twenty-five works that were in operation a very few years ago only thirteen are now worked, eight of the others having been actually dismantled in despair of ever again being able to manufacture soda in them by the LEBLANC process except at a loss. Even in Lancashire, where the manufacture is carried on rather more advantageously in respect to supply of material and nearness to markets, several alkali works are standing still, and few are working up to their full capacity for production. In Belgium the manufacture of soda by the LEBLANC process has absolutely ceased, whilst in France, Germany and Austria, where both soda and chlorine products are protected by high duties, it stands in considerable peril. One of the principal factors to this state of affairs has been the phenomenal growth of the soda manufacture by the ammonia process, which, as Mr. WELDON puts it, "has come upon the makers of LEBLANC soda almost like a thunderbolt out of a clear sky." A dozen years ago the total quantity of soda manufactured by this process barely amounted to one thousand tons in the year, but now it is estimated that on the Continent alone it reaches one hundred and ten thousand tons annually, and it is still rapidly augmenting. No doubt this contrast of prosperity and adversity in the two processes is attributable mainly to the fact that—under present conditions as to the cost of sulphur and the price obtained for the chlorine bye-product—when the manufacture of LEBLANC soda is yielding no profit at all, that of ammonia soda is yielding fully £1 per ton. As if these circumstances were not sufficiently adverse, the makers of the LEBLANC process are now threatened by a new and even keener rivalry from another quarter. It appears that Spanish and Portuguese pyrites are capable of yielding, besides sulphur and iron, about 3 per cent. of copper, and small quantities of the precious metals, sufficient to more than repay the cost of extraction. When most of the sulphur has been burnt off from the pyrites for sulphuric acid, the residual "burnt ore," or "pyrites cinders," is now treated by the wet way for the extraction from it of copper, and in most cases of gold and silver also, and after these have been removed there remains an almost pure oxide of iron—known as "purple ore"—which finds a ready sale for various purposes in connection with the manufacture of iron and steel. Moved by these considerations, and by the fact that French pyrites does not contain copper, the Rio Tinto Company—one of the great companies dealing in Spanish pyrites—has promoted a subsidiary company, with a capital of £1,200,000, for carrying on in France and other countries the manufacture of soda by the LEBLANC process, using Spanish pyrites in the operations. This new Company, however, will not rely for its profits either upon soda or chlorine, but on copper and oxide of iron. Soda and chlorine will be simply extra products in connection with the first stage of converting pyrites into pyrites cinders, which the Company will be content to sell at the bare cost of manufacture if no better price can be obtained.

Notwithstanding the advantages attached to the ammonia process it was at one time thought that these would be limited by the increased cost of ammonia, consequent upon the larger consumption, and by the rise in the price of hydrochloric acid due to the decrease in its production through the non-utilization of chlorine in the ammonia process. So far, however, as ammonia is concerned, the prospect of its cost affecting the question is fading into the remote distance, for here again the occasion has been productive of the application of chemical and mechanical skill. The collection of the ammonia formerly allowed to escape from coke ovens has been remuneratively effected, whilst the application of the same idea to blast furnaces has been sufficiently developed to render probable the early appearance of ammonia from this source in the market. As to hydrochloric acid, with the decrease in its production and the probable consequent increase in its price came attempts to recover the chlorine from the residual calcium chloride which has hitherto been a waste product in the ammonia process; but this has not yet been effected economically.

In the face of all this, Mr. WELDON asks, "How are the English LEBLANC soda manufacturers to continue to live?" The outlook is undoubtedly gloomy; but Mr. WELDON sees some breaks in the clouds in the promise of a more complete utilization of all the raw materials. There appears also to be a probability of an early considerable fall in the price of pyrites; but at the most this would not be likely to make up for more than about one-third of the twenty shillings per ton which is said to be the present difference in the cost of manufacture by the two processes. But there are especially two resources within reach, which he considers to be probably sufficient to turn the tables upon the ammonia process and make the old LEBLANC process the cheaper of the two. These are sulphur recovery and cheaper fuel. The cost of Sicilian sulphur, delivered at Marseilles, is about £5 per ton, and the amount which will have to be made up after the anticipated fall in the price of pyrites to equalize the cost of soda production under the two processes is estimated at about 12*s.* per ton of alkali. By recent modifications in the SCHAFFNER and HELBIG sulphur recovery process it is confidently hoped that the whole of the sulphur may be recovered from soda waste in the free state, and as this would amount to 6 cwt. per ton of soda, the profit on this recovered sulphur should amount to at least 2*s.* per cwt. The problem, therefore, may be stated thus: in order to become masters of the sulphur market, and at the same time to gain by the recovered sulphur the required profit of 2*s.* per cent., it will be necessary that English soda makers should be able to recover sulphur at a cost not exceeding £2 per ton. This, it is satisfactory to learn, Mr. WELDON thinks they will be able to do eventually, though not at first. With respect to economy of fuel, a vast revolution is hinted at. The suggestion is that "the soda maker should entirely cease to use raw "coal as fuel, but should convert all his coal into "coke, collecting for sale the oil and ammonia "evolved during its conversion into coke, and him-"self using for heating purposes the gases evolved "during the coking operation and the coke itself." It is believed that in the Newcastle district, where some two millions of tons of small coal, rich in its yield of oil, is produced annually, and is almost a waste product, the soda maker would be enabled thus to get his fuel for nothing.

It is evident from what has already been said that this paper is singularly rich in suggestive matter, which promises to exercise an important influence on the future of other industries besides the soda manufacture, and we hope to have an early opportunity of printing it *in extenso* in the pages of this Journal.

"HALF AND HALF" DISPENSING.

FOR some time past an active correspondence has been going on in the pages of one of our medical contemporaries as to the advisability and possibility of medical practitioners leaving the dispensing of medicines to pharmacists. We are quite content to note the manifest advance of opinion in the direction that as far as possible pharmacists should be entrusted with the work for which they have been specially trained, and for which, as pointed out by one who speaks with the authority of a medical examiner, medical students under present conditions have scarcely any training at all. But there has also been an ample exhibition of the old bugbears—counter prescribing, exorbitant charges, and even the assumption, as by a writer in the *British Medical Journal* last week, that dispensing is best conducted under the supervision of the prescriber. A case reported on p. 598 of this Journal furnishes a cruel commentary upon these objections. Even "counter prescribing" for simple ailments will pass muster by the side of prescribing for a patient through the intervention of a domestic and a messenger, whilst the dispensing by a housekeeper of "half and half" from two out of a row of bottles is perfectly grotesque. We do not mean to insinuate that this case is typical of medical dispensing, but it is by no means singular, and we feel justified in referring to it for the purpose of enforcing the risks that are inseparable from the practice, not at all unknown, of drawing general conclusions from exceptional cases.

"Polarimeters and their Practical Application" is to be the subject of a Lecture by Mr. C. O'Sullivan, to be delivered under the auspices of the Council of the Institute of Chemistry, in the room of the Chemical Society, Burlington House, on Thursday next, the 25th inst. There are to be experimental illustrations.

* * * *

On Tuesday last, at the Royal Institution, Professor C. W. Williamson began a course of five lectures on "The Primeval Ancestors of Existing Vegetation, and their Bearing on the Doctrine of Evolution," and on Thursday, Professor Dewar began a course of nine lectures on "The Spectroscope and its Applications." An abstract of Professor Williamson's first lecture will be found on p. 594.

* * * *

On Thursday evening next, the 25th inst., Mr. C. F. Cross is to read a paper before the Applied Chemistry and Physics Section of the Society of Arts, on the "Technical Aspects of Lignification."

* * * *

On Wednesday evening, Mr. W. K. Burton brought before the Society of Arts the important subject of the sanitary inspection of houses, in which he pointed out the damages that might arise from the negligent or unskilful carrying out of the best conceived sanitary arrangements and the necessity for provision being made that such work be supervised by competent persons.

* * * *

There seems to be some prospect at last of the proposed amendment of the law regulating the practice of pharmacy in France occupying the attention of the Legislature. A Bill brought forward in the Chamber of Deputies by M. Heppolyte Faure, formerly a pharmacien, having passed the ordeal of the preliminary committee, and been reported as fit to be taken into further consideration. The next stage is to refer the Bill to a special committee nominated by one of the bureaus of the Chamber.

* * * *

Referring to the importance of the crisis, the *Répertoire de Pharmacie* makes some pertinent remarks on the necessity of union among French pharmacists that may find an additional application in this country at the present juncture. It says: "For many years past we have assisted at a heart-breaking spectacle. Many of our brethren, obedient to their personal sentiments, aspirations and wants, have been pleased to criticize the various Bills that have been submitted to the public authorities; none of them has sufficiently borne in mind that a practical result can never be arrived at in proposing to abolish that which exists without stating positively what it is desired should replace it. Some, it is true, have indicated their idea of a pharmacy law, but many among them have not sufficiently reflected upon the inconveniences and dangers that would arise should their ideas prevail. The counsel which we have to give may be stated briefly: Be united, and, above all, be practical."

* * * *

M. Eugène Lebaigue, who for the last ten years has ably edited the *Répertoire de Pharmacie*, retired at the close of the year and his place has been taken by M. C. Thomas, one of his former *collaborateurs*.

* * * *

Two papers have just been issued by the Board of Trade containing returns relating to gas undertakings in England and Wales. These show that, during the year 1881, 6,365,336 tons of coal were carbonized to produce 63,345,300,497 cubic feet of gas, and that of this quantity 57,876,326,386 cubic feet went to supply the wants of 1,581,654 consumers or in the lighting of 293,379 public lamps. The capital and loans authorized amount to £60,577,736, of which £44,626,205 has been paid up or borrowed. The proportion of this business carried on by local authorities is about two-sevenths.

* * * *

The Accounts relating to Trade and Navigation of the United Kingdom just issued, show that the "peruvian bark" imported during the year 1882 weighed 138,763 cwts., and was of the estimated value of £1,781,482, whilst there was exported only 80,014 cwts., valued at £903,332. This would leave a good margin for the quinine manufacturers.

* * * *

The bellicosity that appears to be an essential concomitant of water analysis has invaded a new field. Concurrently with the setting in of the winter season there has been, as usual, an increase in the proportion of organic matter present in the London water supply, and in a report quoted by the Registrar-General the water supplied by four out of five of the London companies is pronounced for this reason "unfit for drinking." Messrs. Crookes, Odling and Tidy, referring to this in the report which they send periodically to the Local Government Board, say: "We take upon ourselves to assert that the analytical results set forth in the report, which are not appreciably different from our own, do not afford ground for any such appalling statements." The public may well be excused for wondering which of these important public departments receives sound scientific advice and which is misled.

* * * *

The *Lancet* mentions a case where an application by a ratepayer for a copy of the report of an analysis which had been made by order of the Local Sanitary Authority, on the well water used by his household, has been refused on the ground that it would "establish a dangerous precedent." An appeal to the Local Government Board only elicited an opinion that the point was one upon which the local authorities must use their discretion.

* * * *

According to the *Newcastle Daily Chronicle* the Public Analyst for the county of Durham is very dissatisfied with the recent magisterial decision in the sweet spirit of nitre case reported on p. 500. In his quarterly report he expresses his surprise and indignation that such a certificate should have been sent from Somerset House, and that the South Shields magistrates should have acted upon it. He maintains that the London Pharmacopœia has given place to the British Pharmacopœia and says that on all occasions he tests drugs submitted to him by the tests contained in the latter work.

* * * *

A medical contemporary, which a fortnight since referred to a "Russian remedy" for heart disease "which rejoices in the name of *Convallaria majalis*," last week made the astounding discovery that the plant is "the familiar lily of the valley," and, under the caption of "Nothing New under the Sun," has published the fact for the information of "those of our readers whose botanical knowledge does not go beyond the plants of the Pharmacopœia."

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The sixth meeting of the present session of this Association was held on Wednesday, January 10, in the Pharmaceutical Rooms, 119, George Street. Mr. Peter Boa, President, in the chair.

The minutes of the previous meeting having been read and adopted, the Chairman explained that Mr. J. D. Robertson was unable to be present and in his absence he called upon Mr. Claude F. Henry to move Mr. Robertson's resolution regarding the sale of patent medicines containing poisons.

Mr. Henry said he regretted Mr. Robertson was unable to be present. He maintained that the sale of poisons by unqualified persons under cover of the patent medicine stamp was a glaring inconsistency and an undoubted public danger. The discussions which are going on both in the pharmaceutical associations and in the medical and pharmaceutical press showed that it only required that the general opinion of those best acquainted with the subject should be brought before the proper authorities in some combined and formal manner in order to bring about a much needed reform. He referred to some remarks made by the President of the Leeds Chemists' Association, which he understood had induced Mr. Robertson to give notice of this motion. As he fully agreed with Mr. Robertson in this matter, he begged to move:—"That this Association resolves to co-operate with all societies which are agreed that the present poison laws should be altered so as to include so-called patent medicines containing poisons and to take steps to bring the matter before the proper authorities."

The motion was seconded by Mr. William Aitken and unanimously agreed to by the meeting.

Mr. J. D. Robertson was appointed to act with the committee in carrying out the resolution.

The members then had an opportunity of examining a most interesting and valuable collection of new drugs, lent for exhibition by Messrs. Thomas Christy and Co., London; living specimens of *Erythroxylon coca, Guaiacum officinale, Theobroma cacao* and *Pilocarpus pennatifolius*; and a collection of microscopic objects, mostly pharmaceutical.

Mr. MacEwan described the more important of the new drugs, remarking that it was a collection of great value and was certainly the most important that had been brought before the Association. It included a series of Mexican drugs, exhibited for the first time in this country, among which the following were noticed:—Capsicum longum, Capsicum cordiforme (Chili mulato), Capsicum cordiforme (Chili ancho), Capsicum speciosum (Chili chilporth), Thevetia icotti, Croton niveus, Lippia citriodora, Ericonia floribunda, and yerba sel pollo. The other specimens included a series of Japanese drugs described by Mr. Holmes, several products of Carica papaya, Euphorbia pilulifera, cola nuts, Duboisia leaves and extract, guaco, Jamaica dogwood, pituri leaves, rusot, erythrina seeds (*Erythrina corolloides*), kombo gumbo bark, etc.

Mr. Hill, in drawing attention to the living specimens, remarked that they were grown in the botanic gardens and were in good condition for the season. The pilocarpus was a seedling plant grown in the gardens from seed brought home by the late Dr. Paterson, of Bahia. The leaves, it was pointed out, were simple not compound. In the case of one of the latest developed leaves, however, there were two leaves showing the gradual transition to the compound imparipinnate leaves characteristic of the fully developed plant. It was mentioned that Dr. Paterson had at the same time brought home some seeds of the goa powder plant (*Andira Araroba*) and these had been successfully propagated, and they had now in the botanic gardens a fine specimen of the plant, which was believed to be the only one in Europe.

Attention was also called to the microscopic specimens.

The President moved that the thanks of the Association should be given to Messrs. Thomas Christy and Co., London, for their collection of drugs, to Professor Dickson for the specimens of economic plants, and to Messrs. Gilmour, Purves, and Thompson, for microscopes and microscopic slides. The motion was cordially responded to by the meeting. A similar compliment was paid to Messrs. Hill and MacEwan for their arrangements and descriptive remarks.

Some further business having been disposed of, the Chairman announced the next meeting for January 31, when a paper on "The Manufacture of Sulphuric Acid," will be read by Mr. John R. Hill, the Secretary to the Association. The meeting then adjourned.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

By the courtesy of Professor C. W. Williamson we are enabled to publish the following *résumé* of the first of a course of five lectures, which was delivered by him at the Royal Institution on Tuesday last, on—

The Primeval Ancestors of Existing Vegetation and their Bearing on the Doctrine of Evolution.

Lecture I.

The object of the course is to examine each of the principal types of vegetation met with in the older fossiliferous rocks; to trace the links found in the newer rocks, connect those ancient forms with living ones, and finally to ascertain how far the results give support to the Darwinian theory of Evolution. The first great and conspicuous fact is that nearly all the flowering plants (angiosperms) are of very modern geological age, and have no true primeval representatives; hence they are not dealt with in the course. The highest types of vegetation found in the older (palæozoic) rocks belong to the group of gymnosperms, *i.e.*, the coniferous and cycadean plants. They indicate, so far as we know, the most advanced form to which vegetation was developed up to the cretaceous age, with the exception of a small number of doubtful monocotyledonous plants from the triassic and oolitic rocks. This general order of appearance is, so far as it goes, consistent with the demands of Darwinism, since the gymnosperms, associated with the ancient cryptogams, undoubtedly occupy an intermediate position between the latter and the monocotyledons, which in turn, are a less highly developed group than the dicotyledonous group which makes its first appearance at a still later age. This relationship of the gymnosperms to the inferior cryptogams on the one hand, and to the higher phanerogams on the other, is demonstrated by the organization of their reproductive structures. Thus, the pollen sacs of the lower conifers and cycads are little more than the sporangia of some cryptogams, and the contained pollen grains of the former correspond to the microspores of the latter. In like manner the flowers of the same conifers are reduced to elements so simple, viz., a single ovule, that each flower is little more than one of the microspores of the other. Attention to these peculiar relationships will again be called in the concluding lecture of the course.

On turning specially to the conifers we find that most of the well-known living genera, such as Pinus, Abies

Larix, Cedrus, and their numerous allies, made their appearance at a late date in the world's history, viz., along with the flowering exogens. When we descend amongst the older strata we find very different types to prevail. So far as the microscopic aspects of their woody tissues are concerned the most ancient conifers approach the semi-tropical araucarias of the southern hemisphere more closely than they do recent and more northern forms; but besides this general araucarian type we can trace back other special forms. One of the most remarkable of these is the Salisburia or gingko of China and Japan, the leaves of which resemble the leaf of a maiden hair fern much more closely than they do those of other conifers. True Salisburiæ lived in the tertiary age, not only in Europe and North America, but even in Greenland. The oolitic rocks of Siberia furnish a well-marked gingko, and the discovery of the peculiar fruits has shown that the widely diffused oolitic Baierias, long regarded as ferns of the genus Cyclopteris, are in reality Salisburias, and the American permians have furnished a similar type. In the carboniferous and Devonian rocks of Great Britain and America numerous stems and branches abound of the remarkable genus Dadoxylon. Recent researches have made it probable that this, apparently the most ancient gymnosperm, has organic features, linking it with the gingkos, and being the ancestral stock from which they have sprung.

Turning to the great group of the Abietaceæ, it is interesting to find a true cedar in the cretaceous rocks as well as a sequoia, a close relative of the so-called Wellingtonia, the great tree of California. In the oolitic we find a numerous group of conifers, apparently including true representatives of the araucarias as well as cypress-like forms. In the liassic strata, forming the base of the oolitic, we find still more generalized plants, in which the cones resemble those of one modern type, associated with the foliage of another. Descending successively to the Keuper, the Triassic and the Permian beds we meet with a succession of yet more generalized types, leading us still further away from the living ones. In many of these the compact cones of the latter gradually become more elongated and lax until some of them more closely resemble branches clothed with woody foliage rather than true cones. Below the Permian the conifers are only represented by the dadoxylons already referred to.

The other great division of the gymnosperms, the Cycadeæ, presents a very similar history only so far as stem and foliage are concerned; the modern type of Zamia abounds not only through the tertiary cretaceous and oolitic rocks, but are met with even in the Permian strata. As is well known the oolitic age has been designated the age of gymnosperms, hence, the peculiar conifers and cycads of that period undoubtedly constituted its dominant forest vegetation.

On reaching the carboniferous beds the oolitic types have wholly disappeared, their place being taken by a remarkable group of which the genus Cardaites is the typical representative. The male and female inflorescence of these plants has been found in remarkable perfection at St. Etienne, in France, and though these structures differ widely from those of living cycads, there is no reason for rejecting the idea that some of them are the ancestral stocks from which the oolitic types and through them the living forms have sprung. That these plants constituted a very important feature in the carboniferous woodland landscape is shown by the fact that the seeds of numerous genera and species of Cycadeæ are met with in vast numbers both in Europe and North America. Though formerly the cycads were so abundant in the northern hemisphere, even within the arctic circle, they have now entirely abandoned that hemisphere, being only met with south of the equator, where they extend in an almost unbroken zone on the outer skirt of the tropical regions from Australia and New Zealand, through Africa to Central America.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Plant Names.*

BY C. E. STUART, B.SC.

"What's in a name? That which we call a rose,
By any other name would smell as sweet."

The truth of this well-worn dictum seems undeniable. And yet the fair Capulet whose thought it embodies was nevertheless anxious to get the name of her ideal altered, or even (in which I believe she would not in the present day be singular) to change her own. This may be merely a characteristic bit of feminine inconsistency, but I think it at once casts a doubt on the literal acceptance of the apparent truism put by the bard into the lips of Juliet.

If we look into the matter we shall find that the principle is true in itself, but that its truthful application is rarely if ever met with. For when is a name merely a name? Perhaps it is to such a country bumpkin as Wordsworth has described, whose

" . . . . primrose by the river's brim
A yellow primrose was to him,
And it was nothing more."

But almost invariably a name has meaning and associations; it calls up in the mind a picture, awakens memories, and affords food for thought and reflection.

Now I want in this paper to try and paint a few pictures with plant-names as subjects, touching up old ones, and presenting perhaps for criticism a few that may be new to you.

Botany used to be contemptuously spoken of as a science of hard names; but that was before organic chemistry existed;—organic chemistry with its many-syllabled names, which are the astonishment of the vulgar, and at which even pharmaceutical students will sometimes open their mouths, yet which are generally what names should be—pictures of the things named, albeit often sadly wanting in arrangement (which is form) and clearness (which is colour).

Of plant names, as given by botanists, the chief fault is that there are too many of them; portentous lists of synonyms being prefixed to the descriptions of very many even of our well-defined British species. This arises mainly from the imperfect knowledge of the structure and affinities of the plants which have been by fabricators of Floras distributed into genera and species. Thus the original discoverer of a plant may, after a cursory examination of it, assign it to a particular genus, or create a new one specially for it; while another observer by more patient and detailed investigation obtains a more accurate knowledge of it, and may change the generic and specific names accordingly. Then comes perchance another ardent student who rediscovers our plant in some other locality, and if, as will probably be the case, it is unknown to him, whether he be Smith or Jones, promptly is *Smithia viridissima* or *Jonesia unica* installed in the new Flora, where its affinities may for time more or less prolonged give rise to interesting discussions, until on comparison of authentic specimens in old and new Floras the duplex designation becomes apparent.

Or of two observers describing the same specimen, one may assign greater diagnostic importance to some one characteristic, and the second to some other characteristic; and the plant may go to this or that group accordingly. This difference of opinion is due to the laxity of the definitions of many genera and species; a laxity which must always exist to a greater or lesser extent, but which may be removed in great part in many cases by careful investigation and reasoning, and also by the study of new species in relation with older ones. As an example of the benefit of this last suggestion may be given the following extract concerning the genus *Parnassia*.—"It has been most generally placed among Thalamifloræ with Droseraceæ, next to Violaceæ and Polygalaceæ;

* Read at a meeting of the above Association, December 20, 1882.

but its close affinity with Saxifraga and Chrysosplenium has now been fully proved, *especially by the recent publication of several curious Himalayan species.*" (Bentham, 'Flora').

At the same time it must be noted that the continual normal variation of species will often render a particular individual difficultly referable to its proper species, and that many species are so nearly allied that they provide links between one genus and another, rendering sharpness of definition impossible.

In connection with this subject it may be mentioned that many of the plants alluded to in classical writings are now difficult of identification; first on account of vague description, and secondly on account of change of name rendered needful by modern knowledge. Thus the Greek "*Jasione*" is our *Convolvulus Sepium*, while we give the name "Jasione" ("the healer") to the sheep-bit. Again, *Hibiskos* is the marsh mallow, *Althæa officinalis*, and not the shrub now termed hibiscus. And in Virgil's beautiful lines, Ruskin translates the "*pallentes violas*" which the white nymph Nais was to gather for Alexis, as "pale flags," not violets which we now associate with Viola.

The multiplication of synonyms appears then in the present state of our science to be to a great degree unavoidable; and having pointed out the reasons for this, I will pass to the consideration of the names of the plants as most commonly accepted:—

In the first place, Have the names been given to plants according to any plan? I may answer, Distinctly not.

Linnæus was, as students of Bentley will remember, the first who definitely laid down the system of binomial nomenclature, that is, the giving of both a generic and a specific name to each kind of plant, and numbers of his names are still the accepted ones.

Jussieu and De Candolle defined most of the natural orders.

In analysing the British orders, genera and species, we shall find examples, so far as I am aware, of all the origins of plant names. I shall, therefore, refer almost entirely to them.

First then of the natural orders:—

1. The names are taken from some typical genus of the order. To this heading place all the British orders, as Rosaceæ from *Rosa*, Ranunculaceæ from *Ranunculus*, etc., with the exception of those to be next mentioned.

2. The names are taken from some peculiarity of flower, leaf, etc., running through the order. Such are—

Cruciferæ
Aquifoliaceæ
Umbelliferæ
Caprifoliaciæ
Compositæ
Labiatæ
Amentaceæ (Cupuliferæ)
Graminæeæ
Coniferæ.

Next:—Genera. These are—

1. Either named after themselves by discoverers, or after discoverers by subsequent describers; or again by discoverers or by subsequent describers are dedicated in the name and to the memory and glory of more or less distinguished botanists whatsoever.

This practice has some merits, but it leads in many instances, as I shall show later, to the most barbarous cacophony and word-coining.

2. Names are given at the sweet or malicious will of the name-maker, and with or without reason (generally the latter, so far as my imagination will let me discover), commemorative of some celebrated personage or place; and these are of two classes, historical and mythical.

Of this practice, the obvious criticism is, where there is rhyme and reason for the doing, where the name fits the plant and violates no probability nor stretches the imagination too sharply, and specially if the name is good Latin or Greek, then let us applaud it; if not, then be it condemned.

And 3. Some peculiarity of a plant or plants of a genus, peculiarity either real or imaginary connected with size, shape, properties and so on, has earned it its name.

This is by far the most general origin of the generic name, and to my mind is about the most legitimate method of name formation.

For as the natural system of plant classification has in its broad basis the advantage over the Linnean system, in that it brings together plants of similar structure and habits, which by the latter were arbitrarily separated and grouped by mere number of certain parts, a method erroneous in principle, for throughout nature number is consequent on structure, and not structure on number; so in the details of the natural system, an arbitrary plan of distributing generic names is to be deprecated and abandoned in favour in this case also of a natural system of name giving; a system carried out on such excellent lines as shadowed forth in the names aconitum, convolvulus, stellaria, and shall I say myosotis? the last a name at which I have heard some sentimentalists rail, but which in its meaning of mouse-ear as applied to the shape and texture of the leaves of the genus has always seemed to me more appropriate than the English Forget-me-not, while its Greek softness is equally pleasing to the ear.

For examination of the various reasons governing the adoption of specific names I can do no better than refer you to Gray, as quoted by Bentley, in his 'Manual,' who takes as an illustration the genus Viola. You will remark that nearly all the specific names indicate qualities or peculiarities of the several plants, but that frequently a botanist's or other name is dragged in as a substantive or as an adjective, and also that as many old species have been transferred to other genera, their former generic name has been retained as a specific name, as is the case with *Lythrum Salicaria*, *Dianthus Armeria*, etc.

Turning back now to develop the peculiarities of the generic names—

Of the first, the discoverer's or celebrated botanist's class, I will remark that the cases are very rare in which it is not a positive insult to a plant to connect it with the name of a man. So delicate is the charm, so quiet and unobtrusive is the growth of our wayside flowers, so elevating are the thoughts which they naturally suggest, that any connection of them with human affairs seems utterly out of place, True, types may be found in plant life of many, I think not of all, of the varied habits and instincts, faults and virtues, littlenesses and greatnesses of human nature; but that is no reason for connecting any plant with that specific unit of humanity known as a botanist. To the great, however, to the illustrious pioneers of the science it may be permitted that their names should be enshrined in and so adorn the catalogue of plant names. Thus I exemplify the name *Linnæa*, and a modest little alpine herb has an undying interest thrown around it by its sweet-sounding and honouring name of *Linnæa borealis*.

But apart from the above somewhat sentimental objection to proper names as generic terms, there is the real one of untranslateability. How many common English, German or French names will translate themselves into Latin with euphony and without outraging the ear of the scholar?

Glance down the list of genera and say what you think of such terms as—

Clarkia
Bouganvillea
Eschscholtzia
Rodriguezia
Catleya
Ludwigia
Saussurea
Scheuzeria
Sibthorpia

Teesdalia
Wolffia
Zannichellia.

These are names proper enough and significant enough in their native garb; but when, like Bottom the Weaver, they are "translated" behold they, as applied to plants, are as much out of place, as ugly and as earthy as was that otherwise worthy Athenian citizen among the fairy denizens of the woodland shades.

Ruskin says, in his odd but suggestive botanical work, 'Proserpina,' that "a day will come when men of science will think their names disgraced, instead of honoured, by being used to barbarize nomenclature," and I hope such may come speedily.

I will, however, note that there are some names which seem made to Latinize; as that of the great Swede Linné already mentioned; Asa Gray, which as Asagræa looks a thoroughly Græco-Latin designation; and Lobel, for which, until I read a sentence in Professor Attfield's address to the School of Pharmacy Students' Association, I should have been fully prepared to turn in my Latin dictionary and find as Lobelia its hidden kernel of meaning. "Lobel" is perhaps unknown to many of you; as adding, therefore, henceforth a new interest to the medicinal plant, I may state that Lobel was a native of Flanders, born in 1538, died 1616, and was botanist and physician to our James I.

Next, of proper names arbitrary and imaginative.—These are in many instances not sharply defined from the next or peculiarity class, some peculiarity of habit or structure often dictating the imaginative proper name.

In this class much of the poetry of plant names is found. We are told by one of Virgil's shepherds that the anger of Amaryllis is to be feared as the wolf to the fold, showers to the ripened corn, or storms to the stout trees; and truly the beauty of many of the Amaryllids is so superb that one can imagine any slight to it being rebuked with a proud and glowing scorn.

Andromeda is to be found by the adventurous vasculum-bearing Perseus in trembling watery peat-bogs, growing blushingly erect in the domains of the amphibian monsters, the frogs and newts.

Atropa suggests the Fate, Atropos (the inflexible), whose shears cut short the thread of human life: hence most appropriately given to the deadly nightshade. The specific name *belladonna* comes oddly in opposition with Atropa, for the Fates were not usually represented as beautiful, but rather as grey old women.

Adonis vernalis with its crimson petals tells of the fatal wound inflicted on the Thracian hunter by the fierce wild boar; but are there not many other things which it might with no furthur exercise of ingenuity be thought to shadow forth?

Iris, the messenger of the gods; Hercules, as *Heracleum* Actæon, as *Actæa*, are other mythological names, the suitability of which my imagination is not sufficiently active to discover.

On the historical side valerian is called after Valerius, who first used it in medicine and who has therefore a rightful claim to memory; but what claim has Gentius, King of Macedon, to immortality in connection with the beautiful tribe of gentians? Ruskin hints him rather undeserving, and suggests *Lucia* as a generic name; Lucy of Teesdale then being the spring gentian, whose blue eyes thrilled a friend and myself with delight as we saw her in April for the first time on her native heaths around the high Force of the Tees.

Now comes an instance of naming which is at first sight puzzling. How comes it that the genus *Euphorbia*, so acrid and poisonous, bears the Greek name for "good nourishment," which it most distinctly is not? The mystery becomes clear only when we find that this is a historical name. Euphorbus, the first to use the plants of the genus for medicine, was physician to King Juba of Mauritania, and possibly this name of his, with its meaning given above, was but a nickname given to him by his patients signifying that as court physician he lived on the fat of the land.

Thirdly, as to intrinsic generic names.

It is in this class of name that we find most of the quaint conceits, old delusions and superstitions, and imagined resemblances of and concerning plants, as well as happily caught characteristics and vestiges of simple-craft still more or less credited,

They may be best divided into names more and names less imaginative. I will give you one or two examples of each, taking the latter first.

Such is *Acanthus*, from the Greek *akantha*, a thorn; *akanthis* being a thistle, probably like our Scotch thistle, and *akanthos*, that acanthus whose spine-tipped leaves adorn the capitals of Corinthian pillars.

Cratægus is a name a step removed from the evident correctness of epithet of the above example; *Kirasos*, its root, meaning strength, and this, as applied to the wood of the wild service-tree, the original *krataigos*, is not so fitting a bestowal as that of the thorn bound up with the thistly acanthus.

Fumaria, the smoky, applied to the fumitorics, is apt, as all will concede who know the grey misty foliage of the genus; but it is more imaginative than the two former instances.

The geraniums of our summer woods recall with their long beak-like fruits the crane whose Greek name *geranos* they bear.

The Robert of *G. Robertianum* is, as some suppose, a Benedictine abbot to whom is dedicated the twenty-ninth of April about which time the herb comes into flower. But it appears to me that it cannot count for nothing that names Robert and Robin are given to *red* creatures, as to this same Herb-Robert, to

"that little weed of ragged red,
Which bids the robin pipe;"

and to robin redbreast; the inference being that savage and almost inarticulate primæval man, struck with the stimulating brightness of the rays of slow vibration in the solar spectrum, signified the effects of them by the purring pleasure of the rolling R, which is more fully developed in *Rhodon*, *Rosa*, *Rose*, *Rhœas*, *Rhoia* (pomegranate), applied to red plants, and in Robin, Robert, Rupert, applied to red men.

Rubus, again, has the same root of redness; and the genus, whether in its pink-hued flowers, its purple fruits or fruit juice, or its crimson autumnal leaf-tints, is fully worthy of its name.

Lysimachia and *Lythrum* are both Englished as Loosestrife; this should etymologically be only of the former; and as I am unable to find that it *does* loose strife, I think we must fall back for explanation on the theory that the name commemorates Lysimachus, a friend and general of Alexander the Great, and hence this belongs properly to the second class of names.

A splendid example of the purely imaginative name is *Chelidonium*, meaning swallow-wort, so called because it flowers at the time when the swallows return in the spring.

Lamium offers us an open choice of derivation. It may either be from "*Lama*," a ditch, from its place of growth; or from "*Lamia*," a snaky monster given to preying on unwary youth (Keats has a fascinating study of one); or else from "*Laimos*," the throat, the root whence *Lamia* is derived. This latter, seeing the gaping throat of the flower, seems the most fitting starting point.

Scrophularia and *Pedicularis* are instances of plants named from diseases for which they were once supposed efficacious.

Now I have run through a few illustrative instances of the various methods of plant naming which I have enumerated. It remains for me to say a few words on hard names. It is a habit with the unreflecting to stigmatize names which they find lengthy and unfamiliar as pedantic, harsh and unnecessary. But they do not perceive, what a little thought would tell them, that in the language to which they belong they may be as fitting and as fraught with pertinent meaning as any familiar English name. Thus, *Pardalianches* is a hard, uncouth-looking word, but it is simply our English Leopard's-bane, and as a Greek word it is by no means unmusical. And so with *Anisopetalum, Cryptarrhena, Eulophia, Ornithidium, Pleurothallus, Stenorrhyncus, Xylobium,* at which Ruskin grimly sneers.

And this reminds me of a new system of plant naming and classification proposed and partially carried out by this distinguished art-critic. Its leading principles are somewhat as follows:—Starting with no scientific botanic knowledge, many of the prejudices of the past may be thrown aside. Begin, therefore, by relying on your own poetic judgment for the division, so that (for instance) *oxalis* and *anemone* both come into the same order, since both are delicate flowers delighting in the woods. That they do delight in the woods is an historic fact, and as historic facts (it is well known) equally with "relative conditions of character and climate," are so unchangeable, if plant classification and naming is founded on them rather than on distinctive differences of form, which are so many, so subtle, so liable to continual reinterpretation, then we shall have unalterable groups which may be added to, but not disturbed or reconstructed. That is, in this world of change and imperfections we shall have at least a perfect and immutable system of both terminology and nomenclature.

Note, that the reasons given for this change are first, that many names are barbarous distortions of Greek and Latin words; second, that many names carry with them coarse and degrading suggestions. Both these propositions may be acquiesced in; but do they furnish sufficient reason for the upsetting and total remodelling of all plant arrangements as well as all plant naming? The third reason is, that the botany of Ruskin, being intended to be useful to the vulgar rather than to the scientific, should give to plants names characterizing them individually, and not founded on their connection with other plants at the Antipodes. Thus, Herb-Robert might be called shortly "Rob Roy, and have done with it," rather than, dwelling on its connections, christen it "Macgregoraceous."

This reason, which is no reason but a dogma, strikes at the root of natural classification, and at once places the system outside serious consideration. It sets out the dream of a poet, imaginative, beautiful, but unpractical. However, there is much to be learnt from the eloquent imaginings of its gifted author; one great lesson being not to look upon plants simply as material for dissection or for preservation in musty folios. Text-books must and text-books do take chiefly this view, but it is a healthy change from the consideration of plants as "subjects" (as the medical student would put it), to regard them as "objects" full of life, beauty and character, with ways, wills and instincts of their own. Dryad-haunted tree, starry flower, fertile grass of the field, to these are we indebted for the filling up of great portion of the wants and pleasures of our existence, and the fuller knowledge of them in all their varied forms, habits and necessities cannot but have favourable effect on human joys both actual and ideal.

Parliamentary and Law Proceedings.

Dispensing in a "Surgery."

On Friday, January 5, the Macclesfield Coroner (Mr. Yates) held an inquest at the Town Hall touching the death of a widow named Elizabeth Walker.

The first witness called was—Hiram Walker, labourer, who said the deceased was his mother, 72 years of age. She had been in pretty good health lately—nothing to cause any alarm, but was taken ill on December 26, complaining of a bad cold. On the 28th he went to the sick club, of which she was a member, for a note to get the doctor to attend her, and afterwards went to Mr. Jotham's surgery in Duke Street, where he waited forty minutes, but could get no one to answer. He left the note on the counter and went home and stayed with his mother, who kept "in a middling way" till after midnight on Saturday night, when she got worse. On Sunday morning, between nine and ten o'clock, he went again to Mr. Jotham's house in Roe Street, but did not see Mr. Jotham. His housekeeper answered the door, and he told her that he had come to see the doctor, about Mrs. Walker. She said Mr. Jotham was upstairs in bed, and that she would tell him. She went upstairs, and from the top of the stair called down to him to know what ailed her—whether she had any pain. Witness replied no, that she was only coughing. The servant then went into Mr. Jotham's room, and eventually came down and mixed a bottle of medicine in his presence. He took the medicine home and gave his mother a dose (a tablespoonful), which she was to take every four hours. She died in about ten minutes after taking the medicine. The servant took the physic out of three different bottles, and put it in the one produced (one of Parkinson's large-size soda water bottles, which was nearly full of a muddy, dark-coloured liquid).

Jane Morton (Mr. Jotham's housekeeper) was the next witness. She said she remembered the last witness coming to Mr. Jotham's house on Sunday morning, December 31, between nine and ten, and stating that his mother was very ill—very low. Mr. Jotham was in bed; and she went upstairs to him, told him what the man said, and by his order she gave him a bottle of medicine.

The Coroner: Did you mix it?—No; it was ready mixed—it always is.

What, for anybody's complaint?—No; but for that complaint. Witness added that she got the medicine out of two bottles which were plainly labelled. She knew from Walker's description what his mother was suffering from, and that kind of medicine was wanted. Asked whether she was in the habit of mixing medicines, witness said Mr. Jotham always handed her a paper stating what medicine she was to "put up." She was not in the habit of mixing medicines. She knew, from conversations she had had with Mr. Jotham over dinner and at other times, that he had called occasionally to see deceased.

Further questioned by the Jury, she said in ordinary cases she "put up" the medicine, but in special cases Mr. Jotham did it himself. There was no entry made in any book of medicines supplied to club patients, neither had Mr. Jotham any report to make on the subject. Club patients should bring their own medicine bottles, and if they did not she put the medicine in any bottle she might have.

The Coroner: Does Mr. Jotham prescribe for a patient on the mere statement of anyone who comes to report a case to him?—He asks what is the matter, and if he isn't able to go he "puts up" the medicine.

The Coroner: Really. Well, I am astonished. I am very sorry for Mr. Jotham's patients if that is the case.

Mr. Gee: Do I understand if twenty patients come and say they have a cough, you give them all the same medicine?—Yes, if the complaint is the same. There are different bottles for different complaints. There are a whole row of large bottles for different complaints, and I feel quite competent to give out the medicine. He tells me what quantity to give out of the different bottles —in this case he told me "half and half"—out of two bottles.

Mr. Geo. Bland, surgeon, said he made a *post-mortem* examination of the body, and found deceased had been suffering from emphysema of the lungs and bronchitis, and that the valves of the heart were very much thickened. The stomach was healthy and contained about a pint of pale brown fluid. The other organs of the body were healthy. In his opinion death was caused by bronchitis, complicated by heart disease.

The Coroner: Is the medicine in that bottle the sort of medicine you would have given, having regard to the age of the woman and all the circumstances?—I do not know the contents of the bottle. It seems to be an ordinary cough mixture.

Mr. Lockitt: Do you think there was anything in the contents of the bottle to cause death?—Judging from what I have heard of the evidence, I should say the medicine had nothing to do with the death. She was dying when she took it.

Mr. Bullock: Is it your opinion she was neglected?—I can't say that.

The Jury eventually returned the following verdict:—"We are of opinion that deceased died from natural causes. We also agree that Mr. Jotham's conduct deserves severe censure for his gross carelessness in not attending to the deceased. We also believe that Mr. Jotham did not see deceased on December 22, as stated in his certificate."—*Macclesfield Courier.*

POISONING BY LAUDANUM.

Mr. J. Hewetson Brown, Coroner for the city of Carlisle, held an inquest, on Monday, touching the death of James Edwin Green, from a quantity of laudanum which he swallowed on Saturday night in the Victoria Hotel bar, Citadel Row. It appeared that the deceased, who had been a polisher and van-man, had been discharged from his situation about a month ago, a circumstance which is said to have preyed on his mind. On Saturday last he was in the bar of the Victoria Hotel, in Citadel Row, under the influence of drink. While there he borrowed an empty bottle from the barman, and sent a friend for twopennyworth of laudanum to the chemist's shop of Mr. Pattinson, in the Crescent. On the laudanum being brought the deceased poured it into a glass and drank it. After the lapse of some time medical help was obtained, but Green died about eleven o'clock. Evidence to the foregoing effect having been given,—

John Pattinson Little, assistant to Mr. Pattinson, chemist, of the Crescent, said he was not a qualified assistant chemist. The witness Scholes, whom he knew, came for twopennyworth of laudanum on Saturday afternoon. He supplied him with it and labelled the bottle "poison." He did not make inquiry as to whom and for what purpose Scholes wanted the drug. Laudanum was not one of the poisons registered under the Pharmacy Act, 1868. About half an hour afterwards he again saw Scholes, who said Green had taken the laudanum and they did not know what to do with him. He told Scholes to get a doctor as soon as possible and keep Green awake. He knew Green, and he was not in the habit of getting laudanum. He supplied Scholes with about half an ounce of laudanum. He was quite aware that it was sufficient to kill a man.

A Juror said he thought witness had acted carelessly.

Witness did not think so. Sometimes a pint at a time was sold.

The Juror: Yes, but to persons whom you know.

Witness: Well, I knew this man.

Medical evidence was given that death had resulted from an overdose of laudanum, and the Jury returned a verdict that "Death was caused by an overdose of laudanum taken in ignorance of its results or effects."—*Carlisle Journal.*

SUPPOSED DEATH THROUGH TAKING A PATENT MEDICINE.

An inquest was held at the County Court House, Stowmarket, on Friday, January 12, before A. F. Vulliamy, Esq., Coroner, touching the death of Sarah Scurrah. The nephew of the deceased said his aunt had complained of tightness of the chest, and on the evening of Tuesday, January 9, she was so much worse that he obtained medical advice. When Dr. Groome arrived he at once pronounced her to be dying. Some brandy and water was administered and other remedies applied, but in a few hours she expired. Deceased had frequently refused to allow him to send for a medical man. She took some patent medicine which she had by her the day before her death.

A nurse, called in to attend the deceased on Tuesday evening, said she was unconscious the whole of the time until her death.

Mr. Thomas Wilson, chemist, Stowmarket, supplied the nephew with some soothing medicine for the deceased, consisting of a mixture of bromide of potassium and aromatic spirits of ammonia. The bottle contained full directions as to how it should be taken.

Inspector Simkin produced two bottles of medicine, from both of which he had been informed the deceased had taken some.

Dr. W. W. Groome said he was called in to see the deceased on Tuesday evening. She was perfectly insensible. Her skin was cold, and her face was covered with sweat; the pupils of the eyes were contracted and insensible to light, the pulse was quick and feeble, and her breathing was rather noisy. Having been shown the medicine which she had taken he came to the conclusion that she was suffering from the effects of opium. The label of the bottle contained the words "Not to be taken by children," and from that fact he should say it contained opium or morphia. He was of opinion that she died from opium poisoning. In a person of her age a small dose might produce considerable effect.

The inquiry was adjourned in order that a *post-mortem* examination, and an analysis of the contents of the stomach and patent medicine, might be made.—*East Anglian Daily Times.*

Review.

A HANDBOOK OF CINCHONA CULTURE. By KAREL WESSEL VAN GORKOM, formerly Chief-Inspector of Cultures in the Netherlands East Indies. Translated by BENJAMIN DAYDON JACKSON, Secretary of the Linnean Society. London: Trübner and Co. 1882.

In this work of nearly three hundred pages the author has given the results of his experience in the cultivation of the cinchona plant in Java whilst acting as Director of the Dutch Government Cinchona plantations. The successful cultivation of the cinchona in Java was first attained under Heer van Gorkom's Directorship, during 1864 to 1875, for when he succeeded Junghuhn in 1864 the Java plantations were in a very languishing condition. Hasskarl's seedlings had been proved to be chiefly the inferior species of cinchona, *C. Pahudiana* (*C. ovata*), of which 531,456 were, at the end of 1863, under cultivation in the open ground, whilst the plantation only contained 7408 calisaya plants. But in 1864 the cultivation of *C. Pahudiana* was restricted, and special attention given to the more valuable species of *C. Calisaya*, and the success of the plantations was assured by the planting out in 1866 of 12,000 young Ledger plants that had been raised from seed obtained from Mr. Ledger in 1865. Since 1872 *C. Ledgeriana*, *C. officinalis* and *C. succirubra* have been exclusively propagated, with the result that in 1880 the plantations contained 498,000 Ledgeriana, 401,000 officinalis, and 278,000 succirubra plants.

The earlier chapters contain the history of the cinchona, its botanical description, an account of its introduction into Java, and of the species and varieties cultivated there. Under the head of Chemical Investigation we find a short account of the cinchona alkaloids, and the results of Moens' analyses of the three species under cultivation, whence it appears that in 1879—

	Total alkaloids. min.	max.	Quinine. min.	max.	Net weight of bark in ½ kilos.
Ledgeriana gave	6·1	8·1	6·0	7·0	7850
Officinalis ,,	5·3	6·8	1·2	4·6	3365
Succirubra ,,	6·0	8·0	0·6	0·9	25,201

It is to be regretted that in these analyses no details are given of the other alkaloids.

In 1878 Moens showed by an analysis of the outside scrapings or shavings of Ledgeriana, that the old method of the cascarilleros, which consisted in depriving the thick branches of their epidermis, was a costly operation, for in the samples of shavings he found 9·5 and 7·5 per cent. total alkaloid, containing 8·3 and 6·7 per cent. quinine respectively.

By the scraping process Moens and Scheffer ascertained that a kilogram of superior bark could be obtained annually from each tree; the author considers, moreover, that scraping might be done once or even many times with good results, but skill is required to prevent injury to the tree.

In Java, as it is now found in Ceylon, no variety of cinchona can be cultivated with better prospects of speedy and ample production than the succirubra; but the author is of opinion that so long as quinine is of primary importance, there can be no satisfaction in the exclusive cultivation of the succirubra.

The amount of alkaloids in the bark does not regularly increase with the age of the tree, and in normally developed trees, the maximum amount of alkaloids will be in trees from six to eight years old. The author does not regard the process of renewing under moss to be applicable to inferior kinds of cinchona; as is now well known, its effect on succirubra is to increase the yield of quinine and to decrease the cinchonidine, and on officinalis to suppress in most cases cinchonidine entirely.

In chapters IX. and X. are fully described the cultivation of cinchona, its propagation by seed, and the gathering and keeping of the seed; and in chapter XI., its artificial propagation by cuttings, with a description and full size illustration of Venleman's method of side grafting Ledgeriana on succirubra stems, which was first carried out in 1879. On this point we read, "For scions young twigs of Ledgeriana trees are taken, those with one joint are large enough, though as there are no reasons for extraordinary economy it is better to use tops of branches with two or three joints. The woody stem of a young succirubra plant serves as a stock, preferably a seedling, because cuttings usually possess a less developed root system. Succirubra stems as thick as a lead pencil offer sufficient surface; stronger stems may perhaps supply more nutriment to the scions, but it is an advantage on the other side that the diameter of stock and scion should agree, that the opposed barks may be united as completely as possible."

The best results are expected from this method, and it has the further advantage of requiring no propagating houses, and of being applicable after cropping an inferior cinchona plantation.

A detailed account is given as to the erection of propagating houses, laying out the beds and preparing the ground and nurseries, and as to the nature of the soil and the space between the plants.

With the exception of a species of beetle, *Bostrichus* or *Dermestris*, which attaches itself chiefly to the sickly and transplanted trees, and a yellowish-brown larva, the only serious plague is "cinchona rust," which seems to be allied to the "tea rust," and is due to *Helopeltis theivora.* Cutting out and burning the prunings is at present the only known remedy to this formidable pest. In the Malawar mountain ranges eight-tenths of an officinalis plantation was rendered worthless by the repeated attacks of the *Helopeltis.*

Interesting details are given as to harvesting the bark, regarding which it is stated that the planter loses by harvesting too early, for the amount of bark obtained in eight years would be doubled in the four succeeding years; also on stripping and drying and on sorting and packing the bark.

In chapter XXII., we read, with regard to the preparation of the quinetum in Bengal, "It appears a deplorable fact that the extraction from the bark is very incomplete, for one-half of the alkaloids go to waste. It appears from the report for 1879 that things are not more fortunate in Java. In the Chemical Laboratory at Weltevreden, from 3000 kilos of succirubra bark, which positively averaged 6 per cent. of alkaloids, there were not more than 56 kilos of quinetum made."

The subsequent chapters do not merit special notice; indeed, some of them might have been omitted with advantage, especially those on the artificial preparation of quinine and on the quinine alkaloids. In the former chapter we are informed that "it has even happened in Germany that an actual artificial fabrication of a cinchona alkaloid has been effected, but it possessed no polarizing power, therefore not identical with the natural production and decidedly differing in other properties," and in the other we are impressed with the belief that the chemical part of the subject has not been thoroughly grasped by the translator. To us, some parts are perplexing, but to the planter, who desires information on the chemistry of the cinchona alkaloids, we fear they would be sorely misleading. On page 215 we meet with "a new quina-basis," "chamæleon mineral," and on page 271 with "an alkaloid which is accumulated in the amorphous basis, and is probably fugitive." In several instances we should have preferred to have had the author's meaning given in equivalent English, rather than "as close a rendering of the original as possible and to run the risk of occasional awkwardness."

Enough has been said, we think, to show the value of Heer von Gorkom's work to cinchona planters, and to others interested in the cultivation of the cinchona plant.

Permanganate of Potash Pills.

Sir,—As these pills have formed the subject of a letter from Mr. Martindale, it might be of interest to some to know of another process. Before his letter appeared, we had occasion to make some of these pills, each containing 2 grains of the salt. The senior apprentice had them given him to do his best with, when, after some failures, he found they were easily made by rubbing the salt first with a little simple syrup, then adding about 2 grains of powdered sugar to each pill.

"THE MONTH."

At the instance of the United States Board of Health a comprehensive investigation has been carried out under the superintendence of Professor J. W. Mallet, with respect to the chief processes in use in the chemical analysis of drinking water, for the purpose of testing the absolute and relative accuracy of the results they are capable of yielding and as far as possible the nature and scope of the practical conclusions that can be drawn from them for sanitary purposes. From a preliminary report (*Nature*, Dec. 28, p. 211, and Jan. 4, p. 231) it appears that nine classes of waters were distributed amongst various chemists to be examined chemically, some using the combustion process, others the albumenoid-ammonia process and others the permanganate process. Class I. consisted of natural waters believed to be wholesome; Class II. of natural waters believed to have caused disease; Class III. of suspected waters; and the remaining six classes of waters intentionally contaminated in various ways. Biological experiments were also made with several of the waters. The report deals first with the degree of accuracy of the three processes, as shown by the amount of concordance in the results obtained by any process in repeated experiments on the same water, and in this respect, on the whole, the most concordant results were yielded by the permanganate process, and the least concordant by the combustion process, the albumenoid-ammonia process holding an intermediate position. As to the agreement of the results obtained with the quantities of organic constituents known to be present in a water, those obtained by the permanganate process were found to be much the least influenced by varying dilution, the combustion process indicating less organic carbon and more organic nitrogen when a weak solution was used, whilst with the albumenoid-ammonia process the weaker the solution the higher were the results obtained both for free and albumenoid ammonia. After stating some special conclusions as to each of the three processes, which can only be mentioned here, the Report passes to the chemical and biological results obtained as contrasted with the actual sanitary history of the natural waters examined. From an inspection of the tabulated results it appears that "no strongly marked generic difference is presented by the results from any of the processes for the estimation of organic matter or its elements between the generally wholesome waters of Class I. and the waters of Class II., which had been medically condemned, and were fairly assumed to be pernicious." It is pointed out, as telling against any chemical theory of the production of disease from this source, that if the whole of the organic carbon and nitrogen present in water of a highly dangerous water existed as strychnine, it would be necessary to drink half a gallon of the water to ingest an average medicinal dose of the alkaloid. But indirectly a larger amount of organic matter may be more dangerous, as furnishing more facilities for the multiplication of organisms. A more conspicuous difference between the waters of Class I. and Class II. was presented by the nitrates and nitrites, which whilst always present and often in large quantity in pernicious waters were either absent or only present in trifling quantity in the wholesome waters. It is suggested "whether the noxious character of water containing much nitrates and nitrites, themselves presumed to be harmless, and little organic matter which ought to be present in some form to support the 'previous contamination' view, may not be in reality due to the presence of a special nitrifying ferment, itself to be classed among the lower organisms capable of propagating disease." The biological experiments did not give satisfactory results, several of the waters believed to be wholesome, and which are largely used, being marked "suspicious," whilst not one of those believed to be pernicious was condemned. Professor Mallet concludes that it is not possible to decide as to the sanitary quality of a water by the mere use of a process for the estimation of organic matter or its constituents, and that there is no sound ground on which to establish such "standards of purity" as have been proposed, fixing the exact amounts of organic carbon or nitrogen, albumenoid ammonia, or oxygen of permanganate consumed, that shall be permissible

Sir William Thompson has delivered an extremely interesting discourse before the Glasgow Philosophical Society on "Approximative Photometric Measurements of Sun, Moon, Cloudy Sky, and Electric and other Artificial Lights." The lecturer pointed out that we have six senses, not five as is commonly made out, viz.:—Sense of force, sense of heat, sense of sound, sense of light, taste, and smell, a definition which was first given by Dr. Thomas Reid. Sir William shows from Pouillet's experiments on the radiant energy of the sun that the solar surface gives out radiant energy at the rate of 50 horse-power per square inch. A Swan incandescent lamp, when incandesced at 20 candles, is calculated to give out three-fourths of a horse-power per square inch. Hence the activity of the sun's radiation is about sixty-seven times greater than that of a Swan lamp per equal area, when incandesced to 240 candles per horse-power (*i.e.*, one Swan lamp at 20 candles requires one-twelfth of a horse-power). In remarking on the Carcel lamp and the standard candle, as photometric standards, the opinion was expressed that if as many precautions had been taken in elaborating the standard candle as have been taken in the use of the Carcel lamp, the standard candle would be as reliable as the lamp. Sir William further mentioned the interesting suggestion made by Violle of the use of molten platinum as a light standard. From Violle's experiments, communicated to the Paris Conference on Electrical Units by M. Dumas, Sir William considers that the tint of Violle's glowing platinum cannot be very different from that of the ordinary Swan lamp incandesced to its "twenty candles," and further that both as to tint and brightness it would appear that melted platinum at its "freezing" temperature is nearly the same as a carbon filament in vacuum incandesced to 240 candles per horse-power. For approximative photometric measurements, the author states that the "shadow method" of Rumford, when used with a reasonable amount of care, will give results within 2 or 3 per cent. of accuracy. The conclusions arrived at by the learned physicist as regards the luminous intensity of the moon's surface are very interesting reading. From his own experiments he concludes that the moon radiates something not enormously different from one-quarter of the light incident upon it. If about, say, one candle to every five square centimetres of surface was present on the moon, and the candles were all burning normally, the light received at the earth would be about the same in quantity, as estimated by our eyes, as it really is.

It would have very much the same tint and general appearance as an ordinary theatrical moon, except that it would be brightest at the rim and continually less bright from the rim to the centre of the circle, where the brightness would be least. The luminous intensity of a cloudy sky, about 10 a.m. one day, in York, during the meeting of the British Association, he found to be such that light from it through an aperture of one square inch area was equal to about one candle. An experiment on sunlight, made at one p.m. on December 8, at his house in the University, showed that the sun's surface as seen through the atmosphere at the time and place of observation was twenty-four times as bright as the Swan carbon when incandesced to 240 candles per horse-power. From the conditions of the experiment it followed that the intensity of the light from the sun's disc was equal to about 53,000 candles. This is more than three times the value found by Arago. "So much for a Glasgow December sun." Sir William considers that it cannot be very far wrong to estimate the light of the full moon anywhere on the earth as about one seventy-thousandth of the sunlight. A very full abstract of the lecture will be found in *Nature* of the 18th inst.

The now familiar cry of gas *versus* electricity has been the subject of a series of letters in the *Times* during the present month. The letters originated with a correspondent who, signing himself "Lux Pura," imagined he had detected large quantities of sulphuretted hydrogen in the gas supplied by the London companies, and gave a popular way of applying acetate of lead paper as a test for the presence of this noxious compound. The letter was full of crudities and a remarkable illustration of the proverb that "a little knowledge is a dangerous thing." Very able rejoinders have been made by Mr. H. Leicester Greville, of the Commercial Gas Company, and by Mr. G. Livesey, the well-known gas engineer, setting forth the true state of the law by which gas companies are bound to supply gas practically absolutely free from sulphuretted hydrogen.

At a recent meeting of the Newcastle-upon-Tyne Chemical Society an adaptation of the electric light for the illumination of microscopic objects, contrived by Mr. C. H. Stearns, was exhibited. It consists in the use of a Swan's incandescent lamp, which is calculated to give from one to three candle power, and is readily controlled by means of a small resistance coil of iron wire interposed in the circuit. Two or three Grove or Bunsen cells suffice as a source of electricity, or where the fumes would be objectionable a Leclanché battery may be employed, or better still an accumulator. The lamp may be readily fixed in any required position by means of a clamp; but in Mr. Stearns's microscope three lamps are permanently attached to and made a portion of the instrument, the body of the microscope forming one connection. One lamp is fitted above the stage; one below it, on the sub-stage; and one below the sub-stage, for polariscope work. Each lamp is connected with a three-way switch, so that the position of the light can be freely altered. At a recent meeting of the Obstetrical Society of London, also, Dr. Aveling exhibited a modification of Swan's incandescent lamp, so made that it could be introduced into cavities of the body for operative purposes.

According to the *Athenæum* of the 20th inst., Messrs. Mawson and Swan, of Newcastle-on-Tyne, have constructed a small accumulator, weighing five pounds, which is capable of supplying electricity for working one Swan lamp continually for two hours, and for a much longer time if the electricity is turned off when not required. This arrangement with Swan's lamp has been adopted with great advantage for the taking of microphotographs.

Mr. Octavius E. Coope has contributed a very valuable summary of his experience in electric incandescent and gas lighting at his mansion Berechurch Hall, three miles from Colchester. He adopted the Swan incandescent lamp and the Burgin machine, and the result of his experience is in every way decidedly in favour of electric lighting. One sentence from his letter is well worth reproducing here:—"The whole has been carried out as specified, and the result has been a success that has exceeded my expectations. The light is quite as easy to manage as gas, while the softness, the purity, and the agreeableness are such that a return to any other method of illumination would be now quite out of the question. The pictures, books, and decorations have no chance of injury; the ceilings and walls remain unsoiled, while the difference in health felt after sitting in a room electrically illuminated and another lighted by gas must be experienced before it can be appreciated." Very full details are given of the relative cost and maintenance of gas and electric light plant. This letter must be pronounced a most interesting and impartial statement of the question in this particular instance.

Electrical amateurs desirous of constructing a powerful plate electrical machine, at the moderate cost of a few shillings, should read the description of the Wimshurst "influence machine," given in the *English Mechanic* of the 12th inst.

According to a communication forwarded to Mr. Weldon by Messrs. Chance Brothers, the plant for treating about three hundred tons of vat waste per week by the Schaffner and Helbig sulphur recovery process, which consists in decomposing calcium sulphide with magnesium chloride (*Pharm. Journ.* [3], xii., 969), is nearly completed in their alkali works near Birmingham. Part of the plant is already at work, and it is said that the problem of the generation, storage and economical combustion of sulphuretted hydrogen thus derived from vat waste, and the construction of suitable apparatus for the purpose, may now be considered solved. At Messrs. Chance's works the sulphuretted hydrogen is stored in a gas-holder of 30,000 feet capacity, the outer water ring of which, in order to prevent any smell through an escape, is covered with a layer of dense mineral oil. At present the sulphuretted hydrogen passes from this gas-holder to a kiln, where it is burnt, the heat evolved being more than sufficient for a Glover's tower, through which the burnt gas, containing sulphurous oxide, is passed, and the conversion into sulphuric acid is uniformly effected with a very low consumption of nitre. In this way it is found practicable to recover from 90 to 95 per cent. of the sulphur from alkali waste as pure vitriol. The carbonic acid gas required for the decomposition of the calcium chloride bye-product, and for making its chlorine available for the reconversion of the magnesium oxide into magnesium chloride, is derived from a lime kiln, but probably it will also be possible to utilize flue gases.

In a communication to the Academy of Sciences (*Comptes Rendus*, xcv., 1363), M. Planchaud has contributed some further observations upon the conditions under which the reduction of sulphates is effected by "sulphuraria" and analogous algæ. He states that the introduction of 2 grams of chloroform into a flask containing these algæ, which had yielded sulphurous water weekly for a period of three months, stopped the action of the algæ for a month, after which, upon the evaporation of the chloroform, they resumed their activity. One gram of carbolic acid produced a similar result, but six grams stopped the action altogether by the killing the algæ. Another experiment consisted in enclosing some of the algæ between cakes of gypsum, the edges of which were luted. Upon separating the cakes some considerable time afterwards a few minute yellow points of crystallized sulphur were visible to the naked eye, due to the reducing action of the algæ, and M. Planchaud considers that this furnishes an explanation of the formation of the sulphur deposits which have been met with under the subsoil of Paris. He also considers that most of the natural deposits of metallic sulphides are attributable to the same origin.

Messrs. Gayon and Dupetit are continuing their investigation of the transformation of nitrates into nitrites under the influence of micro-organisms. They now describe (*Comptes Rendus*, xcv., 1365) four kinds of microbes, two requiring atmospheric oxygen for their development and two not, which are capable of removing two-thirds of the oxygen from alkaline nitrates. The most active of these, when sown in minute quantity in chicken broth containing 10 grams of potassium nitrate to the litre, multiplies rapidly at a temperature of 35° C. The liquid becomes turbid, but there is no evolution of gas, and under favourable conditions this kind of microbe has been found capable of reducing 9·6 grams of nitrate per litre per day. During the reduction some carbonic acid is formed, which is retained in the liquor in the form of potassium carbonate; but this does not represent all the oxygen derived from the decomposition of the nitrate. The least active of the four kinds decomposed 2·8 grams of nitrate per litre per day. Other organisms have been found to exercise this reducing action, and among them the microbe of chicken cholera, the splenic fever bacterium and the septic vibrion, but only to a comparatively limited extent.

M. Gayard describes (*Répertoire*, xi., 16) a method for the preparation of oxygen at the ordinary temperature by mixing potassium permanganate with strong nitric acid. Some nitrate of potash is formed, permanganic acid being set free and reduced. From this point oxygen is evolved with great regularity until two and half equivalents of the permanganic acid have been liberated, when the evolution stops suddenly. But if the vessel containing the mixture be plunged into boiling water, the oxygen from another half equivalent of acid can be obtained.

In a note on the use of asbestos filters for filtering liquids in chemical analysis (*Am. Journ. Pharm.* [4], xiii., 37), Mr. Cassamajor expresess a preference for the Australian kind, because the fibres being less flexible than in the Canadian or Italian they do not felt together and pack so closely on the perforated plate, and therefore allow the liquids to filter more rapidly. He recommends that the asbestos should be prepared for use by first rubbing it upon a coarse sieve (10 meshes to the inch), freeing what passes through from dirt by stirring it with water upon another smaller sieve (25 to the inch) until the water passes through clear, boiling the washed asbestos with strong hydrochloric acid for about half an hour, washing the pulp with distilled water on a perforated platinum plate placed in a funnel until quite free from acid, and then heating it strongly in a platinum dish. After cooling the asbestos should be preserved in a wide-mouthed stoppered bottle.

According to M. Féréol (*Practitioner*, Jan., p. 53), ammoniacal sulphate of copper is of great value in tic-douloureux and neuralgia of trigeminal origin. In almost all cases in which it was tried, it relieved the pain, sometimes instantaneously, and restored sleep to the patient after having been deprived of it for weeks. The usual dose was from 10 to 15 centigrammes, according to the susceptibility of the patient.

Drs. Ringer and Murrell have recently published a communication (*Lancet*, Jan. 6, p. 7) on the use of permanganate of potash in amenorrhœa. This salt is given in doses of one or two grains, beginning with one grain three times a day, increased to two grains four times a day, the desired result being usually obtained in three or four days after administration. It is said to succeed well after the failure of other remedies, such as iron, aloes, nux vomica, strychnia, pulsatilla, nitroglycerine and hot mustard baths. The fact that manganate of soda and binoxide of manganese were found to be "equally efficacious" would appear to indicate that the action is due to the manganese and not to the salt, in which case the use of the permanganate might be only a roundabout way of administration, especially when the necessary speedy reduction of this salt in the stomach is taken into account.

More than one writer to the *Lancet* (January 13, p. 86) calls attention to the fact that permanganate of potash forms a valuable injection for gonorrhœa, generally arresting the discharge in a fortnight. The strength recommended is half a grain to the ounce of distilled water.

In August last, M. Wecker directed attention to the fact that the seeds of the jéquirity plant, *Abrus precatorius*, used in the form of a lotion, were capable of producing artificially a purulent inflammation of the conjunctiva, which could be advantageously used in ocular therapeutics. The cause of this inflammation has been investigated by M. Silva Aranjo (*Comptes Rendus*, xcvi., p. 1204), who has submitted to microscopical examination the infusion and maceration of the seed and the exudation produced by their use. He finds that both preparations of the seed contain a great number of gonidia, which develop abundantly on the conjunctiva, and are probably the cause of the purulent condition which follows the use of the drug.

Dr. M. Carter (*Brit. Med. Journ.*, January 6, p. 9) calls attention to the successful treatment of tetanus with *Gelsemium sempervirens.* Although the suggestion of the probable utility of this remedy in such cases was made so long ago as 1875, the confirmatory evidence recently adduced shows the value of the investigation of the physiological action of drugs.

A correspondent of the *British Medical Journal* (Jan. 13, p. 90) states that he has found the application of a strong solution of chromic acid, three or four times, by means of a camel's-hair pencil, to be the most efficient and easy method of removing warts. The warts become black and ultimately fall off.

The operation of sponge-grafting seems to be coming into favour with surgeons. It is quite possible that the day is not far distant when sponge prepared for this purpose will be required at the hands of pharmacists. In the *British Medical Journal* (January 13, p. 51), Dr. P. W. Perkins Case describes its preparation as follows :—"Our method is to get the finest Turkey sponge free from grit, etc., and slice it as thin as possible, soak it in acid. nitro-hydrochloric. dil. for two or three weeks, till all the calcareous and silicious matters are dissolved, when after repeated washings with water, it has a very soft velvety feel; this, neutralized by washing with liquor ammoniæ and steeping in carbolic acid solution (1 tó 20) for twenty-four hours, is ready for use."

Dr. J. Whitson, in "Notes on the Treatment of Ulcers" (*Practitioner*, Jan., p. 20), remarks that the application of a specially prepared sand to granulating sores has been tried for some time with success, and that it possesses the advantage, since it absorbs the discharge, of seldom requiring removal, so that healing can proceed without interruption. This sand is prepared as follows :—It is first heated to a temperature capable of destroying all organic particles. It is then soaked in a solution of 1 part of bichloride of mercury in 1000 parts of water. After this the mixture is placed in bottles and can be used when required. This mode of treating ulcers is not new, the sandy earth of the termite ants having long been used for this purpose by the natives of the West Coast of Africa. This substance was some time since imported by Mr. Thos. Christy, under the name of 'termite earth," for trial in this country, but whether it possesses any antiseptic properties derived from the white ants is not known.

In the *Practitioner* (January, p. 17), Dr. Ringer states that an antagonism exists between veratrine and potassium salts as regards their physiological action. He was led to experiment in this direction by observing the fact that a saline solution containing lime caused the ventricle of the heart to dilate very slowly after each contraction, an effect produced also by veratrine, and that the presence of a small quantity of a potassium salt prevented this result. He finds that a small dose of potassium chloride will completely obviate this effect of veratria and restore normal contraction. If this view of the antagonistic action of calcium and potassium salts be confirmed, it will throw some light on the effects produced by certain mineral waters, and indicate the importance of a knowledge of the physiological action of even the commonest articles of food and medicine.

According to a recent communication to the Academy of Sciences from M. Bert (*Comptes Rendus*, xcv., 1253), inoculation with the slaver from the mouth of a mad dog, after filtration through plaster, does not reproduce the disease, but if the substance retained on the plaster be used hydrophobia is the result. He has also found that if the secretions which together form the slaver be separated they differ in their action. Thus inoculation with mucus from the respiratory passages of a mad dog will reproduce the disease; but if the secretion of the salivary glands alone be used it is inert in this respect, although it may cause death by setting up local suppuration. The saliva of a mad dog still possesses the property of converting starch into sugar.

M. Sanson has placed on record (*Comptes Rendus*, xcvi., p. 75) some experiments made upon the substance "avenine," isolated by him from oats, with a view to determine its effect upon the neuro-muscular excitability of horses. Avenine is a brown uncrystallizable substance found in the pericarp of the fruit and has the formula $C_{56}H_{24}NO_{18}$. The amount present in different varieties of oats is not uniform; the white sorts contain less than the dark, and the place of cultivation also influences the proportion present. Crushing the grain weakens the excitant property, so that whole grain is the most valuable for feeding purposes when work is required from the animals. Oats containing less than 0·9 per cent. of avenine cannot be relied on to give rise to the neuro-muscular excitability, which is produced with certainty when that proportion is exceeded. If the same effect is produced on human beings, the value of oatmeal porridge as a nutritious food where physical work is required is obviously not exaggerated. The wonderful properties as a nerve stimulant, attributed by Dr. Sell to oats, in the *New York Medical Gazette*, may be due to this active principle.

Lippia Mexicana, a Verbenaceous plant which has been recently recommended as a remedy in asthma and the cough of phthisis, has been submitted to a chemical examination by Dr. Podwissotzki, of Dorpat, who reports (*Ph. Zeit. f. Russl.*, xxi. 925) that he has separated from it a tannin, a crystallizable colouring substance belonging to the quercetin group of no medicinal importance, an oxygenated essential oil and a camphor. This camphor, which has been named "lippiol" and appears to be the principal representative of the medicinal activity of the plant, occurs in small quantity in the leaves, and as it readily volatilizes, it may be easily lost in transport or keeping. It melts between 25° and 30° C., and in composition corresponds to menthol. In the presence of the essential oil ("lippienol"), which occurs in larger quantity, the camphor mixes with water, forming a white emulsion-like mixture, having a bitterish taste. Dr. Podwissotzki considers his results indicate that the best pharmaceutical preparation would be a tincture of the fresh plant, prepared with alcohol strong enough to dissolve both the camphor and the oil, in the proportion of one part by weight of the flowers and leaves to nine of alcohol.

In a paper read before the Pennsylvania Pharmaceutical Association Meeting (*Pharmacist and Chemist*, January, p. 23), Mr. C. C. Klump gave the result of some experiments made upon the podophyllin resin of commerce with the view of ascertaining if the portion soluble in ether represents the active ingredient of the resin. He found that the portion of the resin insoluble in ether did not produce purgative effects, even when taken in the dose of 2 grains; while ½ of a grain of that soluble in ether proved purgative. One specimen examined by him contained 20 per cent. of resin insoluble in ether, and a specimen precipitated by alum yielded above 20 per cent.; while another, prepared according to the process of the U.S. Pharmacopœia, gave only ·6 per cent. The use of alum thus increases the product by 20 per cent. of insoluble resin above the amount of soluble resin yielded by the official process.

A new kind of vanilla has been described by M. Charbonnier (*Répertoire de Pharmacie*, Jan., p. 19. It is called in commerce Guadeloupe vanilla, and is the product of a plantation which was made in that island seven or eight years ago. The pods are compressed, not irregularly triangular like the Mexican, but approaching in aspect those of Bourbon and Java, from which it differs in having a darker colour. It is drier and does not so readily become covered with crystals of vanillin; the surface is striated longitudinally and has very few depressions. The perfume is peculiar and not so fine or so persistent as that of Bourbon vanilla, for which reason it is sold at about half the price. M. Charbonnier doubtfully suggests that it may be produced by a variety of *Vanilla planifolia*.

At this season of the year there are comparatively few medicinal plants in blossom. The coltsfoot (*Tussilago farfara*) has begun to open blossoms here and there; in warm sheltered districts in the South of England, *Daphne Laureola* may be found in flower, and *D. Mezereum* in flower is reported from the Isle of Wight.

In the Cambridge Botanical Gardens a fine shrub of *Hamamelis virginica* was, towards the beginning of the month, covered with its pale yellow starry blossoms; and in the conservatory a gigantic plant of *Aloe plicatilis*, said to be the largest in Great Britain, presented numerous opening spikes of flowers.

The return of coloured sepals to their original green hue is always a matter of interest, inasmuch as the circumstances which lead to the change are worthy of observation. This is more particularly the case when the flower has an abnormal structure like the Christmas rose, *Helleborus niger*, in which the petals are themselves green, and in which from the early period of flowering it is hardly probable that the flowers have been cross-fertilized with species having green sepals, such as *H. viridis* and *H. fœtidus*. Mr. Woolley Dod, writing in the *Gardeners' Chronicle* (January 6, p. 16), believes that the cause of the change is under, rather than above, the soil. From the fact that the same plant one year produces white and another year green flowers, and that the late flowers are more apt to be green than the early ones, it would seem as if a loss of vitality or want of nutrition were the cause. It is possible, however, that the sepals, being persistent, ultimately turn green, as asserted by some (*ibid*, Jan. 13, p. 57), owing to different chemical changes taking place after fertilization, and that when these take place at an early period the white colour more quickly gives place to the green. At all events the matter seems worthy of investigation from this point of view.

The *Gardeners' Chronicle* has lately given several papers from the pen of Dr. Plowright on heterœcismal fungi, a word applied to those leaf parasites which in one stage of their life history live on one plant, and at another stage derive their nourishment from a plant of a totally different natural order. As some of the host plants are used in medicine it may interest some of our readers to observe the fungi for themselves. *Rœstelia cancellata*, appears on the savine, as *Podisoma sabinæ*; and *R. lacerata*, which may be seen on the stems of the juniper in the form of yellow gelatinous linear projections, produces the *Rœstelia lacerata*, found on the leaves of the hawthorn. Two fungi found on wheat, *Uredo linearis* and *Puccinia graminis* exist in another stage on the berberry as *Œcidium Berberidis*; while the rust on oats, *Puccinia coronata*, occurs under another form on the buckthorn as *Œcidium Rhamni*.

It is generally supposed that the sunflower turns its face to the sun, but it is not so generally known that it rapidly returns to its original position soon after sunset. Mr. C. A. White, of Washington, remarks (*Nature*, January 11, p. 261), with regard to the wild variety of *Helianthus annuus*, L. (*H. lenticularis*, Douglas), that the flowers, which had taken the whole day to follow the sun from east to west, in one hour after sunset had already turned their faces to the east.

At a meeting of the Linnean Society on December 21, Mr. T. Cary read a paper on the development and mode of fertilization of *Asclepias Cornuti*. He pointed out that the petals and stamens, which are ultimately adnate, in the early stage originate separately, and that the broad filaments of the stamens form a fleshy pentagonal ring so as to be monadelphous. The stigmatic disc is not formed by the fusion of two stigmas, for the styles proper remain distinct through their entire extent. The pollen appears to exhibit an isolated and peculiar case of formation, approaching in one feature to that of *Naias* and *Zostera*.

Dr. Emerson Reynolds has recently recorded some interesting experiments made with a view to show how differently substances having the same elementary composition may act upon plants. He took sulphocyanate of ammonium and sulphurea, each of which contains two equivalents of nitrogen, four of hydrogen, one of carbon and one of sulphur, and found that the former acts as a poison to plants, while the latter stimulates the growth of the same kind of plants under like conditions and induces healthy development. This result evidently depends on the fact that the molecules of which the two bodies are composed are differently grouped.

M. Mangon has given (*Comptes Rendus*, xcvi., p. 80) the results of his investigation of the leaves of the ice plant, *Mesembryanthemum crystallinum*. The transparent vesicles, which cover the leaves like frozen dew-drops, contain a weak solution of common salt. The whole plant consists of a similar solution of alkaline salts retained in a state of solidity by vegetable tissue the weight of which does not exceed 2 per cent. of the entire mass. The ash, formed of salts of sodium and potassium, constitutes 43 per cent. of the weight of the dried plant. M. Mangon suggests that the capability of the plant to take up alkaline salts might be utilized in the removal of the excess which renders unproductive certain portions of the Mediterranean coast.

Mr. Becker (*Nature*, January 4, p. 231) has lately solved a riddle that has long puzzled travellers. In the white sand of the Ergent mountains, at Sarepta, (Asiatic Russia), curious stones are found which, when broken open, exhibit a brown kernel with a white spot in its centre. Some of these are of the size and shape of a hazel nut or walnut, others are cylindrical. Their surface is rough, and resembles a collection of drops, heaped upon and beside one another. Humboldt believed that they were recent formations. Zwick regarded them as very old. The formation of these stones is ascribed by Becker to the exudation of milky juice from roots of plants. *Euphorbia gerardiana*, *Tragopogon ruthenicus*, and *Scorzonera ensifolia* grow plentifully in the white chalky sand, and their long roots being inhabited and seamed by insects, the milky juice continually flows out and cements the soil around the roots. As the root gradually dies and disappears there remains in its place a white, often hollow, kernel, together with the brown colour derived from the root bark, the cylindrical stones being thus formed. The flat and target-shaped stones may originate from the milky juice running into the sand, since hardly any of them exhibited brown kernels.

According to an editorial notice in the *Journal of Botany*, it would appear that it is carried on at a monetary loss to the editor. This is somewhat of a reproach to the botanists of Great Britain, who it may be hoped will not allow one of the most valuable of botanical publications in the country to die out for lack of subscribers. The tendency in the present day for every natural history society to publish transactions of its own probably leads to the neglect of a journal which should receive notices of discoveries from every part of the country, seeing that it is intended to represent the progress of botany in Great Britain. The editor intends continuing the journal for another year at his own risk, and it is to be hoped the experiment may be a successful one, so that in the coming year he may not merely be able to cover his expenses, but find that the journal brings in a proper remuneration for the time and labour expended in editing it. The interesting "short notes" might form a very valuable feature in the journal if botanists in all branches of botanical science would record their observations, many of which too often are never allowed to see the light. The journal would then become more largely a British Journal of Botany.

At the drug sales this week *Cassia moschata* pods were offered. The false buchu leaves (*Empleurum serrulatum* and *Adenandra fragrans*) which have been put up for sale twice previously have not as yet met with a buyer. Morea galls and oval, smooth, not tuberculated Chinese galls were, among other rare drugs, exposed for sale. A singular kind of scammony, of soft, almost doughy consistence, was also noticed.

LIME JUICE: ITS PROPERTIES AND USES.*

BY MICHAEL CONROY, F.C.S.

Lime juice is the expressed juice of the fruit of *Citrus limetta*, a member of the orange tribe (Aurantiaceæ). The tree is a thorny bushy evergreen, with handsome dark foliage of exquisite fragrance. The flowers are white, resembling orange blossoms, and their perfume is equally delicious. The tree flourishes best in a light sandy soil near the sea, and comes into full bearing in about seven years after the seed is set. It grows wild in nearly all tropical countries, but is now largely cultivated in the island of Montserrat. The fruit is about one-half the size of the lemon, with a smoother and thinner rind, oval, rounded at the extremities, and of a pale yellow or greenish-yellow colour. The exterior of the rind possesses a fragrant odour, and a warm aromatic, slightly bitter taste, somewhat similar to that of the lemon. The juice, when fresh and sound, is sharply acid, with a peculiar refreshing and grateful flavour. In Montserrat the lime fruit harvest is heaviest from September to January, but a good supply of fruit is yielded throughout the whole year. Here, where the lime tree is specially cultivated for the sake of the juice, the work is done in a systematic manner with suitable machinery. The fruit, after collection, is taken to two central factories, where it is sliced by water power, and then squeezed in huge wooden presses, the juice being run into puncheons and quickly bunged up. This is a most important point in preparing the juice in a tropical climate, for if left exposed it would rapidly decompose. I am also informed that the choice fruit is alone used, and that only about two-thirds of the juice is pressed out, thus ensuring greater freedom from mucilaginous and pulpy matter. The further pressings, together with the juice of the unsound fruit, is evaporated to the consistence of treacle, and sent over to this country for the manufacture of citric acid.

It is chiefly owing to these precautions that Montserrat lime juice is so much superior to that produced in Jamaica and elsewhere, where no care or supervision is exercised in its preparation.

Lime juice contains citric acid, gum, sugar, albumen, extractive matter, inorganic salts and water. The most important constituent is the citric acid, but as to the percentage of citric acid contained in juice authorities disagree considerably. Upon this point, however, I am in a position to speak with great confidence, as during the last few years I have estimated the citricity of over 4000 samples of Montserrat juice, each sample representing a puncheon of over 100 gallons, and having been taken from the puncheon on the quay after landing. The citricity was estimated by the volumetric process with solution of caustic soda, made of such strength that 1000 grain measures represented 100 grains of citric acid.

By the kind permission of the sole consignees, Messrs. Evans, Sons and Co., Liverpool, I am enabled to place before you in a condensed form, the results of 4160 separate determinations obtained from the puncheons on the quay as above described.

The first table gives the average of each of twenty shipments, obtained by testing each sample separately, adding the whole together and dividing by the number of samples. The other two tables show twenty samples of high citricity and twenty samples of low citricity selected from the whole.

7·05	11·28
6·95	11·12

By adding up the first table and dividing by 20 (the number of the shipments) we get 7·84 per cent. as the average citricity of 4160 puncheons, equal to about 450,000 gallons.

Lime juice contains only a mere trace of sugar, while the quantity of gum and albumen is much less than that contained in lemon juice, on which account it is much less liable to fermentation and decomposition than the latter. The quantity of inorganic salts contained in lime juice is about the same and is also of the same nature as is obtained from lemon juice. The ash obtained from ten samples gave an average of 0·43 per cent. of the juice.

During the last decade lime juice has become a most popular temperance beverage, chiefly in the form of cordial, but its chief use is that of an anti-scorbutic on board ship, and while on this point I wish to draw your attention to the following extract taken from an excellent editorial, which appeared in the *Pharmaceutical Journal*, of June 3, 1871, and which contains two most important questions, that I trust will be answered in this paper. After treating of the prevalence of scurvy previous to the passing of the Merchant Shipping Act of 1867, the article says:—

"There can be no reasonable doubt that this system has succeeded remarkably well, as it has secured a proper supply of good juice to the mercantile marine, and scurvy has in consequence diminished from 60 to 70 per cent. But there are two unsettled and very important questions in connection with this subject which pharmacists should be specially able to aid in deciding. (1) The exact analytical standard of lime and lemon juice. (2) Does genuine lime and lemon juice require the addition of alcohol for its proper conservation?"

The first, so far as lime juice is concerned, I think is answered by the tables above quoted, and with the second we shall now deal. Some eighteen months ago, I mixed together over one hundred pint samples of lime juice, representing an entire consignment from Montserrat, and divided the bulk into two equal parts. One part was filtered perfectly bright and bottled off into wine bottles, while the other half was simply strained through muslin before bottling, no preservative whatever being added to either. The samples, on the date they were bottled, were tested for citricity and gave 8·15 per cent. free citric acid. They were then put away in a spare corner of the laboratory, exposed to light and occasionally to the direct rays of the sun for six months, when they were again examined (one from each group) with the following result:—

Filtered sample, 7·95 per cent. free citric acid.
Unfiltered sample, 8·15 per cent. "

At the end of twelve months from the date of bottling, another sample from each group was examined and was found to test exactly the same citricity as when last tried, namely 7·95 and 8·15 per cent. respectively. From this it will be seen that while the unfiltered sample retained its full citricity for twelve months, the filtered sample lost only 0·2 per cent.

This experiment, though put in hand for a different purpose, of which I will presently speak, answers the question as to whether alcohol is necessary for the preservation of lime juice, and when I state that in addition to the above test the juice was as sweet and sound as when first bottled, it will be admitted that the only answer is—No.

With lemon juice, however, the answer is the reverse, and I shall go further and show you that the quantity of spirit added by the Board of Trade regulations is insufficient and useless for its preservation. Lemon juice, owing to the fact that it contains much more sugar and mucilage than lime juice, is more liable to fermentation, and in commerce it is always, or nearly always, found in a state of fermentation, and in this state it is passed by the Somerset House authorities, and sent into bond to be fortified and bottled for the Merchant Marine Service. In bond 15 *per cent. of proof spirit* is added to it, and this is expected not only to kill the fermentive germs, but to preserve it from further deterioration. As practical chemists and pharmacists I need scarcely tell you that to obtain the desired result double the quantity should be used. What percentage of alcohol do we add to our freshly pressed juices of dandelion, hemlock, broom, foxglove, henbane, etc.? Twenty-five per cent. at 56 over proof, which is equal to 39 per cent. at proof strength, and this quantity we only consider sufficient for the proper conservation of freshly pressed juices, quite free from fermentation. I have frequently seen bottles of lemon juice bursting in bond during hot summer weather, an hour or two after bottling, from the pressure of carbonic acid gas produced by the fermentation, and frequently cases have to be unpacked to replace bottles that have burst from the same cause, *in bond*. From this it is evident that lemon juice requires to be more strongly fortified, and my experience is that fully 30 per cent. of proof spirit, or better still, its equivalent of a stronger spirit, would be necessary.

I said that the experiment with the filtered and the unfiltered lime juice, to which I have already alluded, was put in hand for a different purpose than that of ascertaining whether or not the addition of alcohol was necessary for its preservation. The object in view was to ascertain whether the clarification of the juice was in any way detrimental to its keeping properties, and I was led to try the experiment by observing that clarified juice sooner became darker in colour, and sooner lost its fresh aroma than the unclarified, and the result showed that my suspicions were correct, though to a less extent than expected, for as already stated the clarified sample lost only 0·2 per cent. in citricity, while the unclarified sample remained intact at the end of twelve months. Why is this? To answer the question it is necessary to remember that in pressing lime or lemon juice many of the essential oil vessels of the rind are ruptured, and the oil thus escaping becomes to a considerable extent emulsified by the mucilage and sugar of the juice, thus acting as an antiseptic preservative to the juice.

It is chiefly owing to the presence of essential oil, thus emulsified, that the turbid appearance of fresh lime and lemon juice is due, and to my mind it is quite a mistake to insist upon juice being quite clear for ship use, since the filtration necessary to attain this would separate almost the whole of the essential oil, the presence of which adds so much to its keeping properties.

As already mentioned the chief use of lime juice is as a preventive and remedy for scurvy, and in the Royal Navy, only lime juice is used, with the gratifying result that the once dreadful disease is practically unknown. In the Merchant Marine Service, however, lemon juice is chiefly used, owing to its cheapness, and here cases of scurvy are frequently occurring. It is not, in my opinion, because lemon juice is inferior to lime juice as an antiscorbutic that this result is due, but simply to the fact that it soon becomes inert and useless by fermentation, as already shown.

Lime juice has become a therapeutic agent of so much importance since the publication of our present Pharmacopœia that its introduction into the next issue is almost a certainty, and in anticipation of such a result I would recommend that the test for citricity be fixed at not less than 7·25 per cent. of free citric acid.

DETERMINATION OF BORACIC ACID.*

BY EDGAR F. SMITH.

When a solution of manganese sulphate is added to one of borax, and to this mixture an equal volume of alcohol, there separates rapidly a white flocculent precipitate of manganese borate, MnB_4O_7, insoluble in the alcoholic liquid. The excess of manganese sulphate remains in solution, and can readily be determined in the filtrate from the borate after the expulsion of the alcohol. To ascertain whether the above might be available quantitatively, the following solutions of definite strength were prepared and the experiments recorded.

1. A solution of manganese sulphate, made by dissolving 3 grams of anhydrous $MnSO_4$ in 250 c.c. H_2O. 10 c.c. of this solution would then correspond to ·0600 gram $MnSO_4$.

2. Potassium permanganate solution of such strength that 18·5 c.c. were equivalent to 10 c.c. of I or 1 c.c. $KMnO_4$ = ·00324 gram $MnSO_4$.

3. Borax solution: 10 grams well-crystallized borax dissolved in 1 litre of H_2O.

The manner of conducting each experiment was as follows: To 10 c.c. of the borax solution were added 10 c.c. $MnSO_4$ solution and an equal volume of strong alcohol. The whole was well mixed, allowed to stand, carefully covered for one half hour, when the manganese borate was filtered rapidly (best with a suction pump) and washed well with alcohol. The filtrate and washings were placed in a platinum or porcelain dish and evaporated to dryness on a water-bath. The residual manganese was then determined according to Volhard's* method, by dissolving it in water, adding zinc sulphate, then heating to almost boiling, and carefully running in potassium permanganate until the liquid assumed a pink colour. The quantity of manganese sulphate thus found and deducted from the whole amount of the salt added, gave a difference representing the manganese sulphate which had combined with the borax. After calculating the amount of manganous oxide to which the sulphate, found by difference, is equivalent, the following equations were employed:—

MnO : $2B_2O_3$ am't MnO : corresponding am't B_2O_3 (x); and

Orig. sub. 10 c.c. borax solution : x :: 100 : y (per cent. B_2O_3 in 10 c.c. of the borax solution).

Experiments.

The calculated percentage of B_2O_3 in borax is 36·60, and from the experimental results it will be observed that the method can be successfully applied in the analysis of soluble borates.

In estimating the boracic acid in insoluble borates, as tourmaline, the following course was pursued. The finely pulverized substance was fused with a weighed quantity of pure sodium carbonate, the fused mass exhausted with water, and to the filtrate containing all the sodium borate, together with some sodium silicate and aluminate, was added an amount of pure ammonium sulphate molecularly equivalent to the sodium carbonate. The solution was then digested until all the ammonia was expelled and the volume of the liquid largely reduced. Any silicic acid or aluminium hydrate which had separated was now filtered off, and the precipitate thoroughly washed with hot water. The solution, again reduced in volume and containing only the borate and sulphate of sodium and excess of ammonium sulphate, was mixed with a definite amount of a manganese sulphate solution (strength previously determined), alcohol added, and after standing one half hour the borate was removed by filtration, the filtrate evaporated to dryness, and the residue carefully ignited to expel the ammonium salt. The manganese sulphate left was dissolved in water, and the same procedure as indicated in the preceding experiments was carried out.

The Pharmaceutical Journal.

SATURDAY, JANUARY 27, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

THE DIGITALIN GROUP OF REMEDIES.

ANY one who has paid attention to recent literature relating to proposed new therapeutic agents must have been struck with the number of substances that have been recommended as possessing properties resembling those to which digitalis owes its value in the treatment of cardiac disease. These substances, however, while possessing points of resemblance in their physiological action, are derived from plants belonging to orders widely separated botanically, and differ considerably in their general chemical properties, although most of them have this character in common that they contain no nitrogen and are not acids. Indeed it is a remarkable fact that most of the extremely poisonous non-nitrogenous pharmacological agents derived from the vegetable kingdom belong either to the digitalin or the picrotoxin group; moreover, several members of the digitalin group yield decomposition products which in their action resemble picrotoxin. Whilst the action of some of these substances, and especially of digitalin, has now been fairly well studied, others have only been very imperfectly investigated, and it may be that valuable remedial agents are consequently in danger of relapsing into oblivion through the natural indisposition of medical practitioners to abandon a tried agent for the purpose of experimenting with others concernimg which little is known. Good service has, therefore, been rendered by Dr. SCHMIEDEBERG, to whom we owe much of our present knowledge of the active principles of digitalis, in contributing to the *Archiv für experimentelle Pathologie und Pharmakologie* an exhaustive and systematically arranged *résumé* of what is known concerning the group of powerful substances of which digitalin may be considered to be more or less the representative. Much of the information collected belongs strictly to the department of "pharmacology," as defined by Professor FRASER to be the "science of the action of remedies," and therefore need not be enlarged upon in these columns; but, besides this, there is information that may be classed under "pharmacognosy," to which reference may with advantage be made.

Dr. SCHMIEDEBERG enumerates fourteen substances as belonging to the digitalin group, and these he divides into four classes. Class I. consists of crystallizable glucosides, and includes digitalin, antiarin, helleborein, euonymin and thevetin. Class II. consists of non-glucosidal substances, not all crystallizable, and includes digitoxin, strophantin and apocynin. Class III. consists of non-crystalline glucosides, very slightly soluble in water: these are scillain, adonidin and oleandrin. Class IV. consists of amorphous glucosides, freely soluble in water and resembling saponin, and includes digitalein, apocynein and convallamarin. It may be mentioned with respect to the foregoing list that Dr. SCHMIEDEBERG has separated a glucoside that he has provisionally named "neriin," which appears to be probably identical with digitalein, from the *Nerium Oleander*, where it is accompanied by the less active glucoside which he has named "oleandrin." The "apocynin" and "apocynein" are the active constituents of the root of *Apocynum cannabinum.* A few other substances are mentioned, among which the most important are erythrophleine, the alkaloid of sassy bark, and neriodorin and neriodorein, the two glucosides separated by Mr. H. G. GREENISH from *Nerium odorum*, the latter two, it is thought possible, may upon closer investigation prove to be identical with oleandrin and digitalein (neriin).

As previously remarked the physiological action of the whole of these substances has not yet been thoroughly worked out, but enough is known to warrant their being classed together in one pharmacological group; for so far as has been at present ascertained they present no important difference in their action, beyond what consists in the different amount of effect produced by doses of equal weight, and their variations as to solubility in water and capability of absorption. Taking the action upon frogs' hearts as the starting-point for fresh investigations upon the digitalin group, Dr. SCHMIEDEBERG states the symptoms that all the members of the group are capable of producing, which may be briefly summarized as follows:—Augmentation of the volume of the pulse, under increase of the diastolic phase, and without any change in the absolute working power of the heart; irregular, "peristaltic" movements of the heart; systolic pause of the ventricle; and, finally, complete paralysis of the heart.

Dr. SCHMIEDEBERG raises the question whether when, as is usually the case, galenical preparations of digitalis are used, only the three constitutents known to belong to the digitalin group—digitalin, digitalein, and digitoxin—come into play, or whether other substances contained in the plant and in the official preparations exercise any influence; because, besides these three substances, there are other constituents, such as digitonin, digitaliresin and toxiresin, which belong to the picrotoxin group, the last two being decomposition products that are met with in the dried plant and may be formed in the intestinal canal through the splitting up of digitalin, digitalein and digitoxin. It is thought probable that digitonin is present in too small quantity to be of therapeutic importance, but that digitaliresin and toxiresin may sometimes exercise a disturbing influence. Moreover, the three principal constituents of digitalis,—digitalin, digitalein and digitoxin,—are themselves absorbed with difficulty and slowly eliminated, and to this is due the so-called "cumulative action" which has been observed in connection with this drug, and which is believed to have led to an unusual number of fatalities.

In consideration of these facts in connection with the digitalin group, Dr. Schmiedeberg is of opinion that in the interest of therapeutics and for the avoidance of great danger from too powerful action, it is of especial importance to use a chemically pure substance, which without producing local disturbance when injected subcutaneously, is readily absorbed, and through which, therefore, any desired degree of action could be maintained for a long time. Of the substances previously mentioned as belonging to the digitalin group he considers that in this respect the first places must be accorded to antiarin and thevetin, the former derived from the milky juice of the upas tree (*Antiaris toxicaria*), and the latter from the seed of the *Thevetia nereifolia*. Antiarin is not met with in commerce, and would be probably difficult to obtain, but thevetin might be more easily available. Of the digitalis constituents digitoxin would be excluded on account of its insolubility in water, which renders its absorption so irregular that the same dose on one occasion will produce little effect and on another will prove too powerful. Digitalin and digitalein are very difficult to prepare in a pure condition and would therefore be too costly. A similar remark applies to scillain, from the bulb of *Urginea scilla*, and adonidin, from *Adonis vernalis*, which are present in their respective plants in only very small proportions. Whether the material for the preparation of euonymin, which occurs in small quantity in the resin bearing the same name from *Euonymus atropurpureus*, or strophantin, from *Strophantus hispidus*, could be obtained at a moderate cost, and whether the preparation of these substances could be easily carried out, would have to be ascertained. But in the opinion of Dr. Schmiedeberg the whole of the four last-named substances would be particularly well suited for internal use. According to experiments helleborein would appear to be more easily absorbed and also more easily eliminated than the majority of the substances of the group; in fact, so rapidly does this absorption and elimination go on, that when administered internally in such doses as produce a strong effect when administered subcutaneously it is quickly dispersed, and all but a small portion passes out of the system without producing any therapeutic effect. Convallamarin and apocynein rank, together with digitalein, in regard to their properties, near to helleborein, but hardly come within consideration, because on account of their amorphous character they are probably not so readily absorbed as helleborein.

There remain only oleandrin and apocynin to be mentioned, the former occurring abundantly in the oleander, which is widely distributed throughout the entire Mediterranean district, and the latter in the North American "Indian hemp" (*Apocynum cannabinum*). Both of these substances can be prepared sufficiently pure without special difficulty, the apocynin even more readily than the oleandrin, because it is not accompanied by decomposition products so troublesome to separate. On account of their comparative insolubility these two substances are suitable only for internal use. In respect to their characters they agree essentially with one another, but they give different decomposition products. Oleandrin is a glucoside, splitting up when heated with dilute acids into sugar and "oleandresin," possessing an action similar to digitalresin; on the other hand apocynin, under the same treatment, passes into an inactive substance. Whether this difference will be of any consequence in the treatment of disease requires to be ascertained by experiment, when the relative capability of absorption of the two substances should also be studied.

The Junior Pharmacy Ball, held on Wednesday evening last at Willis's Rooms, passed off with great success, as many as 370 persons having been present. A telegram from Mr. M. Carteighe was read, regretting that through being engaged in attending a meeting of the Board of Examiners in Edinburgh he was unable to be present. In his absence the toasts of "The Royal Family," and "Success to the Junior Chemists' Ball," were proposed by Professor Attfield.

* * *

The Medical Union Society, which has been established with the object of furnishing "a means of intercommunication and organization" for students and junior members of the medical profession, will hold its first annual meeting and *soirée* in the Holborn Town Hall, on Wednesday next, the 31st inst. At 8 o'clock Dr. B. W. Richardson will deliver an address to students of medicine, after which there will be a vocal and instrumental concert.

* * *

At the meeting of the Chemical Society on Thursday next, February 1, a paper is to be read on "Some Derivatives of Fluorene," by Messrs. Hodgkinson and Matthews. There will also be a ballot for the election of Fellows.

* * *

On the same evening, at 8 p.m., a meeting of the School of Pharmacy Students' Association will be held, when some "Dispensing Notes" will be read by Mr. W. Johnston. A report upon "Secondary Batteries," illustrated by experiments, will be made by the Reporter on Physics, Mr. H. Allen, B.Sc.

* * *

A meeting of the Chemists' Assistants' Association will be held at University Chambers, 53, Conduit Street, on Wednesday evening, January 31, at 8.30 p.m., when a paper will be read by Mr. F. H. Alcock, "On Glycerine and its Application to Pharmacy."

The Annual Dinner of this Association is fixed to take place at the Holborn Restaurant, on Wednesday, February 14. Mr. M. Carteighe is to preside.

* * *

A series of six lectures on "Solid and Liquid Illuminating Agents," by Mr. Leopold Field, will be commenced in the Lecture Room of the Society of Arts on Monday next, the 29th inst. The lectures will constitute the second course of "Cantor Lectures" for the present session.

* * *

At the last meeting of the Newcastle-upon-Tyne Chemical Society it was decided by 52 votes out of 65 that the Society should be amalgamated with the Society of Chemical Industry, and a Committee was entrusted with the arrangement of matters of detail.

* * *

According to a note received from our esteemed correspondent, Dr. J. E. De Vrij, the International Colonial and Export Trade Exhibition which is to commence next May in Amsterdam promises to be very rich in subjects of interest to pharmacists. Dr. De Vrij suggests that intending visitors would do well to fix their head-quarters at Harlem, where they would be within a dozen miles' railway ride of the capital and conveniently situated for visiting the Colonial Museum in the town. Any way, as the demand for accommodation in Amsterdam will probably be excessive, it will be as well, if it be intended to stop in the city, to secure apartments beforehand.

* * *

An American contemporary, after referring to the International Pharmaceutical Exhibition to be held in Vienna this year, expresses an opinion that it might be desirable that it should be followed by another to be held in New York or Philadelphia in 1884 or 1885.

* * *

A lively sensation appears to have been produced in Paris, by a statement that some of the sulphate of quinine supplied to the French hospitals contains as much as 43 per cent. of cinchonine. *L'Union Pharmaceutique*, commenting upon the subject, appears to throw the blame upon the system which allows the public service to be supplied with foreign quinine by contractors who are incapable of detecting a fraudulent substitution if they wished to do so.

* * *

In an article on the deleterious effect of "cram," as carried on in elementary schools, the *Lancet* quotes statistics from various large towns in Scotland to show that there has been an increase in the mortality among children of five years old up to youths of twenty in the ten years during which the Education Act has been in operation as compared with the ten years immediately previous. In Aberdeen it has risen from 7·5 per cent. to 9·2 per cent.; in Edinburgh from 6·5 per cent. to 7·5 per cent.; in Glasgow from 5·5 per cent. to 7·25 per cent.; and in Dundee from 5 per cent. to 8·5 per cent.

* * *

The list of students in the Philadelphia College of Pharmacy for the Sixty-second Annual Session, 1882-83, shows that there are 254 "matriculants" in the "Junior Class" and 191 in the Senior Class.

* * *

The Municipal Council of the city of Paris, at a recent sitting, adopted a proposition to institute for the convenience of the public a night pharmaceutical service, upon the model of the night medical service, and a vote of 3000 francs has been inserted in the municipal budget to cover the expenses.

* * *

There are now in the United States two journals devoted to pharmacy printed in the German language. The *Deutsch-Amerikanische Apotheker-Zeitung* is published in New York twice a month and is now in the third year of its existence. The *Pharmaceutische Rundschau und Zeitung* has made its first bow with the opening of the present year. It also is published in New York; it is to appear monthly, and is to be edited by Dr. F. Hoffmann.

* * *

On the other hand two of the multitudinous United States journals printed in English,—the *Weekly Drug News* and the *American Pharmacist*,—having changed hands and become the property of one person, are henceforth to be consolidated. One of the "features" of the new journal, as stated in the opening number, is to be the printing of the papers read at the evening meetings of the Pharmaceutical Society of Great Britain, together with the consequent discussions. It may be mentioned that in carrying out this arrangement nearly twenty columns, out of thirty-nine which constitute the first number, have evidently been quoted from this Journal; but apparently the programme does not yet include an acknowledgment of the source.

* * *

The *St. Louis Druggist*, referring to Mr. Holmes's paper on "Spurious and Worthless Drugs," and "the excitement existing in pharmaceutical circles in England" upon the subject, congratulates its fellow citizens upon the better protection they enjoy from the importation of rubbish from without, but laments the damage done from within through the disposal by the Government of old medical stores, including tinctures and pills bought during the civil war nearly twenty years ago.

* * *

The same journal, in quoting the first instalment of Mr. Proctor's address on "Atoms and Molecules," introduces it as the production of "Professor Barnum S. Proctor."

* * *

Specialism in medicine is now to be extended to the medical journals. The *Monthly Journal of Medicine and Pharmacy*, a Philadelphia journal which for some time past has claimed to be devoted especially to quinological subjects, has undergone a change of title, and is henceforth to be called, "*The Quinologist.*"

* * *

On the recommendation contained in a report presented to the Paris Society of Pharmacy by M. Gérard, the prize for the competitive theses presented by pupils in the Paris School of Pharmacy last session has been awarded to M. Guinochet, for a treatise on the "Aconitates," in which he describes at least twenty new salts of aconitic acid.

* * *

The name of Mr. John Babtie, Pharmaceutical Chemist and Provost of Dumbarton, has been added to the Commission of the Peace for the County of Dumbarton on the recommendation of the Lord-Lieutenant of Dumbartonshire.

* * *

Information has been received of the death on the 5th inst. of Mr. John Barker, who was elected an Annuitant on the Benevolent Fund in 1880.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held on Monday, January 22, 1883, the undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Aplin, John Henry .... Chard.
Bowell, Horace James Whitney. Ilfracombe.
Churchouse, Charles Herbert... Chard.
Hoare, Austin .... Ilfracombe.

Certificates of the University of Cambridge.

Painter, Frederick Hubert ...... London.
Wilson, Robert John .... Chesterfield.

Certificate of the University of Oxford.

Fryer, Charles John .... Warwick.

The report of the College of Preceptors on the examination held on January 2nd was received.

Three hundred and thirty-one candidates had presented themselves for examination, of whom *one hundred and thirty-seven* had failed. The following *one hundred and ninety-four* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

Abram, Fred. Wm. Joseph...... Wisbech.
Ainley, Edward Theodore ...... Mirfield.
Alexander, Charles Angus ...... Glasgow.
Allen, William Henry Arthur... Norwich.
Allen, Willie .... Basingstoke.
Almack, Edward Ambrose ...... Bedale.
Ames, William Ralph .... Bath.
Asten, Walter .... Birmingham.
Atkins, Frederick John .... Royston.
Badcock, Hy. John Francis ... Sheerness.
Bainton, Arthur .... Manchester.
Baker, William Herbert .... Cosham.
Ball, George .... Manchester.
Ball, John Arthur .... Nottingham.
Bamford, Thomas .... Aberavon.
Barnes, George Arthur .... Heckington.
Barr, Bryce .... Largs.
Bindloss, George Warren ...... London.
Blakelock, John William......... Edinburgh.
Bland, Arthur Whitsed .... Walsall.
Blankley, George William ...... Arnold.
Blewett, William Thomas ...... Penzance.
Bostock, John .... Wilderspool.
Branch, Alfred Ernest............ Colchester.
Branson, Preston James .... Plympton.
Brearley, Wentworth James L. Farnworth.
Brislee, William Henry .... Liverpool.
Broad, Henry Reynolds .... Kidderminster.
Brown, Robert Wells .... Glasgow.
Buck, Edward Thomas .... Goole.
Butterworth, Robt. H. Smethurst Blackpool.
Cadman, Ernest S. Radford ... Horsley Woodhouse.
Casewell, Job Parry.............. Market Drayton.
Castell, Guy John Edward ...... Daventry.
Chantry, John Henry .... Horncastle.
Charlesworth, H. Hodgkinson... Tunstall.
Clarke, James .... Liverpool.
Clarke, Joseph .... Birmingham.
Clements, Robert James......... Kingsbridge.
Clough, Thomas .... Liverpool.
Coates, Robert .... Pickering.
Coleman, Joseph .... Birkdale.
Cooper, John....................... Castletown.
Cruickshank, Gavin Lang ...... Aberdeen.
Cumber, Edwin Guille............ Guernsey.
Dakers, John Israel.............. Newcastle-on-Tyne.
Darby, William .... Spalding.
Davies, Colin Campbell .... Llandyssil.
Davies, Henry .... Dowlais.
Davies, Oliver .... Pontypridd.
Davies, Roger Edward............ Corwen.
Dawson, Edwin, jun. .... Stamford.
Dick, David Laing .... Falkirk.
Dodgson, Fred Henry .... London.
Donach, James..................... Moffat.
Douglas, William Boyce .... Torquay.
Duggleby, Albert Waldby .... Lowthorpe.
Elmitt, William .... Lincoln.
Emmons, Charles.................. Kidsgrove.
Enderby, John Edward .... Spalding.
England, Reginald Arthur...... London.
Escritt, Harold Teal .... Driffield.
Evans, Abdiel Charles............ Ewell.
Evans, Frederic Ernest .... Lymm.
Everett, Walter John .... London.
Eyre, William Robert............ Ashbourne.
Fairburn, Henry .... Hutton Bonville.
Fanshaw, William John......... Wolverhampton.
Fardell, Ernest Matthew .... Leicester.
Featherstone, Robert Horne ... Derby.
Field, Ebenezer .... Cambridge.
Fraser, John Sutherland......... Forres.
Freeman, John..................... London.
Fuller, George Sydney............ Thornton Heath.
Gage, Leonard Charles .... Basingstoke.
Garner, David .... Garston.
Gatehouse, William .... London.
Green, Herbert..................... Hucknall Torkard.
Griffiths, Henry Thomas......... St. Clears.
Gwynne, Samuel .... Leek.
Hacon, Elizabeth Constance ... London.
Haden, Thomas Henry .... Barnsley.
Hague, John James............... Ashton-under-Lyne.
Haigh, Walter .... Halifax.
Hall, Allen Joseph .... Coventry.
Hall, John........................... Aberdeen.
Harris, Herbert .... Kirton Lindsey.
Harard, Henry Lewis .... Penclawdd.
Harvey, James .... Flintham
Hays, Frederick Arthur .... Birmingham.
Hayton, William Pattinson ... Wigton.
Heading, Charles .... Downham.
Hector, Alexander B. .... Aberdeen.
Henderson, Henry Alfred .... Wibsey.
Higson, Joseph .... Blackburn.
Hill, Blair .... Edinburgh.
Hodge, John George .... Galashiels.
Holbeche, Harry .... Stottesden.
Holt, Herbert Collins .... Bowdon.
Horne, George Herbert .... Scarborough.
Horne, John Kay.................. Accrington.
Horne, Joseph .... Aberdeen.
Hughes, John Alfred .... Holywell.
Huntley, Joseph .... Cirencester.
Hutchinson, Edgar .... Newark.
Jackson, Albert Ernest .... Ipswich.
Jackson, Ben Leslie.............. Longton.
Jackson, Oliver Lincoln .... Blackpool.
Johnstone, Edward Straus ...... Whaley Bridge.
Jones, David John .... Cefn Coed.
Jones, Frederick .... Coalville.
Jones, William Owen .... Market Drayton.
Jones, William Rowland. .... Hay.
Kay, Charles William .... Leeds.
King, Alexander William .... Ayr.
Kingston, Percy John .... London.
Kingston, William Richard ... London.
Knowles, Louis..................... Leicester.
Laughlin, Alfred William .... Ramsey, I.M.
Laurence, John, jun. .... Glasgow.
Lavery, Charles .... Dumbarton.

Laycock, James ....Bradford,
Litchfield, John Henry ....Ashford.
Lovegrove, Wallis Sheffield......Crawley.
Low, Alexander Taylor .... Alva.
McCorquodale, John Campbell...Dumbarton.
McDonald, James....................Dundee.
Macleod, Lewis.......................Inverness.
McMaster, Thomas ....Stranraer.
Mason, Joseph Edwin ....Bexley Heath.
Mate, Richard Arnold..............Crewe.
Mather, James Smith ....Arbroath.
Maxwell, John ....Roxburgh.
Morris, Ernest William . ...Market Harborough.
Morris, James Kneeshaw ......Scarborough.
Muddell, Claude ....Southend-on-Sea.
Munns, Henry Ernest.............Birmingham.
Murfet, Edward ....King's Lynn.
Naylor, Edward Alfred ....Scarborough.
Norton, Edward Thomas..........Stow-on-the-Wold.
Nursaw, Francis Theakston ...York.
Parsons, Alfred George ....Exeter.
Parton, John Henry ....London.
Perkins, Frank ....Newcastle-under-Lyme.
Perrett, Samuel ....Bridgwater.
Phillips, Arthur Sydney ....Mitcheldean.
Pick, Alfred ....Chester-le-Street.
Pierce, Michael........................Croydon.
Price, Charles John ....Devizes.
Pridham, Charles Clifford ....Bath.
Rawlinson, William Bright ....Harwich.
Rees, Joseph ....Brynamman.
Renshaw, Frank ....Rochdale.
Reynolds, Philip ....Spalding.
Rippon, Richard Waller ....Leamington.
Robinson, Raymond..................London.
Robson, Thomas ....Hartlepool.
Rossiter, Percy Alex. ....London.
Russell, John ....Broughty Ferry.
Ryott, Harry William ....Gilesgate Moor.
Saunders, Edmund Thomas ...Newport Pagnell.
Sayers, William Charles..........London.
Selle, Louis Sherwood ....Hull.
Shenston, Robert ....Kenton.
Sinclair, Matilda Anne ....Llandudno.
Smith, Henry ....Durham.
Smith, Robert ....Earlestown.
Smith, Walter Woodhouse.......Doncaster.
Stevenson, George Shields C....Portobello.
Strachan, John.........................Aberdeen.
Stuart, William ....Preston.
Sykes, John ....Southport,
Tabor, Thomas Slade ....London.
Taylor, Edward ....Weymouth.
Thom, James ....Edinburgh.
Thompson, James Ebenezer ...Hexham.
Tod, James A. ....Edinburgh.
Tomlinson, Charles Parker.......Peterborough.
Toone, Edwards Roberts..........Bath.
Trickey, Alexander Leslie ....London.
Wain, Charles Oliver ....Bolton.
Watt, Arthur ....Edinburgh.
Weatherston, Francis B...........Peebles.
West, Cecil ....Retford.
Wheatcroft, Hoyland ....Rotherham.
Wheen, Harold.........................Bridlington Quay.
Whitbread, Howard..................Loughborough.
Wilcock, Fred Anderton..........Bradford.
Wilkinson, Frank.....................Nottingham.
Williams, Chalmers ....Carmarthen.
Wilson, William Potter .... Haddington.
Wood, John William ....Darlington.
Wride, William Blake ....Shirley.
Young, Edward ....Sudbury.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Exam-ined.	Passed.	Failed.		Candidates. Exam-ined.	Passed.	Failed.
Aberdeen	10	5	5	Inverness	2	2	0
Birmingham	19	12	7	Lancaster	2	1	1
Brighton	2	0	2	Leeds	22	16	6
Bristol	7	6	1	Lincoln	6	5	1
Cambridge	5	2	3	Liverpool	16	11	5
Canterbury	2	1	1	London	40	24	16
Cardiff	14	6	8	Manchester	25	15	10
Carlisle	4	1	3	Newcastle-on-T.	7	4	3
Carmarthen	8	4	4	Northampton	3	3	0
Carnarvon	6	1	5	Norwich	6	2	4
Cheltenham	1	1	0	Nottingham	16	12	4
Darlington	6	4	2	Oxford	1	1	0
Douglas	3	2	1	Peterborough	9	7	2
Dundee	3	3	0	Sheffield	8	4	4
Edinburgh	19	12	7	Shrewsbury	5	3	2
Exeter	11	6	5	Southampton	5	4	1
Glasgow	14	10	4	Truro	2	1	1
Guernsey	3	1	2	Worcester	3	1	2
Hull	8	5	3	York	8	6	2

The questions for examination were as follows:—

Time allowed: Three Hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Cæsari quum id nuntiatum esset, maturat ab urbe proficisci. (ii.) Omnis civitas Helvetia in quatuor pagos divisa est. (iii.) His responsis ad Cæsarem relatis, iterum ad eum Cæsar legatos cum his mandatis mittit. (iv.) Septimo die, quum iter non intermitteret, ad exploratoribus certior factus est, Ariovisti copias a nostris millibus passuum iv. et xx. abesse. (v.) Hæc eodem tempore Cæsari mandata referebantur, et legati ab Æduis et a Treviris veniebant: Ædui questum, quod Harudes, qui nuper in Galliam transportati essent, fines eorum popularentur; sese ne obsidibus quidem datis pacem Ariovisti redimere potuisse: Treviri autem, pagos centum Suevorum ad ripas Rheni consedisse, qui Rhenum transire conarentur: his præesse Nasuam et Cimberium fratres.

2. Parse fully:—"Omnis civitas Helvetia in quatuor pagos divisa est."

3. In extract (v.) account for the mood of *transportati essent* and *potuisse*, and for the case of *obsidibus* and *his*.

4. Translate into Latin:—(i.) There remained one way by which they could go out. (ii.) He set out from the camp with three legions. (iii.) There is no doubt that you have acted very ill. (iv.) Having heard these things, he led his army to the banks of the river.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. A person buys a tub of butter, weighing 3 qrs. 16 lbs., for £4 2*s.* 6*d.*; the weight of the tub is 10 lbs.; how much does the butter cost him per lb.?

2. What sum must be added to

$$2\tfrac{1}{3}+\frac{3\frac{1}{3}-\frac{1}{6}}{3\frac{1}{3}+\frac{1}{6}}-2\tfrac{5}{7} \text{ of } \tfrac{4}{19}$$

that the sum may be equal to 3?

3. From 37 take ·37 and ·037, add the two results together, and divide the sum by 370.

4. If $3\frac{1}{2}$ sacks of 3 bushels each cost 31*s.* 6*d.*, find the cost of $10\frac{1}{2}$ sacks of $2\frac{1}{2}$ bushels each.

5. At what rate per cent. will the interest on £600 amount to £70 in 2 years 4 months?

III. ENGLISH.

1. Define an *abstract noun*; and form abstract nouns from the following words:—*steal, just, good, know, consider.*

2. There are adverbs of time, place, manner, and degree. Mention one of each, and expand the one you

give into (i.) an adverbial clause, (ii.) an adverbial sentence.

3. Parse fully the following sentence:—

"Pause a while,
And let my counsel sway you in this case."

4. Write a short composition on one of the following subjects:—

(i.) Christmas-tide.
(ii.) Illustrated Newspapers.
(iii.) Letter-writing.
(iv.) The recent Campaign in Egypt.

NORTH BRITISH BRANCH.

EVENING MEETING.

The third evening meeting of the session was held in the Society's rooms, 119A, George Street, Edinburgh, on Wednesday evening, January 17, at 9 o'clock.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the former meeting having been read and confirmed,

The Secretary to the Branch intimated the following donations to the library:—

Journal of the Chemical Society, five parts to complete volumes.
From the Pharmaceutical Society.

Canadian Pharmaceutical Journal, two parts completing volume for 1882.
From the Ontario College of Pharmacy.

'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference,' 1882.
From the Committee of Publication.

For these donations a vote of thanks was moved by the President, and cordially responded to by the meeting.

Mr. William Gilmour then read a paper entitled "Notes on the New Edition of the United States Pharmacopœia."

In the introductory remarks he referred to the constitution of the Committee of Revision as being the best calculated to produce a thoroughly practical work, since a large number of the members were practical pharmacists. He spoke of the duties assigned to the committee and the mode in which they had conducted their labours, and then proceeded to comment upon the Pharmacopœia itself. Some remarks were made on the omission of fluid measure, and the adoption of decimal parts by weight for solids and liquids, so that the use of metric or troy weights, according to the taste of the pharmacist, was practical. Under this heading the influence of the change on the strength of various preparations was brought out, and the exceptions to the rule instanced; in the case of pills, for example, where the quantities in troy and metric weights are given in parallel columns, the product in both cases being for a definite number of pills. In speaking of fluid extracts he referred to the concise yet full directions given regarding the degree of comminution required for the drug used; the choice of a menstruum best calculated to ensure exhaustion according to the nature of the drug, and the various circumstances modifying the percolation process. Regarding the articles of materia medica, additions and omissions were noted, and the concise designation given to each article by adopting the name of the species only, thus leaving out the generic name as well as the name of the part used. It was here remarked that a plentiful adoption of synonyms served to remove any doubt which might arise regarding any given drug. He then referred to the chemical portion of the Pharmacopœia, on which he will treat in a second paper.

The President, in moving a vote of thanks to Mr. Gilmour, said that he was not in a position to remark on the subject, not having read the new Pharmacopœia; he hoped, however, that when Mr. Gilmour brought forward his second paper, he would have an opportunity of discussing the matter.

Mr. Stephenson said that he was sure the meeting was much indebted to Mr. Gilmour for having brought this subject under their notice, and he cordially acquiesced in the President's motion. He had had an opportunity of glancing through the work, but as his acquaintance with it was only that of a few hours, he could not venture to speak of it in a detailed way. He had been anxious chiefly to see how far it corresponded with or diverged from the British Pharmacopœia, and the first difference he noted was the substitution of weight for measure (except to a very limited extent) and the adoption of decimal parts in all the formulæ. The advantages as well as the disadvantages of this change were obvious, but the latter might have been greatly lessened by having specific weights alongside the decimal parts. Then he observed that the minim admitted as the unit of measure for physicians in prescribing differed from ours. He did not know if this minim was introduced for the first time. If it was surely it would have been well to adopt ours, as the basis of it was quite arbitrary. Then the pulv. aromaticus was our P. cinnam. co., but with the addition of nutmeg, not a judicious one, he thought. Another important variation was in tinct. opii, which was ordered as *one* of powdered opium to ten (10) of product. He noted the entire absence of the juices of herbs, whether as succi or for the preparation of extracts, although there was a general formula for tinctures from fresh herbs. Percolation was almost uniformly enjoined, and it was puzzling to find that tinct. myrrh was made an exception. The directions for conducting the process were very elaborate and did not appear to make much allowance for the intelligence of the pharmacist. One of these details he took objection to, viz., the passing the menstruum through the substance until a measured quantity of product is obtained instead of pressing the marc, and making up the required measure afterwards, and so avoiding waste of spirit. He also referred to the preparation of resin of scammony from the gum resin instead of from the root as a wasteful process. He pointed out that in the fluid extracts spirit of different strengths was the solvent, that they were indeed concentrated tinctures while our own were more like concentrated infusions, spirit being only added as a preservative. He had noted also the entire absence of the geographical sources of all articles of vegetable and animal origin. He concluded by referring to the very copious tables of thermometric equivalents, solubilities, saturating powers, etc., which were appended to the work, but while admitting their value he thought it was open to question whether a national pharmacopœia was exactly the place for them.

Mr. J. R. Young said that he had pleasure in listening to Mr. Gilmour's paper, and to Mr. Stephenson's remarks on the new Pharmacopœia of their American brethren. Probably Mr. Gilmour would be able in his next paper to reply to Mr. Stephenson's criticism. He remarked that probably the best pharmacists are those of the United States, and although they may differ considerably from us, we must not suppose that all these differences are bad. He had often admired their way of dealing with galenical preparations, more especially their tinctures and the like. He was struck with the remark of Mr. Gilmour's that the methods of preparing the different alkaloids were omitted; probably this was due to the fact that there were many eminent chemists in the United States, and an assumption thereby that pharmacists did not require to prepare such articles as alkaloids.

The President remarked that he had observed the reason for the omission of directions for the preparation of aconitine was the varying nature of that body, some commercial specimens being 170 stronger than others; they, therefore, tend to adhere more closely to galenical preparations of the strong drugs, which he thought was a very wise tendency.

A paper was then read by Mr. Peter MacEwan, Secretary to the Branch, on—

Pungent Liniment of Iodine.

Some time ago, I had given to me for examination a few drachms of liniment of iodine, which emitted a pungent and irritating vapour when applied to the skin, the vapour smarting and inflaming the eyes very painfully. Complaints have frequently been made of this liniment, owing to its incomplete absorption by the cuticle and the subsequent volatilization of the iodine, which may in some circumstances cause irritation; but in the case which I cite, the vapour was distinct from that of iodine, and suggested that the liniment had undergone decomposition. Old specimens of the official liniment do not differ materially in odour from that of the preparation when freshly made, so that it would appear that the difference shown in the specimen under examination was due to some objectionable modification of the official formula.

From the well-known fact that methylated spirit is used in the preparation of certain liniments, it was natural to presume that the pungent liniment may have been prepared with it. One drachm of this liniment was, therefore, decolorized with potash solution and distilled. The distillate, subjected to Miller's process for detecting the methyl base, gave a faint mirror with nitrate of silver. Subsequent applications of the test, however, showed it to be untrustworthy. A quantity of the liniment was therefore prepared with methylated spirit for comparison with the specimen given to me. This, at the time of preparation differed but slightly from the official liniment, the naphtha odour being partially masked, but in three weeks it became pungent and in every way similar to the objectionable specimen.

In the course of several experiments, directed to ascertain the ingredients of the liniment influencing the decomposition, it was observed that when a small quantity of pure liniment was carefully dropped on a little water contained in a porcelain dish, a flocculent substance separated and floated on the surface, assuming in a few seconds a crystalline appearance. Under the microscope this was seen to be made up of colourless fan-shaped crystals. This particular form of crystal is not given by alcoholic solution of camphor or of iodine. The crystals are probably an iodated camphor, and are of interest here, from the fact that the pungent liniment does not yield them, but an oily like fluid which floats on the surface for a few minutes, afterwards sinking and adhering to the bottom of the dish. This fluid possessed in a high degree the pungency of the liniment. As a careful microscopic examination of the oily fluid and the water surrounding it showed entire absence of crystals, it was assumed that the camphor had in some way influenced the development of pungency. In corroboration of this supposition a quantity of methylated liniment was prepared without camphor, and in this no pungency has been developed in a period corresponding to that in which the liniment containing camphor became pungent.

It is well known that wood spirit, used to methylate pure spirit, contains several bodies as impurities which undergo slow decomposition in presence of any foreign matter. This fact suggested that it is these impurities and not the methyl alcohol which are decomposed in presence of camphor and iodine. To prove this a quantity of the liniment was prepared with rectified spirit to which 10 per cent. of pure methyl alcohol had been added, and no pungency has been developed in the preparation.

I have not, meanwhile, directed any experiments to determine the constitution of the pungent oily compound, as this paper is merely intended to show that methylated spirit is not a fit substitute for rectified spirit in the preparation of liniment of iodine. I may, however, remark that allyl alcohol is one of the impurities of wood spirit and the pungent and irritating nature of the iodo-allyl compounds would indicate the formation of some such body under the conditions already stated. This, however, I hope to ascertain in future experiment with allyl alcohol and the other bodies constituting the impurities referred to.

The President said that the meeting was much indebted to the Secretary for his interesting paper, and he had much pleasure in moving a vote of thanks to him. He did not think that the use of methylated spirit was at all common, particularly in the preparation of iodine liniment.

Mr. Gilmour seconded the motion, and remarked that he had his attention called to the subject some time ago when a specimen of iodine liniment, such as had been described, was shown to him; the pungency reminded him very much of essential oil of mustard. The paper now read recalled the matter to him, and he thought from what he had himself observed that the cause of the pungency was very probably what had been hinted at, namely, allyl alcohol. He did not think that anyone with a reputation to lose would think of preparing his iodine liniment with methylated spirit, knowing the exceedingly annoying odour which was developed in it.

Mr. J. R. Hill said that the paper was of special interest to him for it explained a circumstance which had lately come under his observation. A person had applied for a preparation of iodine to be used for a dog, and he had been unable to satisfy the person even with the pharmacopœial liniment, which was alleged not to be strong enough. This person gave him a small quantity of a preparation supplied by a veterinary surgeon, and which was comparatively weak in iodine, but had an extremely pungent odour, from which the person had judged its strength. This odour was at first thought to be due to oil of mustard, and a careful examination showed the presence of methylated spirit; Mr. McEwan's experience corroborated his own conjecture on this point. He thought that the suggestion made about the crystals referred to in this paper being an iodo-camphor compound was very probable. Similar crystals were given when an alcoholic solution of bromo-camphor was mixed with water, and the likeness exhibited by halogen compounds generally favoured this supposition. He threw out the suggestion that iodo-camphor is first formed in methylated liniment, and the subsequent action of this on allyl alcohol produces this pungency.

Presentation of a Bust of the late Mr. H. C. Baildon.

After the reading of the papers the attention of the meeting was called to a bust of the late Mr. H. C. Baildon, presented by his son, Mr. H. B. Baildon.

The President, in accepting the gift in the name of the Council of the Branch, said that all who had known the late Mr. Baildon knew how thoroughly he had identified himself with the Branch, and how he had interested himself regarding all matters affecting its welfare. As a President of the Branch he had been greatly esteemed by the members, and his cultured mind and gentlemanly bearing lent a dignity to all matters he took part in. It pleased him highly to think that the son of their late friend showed by the gift his interest in the Branch and his attachment of pharmacy, and he had much pleasure in moving a cordial vote of thanks to him, and expressed the gratification which the Council had in placing such a fitting memorial of their late co-worker beside those of others who had in their lifetime been true friends of the North British Branch.

Mr. Young, in seconding this motion, said that he did so with feelings of pleasure and regret, for he had been intimately acquainted with the late Mr. Baildon, and the striking likeness presented by the bust recalled to him many happy meetings. Although Mr. Baildon was of English birth and training, he had spent the greater part of his life in Scotland, and though he was an English gentleman to the last, he was sure that no one had had the interests of Scotch pharmacy more at heart than he had. It pleased him very much to see so fitting a memorial presented to the Branch, and he felt himself indebted to the donor for the handsome gift.

Messrs. Ainslie and Stephenson having made a few remarks, Mr. H. B. Baildon, replied. In the course of his remarks he said that he hoped he would be enabled to merit in some measure the esteem and respect which had been accorded to his father, and he could assure those present that he appreciated the honour which was conferred upon his father in the placing of a memorial of him within the rooms of the Branch.

Before the meeting separated, the members had an opportunity of examining a collection of specimens of new drugs, exhibited by Messrs. Thomas Christy and Co., London, and which had remained in the rooms after their exhibition before the Assistants' Association.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The seventh general meeting of the above Association was held at the Royal Institution on Thursday, January 18. The chair was occupied by the President, Mr. Joseph Woodcock.

The minutes of the last two meetings were read and confirmed, and the following donations announced:— The 'Pharmacopœa Germanica,' 1882, and the 'United States Pharmacopœia,' 1882, from Messrs. Evans, Sons and Co.; the 'Year Book of Pharmacy' from the members of the Pharmaceutical Conference; the *Pharmaceutical Journal* from the Society, and the *Canadian Pharmaceutical Journal* from the Editor.

The President, in proposing a vote of thanks to the donors, alluded particularly to the liberality of Messrs. Evans, Sons and Co., in presenting the new Pharmacopœias, which few had as yet been able to obtain.

The President then called upon Mr. Conroy to read his paper, entitled—

Lime Juice: its Properties and Uses.

Dr. Symes, in proposing a vote of thanks, said the Association was much indebted to Mr. Conroy for his interesting and practical paper. Practical papers were always valuable, but this one was particularly so, as probably no one had had more experience in testing lime juice than Mr. Conroy. He would like to know if the size of the limes named by Mr. Conroy was peculiar to Montserrat, as he had seen some limes which were about twice the size of ordinary lemons. He would also like to know whether Mr. Conroy had found lime juice to vary in citricity according to the season of the year. Lemons in summer time scarcely contained any citric acid, whereas in the winter they held about as much as limes. Regarding the preservation of lime and lemon juice, he believed that the former was certainly more readily preserved than the latter. About twenty years ago he had published in the *Pharmaceutical Journal* the results of some investigations which he had made in connection with this subject, and he then found that by clarifying the lemon juice, heating for about ten minutes at a temperature of 150° Fahr., and then corking quickly and sealing over with beeswax, the juice would keep well for many months without the addition of any alcohol. If heated over the temperature named the juice was apt to become brown. Juice thus bottled in the winter, when the citricity was at the highest, was available in the summer time for effervescing drinks, when lemons contained hardly any citric acid. Dr. Symes, while admitting the beneficial results of using lime juice on board ships as a preventive of and cure for scurvy, thought that the decrease of that dread disease was also due in some measure to the fact that in the naval service, and to some extent in the merchant service also, it was now felt that, if the sailors were to be kept healthy, they must have food supplied to them which contained in larger proportions the constituents of vegetable juices and such principles as creatine and creatinine, found in meat juice. Compressed vegetables, tinned meats and fruits were now more frequently served out to the men. In reference to the respective therapeutic properties of lime and lemon juice, he did not think that the larger number of cases of scurvy in the merchant service was altogether due to the inferior qualities of the lemon juice as compared with lime juice, but because on the vessels of the Royal Navy the men were bound to take the juice which was handed to them, whereas in the merchant service, when given, out it was frequently used by the men for washing the decks instead of being taken.

Mr. A. C. Abraham, in seconding the vote of thanks, asked whether the bottles used in the experiments were full or otherwise, as he found from experience that if lemon juice were bottled quickly after pressing, and before it had time to absorb any germs from the air, it would keep for a considerable length of time in an unimpaired condition. In reference to the fortifying of the juice in bond, he had always understood that rum was ordered by the Board of Trade, and not simply proof spirit. Rum contained a certain quantity of essential oil or ethereal compounds, which no doubt would have considerable preservative power; but that, of course, was a question which would hardly be thought of when the law was drawn up, and the authorities might not have considered the difference between rum and proof spirit of any importance.

Mr. A. H. Mason, said that the paper which had been read was one of peculiar value, as he did not think that in any previous investigations the large number of four thousand experiments had been made to prove the case. Regarding the samples upon which Mr. Conroy based his remarks, he would like to know if Mr. Conroy had tested the filtrate from the clarified samples in order to ascertain the amount of citricity left behind. It occurred to him that the idea of the essential oil of the limes having a tendency to preserve the juice, owing to its emulsification, was a very ingenious one, and was no doubt correct.

Mr. A. H. Samuel wanted to know whether Mr. Conroy had tested samples of lime juice other than Montserrat, as he thought it would be interesting to know how the citricity compared with the samples Mr. Conroy had spoken of. There was such an extraordinary difference of opinion among the different authorities as to citricity that he thought the observations of Mr. Conroy would be very valuable, as they formed a standard which would satisfy everybody as to the relative values of lime juice which was used in the merchant shipping service or otherwise.

Mr. Conroy, in reply, thanked the meeting for the very kind manner in which his paper had been received, and also for the vote of thanks which had been passed. In reference to the remarks of Dr. Symes, he said that he had only seen limes that were grown in Montserrat, and the description he had given was chiefly obtained from Risso and Poiteau's excellent work. The tables supplied were taken from analyses made in both summer and winter, and in his opinion the citricity did not vary much with the seasons, provided the fruit was collected at the proper time and not allowed to become too ripe. He had read Dr. Symes's paper on the preservation of lemon juice, but was of opinion that the therapeutic value of the juice was injured by the application of heat. Although agreeing with Dr. Symes that the nature of food supplied to sailors was of very great importance, it must not be forgotten that in the late British Polar expedition every attention was given to this point; still, because the lime juice was neglected, scurvy broke out to a most serious extent. In reply to Mr. A. C. Abraham, Mr. Conroy said that no special precautions were taken in filling the bottles, and they were not quite full. The Board of Trade only demanded that palatable spirit should be used, and though rum was generally used, any other spirit would be allowed, if good. Replying to Mr. Mason, he found that the filtration did not affect the citricity at the time, and in reference to Mr. Samuel's query, Mr. Conroy said that he had examined many other kinds of lime juice, but found that although the best of them ran very close in respect to citricity to the Montserrat juice, they were inferior in quality, and frequently contained salt and other impurities. He did not think that salt or salt water was always fraudulently added, but was of opinion that its presence was often due to the use of sea water in washing casks and other vessels.

The vote of thanks having been passed, the proceedings terminated.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The twelfth annual soirée in connection with this Association took place in the Town Hall, on Monday evening last, and was very largely attended. On the present occasion, the scientific exhibition which has usually formed a feature of these réunions, was dispensed with. The hall, however, was very tastefully decorated with mirrors, curtains, and various kinds of furniture for the recesses beneath the great gallery and orchestra, and floral decorations in the shape of plants, evergreens, palms, etc. The proceedings commenced at eight o'clock with a promenade concert. Dancing commenced at nine o'clock.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual dinner of the above Association was held on Wednesday evening last, at the George Hotel, when upwards of sixty chemists and druggists and their friends sat down.

The chair was occupied by the President (Mr. Councillor Fitzhugh), and the vice-chair by the Vice-President (Mr. Robert Jackson).

Amongst the visitors present were Mr. Councillor Lees and Mr. Councillor Gibson, of Manchester. The latter, in proposing the toast of the evening, viz., "Success to the Nottingham and Notts Chemists' Association," referred in eulogistic terms to the manner in which it was carried on, and expressed approval of the principles upon which it was founded. The Honorary Secretary (Mr. C. W. Warriner) briefly responded.

The other toasts given were "The Pharmaceutical Society," by Mr. Parker, responded to by Mr. Fitzhugh (Local Secretary); "The Town and Trade of Nottingham," by Mr. C. W. Bolton, responded to by Mr. I. H. Haywood; "The Officers and Council," by Mr. Beilby, responded to by the Vice-President; "The Visitors," by the President, responded to by Mr. Councillor Lees and Mr. George; "The Chairman," "Vice-Chairman," and "The Ladies."

Mr. Holgate again introduced to the notice of those present the claims of the Pharmaceutical Benevolent Fund, when the sum of five guineas was collected in the room.

During the evening the meeting was enlivened by songs and duets by Messrs. Castings, Pickerill, C. Taylor, and T. Selby, Mr. W. T. Cockrem ably acting as accompanyist. Donations were also announced from Messrs. Storey, Witty and Co., Oldfield, Pattinson and Co., Mr. Gibson, Mr. Mason, and Mr. Osbourne.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Wednesday, January 17, a lecture was delivered at the rooms of the above, No. 4, Halford Street, by Mr. J. Garrett on "Mercury" (analytical). The subject was well handled; the tests for the mercuric salts first, and those for the mercurous salts were brought before the audience in an instructive and interesting light, Mr. Garrett thoroughly working out the subject before be brought his lecture to a close.

Mr. E. Brien proposed and Mr. Vultz seconded a vote of thanks, which was heartily accorded to the lecturer.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, January 18, Dr. Gilbert, President, in the chair.

The President announced that the following distinguished chemists would be proposed for election, at the next meeting of the Society, as Foreign Members:—Beilstein, Cléve, Debray, Erlenmeyer, Fittig, Helmholtz, Mendeljeff, Lothar Meyer, Victor Meyer. A ballot for the election of ordinary Fellows will also be held at the next meeting (February 1).

The following certificates were read for the first time: A. C. Abraham, E. Bevan, C. N. Betts, F. J. Cox, A. Collenette, S. Dyson, W. T. Elliott, H. B. Fulton, C. G. Greenfell, B. F. Halford, D. Hooper, W. D. Hogg, H. F. Lowe, T. H. Leeming, J. E. Marsh, W. Newton, C. Rumble, F. Scudder, F. Watts, C. S. S. Webster.

Dr. Roscoe then communicated the substance of a paper entitled—

The Fluorine Compounds of Uranium. By A. Smithells.—Since the preparation of uranium oxyfluoride by Berzelius the above compounds have been investigated by Carrington Bolton, and more recently by Ditte; as the results obtained by these two chemists do not agree, the present experiments were undertaken to clear up the question. The green uranoso-uranic oxide U_3O_8, when acted upon by aqueous hydrofluoric acid, gives a voluminous green powder and a clear bright yellow solution. According to Bolton this green powder is UF_4, whilst the yellow solution furnishes on evaporation UO_2F_2. Ditte assigns to the green powder the formula UO_2F_2, and to the substance in the yellow solution the composition UF_6+8HF; he also represents the reaction thus: $U_3O_8+18HF=2(UF_62HF)+UO_2F_2+6H_2O+H_2$. The author endeavoured to collect the 2·6 litres of hydrogen which should be, according to Ditte, evolved from 100 grams of U_3O_8, but found that none came off. He finds that Ditte is also in error as regards the composition of the other bodies, which are, as Bolton stated, UF_4 and UO_2F_2 respectively. When UF_4 is heated in a closed crucible a white sublimate is formed; if, after five minutes, the crucible is allowed to cool, and the sublimate removed, a fresh sublimate is again formed on reheating, and so on until a residue is left of UO_2. This sublimate is isomeric with the body found in the yellow solution, and is called, therefore, a uranium oxyfluoride UO_2F_2. The author has also investigated the new fluorine compounds obtained by Ditte by fusing U_3O_3 with an alkaline fluoride, and which, he stated, had the composition UO_2F_24MF and $UOF_44MF+xH_2O$. The author concludes that these compounds have no existence, and that really only fluoxyuranates were obtained by Ditte.

The Secretary then read a paper—

On a New Method of Estimating the Halogens in Volatile Organic Compounds. By R. F. PLIMPTON and E. E. GRAVES.—The authors introduce a weighed quantity of the liquid into the tube of a glass Bunsen burner, the tube of the Bunsen is bent into a U; over the end of the Bunsen is placed a glass trumpet-shaped tube, the other end of which is connected with a U tube filled with pieces of glass; these are moistened with pure caustic soda solutions. A second U tube, similarly charged, succeeds the first; to the second U tube is joined a small wash bottle containing nitrate of silver. A Sprengel pump is connected with the wash bottle so that the products of combustion are sucked successively through the two U tubes, and finally bubble through the nitrate of silver solution. The gas having been lighted, the liquid is expelled from the weighing tube by gentle heat. After all the liquid has been thus driven off and burnt, the soda solution is washed out and boiled with sulphurous acid to reduce any chlorates, etc.; nitric acid is added and the solution precipitated with silver nitrate. The combustion usually takes fifteen to twenty minutes. About twelve analyses are given with liquids of various boiling points, the lowest being ethyl bromide boiling at 39°, the highest acetylene bromiodide boiling at 150° The results agree well with the calculated numbers.

Mr. W. A. SHENSTONE then read a short paper—

On a Modified Liebig Condenser.—The Liebig's condenser is placed vertically; to the lower end of the inner tube is fused a short piece of somewhat smaller glass tube, the end of this smaller tube projects upwards about half an inch into the condenser. In this way an annular ledge is formed between the inner wall of the condenser and the outer wall of this smaller tube. This annular space is drained by a narrow glass tube a few inches long, which is fused into the bottom of the condenser like a T piece. This narrow glass tube slopes gently downwards, and is furnished at its extremity with a stopper. The advantages are, first, that the apparatus requires less space on the table than the ordinary condensing arrangement, and secondly, that when substances have to be digested for some time and subsequently distilled, no shifting of the apparatus is required. Thus, in the preparation of formic acid by heating oxalic acid with glycerine, the stopper is inserted in the narrow T tube, any vapour rising into the condenser is condensed, trickles down, fills the annular space, overflows, and runs down into the flask. When it is wished to distil the product the stopper is taken out and the liquid, instead of running back into the flask, drains off from the annular space down the narrow T tube into the receiver. The apparatus is made by Cetti and Co.

The Secretary then read a paper—

On two new Aluminous Mineral Species, Evigtokite and Liskeardite. By W. FLIGHT.—The first mineral comes from the cryolite bed of Greenland. The author gives its formular as $Al_2F_3 + 2\ CaF + H_2O$; it resembles chalk or kaolin in its appearance. Liskeardite is obtained, as a white crystalline mineral with a tinge of blue, from Penzance; it has the formula $3\ R_2O_3As_2O_5 + 16\ H_2OR = Al$ and Fe^{iv}.

The author has made a very minute and careful determination of the water expelled at various temperatures.

The Secretary then read a paper—

On the Volume Alteration attending the Mixture of Salt Solutions. By W. W. J. NICOL.—The author has investigated the changes of volume in mixing various proportions of sodium and potassium chlorides, of potassium nitrate and sodium chloride, of sodium nitrate and potassium chloride, and of copper sulphate and potassium sulphate. The experiments show that when two salt solutions which cannot experience double decomposition are mixed, a change of volume takes place due to the different affinity of the salts for water; that double decomposition takes place in solution, and that the volume change is an index and even a measure of this decomposition.

The Society then adjourned to February 1.

ROYAL INSTITUTION.

THE PRIMEVAL ANCESTORS OF EXISTING VEGETATION AND THEIR BEARING ON THE DOCTRINE OF EVOLUTION.

BY PROFESSOR C. W. WILLIAMSON.

The second lecture of this course was delivered on Tuesday last. The following is an abstract:—

The living Lycopods or Club-mosses consist of two groups, the Lycopodia and the Selaginella, distinguished by their spores. The former group has only one kind of spore, each of which develops a "prothallus," which bears the two sets of organs corresponding to the pollen-grains and ovules of the flowering plants. This is the chief form occurring in cold and temperate regions. The latter group has two kinds of spores, viz., microspores, corresponding to the pollen-grain and the macrospore to the ovule of the higher plants. The group of the Selaginella chiefly abounds in the Tropical and warmer regions. Both groups have virtually the same structure, with the exception of the spores. The stem, which always branches dichotomously, consists of a mass of cellular tissue, in the centre of which is either a single bundle of vessels or there are several such bundles arranged side by side. In both cases, these bundles constitute a vascular axis enclosed within a true bark. On comparing the structure of one of those macrospores of Selaginella with that of the seed of a Coniferous plant we discover several definite features in which they agree so closely as to render a transition from the one to the other no difficult thing for Nature to accomplish. These recent forms are all of dwarf dimensions, and mostly of creeping habit. Though they are very abundant, and widely diffused over the globe at the present time, it is singular that they are very rare in a fossil state. One small form has been detected in Arctic beds of Tertiary age, and one or two that we have reason for regarding as of the same type are met with in the Oolitic beds of Yorkshire. Still finer examples have been discovered in rocks of Carboniferous age, in the coal-beds of the Franco-German frontier, near Saarbrucken, showing that their rarity in the oolites and yet newer beds was not due in all probability to their non-existence, but to their non-preservation, since it can scarcely be doubted that the carboniferous types have been connected with the living ones by a continuous line of descent. When we reach the Permian rocks, following the descending order, we meet for the first time with some of the magnificent arborescent genera so characteristic of the Palæozoic ages, and which evidently attained their grandest development during the Carboniferous epoch. During this age they constituted various vast forests, abounding in trees from 50 to 100 feet in height, with stems having a bulk corresponding to the mass of foliage which they had to support. Though there are several genera of these arborescent Lycopods, they are chiefly resolvable into two—the Lepidodendra and Sigillaria.

The Lepidodendron had a stem covered with the large leaf-scars which marked the former positions of the leaves on the young branches, but which had been much enlarged by the growth of the stem and branches. These scars are arranged in diagonal lines that wind equally right and left round the stem. The leaves, which were more or less elongated and narrowly linear, adhered long to the branches. The latter exhibited invariably the dichotomous subdivisions still so characteristic of the small living species. On turning to their internal organization we find how widely these stems and branches of the fossil forms differ from the recent ones. The youngest twigs of the former approached very closely in structure to that of the stems of the latter. They possessed a single small bundle of vessels enclosed in a thick bark. But very soon advancing growth developed this bundle into a cylindrical ring of vessels enclosing a small cellular pith, thus dividing the stem into a pith, a vascular zone which sent branches to the leaves, and a thick bark, to the exterior of which the leaves were attached by a pulvinus, or thickened base. As the stem or branch grew the vascular ring increased both in size and in the number of its component vessels, the pith growing in the same time and ratio. But after reaching a certain stage of growth, which stage was reached sooner or later in the case of various species, an altogether different structure was added to their stems and branches. The vessels of the existing ring were grouped irregularly and in no definite order. By the process of vegetable growth known as "exogenous," a new vascular cylinder was added to the exterior of the pre-existing one; its vessels were now arranged in regular radiating lines, and separated by cellular medullary rays, and additions seem to have been made to the outer border of these radiating laminæ, as long as the life of the plant endured. This new cylinder differed very little in any essential respect from those similarly produced in the Oaks and Elms of our own time.

French observers, followers of Brongniart, regard the growth of this second cylinder as a distinctive feature characteristic of the next plant to be noticed—the Sigillaria. This idea is altogether contradicted by innumerable facts revealed by our British discoveries. The only real difference between the Lepidodendron and the Sigillaria is seen in the exterior of the bark. In the former, as we have seen, the leaves are arranged on the branches in diagonal spiral lines; in Sigillaria they are arranged in vertical lines. All other supposed internal distinctions are merely due to differences of age. Sigillaria, like Lepidodendron, is an arborescent Lycopod.

Both these genera had the same kind of root. This was once believed to be a distinct plant, known by the name of Stigmaria Ficoides. These roots were, like the stems, of huge dimensions. Like the aerial branches, they branched dichotomously, and were clothed with large cylindrical rootlets, the organization of which bespoke clearly their Lycopodeaceous character. The fructifications of these trees are known to us by the name of Lepidostrobi, which were merely modified half abortive branches, at the base of each leaf of which was developed a little box (sporangium) filled with spores. Possibly some of these Lepidostrobi, like the Lycopodiums, had but one kind of spore; but a large number of them were certainly "heterosporous," *i.e.*, they possessed, like the Selaginellæ, both micro- and macro-spores; the sizes and appearance of both of which, notwithstanding the differences in the sizes of the parent plants, were almost absolutely identical in the primæval fossils and in the living plants. The peculiar branches which bore these fruits have long been known under the name of Haloniæ, and various functions have been attributed to them. It is now certain that they were the fruit-bearing, ultimate branches of some Lepidodendra, and probably of Sigillaria also. The stems, also, known as Ulodendra, are merely these branches from which the Lepidostrobi have fallen, leaving impressed upon the surface of the bark circular scars corresponding to the bases of the fallen fruits, but which, like initials cut long ago on the bark of some tempting Elm, have grown with the growth of the stem on which they were inscribed. That a large number of the fallen cone-like organs shed both microspores and macrospores is shown by the numbers of these two structures which both swell the bulk and improve the qualities of the Coals of which they form so important a part.

The plants just described reappear in the yet older Devonian rocks, but here they are associated with yet more anomalous and archaic forms, especially with the well-marked genus Psilophyton, so abundant in the Devonian strata of Canada. It appears to be Lycopodendrous, though widely removed from all living types. There is further evidence that some of these Palæozoic types were living in the age of the upper Silurians. Fragments have been found sustaining that conclusion.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, January 18, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. F. Ransom read a paper on the "Detection of Strontium," which will be published in a future number of this Journal. A discussion followed, in which the Chairman, Secretary, and Messrs. Dymond and Haward took part. A vote of thanks was passed to Mr. Ransom.

Mr. Elborne then read a "Report on New Remedies," which will probably be published in a future number. The report was illustrated by specimens.

A discussion on the subject of the Report took place, in which the Chairman, Secretary, Messrs. Cripps, Haward and Ransom took part.

The Secretary then announced that the Executive Committee had appointed Mr. R. A. Cripps to be the Reporter on Practical Pharmacy for the ensuing session. The meeting then adjourned.

Parliamentary and Law Proceedings.

Poisoning by Chloral.

On Saturday, January 20, Dr. Diplock held a long inquiry at 29, Upper Phillimore Place, Kensington, as to the death of Mrs. Catharine Gape, the widow of Admiral Gape, aged 36.

Annie Godwin, cook in the service of Dr. Heffenden, said she was requested to go home with the deceased on Tuesday night. The deceased at that time complained of the death of a favourite dog. When they arrived home the deceased went up to her bedroom. Witness followed, and saw her put a chloral bottle on the mantelshelf, at the same time saying, "Oh, God, I'm dying!" Witness answered, "Nonsense, Mrs. Gape." The deceased, who appeared in very low spirits, added, "I have taken fourteen doses."

Dr. Heffenden said he had attended the deceased for some years. On Tuesday night he was sent for, and everything was done to restore the heart's action, but to no effect. Witness had never prescribed chloral for her.

The Coroner informed the jury that the chloral in the bottle was known as "Hunter's Solution of Chloral."

Annie Godwin, upon being recalled, said that the gas in the bedroom was barely alight when Mrs. Gape drank from the bottle.

After a lengthened deliberation the Jury returned a verdict, "That the deceased died from the effects of chloral, and that the said death was accidental." At the request of the Jury the Coroner added the following rider, and promised to forward it to the Home Secretary: "We are of opinion that some restrictions should be placed upon the sale of patent medicines that may be used as poisons."—*Daily News.*

The West Malling Poisoning Case.

At West Malling, on Wednesday, Mr. J. Rogers, one of the coroners for Kent, resumed his inquiry into the circumstances attending the death of Sarah Ann Wright, the daughter of a labourer residing at Malling, who, on December 14, last, died as alleged, from the administration to her by the Rev. J. H. Timins, the vicar of the parish, of a teaspoonful of oil of bitter almonds.

Dr. Pound added to his evidence that he did not agree with various theories advanced by Mr. Timins in his evidence. He was of opinion that if Mr. Timins had taken a teaspoonful of the same oil as caused the death of the deceased, it must have been fatal in his case; while he also believed that if when the girl cried out on swallowing the oil, or even when Mr. Timins had himself taken some of the oil, medical assistance had been called in, the girl's life would in all probability have been saved. As to the suggestion of apoplexy, when he made the *post-mortem* examination, he had in his mind the fact that death might have arisen from apoplexy, among other matters; but he had not the slightest doubt that death was due to prussic acid poisoning, and he had no difficulty in arriving at that conclusion. He could not have made a more searching investigation.

Dr. Pope expressed the same opinion as to the necessarily fatal effects of a teaspoonful of oil such as that given to the girl. He noticed at the *post-mortem* examination an enlargement of the thyroid gland, but there was nothing in that likely to cause death. He was in the house after the girl had taken the oil, and the mother told him Mr. Timins had given her something which made her cry, but this did not make him suspect anything. In hastily passing through the room and cursorily glancing at the deceased he saw nothing in her condition which would lead him to think she was approaching her end.

The Coroner, in summing up the evidence to the jury, said that the result of a *post-mortem* examination of the body of the deceased had been the discovery of prussic acid and of oil of bitter almonds. Such being the case he thought that, notwithstanding the statement by Mr. Timins at the last meeting, death was due to prussic acid poisoning, and not to natural causes. It was for the jury to consider whether or not Mr. Timins was criminally responsible for the administration of the poison, it having been suggested that he was not and that the death was due to misadventure. Mr. Timins had stated that he was originally a student of medicine at St. Thomas's Hospital, but that was some thirty-six years ago, and he never qualified. Since then the science of medicine had developed new theories and practice, so that what might then have been considered proper might now be obsolete. Mr. Timins too, had since been engaged in a very different profession. In order to enable a non-professional man to administer with safety in a case of emergency it was laid down by Lord Lyndhurst in Rex *v.* Webb, that it was necessary it should be at a place where proper medical assistance could not be secured. In this case no one could say that there was a question of emergency, and there were also two or three medical gentlemen resident in the place. That being the case, and death having been caused by the administration of oil of almonds by Mr. Timins, it would be for the jury to say whether or not he was criminally responsible. When the oil was purchased Mr. Timins said it was to be used externally, and they knew that the girl had been induced to drink it, although she did so with some reluctance. Mr. Timins had stated that he also took a dose, but he had admitted that he knew that the oil of bitter almonds contained a certain quantity of prussic acid. He had further stated that he mistook the poisonous for the non-poisonous oil on this occasion: but after he gave it to the girl he did not do what was unquestionably his duty. —send immediately for a doctor. For it was fair to assume that the poor girl's life might have been saved if he had done so.

The Jury, after some consultation, returned a verdict of manslaughter against the Rev. J. H. Timins. At the same time they expressed their belief that the oil of almonds was administered with no evil intent.—*Times.*

G. Brown.—If you refer to the *Lancet* for the 13th inst., you will see that a correction was inserted on p. 88.

"*Dispenser.*"—(1) You have omitted to give a copy of the prescription. (2) "Nut oil," expressed from the seeds of *Arachis hypogœa.*

W. C. M.—You must follow the usual procedure for gas analysis.

Devonia.—A ten volume solution will answer. See *Pharm. Journ.* for March 11, 1882, p. 747.

Correspondence.

Permanganate of Potash Pills.

Sir,—I always held the Scotchman in profound veneration for his transcendant abilities; but after reading Mr. Mackenzie's letter of Saturday last, I was completely dumb, and held my breath in silent admiration of the Celtic soul of Mr. Mackenzie's elder apprentice in particular. The Saturday previous I felt very grateful to Mr. Martindale for his formula for a pill that had given me considerable trouble, now I am quite vexed with him for giving me so much trouble. Why, sir, we have been "fooling around" (as the Americans say) with cacao butter, vaseline, kaolin, and all sorts of things, when we have at hand a nice clean and simple medium on our dispensing counter. Really, Mr. Martindale, you might have known better, and not given us all this trouble for nothing; but now comes the question, How did he do it? One chemist I know tried it (before Mr. Mackenzie's letter). Result: Chemist with a burnt finger, and a charred mass in the mortar, accompanied by a display of fireworks on a small scale. Perhaps for the benefit of these poor ignorant men Mr. Mackenzie himself (not his elder apprentice) will kindly mix the mass, and then tell us how much permanganate remains in each pill; the result will, I think, astonish him.

I was asked fourteen days ago to prepare these pills and use conf. rosæ, and on my suggesting this was worse than useless, was left to find out the best excipient. My resort was cacao butter. This was subsequently verified by an appeal to Dr. Ringer. Cacao butter does certainly make a very nice pill, but is very difficult to make. If the molten mass could be poured into a small mould it would then be perfection.

Mr. Martindale's plan is by far the most practicable one I have come across yet (except, of course, that of Mr. Mackenzie's elder apprentice), the only danger being you are apt to get the pills rather large. This, of course, is avoided with a little practice.

Manchester. J. Hart.

Sir,—If the senior apprentice at 45, Forest Road, Edinburgh, had been experimenting in spontaneous combustion I can easily understand that he would use sugar and syrup to make up pills of permanganate potash. Let him try again and he will see the result and find the mass burnt up in less than three minutes. For my own part, I prefer to adopt the course followed by that cunning artificer in pharmacy, Mr. Martindale, of New Cavendish Street.

Norwich. Octavius Corder.

Sir,—I should not recommend any one to adopt Mr. Mackenzie's method of making permanganate of potash into pills with the aid of sugar.

Apart from the reducing action of sugar on such a substance as permanganate of potash, pills so made are liable to take fire should the pestle be used a little firmly.

Edinensis.

Sir,—I am sure the trade must feel deeply indebted to Mr. Mackenzie (and his intelligent senior apprentice) for publishing his formula for making the above pills.

I tried it and found that the mass "went off" in the mortar in a similar manner as with glycerine (mentioned by Mr. Martindale) only less violently.

I made excellent pills by using to 20 grains of the salt, 4 grains ung. resinæ and 1 grain p. gum. trag.

Chester. F. B.

Communications, Letters, etc., have been received from Dr. Dowse, Dr. Hesse, Dr. Thresh, Messrs. Cowdery, Macnaught Bros., O'Sullivan, Wright, Hutton, Robinson, W. C. M., R. J.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 583.)

Catechu, U.S.P. and P.G.—The U.S.P. still gives the preference to the extract of *Areca Catechu*, and the P.G. to that of *Uncaria Gambir* and *Areca Catechu*. The test that it should show a crystalline structure when examined in glycerine under a lens magnifying two hundred times cannot apply to the areca catechu, since Flückiger and Hanbury were unable to obtain crystals from it.

Catechu should not leave more than 15 per cent. of insoluble residue when treated with spirit or boiling water, nor yield more than 6 per cent. of ash.

Caulophyllum, U.S.P.—The rhizome and roots are official. This new addition is valued as a uterine tonic by the Eclectics,* but is regarded by Stillé and Maisch as "probably destitute of medicinal power" ('Dispensatory,' p. 373).

Cera Flava, U.S.P. and P.G.—The P.G. requires that beeswax shall be soluble in 300 parts of boiling alcohol, sp. gr. 0·830, with the exception of a very small brownish-yellow residue. Upon the cooling of such a solution a white crystalline paste is precipitated, and when the pale yellowish liquor has been filtered it should not be rendered turbid by water, neither should it more that slightly redden blue litmus paper. One part of wax digested for an hour with 300 parts of spirit, sp. gr. 0·96, and 1 part of caustic soda added, should give a clear liquid which, when cooled and filtered, is not precipitated by hydrochloric acid.

According to the U.S.P. cera flava should be soluble in 35 parts of ether and 11 of chloroform. Soap is detected by hydrochloric acid giving a precipitate in water in which the wax has been boiled, and paraffin is recognized by being left insoluble when 5 grams of wax are heated for fifteen minutes with 25 grams of sulphuric acid to 160° C., and the mixture subsequently diluted with water. For the detection of vegetable wax, resin, etc., a test similar to that of the P.G. is given, except that an aqueous instead of a spirituous alkaline solution is ordered.

Cetaceum, U.S.P. and P.G.—The P.G. has raised the melting point from 45°–50° in the last edition, to 50°–54° in the present one. One part of cetaceum should be soluble in 40 parts of boiling alcohol and water should precipitate nothing from the liquid filtered when cold.

Chelidonium, U.S.P.—It is difficult to understand the admission of this drug to the materia medica, more particularly since sanguinaria, which is said to possess the same active principle is retained. Chelidonium is, however, a favourite medicine with homœopaths, and is valued as a domestic remedy in the United States.

Chenopodium, U.S.P.—Chenopodium anthelminticum is made a variety of *C. ambrosioides*, L., and a description is now added.

Chondrus, U.S.P.—*Chondrus mammilosus*, Grev., U.S., is now official as well as *Chondrus crispus*, Lyngb., but the description given does not apply to the latter, which differs in having pedicellate fruit and a channelled stem to the frond. The latter plant is now generally referred to as *Gigartina* and the specific name spelt mammillosa.

Chirata, U.S.P.—Not only is the name altered from "Chiretta," but the name of the plant yielding it, which is now *Ophelia Chirata*, Griesb. No mention is made of the presence or absence of pith in the stem, nor of the relative thickness of its woody portion by which the much less bitter *Ophelia angustifolia* is distinguished from *A. Chirata* (*Pharm. Journ.*, [3], v., p. 481).

Chrysarobinum, U.S.P. and P.G.—The U.S.P. apparently intends a mixture of the chrysarobin of Liebermann and Seidler (*Pharm. Journ.*, [3], ix., 896) and chrysophanic acid, such as is usually met with in commerce under the name of chrysophanic acid, since it describes chrysarobin as "a mixture of proximate principles (commonly named chrysophanic acid)," and gives the test that sulphuric acid dissolves chrysarobin with a deep blood-red colour which does not apply, according to the above-named chemists, unless chrysophanic acid is present in it.

In the P.G., on the other hand, in which the tests given by Liebermann and Seidler to distinguish the two bodies are not adopted, chrysophanic acid would seem to be excluded, since it is required that the water in which chrysarobin has been boiled (1 part in 2000) should not give an acid reaction, nor be coloured by solution of sesquichloride of iron, and if shaken with liquor ammoniæ, should take one day to assume a purplish-red (coccineum) colour. Yet from the statement in the P.G. that chrysarobin dissolves in sulphuric acid, forming a solution of a colour from pale red to yellow, it would appear that allowance is made for traces of chrysophanic acid, since pure chrysarobin, according Liebermann and Seidler, dissolves in that liquid with a yellow colour. The P.G. directs that whenever chrysophanic acid is ordered for external use chrysarobin is to be dispensed, but gives no directions for its use in case the chrysophanic acid is intended for internal administration.

Cimicifuga, U.S.P.—The size of the rhizome as regards diameter (1 inch) is certainly larger than is generally met with in English commerce, ½ to ¾ inch being the usual width. The description of the internal structure, "a smooth fracture with a large pith," is scarcely definite enough, since the central portion is as firm and resinous as the bark and is not at all like ordinary pith.

Cinchona, U.S.P.; Cortex Chinæ, P.G.—"Cinchona," including "the bark of any species of cinchona containing at least 3 per cent. of its peculiar alkaloids," is official for the preparation of the infusion. No definition is given of the alkaloids intended by the word "peculiar," so that a bark containing cinchonine and cinchonidine, but no quinine, may be used provided the total yield of alkaloids amount to 3 per cent. In the U.S.P., under cinchona flava, *C. Calisaya* is still official for the preparation of the extract, fluid extract and tinctura cinchonæ; and under cinchona rubra, *C. succirubra* is ordered to be used in the preparation of tinct. cinchonæ co. The description of calisaya bark is not sufficiently definite to enable any one to detect the substitution of flat pieces of *C. Peruviana*, *nitida*, *australis*, or of *C. scrobiculata* in quills, for the official bark. The statement that the quills of *C. Calisaya* bark are "marked by longitudinal and transverse fissures *about one inch apart*," is not correct. *C. Calisaya* in flat pieces

* *Pharm. Journ.*, [2], iv., p. 52.

and *C. succirubra* in the same state containing the required percentage of the alkaloid rarely enter into retail commerce, and the Pharmacopœia, therefore, might well have omitted bark of this kind.

In the P.G. only the bark of the cultivated species, "especially *C. succirubra*," is official; only a brief description of the bark is given, and it applies more to *C. succirubra* than to any other species. The bark is required to contain alkaloids to the extent of 3½ per cent. and the presence of those proper to cinchona is determined by heating 0·1 gram of the powdered bark in a glass tube, when it should give a purplish-red tar; and that quinine is present is ascertained by the chlorine and ammonia test.

Cinnamomum, U.S.P.; Cortex Cinnamomi, P.G.—The U.S.P. permits the use of both Ceylon cinnamon and Chinese cinnamon (cassia bark); the latter is defined as the bark of one or more undetermined species of *Cinnamomum* grown in China. In the P.G. the barks afforded by species of *Cinnamomum* growing in Southern China now are alone official, exception being taken to such as are mucilaginous. This exception appears to be intended to exclude the bark known in the London market as cassia vera, and which occasionally arrives in large quantities.

It may be hoped that in a future British Pharmacopœia the mistake will not be made of permitting the indiscriminate use of two barks so distinct in flavour as those of *C. zeylanicum* and *C. Cassia*, under one name. The result must of necessity place dispensers of medicine in an awkward position. A patient who has had medicine containing tinct. cinnamomi, U.S.P., made up with tincture of the Ceylon species in one shop, and subsequently at another shop in which tincture of the Chinese drug had been used, would infallibly consider the difference in taste to imply that some error had occurred in dispensing the medicine.

Since chemists are allowed choice in the matter, the fact that the cassia bark is cheaper and that it is the only official kind in the P.G. will, it may be hoped, lead to uniformity in the use of that bark, and so prevent much annoyance both to dispenser and patient. In the next British Pharmacopœia there need be no difficulty in defining the botanical source of cassia bark (*Pharm. Journ.*, [3], xiii., p. 583.

Coccus, U.S.P.—No insoluble powder should separate when the insect is macerated in water, indicating absence of sulphate of barium, etc.

Colchici Radix, U.S.P.—Colchicum root which is of a dark colour internally and which breaks with a horny fracture should be rejected.

Colocynthis, U.S.P.; Fructus Colocynthidis, P.G.—The U.S.P. now adds a description which allows of the use of any commercial variety, except that of Mogador, and compels the use of recently dried mature fruits, by remarking that the seeds are brown. The P.G. omits any description of size and now gives the maximum dose as 0·3 gram.

Conium, U.S.P.—The fruit only is now official, and the division of the umbelliferæ to which it belongs is now mentioned. The plant is no longer represented in the P.G., coniine having been omitted.

Cornus, U.S.P.—The bark of the root is now alone official.

Creasotum, U.S.P.—The tests given in the U.S.P. seem to point to German beechwood creasote as the kind which is official, since it is stated that if 1 volume of creasote be mixed with 1 of glycerine a nearly clear mixture will result, from which the creasote will be separated by the addition of one or more volumes of water (*Pharm. Journ.*, [3], ii., 921; Watts' 'Dictionary of Chemistry,' viii., 580). Its boiling point should be 200° C., and most of it should distil over between 205° and 220° C. It should be soluble in 80 parts of water at 150° C. to a somewhat turbid liquid and in 12 parts of boiling water. It should not coagulate albumen or collodion. Besides the solvents mentioned in the B.P., chloroform, benzol, and disulphide of carbon are given.

Crocus, U.S.P., P.G.—The U.S.P. remarks that "saffron should not be mixed with the yellow styles." This must surely be a misprint for stamens, any unusual length of style being quite an exception, while stamens are present in the majority of samples, being much more easily extracted from the flower than the whole length of the style. It should not deposit any pulverulent matter when soaked in water. The P.G. gives a colour test as follows:—1 part of saffron macerated with 10 parts of water should give a liquor which will give a yellow colour to 10,000 parts of water. This test would probably lead to the discovery of the use of any artificial colouring matter insoluble in water, such as the dinitrocresylate of sodium, which has been used to impregnate marigold petals mixed with saffron (*Pharm. Centralh.*, December 28, 1882, p. 619). Saffron should not give more than 8 per cent. of ash on incineration, 5 to 6 being the usual amount according to 'Pharmacographia.' The percentage of moisture that saffron should normally contain is not mentioned in the U.S.P., although the presence or absence would make a considerable difference in the quantity used in making the tincture; in the P.G. it is estimated at less than 14 per cent.

Cubeba, U.S.P.; Cubebæ, P.G.—According to the U.S.P. cubebs should not be mixed with the nearly inodorous rachis or stalks, these are often present in considerable quantity. The remark that the fruit "is internally whitish and hollow" is, to say the least, an inadequate description. The P.G. also orders the removal of the *peduncle* of the fruits.

Cypripedium, U.S.P.—Now removed from the secondary list and a description added. The fluid extract is the only official preparation. This drug is sometimes confounded with valerian, being known to herbalists as American valerian, and being used for the same diseases as that drug. The difference between the two official species, *C. pubescens* and *C. parviflorum*, has been pointed out by Maisch (*Amer. Jour. Phar.*, 1872, p. 297).

Digitalis, U.S.P.; Folia Digitalis, P.G.—The U.S.P. now gives a description in which it is stated that the midrib is broad near the base, a feature which distinguishes it from the other leaves usually mixed with it, except primrose leaves. From these, however, the acute angle of the lateral veins and their decurrence into the petiole in digitalis leaves would serve as distinguishing characters. The P.G. directs that the leaves of wild plants should be used. The simple, not felted, character of the tomentum is also pointed out as distinctive. The leaves are to be collected when the plant is in flower. The U.S.P. does not give any time of collection, but only requires that the leaves should be collected from plants of the second year's growth. In view of the fact of the varying strength of preparations of digitalis, greater uniformity might probably be obtained either by following the example of the P.G., or by ordering the fresh leaves only to be used, or to be gathered when the plant is in flower, and by omitting the infusion. The maximum dose of the leaves is given as 0·2 gram.

(*To be continued.*)

BACTERIA IN THE SOIL AND THE AIR.

In the laboratory at Montsouris a series of observations has for some years been conducted on the bacterial germs present in the atmosphere and the soil, with especial reference to their relation to the spread of infectious diseases. Experiments were also made on the cultivation of bacteria in artificially prepared nutrient fluids.

The quantity of bacterial germs in the air varies with the time of year, with subordinate temporary fluctuations. It is also largely dependent on the weather, rain clearing the air to a large extent of the germs. While rain is actually falling the number of germs in the air is greatly reduced; it increases as the ground dries, and again diminishes when the drought has lasted for ten or fifteen days.

The following are the artificial nutrient fluids chiefly employed, with the means used for sterilizing them, and the degree to which they are then susceptible to the attacks of bacteria:—

Fluid.	Mode of sterilizing.	Degree of suscepti-bility.
Cohn's nutrient fluid.	Heat of 100° C.	0·05
White of egg . . .	Pasteur's gypsum filter, cold.	0·22
Normal urine . . .	Pasteur's gypsum filter, cold.	0·40
Normal urine . . .	Heat of 110°.	0·50
Neutralized urine .	Gypsum filter, cold.	0·90
Neutralized bouillon.	Heat of 110°.	1·00
Normal urine, diluted	Gypsum filter, cold.	1·80
Serum of blood, diluted	Gypsum filter, cold.	6·00
Juice of strawberry and grape . . .	Gypsum filter, cold.	9·50
Juice of cabbage, diluted	Gypsum filter, cold.	10·90
Juice of calf's flesh .	Gypsum filter, cold.	13·50

The kind of bacteria varied with the different fluids; but in the two years there was found an average of from 65 to 79 per cent. of micrococcus, 14 to 24 per cent. bacillus, and 7 to 8 per cent. bacterium. In the fluids obtained from plants the bacterium amounted to about one-third.

Experiments made at the same time and in the same way in Paris (at the Mairie of the 4th Arrondissement), showed a very much larger quantity of bacterial germs in the air. The following are the numbers from October, 1880, to September, 1881:—

	Paris.	Montsouris.
October	920	142
November	750	106
December	540	49
January	470	45
February	330	31
March	750	74
April	970	48
May	1000	80
June	1540	92
July	1400	190
August	960	111
September	990	105

With some variations, curves formed for the two places would nearly agree, the average at Paris being about ten times that at Montsouris. More exact curves, made for weekly periods, showed a still closer coincidence in the increase and decrease at the two places. The proportion of different forms was 93 per cent. micrococcus, 5 per cent. bacillus, 2 per cent. bacterium. Ammoniacal or urine ferments were also found in the air, and are probably a fruitful cause of infectious diseases. Pierre Miquel distinguishes three kinds of urine-ferments:—*Micrococcus ureæ*, *Bacillus ureæ* and *Torula ureæ*.

The number of bacterial germs found in the air of hospitals was enormous, amounting in the Hotel-Dieu to 5600 per cubic metre in the summer months. The following are the numbers for different months:—

	Men's ward.	Women's ward.	In the city of Paris.
March, 1881 . .	11,000	10,700	750
April	10,000	10,200	970
May	10,000	11,400	1000
June	4,500	5,700	1540
July	5,800	7,000	1400
August	5,540	6,600	960
September . . .	10,560	8,400	990
October	12,400	12,700	1070
November . . .	15,000	15,600	870

The diminution in the summer months Miquel attributes entirely to the better ventilation. The presence of hospitals in large towns he believes to be a most prolific cause of infectious diseases, such as small-pox, scarlet fever, diphtheritis, erysipelas, typhus, etc.

A very interesting comparison is drawn between the presence of bacteria in the air and the prevalence of infectious complaints. The weekly bacterial curves of Paris and the weekly curves of mortality published in the 'Bulletin de Statistique Municipale,' under the authority of M. Bertillon, show an almost complete agreement.

Another series of observations was devoted to the bacteria present in the soil. A gram of earth at the Observatory at Montsouris contained 750,000 germs; in the Rue de Rennes, 1,300,000; in the Rue Monge, 2,100,000.

THE BEHAVIOUR OF DISULPHIDE OF CARBON TOWARDS PERMANGANATE OF POTASSIUM.*

Some time ago, E. Allary proposed to purify disulphide of carbon by shaking it with an aqueous solution of permanganate of potassium, and subsequent washing. This announcement induced Eugene Obach, who had previously used this method without success, to study the behaviour of the two substances upon each other, under varying circumstances. We give an abstract of his results in the following:—

1. *Behaviour of permanganate of potassium towards pure disulphide of carbon.*

a. Pure disulphide of carbon, when shaken and left in contact with the solid permanganate, remains entirely unaffected.

b. If pure water be poured upon the pure disulphide, and solution of permanganate be dropped into it, until the water has a rose-red tint, on shaking the tint passes to onion red in a few minutes. If a little more permanganate is added, the same thing happens. And if the water be separated, the disulphide washed with water and then again covered with fresh water, a new addition of permanganate will again show a reduction. After the treatment has been repeated four times, the reduction takes place very slowly.

If light is excluded from these manipulations, the reduction is greatly retarded.

c. If the previous operations are repeated with water containing a small amount of sulphuric acid, the reduction takes place comparatively more rapidly. Naturally, the result is not an onion-red colour, but perfect colourlessness.

---

* From *Journ. f. pract. Chem.* Reprinted from *New Remedies*, January, 1883.

d. It was noticed that the longer the water had been allowed to remain in contact with the disulphide, the more energetic was the reduction. Two experiments were made under otherwise identical conditions. In one of them the permanganate was added immediately after the water had been added, and the results corresponded with what has been described above. In the other experiment, the water was left in contact with the disulphide for fifteen hours, and, on opening the flask, a distinct odour of sulphydric acid was perceptible, which was confirmed by the reaction with lead paper. This odour entirely disappeared after the treatment with permanganate.

e. As it was suspected that contact with water developed sulphydric acid even from pure disulphide of carbon, three flasks were partly filled, respectively, one with the pure disulphide, the other with pure water, and the third with a mixture of the sulphide and water. In each of the flasks was suspended a strip of lead-paper. After one hour, the strip in the third flask showed traces of the formation of the disulphide, after four hours it was brown, and later it turned completely black. The other strips remained uncoloured, although, after *very long* standing, there was perceptible a faint trace of discloration in the strip over the pure disulphide, undoubtedly owing to the presence of water in the paper, which had been moistened with solution of acetate of lead.

f. After every treatment of pure disulphide with permanganate, the disulphide was tested for free sulphur by means of metallic mercury, and the water was tested for sulphuric acid by means of chloride of barium. Sulphuric acid was always found present; free sulphur was sometimes found developed in the disulphide.

The occurrence of free sulphur was found to be dependent on the fact whether sulphydric acid was present, already formed in the disulphide while standing under water, or whether it was freshly given off from the water on the addition of permanganate. In the former case, free sulphur could be detected, but not in the latter. In fact, any disulphide of carbon, which originally has been quite free from free sulphur, may develop the latter either by the decomposition of any sulphydric acid contained in it by permanganate, or even by exposing the disulphide for a comparatively short time under water, to sunlight.

g. Commercial disulphide of carbon contains various impurities which may be—

Solid, chiefly consisting of free sulphur.

Liquid, fetid, sulphurated oils belonging to the allyl series (like oil of garlic, mustard, etc.).

Gaseous, also mostly fetid, among them chiefly sulphydric acid.

h. Neither solid permanganate nor its solution can remove free sulphur or the sulphurated oils; but it quickly and completely removes any sulphydric acid.

PURIFICATION OF COMMERCIAL DISULPHIDE OF CARBON.*

In the course of the paper, from which the preceding article is abstracted, E. Obach gives his method for purifying commercial disulphide of carbon. This method is mainly suitable for purifying smaller quantities for use in laboratories, and may not be quite applicable on a large scale, since it is somewhat circumstantial. But it will always furnish a pure product, unless very abnormal impurities should be present.

The crude liquid is first separated from any water which may be present, freed, by means of a dry filter, from mechanical impurities, and at once filtered into a capacious flask, in which a few pieces of burnt lime are contained. The liquid is next distilled from a water-bath heated to 70°–80° C. until only a small residue remains, which contains nearly all the free sulphur and a portion of the fetid oils. The distillate, in most cases, contains sulphydric acid, caused by the decomposing action of the lime upon some of the foreign sulphur compounds; besides, some fetid oils and a trifle of free sulphur. It is now shaken with coarsely powdered permanganate of potassium (about 5 gm. per litre), and left in contact therewith for some time, *until the sulphydric acid is removed.* The liquid poured off from the permanganate contains still some of the sulphurated oils, and a little *more* sulphur than before the treatment with permanganate. It is now briskly shaken, in a stoppered flask, with a small quantity (a few c.c. per litre) of pure mercury, *until all free sulphur is combined*; next, 25 gm. of mercuric sulphate (per litre of disulphide) are added, and the whole mixture again shaken. The reason of this mode of manipulation is this, that the mercuric salt acts more rapidly and easily upon the sulphurated oils, if the free sulphur has previously been removed. A still better way is to pour off the disulphide from the metallic mercury before treating it with the salt. The odour will indicate when *all the fetid sulphurated oils have been removed.* The disulphide is now poured off from the salt into a flask containing some pieces of porous chloride of calcium, and distilled immediately into the bottle in which the pure product is intended to be kept. The bottle must be perfectly dry, and provided with a well-ground stopper. During the last operation, day-light should be excluded. A very good way is to keep the disulphide in bottles (say of about five-pint capacity) which are themselves kept in tin boxes, blackened internally. On pouring out a little of the liquid, only the lid of the box is removed, and light can strike only a small portion of the liquid.

It is particularly to be observed that the above described processes must be performed in the precise order mentioned, since each successive manipulation is intended not only to remove an impurity already present in the disulphide, but, at the same time, also the impurity produced by the previous reagent.

The author fears to trust to the method of purification recommended by Friedburg,* viz., shaking with fuming nitric acid, since he suspects that the disulphide will obstinately retain at least traces of acid vapours.

Disulphide of carbon contaminated with sulphydric acid—but otherwise pure—acts with comparative rapidity upon metallic silver, mercury, and copper, *in presence of air*, with formation of the corresponding sulphides. If air is excluded, silver remains entirely unaffected, mercury is but very slightly affected, but copper is always distinctly coloured. If disulphide of carbon, containing sulphydric acid, is to be tested for free sulphur (the latter being present only in small quantity), this should be done in a perfectly filled bottle with exclusion of air. In this case, the blackening of metallic mercury does not proceed from the sulphydric acid, but from the free sulphur. Alkaline solutions of lead-salts decompose the vapour of the disulphide (and also various allyl-compounds) after a longer or shorter period with formation of sulphide of lead. Hence they cannot be employed as reagents for sulphydric acid.

PYROLEINE.†

Dr. Don Jaime Arbós y Tor, Professor of Physics and Chemistry in Buenos Ayres, has published the results of some investigations on the products of the distillation of fixed oils under certain conditions, which he believes will be serviceable towards proving the identity and purity of at least some of them.

If 2 parts of glycerin are distilled with 1 part of a fixed oil, both substances undergo decomposition, the

† From *Revista Farmaceutica* (Buenos Ayres), 1882, Nos. 17–20. Reprinted from *New Remedies*, January, 1883.

glycerin losing 2 molecules of water and passes into the receiver as acroleine, forming the denser layer. The upper layer contains the *pyroleine*, an oily, limpid liquid of an acid reaction. If a little be taken up by the points of the index-finger and thumb, previously moistened with water, it imparts to them an extraordinary degree of slipperiness. It is insoluble in water and completely soluble in a little alcohol. When treated with an excess of alcohol, it becomes turbid, and precipitates an oil which is soluble in ether and in an excess of pyroleine. The alcoholic solution of pyroleine, treated with acetate of lead, appears like an emulsionized fat.

Pyroleine from olive oil, obtained as the upper layer in the receiver by distilling together 2 parts of glycerin with 1 part of olive oil, possesses a penetrating odour, a dark blackish-brown colour by reflected light, and a deep red colour by transmitted light. On exposing it for ninety-eight hours to a temperature of 10° R. (54·5° F.), it begins to crystallize, forming a number of small grains which fuse at 13° R. (61·2° F.). After these have once been formed, the remaining liquid portion has a dark brown colour by reflected and a red colour by transmitted light. It is soluble in a small quantity of alcohol, communicating to it a reddish-yellow colour, which, on addition of an excess of alcohol, turns to straw-yellow, while the liquid itself becomes turbid, and there is deposited an intensely red oil soluble in ether and in an excess of pyroleine.

The alcoholic solution of pyroleine obtained from olive oil, when treated with ammonia, immediately turns dark-brown, and, after twenty-four hours, separates into a lower, transparent layer of a golden-red colour, and a very small supernatant layer of oil, but little coloured and turbid, remaining in this condition for forty-eight hours.

Nitric acid turns the liquid dark, and, after standing, causes a dark-brown oily layer to rise. After twenty-four hours, the lower layer is a rose-red liquid, and the upper one an oil, blackish by reflected, and deep red by transmitted light.

Treated with sulphate of copper, it forms a dirty-green precipitate and, after one hour, the supernatant liquid has a slightly green colour by reflected, and a dark rose-red colour by transmitted light.

Dr. Arbós concludes that any olive oil which yields a "pyroleine" having the above reactions is pure.

If a mixture of 20 parts of glycerin, 9 of olive oil, and 1 of oil of sesame be distilled, the mixture will be found to foam considerably, and the receiver will contain two layers, the lower one of which is glycerin unaltered, but having a yellowish tint.* The lighter portion is "pyroleine," in form of a limpid oil, insoluble in water, of an acid reaction, a dark-red colour, and a faint, inoffensive odour.

When allowed to stand at rest, at 10° R. (54·5° F.), it forms small, striated grains. The remaining liquid mass has a dark-greenish colour by reflected, and a dark-red colour by transmitted light. At 17° R. (70·2° F.), the crystals melt.

The alcoholic solution of this pyroleine, when treated with ammonia, becomes turbid, acquires a yellowish tint, and, after forty-eight hours, separates a light upper layer of a solid and yellowish oil.

Treated with nitric acid, the liquid assumes a reddish colour, gradually turning dark; on standing, a black oil rises, and, after twenty-four hours, there are two layers, a light yellowish liquid, and an oily layer of a dark cherry-red by reflected, and a scarlet colour by transmitted light.

* Dr. Arbós adds a note that an amount of 5 per cent. of oil of sesame in olive oil is sufficient to prevent the development of acroleine from glycerin during this distillation.

[It appears to us that the facts stated by Dr. Arbós need re-investigation and further confirmation. We lack the time to do so, ourselves, at present; but we would recommend the subject to some of our readers.—Ed. N. R.]

When treated with platinic chloride, it becomes turbid and, after a while, separates into two portions, the denser being golden-yellow, and the other red; after twenty-four hours, the oily layer has a greenish-red tint by reflected, and a dark-red colour by transmitted light.

Sulphate of copper produces a precipitate of a dirty-green colour; after one hour, the supernatant liquid has a dark reddish-brown tint by reflected, and a very dark colour by transmitted light.

Acetate of lead renders it very turbid, and forms with it a sort of fatty emulsion which, after twenty-four hours, becomes pasty.

If a mixture of 20 parts of glycerin, 10 of olive oil, and 1 of cotton-seed oil be distilled, the receiver will contain two layers, of which the lower one is yellowish acreoline. The mixture does not foam up during the distillation. The "pyroleine" obtained in this case is acid, has a reddish tint, and a peculiar odour, which is quite penetrating during the distillation, and irritant to the fauces.

When exposed at a temperature of 10° R. (54·5° F.), for twenty-four hours, minute crystalline grains are formed, which melt at 20° R. (77° F.). As long as the grains exist, the liquid portion has a buff colour by reflected, and a reddish-yellow colour by transmitted light.

The alcoholic solution of this pyroleine, treated with ammonia, becomes turbid and acquires a dark-brown colour, which, after twenty-four hours, becomes golden-yellow, surmounted by a very small oily layer of the same tint.

Nitric acid turns the liquid dark, and, after standing, a blackish oil separates. After twenty-four hours there will be a yellowish liquid and a layer of oil, of a clear carmine colour, by reflected, and a bright scarlet colour by transmitted light.

When treated with platinic chloride, it becomes at once turbid, then divides into two layers, the denser being golden-yellow, and the upper one dark yellowish-brown. After twenty-four hours it becomes quite limpid, and has a reddish colour by transmitted light.

Sulphate of copper forms a precipitate of a dirty-greenish colour; after one hour, the supernatant liquid has a greenish colour by reflected, and an olive-brown colour by transmitted light.

The foregoing results may be summarized in a table, as follows:—

Reactions.	Pyroleine from		
	Olive Oil.	Olive and Sesame Oil.	Olive and Cotton-seed Oil.
During distillation the mixture	Does not foam.	Foams.	Does not foam.
Odour of pyroleine	Faint.	Inoffensive.	Peculiar, penetrating, irritating the throat.
At 10° R. it crystallizes after	96 hours.	40 hours.	24 hours.
The liquid portion, by reflected light, is	Somewhat dark-brown.	Dark-greenish.	Buff-coloured.
By transmitted light	Red.	Dark-red.	Reddish-yellow.
The alcoholic solution is	Reddish-yellow.	Reddish.	Golden-yellow.
When treated with ammonia, set aside for 24 hours	Separates much oil, but slightly coloured and turbid, remaining so 48 hours.	Separates a very small quantity of solid yellowish oil after 48 hours.	Separates a very small quantity of solid yellowish oil after 48 hours.

Reactions.	Pyroleine from		
	Olive Oil.	Olive and Sesame Oil.	Olive and Cotton-seed Oil.
Nitric acid colours it	Brown.	Reddish and then blackish.	Blackish.
On standing, the supernatant oil is	Dark-brown	Black.	Black.
The liquid becomes, after 24 hours	Reddish	Light yellowish.	Yellowish.
And the supernatant oil by reflection	Blackish.	Dark cherry-red.	Bright carmine.
And by transmitted light	Deep-red.	Scarlet.	Bright scarlet.
Platinic chloride produces two layers, the denser being	Muddy-red.	Red.	Dark yellowish brown.
After 24 hours, liquid clears and, by transparent light, is	Deep-red.	Dark-red; and greenish-red by reflection.	Reddish.
Sulphate of copper leaves a supernatant liquid which is	Dark-greenish.	Bottle-green.	Greenish.
And by transmitted light	Dark buff-reddish.	Very dark reddish-brown.	Olive-brown.

NOTE ON THE DETECTION OF STRONTIUM.*

BY F. RANSOM.

The accurate separation of the three metals, barium, strontium and calcium, is not unfrequently attended with some difficulty. The usual method for their detection is framed upon the difference in solubility of their respective salts; more especially the sulphates and chromates.

It is well known that with very dilute sulphuric acid or similarly weak solution of sulphate in water, barium may be immediately and entirely separated. With strontium salts a somewhat similar result occurs, but it is necessary to stir the solution and set aside for some time. With calcium salts the difference is still more marked, the sulphate produced being to an appreciable extent soluble in water, and thus forming the readiest test for strontium after the removal of barium.

Another test solution, which is invariably used in the detection and confirmation of these metals, is that of yellow chromate of potassium. As with the sulphates just mentioned, so also the chromates formed on adding this test vary in solubility, and this gradation occurs in the same order. Barium chromate is insoluble, calcium chromate is very soluble, while strontium occupies the intermediate position. This latter case is most liable to be overlooked, and to the facts connected with it, I wish specially to refer.

On adding a solution of potassium chromate to a dilute solution of strontium nitrate, I obtained, contrary to expectation, a marked turbidity, and on applying a gentle heat this increased to a dense precipitate. To what extent of dilution and under what conditions this test is available, were the objects of the following experiments:—

A 5 per cent. solution of pure chromate of potassium was prepared and used throughout, the mixture being well shaken after each addition of this solution. The nitrate was chosen as being one of the commonest salts of strontium, and readily obtainable in a pure condition. Of this salt, aqueous solutions of definite strengths varying from 40 per cent. to ·25 per cent. were prepared. With the 10 per cent. solution an immediate precipitation of strontium chromate was obtained, and on setting aside for three hours this had so much increased as to convey a solid appearance to the whole contents of the tube. On applying heat to a similar solution immediately after admixture the same result was obtained as previously noticed after standing. On using more dilute solutions an immediate precipitate or turbidity appeared until reaching 1·25 per cent., which latter showed no indication until boiling, when precipitation again took place. Descending to still weaker solutions and applying heat distinct turbidity was obtained until reaching ·25 per cent., when only slight cloudiness was observable. A peculiarity in these most dilute liquids was that the slight precipitate formed became aggregated into circular discs adhering closely to the glass.

In order to compare these results with those obtainable by treating a calcium salt in the same manner, a 20 per cent. solution of calcium chloride was prepared, and to this was added the solution of potassium chromate. No precipitate was formed in the cold, but after boiling a slight turbidity was observed. This, however, unlike the slight precipitates with very dilute solution of strontium nitrate did not aggregate into discs, but remained diffused in the liquid.

From these results it is evident that under ordinary conditions strontium is partially precipitated as chromate from comparatively dilute solutions, and that this precipitation is largely increased by the application of heat. Calcium chromate, on the other hand, is practically not precipitable even from strong solutions and with the aid of heat.

The next question which arises is whether this comparative insolubility of strontium chromate is liable to affect its detection in the ordinary mode of analysis of metals in the fourth group, where barium is firstly removed with potassium chromate. In this case, however free acetic acid is sure to be present, having been used to dissolve the precipitated carbonates. To determine this experiments were performed similar to those already described, but acidulating the solution with acetic acid previously to adding the potassium chromate. With this alteration very different results were obtained.

A 5 per cent. solution under this treatment did not produce the least turbidity even after boiling, and even with a 20 per cent. solution no immediate effect was apparent, although considerable turbidity occurred after the application of heat. With a 40 per cent. solution distinct turbidity appeared, immediately increasing to a marked precipitate when heated.

From this it is evident that there is no danger of losing a sufficient amount of strontium to interfere with its subsequent detection in the presence of acetic acid, provided that the solution has been kept cold.

Finding that strontium chromate which was previously precipitated is now kept in solution with the acid, it might be supposed that on neutralizing this with ammonium hydrate, precipitation would again occur. The experiment was therefore repeated with the 10 per cent. solution of nitrate in presence of acetic acid, and finally ammonia added until the colour changed from orange to yellow, and the liquid was slightly alkaline. The bichromate was now reduced to neutral chromate, and the acetic acid converted into ammonium acetate. The result, however, differed materially from that obtained in the first case. Instead of a dense precipitate only a turbidity appeared, increasing to a moderate precipitate on the application of heat. Testing more dilute solutions, only a slight precipitate fell with the aid of heat from the 5 per cent., and below this no visible effect could be obtained.

* Paper read at a Meeting of the School of Pharmacy Students' Association, January 18, 1883.

From this it appears that although precipitation occurs somewhat more readily than in the presence of free acetic acid, yet the ammonium acetate which is present retains in solution the larger portion of the strontium chromate that is formed.

To briefly sum up we may therefore say—

Firstly, that strontium salts in solution may be detected by the addition of neutral chromate of potassium, and the subsequent application of heat, provided that we are dealing with a simple solution of strontium nitrate not more dilute than ·5 per cent.

Secondly, the presence of free acetic acid prevents this precipitation, especially in the cold.

Thirdly, this latter condition is not materially altered when the free acid is entirely neutralized.

Lastly, in the usual method for the detection of the three metals, barium, strontium and calcium, care must be taken to add excess of acetic acid when dissolving the carbonates, in order that free acid may be present and thus prevent the precipitation of strontium with potassium chromate.

Precipitation of Strontium Chromate.

PREPARATIONS OF ERGOT, BASED UPON THE LATEST SCIENTIFIC INVESTIGATIONS OF ITS MOST VALUABLE MEDICINAL CONSTITUTENTS.*

BY C. S. HALLBERG, CHICAGO.

Ergot of rye ranks undoubtedly among our most largely used and important remedies. Like opium and cinchona, it plays a *role* in relieving human suffering, specific in its character and not easily displaced by any other agent. But unlike these, although the history of ergot is even more ancient and in its universal occurrence is familiar even to the less well informed, our chemical and pharmaceutical knowledge of it is far behind that of these two contemporaries. So much more is this to be wondered at since, owing to its occurrence where it is encountered every day, and its occasional presence in the "staff of life" has been followed by the most serious consequences. Long after its therapeutic value was conceded its constituents were little known, very erroneous conclusions were arrived at by those to whom the credit of its first chemical investigation is due and upon these were based processes for the various pharmaceutical preparations. It is only necessary to compare the product ergotin, formulated by Bonjean and Wiggers respectively, to see the lack of uniformity in the views held by these investigators. These two processes were so radically different that the products were equally distinct in physical and therapeutic properties. The first mentioned aimed at presenting those constituents soluble in diluted alcohol *only*, as being of the most value, to the exclusion of the fixed oil, alcoholic extraction and other well recognized disturbing principles; in Wiggers' process the matter soluble in diluted alcohol, considered the most important by Bonjean, was rejected and the poisonous products claimed to represent the most valuable medicinal properties of the drug. Although ergot is largely obtained in this country, it is small in grain and cannot favourably compare with the large grain Spanish, which, though commanding a greater price, is to be preferred when it can be obtained fresh and free from worms. This ergot presents a dark pearl colour, and when of good quality should present a smooth fracture with a curved violet line; it must not be spongy or yellowish. The preservation of ergot is rather difficult, particularly of the powdered, and different means have been devised to prevent it becoming worm eaten, etc., such as heating before bottling, and addition of camphor, ether and chloroform. Hager has proposed:—

Pulvis Ergotæ Purificatus, which is prepared as follows: Ergot in coarse powder is first exhausted of its fixed oil, by means of percolation with deodorized benzin, it is then extracted with strong alcohol which displaces the benzin and takes up about 2 or 3 per cent. of a black resinous matter and the poisonous alkaloid *ergotinina*. The alcohol is recovered by distillation, and the ergot is spread out in shallow pans set in a warm place so that any remaining odour of benzin may be dissipated. The original process consists only in freeing the ergot from the fixed oil, but the subsequent percolation with alcohol is desirable, as it displaces the greater portion of the benzin, extracts the asphalt-like resin, thus rendering the ergot more readily exhausted with water, and deprives it of the poisonous principle. The purified ergot thus obtained loses from 25

* Read at the third annual meeting of the Illinois Pharmaceutical Association.—Reprinted from the *American Journal of Pharmacy*, January, 1883.

to 30 per cent. in weight, and is therefore of correspondingly greater strength than the crude drug. Unlike the ordinary powdered ergot, this article can be preserved in glass-stoppered bottles for any reasonable length of time, according to the writer's experience, owing probably to the fact that it does not contain any ergotinina to the decomposition of which the rapid spoiling of ergot is due. The coarse powder will be found very convenient for the preparation of wine, infusion, etc., and the finely pulverized can be administered in substance. The petroleum benzin used in this process is the commercial sp. gr. 716. The mode of deodorizing it is as follows: To the benzin add gradually with agitation about 3 per cent. sulphuric acid diluted with an equal quantity of water; after standing decant from the black tarry residue. Wash the benzin with water to which has been added sufficient carbonate of soda to neutralize the acid, decant and then wash repeatedly the benzin, lastly separate carefully from the water or distil. This yields a product possessing very little taste or odour, and will be found very useful in the laboratory and for domestic use.

Oil of Ergot.—The yield of fixed oil from ergot ranges from 25 to 30 per cent. It is very heavy, dark-brown in colour, almost odourless, and sometimes separates, upon standing, stellate tufts of a pearl colour supposed to be *cholesterin.* The oil yields an orange-yellow soap. It has been lately recommended for skin diseases, and the soap could possibly be used to advantage. The writer has used several hundred pounds of the oil as a *lubricator* for machinery and found it *unequalled.*

To determine if the oil contained any alkaloid, it was agitated with very little dilute sulphuric acid; the acid liquid concentrated and an excess of caustic soda added, which threw down a cinnamon-brown body. This precipitate was washed with water, in which it seemed insoluble, and citric acid added. Upon further standing well-defined crystals were formed, which were coloured orange-yellow by sulphuric acid; *but showed no precipitation with alkaloid reagents.* This substance was supposed to be *sclerocrystallin* which, according to Dragendorff, is of no medical importance.

Alcoholic Extractive.—The asphalt-like resinous mass above referred to, extracted with strong alcohol, which, according to Hager, is only fit to burn up, was examined with a view to isolate the alkaloid ergotinina. It was broken up, some soda added and extracted with ether and the ethereal liquid mixed with water, but sufficient soap was held in solution to prevent the liberation of the ether, which should contain the alkaloid, the mixture forming a thick emulsion which after long standing did not show any signs of separation. The production of this rare alkaloid was therefore temporarily abandoned and its isolation is undoubtedly coupled with great difficulties as the most thorough pharmaceutical chemist, Dragendorff, failed in it and is of the opinion it is almost impracticable. The ethereal solution previous to the addition of water left upon evaporation acicular crystals which corresponded in tests and appearance to sclerocrystallin.

Fluid Extract of Ergot.—The official process of the last pharmacopœia was based upon too general a method without any regard for the extraction of the active constituents or their preservation. The addition of acetic acid previous to the concentration of the weak percolate was unnecessary and irrational, as the active principle being itself an acid, an alkali would have been better adapted to prevent its volatilization if fugitive. The alcoholic strength of the menstruum was too great, as it extracted none of the *scleromucin* which is only soluble in alcohol of 40 per cent. and under. The glycerin and the high alcoholic percentage were favourable to the extraction of the oil and the ergotinina, which were possessed of undesirable, if not actually poisonous, properties. The menstruum adopted in the new pharmacopœia will undoubtedly be as *aqueous* as possible to insure a permanent product. Alcohol of 40 per cent. yields a very good preparation representing the drug *fairly,* but still containing more or less fixed oil and alcoholic extractive. The writer is, therefore, of the opinion that the ergot should first be freed from oil and resin, before a fluid preparation can be made from it, representing *all* the valuable medicinal constituents of the drug to the exclusion of inert matter and those principles possessed of undesirable qualities.

Fluid Ergot.—Upon the investigations of Dragendorff, Podwissotzky, Blumberg and others having been made public, new processes were adopted for preparations that would conform to these theories. The writer constructed a formula for a preparation termed fluid ergot, in contradistinction to the officinal fluid extract. As this article has proved during several years' increasing use its superiority over the ordinary fluid extract, and clinical experience sustained the views held in regard to it on theoretical grounds, the process for its preparation might be of interest. The powdered purified ergot, prepared as above, is digested with twice its weight of water at 150°F., for twenty-four hours and expressed, the residue is again macerated in warm water for twelve hours. After settling, the expressed liquids are strained and evaporated separately, when both together measure one-half as much as the ergot employed; they are mixed and sufficient alcohol added to make the liquid of 25 per cent. alcoholic strength, or one-third as much as the aqueous solution. After standing the liquid is filtered and the gummy residue washed with so much 25 per cent. alcohol as to make the filtered liquid measure three-fourths or 75 per cent. of the amount of crude drug employed (volume for weight). To this glycerin is added to make the finished preparation represent the amount of crude ergot originally used, pint for pound. As will be seen, this preparation contains 18 per cent. alcohol, rendering it unobjectionable for hypodermic use. Fluid ergot is an opalescent, amber-coloured liquid possessing a peculiar musty odour. It remains pretty clear unless exposed for a long time to the light or atmosphere. It should, therefore, be kept in small well-filled bottles in a dark place. As stated above, the writer introduced this preparation immediately after the Dragendorff and Podwissotzky investigation; similar products at once appeared under different names, and Hager in his 'Supplement' gives a process for what he terms *extract. secalis corn. purif.* or *ergotina rationaliter parata.* The ergot, according to this process, is extracted with benzin and alcohol, and then exhausted with water, and the liquid concentrated to one-half the bulk of the drug; here the similarity ceases, as Hager employs sufficient alcohol to make the mixture represent 60 per cent. alcohol by volume which precipitates the gum, etc., but also *scleromucin* and renders it necessary to again recover the alcohol by distillation. After this is accomplished the liquid is transferred to a dialysator and dialysed. This part of the process the writer thinks is entirely unnecessary, and almost, if not entirely, impracticable, as decomposition sets in very rapidly in dilute aqueous solution of ergot. The formula for a preparation termed M. Yvons' Solution of Ergotin, appears in Lloyd's 'Supplement to the American Dispensatory.' In this process the crude ergot is extracted with water acidulated with tartaric acid, which is *irrational.* Moreover, the amount of alcohol used in precipitating the aqueous solution is *too* great (70 per cent.), being even more than Hager employs, that all the *scleromucin* and part of the *sclerotic acid* is in danger of being thrown out of solution. Further, to the finished preparation salicylic acid is added to preserve it from change, which is not desirable. After a series of experiments the writer has come to the conclusion that the gummy matter is precipitated with 25 per cent. of alcohol, and as this is all that is necessary to free the liquid from, the employment of more spirit would not be desirable in administration, or entail redistilling, and what is of greater importance the scleromucin, which ranks second in medicinal value of all the constituents of ergot, would not be represented in the preparation. The previous exhaustion of oil, and especially the alcholic extractive favours the easier precipitation of the inert matter with a small percentage of alcohol.

In the commencement of this paper the different methods in preparing ergotin were referred to as indicating the conflicting views held by the various framers of the processes for its preparation. The subject had received scarcely any attention till C. Lewis Diehl's article in the *American Journal of Pharmacy* of Nov. 1881. Mr. Diehl points out the indefinite instructions in Bonjean's original process, in regard to the amount of alcohol used in the precipitation, making also comparative experiments with Carles' and the formula official in the German pharmacopœia. The fact that no difference in yield of ergotin resulted between Carles' and Bonjean's method, in which 77 and 65 per cent., respectively, of alcohol was used, may be accounted for on the theory that all the scleromucin had been precipitated when the alcoholic strength had reached 65 per cent., and that no further precipitation took place to any great extent, till the sclerotic acid is thrown down, which does not commence till the alcoholic strength reaches 80 per cent. The large yield of ergotin obtained by Mr. Diehl by the method of the Phar. Ger. is accounted for by the fact that the alcoholic strength did not exceed 30 per cent., and the preparation contained therefore *all* the *scleromucin* and a great proportion of oil and resinous matter, which are not precipitated till the alcoholic strength reaches 40 per cent. The presence of oil was also shown by the fluidity of the preparation and the resinous matter by its colour. An ergotin of firm pilular consistence cannot be obtained by these methods unless the ergot is previously extracted with benzin, and, still better, subsequently with strong alcohol. The extraction of oil and resin (?) is not advocated on the ground *alone* of rendering the ergot more readily extracted by water, although free from oil, the drug is more readily disintegrated as it lacks that horny surface, but *more* on account of that the *ergotin* will be more concentrated and of better *consistence.*

Sclerotic Acid.—In preparing some sclerotic acid, an opportunity presented itself to determine whether the *purified ergot* was more readily exhausted with water than the crude drug. Ten pounds of purified ergot was macerated and expressed with three times its weight of water in three equal portions, the liquid concentrated to five pounds and alcohol added to bring the mixture to 50 per cent. and filtered. The filtrate was concentrated to a syrup in consistence and alcohol added to make the liquid of 85 per cent. alcoholic strength. The sclerotic acid was quickly precipitated and obtained quite pure after washing with 85 per cent. alcohol. It was of a slate colour, but soon turned brown. Ten pounds of crude ergot in coarse powder was macerated for twelve hours with water, packed in a percolator and eight pints of percolate obtained, again macerated and a second similar quantity of liquid received, alternate maceration and percolation was enforced till the drug was exhausted, which was scarcely accomplished when thirty-two pints of fluid had been recovered. When the orifice was opened after the second maceration quite an explosion took place, indicating the formation of carbonic acid gas, and the process must therefore be watched. The liquids obtained were treated in the same manner as above, nearly 25 per cent. of matter being precipitated and rejected; when the alcoholic strength reached 85 per cent. the sclerotic acid was thrown down, but so contaminated with resinous matter that subsequent washing with alcohol failed to purify it; comparative estimation of the acid was therefore abandoned. Ergotin is largely used in pills and prescribed in pretty large doses, it is therefore desirable to have a preparation of firm consistence and as concentrated as practicable. The following formula is therefore proposed as yielding a product possessing these advantages. The purified ergot as above is exhausted with water as in the preparation of fluid ergot, and the liquid evaporated till one-half the volume of the ergot used, alcohol is added to 25 per cent., after standing filtered and the filter washed with 25 per cent. alcohol. The alcohol is recovered and the aqueous solution evaporated to pilular consistence. The yield is about 15 per cent. of the drug used. This ergotin will be found to keep well, it is not very hygroscopic and one grain represents about six grains of ergot. It can be mixed with sugar-of-milk in various proportions, when of hard consistence and the desiccation completed until it is sufficiently brittle to be triturated to a fine powder. By adding sufficient sugar-of-milk to replace the inert matter of the drug, namely 85 per cent., saccharated extract of ergot is obtained. It was on account of the difficulty experienced in preparing this in a powdered form, which led the writer to extract the fat primarily from the drug. By adopting this procedure all impediments are removed to obtain an extract in the powdered form with even less proportion of sugar-of-milk than the above.

In conclusion, the writer will state that there is no doubt that this extraction of fat from crude drugs with a cheap solvent like benzin can be carried on to a considerable extent, and the extract subsequently obtained can be reduced to, and preserve its pulverulent condition without difficulty, rendering the admixture of absorbent powders in such *great* and *deceiving* proportions unnecessary. But great care should be exercised that the active principles of the drug are not also *even partially* extracted. The extraction of fat, in nux vomica, with benzin, seems, according to some authorities, coupled with danger of dissolving some of the alkaloids, although the writer thinks this is due *more* to an excessive use of the solvent employed. In order to extract the fat from a drug by benzin it is not necessary to have it in fine powder, nor subject it to the action of the solvent by long maceration, as the fat is rapidly taken up. In the main an equal portion, volume for weight, of the benzin is sufficient, and this can be lessened by increasing the height of the column of the drug operated on. With ergot, however, no precaution is necessary, as the alkaloid is sought to be discarded, and the benzin has no action on sclerotic acid of scleromucin.

FERROUS CITRATE AND ITS DOUBLE AND SECONDARY SALTS.*

BY R. ROTHER.

When two or more dissimilar elementary molecules unite, the force which holds each individual molecule together is redirected and distributed in a coincident aggregate whereby the compound molecule is maintained. When the utmost power of all the molecules is exerted the proportional energy of each is termed the atomicity, quantivalence or simply valence of the particular element implied. Since all forces, being modes of motion, are interconvertible, there must be stages during the conversion when the prior and post-prior states are no longer of a kind. Neither is the post-prior mode like the new condition of which it is the immediate antecedent. These peculiar and highly interesting phases may be termed transition forces. They are the dynamic analogues of the states of aggregation that intervene between the solid, liquid, gaseous, and ultra-gaseous conditions of matter. When chemism begins to merge into mere cohesion the bonds of atomicity suffer a further and continuous subdivision no longer definitely characterized in terms of quantivalence. This transitory state may therefore be properly distinguished as ultra-valence. It becomes evident in such cases where compound molecules of saturated valence still continue to combine, and where elementary molecules coalesce with seemingly abnormal capacities. In the opposite direction we also find that many elements most usually do not exert their full atomic power. Such instances are termed apparent valence. This important condition is most thoroughly representative of chemism at its climax. Apparent valence generally gives rise to

* From the *American Journal of Pharmacy*, Jan. 1883.

compounds of the greatest stability owing to the fact that the intra-molecular affinities have been subjected to fewer subdivisions than in the states of higher atomicity. In chemical notation some difficulty is experienced in expressing the formulas of compounds containing the same element in different degrees of valence. Although the atomicity is most usually noted by indices, a much more striking and definite notation would be acceptable. To illustrate a change in that direction the ferrous condition might be indicated by Fo, the ferric by Fi, and the ferrate by Fa. Other elements of varying atomicity could be similarly treated. In course of time ultra-valence will probably command commensurate notice. The chemical notation used in pharmacy is often conveniently abbreviated, especially to avoid writing out in full the complicated formulas of the acids of carbon. But the system employed is not only confusing, but erroneous. The abbreviation for citric acid, for instance, was written Ci, and in its combinations it still appeared as Ci. Now the proper and consistent plan is to designate the radicles only in shortened forms, and hence citric acid may be written H_3Ci.

On a former occasion when treating of ferro-ferric or ferroic citrate the writer obtained the formula for ferrous citrate from a faulty source, stating it to be a triferrous salt, thus, Fe_32Ci. When recently operating on definite quantities of material the writer, however, found that it is a diferrous citrate, thus, $Fe_2H_2Ci_2$, or FeHCi, that is, in fact, a double citrate of iron and hydrogen, or, properly, a hydroferrous citrate. Correctly speaking, a double, triple, etc., salt is invariably derived from a single acid by substitution of the basic hydrogen by one or more basic radicles partially, or by more than one basic radicle wholly. But when the conditions are reversed, that is, when one basic radicle unites with more than one acid radicle, secondary, tertiary, etc., salts are formed. Yet further, when a multiplicity of both acid and basic radicles converge to form a compound molecule then secondary double salts, tertiary triple salts, etc., are produced.

Ferrous citrate, when prepared by boiling citric acid with metallic iron, is a dingy white and sparingly soluble salt. Prepared, however, by acting on ferrous hydrate or carbonate with citric acid it dissolves rapidly in the generated ferric citrate formed by atmospheric oxidation and produces one of the numerous ferroic citrates. Owing to this peculiarity ferrous citrate was credited with such solubility as to be even deliquescent.

One equivalent of ferrous citrate treated with one equivalent of hydrosodic carbonate yields a very soluble apple-green amorphous double salt, the sodio-ferrous citrate FeNaCi, which is readily obtained in elegant scales. But when one equivalent of ferrous citrate is acted on by two equivalents of the carbonate a very soluble grass-green amorphous secondary double salt is formed, the sodio-ferrous hydrocitrate.

$$FeNa_2Ci(OH) \text{ or } \begin{array}{l} Fe\text{—}(OH) \\ \quad \diagdown \\ \qquad \diagdown \\ \qquad Na_2 = Ci. \end{array}$$

Ferrous citrate heated with even four equivalents of sodic phosphate is not entirely dissolved, but the solution is deeply green, and on cooling yields a large crop of spiny crystals of sodic phosphate. Addition of citric acid to the heated mixture immediately separates a copious transparent green gelatinous precipitate, which requires a very large proportion of sodium citrate for solution. It is therefore evident that ferrous citrate cannot be successfully treated with sodic phosphate alone.

If two equivalents of sodio-ferrous hydrocitrate are mixed with two equivalents of sodic phosphate an abundant precipitate of ferrous phosphate, together with a deep green solution, results. An equivalent of citric acid now added dissolves the precipitate completely, or, if incorporated previous to the sodic phosphate, prevents the precipitation.

The admixture of one equivalent of sodic phosphate to two equivalents of sodio-ferrous citrate also occasions a precipitate of ferrous phosphate, redissolved by an equivalent of citric acid, or prevented when this is previously added.

Both of the above cases, therefore, show that half as much more citric acid as these double salts already contain counteracts the formation of precipitates insoluble in the presence of sodic phosphate. The resulting splendidly emerald-green solution contains two very remarkable amorphous salts, the one a double citrate of sodium and iron, the other a citro-phosphate of these metals. Their generation is represented by the following equation:—

$$2\,(FeNaCi) + H_3Ci + Na_2HPO_4 = FeNa_2H_2Ci_2 + FeNa_2H_2CiPO_4.$$

The hydro-sodioferrous citrate and citrophosphate may also be written thus:—

$$\begin{array}{lcl} Fe = Ci & \qquad\qquad & Fe = PO_4 \\ \quad / & & \quad / \\ Na_2 & & Na_2 \\ \quad \backslash & & \quad \backslash \\ H_2 = Ci & & H_2 = Ci \end{array}$$

This saline mixture admits of scaling, but not so readily and elegantly as the sodioferrous citrate above described.

The object in preparing these compounds was to employ them in the various phosphatized and citrated mixtures where permanency of solution is a desideratum. Hence their behaviour towards phosphoric acid is interesting.

Phosphoric acid, when added to any of these salts in moderate proportion, discharges their colour to a great extent, but wholly when added in sufficient excess. The acidulated solution is apparently permanent; however, with a certain inferior proportion of acid, a slight precipitate of ferrous phosphate appears; but the sodioferrous citrate comports itself, in a particularly special manner, distinct from all the rest of these compounds. A sufficient excess of phosphoric acid added at once to this salt produces a clear, permanent and perfectly colourless solution; yet, when phosphoric acid is added in such amount as to leave the solution lightly green, a profuse cream-coloured granular precipitate of the noteworthy triferrous phosphate, $Fe_3(PO_4)_28H_2O$, is produced. This precipitate, when once formed, requires a much larger proportion of phosphoric acid for solution, and also considerable time. Chlorhydric acid dissolves it more freely, yet slowly. Nitric acid attacks it with difficulty after much time. Normal monad citrates are also indifferently active. The reason for its formation under such peculiar conditions is that the salt which yields it contains no hydrogen.

Ferrous citrate is best prepared by heating for about three hours, or until reaction ceases, 56 parts of very fine iron filings with 210 parts of citric acid and a nearly constant 1500 parts of water. As the iron always contains carbon, the quantity will practically have to be about 60 parts. Since the citrate only serves to prepare the soluble forms, any amount of iron in excess is immaterial.

The sodioferrous citrate is prepared by adding to the ferrous citrate of the above process 84 parts of hydrosodic carbonate, heating until effervesence ceases, setting the solution aside till the carbonaceous residue has subsided, decanting the clear liquid, evaporating it to a syrupy consistence, and spreading it on glass or porcelain plates to dry. A definite solution can also be kept on hand.

The sodioferrous citrophosphate is prepared by adding 105 parts of citric acid and 179 parts of sodic phosphate to the product of the preceding process, and proceeding in a similar manner as there directed.

The ferroic citrate above mentioned is a very useful compound, and could, perhaps, in many instances, supplant the ferric citrate. Nevertheless, a complete conversion of the ferrous into ferric citrate would be very desirable. At one time the writer deemed it impossible to convert the ferrous citrate by means of nitric acid, but recent quite successful trials show that it can be done. If 45 parts of nitric acid is added to the ferrous citrate above obtained, and carefully heated to dryness, perfect transformation is effected.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 3, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

POLARIZATION OF LIGHT AND ITS PRACTICAL APPLICATIONS.

IT was a well-deserved compliment paid to Mr. D. CORNELIUS O'SULLIVAN when the Council of the Institute of Chemistry invited him to deliver before the members of its guild and their friends a lecture upon the "Polarimeter and its Practical Applications." If to a minor degree those feelings of reluctance and misgiving which the lecturer confessed himself to have at first experienced still existed, they must surely have been dispelled by the unmistakable signs of appreciation which were manifested by a large and attentive audience. A description of a NICOL'S prism formed a convenient and rational starting point as affording a means by which there could be obtained a single beam of polarized light producing a single image. Two such prisms used together constitute respectively the polarizer and analyser. On placing the prisms one before the other light passes only when the vibrations in the image transmitted by the one are parallel to those transmitted by the other. If now the analyser be turned, the light will be seen to fade, and will be totally extinguished when at right angles to the polarizer. Those instruments which have been devised for the purpose of determining the position of polarized flames are known as polarimeters, and in their construction are dependent on the phenomena produced by plane and circular polarization.

If a ray of light be caused to pass through a plate of quartz, cut perpendicular to the axis, it is divided into two, the vibrations in each being circular and in opposite directions. Hence the terms right-handed and left-handed are applied to the direction of the circularly polarized ray. To distinguish between the two kinds of rotation it is only necessary to imagine oneself looking in a direction opposite to that in which the light is moving; if the plane of vibration be from left to right its rotation will be left-handed and if the conditions be reversed it will be right-handed. Further, it is important to remember that the different coloured rays after leaving the quartz enter the analyser in a condition of plane polarization. It was here observed by the lecturer that a very delicate test for determining the displacement of the plane of polarization was by the use of a bi-quartz arrangement. This consisted in placing side by side two parts of a quartz plate, one being right-handed and the other left-handed quartz. The change of colour in the one would therefore be from red to violet, while in the other this order would be reversed. A uniformity or identity of colour would be observed at the point of transition between the violet and the red. This is known as the neutral tint—*teinte sensible*—and the slightest change in the plane of polarization is followed by the appearance of one of the two distinctive colours (red or violet). Following these observations came a description of JELLET'S prism and saccharimeter; CORNU'S prism; the JELLET-CORNU; LAURENT'S semi-quartz disc; the LAURENT-SAVART'S prism; the WILD and HOFMANN—Quartz Wedge Compensators; the SOLEIL; SOLEIL-DUBOSCQ; SCHEIBLER. The various modifications introduced in these instruments with the object of determining with greater precision the amount of change of the plane of polarization produced by the interposition of an optically active substance here received a merited share of consideration. BIOT'S law, which affirms that the angle of deviation is proportional to the length of the column of liquid and to the quantity of substance contained in that given column, was declared to be true only when the substance was examined under uniform conditions. The rotatory power of a body was alleged to vary in accordance with the solvent employed, the presence of inactive bodies, and the temperature of its solution at the time the observation was recorded. The lecturer appeared less happy in his efforts to explain the meaning of the terms *absolute* and *apparent* specific rotatory power as applied to liquids and solids in solution optically active. The employment of specific rotatory power as a means of testing the purity of those organic bodies which possess the power of displacing the plane of polarization received but an insignificant share of attention, direct reference only being made to quinine and to the terpenes generally. The practical value of the polarimeter in its application to purposes of investigation was little more than hinted at in a passing allusion to the hydration of lactose.

The decomposition of lactose by dilute sulphuric acid into two well-defined bodies, galactose and dextrose, each possessing a rotatory power corresponding to +83·3 and +56° respectively, was instanced as an illustration of the usefulness of prismatic analysis in discriminating between simple bodies and mixtures. At this stage the lecturer, outstripped by the lapse of time, was unavoidably compelled to suppress many important facts, the headings of which found a place in his published syllabus. The hope that the lecture would be published in a complete form found expression through the Chairman, Dr. ODLING, and was unanimously endorsed by the audience. It is not, therefore, too much to expect that the substance of Mr. O'Sullivan's lecture will shortly appear in the form of a monograph and will be placed at the disposal of those who are associated with the Institute of Chemistry.

THE CALENDAR OF THE PHARMACEUTICAL SOCIETY.

The 'Calendar' of the Pharmaceutical Society for 1883 is now ready and copies may be obtained from the Secretary. We observe that this useful annual has now reached no less than 500 pages, for a list of the contents of which we refer to an advertisement on another page.

In addition to the lists of members and others connected with the Society, the donors and subscribers to the Benevolent Fund, the Charter and the three Acts of Parliament directly referring to the establishment and functions of the Society, the 'Calendar' contains abstracts from numerous Acts of Parliament and General Orders issued by Government Departments, the provisions of which are of importance and interest to pharmacists generally. The questions set at the four Preliminary examinations in 1882, all the papers given last year in the competitions for the Jacob Bell Memorial Scholarships, and for the School of Pharmacy prizes are also published in the 'Calendar.'

Once more we must reiterate that we should be glad if the Society's 'Calendar' were more widely known and more frequently consulted, as many of our correspondents would thus be saved the trouble of seeking elsewhere the information it contains, which has been specially compiled for the class to which our readers belong.

POISONING BY MISADVENTURE.

Another of those deplorable cases of fatal poisoning which raise a doubt whether the victims were sufficiently aware of the dangerous character of the preparations they have administered to themselves has during the week formed the subject of an inquest held by Dr. Danford Thomas at Paddington. The medical evidence went to show that death resulted from an overdose of a narcotic preparation. Though it was, of course, impossible to say whether that had been taken intentionally or not, we must of necessity concur in the regret expressed that the practice of taking these dangerous sleeping draughts is so much on the increase.

We desire also to direct attention to the remark of the Coroner that the law would seem to encourage this practice, for though a person going to a chemist's shop and asking for anything which was known to contain poison, would not be supplied with it without signing his name and address, it is possible to purchase patent medicines containing any amount of poison without the least restriction or safeguard. We gladly take the opportunity of endorsing the opinion expressed by the Coroner that in this respect the law is most defective and ought to be amended.

THE NEXT EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, February 7, when the following papers are to be read :—

"A Research on the Alkaloid Gelsemine and some of its Crystalline Salts." By A. W. Gerrard, F.C.S.

"Aromatic Spirit of Ammonia." By Dr. Thresh.

"An Apparatus for Continuous Extraction." By Wyndham R. Dunstan and F. W. Short.

"The Assay of Nux Vomica." By Wyndham R. Dunstan and F. W. Short.

"The Constitution of Liquor Sodæ Chloratæ." By Wyndham R. Dunstan and F. Ransom.

"The Action of Chlorine upon Solutions of Sodium Carbonate." By Wyndham R. Dunstan and F. Ransom.

The next meeting of the Chemists' Assistants' Association will be held on Tuesday evening, Feb. 6, at 9 o'clock precisely, at University Chambers, 53, Conduit Street, W., when a paper will be read by Mr. W. Temple Cooper, Jun., on "Practical Hints on the Examination of Urine."

* * *

Some drysalters and grocers who were recently charged at Strassburg with the sale of adulterated saffron escaped conviction through two curious technicalities. As by the French law, which still rules the practice of pharmacy in Elsass-Lothringen, saffron can not be sold for medicinal use by others than pharmacists without incurring a penalty, it was held by the local tribunal that these sales must have been made for tinctorial purposes; and on the further ground that grocers commonly sell carthamus under the name of saffron, as a substitute for use in dyeing, the accused were aquitted.

* * *

Two medals of gold and two of silver have been placed at the disposal of the National and Central Horticultural Society of France to be awarded to the authors of the best essays on the popular names of plants, especially of those that are cultivated.

* * *

The curious theory has been put forward recently by Dr. W. A. Hammond, of New York, that the seat of instinct is in the medulla oblongata, his argument being based among other observations upon the capacity in acephalic monsters for suckling and similar instinctive acts, providing the medulla be present.

* * *

The *Sanitary Record* mentions the prosecution of a New York grocer for selling as pure cream of tartar a mixture consisting of 92 per cent. of ground gypsum and 8 per cent. of tartaric acid. After more than a day spent in raising and disposing of technical objections, amongst which was one as to the Pharmacopœia being quoted in evidence, a fine of ten dollars was imposed.

* * *

According to some returns recently quoted by Sir J. Fayrer the number of human beings known to have met their death through snake bites in India during the year 1881 was 18,610. Of these deaths 9204 occurred in the Bengal Presidency alone.

* * *

In a discussion on the question of "women pharmacists" in the United States it has been stated that since the year 1868 eleven ladies have graduated from the department of pharmacy in the University of Michigan, but of these nine are not now practising pharmacy. The *Weekly Drug News and American Pharmacist* remarks upon this: "What woman is capable of doing must not be confounded with what she does. . . . After fifteen years the foremost college of pharmacy in the country has been successful in graduating two women who are following the profession.

* * *

The *British Medical Journal* states that in Wisconsin any druggist, apothecary or vendor of medicine is liable to a fine of ten dollars and costs for refilling a prescription marked, "No duplicate."

* * *

Referring to a case of death by poisoning at Poplar, through the substitution of carbolic acid obtained for disinfecting purposes for a medicine, the *British Medical Journal* remarks that "there ought surely to be some method of treating carbolic acid, either by colouring the liquid strongly, or by the use of strongly smelling powders in lieu of liquid, which should put an end to such frequent disasters."

* * *

In a criticism upon the new United States Pharmacopœia, after referring to the preponderance of pharmacists on the Committee of Revision, Dr. Squibb remarks, rather pathetically, that "the prevailing drift of the times seems to be for the medical profession to turn over its most valuable and most practical interest to pharmacy, and that pharmacy as a trade takes no more advantage of this unsafe and unwise drift, is highly creditable to the leaders of that branch of medicine." But Dr. Squibb admits that of the resulting volume "it can hardly be said with too much emphasis that it seems to be by far the best Pharmacopœia of the time." This is a candid admission from the medical gentleman who failed to persuade the American Medical Association to undertake the work.

* * *

The occasion of the resignation by Professor Bentley of the post he has for so many years held as Dean of the Faculty of the Medical Faculty of King's College is to be made the opportunity by many of his old pupils to present him with a memorial of their regard and esteem. The Treasurer of the Fund is Professor John Wood, F.R.S.

* * *

According to the *Lancet* the annual drug bill of one of our largest metropolitan hospitals includes among its items ten tons of linseed meal for poultices, £125; lint, £443; cotton-wool, £183; carbolic acid, £223; carbolized muslin, £180; spirit of wine, £585; potassium iodide, £80; silver nitrate, £111; quinine, £300; cod liver oil, £190; bismuth preparations, £93.

* * *

The "Southall Choral Society" gave its first vocal and instrumental concert on Saturday last at the Priory School rooms in Birmingham. There was a large attendance, and the programme was well sustained by the ladies and members of the choir.

* * *

At the meeting of the Society of Chemical Industry, to be held at the Chemical Society's Rooms, Burlington House, on the 5th inst., Mr. A. H. Allen, of Sheffield, will read a paper on "The Chemistry and Methods of Examining Fixed Oils."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

January 24, 25 *and* 26, 1883.

Present on each day—Mr. Carteighe, President; Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kinninmont, Nesbit and Stephenson.

Professor Maclagan was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

24*th.*—*Four* candidates were examined. *Two* failed. The undermentioned *two* passed, and were declared qualified to be registered as Phamaceutical Chemists:—

Foggitt, John Blackett ....Thirsk.
Gilbert, William John ....Ventnor.

MINOR EXAMINATION.

24*th.*—*Eight* candidates were examined. *Four* failed The undermentioned *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Boyd, Alexander ....Glasgow.
Brown, John ....Stirling.
Buchanan, John ....Bonnyrigg.
Crawford, Thomas ....Leith.

25*th.*—*Eleven* candidates were examined. *Five* failed the undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Harris, Stephen...... ....Droitwich.
Hudson, William ....Sunderland.
Ivatt, Albert.........................Cottenham.
Jary, Joseph James ....South Shields.
Jenner, Harry Albion ....St. Leonards.
Mackenzie, James Calder ......Grantown.

26*th.*—*Ten* candidates were examined. *Six* failed. The undermentioned *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Pirie, William ....Arbroath.
Raine, Ralph William............Newcastle-on-Tyne.
Stirling, George ....Dunoon.
Turner, Alexander ....Dumfries.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Wednesday, January 24, 1883, a lecture was delivered in connection with the above Association, on "Flowers: their Structure and Arrangement," by Mr. F. W. Lewitt.

In the absence of the President, the chair was occupied by Mr. J. Garrett.

In the course of an instructive lecture Mr. Lewitt drew attention to the difficulty which has been experienced in endeavouring to define a flower, and pointed out some of the definitions which had been made by botanists. The arrangement of flowers on the axis of growth was shown and the structure of the different parts and their functions were displayed and by the aid of diagrams ably brought before the audience.

The Chairman proposed a hearty vote of thanks and, upon Mr. G. M. Winter seconding it, in a few appropriate remarks, it was accorded to the lecturer.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

The Present Condition of the Soda Industry.*

BY WALTER WELDON, F.R.S.

About a fortnight ago, the *Times* spoke of the manufacture of soda by the Leblanc process as being, "to some extent, a dying industry." Although I hope to show this evening ground for believing that that industry is not going to die just yet, it has certainly for some time past been in a condition by no means satisfactory to the greater number of those whose capital is engaged in it. For manufacturers of soda by the Leblanc process recent years have been years, in very many cases of loss, and in not a few cases of disaster. Of twenty-five alkali works which were in operation in the neighbourhood of Newcastle-on-Tyne a very few years ago, only thirteen are in operation now; and of the other twelve,† not fewer than eight have been actually dismantled, in utter despair of its ever again being possible to manufacture soda in them by the Leblanc process except at an absolute loss. The alkali-making districts of Lancashire have advantages over the Newcastle district in respect alike of the price of salt, of facilities for supplying the American market, and of nearness to certain of the great English centres of soda consumption; but, nevertheless, even in Lancashire some seven or eight alkali-works are standing idle, and but few of the others are working up to their full capacity. In Belgium, where there are five or six works which formerly made soda by the Leblanc process, matters are even worse, since in that country the manufacture of Leblanc soda has entirely ceased. The only other European countries in which the soda-industry as yet exists are France, Germany and Austria. In these countries the soda-manufacture is protected by the import duties which are stated in the following table:—

Import Duties per Ton.

	France.	Germany.	Austria.
	Francs.	Marks.	Florins.
Soda-ash	41	25	12
„ crystals	19	15	8
Caustic soda	64	40	40
Bleaching powder	35·5	30	15

—duties which, I believe, more than compensate for the greater cost of raw materials in those countries than in England; while in all these countries there is, moreover, a large demand for that bye-product of the Leblanc process, hydrochloric acid. Notwithstanding that the French, German and Austrian manufacturers of Leblanc soda have thus two very sensible advantages over their fellow manufacturers in this country, they have nevertheless grave cause for anxiety: the French manufacturers, indeed, in part owing to a special circumstance which I will mention presently, having reason to regard the future, not only with alarm, but even with dismay.

From information kindly supplied to me by manufacturers in all the countries in which the soda-industry is practised, I have been enabled to draw up a statement of the present total soda-production of the world, and of the proportions in which that production is divided between the Leblanc process and the ammonia process. In drawing up the following table, I have converted all the figures supplied to me, alike those for soda-ash, those for crystals, those for caustic soda, those for bicarbonate, and those for black-ash sold as such, into terms of pure Na_2CO_3:—

Present Soda Production of the World.

	Leblanc Soda.	Ammonia Soda.	Totals.	Ammonia Soda per cent. of Total Soda.
Great Britain	380,000	52,000	432,000	12·0
France	70,000	57,125	127,125	44·9
Germany	56,500	44,000	100,500	43·8
Austria	39,000	1,000	40,000	2·5
Belgium	...	8,000	8,000	100·0
United States	...	1,100	1,100	100·0
Total...	545,500	163,225	708,725	23·0

This table shows that the total quantity of soda now being manufactured annually is nearly 710,000 tons, and that of this quantity more than 163,000 tons are produced by the ammonia process.

I need scarcely say that it is to the very rapid growth of this latter process that is mainly due that condition of the Leblanc process which I have endeavoured to indicate.

Although it is now more than forty-seven years since the ammonia process was first proposed by Dyer and Hemming, it is less than seventeen years since that process was first realized industrially. As an industrial process, capable of being worked continuously and with satisfactory commercial results, the ammonia process dates only from 1866, being the year in which M. Ernest Solvay, of Brussels, began to produce ammonia soda at works which he had established for the purpose at Couillet, near Charleroi. M. Solvay has now two other ammonia soda works in operation,—one in France, at Varangeville-Dombasle, near Nancy, and one in South Germany, at Wyhlen, in the Grand Duchy of Baden,—and by his courtesy I am enabled to place before you the following statement of the quantities of ammonia soda which he has manufactured in each completed twelve months from the 1st of May, 1866:—

		Tons.	
1866—67	...	179	Couillet only.
1867—68	...	465	
1868—69	...	719	
1869—70	...	940	
1870—71	...	1,862	
1871—72	...	2,805	
1872—73	...	3,423	
1873—74	...	3,980	
1874—75	...	4,678	
1875—76	...	5,768	Couillet and Dombasle.
1876—77	...	11,579	
1877—78	...	19,247	
1878—79	...	25,023	
1879—80	...	32,326	
1880—81	...	42,669	Couillet, Dombasle, and Wyhlen.
1881—82	...	53,400	

These figures come down to the 30th April last. Since that date, however, M. Solvay has increased his production by nearly 60 tons per day, or 21,000 tons per annum, so that he is now making ammonia soda at the rate of very nearly 75,000 tons a year. He is thus making ammonia soda on nearly three times the scale on which he was making it four years ago, and on nearly twice the scale on which he was making it only two years ago. In France and Germany, M. Solvay's great success has tempted other manufacturers into the field, and, although none of them

* A paper read before the London Section of the Society of Chemical Industry, at the Chemical Society's Rooms, Burlington House, London, January 8, 1883.

† The quantity of salt decomposed in these twelve works was about 67,000 tons a year. The quantity decomposed in the thirteen works still in operation is about 220,000 tons a year.

are as yet large makers, their total production amounts to fully 35,000 tons per annum, raising the total Continental production of ammonia soda to about 110,000 tons per annum out of a total production by both processes of 275,000 tons. Of the total soda now being made on the Continent, therefore, about 40 per cent. is being made by the ammonia process. While the quantity of Leblanc soda made in France has neither increased nor diminished during the last few years, the quantity of Leblanc soda made in Germany and Austria has increased by several times the quantity formerly made in Belgium; so that not only these 110,000 tons of ammonia soda per annum, but also fully 25,000 tons per annum of Leblanc soda, have been added, comparatively recently, to the soda production of the Continent: going partly to supply increased consumption, but largely to diminish importation from England. And of this vast increase in the Continental production of soda,—four-fifths of which increase is due to the ammonia process,—two-thirds have sprung into existence within the last five years, and a large part of those two-thirds within only two years.

In England, within the last two years, the production of ammonia soda has been nearly trebled. The ammonia process is practised in this country as yet only by one firm. In 1873 it was not in operation in this country at all. In that year our Honorary Foreign Secretary, Mr. Ludwig Mond, arranged with M. Solvay for the right to work under his patents in this country, and in the following year, in conjunction with Mr. J. T. Brunner, Mr. Mond began to make ammonia soda at Winnington, near Northwich. Messrs. Brunner and Mond began on a very modest scale, their production in 1875 not exceeding 2500 tons; but in 1878 their production rose to 10,000 tons; in 1880 it was 18,800 tons; and it is now at the rate of not less than 52,000 tons per annum, or at very nearly three times the rate of only two years ago.

The competition of the ammonia process with the Leblanc process has thus attained its present degree of seriousness only very recently indeed. It has come upon the makers of Leblanc soda almost like a thunderbolt out of a clear sky.

And, serious as that competition is already, it is about to become even more serious still. Not only is it to be expected of the existing ammonia soda works that those of them which have recently so greatly increased their production will go on increasing their production, and that those of them which have more recently started will grow as the older ammonia soda works have grown, but new ammonia works are being built. M. Solvay, who has already, as I have said, a work in operation in South Germany besides his French and Belgian works, and who is already by far the largest soda-maker in the world, will soon have a work in operation in North Germany also, at Bernburg, near Stassfurt; and he is now, moreover, erecting a work in Russia, and also a work in the United States, and is on the point of commencing the erection of a work in Austria, so that by-and-by he will be making soda in no fewer than seven distinct works, in six different countries. In addition to all this, a large work to make ammonia soda, not on M. Solvay's system, but on a system modified from that practised at Dieuze, is being erected near Stassfurt by the Company of Buckau; an ammonia soda work is building, and will be started in the spring, at Favorznow, near Cracow; and one is about to be built at Siebenburgen, in Transylvania,—not to speak of the intention of Messrs. Bell Brothers to build an ammonia soda work at Middlesbro. The new works which are thus in course of construction, and some of which are nearly completed, will throw on the market more ammonia soda, to the extent of not less, from the commencement, than from 65,000 to 70,000 tons a year.* For Leblanc soda makers, it is thus as though ammonia soda had latterly rained from the skies during two days out of every three, and the shower were now on the point or becoming continuous.

While face to face with so serious an amount of competition, actual and imminent, on the part of the ammonia process, the Leblanc process pure and simple is now further threatened with what is surely the "most unkindest cut of all," namely, with competition from the Leblanc process itself—combined with the extraction of copper from Spanish pyrites.

To explain how this has come about, I must remind you that the sulphuric acid used in the Leblanc process is now invariably manufactured from the sulphur of pyrites; that the pyrites used in this country is now almost exclusively either Spanish or Portuguese pyrites, containing two to three per cent. of copper and very small quantities of silver and gold; that after most of the sulphur has been burnt off from the pyrites, as the first step in the manufacture of sulphuric acid, the residual "burnt ore," or "pyrites cinders," as it is called, is treated by the wet way for the extraction from it of copper, and in most cases now of gold and silver also;* and that what remains when these have been extracted is an almost pure oxide of iron, which finds a ready sale for use for various purposes in connection with the manufacture of iron and steel. The supply of this cupreous pyrites is for the most part monopolized by three great companies—the Tharsis Company, the Rio Tinto Company, and Messrs. Mason and Barry. These companies not only supply nearly the whole of the pyrites used in the manufacture of sulphuric acid in England, but the Rio Tinto Company also supplies annually some 60,000 tons of pyrites to Germany, and is also beginning to send pyrites into Austria. None of the three companies, however, has been able to sell an ounce of pyrites in France.

The reason of this is that in France itself there are two large deposits of pyrites, both belonging to soda-makers: one belonging to the Compagnie de St. Gobain, and the other to MM. Pechiney et Cie. Each of these companies itself uses its own pyrites; and the former of them supplies with pyrites the greater number of the other alkali-makers in the North of France, while the latter

---

* As no complete list of ammonia soda works has yet been published, it may be interesting here to give one. The following list includes all the works now actually in operation:—

England:—
Winnington
Sandbach

Germany:—
Wyhlen
Duisburg
Inowrazlaw
Grevenberg
Dieuze
Trotha
Heilbronn
Nürnberg
Rothenfelde

France:—
Dombasle
Giraud
Sorgues
St. Denis
Lille

Belgium:—
Couillet

Austria:—
Boszko

United States:—
Bay city

Ammonia soda works are now being built in the following localities:—

Austria:—
Favorznow
Siebenburgen
?

Russia:—
Beresniki

Germany:—
Stassfurt
Bernburg

United States.—
Syracuse.

There is a reason why the locality of the work which M. Solvay is about to build in Austria may not yet be published.

* A German analysis of Rio Tinto pyrites gives the following results per 1000 kilos:—

495 kilos sulphur.
430 ,, iron.
30 ,, copper.
10 ,, lead.
26 grammes silver.
180 milligrammes gold.
150 grammes bismuth.

supplies with pyrites all the other alkali-makers of the South of France. It has obviously been impossible to sell Spanish pyrites to either of the two great soda-making firms, each of which thus has pyrites and by no means dear pyrites of its own, and each of which is a large seller of pyrites to other soda-makers; and the other French soda-makers, for the most part, have been precluded from even considering the question of changing to Spanish pyrites, if only by reason of the French habit of contracting for the supply of raw materials over very long periods. A French manufacturer's contract for raw materials is generally a contract for fifteen years; and most of the French soda-makers are now obtaining their pyrites under contracts which have yet a considerable time to run.

Under these circumstances the Rio Tinto Company has taken a remarkable step. To understand the motive to this step, it must be borne in mind that while French pyrites does not contain copper, and so has scarcely any value beyond that of the sulphur which it contains, Spanish pyrites has a considerable value in addition to its sulphur value. While the value of Spanish pyrites for the sulphur in it is equal to that of the best non-cupreous pyrites, its value for copper is greater than its value for sulphur, and, not to speak of its value as regards precious metals, it has also a considerable value for its iron. In this country, the cinders left after as much as possible of the sulphur of non-cupreous pyrites has been burnt off are considered to have no value at all; and even in France,—where the import duty on cast-iron is greater than the present price of Glasgow pigs, and where all forms of iron are therefore appreciably more valuable than in this country,—the cinders of non-cupreous pyrites are not worth more than three francs per ton. They always contain sulphur, and sometimes contain phosphorus. The cinders of cupreous pyrites, before treatment for the extraction of copper from them, also contain sulphur, and in larger quantity than the cinders of non-cupreous pyrites; but the treatment to which they are subjected for the extraction of their copper removes the whole of their sulphur, and also the whole of their phosphorus, if they have contained any, leaving a residual oxide of iron of great purity. This residual oxide, or "purple ore," as it is called, now sells in this country for 12*s.* per ton, and in France it would doubtless command a higher price.

Now, in this country a state of things has grown up under which the manufacturers of Leblanc soda derive no advantage from the value for copper and iron of the pyrites which they employ. The treatment of the cinders of cupreous pyrites has become in this country a separate industry, practised only in a few instances by alkali-makers themselves, but practised for the most part by companies or individuals who do not themselves make soda, but who either buy from soda-makers the cinders of pyrites of which the soda-makers have bought both values, the copper value as well as the sulphur value, or themselves buy both values, selling only the sulphur value to the soda-makers, or else buy direct from the pyrites sellers the copper value only: the pyrites sellers in such cases selling the copper value of their pyrites to one purchaser and its sulphur value to another. It is an industry which yields fair commercial profits, so that soda-makers may be incurring actual loss, while those who deal with the cinders of the pyrites from which the soda-makers have burnt off sulphur are at least making a living. And while the treatment of the cinders of Spanish pyrites is fairly profitable in this country, the greater value of iron and iron ores there than here would doubtless render it more profitable in France. It is true that coal is more costly in France than in England; but the quantity of coal required for treating pyrites cinders is not great.

The course, then, which the Rio Tinto Company is taking is this. Unable to sell its pyrites to the French Leblanc soda-makers, it has determined that the Leblanc soda made in France, or at least a large part of it, shall nevertheless be made by means of Rio Tinto pyrites, and to this end it has promoted a subsidiary company, "La Compagnie d'Exploitation des Minerais de Rio Tinto," which company is to make Leblanc soda in France and elsewhere, relying for its profits neither on soda nor on chlorine, but on copper and oxide of iron. For this company, soda and chlorine will be simply bye-products, which it will be glad to sell at a profit, if that may be, but which, if that may not be, it will be content to sell at the bare cost of manufacturing them. It will manufacture them only for the sake of converting Rio Tinto pyrites into pyrites cinders.

This new company proposes to operate upon an enormous scale. It has a capital of 1,200,000 pounds sterling, of which one-half is already paid-up, and there is talk of its building in France no fewer than five great works: one of which, designed, and to be managed, by Englishmen, it has already commenced, in the neighbourhood of Marseilles. The result cannot but be very grave for the existing French Leblanc soda-makers, and must inevitably affect the makers, both of Leblanc soda and of ammonia soda, in this country also.

Moreover, this new company will not confine its operations to France. Not only will it take Spanish pyrites to the United States, and there make sulphuric acid, extract copper, and obtain "purple ore,"—large quantities of which at present go from England to America,—but it will also build a large soda-making and copper-extracting work,—which will certainly affect the English alkali trade,—in the neighbourhood of Antwerp. The Leblanc process will thus be re-introduced into Belgium, not as a substantive process, but simply as a part of a combination of processes for the utilization of cupreous pyrites.

To such complexion has the Leblanc process come at last. Originally, soda was its only commercial product, the hydrochloric acid produced during the first stage of it being turned to no account. In time a demand grew up for chlorine, that hydrochloric acid began to be utilized, and the manufacturers of Leblanc soda now sent into the market two products, by each of which they gained profits. Then their soda ceased to be profitable, and became a kind of bye-product, which they continued to make only because they could not otherwise make chlorine. Now, Leblanc soda gives no profit at all, and chlorine none to speak of; and both have come to be regarded as secondary products, to be made only incidentally, and only because making them is essential to the application to certain ores of the wet method of extracting copper.

Returning to the ammonia process, when that process first began to threaten them, the makers of Leblanc soda comforted themselves by two considerations: one of which was that the ammonia process must itself tend to check its own extension, by reason of the loss of ammonia inseparable from that process so increasing the demand for ammonia as to materially raise the price of that body. They knew that the constantly increasing demand for ammonia for the purposes for which it was already employed had doubled its price within twenty years; and they thought that every further extension of the ammonia soda process must still further increase the market-value of ammonia, until at length the ammonia process would cease to have any advantage over the Leblanc process. So far, however, from that anticipation having been realized, despite the immense extension which the ammonia soda process has recently undergone, the price of ammonia is now beginning to fall. The delusion that it was impossible to collect the ammonia given off from coke-ovens without spoiling the coke is at last giving way before accomplished facts; ammonia is now being obtained commercially not only from coke-ovens, but also from another source, wholly unforeseen and unexpected; and the time, moreover, seems at last to have dawned when there will be collected and utilized as ammonia at least a portion of the nitrogen of nearly all the fuel burnt either for industrial or for domestic purposes.

In France, ammonia has been collected from coke-ovens for a number of years past.* It is fully ten or twelve years since M. Carvés said to French coke manufacturers: "I wish you to try my system of making coke, but I do not ask you to risk one farthing in doing so. If you will permit me, I will build coke-ovens in your works at my own expense. I will guarantee you against all risk of the coke produced being of inferior quality; so that, if I fail, you shall be no loser. If I succeed, I will ask you for no money royalty, nor will I ask you to pay me for the coke ovens: I will only ask that you shall give me for a short term of years one-third of those products which I shall condense, but which, at present, you do not condense." This offer was accepted by some of those to whom it was addressed, with results quite satisfactory both to them and to M. Carvés. Quite recently, coke-ovens on the Carvés system have been erected in South Durham, and about three months ago ammonia from them began to appear in the market.

This fact, however, is not nearly so important as something which has been done simultaneously in North Durham. While the Carvés system of making coke gives important results, it has the disadvantage of requiring coke-ovens of a special construction. It could thus extend only in proportion as the existing coke-ovens were replaced by new ones; and replacement of the present ovens by Carvés ovens would naturally be a slow process. For a method of collecting ammonia and other volatile products from coke-ovens to obtain wide application rapidly, it must be a method applicable to existing coke-ovens; and a method applicable to existing coke-ovens at a very slight expense, has been recently devised by an English inventor, Mr. John Jameson, of Newcastle-on-Tyne. His method has now been in operation for nearly six months at the works of our vice-president, Mr. Hugh Lee Pattinson, at Felling, near Gateshead; and Mr. Pattinson authorizes me to state that he has "reason to be abundantly satisfied with the results." The products condensed are the products of the distillation of coal at a very low temperature. They include, per ton of Northumberland steam coal operated upon, an average of 11 gallons of oil, and ammonia equal to 12 pounds of ammonium sulphate. The oil is a crude paraffin oil, of 0·9 sp. gr., containing from 8 to 10 per per cent., according to the coal employed, of solid paraffin. The yield of oil will probably not be greatly increased; but it is expected that the yield of ammonia, the appliances for collecting which at Felling have hitherto been imperfect, will be increased considerably. There is also obtained, per ton of coal treated, from 12,000 to 15,000 cubic feet of combustible gases. The coke obtained is fully equal, both in quantity and in quality, to that obtained by coking the same kind of coal in the ordinary way. The cost of applying the system to existing coke-ovens does not exceed £30 per oven. Licences for applying it to 100,000 tons of coal per annum have already been applied for, and there is every prospect that its application will extend very rapidly.

While during the last few months ammonia has thus begun to be collected from English coke-ovens, it has also begun to be collected from Scotch blast-furnaces. In Scotland, there are some handred and twenty blast-furnaces which are worked with raw coal. Some months ago a member of the firm of William Baird and Co., who happens to be also a director of a gaswork, Mr. William Ferrie, was struck by the idea that the methods employed for separating ammonia and tar from crude illuminating gas might be used for separating the same bodies from the gases from blast-furnaces in which raw coal is used; and although the volume of the gases from such furnaces, per ton of coal employed, is about thirteen times greater than that of the gases obtained by distilling the same kind of coal in retorts—is not less, that is to say, than 130,000 cubic feet—Mr. Ferrie's idea has been put into execution with complete success. From two of the sixteen blast-furnaces at the Gartsherrie Ironworks ammonia and tar have been regularly collected for some months past, and preparations are in progress for collecting them from the other fourteen blast-furnaces there. The quantity of ammonia at present being obtained at Gartsherrie is the quantity corresponding to about 18 cwt. of ammonium sulphate per day, being at the rate of 20 lb. of ammonium sulphate per ton of coal consumed. The other products condensed from the blast-furnace gases have more resemblance to ordinary gas-tar than the corresponding products obtained from the Felling coke-ovens. They are products of the distillation of coal at a temperature intermediate between the temperature at which distillation goes on in those coke-ovens and the temperature at which it is performed in gasworks; and, though the value of the blast-furnace tar has not yet been fully ascertained, it is believed to be nearly as valuable as ordinary gas-tar, though not quite. The results thus obtained at Gartsherrie have led to endeavours at other Scotch ironworks to accomplish the same object in other ways; and experiments to this end are in progress at the Monkland Ironworks, the Summerlee Ironworks, the Airdrie Ironworks, and others; so that we may fairly expect that the time is not far distant when all the ammonia and all the tar which are evolved from Scotch blast-furnaces will be collected and sent into the market.

Each of these one hundred and twenty Scotch blast-furnaces consumes, on an average, 50 tons of coal per twenty-four hours. The total quantity of coal consumed in them per annum is thus $50 \times 120 \times 365 = 2{,}190{,}000$ tons. The quantity of ammonia yielded per ton of coal being, as I have said, the quantity corresponding to 20 pounds of ammonium sulphate, there can thus be obtained per annum from these one hundred and twenty blast-furnaces a quantity of ammonia corresponding to nearly 20,000 tons of ammonium sulphate, worth, at the present selling price of that commodity, not less than £400,000.

Large, however, as is this quantity, it is only one-tenth of the further quantity which can be obtained from English coke-ovens. The quantity of coal coked annually in England is not far short of 20,000,000 tons, and if Mr. Jameson's system were applied to the whole of our coke-ovens, with the result of collecting, per ton of coal treated, the same quantity of ammonia as is obtained from the Gartsherrie blast furnaces, there would be obtained from this source per annum the quantity of ammonia corresponding to 180,000 tons of ammonium sulphate, at present worth more than three and a half millions sterling. Nor is even this all; for I shall have to speak in a moment of another possible, and I believe probable, source of ammonia, even more extensive still.

Now, of the ammonia employed by the ammonia soda maker, he loses from one-fiftieth to one-fortieth part. As he has to employ from one and a half to one and three-quarter equivalents of ammonia for each equivalent of sodium carbonate finally obtained, we may take it that he loses about one twenty-third of an equivalent of ammonia for each equivalent of sodium carbonate manufactured. In terms of ammonium sulphate, being the terms in which the loss of ammonia in the ammonia soda process is usually stated, this loss corresponds to about five and a half parts of ammonium sulphate per hundred parts of sodium carbonate produced. The total annual loss of

* Not, however, I find, to any considerable extent. The only system of collecting ammonia from coke-ovens which is in use in France is the Carvés system, and that is in use only in three works—at Tamaris, at Terre Noire, and at Bességes. The total quantity of coke produced in Carvés ovens in France is 300 tons per day, and the total quantity of volatile products condensed from these ovens per day consists of 6 tons of tar and ammonia equal to from 2 to 2½ tons of ammonium sulphate. The coal used in the works in question is much less nitrogenous than ordinary English coal.

ammonia in the manufacture of the 163,000 tons of ammonia soda now being produced per annum thus corresponds to just about 9000 tons of ammonium sulphate. This is, no doubt, a large quantity of a commodity worth £20 per ton; but, in comparison with the extent of the new sources of ammonia which have just begun to be turned to account, it is utterly insignificant. It is less than one-twentieth part of the quantity capable of being yielded by blast-furnaces and coke-ovens in Great Britain alone, and is a smaller fraction still of the quantity which, I believe, can be obtained from another source which has yet to be mentioned. We may, therefore, be quite certain that the progress of the ammonia soda process will not be hindered or limited by any difficulty as regards supply of ammonia.

(*To be continued.*)

CHEMISTS' ASSISTANTS' ASSOCIATION.

The first paper for the second half-session 1882-83 of this Association was read on Wednesday evening, January 17, by the President, Mr. W. A. Wrenn, entitled "Half an hour with the Plants used in Perfumery." The chair was occupied by the Vice-President, Mr. C. Parkinson.

In his opening remarks Mr. Wrenn alluded to the controversy which has existed as to the propriety of pharmacists to engage in the manufacture and retailing of perfumes and toilet essences, or whether it would be more advantageous (the matter of £ *s. d.* excepted) to leave the sale to the perfumer proper. The flowers and fruits yielding essential oils most prominently mentioned were bergamotte, cloves, jasmin, lavender, narcissus, orange, pelargonium, rose, tuberose and violet. When referring to the oil distilled from the fruit of *Citrus Bergamia*, Mr. Wrenn exhibited some crystals obtained from the following mixture, which had been allowed to remain for two months, with occasional agitation.

Take—

Ess. bergamotte . . .	40	cubic centimetres.
Spirits of wine . . .	5	„
Acid nitric (sp. gr. 1·200)	10	„
Water	45	„

The crystals were said to resemble those of terpin hydrate as obtained by Mr. R. H. Parker from turpentine, detailed in a paper read before the British Pharmaceutical Conference last year. Reference was also made to substances used in perfumery, such as musk, ambergris, etc. In the preparation of essence of musk the author recommended the addition of a small quantity of acetic acid to prevent the accumulation of ammoniacal gas. The use of benzoic acid in cases in which essences were not made from French pomades was noted as increasing the lasting fragrance of the perfume.

The paper, which was profusely illustrated by samples of pomades, essential oils, flowers, etc., kindly supplied by numerous well-known Grasse perfumers and their London representatives, was listened to by a full complement of members and visitors.

A lengthy discussion followed, in which Messrs. Alcock, Braithwaite, Glen, Millhouse, Palmer, Parkinson, Wyatt, and others took part.

A vote of thanks to the President, proposed by Mr. Sangster, and seconded by Mr. Cooke, brought the meeting to a termination.

ROYAL INSTITUTION.

The Primæval Ancestors of Existing Vegetation and their Bearing on the Doctrine of Evolution.

BY PROFESSOR C. W. WILLIAMSON.

The third lecture of this course was delivered on Tuesday last. The following is an abstract:—

The living Equisetums constitute a very distinct group, the members of which exhibit very slight variations from a common type, either of appearance or of organization. The British species vary in height from 1 to 5 or 6 feet, but some South American forms are as much 20 feet in height; but even these tallest examples rarely attain an inch in diameter. The most conspicuous external characteristic of the order is seen in the leaves. These spring from each node of the stem or branch in verticels, in each of which the bases of the leaves are coalesced for fully half their length from a cylindrical sheath. In most of the species branches are also given off from the nodes. Turning to their internal organization, we find that in the Equisetaceous stem the vascular element is reduced to a lower condition than in any other of the vascular Cryptogams. The pith is usually hollow at its centre, whilst at its periphery it is perforated by a ring of vertical canals, which branch at each node, so that those of each internode are vertically intermediate to those of the respective nodes above and below. This alteration in the position of these internodal canals is important, since it reappears in the most ancient fossil forms. Immediately external to each canal we find a very small number of scalariform vessels, the sole representatives of the developed vascular zones of the higher plants. In British forms we usually have but one or two such vessels at each of the outer angles of the canal. In some South American forms these vascular bundles are rather more developed, but are always insignificant. Externally to this ring of vascular bundles is an ample bark enclosed within an epidermal layer, which is more or less silicified.

The reproductive system of the Equisetums is very distinctive of the order. The spore-bearing structures are often at the upper extremities of each of the stems indiscriminately. In some species they are only found on specialized branchless stems. In every case the fruit is a strobilus or cone, in which the several verticels of leaves are peculiarly modified. Each leaf of each verticel stands out at right angles from the central stem or axis, and terminates in a flattened shield-like expansion, from the margin of the inner surface of which there projects yet more internally a ring of cellular bags, or "*Sporangia.*" Each of these bags is filled with small spores of very distinctive forms. Each spore has four radiating arms, with club-shaped extremities. When unripe these arms closely embrace the central spore. When ripe, they uncoil themselves, and thus, occupying more space, they burst the walls of the enclosing *Sporangium* and make their escape. Each spore when germinating develops a small branching *Prothallus.* These Prothalli are usually diœcious; the smaller ones bearing *Antheridia* or male organs, representing pollen sacs, and the larger ones bearing *Archegonia* or female structures. Some few are monœcious, both antheridia and archegonia being found on the same Prothallus. These prothalli develop young *Spongonia* or bud-bearing organs, and then wither. The spongonium then develops into the spore-bearing plant known as the Equisetum.

This modern type of Equisetum seems to have existed from a remote period of the world's history, being found in but slightly modified forms in the Tertiary, Cretaceous, Oolitic and Triassic strata. In the latter bed they attained to much more gigantic dimensions than is reached by any living forms, both as regards height and diameter. On reaching the Carboniferous strata we leave behind us the true Equisetums which are now represented by the grander forms known as Calamites, but in the rhœtic and triassic beds, between the base of the Oolites and the Peruvian and Carboniferous strata, we find a genus Schizoneura, intermediate in some respects between the Equisetums and the Calamites. In its young state it has the coalesced sheathing verticles of leaves of the Equisetums; but at an early age each verticellate sheath spilts longitudinally into two or more free leaves, approaching the verticels of free leaves, devoid of sheaths, characteristic of the foliage of the Calamites.

This latter genus assumed an aborescent form both in its growth and organization. We now understand much of its structure, from that of its smallest twigs up to stems of considerable magnitude. That it sometimes exceeded 30 feet in height is certain, whilst specimens exist which when living must have been from 2 to 3 feet in diameter. The young twigs were purely cellular in structure, but a series of vertical canals, like those of the Equiseta, ran from node to node. Almost simultaneously with the formation of these, woody wedges began to be developed externally to each of these canals and the cellular pith became fistular or hollow, except at such node. Outside the vascular layer was a uniform bark.

In this early state of growth the Calamite seems to have had regular verticels of small branches given off from at least several of its uppermost nodes, which branches have verticels of free, more or less, linear leaves; but it rapidly underwent further changes. Immediately external to the vascular zone was a cambium layer, which added a succession of exogenous growths to that zone, which thus attained to considerable dimensions. A second, more external zone, capable of forming new growths, existed near the outer part of the bark, and which developed a very dense layer of prosenchyma, approaching somewhat closely to the Bast of modern barks. The ordinary Calamites found in sandstones are usually but the inorganic casts of the central cavities of the pith, and may always be recognized by the transverse constrictions at the nodes. These constrictions have no existence, even at the exterior of the vascular zone, still less so outside the Bark. The specimens found in shales also represent similar casts of the pith, invested by a thin layer of coal, which is the sole and insignificant residue of the thick tissues of the pith, wood and bark, nearly the whole of which have disappeared. Most of the verticellate branches also have been arrested in their growth, those that underwent permanent development having an unsymmetrical arrangement, giving the matured stem a very different aspect from that of the young growth.

Many verticellate-leaved plants have been mixed together under the names of *Asterophyllites*, *Annularia*, *Sphenophyllum*, etc. That some of these were leafy branches of Calamites is most certain. Equally so that many of them were not, as is proven by the peculiarities of their internal organization. We have not yet learned to distinguish the true calamitean leaves from what are not calamitean, in the case of those structureless specimens of which the external form alone is preserved. This is also the case with the calamitean fruits. We possess a large number of Strobili under the names of *Volkmannia*, *Bruckmannia*, *Calamastachys* and others, each of which possesses some features in common with those of living Equisetums, and from each of which forms these Equisetums may have derived one or other of their peculiarities; but this portion of the subject will require much further investigation before it will be finally understood. Two things, however, are certain. One is that these most ancient Equisetiform plants had no appendages to their spores corresponding to the elastic club-shaped *Elaters* of the living Equisetums. The other is that some of them were Heterosporous, *i.e.*, possessed both male and female spores like many of the Lycopods and other Cryptogams, which is not the case with any known living Equisetum. The latter are but the degraded representatives of a once magnificent race of forest trees which culminated in the carboniferous age.

Parliamentary and Law Proceedings.

Prosecutions under the 17th Section of the Pharmacy Act.

At the Petty Sessions, Northampton, on Wednesday, January 24, before W. Coulson, Esq. (Mayor), Chairman, and a full bench, Mary Ann Carter, 42, Leicester Road; Alfred Hughes, 49, Bearward Street; Thomas Welford, 11, Upper Mounts, and Thomas Cattell, 34, Wellingborough Road, appeared in answer to a summons charging them for unlawfully selling poison in a packet, the cover of which did not set forth the name and address of the seller of the same.

Mr. Henry Glaisyer, Solicitor, Birmingham, prosecuted on behalf of the Chemists and Druggists' Trade Association of Great Britain. Mr. A. Andrew, Solicitor, Northampton, appeared for the defendant Cattell, the other defendants appeared in person.

Mr. Glaisyer said the summonses had been issued under the 17th section of the Pharmacy Act, 1868, which enacted—"It shall be unlawful to sell any poison either by wholesale or by retail, unless the box, bottle, vessel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller of the poison." Mr. Wright came to Northampton on January 16, and visited the shops of the defendants where he purchased one pennyworth of oxalic acid which was labelled "Oxalic Acid—Poison. J. H. Blunt and Son, Wholesale and Retail Druggists, etc., 46, Drapery, Northampton." The defendants had no right to sell oxalic acid or any other poison scheduled under the 17th section of the Pharmacy Act, as they were not registered as chemists and druggists.

Mr. Andrew pleaded guilty on behalf of his client.

The Mayor remarked that oxalic acid was used a good deal in the shoe trade, and informed the defendants that only registered chemists and druggists had a right to sell it.

Mr. Glaisyer said he had brought the defendants there in order that publicity might be given to the law.

A fine of 1s. and costs was inflicted in each case.

Review.

A Dictionary of Medicine, including General Pathology, Therapeutics, Hygiene, etc. By various Writers. Edited by Richard Quain, M.D., F.R.S., etc., etc. London: Longmans. From the Publishers.

It will take a long time to fully appreciate the value of Dr. Quain's 'Dictionary of Medicine.' It stands alone in the great world of literature, and will for many years mark an epoch in the medical literature of the nineteenth century. We do not believe that anything comparable to it has previously existed. It is true that Dr. Copland wrote a dictionary of medicine, whic cost him a life's labour, and as a book for reference it had a large circulation and unquestionably a deserved reputation. When, however, the science of medicine of to-day is compared with what it was when Dr. Copland lived we see what a hopeless task it must be for any man to try to accomplish unaided this truly great work with which Dr. Quain's name is so honourably associated. We find many of the articles are written by Dr. Quain himself, and by his co-workers Dr. Mitchell Bruce and Dr. Roberts, to whom Dr. Quain generously admits in the preface that he is greatly indebted. Yet, the battle has been Dr. Quain's, and he must ever be looked upon as the victorious general who has not only planned, but worked out, even to the minutest detail, the entire work of this herculean and successful literary campaign. It is truly a campaign which has extended over eight years of Dr. Quain's life, and scarcely a day of this somewhat long period of time has passed without something being done towards its accomplishment. It is truly a lasting monument of indefatigable and unwearying labour, and we should not be doing our duty either to the profession which it represents or to its respected and esteemed editor, if we did not preface this notice of the work with words of cordial congratulation. The articles are generally well written, with a terseness and conciseness which is most commendable, though not easily attainable. Some few have apparently been in hand some time, even years, and might with advantage be re-written for the next edition. In looking over the army of contributors we find the names of men of the highest position in the sphere of medicine and men who are known to do well everything which they undertake to do, and this we maintain is the best guarantee which can be given that their work is well done, not only with regard to the highest scientific truth, but with moral truthfulness, earnestness and sincerity.

There are a hundred and fifty-eight contributors, and among these we find the time-honoured names of James Paget, Erasmus Wilson, Joseph Fayrer, William Jenner, W. B. Carpenter, Murchison, Parkes, Henry Thompson, Spencer Wells and Miss Nightingale. It is curious and important to notice how prominently specialism manifests itself in every page of this work. The specialist who, twenty years ago, was denied and almost tabooed as though he were some impostor or quack, now ranks foremost in the best literary work of our time. We find excellent articles by Mr. Brudenell Carter, "On the Diseases of the Eye and its Appendages;" by Dr. Jones, of New Orleans, "On Yellow Fever;" by Sir Henry Thompson, "On Diseases of the Bladder;" by Dr. Playfair, "On Diseases of the Womb;" by Miss Nightingale, "On Nursing, and the Training of Nurses;" by Mr. Spencer Wells, "On Diseases of the Ovaries;" by Erasmus Wilson, "On Eczema;" by Dr. Roberts, "On Gout;" and by the late Dr. Silver, "On Diabetes." Dr. Grainger Stewart's carefully written article "On Diseases of the Kidneys" is unique, and it is surprising to find that he has been able to treat so important a subject with such thoroughness and completeness in so small a space. We are pleased to find so great an authority advocating local blood-letting and dry cupping in active congestion of kidney, a mode of treatment deserving more attention than is usually admitted by the dreamy and hazy therapeutics of this period. Dr. Wiltshire's contribution "On Blood-letting" deserves attention, and at every point of importance it develops the practical mind of the author. He says:—"It is almost certain (we would say it is quite certain) that in either extreme there is an evil, and that we may have recourse in certain cases to abstraction of blood with some degree of that success which formerly led to its extensive use if not its abuse." The late Dr. Pearson Irvine gave a very interesting article "On the Causes of Disease," and in speaking of heredity as a prolific source of predisposition to disease. he says, "There is amongst men not only an inheritance of such prominent diseases as phthisis, but of peculiarities in the manner they meet and pass through minor ailments. Thus in families with a 'nervous history' we meet with predisposition to headaches of nervous type, irregularities of digestion in the form of diarrhœa and vomiting, and a multitude of conditions which have of late been ascribed to vasco-motor disturbance. The members of some families live long in spite of exposure to almost every exciting source of mischief, and contrast most favourably with others, who, as far as one can determine, have all things in their favour." We quote these observations merely as an indication of the nature of the article. Dr. Bastian writes a short but good article on "Bacteria." It is well known that Dr. Bastian is not a believer in the germ theory of disease, and he even doubts that germs have an essential share in fermentation. He says, "The vital or germ theory of fermentation would be broken down and become untenable whenever it is shown that fermentation can originate independently of the bacteria and their germs, which appear as part of the process. Similarly the germ theory of disease would be refuted if it could be shown that some of the morbid processes in question would originate in the absence of the living organisms which subsequently appear as part of the pathological products. The question of 'spontaneous generation' comes, therefere, to be inextricably mixed up with the question of the truth or falsity of the germ theory of disease, so that the study of the latter, to the neglect of the former, can only end in vagueness and uncertainty." Dr. Lauder Brunton, in his article on tonics, gives a bit of advice which may prove serviceable. He says, "In administering tonics care should be taken to ascertain that the case is suitable, for in very many cases of apparent debility the imperfect functional activity of the body or of its parts does not depend upon insufficient nutrition but upon imperfect removal of the products of waste. The proper treatment in these cases is not to give tonics but to remove the waste products by cholagogues, purgatives and diuretics." All the articles "On Nervous Diseases" are well written, but we would draw the special attention of our readers to the very valuable contribution "On Epilepsy," by Dr. Brown-Séquard, and "On Epileptic Insanity," by Dr. M. G. Echeverria, and at the same time we must admit that we regret not to find the respected name of Hughlings-Jackson amongst this class of contributors. Dr. Green gives an exhaustive article on "Pneumonia," and Dr. Powell and Dr. Williams deal with the subject, of "Phthisis. Dr. Gee writes on "Tubercles." Sir James Paget has something to say upon his old love "Pathology." Sir William Jenner writes upon one of his favourite themes, "Deformities of the Chest." Dr. Broadbent writes upon "Fevers," treating the subject with the authority of experience, and he does not fail to remind us that quinine and salicylic acid are valuable therapeutic agents to reduce temperature. Mr. Simon writes on "Contagion," and Dr. Southey "On Personal Health;" both of these articles must be of great interest to those engaged in the study of "Preventive Medicine." It will be a grand day for science and a day of comfort and happiness to living beings in general when the generation and propagation of disease germs can be snuffed out of existence and when health shall reign supreme. It need scarcely be said that this day has not arrived, but the future lies before us and who is there bold enough to predict what shall or what shall not come to pass? To attempt anything like a review of this Dictionary is as impossible as it would be out of place in the columns of this Journal, but the work is one which could not be passed by without some notice and we do hope that sufficient has been said of it to commend it to the highest consideration of our readers.

Permanganate of Potash Pills.

Sir,—As permanganate of potash pills seem to be attracting some attention and no one has as yet suggested the method which has appeared to me best, I venture upon offering you a few lines which I extract from notes for the next edition of my 'Pharmacy.'

"There are a few chemicals occasionally prescribed in pills which are more or less subject to decomposition by contact with organic matters; the silver salts may be taken as common examples and permanganate of potash as an extreme case of this kind. The latter body is best made up with China clay and water.

"No. 27.

"℞ Potassæ Permangan. . . . . . . gr. xxiv.

"Ft. pil. xii.

"Add China clay in powder, 36 grains; water, 18 dropss

"A good pilular mass is thus obtained which keeps it physical and chemical condition satisfactorily, and disintegrates promptly in water, yielding the permanganate unchanged."

I do not know why any one should add grease to clay when water is all that is required to make it "as plastic as clay," and the absence of organic matter is desirable.

Newcastle. Barnard S. Proctor.

A RESEARCH ON THE ALKALOID GELSEMINE AND SOME OF ITS CRYSTALLINE SALTS.*

BY A. W. GERRARD, F.C.S.

The alkaloid under notice is yielded by the *Gelseminum sempervirens*, or Carolina jasmine. The natural order of the plant is doubtful, being placed by De Candolle in the Loganiaceæ, by Decaisne in the Apocynaceæ. The drug found its way into regular medical practice through the eclectics, and is now official in the United States Pharmacopœia.

In this country it has attained a good reputation for the treatment of toothache and neuralgia. The part of the plant used is the root, from which are prepared a tincture and liquid extract, also a resin called gelsemin. A detailed account of the history, characters and composition of the plant will be found in a valuable paper by E. M. Holmes, in the *Pharmaceutical Journal*, December 18, 1875.

The first communication within my knowledge, having reference to the chemical constituents of gelseminum root, was contributed by Kollock to the *American Journal of Pharmacy*, 1855, p. 203, the principal facts elucidated being, that it contained gelseminia, dry resin, volatile oil, fatty resin and a yellow colouring matter. This was followed in 1869, with a paper by Eberle, who examined the woody portion of the root for alkaloid, and states, "The wood of the root can be safely asserted, from careful experiment, to be free from alkaloid." This observation I have corroborated. In 1870 an important addition was made to our knowledge of its constituents by Dr. Wormley, who discovered the presence of an interesting highly fluorescent body, which he named gelseminic acid. At the same time he described the physical characters and chemical reactions of the alkaloid gelsemine.

In 1876 Professor Sonnenschein communicated to the *Berichte d. deutschen Gesellschaft, Jahr.* ix., the results of analyses of gelseminic acid and the alkaloid gelsemine. For the alkaloid was found the formula $C_{11}H_{19}NO_2$, and for its hydrochloride $(C_{11}H_{19}NO_2)_2HCl$. No simple crystalline salts were obtained by either Sonnenschein or Wormley. For gelseminic acid Sonnenschein gave the formula $C_{30}H_{34}O_{19}$ and claimed its identity with esculin. This claim has since been controverted by Wormley.

Five years ago, I prepared some gelsemine for physiological use, and particularly noticed that the published processes for its extraction did not yield a product that could be called pure, as it was more or less coloured yellow or brown. I also observed that traces of gelseminic acid persistently adhered to the alkaloid, as evidenced by the fluorescence of the latter in the presence of alkalies. At this time I was strongly impressed with the above defects, and doubted not that if gelseminia could be obtained in a sufficient state of purity (possessed as it is of such strongly basic characters) its salts could be made to crystallize. The small quantity of alkaloid at my command did not admit of many experiments, and these were without result. Later on, I prepared the alkaloid in small quantity, and obtained one of its salts in microscopic crystals, sufficiently well defined to determine me to make an investigation on a larger portion of material. I am now able to state I have prepared in the crystalline form the pure alkaloid and a number of its salts.

Method of Extraction.—Twelve kilogrammes of well-powdered root were exhausted with alcohol, which left after distillation 1703 grams of soft extract. The extract, on resting, separated into two strata.

The superstratum, green in colour and having the appearance of an oleo-resin, was removed and found to be practically insoluble in water; it was well shaken with dilute hydrochloric acid to remove traces of adhering alkaloid, and the acid solution mixed with the substratum. The substratum, containing the alkaloid, was diluted with water until it ceased to precipitate resin, and left a clear bright brown solution, which was evaporated at a temperature below 60° C., treated with ammonia in excess and thoroughly washed with ether. The ether solution, now containing the gelsemine and beautifully fluorescent from the presence of gelseminic acid, was decanted and exposed a short time to allow excess of ammonia to escape. Hydrochloric acid was next added in fractions with agitation until the fluorescence was destroyed, a certain indication that the whole of the alkaloid had been removed from the ether. The hydrochloride of gelsemine had now separated from the ether, forming a layer of pale yellow amorphous precipitate, which upon separation was subjected to several reconversions, until the last traces of colour and fluorescence had disappeared, the product being 20·2 grams of perfectly white hydrochloride of gelsemine. It may here be mentioned that the pure alkaloid obtained from the hydrochloride by alkali, and chloroform or ether, holds its solvents tenaciously, and requires the heat of a water-bath to effectually remove them. During their removal the gelsemine swells into vesicles which, on cooling, can be easily powdered.

Properties of Gelsemine.—It is a brittle transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it, the solution on cooling becoming faintly turbid from separation of gelsemine. It softens at 38° C. and becomes fused at 45° C. Heated on platinum it ignites, burning with an orange-yellow flame and leaving no trace of residue. Solutions of its salts have a distinctly but not powerfully bitter taste, and give with potash or ammonia white precipitates soluble in excess. If the solution containing excess of ammonia be exposed to the air, as the ammonia is eliminated the gelsemine separates in granular crystals. The pure base gives no colour reaction with strong nitric acid, and the mixture is scarcely changed in colour by heating. Strong sulphuric acid has no apparent reaction upon it; but if to the mixture a little manganic oxide be added and rubbed with a glass rod, a deep crimson red is obtained, passing to green. This reaction is exceedingly delicate, and can be easily shown by dissolving 1 milligramme of pure gelsemine in 10,000 milligrammes of strong sulphuric acid, then adding a few milligrammes of manganic oxide. It can be even demonstrated with a solution of 1 in 100,000. If the preceding reaction is performed upon the pure alkaloid, the colour is sufficiently intense to cause it to be mistaken for strychnia; but if a parallel experiment be carried on with strychnia the two alkaloids cannot

* Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.

be mistaken, for the strychnia gives an intense purple, passing to red. Picric acid gives a yellow crystalline precipitate; gold chloride, a yellow amorphous precipitate, soluble in boiling water, separating on cooling, partly in crystals. Platinic chloride gives a yellow precipitate, soluble on boiling.

REACTIONS ASCRIBED TO GELSEMINE.

	Gerrard.	Sonnenschein.	Wormley.
Strong nitric acid . . .	No reaction.	Yellow-green colour.	Brownish-green, changing to deep green colour.
Strong sulphuric acid. .	No reaction.	Yellow-green, passing to reddish-brown colour and upon heating to dark red.	Dissolves with a red or brown colour which after a time assumes a pinkish hue. Warmed it acquires a chocolate or violet colour.
Sulphuric acid and manganic oxide	Gives a damask red colour, passing to green or blue.		
Strong sulphuric acid, and bichromate of potash in crystal . . .	A crimson evanescent redness passing to a green colour.	A cherry-red colour, changing a little to violet, which soon form a bluish-green spot.	Reddish-purple streaks along the path of the crystal.
Gold chloride	Yellow precipitate, soluble when heated.	Yellow precipitate, not altered by heat.	
Platinum chloride . . .	Amorphous yellow precipitate, soluble in water on heating.	Amorphous yellow precipitate, soluble in water on heating.	
Potash mercuric iodide .	White precipitate, which dissolves on heating and separates on cooling.	A white precipitate, which dissolves on heating and separates on cooling.	

The following salts were prepared and obtained in crystals. Hydrochloride, hydrobromide, sulphate and nitrate. The hydrochloride is a moderately soluble salt, separating from water as an apparently amorphous powder, consisting really of small granular crystals. It is sparingly soluble in cold, more soluble in hot alcohol; from the latter it separates slowly in prismatic crystals. The hydrobromide crystallizes more readily from water and alcohol than the hydrochloride, forming prisms. The sulphate and nitrate were freely soluble in water and alcohol, and crystallized indifferently on spontaneous evaporation.

Since the alkaloid I obtained differed in important respects from that experimented upon by others, and was evidently in a higher state of purity, it was thought desirable to submit it and some of its compounds to combustion.

Three determinations of nitrogen were made by the absolute method, from the pure alkaloid, and the following percentages by weight calculated:—7, 7·3 and 6·9.

Four combustions with cupric oxide and copper of quantities varying from ·100 to ·200 gram gave the following percentages of carbon and hydrogen:—

	C.	H.
1.	70·4	7·2
2.	70·1	7·3
3.	70·3	6·9
4.	70·45	7·3

Taking the oxygen by difference these figures admit the construction of the following formula for gelsemine, $C_{12}H_{14}NO_2$, for which theory requires 70·6 C, 6·86 H, 6·86 N, and 15·68 O.

The chlorine was estimated from the hydrochloride, and 8·1 per cent. found, showing the composition of this salt to be $(C_{12}H_{14}NO_2)_2HCl$, which requires 7·96 per cent. chlorine. In like manner, the hydrobromide was found to yield 16·21 per cent. bromine $=(C_{12}H_{14}NO_2)_2HBr$, which requires 16·3 per cent.

The platinum and gold salts of the alkaloid were purified and burnt; the former gave 16·7 per cent. platinum, the latter 36·9 per cent. gold, pointing to a composition for the former of

$$(C_{12}H_{14}NO_2)_4(HCl)_2PtCl_4,$$

for the latter $(C_{12}H_{14}NO_2)_2HCl(AuCl_3)_2$, these requiring respectively 16·4 platinum and 37·4 gold.

The main features of this as differing from previous researches show—(1) that the alkaloid gelsemine can be obtained in a state of purity as a crystalline colourless solid, forming crystalline salts with acids, and giving no colour reactions with nitric or sulphuric acids; (2) that the pure base has the formula $C_{12}H_{14}NO_2$, thus differing greatly from the formula obtained by Sonnenschein, who, it is certain, must have used an impure substance, as shown by the colour reactions his alkaloid gave with nitric and sulphuric acids.

Forensic Note.—In cases of poisoning by gelseminum, where the resin, extract, or tincture have been employed, no difficulty need be experienced in detecting its presence, all these preparations containing gelseminic acid, which imparts its powerful blue fluorescence to any mixture on the addition of an alkali. When the alkaloid gelsemine has to be sought, its isolation can be effected by any of the methods followed for strychnine, especially taking advantage of the fact that gelsemine like strychnine is not destroyed by strong sulphuric acid. After isolation, and showing its alkaline and alkaloidal nature, its most special reaction would be the red colour with sulphuric acid and manganic oxide. These characters alone should scarcely be deemed sufficient evidence of its presence. In addition, its physiological action should be sought and demonstrated; if this be obtained it may be concluded gelsemine is present.

The Physiological Action of Gelsemine. By Dr. G. Rouch.

The results at which I have arrived are somewhat doubtful, so that I submit them without being too positive as to their significance.

If 2 to 5 milligrams of the hydrobromide of gelsemine in aqueous solution are injected into a red frog (*Rana temporaria*) there is observed a slight shaking and some manifestations of excitability which pass frequently unperceived; there is a notable loss of vivacity and the animal does not jump so easily; placed on his back he turns himself over with difficulty and is not long before he remains completely torpid. This condition, which begins ten to fifteen minutes after the injection, is about complete in half an hour.

The difficult respiration set up on the administration of the drug becomes speedily normal in all cases where the dose has been a weak one; nevertheless it may continue for a long time, especially as regards the hyoidiene region. In the particular case to which I refer, I cannot estimate it, a portion of the dose having been spilt. When the movements have quite disappeared the posterior limbs quite relaxed are drawn towards the body, but the anterior limbs are in a peculiar position. They are sometimes in the form of a bow, and crossed under the sternum, thus lifting the anterior region; occasionally they are divergent on the sides of the body, the forearms bent at right angles on the arms, and the hands resting on the ground. They keep this position whatever may be the posture given to the animal, and in the first case if he is turned on his back they form a bow into which the finger can be introduced and the animal lifted. The animal may die in this position after several hours, or the next day, the heart being the last to stop. If the dose is weak this state may last several days.

From the beginning the frog seems to have lost voluntary power, it remains completely inert, but the reflex movements are kept up longer, the contact of a corrosive liquid producing co-ordinate movements which end subsequently to the complete paralysis.

The above results do not change if one of the posterior limbs is preserved by the ligature of the iliac artery, the two members lose their reaction equally, and on the other hand the electric excitability of an induced current, even very feeble, on the sciatic nerves, produces tetanus of equal intensity on both sides, and this happens several hours after the complete paralysis, whilst the heart has almost stopped. This would lead us to conclude that the hydrobromate of gelsemine has a paralysing action on the excito-motor centres.

In experimenting on the green frog (*Rana esculenta*) I observed quite different toxic manifestations. As I have not been able to repeat these experiments I shall give them with reserve.

After toxic effects almost similar to those I have described in the case of the red frog,—less violent, however, and with greater allowance made for the medullary hyperexcitability,—I found two days after injection the animal breathing in the position described above, lifted up by the anterior limbs crossed in a circle under the sternum, but different from what I had seen before by a notable reflex hyperexcitability. A blow on the vessel which contained it produced a tetanic extension of the posterior limbs, the two limbs parting forcibly in complete extension, the fingers like a fan, sometimes simultaneously, sometimes one after the other, but diverging and not approaching the middle line as with strychnine. These manifestations resemble rather the symptoms of picrotoxin, or the beginning of the intoxication by brucia. These tetanic contractions are of very short duration, but are unique for each excitation and rarely spontaneous. The tetanus can be reproduced by a shock of the vessel; a blow on the table would not be sufficient. Occasionally the animal utters a little cry. These symptoms lasted three days, improving gradually until they had completely disappeared, and the animal executed voluntary movements which allowed it to escape.

One can only be astonished at such a different action. The dose stands for nothing in the present case, for I have kept a red frog slightly intoxicated which did not give similar phenomena, any more than others which had received considerable doses. I am thus brought to admit there is a different susceptibility in the two species of frogs. The experiments of Messrs. Prevost and Wintzmie on brucia had led them to analogous results, although inversely.

I should have liked to have analysed all these toxic manifestations and to have defined more clearly what belongs to different parts of the nervous system. I would also have liked to repeat my researches on warm-blooded animals; but I have sacrificed what I had left of the gelsemine on a guinea pig, without result. I prefer, then, to leave the facts which I have thus crudely demonstrated to be decided by a future study.

Paris, January, 1883.

Action on the Eye. By Prof. J. Tweedy, F.R.C.S.

Though less irritating and more prompt in its action than the earlier preparations, I could not in any case with the crystallized gelsemine obtain distinct paralysis of accommodation such as follows the instillation of a solution of atropine. As with the earlier preparations, I found the dilations of the pupil preceded by a brief contraction stage, accompanied with a zone of ciliary injection. The contraction and ciliary injection passed away with equal steps.

COMPLETE EXHAUSTION OF NUX VOMICA.*

BY R. ROTHER.

Tincture of nux vomica is an important and useful preparation, and by virtue of its active principles a very powerful one. Definiteness in its construction should therefore be one of its prime features. It is questionable whether the primitive method at present in use really secures a saturated solution. Neither the strychnine or the other alkaloids are free, since the great excess of igasuric acid insures compounds which, although soluble in alcohol, are but sparingly soluble in water. Now, by reason of a peculiar gummy substance contained in nux vomica, insoluble in alcohol, in which the alkaloidal compounds are imbedded, alcohol can only exert a surface action, and hence will be effective in a measure in proportion to the fineness of the powder. Although water or weak alcohol softens and permeates the horny body, either of them fails to extract the now sparingly soluble igasurates. It is therefore evident that nux vomica cannot be exhausted by any form of alcohol. Acidulated alcoholic menstrua

* From the *American Journal of Pharmacy*, January, 1883.

are equally powerless, because igasurates, like tannates of the alkaloids, are indecomposable by weak acids.

Seeing that the gummy matter is the chief obstacle to exhaustion, the writer sought to decompose it, in a preliminary operation, by means of dilute sulphuric acid. Failing with this, ammonia was tried with a little success; but having accidentally added some borax to the ammoniacal mixture a rapid coagulation was noticed. Upon this, powdered nux vomica was mixed with borax and percolated with a menstruum composed of equal measures of alcohol and water, and, although absolute exhaustion of the powder was readily achieved, the percolate possessed such an obstinate turbidity that the process, otherwise so satisfactory, was yet a failure. Boric acid, applied in a similar manner, was as inefficient as other acids previously tried. It was next resolved to test potassium citrate, which insured a satisfactory product, and absolute extraction of the drug. Deeming a simpler saline body more appropriate and obtainable, the writer resorted to sodium chloride, and attained, above all others, the most perfect result.

It is remarkable what a solvent action a saline substance has on the active constituents of nux vomica; the horny matter is speedily softened, permeated and extracted without becoming in the least mucilaginous or distended. The weak alcoholic saline menstruum percolates the powder with such freedom that this must be very firmly packed, and the flow of the percolate further regulated with appropriate checks. The thorough exhaustion is effected, in all probability, by reason of a double decomposition occurring between the igasurates and the sodium chloride in the presence of weak alcohol, resulting in the generation of strychnium chloride, brucium chloride and sodium igasurate, all of which being very soluble in diluted alcohol. When this solution is diluted with water a retrograde decomposition sets in, the igasurates of the alkaloids are precipitated, and sodium chloride remains in solution.

From a consideration of the above cited results the following facile formula for an absolutely representative tincture of nux vomica is obtained.

Take of—Nux vomica, in fine powder . . 8 troy ounces.
Sodium chloride . . . . 6 drachms.
Alcohol,
Water . . . . of each $1\frac{1}{2}$ pint.

Dissolve the sodium chloride in the water; then add the alcohol, and mix them. Upon two troy ounces of the nux vomica, contained in a large capsule, pour two fluid ounces of the menstruum, and mix them by means of a pestle; then gradually add the remainder of the nux vomica, and thoroughly mix the whole as before. Pack this mixture very firmly into a cylindrical glass percolator, and pour on of the menstruum little by little until, in the course of six to eight hours, the liquid has descended to the bottom of the column. Now suspend the operation, and after twelve hours pour on more of the menstruum, and regulate the flow at the exit so that after twenty-four hours two pints of percolate may be obtained. To avoid a trace of turbidity, which is liable to appear in the first fluid ounce of percolate when the menstruum is added too rapidly at first, $1\frac{1}{2}$ drachm of the sodium chloride may be mixed with the nux vomica before packing, and the remainder dissolved as before. The finished tincture contains $\frac{1}{4}$ grain of sodium chloride in 15 minims.

DELPHINIUM AJACIS.

From experiments with acetic and aqueous infusion of the larkspur, Dr. Benvenuti draws the following conclusions:—The flowers of the *Delphinium Ajacis* possess an insecticide action, and are to be preferred to other remedies of similar action on account of cheapness and absence of smell. They have a marked anæsthetic action, are excitant, rubefacient, astringent and antizymotic. Dr. Benvenuti thinks this remedy has many points of resemblance to carbolic acid and iodoform.—*Louisville Med. News.*

A BILL

INTITULED AN ACT TO REGULATE SALES OF POISONOUS ARTICLES, ALSO TO FURTHER REGULATE THE SALE OF POISONS AND ALSO TO ALTER AND AMEND THE PHARMACY ACT, 1852, AND THE ACTS AMENDING THE SAME.

Preamble.—Whereas it is expedient for the safety of the public that sales of poisonous articles should be regulated, also that any seller or keeper of an open shop for the retailing, dispensing or compounding of poisons and medical prescriptions should possess a competent skilled knowledge, and also that sales of poisons should be further regulated. And for the purposes aforesaid or some of them it is expedient that the provisions contained in the Act passed in the 15th and 16th years of the reign of Her present Majesty intituled an Act for regulating the qualification of Pharmaceutical Chemists, hereinafter described as the Pharmacy Act, 1852, and in the Acts amending the same, should be amended, Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by authority of the same, as follows:—

1. *Definition Clause.*—Words importing the singular number only shall include the plural number.

2. *Regulations to be observed in the Sale of Poisonous Articles.*—It shall be unlawful to sell by retail any poisonous article for the time being in the Schedule of poisonous articles hereto, unless the box, bottle, vessel, wrapper or cover in which the same is contained be distinctly labelled with the name of such poisonous article and the word "poisonous," and with the name and address of the seller thereof. And the Council of the Pharmaceutical Society of Great Britain may, from time to time, declare by resolution that any article ought to be added to the said Schedule of poisonous articles, and shall submit the said resolution for the approval of the Privy Council. And if such approval shall be given such resolution and approval shall be advertised in the *London Gazette*, and on the expiration of one month from the advertisement any article named in any such resolution shall be deemed to be added to the said Schedule.

3. *Regulations on Sales by wholesale of Poisons in Part 1 of Schedule A. to the Pharmacy Act,* 1868.—Notwithstanding any exception or thing in section 17 of the Pharmacy Act, 1868, contained, every seller by wholesale of any poison for the time being in the first part of Schedule A. to the Pharmacy Act, 1868, shall keep a record in writing of the name of such poison, the quantity sold, the name and address of the purchaser, and the date of the sale, and shall preserve such record for twelve calendar months.

4. *Labelling of Patent Medicines being or containing a Poison.*—It shall be unlawful to sell by wholesale or by retail any patent medicine or any article bearing a patent medicine stamp (herein comprised in the words patent medicine), being or containing a poison within the meaning of the Pharmacy Act, 1868, unless the box, bottle, package or vessel in which the same is contained, the wrapper, if there be only one, or the outermost wrapper if there be more than one, be labelled with the name and

address of the first seller of the same, the name of the patent medicine and the word "poison."

5. *Penalties for certain Offences.*—Any seller acting in contravention of either of the preceding sections shall, upon a summary conviction before two justices of the peace in England or the sheriff in Scotland, be liable to a penalty not exceeding £5 for the first offence, and to a penalty not exceeding £10 for the second or any subsequent offence.

6. *Duly Qualified Keepers of Open Shops Entitled to Remedies in certain Cases.*—In case a duly qualified keeper of an open shop for the sale of poisons is exposed to a penalty in respect of a sale by retail of a patent medicine not prepared for sale by him by reason of the box, bottle, package, vessel, or wrapper in which the same is contained not having been duly labelled in the manner hereinbefore provided, he shall, after having paid the same, be entitled to be indemnified in respect of the same, and any costs properly incurred by him in relation to the offence or conviction, or his defence thereto, by the owner of the said patent medicine, or by any intermediate seller of the same, and every intermediate seller shall be entitled to be indemnified over by the first seller of the said patent medicine, or any intermediate seller of the same: provided always that in claiming such indemnity the seller must prove that he purchased the said patent medicine not knowing it to be otherwise than properly labelled, and sold it in the same state in which he purchased it, and any seller or owner from whom such indemnity is claimed may prove that the conviction was wrongful, or that the amount of costs awarded or claimed was unreasonable.

7. *Persons Keeping Open Shops to be liable for their Assistants, Apprentices and Servants.*—All the provisions of the Pharmacy Act, 1868, which apply to sales of poisons, and all the provisions of this Act which apply to sales of poisonous articles, or to sales of poisons whether as patent medicines or otherwise, or to medicines compounded from medical prescriptions, shall be deemed and taken to apply to any seller on whose behalf any sale is made by any assistant, apprentice or servant, and such assistant, apprentice or servant shall be deemed to be the agent of the seller on whose behalf any such sale is made.

8. *Regulation for Conducting Branch Businesses.*—It shall be unlawful for a duly qualified keeper of an open shop for retailing, dispensing or compounding medical prescriptions or poisons to keep open shop in more places than one, unless he shall engage and employ at each branch shop a person who would himself be a duly qualified keeper of an open shop for retailing, dispensing or compounding medical prescriptions or poisons, and such person is *bonâ fide* occupied in such branch shop, provided always that each partner in a duly qualified partnership may keep a separate open shop for retailing, dispensing or compounding medical prescriptions or poisons.

9. *Duly Qualified Persons to sell Medical Prescriptions and sell Poisons.*—It shall be unlawful to sell by retail, or to keep open shop for retailing, dispensing or compounding medical prescriptions or (whether as patent medicines or otherwise) poisons within the meaning of the Pharmacy Act, 1868, and any Act amending the same, unless the seller and the keeper of any such open shop be a pharmaceutical chemist, or chemist and druggist, or a medical practitioner entitled to and acting within the exemption concerning certain medical practitioners made by section 1 of "The Pharmacy Act (1868) Amendment Act, 1869," or entitled to and acting within the exemption concerning certain executors, administrators and trustees made by section 16 of the Pharmacy Act, 1868, provided, nevertheless, that nothing in this section contained shall extend to or interfere with the business of wholesale dealing in patent medicines, nor with the business of wholesale dealers in selling poisons in the ordinary course of wholesale dealing, or of any member of the Royal College of Veterinary Surgeons of Great Britain, or person holding a certificate in Veterinary Surgery from the Highland and Agricultural Society in Scotland, or whose name appears on the Register of "existing practitioners" under the Veterinary Surgeons Act, 1881, in dispensing medicines for animals under his care.

10. *Persons keeping Open Shop must, on Application, Inform the Registrar of the Name or Names of Proprietor or Proprietors, and Penalty for Non-Compliance.*—The Registrar of the Pharmaceutical Society of Great Britain may, at any time, and from time to time deliver, or cause to be delivered to the seller or the keeper of any open shop for the retailing, dispensing, or compounding of medical prescriptions or poisons, or at any shop purporting to be the shop of a pharmaceutical chemist, or pharmaceutist, or chemist and druggist, or chemist, or druggist, or whereat there shall be assumed, used, or exhibited any name, title, or sign implying that it is the shop of a person registered under the Pharmacy Act, 1852, or the Pharmacy Act, 1868, a notice signed by him requiring delivery to him within seven days thereof of a statement in writing of the name and address of such seller, or the keeper of such shop, and of his qualification so to sell or to keep such shop, and thereupon such seller or the keeper of such shop shall, within such seven days, cause to be delivered to the said Registrar a statement accordingly, and in default thereof, every such seller or keeper of such shop shall be liable to a penalty of £5 for each day so long as such default shall continue, and every person afterwards, during continuance of the default, found selling poison at, or compounding medical prescriptions at, or acting in the management of the business at such shop shall be liable to a penalty of £5 for each such offence, and the said penalties may be sued for, recovered and applied in the manner provided in section 11.

11. *Penalties and Recovery and Application of Certain Penalties.*—Every seller or keeper of an open shop for retailing, dispensing, or compounding medical prescriptions or poisons, acting in contravention of either of the three preceding sections numbered 8, 9 and 10 shall, for each contravention, be liable to pay a penalty of £5, and the said penalties of £5 may be sued for and recovered in the manner provided by the Pharmacy Act, 1852, for the recovery of penalties under that Act, and all and every sum and sums of money which shall arise from any penalties so recovered for offences incurred

under sections 8, 9, and 10 of this Act, or under the said Pharmacy Act, 1852, or under section 15 of the Pharmacy Act, 1868, shall be paid to the Treasurer of the Pharmaceutical Society of Great Britain, and shall by him be applied to the purposes of the said Acts, and this Act or either of them. And in any action or proceeding for the recovery of any penalty directed to be sued for by the Registrar of the Society in the name and by the authority of the Council of the said Society, the name of the said Society alone may be used, and it shall not be necessary to give evidence of the appointment of the said Registrar, or of the authority of the said Council and the full amount of the penalty incurred shall be recovered.

12. *Regulations may be made by Bye-law to Sub-divide Examinations, etc.*—It shall be lawful for the Pharmaceutical Society of Great Britain from time to time by any bye-law to make, alter, or amend regulations respecting examinations so as to divide or sub-divide the same, and to require and regulate periods of time and of practical experience, or any course of study between examinations, or any divisions of the same, and to regulate the notices to be given and the fees to be paid by candidates on the giving of notices for, or the passing of examinations or the several divisions of the same and on registration.

13. *Certificates of having passed Preliminary Examination Requisite to Apprenticeship.*—On any division or sub-division of examinations there shall be provided a division to be called the Preliminary examination and a Register of the persons who have passed the same, and thenceforth any pharmaceutical chemist or chemist and druggist who shall take as apprentice any person who has not previously obtained from the Registrar of the Pharmaceutical Society a certificate to the effect that he is registered as having passed the Preliminary examination shall be liable to a penalty of £5, to be sued for and recovered in the manner provided in clause 5.

14. *Certificates may be accepted in lieu of Preliminary Examination.*—It shall be lawful for the Society from time to time by any bye-law to accept evidence of degrees, qualifications, or certificates granted by other examining bodies in lieu of the said Preliminary examination and thereupon to authorize the Registrar to register the person entitled to the same as having passed the Preliminary examination.

15. *Certificates of Death and Expense of same.*—Notwithstanding the provisions of section 11 of the Pharmacy Act, 1868, every registrar of deaths in Great Britain shall, on transmitting to the Registrar under the Pharmacy Act, 1852, of every certificate of the death of any pharmaceutical chemist, or chemist and druggist, charge the cost of such certificate and transmission as an expense of his office.

16. *Certain Persons to be Registered as Pharmaceutical Chemists and Eligible for Membership.*—Every person who, after December 31st, 1886, shall obtain a certificate of competent skill and knowledge and qualification under section 6 of the Pharmacy Act, 1868, shall be entitled to be placed on the Register of Pharmaceutical Chemists and shall be eligible for election to membership of the Pharmaceutical Society of Great Britain according to the bye-laws thereof.

17. *Certain Persons to be Eligible for Membership.*—Every person who, on or before December 31st, 1886, shall have been registered as a Chemist and Druggist by reason of having obtained a certificate of qualification from the Board of Examiners, shall be eligible to be elected a Member of the Pharmaceutical Society of Great Britain, according to the bye-laws thereof, but no person shall, in right of membership acquired pursuant to this clause, be placed on the Register of Pharmaceutical Chemists.

18. *Certain Claims for Registration not valid unless made before 1st January, 1885.*—No claim for registration as a Chemist and Druggist made by notice accompanied by certificates of having carried on business before the passing of the Pharmacy Act, 1868, shall be valid or effectual unless notice in accordance with section 5 of the said Act be duly given prior to the 1st January, in the year 1885.

19. *Repeal of Section XI. of Pharmacy Act, 1852, and Section XX. of Pharmacy Act, 1868.*—Section XI. of the Pharmacy Act, 1852, and Section XX. of the Pharmacy Act, 1868, are hereby repealed.

20. *Penalties under Act not to Exempt from other Penalties.*—No penalty under this Act shall exempt any person from being liable to any other penalty, damages, or punishment to which he would have been subject if the Pharmacy Act, 1868, or this Act had not been passed.

21. *Penalty for Wilful Falsification of Register, or for obtaining Registration by False Representation.*—Any Registrar who shall wilfully make, or cause to be made, any falsification in any matter relating to the said Registers, and any person who shall wilfully procure, or attempt to procure himself to be registered under the Pharmacy Act, 1852, the Pharmacy Act, 1868, or this Act, by making, or producing, or causing to be made or produced any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding or assisting him therein, shall be deemed guilty of a misdemeanour in England and in Scotland of a crime or offence punishable by fine or imprisonment, and shall on conviction thereof, be sentenced to be imprisoned for any term not exceeding twelve months.

22. *Extent of Act.*—This Act shall not extend to Ireland.

23. *Commencement of Act.*—This Act shall come into operation on the first day of January, one thousand eight hundred and eighty-four, and may be cited for all purposes as "The Pharmacy Act Amendment Act 1883."

Schedule of Poisonous Articles.

Sulphuric acid, commonly called oil of vitriol.

Hydrochloric acid, commonly called spirits of salts.

Nitric acid, commonly called aqua fortis.

Solution of chloride of antimony, commonly called butter of antimony.

Carbolic acid.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 10, 1883.

THE PHARMACY ACTS AMENDMENT BILL.

It is now no less than six years ago when Mr. Hampson brought forward at a Council meeting a motion that in anticipation of an opportunity for amending the Pharmacy Act of 1868, which might arise during the then ensuing session of Parliament, it was desirable the subject should be considered by a small Committee, and a report submitted to the Law and Parliamentary Committee suggestive of the amendments requisite. To those who have watched the course of events since that occasion it will be unnecessary to point out that the action thus commenced has been steadily followed up so far as circumstances would permit, and to those who have not done so, we may point to the lapse of time that has occurred without the introduction of a Pharmacy Act Amendment Bill as evidence of the difficulty of the task then entered upon by the Council of the Pharmaceutical Society. At length, however, we are enabled to place before our readers the draft of a Bill which has been adopted by the Council at its late meeting, and having been so adopted on the motion of Mr. Hampson, is to be regarded as the legitimate outcome of the work initiated by him six years ago.

At the commencement of the period we refer to experience had shown that notwithstanding the generally beneficial effect of the Pharmacy Act of 1868, it had proved in some important respects so far a failure that the Council had hesitated to test its strength from the fear that it might prove too feeble to bear the tension of a trial at law. Since that time the view then entertained by the Council has been conclusively proved to have been well founded and the necessity of an amendment of the Act has been demonstrated beyond dispute. Passing over the failure of an attempt to introduce a Bill in 1881, owing to the state of public business in Parliament at that time, we may remind our readers of what took place at a later period when a recommendation to make certain additions to the schedule of poisons was submitted to the Privy Council by the Council of the Pharmaceutical Society, inasmuch as the opportunity now offered for the introduction of a Pharmacy Act Amendment Bill has arisen out of the communications which then took place between the Council and that department of the Government. In November last the Lord President of the Council intimated that he would be glad to have the views of the Society in regard to the sale of poisons submitted for the consideration of the Privy Council in the form of a draft Bill amending the existing law. This has now been done, and the text of the draft Bill submitted will be found in our present number.

The discussion of the various subjects requiring consideration in the preparation of this Bill having been carried on in committee, we are, of course, unable to enter into any critical review of its several clauses, or of the reasons which led to their adoption, and can only refer to the remarks made by the individual members of Council as furnishing assurance of the care and pains that have been bestowed upon the elaboration of the Bill. It will suffice if we offer a brief *résumé* of the leading features of the Bill in language somewhat less technical than that employed in the document itself.

From the mere title and preamble of the Bill it will be seen that, in conformity with public demands, attention has been directed in the first place to the indiscriminate and unguarded sale of poisonous articles which has for some time past given rise to much just complaint from various points of view. In order to carry out the regulation of such sales, which is deemed to be expedient, the second clause provides that the retail sale of the articles named in the schedule shall be unlawful, unless they be distinctly labelled with their names and the word "poisonous," as well as the name and address of the seller. Power is also given to the Council of the Pharmaceutical Society, subject to approval by the Privy Council, to add to this schedule any articles the sale of which it considers ought to be thus regulated. In like manner Clause 3 provides that wholesale dealings in the articles included in the first part of the poison schedule of the Pharmacy Act, 1868, shall be so far regulated that the seller shall make a record in writing of each transaction and preserve it for twelve calendar months. The fourth clause also provides that it shall be unlawful to sell any patent medicine containing a poison within the meaning of the Pharmacy Act, 1868, unless labelled with the word "poison," and the name and address of the first seller of such article. This provision applies to wholesale as well as retail sales, and it is calculated to furnish some protection against the too frequent fatal cases of poisoning referrible to the undisclosed presence of narcotics or other potent drugs in various popular preparations, to the ignorant or careless use of which medical men have lately drawn attention as constituting a serious evil. In reference to the provisions of each of these three clauses, a penalty of from five to ten pounds for their infringement is defined by the fifth clause as that to which an offender is to be liable upon summary conviction. The sixth clause, however, provides a remedy in certain cases where the duly qualified seller of a patent medicine is exposed to penalties by reason of the infringement of the provision above mentioned and gives him a right to indemnification by the owner of the patent medicine or any intermediate seller of it, provided he furnishes proof of having purchased the patent medicine in question not knowing it to be otherwise than properly labelled and of having sold it in the same state as he purchased it. The adoption of precautionary measures in regard to popular preparations containing dangerously potent drugs would be thus in some degree ensured, and the responsibility of complying with the demands of medical men and others, in this respect, would rest upon the proprietors or original vendors of such articles.

To ensure the possession of the competent skilled knowledge held to be expedient in keepers of open shops for retailing, dispensing, or compounding medical prescriptions and poisons, clause nine provides that every such person shall be legally qualified under the Pharmacy Act, 1868, or entitled to and acting within the existing exemptions concerning medical practitioners, executors, administrators and trustees, and veterinary surgeons; but that the provisions of this clause shall not extend to, or interfere with, the business of wholesale dealers in patent medicines or poisons in the ordinary course of wholesale dealing.

Among the clauses which provide for the further regulation of sales of poisons by qualified persons which the preamble of the Bill sets forth as being expedient for the safety of the public the most important are first, clause seven, providing that the person on whose behalf any sale is made by an assistant, apprentice or servant, shall be subject to all the provisions of the Act in that respect; and secondly, clause eight, providing that the proprietor of any branch shop for retailing poisons, etc., dispensing medical prescriptions, shall employ there an equally qualified person occupied *boná fide* in the conduct of the business, the only exception to this requirement being that each partner in a duly qualified partnership may keep a separate open shop for retailing, dispensing, or compounding medical prescriptions, or poisons. By the provisions of these clauses due cognizance is therefore taken of the necessary possession of competent skill and knowledge by those engaged in dispensing medicines and retailing poisons as well as the personal reponsibility of proprietors of open shops. For the further attainment of these objects in conformity with the fundamental principles of the Pharmaceutical Society, while the first clause of the Bill provides that words importing the singular number only shall also include the plural number, clause ten provides that the keeper of any open shop for retailing, dispensing or compounding medical prescriptions or poisons, apparently implying that it is the shop of a person registered under the Pharmacy Acts, may be called upon by the Registrar of the Pharmaceutical Society to furnish a statement in writing of his name and address and qualification to sell or keep open shop, subject to a penalty of five pounds for each day that he fails to do so, and every person found selling poison or compounding medical prescriptions or acting in the management of such shop is likewise to be subject for each offence to a penalty of five pounds.

In a Bill to amend the Pharmacy Acts it is only natural and consistent with the progress which has been made during past years that provisions should be introduced in regard to the system of education by which competent skilled knowledge is to be acquired by pharmacists. As bearing upon this very important point in connection with pharmaceutical advance, clause twelve of the Bill empowers the Pharmaceutical Society to make, alter or amend regulations respecting examinations as may be from time to time found desirable, and as a further important step in the same direction clause thirteen provides that after a specified time the passing of the Preliminary examination shall be a condition indispensable for the reception of an apprentice by a pharmacist.

Clauses sixteen and seventeen contain provisions to facilitate admission to the Register of Pharmaceutical Chemists and to membership of the Society. These it is believed would materially assist in raising the public appreciation of the general body, and contribute largely towards the attainment of those objects which some of our correspondents have from time to time pointed out as necessary and for which they have suggested the establishment of a Fellowship of the Society.

The Evening Meeting held last Wednesday was a very interesting one; the attendance was better than usual, and no less than six papers were brought under notice. The first of these, on "Gelsemine," by Mr. Gerrard, will be found in another part of this number; but the publication of the others, together with the discussion, is deferred, through want of space, until next week.

* * *

At the Evening Meeting of the North British Branch of the Pharmaceutical Society, on Thursday evening next, the 15th inst., a paper will be read on "The Methods for the Separation of Alkaloids," by Dr. Matthew Hay.

* * *

From the report on another page it will be seen that the Committee of the Chemists' Ball have been able once more to send a subscription of twenty guineas to the Benevolent Fund. It appears probable also that the Committee of the Junior Pharmacy Ball will be in a position to contribute a similar sum. Mr. W. H. Kerr and his colleagues may well be congratulated upon the success which this result indicates as having attended their efforts to cater for the enjoyment of the younger members of the calling.

* * *

At the meeting of the School of Pharmacy Students' Association, to be held on Thursday, February 15, at 8 p.m., a paper will be read on "Linnæus," by Mr. W. E. Crow, and Mr. C. Thompson will make a communication on the "Separation of Cadmium from Copper."

* * *

The Annual Dinner of the Chemists' Assistants' Association will take place on Wednesday next, the 14th inst., at the Holborn Restaurant. The chair will be taken by Mr. Michael Carteighe.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 7, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, W. Hills, Radley, Richardson, Robbins, Savage, Schacht, P. W. Squire, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

Members of the Council who Retire.

The lot being taken in the usual manner for the seven members of the Council who should retire in May next, the following names were drawn:—

Andrews.	Butt.	Robbins.
Atkins.	Radley.	Savage.
Borland.		

The following, who remained in by lot last year, now retire by rotation:—

Bottle.	Hills.	Symes.
Carteighe.	Richardson.	Woolley.
Hampson.		

The following remain in office for another year:—

Churchill.	Schacht.	Williams.
Gostling.	Squire.	Young.
Greenish.		

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Foggitt, John Blackett.
Gilbert, William John.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Foden, Edwin ....Manchester.
Fowler, George..............Birmingham.
MacDermott, Robert John ......London.
Nichol, Anthony ....Carlisle.

Chemists and Druggists.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Gater, James..............London.
Herring, Thomas ....Thorner.
Turner, Robert John ....Brighton.
Watts, John Newton ....London.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Allen, Samuel ....London.
Bridge, George Edward ....Southsea.
Christmas, William ....Croydon.
Clayton, Christopher ....Oxford.
Cluckie, Andrew ....Stranraer.
Dickinson, David ....Derby.
Fox, Charles James ....Croydon.
Francis, George Bult ....London.
Gelsthorpe, James ....Long Eaton.
Harris, Stephen..............Droitwich.
Jeans, Thomas Robert..............Pendleton.
Joy, Francis John Jessopp ......Cardiff.
Macaulay, William Henry .. ...Huddersfield.
Machin, William George.........Winchfield.
Mackaness, Charles ....Chesham.
Mackay, David..............Dundee.
Moore, Jonathan Reuben ......Kettering.
Norton, Thomas ....Broseley.
Patman, Frederick Thomas......Whitehaven.
Raine, Ralph William ....Middleton-in-Teesdale.
Ranken, John ....Forfar.
Thomas, John Henry ....Hampton.
Whitrod, Henry Frederic ......Diss.
Wilding, George James ....Cressington.

Modified.

Abernethy, John ....Hoyland.
Martin, James ....Motherwell.
Morrell, Frederick Kent ... .London.
Thrower, Edward Arthur ......Diss.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Adamson, William Stewart ...Edinburgh.
Adler, Martin Woldemar ......London.
Bain, John ....Edinburgh.
Bing, Charles ....Canterbury.
Brisley, George..............Margate.
Cobden, Alfred George ....London.
Dunn, George Stewart ....Landport.
Fraser, James ....Edinburgh.
Gulliver, Walter Frederick ...London.
Holloway, Edwin Arthur ....Leominster.
Hopkinson, Harry ....Grantham.
Ivatt, Albert..............Cottenham.
Kerr, William ....Edinburgh.
Marsh, Edward..............Luton.
Pirie, William ....Arbroath.
Pope, Albert Harry..............Southport.
Ricketts, James ....Plymouth.
Rigden, George..............Folkestone.
Rowand, Robert ....Glasgow.
Shackleton, Thomas..............Accrington.
Smalley, Arthur William ......Stamford.
Sutherland, John William ......Edinburgh.
Watson, Robert William ......Maryport.
Worts, Harry Augustine.........Harwich.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adamson, Joseph William ......Epworth.
Alderton, James, jun. ....Leamington.
Almack, Edward Ambrose......Bedale.
Archer, Luke ....Bolton-le-Moors.
Atkins, Alfred Edward ....Newport.
Austin, William Hoskin... .....Devonport.
Badcock, Henry John Francis Sheerness.
Bayley, Edward George ....Rye.
Beauchamp, Frederic Crawley...Hemel Hempstead.
Bellamy, Arthur ....Louth.
Bishop, George Henry.......... Southampton.
Blain, William Rushton ....Bolton.
Blankley, George William ......Arnold.
Bostock, John ....Wilderspool.
Broomfield, Walter Henwood...Monmouth.
Burgess, Thomas ....Liverpool.
Burgess, William ....Runcorn.
Chantry, John Henry ....Horncastle.
Chapman, John ....Bedford.

Clarke, Richard ....Ruthin.
Clough, Thomas ....Liverpool.
Cooper, John James ....Castletown.
Crosthwaite, Daniel................Blackpool.
Dick, David Laing ....Falkirk.
Dobson, George Edwin ....Bridlington.
Elliot, William Marshall..........Kelso.
Ellithorn, Arthur Henry..........London.
Evans, Frederic Ernest ....Lymm.
Fardell, Ernest Matthew ....Leicester.
Felton, William ....Maidstone.
Fraser, James Leslie ....Inverness.
Fraser, John Sutherland..........Forres.
Fryer, Charles John ....Warwick.
Gale, William Gillam..............Worksop.
George, Isaac ....Great Yarmouth.
Glanville, Henry Charles..........London.
Gradidge, James Henry ....Truro.
Gray, William Edwin ....Pickering.
Green, Herbert........................Hucknall Torkard.
Gregson, Joseph ....Manchester.
Greig, John ....Montrose.
Grime, James ....Darwen.
Haigh, Walter ....Halifax.
Hamer, Edward Sidebottom ...Pendleton.
Harradine, Holben Montfort ...London.
Harvey, James ....Flintham.
Harwood, John L. ....Redhill.

Restorations to the Register.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Joseph Hughes Merrett, 57, Hyde Park Road, Southsea.
George Oakes, 7, Market Street, Chorley.
Edmund Wood, 14, Cleveland Terrace, North Cross Road, East Dulwich, Surrey.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Additions to the Register.

The Registrar reported that:—

John Herring Dingle, Bideford, Devon,
Septimus Frederic Leete, Thrapston,

having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and this declaration having been supported by duly qualified medical practitioners, their names had been placed on the Register.

Registrar's Report.

This Report, which is printed on pp. 652 and 653, as to the numerical strength of the Society, etc., was presented by the Registrar.

Reports of Committees.

Law and Parliamentary.

The Draft Pharmacy Bill.

The Council went into committee, while the President explained the alterations which had been made in the draft Pharmacy Bill since it was last before the Council, and the result of his interview with the officials of the Privy Council.

The Council then resumed, and the report of the Committee recommending for adoption the draft Bill, printed on p. 644, was read.

Mr. Hampson said he was very glad to find that the Pharmacy Acts Amendment Committee had been able to produce a draft Bill to the Council for its acceptance, though it had taken a long time to elaborate this Bill. He remembered the early stages of this question being raised by his friend Mr. Betty and himself, when it was found there were certain amendments required in the law, and it was thought desirable to have a committee to go thoroughly into the whole question. In accepting the position of moving the adoption of the report and the acceptance of this draft Bill he felt that it was a privileged position to occupy, inasmuch as, notwithstanding there were certain points which might be objected to, and others with which he might not feel in perfect sympathy, still looking all round the question, and looking at the condition of pharmacy in this country, and the agitation in respect of the sale of poisons, he felt that it would be scarcely possible to have a better Bill at present. It met all that was required at the present time; it might not go far enough in certain directions—it might go too far in others, but he believed it thoroughly met the exigencies of the occasion, and therefore, he had much pleasure in proposing its acceptance. He did not think it was necessary now to go into the details of the Bill, but he would just refer to the Education Clause, for after all that ought to be the keynote which should be struck when asking for any fresh powers in connection with pharmacy. Pharmacists asked for these powers because they were educated men practising pharmacy, and it was necessary that certain legislation should take place. He was extremely happy to find that a young man when entering the business would be protected; that he would enter pharmacy under quite different auspices for the future; that it would be necessary for him to pass a Preliminary examination before he was apprenticed to a chemist, for that was really an important point. Then he should like also to refer to a portion of the Bill which would possibly raise opposition on the part of some pharmaceutical chemists. It was thought desirable at some of the earlier meetings of the first Committee that there should be an additional title adopted, that of "Fellow of the Pharmaceutical Society;" but it appeared to him that rather than make things more complex the true method was to make them more simple, and he maintained that by instituting, as was proposed by this Bill, one title only, which would be understood by all sections of the public, they were taking a very important step indeed. It would not only be a step in the simplification of the title, but would establish a means by which the Society would be strengthened. It had been found by experience that the number of pharmaceutical chemists joining the Society was so small that this class had already become weak, and if some steps were not taken it would become exhausted. This change was one which would tend to strengthen and consolidate the Society, and he was quite sure that although some pharmaceutical chemists might view it with suspicion and dislike, if they took a broad and loyal view of the position they would ultimately give it their cordial support. He would ask them to do this in the interests of the Society and of pharmacy, because it appeared to be a necessary amendment of the law. He would not occupy time further, but he hoped that when this Bill was seen by the pharmacists and chemists of the country they would, before forming a hasty opinion upon it, try to take an all round view, and that they would consider, as the Committee had considered, what was absolutely necessary and what was possible. There would be many disappointments, no doubt, that the Bill did not ask for further powers; for instance, that it did not provide that the compounds of the Pharmacopœia and drugs should only be sold by chemists, with other matters in the same direction; but the Committee had found such proposals utterly Utopian, and he was quite sure if the matter was thoroughly considered they would come to the conclusion that this Bill fully and consistently met the requirements of the times. He, therefore, begged to move—

> "That the report and recommendations of the Law and Parliamentary Committee of January 10th and February 6th be received and adopted, and that the Pharmacy Bill in its present form be sent to the Lord President of the Council."

Mr. Savage, in seconding the motion, said he must endorse all that Mr. Hampson had said, and he believed the country generally would accept the Bill now submitted, and express its very grateful thanks for the time and trouble which the Committee, and especially the President, had taken in connection with it. A great deal of credit was due to those who had framed the Bill, for many difficulties had presented themselves. Those who read the Journal from week to week were aware that every now and then some proposition came forward from a country member under the supposition that the Society could do everything and without taking into account for one moment the necessity of considering public requirements in this matter. He thought, so far as they could possibly be carried out, the propositions submitted in this Bill were such as would meet with the general approval of the trade.

Mr. Schacht said probably it would be as well if he now rose to say a few words which he thought it his duty to address to the Council. Although they might sound as a repetition in the ears of several gentlemen who might hear them, he should make no apology for doing so, because this was the first time the subject had been discussed with open doors. He was sure the President and the gentlemen sitting round the table would agree that they were not the only persons interested in the matter, and that not only their fellow members practising pharmacy, but the great body of the public were very materially interested in the provisions of this proposed Act. With regard to the Bill itself he should like to say at once that there was a very large portion of it with which he entirely sympathized, but there was no occasion for him to specially indicate which those portions were further than to say he referred to those portions which were continued on the lines of the existing traditions of the Society—those which aimed at protecting the best interests of the public by more or less limiting its powers of getting dangerous articles promiscuously. As far as all that went he was in entire sympathy with the Bill; but in those two portions in which new departures were made, and he emphatically asserted they were new departures, notwithstanding his radicalness of character he found himself too conservative to agree with the suggestions now made, and to these points he would briefly draw attention. In the preamble to the Pharmacy Act were these words, "Whereas, it is expedient for the safety of the public, that persons keeping open shop for the retailing," etc., "of poisons, should possess a competent knowledge of their business," and so on, and in order to insure this, should pass certain examinations, and so forth, "be it enacted." All the rest of the Act included a recognition of the broad principle that in the best interests of the public it was not safe that everybody should have the possession or keeping and manipulating of dangerous drugs; but that a trained body should be recognized, into whose hands should be committed the charge of these dangerous materials, and that they should be responsible to the State for the individual members of the State using those articles for their advantage, and not their disadvantage. That was the principle which he believed had been acted upon by the Society from the beginning, and it was one he was exceedingly sorry to see in the least degree interfered with. In the provisions of this new Bill that principle was utterly torn asunder, and it was declared that though technically six or seven articles might be called poisons, and were still to be regarded as such, dangerous articles in the broad sense were to be manipulated exactly as the public liked, with the single exception that they were to be called "poisonous articles." That was the only limit to be put upon the traffic in them. The principle was to be admitted that it was not to the disadvantage of the public that all persons should be permitted to do what they liked with dangerous articles in the shape of drugs and chemicals. That was a principle he should be sorry to admit. If he were a member of Parliament he should oppose it to the utmost, and though the Government officials of to-day might recognize this principle, he believed the Government officials of to-morrow would not do so. The first occasion on which a disaster occurred they would all have to turn round and regret the action which to-day they were beginning to take. He exceedingly regretted that they should not have adhered to that policy which lay at the basis of all their previous efforts for improvement, one which he might say had the sanction and the whole prestige which attached to the action of the Society from its beginning. He had said this before, and would only say it this once more in public, be-

cause he knew from the experience of the Committee meetings that he was in a hopeless minority; still he thought it his duty to call public attention to the fact and to express his opinion plainly and clearly. There was also another departure in clause 8 which he regretted, because it seemed to contravene the principle which he believed the Society had allowed itself to be mainly influenced by in all its efforts to promote high pharmacy, namely, to endeavour as much as lay in its power to provide that the individual pharmacist should be qualified to the highest degree; that he should be trained to exercise his powers with a due sense of responsibility, and that everything conducted in his name should have his own personal supervision. That it was not absolutely and legally possible to prevent supervision passing into other hands might be true, but to boldly sanction the handing over of responsibility to an assistant, to any extent, which this clause did, would be so far a departure from principle, which he exceedingly regretted. It seemed to him, once more, if it was to be considered right and proper that the pharmacist should have—as he would be hereby allowed by the authority of the Council to have—any number of shops in any number of places, so long as he carried them on under registered assistants, he could not see why anybody should not do so, because it was absolutely clear that practically a man could not supervise ten shops, and if power were given him to carry on ten shops by the aid of ten qualified assistants he could not supervise those ten shops any more certainly than a corporation calling itself a limited liability company could do. Therefore, he believed this was a great departure from the principle on which the Society had hitherto largely rested, and was giving up the position it had hitherto maintained, namely, holding the individual owner personally responsible for what went on in his establishment. Those were the two portions he had at other times protested against and still felt it his duty to object to. He was quite content to take the defeat which he knew was inevitable, but in the meantime he felt bound to make one public protest, and would, therefore, conclude by moving an amendment, namely—

"That the report of the Law and Parliamentary Committee be approved, with the exception of clauses No. 2 and No. 8 of the Bill."

Mr. Woolley said, in order that the amendment might come properly before the Council, he had much pleasure in seconding it. He held the same views as Mr. Schacht had just expressed, but he did not think it was necessary to take up time by going any further into them. He should, however, just like to say how much he appreciated the time and trouble which the President had given to this work. They were all under a deep debt of gratitude to him for the work he had done, and whether they agreed with the outcome altogether or did not, still the debt remained, and should be acknowledged. He took exception merely to the two points which Mr. Schacht had indicated, namely: the introduction of the term "poisonous" in the new schedule, and clause No. 8. The Bill in other respects contained much which would be beneficial to the trade, but the eighth clause seemed to him to acknowledge a mischievous principle, and might very well be omitted without any loss to the Bill.

Mr. Gostling felt some considerable sympathy with Mr. Schacht in the convictions which he held with reference to adding a list of poisonous substances which were to be sold by any person, and also with reference to keeping branch shops. No doubt if they were in a perfect state of society Mr. Schacht's views might be practicable; but he felt he must support the motion very cordially, because he thought the efforts of the Committee had resulted in suggesting the only practical means of meeting the position of pharmaceutical chemists, and of insuring to the public the amount of security it was possible to give. He felt that the provision with reference to patent medicines was one of the most important in the Bill, inasmuch as undoubtedly, especially in the case of narcotics, which were doing so much harm, the word "poison" being put upon them would have a great effect in limiting the use of those dangerous substances. He felt also with regard to branch shops that they could not be altogether dispensed with and that the provision here made was a very proper one. No doubt, in some cases, where branch shops existed under competent management, they were of great service to the public. With regard to this new schedule of "poisonous substances," he felt that that was the only practical way out of the difficulty. They all knew, and the public knew, that the Council had attempted to get certain things added to the schedule of poisons, but the Government had declined to accede, considering that it would be impracticable that chemists and druggists only should have the sale of the articles mentioned. With regard to the title of "Pharmaceutical Chemist," that was going in a liberal direction which he trusted would be accepted. Some pharmacists might feel aggrieved by it, but on a broad view he thought it might be accepted that the Committee had done the right thing.

Mr. Radley said his sympathies had gone a little beyond this Bill in certain matters, for considering the expense of the education which was likely to be required by those entering the trade, he thought they wanted some further protection, and his thoughts had gone in that direction, at any rate, in so far as regarded the compounds of the Pharmacopœia. But he had arrived at the conclusion that by pushing this point the whole Bill might be endangered, and as there were so many points which were desirable in this Bill he could not press those views at the present time. In reference to both the points named by Mr. Schacht, a decided advance was being made on anything that had been done before in protecting the public and with reference to themselves. With regard to branch shops there was something to be said as to the responsibility of the proprietor, which was a matter of very considerable importance. It was not simply having a branch shop with an assistant, but there were matters connected with the purchase of drugs, and the general supervision which the principal would have to attend to.

Mr. Bottle supported in its entirety the Bill now brought forward. He did not say it was all that he would aim at if he could see his way to its accomplishment, but he looked at legislation altogether as a series of compromises. Certain things were pressed upon the Council last year by the Lincolnshire Farmers' Association which the Government would not entertain, and Mr. Schacht had certain views of his own with regard to education, and he looked upon the Bill as a compromise. When it was printed and went the round of the trade, and of those interested in pharmaceutical matters, he believed there was no part which would be more objected to than the part which Mr. Schacht most energetically supported himself. So far as regarded the observation that the Council was making two new departures he differed from Mr. Schacht altogether. It was only recognizing that which already existed, and putting under surveillance that which had been winked at for the last ten years. He would not detain the Council longer except to personally thank the President for the zeal, energy, and ability which he had thrown into the business.

Mr. Young said it was not necessary to make any lengthened remarks on this occasion, and he might simply say he acquiesced entirely with the motion. He was satisfied from what he knew of the feeling of druggists in the North that this Bill would be received with acclamation. He was quite satisfied it was one of the best Bills which had yet been passed by the Council. It seemed to him to deal practically with all those matters which were the peculiarly crying evils of the present time, and none appeared to him so important as those which Mr. Schacht had referred to, No. 2 and No. 8. No. 2 was just one of those things of which every one sought a solution, but no one seemed to be able to find the real one. Members of the Council knew that the public were supplied on all hands with these commodities. They felt that they could not hope to have them restricted to pharmacists without being actuated by a monopolizing spirit, which would have spoilt their case with any Government, because Governments now-a-days would act for the benefit of the general public. Pharmacists could not ask that the sale of all these things which had been sold by drysalters for so long a period should be given into their hands entirely. Three or four hundred years ago the sale of *aqua vitæ* in Scotland was restricted to the College of Physicians and Surgeons in Edinburgh. Then came some kind of reason by which for some composition they parted with it to the barbers, they being then qualified as surgeons. Nobody would ever think of restricting the sale of *aqua vitæ* now, and yet many people looked upon it as a very glaring poison. Clause 2 seemed to him to be the only practical means of getting over the difficulty. Then, as regards branch shops, if the clause passed it would place matters on a much better footing than they were now. It must be remembered that there were great changes in towns during the last twenty years. In Edinburgh and Glasgow there were old businesses which would have fallen to a very low ebb unless the proprietors had had it in their power to open branch shops. There were districts in those cities formerly inhabited which were now left entirely empty or converted into warehouses, and those who occupied them went into the suburbs. You must follow your customers if you wish to retain your business. He had often noticed the advertisements of Mr. Schacht, in which he described various articles which were manufactured by himself personally, but he did not see how he could be both in the laboratory and in the shop at the same time.

Mr. SCHACHT said he had a partner.

Mr. YOUNG said a qualified assistant was much the same as a partner. If this clause were carried out it would be a very great safeguard which did not exist at the present time, for there were many shops throughout the country which had not qualified persons to manage them. But the Council could go to the Government and say this was for the welfare of the community, and, therefore, demanded legislation. All were greatly indebted to the Committee which had charge of this matter so long, and especially to the President for the manner in which he had been able to negotiate it.

Mr. SYMES said, considering the position of pharmacy in the country and its relation to the public generally, he was prepared to accept the labours of the Committee, and the gigantic labours of the President, without any qualifying conditions whatever. The discussion would, he trusted, help members of the trade to understand at least some of the surrounding circumstances and difficulties under which the Committee brought forward the Bill. He should scarcely have felt it necessary to speak on the question, because most of the clauses were very clear, but as there had been some opposition to one or two of them he would say, in a few words, why he supported the Bill. The Pharmacy Act of 1868 had been quoted as containing the lines on which pharmaceutical progress should proceed, and from which it was a sort of sin to depart. If so, why was the Council going in for a new Bill at all? When that Bill was first drafted it was with the view to get as much as could be got at the time, seeing the opposition that had to be contended with, but it had not existed very long before chemists and druggists generally found reason to complain of it. This had gone on for a number of years, and it had been recently decided that it was a very imperfect Act. No doubt that had become the case by the growth of time, circumstances now not being the same as they were when the Act was framed. He simply asked the members of the trade that they should progress with the times and also be prepared to accept conditions to-day which they were not prepared to accept when the Act was first introduced. Exception had been taken to two clauses, and it was said the Council was initiating new departures. He thought that had been sufficiently answered already, inasmuch as provision was simply being made for restrictions on the sale of certain poisonous substances, which now could be sold without those restrictions, since the Council had failed to get any power to control the sale in any other way. The Council was not called upon to be the guardian of the public in all things, and he failed altogether to follow Mr. Schacht's argument that it was a very serious thing that the public should be allowed to have to do with dangerous things which did not go through the pharmacist's hands. If that principle were enlarged upon it would prevent the public having pistols, razors, and all that sort of thing, which had not come through their hands. It could not be recognized as a principle that the public should not have dangerous articles unless they were sold by a pharmacist.

Mr. SCHACHT said he referred to drugs and chemicals.

Mr. SYMES said, leaving that point the Council was providing for the good of the public. He must dissent from one word which had been used by Mr. Radley, when he said he had hoped for some further protection in the Bill. He would not use that word in a sentimental way, because he was no politician; but in considering this matter it must be considered apart from any idea of protection; if it were considered as the best means of protecting chemists and druggists it was an entirely erroneous idea. Those things were placed in their hands because they were more or less technically acquainted with them, and they had to administer them for the advantage of the public, not for their own benefit, though they should hope, as a matter of course, that in benefiting the public they would also benefit themselves. With regard to the question of branch shops, Mr. Schacht failed entirely to see how a branch shop carried on by a qualified pharmacist with a qualified assistant differed at all from a shop carried on by an unqualified person with a qualified assistant. Now that was thoroughly opposed to everything Mr. Schacht had said, year after year, hundreds of times almost, at the Council, and he was perfectly astonished to hear such a statement from him. He had told them all along that there was all the difference, and at any rate that the qualification of the master should cover everything. He had been seeking to have the individual pharmacist doing all the work himself. Now he (Mr. Symes) did scarcely any of the detail work in his own shop, though probably many of the public might think he made up all their medicines himself; but the commercial aspect of the question must be remembered as well as this ideal of professional character. If pharmacy were purely a profession, as it was more nearly on the Continent, that state might be arrived at. He was not intimately acquainted with continental pharmacy, but he knew something of it, and he should be sorry to see the pharmacists of this country drift into the condition of those in Paris; notwithstanding their professional character they seemed so utterly divested of vitality, of energy, and progress, of anything that would take them beyond the narrow limits of their immediate duties. He did not say there was not much scientific work done there occasionally, but he could not support that which would tend to narrow down pharmacy in this country, and to interfere with its progress. In the United States pharmacy was practised more freely probably than in any other country in the world, and they had been told by the President at that table that the pharmacists of the United States were the best in the world. He did not object to sentiment anywhere except in business, but if this matter were to be dealt with in a business way, the facts must be dealt with. There really was much greater protection where a business was owned by a qualified man and conducted by a qualified assistant than where it was owned by an unqualified person, and, therefore, he trusted what Mr. Schacht had said would not influence the Council in dealing with the Bill now put before it.

Mr. ROBBINS thought the Committee might be congratulated on bringing forward a Bill which was approved by nine-tenths of the Council. This was not the first Pharmacy Bill which had come before it, and when the former one came forward there was a good deal of opposition all round, and at the last it was passed by a majority. There was nothing like the unanimity which existed to-day, and from that circumstance he hoped it might be taken that the present Bill would be received by chemists and druggists throughout the country in the same spirit. He had always noticed that where the Council had been much divided members outside had been divided in the same proportion, but where there had been anything like unanimity in the Council its resolutions had received general approval by the trade at large. Of course in a Bill of this kind there were many points on which individually they would like to make alterations, but they would never get a Bill which met the views of every one.

Mr. WILLIAMS said taking the Bill as a whole he supported it thoroughly. He had taken exception to one or two clauses in committee, but being defeated by a large majority it was not his intention to again raise a discussion on the matter; he bowed to the decision of the Committee, which was a large and influential one, and he was quite sure it represented the Council. He, therefore, accepted the Bill as a whole, and was satisfied that the more unanimous they were—and it would be better if they could be entirely unanimous—the better chance there would be of carrying it.

Mr. ANDREWS said the patience of the Council must be getting exhausted, but he should like to say a very few words. He could not commence without paying a tribute to Mr. Schacht and Mr. Woolley, for the very consistent way in which they had always acted as regarded this Bill on questions which they considered questions of principle, and if they had not spoken as they had done, he thought they would have acted wrongly. He sympathized with them to a considerable extent, but he thought they were mistaken, and he could not vote for the amendment, seeing the importance of the Bill and the necessity of the Council being agreed. He did not see that there was such a question of principle as they imagined, particularly with reference to clause 2. Chemists had never claimed a monopoly in the sale of dangerous things, nor could they get it if they tried. If the Bill were a new departure, if it were lessening in any way the power the Society previously possessed, Mr. Schacht would be right; but as it only regulated the sale of dangerous things by certain persons who already sold them, he could not see that there was any question of principle involved. With respect to clause 8 he was more in accord with him, but still he could not support the amendment, and looking at the necessity for a Bill in the interest of public security he was obliged to waive any objection he might have to that clause and support the Bill in its entirety. He should like to say, however, that he did not agree with the defenders of clause 8. Mr. Young had defended it because old houses of business, when their neighbourhoods altered, had to start branches in new neighbourhoods. That might be a good argument for such houses, but not for the public or for the necessity of the case. Taking the Bill as a whole, and recognizing the fact of its being in the interests of the trade generally, he must support it.

Mr. RICHARDSON wished simply to add his feeble thanks to the President and the Committee which had taken so much trouble in framing this measure, which he hoped would soon be presented to Parliament and become law. The President must have had considerable trouble in framing a Bill of this description, which would, as far as possible, meet the wishes of the trade and yet be acceptable to the Government, and he feared the constituents of the members of Council were hardly aware of the great difficulties the Council had had to encounter. Still he could not but think that, taking it all round, this Bill would prove acceptable to the great bulk of pharmacists. As to attempting to please everyone, it was evident from the letters which were written to the Journal, time after time, how impracticable some people's ideas were. He had considerable sympathy with Mr. Schacht, who was one of the leaders of pharmacy, and regretted that he took this stand on the present occasion, because it was a great misfortune that a gentleman holding such a position should not go heartily with the rest of the Council in this business. With regard to the schedule of "poisonous articles" it simply placed illiterate vendors of those articles under restrictions, which would to a certain extent assist pharmacists; it would tend to drive the trade in those articles more to the legitimate chemist, because there could be no doubt that a great many people, especially the smaller shopkeepers, when they found there were these restrictions placed upon them, would give up the sale in disgust. One thing he did not see in the Bill, but no doubt it had been discussed, and that was a clause exempting all chemists from jury service.

The PRESIDENT said it would have been impossible to claim that exemption for all existing chemists and druggists, and any attempt to do so would simply have led to an abolition of the existing exemption. But the provisions embodied in the Bill would exempt all chemists who qualified hereafter.

Mr. RICHARDSON said that was quite satisfactory. He had some knowledge of pharmacists abroad, and had never before heard them spoken of in the depreciating tone which Mr. Symes had used. He had always looked upon them as the great pioneers of scientific chemistry. He had much pleasure in supporting the Bill as a whole, and thought it would be acceptable to the great majority of wise-thinking chemists and druggists throughout the country.

Mr. GREENISH said that all he had to say on this Bill had been better said by those who had preceded him, but as a member of the Committee it might be thought if he did not say one word, he was lukewarm on the matter and that the Bill had not his entire sympathy. Such, however, was not the case; he believed if it could be accepted and passed the year 1883 would be a memorable epoch in pharmacy. He should have been quite prepared to accept another schedule of poisons. It seemed to him necessary that the public should be protected by having these articles labelled "poison," and chemists were not all in a condition to supply the public as they were now supplied with them; therefore a compromise must be come to, and he thought it was a most important alteration introducing the distinction between "poison" and "poisonous articles." Several other clauses also, such as Nos. 15 and 16, were very important.

Mr. HILLS said he should vote very cordially for the Bill in its entirety, but he considered it a compromise between conflicting interests, and in the main for the advantage of the public. The Council might not approve of certain evils or doubtful advantages which existed, but thought it better to regulate them than to leave matters as they were. The amendment had sole reference to two clauses. But there was another clause (No. 4) on which there might be difference of opinion. To his mind the sale of patent medicines, especially those containing poison, for internal use, was a matter of very doubtful advantage to the public; still the existence of those patent medicines had been already recognized, and it was better in the public interest that the word "poison" should be affixed to those which contained poisons than that the sale should be continued unrestricted. He objected to the principle of branch shops, but the practice existed, and therefore it was better to make some regulation for the protection of the public than to leave the matter open.

Mr. Borland said he gave the Bill his warmest support. At first he had no great liking for clause 2, as he thought the Society would be really legislating for a body outside of pharmacy, and that it would be virtually placing drysalters and others who were the sellers of the poisons mentioned in that schedule in what might be called a legalized position. But when he viewed the question from the point of public safety and considered that the schedule contained so very few poisonous articles he came to the conclusion to support the clause. The danger to the public under this proposed Bill would be really less than at present and that was one of the primary considerations which should be kept in view. With regard to keeping more shops than one, he might say that many medical men in Scotland, who visited in a large area, had assistants whom they placed in villages to meet the wants of the people; and where a privilege of that kind was accorded to medical men, he did not see why the Society should lay an embargo on some of its best members and prevent them carrying on a good business in the same way. The whole centre of Glasgow had been virtually converted into commercial offices and the inhabitants had gone west; so that those having shops in Glasgow must have shut them up if they had not the opportunity to carry shops westward after their customers. From conversations he had with many pharmacists in the North, he believed the Bill would meet with general acceptance.

Mr. Butt was very pleased to be able to give his support to the Bill in its present form. For many years past he had seen the great difficulty arising from the want of a schedule of "poisonous articles," and it seemed to him that the Bill met that difficulty in the best possible way. Another clause embodied a principle he had supported for some years—that of making it compulsory for young men to pass a Preliminary examination before entering on their apprenticeship. A great hardship was often inflicted on young men who entered the business without knowing what they would have to go through, and as soon as this clause came into operation he felt certain it would have the effect of reducing the number of failures, by weeding out the greater proportion of those who were totally unfit for the business.

Mr. Squire said that, being a member of the Committee, and having heard the discussions on these clauses, he was quite satisfied the Bill was the best which could have been framed at the present time. All the subjects connected with pharmacy had been brought under discussion while the Bill was before the Committee, and he believed the best result had been arrived at. Branch shops had existed and would continue to exist, for it could not be expected that any Act of Parliament could be brought in which should shut them up, and as they could not be shut up it was better to legislate for them. There was a vast difference between a branch shop owned by a qualified man and conducted by a qualified assistant and one owned by a person who knew nothing whatever about medicine, trusting entirely to an assistant who would have but a small monetary interest in the concern. As regards the schedule of "poisonous articles," he thought it would be a great protection to the public.

The Vice-President did not know that there was anything he could say which had not been said already, but he must thank the President for his exertions, and he hoped that his term of office would be marked by the passing of this Bill as an Act of Parliament. He must also express his admiration of Mr. Schacht's independence, for it required no small courage with the consciousness of standing almost alone to express his convictions as he had done, and he honoured that courage. However, he differed from Mr. Schacht and Mr. Woolley in the view they took, especially in regard to the first clause they had objected to, because chemists had never had a monopoly of the sale of poisonous articles, and never could ask for it, and if they did Parliament would never give it. Hence it was not a new departure when the Council was simply called upon to recognize that which already existed, but to recognize it only by imposing considerable restrictions which were all to the advantage of the public. He quite agreed with Mr. Bottle that all legislation in this country was, and must be, a matter of compromise, and for the chemists to go to Parliament to advocate their own interests alone would be simply to invite and secure defeat. That the Government department should have honoured the Society by asking it to be the co-ordinate power in imposing fresh legislation was a distinction which should be highly valued; things of infinite importance, upon which all were agreed, could be secured by conceding matter of infinitely less importance, and, therefore, he had no hesitation in giving the Bill his hearty support. He was not in favour of branch shops, but he was in favour of recognizing what could not be prevented by Act of Parliament, and legislating in favour of public security. If controversy arose on this Bill, as no doubt it would, it would probably be with regard to those points in which Mr. Schacht was most warmly interested. He was not sure that every existing pharmaceutical chemist would be willing to concede the right to this title conceded by this Bill, but he thought he might be asked to do so, as the concession would secure for the trade and for the country generally a much greater boon.

Mr. Hampson said, in reply to Mr. Schacht's objection to the schedule of "poisonous articles," he would specially state this broad fact; if the Committee had not undertaken to introduce a clause regulating the sale of those articles, Government would probably do it. Was it not better that the Council should have the control of this matter to a considerable extent rather than that the Government should introduce a Bill independently? He thought Mr. Schacht's opposition was altogether due to his having an exaggerated notion of what the true position was. If his position was sound, the trade ought to go to the Government and ask for a monoply for the sale of tobacco and cigars, because tobacco was included in the Pharmacopœia. The position of a branch shop was very different when the owner was an examined person, and when he was not; a qualified man being the owner of a shop could examine his assistant, could look generally to the conduct of the business, could hear complaints, and from his experience could assess the value of those complaints, whilst an unqualified man could not. He regretted that Mr. Schacht felt incapable of accepting this Bill on account of these two points, which seemed to him to be of secondary importance.

Mr. Schacht asked if he, as mover of the amendment, was not entitled to reply.

The President said that strictly he had not the right to a reply, but no doubt the Council would willingly listen to anything he wished to say.

Mr. Schacht said his position had been to some extent misunderstood. He never for a single moment argued that this Bill or any other Bill should contain a clause prohibiting the keeping of a second shop. There was no such prohibition now existing. But it was one thing to endure what you did not approve of, and another thing to endorse it by making regulations with regard to it; that was the aspect of the matter against which he wished to protest. Some of the gentlemen who had spoken considered that in adopting clause 2 there was no fresh departure from the course the Society had hitherto taken, but that was just where he differed from his colleagues. He had been told by one gentleman on the previous night that the position he took up was the most illogical he had ever heard of in his life; but it appeared to him that that gentleman was entirely wrong. The new departure consisted in this, that the Bill positively recognized that the interests of the public were sufficiently served in the matter of certain poisons by placing on the packet containing the "poisonous article" the word "poisonous." That never had been recognized by the Society hitherto. It had always been understood that the principal advantage given to the public was that—the public being ignorant of the nature of poisonous articles, whilst pharmacists were educated to a full knowledge of them—the sole keeping and manipulation of poisonous articles had been placed in the hands and care of trained persons, and that it was those trained people alone who had the control of such materials; so that merely putting the word "poison" on should not be sufficient, but that the persons dealing with these things should know the nature and character of them and be responsible for them. The new departure was this, that the Bill would sanction the idea that sufficient care was taken of the public if the articles were simply labelled "poisonous." He believed that to be mischievous, and therefore opposed it in the best interests of the public as a distinctly new departure. There was already a poison schedule, and the Council went to the Government to get it enlarged. But the department said "No; you shall not do that, but on the contrary you shall recognize,"—at least, he supposed that was the purport of the communication—"that other people may deal in these things." It was mere nonsense to say that oil of vitriol was not as poisonous as oxalic acid or strychnine; he would rather swallow an ounce of strychnine than an ounce of sulphuric acid. What was the use of selling a groom chloride of antimony labelled "poisonous"? It would not prevent his buying it. It was now proposed to allow anybody to sell a groom chloride of antimony, and the groom did not care a straw for the label. He got the thing he wanted to give to the horse surreptitiously. On the other hand, if he had to go to the Vice-President's establishment to get it he would be very likely told he had better not have it, and if he insisted it might be refused. He objected to anyone being allowed to go to a blacksmith's shop and buy chloride of antimony under the idea that placing the word "poisonous" upon it was a sufficient precaution. It appeared to him that this was a distinct departure from the principle hitherto acted upon.

The Vice-President appealed to Mr. Schacht to withdraw the amendment, so that the Council might go to the department with a united front.

Mr. Schacht said he was in the hands of the President. Of course it would be hopeless to press the amendment, and if it were desired he should not object to withdraw it.

The President said if he were appealed to he must say that in his opinion it would be most fitting for Mr. Schacht to withdraw the amendment.

The motion was then put and carried *nem. con.*

FINANCE.

The report of this Committee was received and adopted and sundry accounts were ordered to be paid. Amongst the subscriptions towards the Benevolent Fund was a sum of twenty guineas from the Committee of the Chemists' Ball, and the President stated that he had reason to believe that a similar sum would be handed over by the Committee of the Junior Pharmacy Ball.

Mr. Schacht drew attention to an item of £18 12*s*. 6*d*. for cleaning two pictures in the Museum.

The Council went into committee to discuss this item, and also the question of the investment of part of the Society's funds at a higher rate of interest. It was arranged that this subject should be brought before the Committee at its next meeting, at which Mr. Butt was requested to be present.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£20 to a pharmaceutical chemist member from 1842 to last year, aged 82.

£20 to a pharmaceutical chemist member for many years, aged 62.

£10 to the widow of a former member.

£5 to a former associate of the Society, aged 58, who is out of employment.

£10 to the widow of a registered chemist and druggist.

£20 to the widow of a chemist and druggist to aid in getting a child into an orphan asylum. 2 previous grants of £15 each.

£5 to a registered chemist and druggist aged 60.

£5 to a registered chemist and druggist aged 59.

£5 to a registered chemist and druggist who has had eight previous grants.

£10 to a registered chemist and druggist, to assist him to emigrate.

£10 to the widow of a registered chemist and druggist, aged 32.

£10 to the widow of a registered chemist and druggist, aged 59.

£10 to the widow of a registered chemist and druggist, aged 62.

£10 to the Secretary's Casual Fund.

A letter was read from Mr. Houghton, who has charge of two of the Isherwood orphans, stating that he hoped to get the eldest boy into a wholesale house in the city before long.

Several other cases had been submitted to the Committee which had not been entertained.

This report was read in committee; on resuming the report and recommendations were unanimously adopted.

Vote of Thanks to the Local Secretaries.

It was moved by the Treasurer and carried unanimously:—

"That the best thanks of this Council be given to the Society's Local Secretaries for their efforts last year on behalf of the Benevolent Fund in making a personal canvass, accompanied by one or more members of the trade, and that they be earnestly requested to renew their efforts in the same direction this year."

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
December	Day	414	30	1	17
	Evening	124	18	2	8
Year 1882.	Day	4260	33	0	15
	Evening	1513	19	1	7

Circulation of books.	Town.	Country.	Total.
	No. of Entries.		
December	144	113	257
Year 1882	1806	1444	3350

Carriage paid.

December	£1 10*s*. 5*d*.
Year 1882	£23 9*s*. 10*d*.

The following Donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Accum (F.), Chemical Amusement, 4th ed., 1819.
From Mr. Joseph Stapleton.

British Pharmaceutical Conference, Year-Book of pharmacy, 1882. 2 *copies*. From the Conference.

Gorkom (K. W. van), Handbook of Cinchona Culture, translated by B. D. Jackson, 1883.
From Messrs. Trübner and Co., the Publishers.

Hooker (J. D.), Flora of British India, part 9.
From H.M. Secretary of State for India.

Méhu (C.), Sur l'extraction des matières colorantes des urines bleues (indigotine et indirubine), 1882.
From the Author.

Meyer (A.), Über Chlorophyllkörner, Stärkebildner und Farbkörper, 1882. From the Author.

New York State Pharmaceutical Association, Proceedings, 1880, 1882. From the Association.

Pennsylvania Pharmaceutical Association, Proceedings, 1880. From the ASSOCIATION.
Stocken (J.), Elements of Dental Materia Medica, 3rd ed., 1882. From the AUTHOR.

Curator's Report.

The Curator had reported the attendance in the Museum during December to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	240	25	1	12
Evening	36	5	0	2

The following Donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of Crystallized Xanthate of Potassium. From Mr. F. H. ALCOCK.

Specimens of the Leaves of *Eucalyptus globulus*, from which the oil previously presented was prepared. From Messrs. WARRICK BROTHERS.

Specimens of the Fruit of *Pterocarpus guianensis*, used in skin diseases. From Dr. H. E. CAUTY, Liverpool.

Specimens of the Root of *Tephrosia macropoda*, *Sium Thunbergii*, and of a native root called *Umundi*, of a bark called *Isibaha* and three bottles of Aloe Juice. From Mr. J. M. WOOD, Curator of the Botanical Gardens, Natal.

Specimens of Crystallized Naphthalene and of Naphthol. From Messrs. DOMEIER and Co.

Herbarium specimens of two varieties of the Damiana plant. From Messrs. PARKE DAVIS and Co.

A specimen of Ispahan opium had been purchased for the Museum.

The Professors had attended the Committee and reported satisfactorily of their respective classes.

Sundry applications had been received for loans of specimens, which had been acceded to.

Mr. HAMPSON asked if anything had been done lately respecting wood pavement in Great Russell Street.

The PRESIDENT said he had every reason to hope that this much-needed improvement would soon be carried out.

Mr. GREENISH drew attention to the gratifying fact that the attendance in the Library and Museum had lately been gradually increasing.

The report and recommendations of the Committee were received and adopted.

GENERAL PURPOSES.

This report, which, as usual, was read in Committee, included the monthly letter from the Solicitor as to cases which had been placed in his hands for prosecution. He reported that—

Sinton Michael Honan, 90, King Street, Hammersmith, had paid the penalty and costs.

George Theodore Imeson, 172, Caledonian Road, had paid the penalty and costs into court.

Also that execution had been issued in the case of—

James Kelsall, of 33, Sandy Lane, Stockport,

for the recovery of penalty and costs, but that "the officer of the court had reported that Kelsall had sold up and left the place."*

Several cases of alleged infringement of the Pharmacy Act were recommended for prosecution, and in the case of a member of the Society, who was reported to be practising medicine in the treatment of venereal diseases, etc., it was recommended that in accordance with the bye-laws, section xvii., the Secretary should be instructed to write to him for an explanation.

The report and recommendations of the Committee were received and adopted.

* This was the case reported in the *Pharmaceutical Journal* for November 18 last, p. 410.

REPORT OF EXAMINATIONS.

January, 1883.

SCOTLAND.

	Candidates. Examined.	Passed.	Failed.
Major (24th)	4	2	2
Minor (24th)	8	4	4
„ (25th)	11	6	5
„ (26th)	10	4	6
	—29	—14	—15
	33	16	17

Preliminary Examination.

Candidates. Examined.	Passed.	Failed.
331	194	137

Seven certificates were received in lieu of the Society's examination:—

4 College of Preceptors.
2 University of Cambridge.
1 „ Oxford.

The PRESIDENT said it might be interesting to read a letter which had been written by a former Bell Scholar, having reference to the examinations. It was always pleasant to find that the good intentions of those who had given money for educational purposes had not been mis-spent.

The letter spoke in the highest terms of the advantages which the writer had derived from the educational training he had received in the School at Bloomsbury Square.

THE ANNUAL MEETING.

The VICE-PRESIDENT, who had given notice of motion for holding the Annual Meeting and Conversazione, said he found that the usual day would fall at Whitsuntide, which would be inconvenient to many country members, and tend to prevent so large an attendance as usual. He therefore moved—

"That the Annual General Meeting of the Society be held on Wednesday, May 23, at 12 o'clock precisely, to receive the report of the Council; and to elect the Council and Auditors for the ensuing year."

"That a Conversazione be held on Wednesday, May 23 next. That the President, Vice-President, Treasurer, Messrs. Butt, Greenish and Squire, be appointed a Committee to carry out the necessary arrangements; and that the Secretary be instructed to apply to the Lords of the Privy Council for permission to hold the Conversazione in the Museum as usual."

The resolutions were carried unaminously.

PRELIMINARY EXAMINATION.

The PRESIDENT said he had received a communication from the Sub-Warden of Durham University, enclosing a scheme of examination which it was proposed to establish as a preliminary examination for any professional career, and asking if it would be accepted in lieu of the Preliminary Examination of the Pharmaceutical Society. He had examined the syllabus, which seemed excellent in every way, and suggested that he be authorized to state that the examination would be accepted.

This was unanimously agreed to.

A letter was also read from Mr. J. Clower, enclosing a list of subscriptions to the Benevolent Fund amounting to £1 17*s*. 6*d*., which he had collected from Chemists' Assistants in Leamington.

Parliamentary and Law Proceedings.

Substitution of Sulphate of Cinchonidine for Sulphate of Quinine.

At the Bradford West Riding Police Court, on December 28, Joseph Walker, chemist and druggist, of Chapeltown, Pudsey, was summoned for selling a prescription different to what had been prescribed.

Superintendent Symonds said that from complaints received he sent a man to the defendant's shop with a prescription, and after receiving it he sent it to Mr. Allen, the analyst, Sheffield, who had sent back the following certificate:—The sample had not been dispensed in accordance with the prescription. It contained little, if any, real sulphate of quinine, the most important remedy prescribed. It contained, apparently as a substitute, sulphate of cinchonidine, to the amount of nearly half a drachm, or 30 grains in the 8 fluid ounces, or in the same proportion as sulphate of quinine was ordered. Cinchonidine was a body presenting many resemblances to quinine, but of much lower commercial value, as it was commonly considered to have inferior medicinal properties.

The defendant said that he was getting old and could scarcely see. On the 3rd inst., when the man came to his house, and asked for the prescription to be made up, he had had a very restless night, and was aroused out of bed by his wife; it was by a mistake that the wrong quinine was sold.

The Chairman said he had made his case worse by stating that he could scarcely see, as he had shown that he was not a fit man to be in a place to mix medicines for the public.

Defendant said that it was very seldom that a prescription came in the country.

The Chairman: And very lucky too.

The defendant said he hoped the bench would deal leniently with him.

The Chairman said that the defendant had made himself liable to a penalty of £20, but taking all into consideration, the case would be met with a fine of £5 and costs.—*Bradford Daily Chronicle.*

Correspondence.

Permanganate of Potash Pills.

Sir,—From an old story, whose date is coeval with the early days of chemistry, we learn that it was the boast of some devotees of this science, that by the use of a given quantity of sulphur, nitre and charcoal fire might be brought down from Heaven; but the significant postulate was added, "If you only know the way." Little did I think, when I forwarded you my mite of information, that 2 grains of permanganate of potash could be successfully mixed with the same quantity of powdered sugar in order to form an excipient, that I would thereby bring down the ire of Mr. Hart (no disciple obviously of Dalton), the sarcasm of Mr. Corder, and ironical compliments from Chester. The nature of the combined remarks might justly call for a reply to each, after its kind, but I forbear. I would rather commend to all your correspondents Mr. Corder's own recommendation, "Try again," in the hope that they may meet with more success, and in particular, that Mr. Hart may, thereafter, breathe with his wonted freedom. I confidently state that the pills were prepared as formerly described without any sign of combustion. They were also readily soluble in cold water, and, after subsiding, gave a distinct permanganate of potash colour and taste. Since then the process has been repeated several times with the same results. But in order to discern some of the wonderful results given by two of your correspondents, another sample of sugar was tried, and with care, pills were also prepared, which exhibited no signs of combustion. At the same time, when roughly handled and removed from the mortar with an iron or horn knife, a mild form of combustion was produced. In my former letter, I merely stated the result of my observations, and how the pills could be prepared. This I repeat. I decline, however, to enter upon any other question, while I do not consider myself called upon to account for the failures of others.

Edinburgh. James Mackenzie.

*** We insert the foregoing letter simply for the satisfaction of Mr. Mackenzie, though we do not think it would be conducive to that of our readers if they were so unwise as to follow the lead of his senior apprentice.—Ed. Ph. J.

Sir,—It being necessary that permanganate of potash be taken in a tasteless form, I would suggest that it be powdered and enclosed in ordinary gelatine capsules. Three grains of the salt can, with a little trouble, be compressed into a capsule no larger than an ordinary 5 grain pill, and in this form would undergo no decomposition.

London, W. W. H. Thomas.

Pungent Liniment of Iodine.

Sir,—Mr. MacEwan's note on the above is well worth the attention of any pharmacist who may be in the habit of preparing B.P. liniments with methyl alcohol.

Some years ago, when using liniment of iodine for articular rheumatism, I was very much annoyed with the pungent odour which it emitted, and which, to the eyes, was very irritating. The liniment I used was made with methyl alcohol, which Mr. MacEwan has proved to be an objectionable (and consequently unjustifiable) modification of the official formula.

Query—Is a chemist justified in using methylated alcohol in the preparation of any of the B.P. liniments?

John.

*** The use of methylated spirit in the preparation of medicines is restricted by law to those which are not capable of being administered internally; but even such preparations should not be made with it except with the cognizance of the persons ordering them.—Ed. Ph. J.

F. W. Doubleday.—Your letter has been handed to the Secretary, to whom all complaints as to non-delivery of Journal should be addressed.

Inquirer.—It does not appear probable that if such a contract were entered into by a Minor it could be enforced. But the question is one that should be submitted to a solicitor.

Frank C.—Your letter has been handed to the Secretary, who will forward to you the required information.

Nemo.—We do not think there is any pharmacy law in force in the State mentioned.

G. K.—Decoct. Aloes Co.

Veritas.—The mixture when recently prepared is not clear, the opacity being due to separation of the resinous matter of the tinctures, which subsides as a flocculent precipitate. There is no apparent decomposition in the mixture of liq. bismuthi and solution of sodæ bicarb. The liquor bismuthi used should be the B.P. preparation.

F. S. S.—A flocculent separation of colouring matter takes place and crystals of a salt of quinine appear to be formed; but the whole mixture should not become a solid mass.

W. F. Garry.—An answer to your question appeared in the number for Dec. 23. See before, in the present volume, pp. 90, 156 and 510.

Communications, Letters, etc., have been received from Messrs. Llewellyn, Johnson, Davis, Rees, Pollard, Sampson, Martin, Bradley, Warden, Vincent, Thomas, Powell, Kermath, Hetherington, Dodd, Paris, Inquirer, Alpha, Assistant, Local Assistant, H. M. H., W. G. W.

AROMATIC SPIRIT OF AMMONIA.*

BY DR. THRESH,
Pharmaceutical Chemist.

History.—An aromatic spirit of ammonia appears for the first time in the Pharmacopœia Londinensis in the issue of 1721. Under "Medicamenta Chymica" is a "spiritus salis volatilis oleosus," prepared by distilling a mixture of cinnamon, mace, cloves, citron, sal ammoniac, salts of tartar and spirit of wine. In the 1746 edition the name is changed to "spiritus volatilis aromaticus," and the method of preparation is very different, for a "spiritus salis ammoniaci dulcis" is first made by distilling fixed alkali with sal ammoniac and proof spirit, and to this is added the essential oils of lemon, nutmegs and cloves, and the whole is again distilled. These are placed amongst the "Sales et Salina." In 1788 the name and mode of preparation are again altered. A "spiritus ammoniæ" is made by distillation and in this the oils of lemon and nutmeg are simply dissolved, forming "spiritus ammoniæ compositus." This is placed in the "Misturæ." In 1809 the name becomes "spiritus ammoniæ aromaticus," but the mode of preparation remains the same. In 1824 the compound bearing this name was ordered to be made in the same way as the "spiritus salis volatilis oleosus" of 1721, the mace being omitted and lemon substituted for citron. The alteration in the P.L. of 1836 was less than in any previous edition, the name remaining the same, the mixture to be distilled varying from that of the 1821 edition only in the strength of the spirit. Finally, in 1851, the proportions of nearly all the ingredients are altered, but no change is made in the method of preparation.

In the Edinburgh Pharmacopœia of 1722 occurs "spiritus salinus aromaticus" made by distilling a tincture of angelica, galangal, marjoram, anthos flowers, cinnamon, cloves, mace, nutmegs, orange and citron with salts of tartar and sal ammoniac. In 1792 the name becomes "sp. amon. ar. vulgo sp. salinus aromaticus," and the preparation is made by dissolving the oils of lemon and rosemary in a distilled spirit containing ammonium bicarbonate. In 1803 the same preparation occurs, but under the name of "alcohol ammoniatum aromaticum," which is changed in 1817 to "tinctura aromatica ammoniata." In 1839 the name again becomes "spiritus ammoniæ aromaticus" and the character of the article is somewhat altered, since the spiritus ammoniæ from which the compound spirit is made by addition of the essential oils of rosemary and lemon, contained *free* ammonia only.

The Dublin Pharmacopœia in 1807 contained a "spiritus ammoniæ aromaticus," and although in every subsequent issue the mode of preparation was altered the name was retained unchanged. In 1807 it was ordered to be made by distilling a dilute spirit with muriate of ammonia and wood ashes, adding bruised nutmegs and oil of lemon, and again distilling. In 1827 carbonate of ammonia (3½ ounces) was ordered to be dissolved in rectified spirit (3 pints); then after maceration with cinnamon and nutmeg and addition of lemon oil the mixture was distilled. This method was discarded in 1850, and distillation entirely dispensed with, a strong solution of ammonia being simply mixed with rectified spirit in which the oils of lemon, nutmeg and cinnamon had been dissolved.

Official Processes.—It will be observed that at the time when the British Pharmacopœia was compiled, there were in the British Isles three official aromatic spirits of ammonia, differing in flavour, strength, and in mode of preparation, and that in all the Pharmacopœias the processes given for the production of this medicament had varied with nearly every issue. At the present time compounds corresponding to our "spiritus ammoniæ aromaticus," B.P., are to be found in the U.S.P., the French Codex, and the Ph. Belg., all made by dissimilar processes. As the principal object of this communication is to point out a method of making this important galenical preferable to any yet adopted, it may be of interest to give somewhat more in detail the various processes and formulæ which the compilers of the above Pharmacopœias believed to be the best, after duly considering the experience of the two previous centuries.

The formula of the B.P. is too familiar to need quoting.

The sp. ammon. ar. of the new United States Pharmacopœia, which differs only very slightly from that of the previous edition, is ordered to be made as follows:—

"Take of

Carbonate of ammonia .	40	parts by weight
Water of ammonia . .	100	"
Oil of lemon	12	"
Oil of lavender	1	"
Oil of pimento	1	"
Alcohol recently distilled and which has been kept in a glass vessel . . .	700	"
Water	146	"

"To the water of ammonia contained in a flask, add 140 parts of distilled water, and afterwards the carbonate of ammonia reduced to moderately fine powder. Close the flask and agitate the contents until the carbonate is dissolved.

"Weigh the alcohol in a tared flask of suitable capacity, add the oils, then gradually the solution of carbonate of ammonia, and afterwards sufficient distilled water to make the product weigh 1000 parts. Lastly filter the liquid, through paper, in a well covered funnel.

"Keep the product in glass stoppered bottles in a cool place.

"A nearly colourless liquid when freshly prepared, gradually acquiring a slightly darker tint, of an aromatic, pungent, ammoniacal odour, and having a sp. gr. of about ·885."

In the French Codex we have—

"*Alcoholat aromatique ammoniacal.*

Ecorces fraîches d'orange . .	100	grammes
Ecorces fraîches de citron . .	100	"
Vanille	30	"
Cannelle de Ceylan	15	"
Girofles	10	"
Chlorhydrate d'ammonique .	500	"
Carbonate de potasse	500	"
Eau distillée de cannelle . . .	500	"
Alcool à 80° (·864)	500	"

"Incisez les écorces d'orange et de citron ainsi que la vanille; concassez la cannelle et les girofles, et introduisez le tout dans une cornue de verre, avec le sel ammoniac, l'eau de cannelle et l'alcool. Laissez macérer pendant trois ou quatre jours, en agitant de temps en temps. Ajoutez le carbonate de potasse; mélangez exactement, et, apres quelques heures distillez au bain-marie pour retirer 500 grammes d'alcoolat aromatique.

* Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.

"Cet alcoolat se colore assez promptement à la lumière. Il faut le conserver dans des flacons de petite capacité, bouchés à l'émeri."

The Belgian spirit is called—

Alcoholetum aromaticum ammoniacale.

and is prepared as follows:—

"Alcoholat aromatique	920
Ammoniaque liquide	50
Carbonate d'ammoniaque pulvérisé	20
Huile essentielle de girofles	2
Huile essentielle de macis	2
Huile essentielle de marjolaine	2
Huile essentielle de citron	4

"Mêlez le tout dans un flacon bouché à l'émeri et secouez pour obtenir un solution homogène."

The "alcoholat aromatique" is obtained by distilling a tincture of marjoram, cinnamon, nutmeg, cloves and coriander.

Comparison of Typical Processes.—The method official in the Codex is one of the oldest and most defective. The product is very variable and contains much free ammonia produced by dissociation of the carbonate. It rapidly becomes coloured by the action of light, and contains less than 70 per cent. of absolute alcohol. As the process is unscientific, yields a defective product, and has consequently been discarded by all other Pharmacopœias, it does not require further notice.

The process official in the United States has the great advantage of dispensing entirely with distillation, and should yield a product of perfectly definite strength. Unfortunately in the new Pharmacopœia the "alcohol" is ordered of sp. gr. ·820, and therefore containing about 91 per cent. of absolute alcohol by weight, whereas in the last Pharmacopœia the "alcohol" was of same strength as our rectified spirit. With spirit of 84 per cent. all the carbonate of ammonia remained dissolved when the solution was added, whatever might be the temperature at the time; but with this stronger spirit I find that at 50° F. a considerable amount of ammonium carbonate is deposited when the two fluids are mixed. If put in a warm place (temperature 70° F.) for a short time, however, the carbonate is dissolved, but upon cooling a portion is redeposited. When made with the alcohol, sp. gr. ·834, of the last Pharmacopœia, the whole of the salt remains in solution at 32° F. Even with the stronger alcohol, if the solution of ammonium carbonate be heated to 150° for a few minutes, and then when cold added to the spirit, no precipitate is formed.

When all the salt is in solution this aromatic spirit contains 4·88 per cent. of normal ammonium carbonate, and ·42 per cent. of free ammonia, together with 63·4 per cent. of absolute alcohol. The spirit of the last edition contained only 59·5 per cent. of alcohol.

The only real objection to this process is that by keeping the spirit becomes discoloured. In my opinion also the aroma of a sal volatile made in this way is not so fragrant as it is when prepared by distilling the spirit and essential oils together.

The Belgian process resembles somewhat that of the United States, differing only in the fact that a distilled aromatic spirit is employed as the menstruum instead of plain spirit. Inasmuch as essential oils are afterwards added to the spirit, together with the ammonia salt the same objections apply to this process as to the previous one. It contains 2·4 per cent. of ammonium carbonate, ·6 per cent. of free ammonia and 62·1 per cent. absolute alcohol.

The B.P. spiritus ammoniæ aromaticus differs from all the above in being prepared entirely by distillation. It would appear as if the compilers of the Pharmacopœia had intended the finished product to contain 8 per cent. of normal ammonium carbonate and no free ammonia; but, inasmuch as it contains 67·7 per cent. of absolute alcohol, 4 per cent. of ammonium carbonate is the maximum amount it can hold in solution, and to obtain it of this strength it is necessary to operate on small quantities, and observe a number of precautions during the distillation; the remainder of the ammonia is then found dissolved in the free state, the carbonic acid corresponding thereto having escaped. A very considerable experience in the manufacture of this article in quantities of from 1 to 4 gallons has led me to form the following conclusion:—

1st. That the product varies considerably in strength and in relative proportions of ammonia and ammonium carbonate, this variation depending upon the quantity of material operated upon, the rapidity with which the distillation is conducted, and probably upon other factors.

2nd. That the larger the quantity of spirit distilled the poorer is the product in carbonic acid.

3rd. That working with the B.P. quantities *in warm weather*, and employing every precaution to prevent loss of ammonia, and to transfer all the carbonate deposited in the condenser into the distillate, the product will contain 4 per cent. Am_2CO_3, and 1·42 per cent. NH_3.

4th. That in cold weather the solution thus made deposits crystals of the ammonium carbonate. If made in winter, the whole of the salt condensed in the worm does not dissolve when shaken with the distillate, unless the latter is heated. Of course, upon cooling, the excess again separates.

5th. That in the B.P. process from 1·4 to 1·6 per cent. of the spirit remains behind in the still. To obtain all the alcohol at least 7½ pints must be distilled.

These conclusions are fully substantiated by the results obtained upon the analysis of samples from the first pharmacies, and from manufacturers of the highest repute, which results were communicated to the Pharmaceutical Conference in 1880. With regard to appearance, aroma, and keeping qualities, our spiritus ammoniæ aromaticus leaves nothing to be desired, but in the more important matter of constancy in strength, it is anything but satisfactory.

As the numerous proposals which have been made to remedy this serious defect in the official process have all either been obviously inapplicable, or have not been submitted to the test of actual experiment, a series of experiments was planned and carried out in my laboratory. As a consequence, I most unhesitatingly condemn every process necessitating the distillation of the ammonium carbonate with the spirit. A number of samples of spirit of ammonia was prepared, in which the quantity of free ammonia and official carbonate used corresponded to from 0 to 1·5 per cent. of NH_3, and from 2 to 4 per cent. of $(NH_4)_2CO_3$ in the finished product. Invariably during the distillation CO_2 was lost, and the spirit was deficient in carbonate. This was the case, however the proportion of water and alcohol in the retort was varied, and whatever was the alcohol strength of the distillate. The suggestion to make the B.P. spirit without distillation has been offered by several pharmacists, but none of them have shown that this can be done. True, a sal volatile is ordered in both the Belgian and United States Pharmacopœias to be made without distillation, but both contain considerably less alcohol than our preparation. Taking the official quantities, the ammoniæ carbonas refuses to dissolve in the requisite amount of water and solution of ammonia without the aid of heat, and of that which does so dissolve *nearly the whole* is thrown out of solution on addition of the spirit. When, however, the solution has been effected by the aid of heat in a securely closed vessel, the addition of the alcohol causes, at ordinary temperatures, the precipitation of only about half the ammonia as normal carbonate, the other half remaining in solution also as normal carbonate. When the proportions of ammonia and ammonium carbonate employed are such as to yield a product containing 4 per cent. of normal carbonate, the aqueous solution prepared without heat precipitates copiously on the addition of the spirit; but when the salt and dilute ammonia have been heated in a tightly corked bottle to about 150°, and then when cold mixed with the spirit, only a small quantity of the normal carbonate, depending upon the temperature, is thrown down. Evidently, therefore, when the official carbonate is dissolved in cold dilute ammonia it does not combine with the free NH_3 to form the normal carbonate until heat is applied. The further application of heat then, in either alcoholic or aqueous solution, causes at least partial dissociation and evolution of CO_2. As yet the temperature limits at which the combination of the ammonia and acid carbonate takes place and the rapidity of the combination at any given temperature have not been observed.

Using a more dilute spirit an alcoholic solution can be prepared without the aid of heat, which will contain at 0°, 4 per cent. of normal carbonate or its equivalent of acid carbonate. This was done in the last U.S.P. by adding so much spirit to the aqueous solution that the product contains 59 per cent. of alcohol, or 9 per cent. *less* than is contained in our sal volatile. The process of the Belgian Pharmacopœia also yields a product of reliable strength, but neither this nor the spirit official in the United States is equal to our own in appearance, aroma, and keeping qualities. It would serve no useful purpose to recount all the experiments made to produce a sal volatile having the advantages with regard to aroma, etc., of the one, and the definite composition of the others, by a process which should also entail no loss of alcohol in the distillation. The formula which appears to me to be the most likely to supersede the present one is as follows:—

Take of

Oil of lemons	℥viss.
Oil of nutmeg	ʒivss.
Rectified spirit	6 pints.
Water	3 pints.

Distil 7 pints, set this apart; then continue the distillation until 9 ounces more have been collected.

Take of

Ammonium carbonate	4 ozs.
Stronger solution of ammonia	8 „
The last portion of above distillate . .	9 „

Place in a bottle holding a little more than 1 pint, cork securely, and place the bottle in a water-bath at about 140° F.,* shaking from time to time until all the salt has dissolved. When cold, filter if necessary through a little wool, and pour into it gradually the seven pints of distilled spirit.

The product will measure 1 gallon; its specific gravity is ·886, and it contains 3·45 per cent. of normal ammonium carbonate and 1·23 per cent. of free ammonia. Whilst not quite so strong as it is possible to make a spirit of ammonia by the official process, it is considerably above the average strengh of the sal volatiles of commerce. From the more dilute character of the spirit none of the carbonate is thrown out of solution even at 0° C., and by the continuing the distillation a little beyond the point now ordered (in the B.P.), the whole of alcohol is contained in the finished product instead of a portion being wasted as heretofore.

One fluid ounce requires for neutralization 558 gr. measures of the volumetric solution of oxalic acid, and the same quantity after the addition of 330 grain measures of solution of barium cloride (1 in 10) should yield when filtered a further precipitate when more of the reagent is added.

Doubtless this formula may be varied in many ways, but so far as my experience goes, it is the one which is most likely to give general satisfaction. Probably many would prefer to be able to purchase the spiritus aromaticus, and add thereto the solution of ammonium carbonate. Should it be deemed advisable to encourage this, 7 parts only need be distilled, and water used for dissolving the salts. To form the sp. am. ar. it would then only be necessary to add 7 parts of the spirit to 1 of the alkaline solution, and this product would not appreciably differ from that made by the beforementioned process. The loss of alcohol (on an average 1½ ounce) would be the same as in the process at present official.

For comparison, the results obtained by analysis of a sample of sp. am. co., made by the method here recommended, are given, together with the mean of the results obtained from nineteen B.P. samples examined in 1880.

	Free NH_3 per cent.	Am_2CO_3 per cent.	Total, NH_3 per cent.
New process . .	1·25	3·53	2·49
B.P. process (means of nineteen samples)	1·33	1·88	1·99

AN APPARATUS FOR CONTINUOUS EXTRACTION.†

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry,
AND F. W. SHORT,
Assistant-Demonstrator of Chemistry
in the Laboratories of the Pharmaceutical Society.

During an investigation which necessitated speedy and thorough exhaustion, trial was made of the principal forms of apparatus proposed for this purpose, and which admitted of construction out of the materials ordinarily found in a chemical laboratory. Among these was the second apparatus proposed by B. Tollens (*Zeits. f. anal. Chem.*, xvii., 320). It consisted of two tubes, the larger one of which was

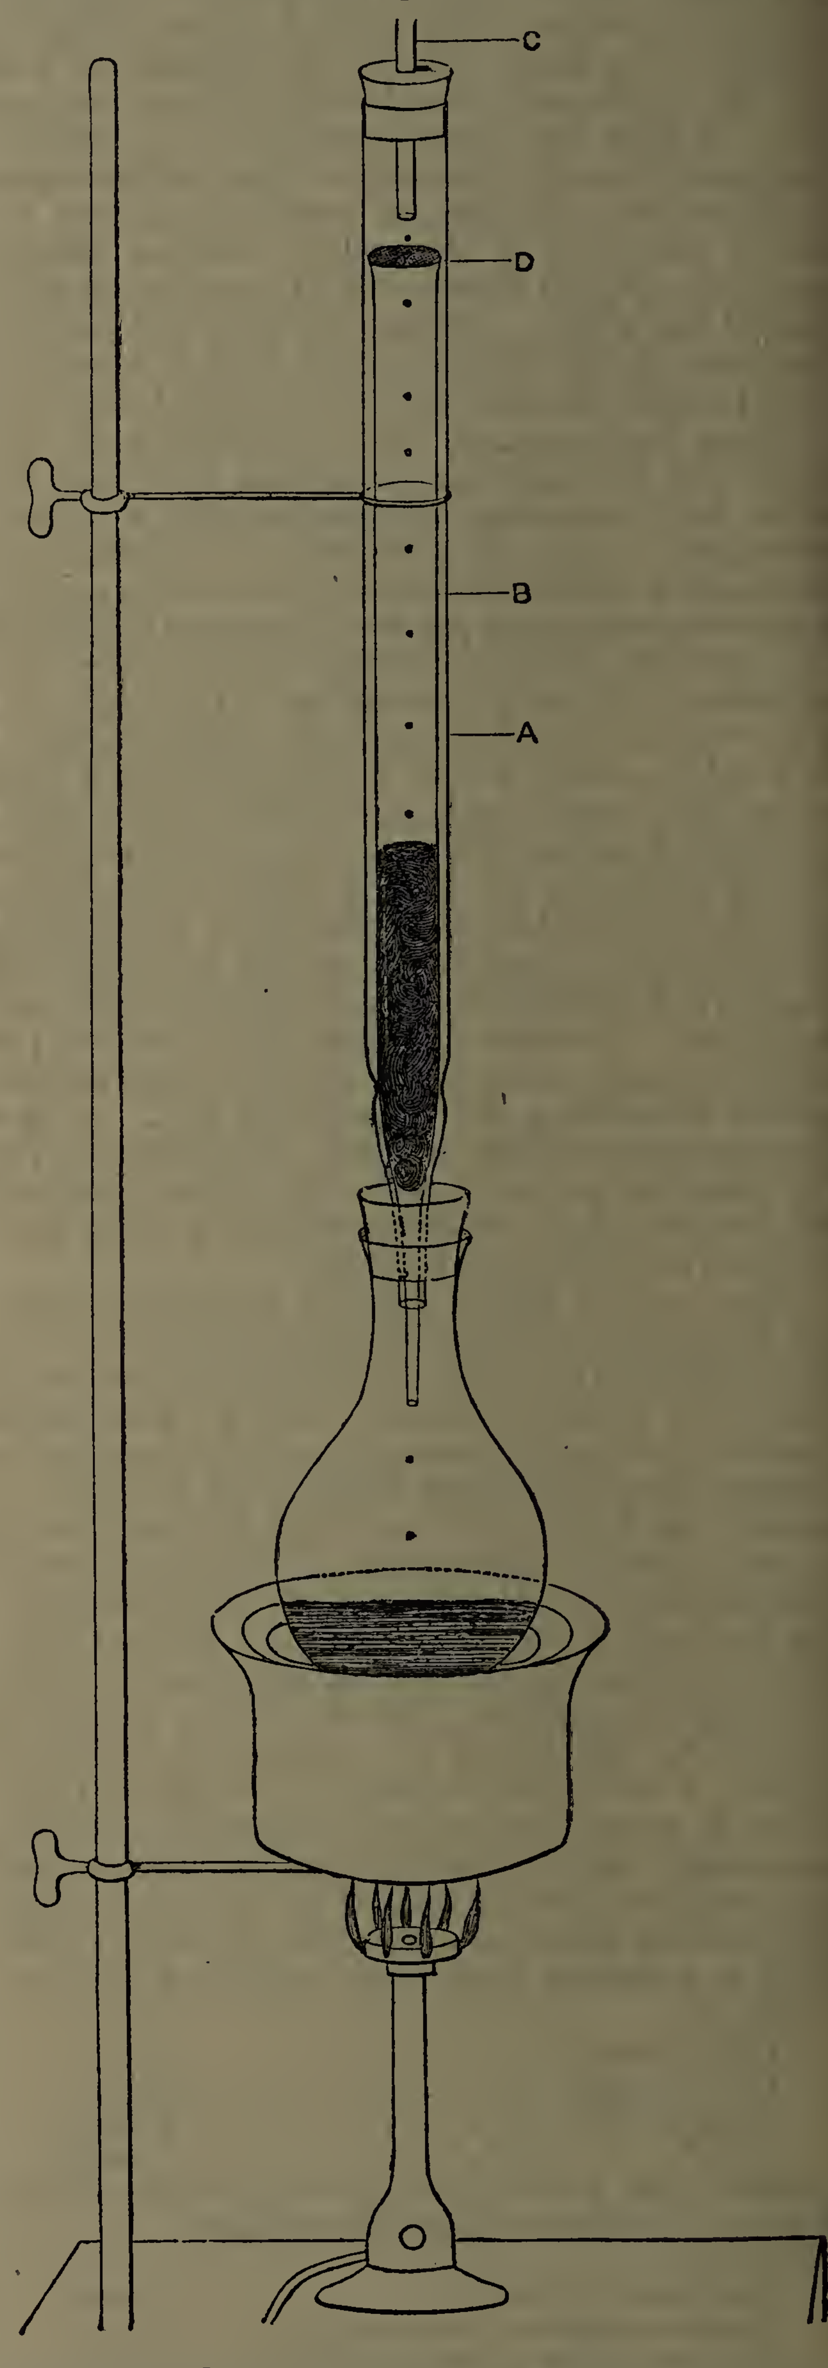
* Solution may be effected without the aid of heat, but not nearly so readily.

† Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.

drawn out to pass through a cork in the ordinary way; the smaller tube was of a size which allowed it to fit with much margin into the larger tube, and was cut off straight at both ends, one end being tied over with a piece of filter paper. This tube was packed with the material and placed in the larger tube, so that the closed end rested upon a piece of curved glass rod placed across the contracted portion of the larger tube. This tube was then connected with a condenser. In the use of this apparatus many difficulties were experienced, which suggested the form of apparatus which we now describe. The principle is the same as that involved in the apparatus of Tollens, and, indeed, in many other forms of apparatus which have been used for a similar purpose. It differs in construction and in the fact that it can be used either for digestion, for repercolation, or for both at the same time, the whole operation being conducted at the boiling point of the solvent.

It consists of two tubes, A and B, the larger one being drawn out at one end to such a diameter as will admit of the smaller tube, which is also drawn out, passing through it. The outer tube is indented on each side, by which means two ledges are formed within the tube, which serve as supports for the smaller tube. This is easily accomplished by gently pressing each side of the tube when red hot by means of crucible tongs.*

The substance to be exhausted is placed in the inner tube, the narrow end of which has previously been plugged with a piece of cotton wool. A wire gauze cap, D, fits upon the other end of this tube and prevents possible ejection of the substance from the tube; the use of this cap, however, may usually be dispensed with. The outer tube containing the smaller tube is now connected with a flask by means of a cork though which the contracted portion of the tube passes, the other and open end being fitted with a cork and long upright tube C which acts as a condenser, its length depending upon the nature of the solvent operated with. The extent to which the inner tube is drawn out depends upon the purpose for which the apparatus is required. If drawn out to a fine point and allowed to pass someway beyond the rim of the outer tube the apparatus can be used for digestion. The vapour of the solvent will pass up the outer tube, and after condensation by the upright tube will drop into the inner tube, forming a column of liquid above the marc which will slowly permeate the substance, but while the liquid in the flask is boiling but little will return to the flask. In this way the substance is digested with the solvent at a temperature close upon the boiling point of the liquid. When the source of heat is removed the column of liquid will percolate through the marc into the flask, and the digestion can again be effected with a fresh portion of the solvent. If the inner tube be drawn out so that it extends only a short distance beyond the rim of the outer tube, as shown in the diagram, and its diameter is but little smaller, digestion and repercolation will go on together. The most advantageous way of using the apparatus is as follows:—The substance having been loosely packed in the inner tube and some of the solvent poured over it and the rest placed in the flask, heat is applied; the liquid in the state of vapour will pass up the outer tube and be condensed by the upright tube, the drops of liquid falling upon the substance and rapidly percolating through it into the flask. If the boiling be now continued fairly rapidly, the amount of liquid condensed in a given time will exceed that



which percolates through, with the result that a column of liquid will gradually form over the marc

* The tube A should not be too long or the vapour will be condensed to a greater or less extent in this tube before reaching the condenser C.

in the inner tube. When this has occurred it will be found that the vapour has made its way through the marc and is bubbling through the column of liquid, thus keeping the marc in an agitated condition, yet, be it observed, liquid is still dropping into the flask, which thus never becomes dry. This process of digestion and repercolation will now go on continuously, but the extraction is hastened if after a column of liquid has filled the inner tube, the apparatus be momentarily removed from the source of heat, when the liquid will quickly pass through the solid into the flask, after which heat can be again applied and the operation repeated. The apparatus may be made of any dimensions; an apparatus four times the size of the diagram has been found convenient for general laboratory use. Having made upwards of two hundred extractions with this apparatus, using different solvents, we have no hesitation in recommending it as an efficient apparatus for accomplishing complete exhaustion in a short space of time.

[*The discussion on this paper is printed at p.* 676.]

THE ASSAY OF NUX VOMICA.*

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry,
AND F. W. SHORT,
Assistant-Demonstrator of Chemistry
in the Laboratories of the Pharmaceutical Society.

It will be immediately obvious that the accurate estimation of the total alkaloids in nux vomica seeds is a matter of great importance, for upon the amount of alkaloid contained in the seeds depends the physiological activity of the tinctures and other pharmaceutical preparations made from them. Considering the fact that nux vomica contains one and probably two alkaloids of potent activity, it is somewhat surprising that so little work has been done in this direction. The present paper is the outcome of an investigation made with the view of perfecting a method which should be at once accurate in result and simple in procedure. Professor Dragendorff† has proposed extraction of the seeds in a finely powdered state by boiling with dilute sulphuric acid. This solution is treated with magnesia until nearly all the acid has been neutralized and evaporated. The mixture, which should be decidedly acid, is extracted with alcohol. The alcohol is distilled off and the aqueous residue shaken with benzene, after which the solution is rendered alkaline and the alkaloids extracted with chloroform or benzene. According to results quoted by the author, from experiments upon known quantities of strychnine and brucine, the process yields very satisfactory results. It seemed to us that a process might be devised which should be less long and intricate than this, by taking advantage of the extreme solubility of strychnine and brucine in chloroform. We first attempted directly to extract the alkaloids liberated by an alkali from the seeds by means of this solvent. In the light of the researches of Gal and Etard,‡ Shenstone§ and others, we avoided prolonged heating of the alkaloids in contact with strong acids and alkalies. Fifty grams of nux vomica were made into a paste with a solution of sodium carbonate containing 50 grams of crystallized sodium carbonate, the mixture being dried over a water-bath. It was then powdered and packed in a percolator and percolated with chloroform, which passed through nearly colourless. This was shaken with dilute sulphuric acid and the chloroform separated; when evaporated it left a large quantity of oil which was not at all bitter, thus indicating that the alkaloid had been completely extracted. The acid solution on standing deposited perfectly white crystals of the acid sulphates of strychnine and brucine. By this means we have obtained large quantities of these salts. It now remained to examine the extent to which extraction had been effected. Already about 200 c.c. of chloroform had slowly passed through the mixture yet the marc was intensely bitter. 200 c.c. more of chloroform were then added, but even after this had percolated the marc was intensely bitter. A smaller quantity of the nux vomica was next operated upon in a similar manner with no better result, 10 grams after percolation with 200 c.c. of chloroform being still intensely bitter. The quantity of sodium carbonate added was now doubled, 10 grams being mixed with 5 grams of nux vomica, chloroform was boiled with the mixture and poured off, the residue being treated successively with more chloroform. In this way six successive 25 c.c. of chloroform were employed and failed to render the marc free from bitterness. Experiments were now made in which calcium oxide and hydrate and barium oxide and hydrate were respectively used in place of the sodium carbonate but with no better result. Finally, the experiments with these different alkalies, including sodium carbonate, were repeated, using the extraction apparatus which we have described in a previous paper. After six hours' extraction the marcs were appreciably bitter. The marc containing sodium carbonate was extracted with dilute sulphuric acid until free from bitterness, the solution rendered alkaline with ammonia and the alkaloid extracted with chloroform; 0·10 per cent. was obtained. When calcium hydrate was used, in one experiment 0·108 per cent. of alkaloid was found remaining in the marc, in another 0·1 per cent. The chloroform which had been used in the experiment with sodium carbonate deposited a soap on cooling; with calcium hydrate this was not noticed. Thus it was clear that another solvent was required in order to completely extract the alkaloid from the seeds.

Five grams of nux vomica prepared with sodium carbonate were extracted with the aid of the extraction apparatus by a mixture of equal parts of chloroform and alcohol. The marc was absolutely free from bitterness; the operation occupying about one hour. The mixture of chloroform and alcohol was shaken with dilute sulphuric acid, two separate ounces of a ten per cent. solution of sulphuric acid being used. The chloroform solution after evaporation left a residue which was distinctly bitter, hence the quantity of acid had been insufficient to extract the whole of the alkaloid from the mixture of chloroform and alcohol. Thus while the difficulty of completely extracting the seeds had been overcome, another difficulty had made its appearance. Experiments were next made where

* Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.
† *Die Chemische Werthbestimmung einiger Starkwirkender Droguen.* St. Petersburg, 1874.

§ *Journ. Chem. Soc.*, xxxix., 453.

extraction was effected, and completely effected, by chloroform containing respectively 40, 30 and 25 per cent. of alcohol. In the first two cases the extraction of the chloroform by dilute acid was effected, but with some difficulty; with the mixture containing 25 per cent. of alcohol it was at once accomplished. After some further experiments upon points of manipulation we adopted the following process. Five grams of the finely powdered nux vomica is made into a paste with a solution containing five grams of crystallized sodium carbonate; the mixture is spread on a plate, and dried over a water-bath. It is then powdered, placed in the extraction apparatus, and exhausted with 40 c.c. of chloroform containing 25 per cent. by volume of alcohol. This operation usually takes between one and two hours. The chloroform is then shaken with 25 c.c. of dilute sulphuric acid (5 per cent.) in a separating funnel, the chloroform is separated, and again shaken with half-an-ounce of the dilute acid. The mixed acid solutions are now filtered, if necessary, rendered alkaline with ammonia, and shaken with chloroform in a separating funnel, the chloroform is then evaporated to dryness over a water-bath, and the residue weighed when constant. If the chloroform is at all turbid it should be filtered before evaporation. In this way the alkaloids are obtained in a fused condition having a pale yellow colour. The residue totally dissolves in dilute sulphuric acid, from which the acid sulphates are deposited in perfectly white crystals. A genuine sample of nux vomica seeds, estimated in this way, yielded 2·67 per cent. of total alkaloid. Dragendorff* found in various specimens from 1·65 to 2·88 per cent. Shenstone† isolated approximately rather more than 2·25 per cent. This process then was, in result, satisfactory; the treatment, however, with sodium carbonate was somewhat tedious, and we therefore commenced a new series of experiments with various solvents to endeavour to extract the alkaloidal salts direct from the seeds.

Five grams of nux vomica were treated in the extraction apparatus with 65 c.c. of alcohol, the operation being allowed to proceed for two hours. The marc was still decidedly bitter, and the alcoholic liquid much coloured. The alcohol was partially distilled off and the residue mixed with chloroform; this solution was now shaken with dilute sulphuric acid and the acid liquid, after the addition of ammonia, again treated with chloroform. The solutions were all much coloured and impure; so, also, was the final residue. Thus alcohol alone is an inefficient solvent, both on account of the length of time required for complete extraction and of the amount of matter other than alkaloid which is dissolved by it. Five grams of nux vomica were extracted with 65 c.c. of chloroform for three hours. The marc was slightly bitter, but it was evident that nearly the whole of the alkaloidal salt had been extracted. The chloroformic solution was treated with dilute sulphuric acid, the mixture being well shaken. The chloroform after evaporation left a large quantity of oil which was not at all bitter, indicating that the sulphuric acid had completely converted the alkaloidal salts into sulphates. The acid solution after the addition of ammonia and agitation with chloroform yielded the alkaloids in a pale yellow fused condition. This experiment had shown that chloroform alone was not a good solvent, and having experienced the difficulty before, an experiment was made in which a mixture of alcohol and chloroform was used. Five grams of nux vomica were exhausted in the extraction apparatus with 40 c.c. of chloroform containing 25 per cent. of alcohol. In less than two hours the seeds were entirely exhausted, the marc being absolutely free from bitterness. The solution was treated with dilute sulphuric acid and afterwards with ammonia and chloroform in the usual way. A nearly white residue of alkaloids was obtained, which totally dissolved in dilute sulphuric acid. It now remained to quantitatively determine whether this residue, which weighed 0·161 gram, consisted wholly of alkaloid. After solution in a small quantity of dilute sulphuric acid, tannic acid was added until a precipitate ceased to fall. The precipitate, after washing, was dissolved in ammonia and shaken with chloroform, when 0·1566 of alkaloid was obtained. This process with tannic acid is not altogether a satisfactory one. It is extremely difficult to completely precipitate the alkaloids by its means from acid solutions, and from the solution of the tannates in ammonia the chloroform separates with much difficulty. These experimental difficulties are sufficient to account for the small loss that occurred in the preceding experiment.

Hence this direct method for the estimation of the alkaloids in nux vomica proved satisfactory. In detail the method is as follows:—5 grams of the finely powdered nux vomica seeds are packed in the inner tube of the extraction apparatus and exhausted by 40 c.c. of chloroform containing 25 per cent. of alcohol. This is usually accomplished in one or two hours. The solution thus obtained is well agitated with 25 c.c. of a 10 per cent. solution of sulphuric acid. The separation of the chloroform is much aided by gently warming the mixture on a water-bath. After repeated agitation the chloroform is separated by means of a funnel and again shaken with 15 c.c. of dilute sulphuric acid. The mixed acid solutions, from which all the chloroform has separated, should, if necessary, be filtered,* then made alkaline with ammonia and shaken with 25 c.c. of chloroform in a separating funnel. After the chloroform has completely separated it is slowly run into a dish, evaporated and weighed after exposure for one hour on the water-bath, by which time it is usually constant in weight. It is sometimes necessary to filter the chloroform after separation from the alkaline liquid. In this way we have estimated the amount of alkaloid contained in samples of the powdered nux vomica of commerce, with the following results:—

I. 2·92 per cent.; II. 3·57 per cent.; III. 3·32 per cent.; IV. 3·38 per cent.; V. 2·56 per cent.

In conclusion, we wish to lay especial stress upon the use of a mixture of chloroform and alcohol for the extraction of the alkaloids, and upon the fact that chloroform is an inefficient solvent when used alone. We have already successfully applied the mixture to the extraction of other alkaloids which are soluble in chloroform, but only with difficulty extracted by it. It is doubtless capable of further extension.

* Work cited, p. 65.

† Paper cited.

* It not unfrequently happens that the acid solution is turbid, not from the presence of solid matter, but from suspended chloroform in a finely divided state. This may be removed by agitation with a small quantity of chloroform. It is manifestly important that the acid solution should be free from impure chloroform.

The process which we have described can probably be advantageously used for the extraction of the alkaloids upon the large scale. The acid sulphates can be prepared in a pure condition by merely shaking the chloroform-alcohol mixture with a small quantity of dilute sulphuric acid and gently warming. Upon cooling, the acid liquid deposits perfectly white crystals of the acid sulphate. The results of our examination of the nux vomica of commerce show that the specimens vary considerably in alkaloidal content. It is extremely desirable that a definite alkaloidal standard should be fixed for seeds intended for pharmaceutical use.

THE CONSTITUTION OF LIQUOR SODÆ CHLORATÆ.*

BY WYNDHAM R. DUNSTAN,

Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society,

AND F. RANSOM.

The liquor sodæ chloratæ of the British Pharmacopœia, which is made by passing chlorine gas into a solution of sodium carbonate, is usually stated to contain sodium hypochlorite and chloride, with sodium bicarbonate. From the observations of Williamson (*Mem. Chem. Soc.*, ii., 234), and also from the results of some experiments of our own upon the action of chlorine upon certain metallic oxides and carbonates, we were led to the conclusion that liquor sodæ chloratæ contained no sodium hypochlorite, but hypochlorous acid in the free state. The experiments which are here described were made with the object of ascertaining the validity of this conclusion and of investigating the chemical changes which occur. At the outset a difficulty was encountered by reason of there being no ready and reliable qualitative test for hypochlorous acid when mixed with other salts, especially with hypochlorites and carbonates. After a great number of experiments with various reagents it was found that hypochlorous acid was readily soluble in ether, and that it could be removed from its aqueous solution by means of this solvent. Hypochlorite of sodium is not soluble in ether. It should be noted that free chlorine is also soluble in ether; for this reason when this substance was present, the solution was freed from it by a current of air.

A solution of liquor sodæ chloratæ of the British Pharmacopœia was prepared according to the official directions, with the additional precaution of passing the chlorine through a wash bottle containing a saturated solution of copper sulphate, by which means the gas was freed from the hydrochloric acid with which it is always associated when prepared by the ordinary means.† The solution of liquor sodæ chloratæ was shaken with ether. The ethereal solution possessed a powerful smell of hypochlorous acid and readily bleached a solution of litmus. As a further test of the presence of hypochlorous acid, the action of sodium hypochlorite upon green nickelous hydrate which results in the formation of black nickelic hydrate was employed,

$$2\,Ni(HO)_2 + NaClO + H_2O = Ni_2(HO)_6 + NaCl.$$

For this purpose the ethereal solution was shaken with a dilute solution of sodium hydrate and a few drops of nickelous chloride added. A green precipitate of nickelous hydrate alone was produced, and no change in this was produced even on boiling. The experiment was repeated many times with the same result. As it had already been proved by other tests that hypochlorous acid was present, and having previously noticed that a concentrated solution of hypochlorous acid in ether quickly decomposes, the ether being powerfully attacked, the action of ether upon nickelic hydrate was examined. To a solution of nickelous hydrate sodium hypochlorite was added; a black precipitate of nickelic hydrate was produced. The mixture was shaken with ether, the nickelic hydrate was speedily reduced to green nickelous hydrate. Cobaltic hydrate is by no means so readily reduced by ether, the reaction requiring a considerable time; in fact, the reaction is sufficiently characteristic to constitute a distinguishing test for the two metals. In view of this fact the ethereal solution was treated with sodium hydrate and this solution decanted from the ether. It gave an abundant precipitate of nickelic hydrate on the addition of a nickel salt. It was then evident that hypochlorous acid was a constituent of the solution. It now remained to examine the solution which had been extracted with ether. This had no odour of hypochlorous acid, did not react with a nickel salt and did not bleach a solution of litmus even after the addition of tartaric acid. Sodium chloride and bicarbonate with a trace of sodium chlorate were present. As this solution had been prepared two or three days it seemed likely that this latter constituent had been developed during this time. A solution was therefore prepared and at once treated with ether and the aqueous solution examined; no sodium chlorate was present. On further keeping the first solution, and especially upon exposing to light, more and increasing quantities of sodium chlorate were developed. This substance is most probably formed by the action of hypochlorous acid upon sodium chloride, thus, $6\,HClO + NaCl = NaClO_3 + 3\,Cl_2 + 3\,H_2O$. Williamson has shown that the decomposition is instantaneous upon the application of heat. We have found that only concentrated solutions of hypochlorous acid will act upon sodium chloride when evaporated together, as in dilute solutions the hypochlorous acid is volatilized with the steam. Hence the reaction is not applicable as a general test. Owing to this decomposition liq. sodæ chloratæ is unstable. The above experiments show that the liq. sodæ chloratæ of the British Pharmacopœia is a solution containing free hypochlorous acid, sodium chloride and sodium bicarbonate. The general reaction attending its production is symbolized by the following equation.

$$Na_2CO_3 + Cl_2 + H_2O = HClO + NaHCO_3 + NaCl.$$

Commercial specimens of liquor sodæ chloratæ were now examined. Samples from four of the

* Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.

† Throughout these experiments, the chlorine was generated from hydrochloric acid and manganic oxide. It may be here remarked that when chlorine is required free from hydrochloric acid the process with sulphuric acid, sodium chloride and manganic oxide is next to useless unless special precautions be taken. We have noticed that with more than one sample of manganic oxide, when the proportions recommended by Fresenius and others are employed, more hydrochloric acid than chlorine is at first evolved, probably due to deficiency in the strength of the manganic oxide.

principal wholesale houses in London were obtained. They were all alkaline to test paper. On shaking with ether nothing was dissolved from any of the four samples, hence no free hypochlorous acid was present. On the addition of tartaric acid they gave abundant evidence of the presence of sodium hypochlorite, which was also proved by the nickel reaction. Each contained traces of calcium. It was evident that they had been obtained by the decomposition of a solution of bleaching powder with sodium carbonate, and therefore contained sodium hypochlorite but no free hypochlorous acid.

[*The discussion on this paper is printed at p.* 677.]

THE ACTION OF CHLORINE UPON SOLUTIONS OF SODIUM CARBONATE.*

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society,
AND F. RANSOM.

The general subject of the action of chlorine upon metallic carbonates in presence of water has been studied by Williamson (*Mem. Chem. Soc.*, ii., 234). He concluded that no sodium hypochchlorite was formed, but free hypochlorous acid. In order to chemically explain the results of our former experiments with liquor sodæ chloratæ it was thought desirable to make a complete investigation of the action of chlorine upon solutions of sodium carbonate under different conditions. In all the experiments chlorine which had been purified by means of copper sulphate was employed in the manner described by us in a previous paper. 50 c.c. of a solution containing 25 per cent. of crystallized sodium carbonate, such as is used in the preparation of liquor sodæ chloratæ, were treated with about one hundred bubbles of chlorine gas; the escaping gas was collected and analysed. It consisted mainly of chlorine with a small quantity of carbon dioxide. No effervescence or other visible sign of the evolution of carbon dioxide was observed. The liquid had a characteristic odour quite distinct from that of chlorine in the free state and did not bleach a solution of litmus. The liquid was treated with ether and the ethereal solution after washing with a little water to remove adherent liquid possessed no bleaching properties. We have shown in a previous communication that hypochlorous acid is soluble in ether and sodium hypochlorite insoluble. The extracted aqueous solution was alkaline, and gave the hypochlorite reaction with a nickel salt, but did not bleach until after the addition of tartaric acid. It was then evident that this solution contained sodium hypochlorite but no free hypochlorous acid. We have found that sodium hypochlorite is incapable of bleaching in the presence of much free alkali, whether it be in the form of hydrate or carbonate; after the addition of an acid the usual bleaching effects are observed. Throughout these experiments the acid used for this purpose has been tartaric acid, for this acid does not liberate chlorine or an oxide of chlorine from sodium chlorate, which was frequently present in the solutions.

Fifty c.c. of sodium carbonate solution of the same strength as the preceding were treated with about three hundred bubbles of chlorine. No effervescence occurred. After about one hundred bubbles of gas had passed the small quantity of escaping gas was collected and analysed; it consisted principally of chlorine with some carbon dioxide. The solution was treated with ether in the manner before described. No free hypochlorous acid was found, but sodium hypochlorite in larger quantity than in the first experiment.

Fifty c.c. of the solution of sodium carbonate were treated with about five hundred bubbles of chlorine gas, and as before no effervescence occurred. After three hundred bubbles of gas had passed the escaping gas was collected and analysed; a small quantity of carbon dioxide was obtained. The solution was only faintly alkaline and bleached powerfully. A rapid current of air was passed through the liquid to remove the small quantity of free chlorine contained in it, and the solution shaken with ether. The ethereal solution instantly bleached a solution of litmus. The aqueous solution was freed from hypochlorous acid by repeated treatments with ether; the aqueous liquid bleached litmus solution rapidly, especially after the addition of tartaric acid. In this solution, both sodium hypochlorite and free hypochlorous acid were contained.

Fifty c.c. of the sodium carbonate solution were acted upon by about eight hundred bubbles of chlorine gas; no effervescence occurred, and the escaping gas contained only a small quantity of carbon dioxide. The solution had the physical properties of liquor sodæ chloratæ. It bleached litmus powerfully. After a current of air had been passed through the liquid it was shaken with ether; the ethereal solution bleached, but the extracted aqueous solution did not, even after the addition of tartaric acid. This liquid upon analysis was found to contain sodium bicarbonate and chloride. Thus, the original liquid contained hypochlorous acid, but no sodium hypochlorite.

Fifty c.c. of the sodium carbonate solution were treated with chlorine gas in larger quantity than in the preceding experiment. Effervescence commenced, and at this point the escaping gas was collected and found to consist entirely of carbon dioxide. As more chlorine was passed through the liquid the effervescence increased; the gas evolved was wholly carbon dioxide. Effervescence having ceased, the liquid was examined after the passage of air and found to consist of free hypochlorous acid which was extracted by ether, the remaining aqueous liquid containing sodium chloride with some sodium chlorate.

The experiments above detailed have been repeated many times with the same results. It was always noticed that no effervescence occurred until a large quantity of chlorine had been passed through the liquid.

The action of chlorine upon stronger solutions of sodium carbonate was now studied. A saturated solution of sodium carbonate was treated with a small quantity of chlorine; carbon dioxide was evolved in quantity rather greater than with more dilute solutions. The solution was analysed by means of ether as before described and with the same result, the formation of sodium hypochlorite without any free hypochlorous acid. On passing more chlorine through the liquid a precipitate was observed to form. At this point the reaction was stopped and some of the solution examined after filtration. It still contained only sodium hypo-

* Read at an Evening Meeting of the Pharmaceutical Society, February 7, 1883.

chlorite. The precipitate was examined and found to be sodium bicarbonate. On continuing the passage of the chlorine the precipitation increased, and when this had ceased the chlorine gas was allowed to pass until effervescence was first observed. The solution now, after removal of the free chlorine, contained no sodium hypochlorite, but hypochlorous acid in the free state. The aqueous liquid contained sodium chloride with some chlorate.

When chlorine was again passed through the liquid copious effervescence occurred and the precipitate of sodium bicarbonate rapidly disappeared, the solution finally being found to contain free hypochlorous acid, sodium chloride and chlorate. Experiments were now made at low temperatures and it was found that at 0° C. the reaction which occurred was the same as that at ordinary temperatures. At 100° C. it was found that the product consisted entirely of chloride and chlorate of sodium, carbon dioxide being evolved from the commencement of the reaction.

The first action of chlorine, then, upon a solution of sodium carbonate at ordinary temperatures and at lower temperatures, even to the freezing point of water, results in the production of sodium hypochlorite, chloride and bicarbonate. It may be represented thus:—

$$(1)\ Cl_2 + Na_2CO_3 = NaClO + NaCl + CO_2$$

$$(a)\ CO_2 + H_2O + Na_2CO_3 = NaHCO_3.$$

When more chlorine is passed through this solution the sodium bicarbonate is not appreciably affected, but the sodium hypochlorite is decomposed with the production of hypochlorous acid. We here assume that sodium hypochlorite is at first formed as the simplest hypothesis, but our experiments do not negative the possible existence of intermediate or double salts. The only two agents present which would affect the decomposition of the sodium hypochlorite are carbon dioxide and chlorine. The action of the former would result in the reproduction of sodium carbonate, an improbable result, and for which there is no experimental evidence in the present case. Williamson has shown that chlorine is capable of decomposing a solution of bleaching powder which contains calcium hypochlorite with the formation of hypochlorous acid, thus—$Ca2ClO + 2Cl_2 + 2H_2O = CaCl_2 + 4HClO$. We, therefore, made some experiments to discover whether this reaction obtained with sodium hypochlorite. A solution of sodium hydrate was treated with chlorine gas, and after a current of air had been passed through the liquid the solution was shaken with ether; the ethereal solution did not bleach, but the aqueous solution possessed strong bleaching powers. The solution was now treated with excess of chlorine. It possessed the very powerful and characteristic odour of hypochlorous acid. After passing air through the liquid it was treated with ether; the ethereal solution possessed all the properties of hypochlorous acid. The extracted aqueous solution contained sodium chloride and chlorate, but no sodium hypochlorite. Thus it was conclusively shown that chlorine possessed the power of decomposing sodium hypochlorite, forming hypochlorous acid. It now remained to examine the action of chlorine upon a mixture of sodium hypochorite and bicarbonate. Chlorine was passed through a solution containing about an equal quantity of these two salts No effervescence at first occurred and only a small quantity of carbon dioxide was found in the escaping gas. Just before effervescence occurred the passage of the chlorine was stopped and the solution analysed; it contained much free hypochlorous acid which was extracted by ether, leaving sodium chloride and bicarbonate with a trace of sodium hypochlorite in the aqueous solution. The further action of chlorine upon solutions of sodium carbonate may then be represented thus—

$$(2)\ NaClO + Cl_2 + H_2O = NaCl + 2HClO.$$

The solution at this stage represents the liquor sodæ chloratæ of the British Pharmacopœia, and the above equations explain the genesis of each of its constituents,—hypochlorous acid, sodium chloride and bicarbonate. If more chlorine be now passed into the solution effervescence occurs, owing to the decomposition of the sodium bicarbonate, thus—

$$(3)\ Cl_2 + NaHCO_3 = NaCl + HClO + CO_2.$$

Thus the final constituents of the solution are sodium chloride and hypochlorous acid. The liquid also contains sodium chlorate; this is doubtless produced by the action of hypochlorous acid upon sodium chloride, thus—

$$NaCl + 6\,HClO = NaClO_3 + 3\,Cl_2 + 3\,H_2O.$$

When chlorine is passed into a boiling solution of sodium carbonate, the reaction is as follows:—

$$3\,Na_2CO_3 + 3\,Cl_2 = 5\,NaCl + NaClO_3 + 3\,CO_2.$$

This reaction may be considered to take place in two stages:—

$$(1)\ Na_2CO_3 + 2\,Cl_2 + H_2O = 2\,NaCl + 2\,HClO + CO_2.$$

$$(2)\ NaCl + 6\,HClO = NaClO_3 + 3\,H_2O + 3\,Cl_2.$$

We are at present engaged in studying the action of chlorine upon certain metallic oxides and carbonates, and have already obtained some interesting results.

NEW PROCESS FOR THE EXTRACTION OF FISH OIL.*

A foreign exchange, speaking of the processes of extracting fish oil, invented by Messrs. Moride and Joulie, says:—The oil in fishes is contained in the network of the tissues, and cannot be liberated until they are destroyed, either by putrefaction or by the application of heat. In both these cases, the oil is subjected to an alternative process of a more or less decided character. It has, however, been noticed that under the influence of certain substances, the albuminoid matters, which form the tissues, contract, become tighter, and cause the oil to exude in a cold state, and in a condition of remarkable purity. The substances which produce this effect are notably lime, perchloride of iron, the sulphates of peroxide of iron, and the chlorides and sulphates of alumina. Of all these reagents, the salts of iron produce the best results, because they cause the disinfection of the substances to which they are applied, and, at the same time, secure them against putrefaction.

In the industrial application of this theory to fish, the inventors sprinkle it with five per cent. of its own weight of a solution of perchloride or persulphate of iron at 45° Baumé; it can then be easily kept three or four days, either entire or in pieces, without undergoing any alteration. It is passed into a machine which crushes it, and reduces it to a thick paste, which is received in bags and taken to the press. A rather large quantity of water is forced out, bringing with it the liquid oil contained in the fish. The cake which is withdrawn from the press dries readily, becomes very friable, and is easily pulverized. It still contains a small quantity of fatty mate-

---

* Reprinted from *New Remedies*, February, 1883.

rial, less liquid than oil, which can be extracted by a solvent, such as benzin or carbon disulphide. The greater part of this fatty material can also be obtained by submitting the cake to a second pressure between heated plates of metal.

The cake, freed from oil, dried and pulverized, forms an excellent fertilizer, containing 7 to 10 per cent. of nitrogen and 10 to 15 per cent. of phosphate of lime, according to the substance which has been employed in the anterior processes.

CONDENSED WHEY. A NEW INDUSTRY AND A NEW FOOD PRODUCT.*

BY PROF. ALEXANDER MUELLER.

Whey, which is a bye-product in the manufacture of cheese, contains about an equal quantity of milk-sugar and albumen, as well as a considerable quantity of salts and particles of caseine and butter-fat that have escaped being made into cheese. Only a very small percentage of all the whey produced in Germany is utilized directly for human nutriment, either as drink or as an addition to food and pastry, nor is much used for making milk-sugar. The greatest part of it is used as food for animals—hogs, calves, cows, and even horses—at least among country cheese-makers. Where large cheese factories are situated in cities, a considerable quantity runs off in the gutters and sewers.

The value of whey for feeding cattle and hogs is scarcely higher as an average than one-half cent. per gallon; its value as human food, on the other hand, is at least six times as high. This disproportion between supply and demand has frequently attracted the attention of milk producers and economists generally, without as yet, however, having met with any satisfactory solution.

The chief difficulty lies in the great dilution of nutriment in the whey, and the consequent tendency to sour or putrefy. The first step toward a better utilization of whey must be taken in the direction of concentration. As in the case of most other kinds of food, concentration will improve its keeping qualities.

It is a fact that the small dairymen of Norway have been wont from time immemorial to boil down the greater part of their whey, sweet as well as sour, more or less to a "mesost" or "prim," sometimes alone, sometimes with the addition of buttermilk, or even of cream. The boiling down in open vessels over an open fire of course demands the most painful attention to prevent burning, which would spoil the taste of the whole lot, and make it uneatable, for us at least. Then, too, the consumption of coal is so great as to make the product unreasonably costly. The use of a water or steam bath would overcome the former of these objections, but not the latter. A solution of the problem must be sought in the use of a vacuum apparatus, which, assuming the operations to be conducted on a large scale, guarantees at once the cheapest and best preparation.

After many fruitless attempts, an opportunity was afforded me last autumn, at the Cismar Condensed Milk Factory, in Eastern Holstein, to evaporate whey in a vacuum. But before the experiment had been made there, the firm of Heckmann, in Berlin, kindly placed at my disposal a suitable vacuum apparatus, with an arrangement to prevent foaming over, and all its attachments and service. I first made use of it last January. Part of the whey was evaporated until it just began to crystallize when cold; another part to a stiff dough, which, in a few days, hardened to a solid cake.

In both cases, but especially in the latter case, a very permanent product was obtained, which could be kept for months in pure, dry air without spoiling or moulding. Whey condensed *in vacuo* is better for making milk-sugar than any other preparation. For daily use in the household, it is capable of the greatest variety of uses for food and drink, the most important of which, it seems to me, is in making different kinds of pastry, for which purposes its milk-sugar and milk salts especially fit it, and this is the easiest way to utilize them in nourishing and sustaining large classes of people. C. Becker made experiments on baking with whey concentrated on a water-bath, while Bolle used a portion of the whey extracts obtained by me in Heckmann's factory here. These bakery experiments were so satisfactory that Bolle decided to have a vacuum apparatus set up in his own place, and to offer his whey to the Berlin public in the form of bread or cake.

In the course of the following winter and spring, Bolle put up the necessary apparatus, and having secured regularity in working the process, he began the regular manufacture of whey-rye bread, and of two kinds of wheat bread, one a fine article in rolls, made of the best wheat flour, with the addition of milk, butter, eggs, etc., the other plain bread in round loaves for daily use, without the addition of the more expensive ingredients. The public seems to have a taste for this new form of bread, and the example is worthy of imitation in other places.

By careful treatment of the whey, and if the bakery were properly conducted, I have not the slightest doubt that all large cheese factories which are situated in towns could make a profitable use of their now worthless whey by evaporating and baking it, and at the same time contribute to the sustenance of the people.

Besides this, cooks and housekeepers would soon learn to use extract of whey in the preparation of their daily food, both to improve the flavour and render it more digestible.

The fear that there will soon be too much whey extract made and offered to the public, is met by the idea that the larger cheese factories will in time cease to make use of thin or skimmed milk, but to sell it as condensed skimmed milk, as this would be more profitable than condensing the whey.

TOOTH WASH.*

Tooth washes prepared with soap bark as a base are not injurious to the teeth. Among the published formulæ, we select the following, giving the proportions according to Hager:—

Bennet's Tooth Wash.

Quillaia, in moderately coarse powder	20 parts.
Glycerin	20 „
Diluted alcohol	q.s.
Oil of gaultheria	q.s.
Oil of peppermint	q.s.

Macerate the quillaia with the glycerin and 180 parts of diluted alcohol, and enough of the oils to flavour the mixture, for twenty-four hours, occasionally agitating. Then filter and add enough diluted alcohol to make the product weight 200 parts.

Meyers' Tooth Wash.

Quillaia, in moderately coarse powder	50 parts.
Peppermint water	300 „
Alcohol	300 „

Macerate for a few days, then add

Cochineal, powdered	1 „
Peppermint water	100 „
Glycerin	100 „
Oil of gaultheria	1·5 „

Again macerate during one day, occasionally shaking. Finally add

Peppermint water, enough to make . 1000 parts.

Lastly filter.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 17, 1883.

THE REGISTRAR'S REPORT.

The Report on the state of the Registers of Pharmaceutical Chemists and Chemists and Druggists, presented annually by the Registrar under the Pharmacy Act, 1868, to the Council of the Pharmaceutical Society at its meeting in February, offers a convenient opportunity to all interested in the welfare of pharmacy in Great Britain for observing the effect of existing legislation in controlling the number of persons carrying on the business of a chemist and druggist in this country. Especially is this the case with the Report presented next after each of the general expurgations of the Register, such as have hitherto been effected at intervals of two years; because so imperfectly is the provision of the Act as to the communication of information concerning the death of registered persons carried out by registrars of deaths throughout the country, that the Register quickly becomes cumbered with a number of names that ought to be removed. For instance, the recent exercise by the Registrar of the power conferred on him by the Act, led to the removal of 253 names of persons to whose registration address the legal number of registered letters had been addressed and had been returned through the dead letter office.

The Report shows that the total number of persons whose names are included in the new Register of Chemists and Druggists is 13,447; this is 208 less than the number in the Register for last year, and 15 less than in that for 1881. From this it would appear that the number of persons who during the last two years have passed the qualifying examinations has been barely sufficient to counterbalance the removals from the Register occurring during the same time through deaths and other causes. Of course this is explained by the fact that the additions have necessarily been limited mainly to examined persons, whilst the proportion of deaths has naturally been much higher among those who were registered in virtue of having been in business before the passing of the Pharmacy Act, 1868. The result is that of the 13,447 persons whose names are now on the Register, 4798, or 35·68 per cent., have passed at least the Minor examination.

Turning to the smaller Register of Pharmaceutical Chemists, we find that here also there has been a decrease in the gross total, the number in the Register for the present year being 2275, against 2308 in those for 1881 and 1882. This apparently disproportionate decrease in so important a class will naturally attract attention and provoke anxiety, or may even lead, as in former years, to assumptions as to the looming failure of the efforts of the Pharmaceutical Society to establish a class of pharmacists who have voluntarily qualified themselves for carrying on their calling to an extent beyond that which is required by law. Should the Bill which it is intended to introduce into Parliament in the coming session pass into law the whole position will be altered, and it will be hardly worth while to discuss the pros and cons of this question. But, meanwhile, we are inclined to think that an undue importance may be attributed to any absolute decrease in the gross total of pharmaceutical chemists, since, as we have pointed out before, the decrease is considerably affected by the presence on the Register of a large number—still amounting to more than one third of the whole class—of persons who were admitted as pharmaceutical chemists in virtue of having been in business on their own account at least thirty years ago, whilst the class is entirely dependent for recruits upon persons passing the Major examination. We are of opinion that a truer estimate of the probable strength to which the class of pharmaceutical chemists would attain under present conditions may be formed by taking into account in the calculation only the numbers affecting those who have passed the Major examination. More than thirty-six years have now elapsed since the first Major certificates were signed, and this is a sufficiently long period of time to allow of some approximation to an average in gains and losses. Calculating upon these lines we find that the number of Major men steadily increases year by year, being 1511 in the new Register against 1498 in 1882, and 1450 in 1881. Last year 40 persons passed the Major, and the foregoing figures show that these were sufficient to replace the loss in examined Pharmaceutical Chemists and to increase the number by 13. Therefore these figures point to the conclusion that the number who passed the Major examination last year would have been equal to maintaining the equilibrium in a body of 2000 men, and assuming that the examination is usually passed early in life this is not far from what might be expected.

For convenience of comparison we append the figures in a tabular form as in previous years:—

	January 1, 1882.		January 1, 1883.	
	Number.	Per cent.	Number.	Per cent.
Pharmaceutical Chemists:— Examined . . / Non-examined	1498 / 810 } 2308	10·97 / 5·93 } 16·90	1511 / 764 } 2275	16·92
Chemists and Druggists who have passed the Minor only . .	3011	22·05	3287	24·44
Remainder, including those who have passed the Modified . .	8336	61·05	7885	58·64
Total	13,655	100·00	13447	100·00

The simultaneous presentation of statistics as to the numerical strength of the Pharmaceutical Society enables us also, as in former years, to call attention to some points bearing upon the extent to which the Society is representative of the whole body of chemists and druggists. In the first place it appears that the gross number of registered chemists and druggists connected with the Society at the beginning of the present year, either as Members or Associates was 4592, or 34·15 per cent. of the whole number on the Register. This shows a decrease of 15 in the absolute number as compared with the previous year, when it was 4607; but in consequence of the smaller number on the Register the relative proportion, which last year was 33·73 per cent., is higher by 0·42 per cent. The gains and losses are unequally distributed; but they are instructive as indicating that the point has been passed at which recruits from the unexamined class will be sufficient to replace losses of unexamined Members, and that under present conditions the maintenance of the numerical strength of the Society will depend upon a sufficient proportion of the men examined year by year joining it. It will therefore be interesting to see how far this requirement has been satisfied during the last twelve months. The decrease has been entirely confined to the two classes of Members, being 51 in the class of Pharmaceutical Chemists and 9 in that of Chemists and Druggists. The latter may be disregarded altogether in discussing this point, since this decrease must go on in an increasing ratio, and the disappearance of the entire item of 779 is only a question of time. The decrease of 51 in the class of Pharmaceutical Chemist Members is much more serious, especially in the face of the fact that the number elected or restored to membership was 43, and of these 40 would appear to have been examined men, or exactly the total number of persons who passed the Major examination in 1882. It will be seen from the preceding table that the number of non-examined Pharmaceutical Chemists on the Register was during the year 1882 reduced by 46,—from 810 to 764;—and since the roll of members must necessarily have been diminished to this extent, it follows that the accession to the Society of a number of examined men equal even to the total who passed the Major was insufficient by 5 to compensate the losses to the Society through deaths and secessions of examined men during the same time. It is worth mentioning, however, that 74 per cent. of all the holders of Major certificates at the present time are Members of the Pharmaceutical Society. Turning to the two classes of Associates the results are more satisfactory. The important class of Associates in Business, who, if the projected Bill passes in its present form, will become Chemist and Druggist Members, and eligible as members of Council, continues to increase steadily, the number being 1107 against 1069 last year; whilst the Associates not in Business, who also would have the option of becoming Members, have increased from 817 to 824.

The following is a tabular comparison of the numerical strength of the Pharmaceutical Society with the number on the Registers:—

	January 1, 1882.		January 1, 1883.	
	No.	Per cent of whole.	No.	Per cent of whole.
Pharmaceutical Chemists, Members of the Society .	1933	83·75	1882	82·72
Other Registered Chemists and Druggists connected with the Pharmaceutical Society	2674	—	2710	—
Total number of Registered Chemists and Druggists connected with the Pharmaceutical Society. . .	4607	33·73	4592	34·15
Registered Apprentices subscribing to the Society .	1046	—	1037	—

THE CHEMISTS' ASSISTANTS' ASSOCIATION.

It speaks well for the *esprit de corps* prevailing among the junior pharmacists in the metropolis that recently, at least, so keen an appreciation has been shown of the opportunities afforded them for social intercourse. The Dinner on Wednesday evening, in connection with the Chemists' Assistants' Association, proved no exception to the rule, about one hundred and thirty members and friends having been present on that occasion, under the presidency of Mr. M. Carteighe, President of the Pharmaceutical Society.

After the usual loyal toast of the Queen and Royal Family had been duly honoured, the Chairman proposed "The Medical Profession," coupling with it the name Dr. J. Langdon Down, as linking together in his experience medicine and pharmacy. In acknowledging the compliment, Dr. Langdon Down referred to a time when he unsuccessfully sought an engagement in London as a chemist's assistant, and spoke of his training in the School at Bloomsbury Square as awakening in him a love for science that had been very helpful to him in his medical studies. "The Pharmaceutical Society" was proposed in an able speech by Mr. Parkinson, who, quoting the Charter as to the four objects for which the Society was established, expressed an opinion that these had been steadily kept in view. The toast was acknowledged in eloquent terms by Mr. S. R. Atkins, Vice-President of the Pharmaceutical Society. The toast of the evening, "The Chemists' Assistants' Association," was proposed by the Chairman, who in the course of his remarks referred to the proposed Pharmacy Bill as closely affecting the future interests of assistants, and appealed to his hearers to consider it carefully, in a broad and liberal spirit, and then, if they approved of it, to give the Council their hearty support. The toast was coupled with the name of the President of the Association, Mr. W. A. Wrenn, who replied. The other toasts were, "The Pharmaceutical Press," proposed by Mr. Winfrey and acknowledged by Mr. Wootton; "The Visitors," proposed by Mr. H. H. Millhouse and acknowledged by Mr. R. W. Giles; and "The Chairman," proposed by Mr. W. H. Kerr. It is only due to the Dinner Committee to say that all the arrangements were excellent, and that the meeting was successful in every respect.

THE REGISTERS FOR 1883.

It will be seen from the advertisement that has appeared that the Registers of Pharmaceutical Chemists and Chemists and Druggists for 1883 are now ready and that copies may be had from the Registrar. It may be mentioned that the preliminary matter includes the latest addition to the Poison Schedule, and that in accordance with a suggestion made at the last Annual Meeting a summary has been prepared and inserted of all the regulations required by the Pharmacy Act, 1868, to be observed in selling by retail, and in dispensing "poisons."

At a recent meeting of the School of Pharmacy Students' Association, the new Faure-Sellon-Volckmar Accumulator was exhibited to illustrate a paper by Mr. H. Allen, B.Sc. As an example of its power a piece of platinum wire 9 inches long and $\frac{1}{8}$th inch thick, weighing 637·5 grams, was maintained at a bright red heat by one cell. Two cells were sufficient to raise the same platinum wire to a white heat. Each of the cells weighed about 15 pounds and contained nearly 1,000,000 foot pounds of energy.

* * *

There is to be an International Exhibition in Calcutta, under the patronage of the Viceroy, the day fixed for the opening being the 4th of December next. It is to be held in the "India Museum," a magnificent pile of buildings in the centre of the city, the use of which and of the adjoining grounds has been granted by the Indian Government, together with a lac and a half of rupees to defray the expenses of the Indian court. Full information concerning details may be obtained by persons resident in this country on application to the official agent, Mr. W. P. Dilworth, 4, Westminster Chambers, S.W.

* * *

At the quarterly examinations held under the Pharmacy Act of Victoria in December five candidates out of six passed the Major (there is no Minor) and became entitled to registration as Pharmaceutical Chemists. Three other persons acquired the same right by passing a "Modified" examination.

* * *

The Pharmaceutical Society of Victoria held its annual dinner in aid of its Benevolent Fund on the 13th of December. Among the toasts was one to the "Pharmaceutical Society of Great Britain and Kindred Societies." We regret to notice that Mr. Bosisto, who has presided over the Pharmacy Board since the passing of the Victoria Act, announced on that occasion his intention of retiring.

* * *

Vigorous attempts are being made in the United States to deal with the practice—not unknown in this country—of certain retailers making the sale of proprietary preparations at little or no profit a leading feature of their businesses as a "draw." A committee appointed by the Massachusetts Pharmaceutical Association has issued a circular calling upon the manufacturers of such articles to supply them only to such jobbers as will engage to adopt a "rebate" system similar to that which has been found to work well in the wholesale trade. It consists in invoicing the goods at an advance of 50 per cent. on the actual price and deducting a corresponding amount on payment of the bill, only when the retailer guarantees in writing that he has not and will not sell, directly or indirectly, to consumers below the marked price.

* * *

In a report recently presented to the Illinois Pharmaceutical Association by its Committee on Trade Interests attention is called to the prevalence of the practice of "cornering," or securing the control of the supply of a drug, in order to raise the price unduly. It was mentioned, as an instance, that the quotations for cubebs represented at that time three times the actual value of the drug.

* * *

The number of students attending the present sessions of the different colleges of pharmacy in the United States is, according to the *Pharmaceutical Record*, 1454. They are distributed as follows:—Albany, 31; Chicago, 160; Cincinnati, 94; Louisville, 57; Maryland, 80; Massachusetts, 112; National, 33; New York, 300; Philadelphia, 400; Pittsburg, 41; St. Louis, 96; San Francisco, 50. No return had been received as to the number attending Iowa College.

* * *

The editor of the *Chemiker-Zeitung*, Dr. Krause, calls special attention to a suggestion that has been made for the erection of a memorial to the late Dr. Friedrich Wöhler.

* * *

The "adulterated quinine" sensation in Paris has undergone further development. According to the *Times*, some of the French newspapers, in an excess of patriotic zeal, attributed the fraud to "a chemical manufactory at Milan, which some time ago amalgamated with a German one." It turns out, however, that the substitution was effected in Paris, and the foreign "chemical manufactory" so significantly pointed at is having recourse to the law courts to rehabilitate its character.

* * *

The first of a series of six lectures on the Applications of Electricity, for which arrangements have been made by the Council of the Institution of Civil Engineers, was delivered on Thursday evening, by Mr. W. H. Preece, the subject being "The Progress of Telegraphy." The other lectures of the series will be, on March 1, "Telephones," by Sir F. Bramwell; March 15, "The Electrical Transmission and Storage of Power," by Dr. C. W. Siemens; April 15, "Some Points in Electric Lighting," by Dr. J. Hopkinson; April 19, "Electricity Applied to Explosive Purposes," by Professor F. A. Abel; and May 3, "Electrical Units of Measurement," by Sir W. Thomson.

* * *

At the meeting of the Chemists' Assistants' Association to be held on Wednesday evening next, a paper will be read on "Lithiæ Citras," by Mr. C. Thompson.

Transactions of the Pharmaceutical Society.

EVENING MEETING.

Wednesday, February 7, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Pharmaceutical Society was held on Wednesday last, February 7. The chair was taken at half-past eight o'clock.

The minutes of the previous meeting having been read and confirmed, the first paper read was entitled—

A Research on the Alkaloid Gelsemine and some of its Crystalline Salts.

BY A. W. GERRARD, F.C.S.

The paper was printed last week (see p. 641), and gave rise to the following discussion:—

The PRESIDENT, in proposing a vote of thanks to Mr. Gerrard, said that it was obvious that the paper would not bear so much discussion as some of the papers which were read. At present Mr. Gerrard had the field all to himself.

Professor ATTFIELD said that the paper was one into which a great deal of labour had been thrown, and he hoped that it would not pass without those present showing that they appreciated it. Perhaps they would especially appreciate the new departure which Mr. Gerrard had made in his experiments. As far as could be judged, it appeared that the probabilities of truth lay with Mr. Gerrard rather than with Professor Sonnenschein. When two men were working at the same drug, and each got an alkaloid, and when one obtained it quite white, while the other got it slightly coloured, and when one obtained it in such a state that it gave no reaction with that great charrer of many organic substances, namely, sulphuric acid, and was not apparently acted upon by nitric acid, while the other got it in such a state that it was affected to some extent by those reagents, the probabilities lay with the investigator who got it in the white state in which it was not so attacked. Certainly Mr. Gerrard's figures, which justified his formula, were much nearer to those required by his formula than to those required by the formula of Professor Sonnenschein. Even if they supposed that Professor Sonnenschein's alkaloid was burnt in such a way that the oxidizer yielded a little water, as such materials commonly did, and that, therefore, his formula should contain less hydrogen than it did, and thus come somewhat nearer to Mr. Gerrard's formula, so that instead, say, of the formula being $C_{11}H_{19}NO_2$ as given by Professor Sonnenschein, it should be $C_{11}H_{12}NO_2$; even then the numbers which Mr. Gerrard got were much nearer to the formula which he suggested than to that suggested by Professor Sonnenschein, or that which might be inferred, assuming that he had got too much hydrogen. Mr. Gerrard's formula required 70·6 per cent. of carbon, and he got 70·3. Professor Sonnenschein's formula required only 67 per cent. of carbon. He (Professor Attfield) took the carbon for the purpose of illustration. Even admitting that there was too much hydrogen, contributed by the process rather than by the alkaloid, the formula $C_{11}H_{12}NO_2$ would require 69 per cent. of carbon, while Mr. Gerrard obtained 70·3 per cent. He hoped that Professor Sonnenschein or Dr. Wormley would go into the question. One matter he would suggest should occupy the attention of investigators, namely, a careful consideration of the set of reactions which pointed to a somewhat close analogy between this alkaloid and strychnine.

Mr. MARTINDALE said that having tried some years ago to repeat Dr. Wormley's experiments he had been struck with the great affinity which gelseminic acid had for gelsemine. He had little doubt that the product which had been in the market, and had been known as Sonnenschein's gelsemine, contained gelseminic acid as an impurity. It would be a great advantage to oculists and others to have the alkaloid free in a crystalline condition and its salts as Mr. Gerrard had produced them.

The PRESIDENT proposed a vote of thanks to Mr. Gerrard, and associated with the proposition the names of Professor Rouch and Dr. Tweedie.

The next paper was on—

Aromatic Spirit of Ammonia.

BY DR. THRESH.

The paper is printed on p. 661, and gave rise to the following discussion.

Mr. MARTINDALE said that he had twice suggested in the *Pharmaceutical Journal* that sal volatile might be made by admixture, without distillation. Referring to the British Pharmacopœia formula Dr. Thresh had stated in his paper that the official quantity of carbonate of ammonia refused to dissolve in the requisite amount of water and solution of ammonia without the aid of heat. He had, however, found that it dissolved perfectly; in fact, he had found that it would dissolve in a third of the quantity of water there ordered. He had 5 drachms of water with ¼ ounce of carbonate of ammonia; he would add to it 1 drachm of liquor ammon. fort., and it would be seen that it dissolved immediately, although he only used one-third the pharmacopœial proportion of water. The process in the British Pharmacopœia theoretically produced only normal carbonate. In Dr. Thresh's process the result would contain about four times as much caustic ammonia as was necessary for this purpose, and very much more than was contained in the United States Pharmacopœia preparation. He arrived at that fact simply by calculation.

The CHAIRMAN asked whether Mr. Martindale was prepared to say that his calculations were right. The basis of the paper was experimental evidence, and Dr. Thresh stated that the result which Mr. Martindale alleged did not occur.

Mr. MARTINDALE said that when the carbonate of ammonia was finely powdered and mixed in the British Pharmacopœia proportions, leaving out the spirit, and adding only a third of the water, it made a perfect solution even in the cold. The United States Pharmacopœia gave a preparation containing normal carbonate of ammonia with very little free ammonia; so that it was much more palatable than the British Pharmacopœia preparation, which contained a large quantity of free ammonia owing to loss of CO_2 during distillation. He had shown this experiment, because it referred to a paper he had published some years ago (*Pharm. Journ.*, 1871, p. 704), giving results obtained in testing some samples of aromatic spirit of ammonia. He at that time suggested three experiments. One was that which he had now performed. Another was performed with double the quantity of water; and in the third there was three times the quantity of water. The quantities of water, carbonate, and liquor ammon. fort. were those of the British Pharmacopœia, less the spirit. It was possible that there might not be an intimate chemical combination between the official carbonate and the liquor ammonia, but the solution was perfect. He knew that normal carbonate of ammonia dissolved very slightly in rectified spirit, and as soon as the solution was added the normal carbonate was precipitated.

Professor ATTFIELD: Is it normal?

Mr. MARTINDALE said that he supposed that it was normal as no CO_2 was given off. The normal carbonate was very soluble in water. In dissolving the arbonate of ammonia he had noticed that if he used only half the quantity of water which was necessary to dissolve it the salt split up in the process of solution, and he got a solution which left behind the acid carbonate. If he put to this, as he had done in his experiment, the small quantity of liquor ammonia which was necessary to dissolve it, the whole would dissolve in less than three volumes. The carbonate of ammonia of the British Pharmacopœia only dissolved in the proportion of one part in six. His idea was that this preparation should not contain so much caustic ammonia as Dr. Thresh suggested, and be less alcoholic. It would, no doubt, be a great advantage to have a preparation which would contain definite quantities of carbonate of ammonia and free ammonia in solution. The preparation which was made by admixture certainly had the advantage; but the carbonate of ammonia of commerce was not so pure as it ought to be, and some of its impurities were kept back by distillation. The fault he found with the paper was that Dr. Thresh made the preparation to contain too much free ammonia gas.

Mr. TANNER said that some years ago he made a great many experiments on this subject, and the results which he obtained pointed to the conclusions to which Dr. Thresh had arrived. The quantities of official carbonate of ammonia and ammonia ordered in the British Pharmacopœia were in the proportions to produce normal carbonate. He found that when they were in the still, and before distillation commenced, a considerable effervescence took place, and there was a consequent loss of carbonic acid. On estimating the amount of carbonic acid in the distillate he found that exactly 50 per cent. of the carbon dioxide was lost. The proportions ordered in the British Pharmacopœia were calculated to produce about 8 per cent. of normal carbonate of ammonia. If the distillation was conducted carefully and in small quantities about 4 per cent. would be found. The other 4 per cent. was dissociated. Its ammonia existed as free ammonia in the distillate, and its carbonic acid had disappeared.

Mr. SCHACHT said he had for some years manufactured a "sal volatile" without distillation for sale as "sal volatile," and a spiritus ammoniæ aromaticus, according to the Pharmacopœia, for dispensing. The constancy of strength in the former article was, he thought, an important advantage; and in respect of one alleged disadvantage, namely, that it gradually became coloured, he did not find that this invariably occurred. Perhaps the development of colour might depend upon the age of the samples of essential oils employed. He felt gratified to Dr. Thresh for having discussed the subject in so practical a manner, and for having offered so useful a suggestion to future Pharmacopœia compilers. Upon one point he did not quite agree with Dr. Thresh, namely, as to the necessity of employing heat in the solution of the ammonia salt. It is quite true that if made cold a precipitate occurs when the spirit is added; but if time be allowed, say two or three days, this precipitate is again dissolved.

Dr. SYMES said that Dr. Thresh was working towards the attainment of a very desirable object, namely, the production of a satisfactory sal volatile without distillation. One difficulty which he seemed to point to was that after admixture the preparation sometimes became coloured, and it would not do for chemists to trust a formula which was liable to give such a result. Dr. Thresh also found that the aroma of distilled sal volatile was more mellow than that of the product formed by simple admixture. He thought that the object sought had scarcely yet been attained in the best possible manner, but perhaps the author's object was to direct the attention of workers to this subject early in the day, that he might get their assistance. The work now required was, perhaps, to ascertain what results were produced by distillation, and whether the colour in the undistilled product was due, as Mr. Schacht suggested, to some oxidized matter in the essential oils, which matter might be separated by distillation. At the same time, he did not think that anybody could deny the value of the results so far as they went.

Mr. INCE thought that distillation could not be given up altogether in the preparation of sal volatile, and that it must be retained at least half way. It would be necessary to investigate whether there were not certain oils which could be used by simple admixture, and whether there were not others which could not be so treated. It was well known to pharmacists that there were certain oils which it would be useless and deleterious to attempt to distil. This was the case with heavy essential oils, by which he meant heavy oils having a very permanent and persistent odour, and it was a sort of law in pharmaceutical work that such an oil should be presented mixed with spirit, and this could always be done in the cold. In the case of such oils it would be best to use a simple admixture. The best way to use oil of peppermint was simply to make a mixture in spirit. It formed a very bad pharmaceutical preparation if distillation was used. The same was the case with oil of rosemary. If oil of lavender, which was a very heavy oil with a persistent odour, were distilled with spirit, the preparation was nearly worthless. He thought that at present there was no better formula before the public than that of the Pharmacopœia. In the case of a very light oil, like the essence of lemon, they would fail altogether if they simply resorted to mixture with spirit. The new preparation recommended itself in many ways, and particularly by the convenience of the process; but convenience must not be made a motive for departing from the instructions of the Pharmacopœia.

Mr. GILES said that the paper had two distinct aspects—one scientific, and the other practical. The characteristic feature of the practical aspect had not been spoken of. It was that it put into the hands of every pharmacist an easy means by which he might himself prepare sal volatile, and that was one of the most important considerations for a pharmacist. Many years ago he (Mr. Giles) attempted to make sal volatile. He thoughtlessly mixed the ingredients, *secundum* the Pharmacopœia, but not *secundum artem*, in a copper still. The meeting might imagine what a beautiful green he got. He corrected his mistake and then blundered into some of the results at which Dr. Thresh had arrived scientifically. He calculated out the results which the Pharmacopœia ingredients ought to produce and he dissolved these calculated products in the due proportion of water, but he found, for some reason which Dr. Thresh had now explained, that they would not remain dissolved when mixed with the spirituous solution of the aromatic oils. This difficulty was, however, removed by moderately heating the solution before mixing. Mr. Schacht seemed to think that heat was not necessary, but at all events it was convenient, and there was no objection to employing it. There was no magic in distillation, but there was a great deal of efficacy in heat. As Mr. Ince had said, there were two distinct processes with a distinct *rationale* for each. The *rationale* of the combination of the ingredients which went to form the ammoniacal constituents could be easily fulfilled by heating them in the aqueous solution to the required temperature. The perfection of the spirituous solution could be best obtained by distillation. But if the spirituous solution was treated separately it could be distilled in a copper vessel without any fear of contamination, and the anxiety arising from the fear of the fracture of a glass vessel could be avoided. If the process described was perfected and accepted there could be no excuse for any pharmacist not making his own spirit of sal volatile. He hoped that this subject would be prosecuted, and the next Pharmacopœia,—in which, of course, he anticipated, pharmacists would be concerned,—would contain a spiritus ammoniæ aromaticus which every one could make at home.

Mr. EKIN said that he believed that the discrepancies in the strength of sal volatile, to which Dr. Thresh had alluded, arose from a very simple cause. They might always get a uniform strength if there was sufficient condensing power. This was necessary whether they operated on a large quantity or a small quantity, and in summer or in winter.

Mr. TANNER, referring to Mr. Schacht's remark that time was necessary for the disappearance of the precipitate, said, as the result of the experimental trial which he had made, that neither three days nor three months would suffice to effect the combination of which Mr. Schacht spoke; but a temperature of 140° Fahrenheit would do it in a few minutes. The combination required was that of the ammonia with the official carbonate so as to be soluble in spirit. He had now in his possession some of the preparation which might have been made six months ago, and as nearly as he could judge the deposit was still the same as it was at first. Elevation of temperature was absolutely necessary to effect combination. If distillation be necessary all risk arising from the use of easily fractured glass veesels might be avoided by the use of a common tin bottle. Both the ammonia and the aromatic ingredients might be put into this vessel, and the distillation would be entirely free from metallic contamination. A one gallon or two gallon tin bottle, purchased at an oil shop and fitted with a cork and tube, would answer the purpose. He thought that it had been settled in that room, long ago, that the distillation of oil of lemons was not an improvement, and that the expressed oil was decidedly superior in flavour to any distilled product. In this respect he differed from Dr. Thresh. He failed to see the necessity for distillation at all, provided that the essential oils were fresh and pure.

Mr. SCHACHT said that it was very likely that Mr. Tanner and he were speaking of different things. Probably a mixture of ammonia in exactly the proportions given in the Pharmacopœia might result as Mr. Tanner had stated. He (Mr. Schacht) was rather directing attention to the results as detailed by Dr. Thresh, and he wished to say once more that if the proportions recommended by Dr. Thresh were adopted, it was certain that in three days a clear solution would be obtained without the aid of heat.

Mr. ANDREWS said that his experience was that oil of lemons was much more fragrant when it was simply dissolved in spirit than when it was distilled.

Professor ATTFIELD, on being asked by the President to reply on behalf of Dr. Thresh, said that it was with great hesitation that he did so. Indeed, he must leave Dr. Thresh to settle with Mr. Martindale the question of the solubility of carbonate of ammonia in ammoniacal water. He thought that it would be clear that the paper contained three leading points. Dr. Thresh recommended what had been happily called semi-distillation, and in this he would be glad to receive the support of such pharmacists as Mr. Ince and Mr. Giles. Secondly, Dr. Thresh recommended the use of warmth in combining the bicarbonate in "carbonate" of ammonia with ammonia; and here he was supported by the practical experience of Mr. Tanner and Mr. Giles. Thirdly, the author pointed out the fact that if they did not use warmth a deposition of ammoniacal salt would occur when the alcohol was added. And in this he was supported by two most practical men—Mr. Tanner and Mr. Martindale. He (Professor Attfield) was sure that Dr. Thresh would also thank Mr. Giles for pointing out the extremely practical value of such papers, and how that with light of this kind thrown on their work retail pharmacists could now make preparations like sal volatile far more conveniently than they could make them previously.

The PRESIDENT said it would be convenient to discuss the next two papers together. They were on—

AN APPARATUS FOR CONTINUOUS EXTRACTION,
and
THE ASSAY OF NUX VOMICA,
BY W. R. DUNSTAN AND F. W. SHORT.

The papers are printed on pp. 663 and 665, and gave rise to the following discussion:—

Dr. SYMES asked whether the authors in constructing the apparatus for extraction had tried the method, which he suggested about two years ago, of making the tube from the vessel pass through the centre of the marc rather than outside it. A large amount of condensation took place in the outer tube of the apparatus before them; but when the tube through which the vapour passed was carried through the centre of the marc, that condensation could hardly occur; and a larger proportion of marc also could be contained in the vessel. He had found from experience that a shorter tube might be used if the upper part was packed with silver gauze. This seemed to act mechanically, presenting a large surface and a number of points for condensation.

Professor BENTLEY said that he had long been aware that the nux vomica seeds of commerce varied considerably in strength; and having been in the habit of taking extract of nux vomica as a tonic he had suffered serious personal inconvenience from the variation. He had since taken solution of strychnia in order to get a definite compound. Mr. Hodgkinson had told him many years ago that it was well known to makers that certain commercial specimens of nux vomica yielded more strychnia than others, and he sent him samples of five varieties from Bombay, Madras and Cochin. This matter had been referred to in Bentley and Trimen's 'Medicinal Plants," where it is also stated that the Bombay variety yielded the most strychnia; and he (Professor Bentley) had also called attention to it for some years in his lectures. Perhaps it would be found that the strength of the seed differed according to its degree of maturity.

Mr. GILES asked to what Mr. Dunstan attributed the fact that chloroform mixed with spirit acted better as a solvent than chloroform. Was it due to the mixture penetrating better than the chloroform alone? And could Mr. Dunstan explain why the addition of sulphuric acid did not cause the alcohol to separate from the mixture?

Mr. TANNER said that it appeared to him that when two liquids of different boiling points were used in the same apparatus the marc was subjected to the action first of the one having the lower boiling point, and then to that of the one which had the higher boiling point. He had some time ago used a similar apparatus to that now exhibited, but it was made of tin ware, as described in Dorvault's 'L'Officine,' under the name of "Extracteur à distillation continue." He found that it answered well when a homogeneous liquid was used. With regard to Professor Dragendorff's process, he should like to ask whether sulphuric acid was the best thing with which to extract nux vomica. It appeared to him that the acetate of strychnia being much more soluble than the sulphate, dilute acetic acid would be preferable to dilute sulphuric acid. In the extraction of the chloroform particularly he should suggest the use of acetic rather than of sulphuric acid.

Professor ATTFIELD said that there could be no doubt that a great many apparatus had been suggested which had some resemblance to the present one, but the point of novelty in the apparatus which was now exhibited was that one could carry on either infusion or distillation or percolation with it, and no apparatus had been previously made in which that could be done.

Mr. GERRARD said that the apparatus before them was very ingenious and simple, and in that respect it recommended itself; but there appeared to be an objection to it in the long continued application of heat to the matters exhausted by the solvents. They would never think of estimating the amount of alkaloids in cinchona bark by such a process, for the long continued application of heat would interfere with the result. He should rather use hot percolation and evaporate at a low temperature. Temperature made a great deal of difference, especially in the case of alkaloids. He should like to ask to what extent alcohol was extracted by the water from the mixture of chloroform, alcohol and alkaloid. Probably it was nearly all removed, and, therefore, the aqueous alcoholic solution retained a considerable quantity of the sulphate of strychnine; and it would be necessary to have recourse to distillation or evaporation to obtain the full yield.

Mr. DUNSTAN, in reply, said, with regard to Dr. Symes's remarks as to condensation in the outer tube, that of course condensation occurred at first, but by fairly rapid boiling it was possible to get a temperature sufficient to volatilize the whole of the solvent from this tube. He had used the apparatus which Dr. Symes mentioned, but had not found that it was so efficacious for extraction as the present one. As to the different varieties of nux vomica which existed in commerce, if Professor Bentley would hand the samples he spoke of to Mr. Short and himself, they would be glad to examine them. Mr. Giles had asked why chloroform and alcohol extracted more readily than chloroform alone. The reason probably was that the chloroform alone was incapable of thoroughly penetrating the seeds. Mr. Giles mentioned that when chloroform and alcohol were mixed and shaken with sulphuric acid probably the alcohol would separate. Where chloroform and alcohol were present in equal quantities there would be a considerable separation taking place. It was not easy to see why the alkaloid was not wholly extracted by the dilute acid in that case, but it was a fact that it was not. As to the different boiling points of the two liquids, the result which Mr. Tanner had described might occur when there was a large proportion of solvents of very different boiling points, but it had not occurred with the present mixture. With chloroform containing 25 per cent. of alcohol the whole of the alcohol was carried up by the chloroform. Mr. Gerrard had spoken of the effect of the continuous application of heat upon the alkaloids; but he (Mr. Dunstan), failed to see that the method which Mr. Gerrard proposed avoided this. It was proved that strychnia and brucia were not altered by the temperature of boiling chloroform or of a mixture of chloroform and alcohol; nor were they altered by boiling in dilute sulphuric acid, according to Dragendorff. Of course there might be certain alkaloids which were altered at this temperature, but strychnine and brucine were not.

Two papers were then read—

ON THE CONSTITUTION OF LIQUOR SODÆ CHLORATÆ

and

THE ACTION OF CHLORINE UPON SOLUTIONS OF SODIUM CARBONATE.

BY W. R. DUNSTAN AND F. RANSOM.

The papers are printed on pp. 667 and 668, and gave rise to the following discussion:—

Mr. WILLIAMS said that he wished to congratulate the authors upon the papers which they had produced. He had had a good deal of experience in the subject to which they alluded, and these papers had cleared up some difficulties which had existed in his mind for a long time.

Professor ATTFIELD said that he had carefully followed the work of the authors, and he gave it as his candid opinion that they had clearly established the point which they had set out to establish. They had satisfactorily made out that chlorine acting upon a solution of carbonate of sodium gave a solution not of hypochlorite of sodium, but of hypochlorous acid. It was quite another question whether the solution which medical men prescribed should be one of hypochlorous acid or one of hypochlorite of sodium. It would be for therapeutists to decide that.

The meeting was adjourned to March 7.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, February 7, in the College of Physicians, Kildare Street, Dublin, at three o'clock.

Dr. Charles Tichborne, President, in the chair.

The other members of the Council present were—Dr. Aquilla Smith, Vice-President, Messrs. Allen, Brunker, Dr. Collins, Messrs. Draper, Grindley, Hayes, Minchin, Dr. Montgomery, and Mr. Simpson.

The President stated that Mr. Brunker had written to him suggesting that the Council should seek an interview with the Chief Secretary relative to the amendment of Irish Pharmacy Act, as if an interview were not obtained before the meeting of Parliament there would be no chance of doing anything this year. He (the President) coincided in that opinion and directed Mr. Fennell to write asking for an interview. Mr. Fennell would now read the reply which had been received.

Mr. Fennell read a letter from the Chief Secretary, Mr. Trevelyan, dated January 27, acknowledging the receipt of a copy of the report of the Pharmacy Act Amendment Committee of the Society, and expressing his regret that it was not in his power to receive a deputation from the Council, as he should have to leave town shortly after the beginning of February. He should be glad to consider any further views the Council might wish to state, if they would forward them in writing; and he would take the earliest opportunity he could of receiving a deputation.

On the motion of Dr. Collins, seconded by the Vice-President, the letter was ordered to be entered on the minutes.

A letter was read from Dr. Kaye, Q.C., Clerk of the Privy Council, dated January 22, which stated that a communication having been received from the Lords of the Privy Council of England, stating that the question of the amendment of the Pharmacy Act, of 1868, was now under consideration, and that he was desired to request the Council to give replies to the following questions:—(1) Whether the provisions of the Sale of Poisons (Ireland) Act, 1870, so far as regards the sale of poisons to persons unknown to the seller, are generally observed in Ireland; and, if so, whether any inconvenience has been caused thereby. (2) Whether it is considered desirable that any alteration should be made in the existing law by the amendment of the Sale of Poisons (Ireland) Act, 1870, or the Pharmacy (Ireland) Act, 1875, and if so, in what respect?

The President: Does not our report convey all our views?

Mr. Brunker; I do not think it does. We should get some more information as to the inconvenience arising from the sales of poisons.

Mr. Brunker moved—

"That the letter from the Clerk of the Privy Council of Ireland be referred to the Pharmacy Act Amendment Committee, who shall draw up a reply to same and report it to this Council, and that in the meantime circulars be sent to all licentiates residing in Ireland, requesting them to give any information in their power as to irregular sales of poisons in country districts."

Mr. Grindley seconded the motion, which was unanimously agreed to.

On the motion of Mr. Draper, seconded by Mr. Grindley, Mr. Brunker was appointed Chairman of the Pharmacy Act Amendment Committee.

A letter was read from Dr. Edmund W. Davy, examiner in chemistry, stating that the two other examiners, Dr. Duffey and Mr. Evans, concurred with him in suggesting that one entire day should be allowed to him (Dr. Davy) for written and practical examinations in chemistry, and that the other of the two examination days should be divided between Dr. Duffey and Mr. Evans.

Mr. Draper said the suggestion was a most reasonable one, and moved that it be adopted, and that Dr. Davy's letter be entered on the minutes.

Mr. Hayes seconded the motion, which was agreed to unanimously.

A letter was read from Dr. Moore, Registrar of the College of Physicians, conveying the permission of the College for the use of the Fellows' Room once a quarter for meetings of the Council.

Dr. Collins moved—

"That the thanks of the Council be conveyed to the President of the College of Physicians, and that the letter of Dr. Moore be entered on the minutes."

Mr. Brunker seconded the motion, which was unanimously carried.

A letter was received from Dr. Pollock requesting, on behalf of the Academy of Medicine in Ireland, permission to use the Council room in February and April for the exhibition of sanitary improvements to the members of the Academy. The improvements were to be shown under the direction of Mr. Maguire, of Dawson Street, to a meeting of a sub-section of the Academy on State Medicine.

The President said he took on himself to give the permission asked, because he felt sure that the Council would be glad to assist so important a body as the Academy of Medicine. The appliances had accordingly been put into the room. But he wished to call attention to the fact that the Academy of Medicine had also asked for the use of the room on a second day, namely, the 12th of April. He did not know whether that would clash with the examinations of the Society or not.

The Vice-President: We have no right to give the room without the leave of the College of Physicians.

The President: Dr. Pollock stated that he had applied to the College of Physicians and they referred them to us. Was Dr. Moore consulted in the matter?

Mr. Fennell: Yes, he spoke to us about it.

Dr. Montgomery: The Council ought to assist as much as possible the improvement of sanitary arrangements.

Mr. Brunker moved—

"That the Secretary of the Department of State Medicine of the Academy of Medicine be informed that the department can have our room on the 12th of April next, provided their arrangements do not clash with our examinations which will take place on the 5th and 6th of that month, and also provided the sanction of the College of Physicians is obtained."

Mr. Allen seconded the above, which was adopted unanimously.

A letter was read from Mr. A. Davison, chemist, of Kimberley Diamond Fields, South Africa, presenting two packets of original prescriptions to the Society.

On the motion of Mr. Allen, seconded by Mr. Grindley, a vote of thanks was passed to Mr. Davison.

The President moved—

"That a notice must be forwarded by the Registrar to all members of the Pharmaceutical Society a fortnight before the expiration of their subscription to the effect that the *Pharmaceutical Journal* will not be supplied after the date which closes their subscription. That the Registrar be directed to act strictly in conformity with this resolution, but that on receipt of the lapsed subscription within a reasonable time he may forward the back numbers as supplied."

Last year the Society lost money by the *Pharmaceutical Journal* being supplied to members who neglected to pay their subscriptions. According to the existing regulation they were bound to supply the Journal for six months; and if a man then dropped off they lost his six months' subscription to the Journal, because he never informed them that he was going to drop off. He simply did not pay his money. They did not want members of that kind; they were a great drag on the Society. One object of his motion was to put an end to this state of things. Another was to test whether the supply of the Journal was an inducement to members to subscribe. The practice which he recommended was in existence in connection with all subscription journals in London and elsewhere; immediately the subscription was up the supply of the journal was stopped. One member of the Council had said that he did not like his (the President's) arrangement, and that the very day the notice appeared upon the paper three gentlemen had said they were taken by surprise, and had paid up their subscriptions. That he considered an excellent argument in favour of his motion.

Mr. Draper seconded the motion.

Dr. Montgomery said he thought it was a pity that gentlemen desiring to belong to the Society were also obliged to take the Journal. He thought members should be at liberty to take the Journal or not, as they pleased. Of course, the question was a broad one; but it would be a great matter if the Council could see their way to making the Journal a separate thing. The subscriptions of those who did not take the Journal might be reduced.

Mr. Draper: You should bring that question before a general meeting of the Society.

A Member of the Council pointed out that the supply of the Journal was merely an act of grace, and that the subscription, in any case, could not be reduced.

The latter part of the resolution was modified, so as to declare that the lapsed subscription should be sent in within two months; and with that alteration it was put and carried unanimously.

A report of the Law Committee, which recommended amongst other things that a circular should be issued to members of the Society asking them were they willing to contribute to a prosecution fund, was adopted.

A report of a Committee on the new mode of marking suggested for the examiners, was brought up. It stated that the members who attended the Committee were the President, Messrs. Allen, Brunker and Montgomery, together with Dr. Duffey and Mr. Evans, examiners. They had discussed the proposed rule as to percentage, and recommended that the minimum for Pharmacy should be 45 per cent., and that for Chemistry, Materia Medica, and Botany 40 per cent., and that the candidate should make a total of not less than 55 per cent. It was suggested that the examiner in arts should be requested to make his marking in conformity with this arrangement. The examiners had suggested that the written and the practical examinations should be on separate days, and the Committee recommended that that suggestion be acquiesced in.

The report was adopted.

The Council then adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting of the above Association was held at the Royal Institution, on Thursday, February 1, 1883. The President, Mr. Joseph Woodcock, occupied the chair.

The minutes of the last meeting were read and confirmed.

The following donations were announced:—The *Pharmaceutical Journal*, from the Society; the *Canadian Pharmaceutical Journal*, from the Editor.

Mr. A. H. Samuel called attention to the recent discovery that some of the Paris Hospitals had been supplied with a preparation under the name of quinine containing upwards of 40 per cent. of cinchonine.

Mr. Symes mentioned the subject of permanganate of potash pills.

Mr. T. Farmer, F.C.S., F.R.H.S., then read a paper upon the "Development of Theory in Chemistry."

A vote of thanks, proposed by Mr. A. H. Samuel, was passed to Mr. Farmer for his interesting and elaborate paper.

ABERDEEN CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The weekly meeting of this Association, was held on Thursday, February 8. The President occupied the chair and there was a fair attendance.

The subject on the syllabus was a debate on "Should the Proposed Curriculum be adopted." It was opened in the affirmative by Mr. Charles Moir, and the negative was argued by Mr. R. Eden. The discussion was entered into with great spirit, being taken part in by nearly all present.

On the vote being taken at the close it was found that the negative view had commanded the majority of votes.

A vote of thanks to the leaders terminated the proceedings.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the above Association was held at the rooms, Halford Street, on Thursday, February 1, 1883. The President, Mr. J. J. Edwards, in the chair.

After a few remarks from the President, a report of the past half-year's work was read and adopted, from which the following has been abridged:—

The Committee stated that the materia medica class had been continued, and a chemistry class again started, both attaining a fair amount of success. The number of members had increased; but it had been found absolutely necessary to resort to some practical means for the increase of the funds, and with this object in view, the fees of the members had been raised. This to some degree had had the desired effect, but as there had been shortcomings elsewhere, it had not entirely removed the difficulty. It is earnestly desired that the Association should receive the full support of the members of the trade, lest that which has been the means of untold usefulness in the past, and held a high place amongst associations of its kind, should come to an issue by no means pleasing. The hearty thanks of the Committee were tendered to the honorary members for their subscriptions; the Pharmaceutical Society, for the Journal; the British Pharmaceutical Conference, for the last 'Year-Book of Pharmacy'; and the gentlemen who had delivered lectures during the half-year.

The meeting then proceeded to the election of a Committee for the ensuing session, with the following result:—Mr. J. Garrett, President; Mr. J. J. Edwards, Vice-President; Mr. W. B. Clark, Treasurer; Mr. R. E. Broof, Secretary; Messrs. Kelly, E. Brice and Winter.

The balance sheet showed that the receipts during the half-year had amounted to £13 17*s.* 4*d.*, and that the balance due to the Treasurer had been reduced from £5 13*s.* to 15*s.* 9*d.*

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The seventh meeting of this session was held in the Pharmaceutical Society's Rooms, 119A, George Street, on Wednesday, January 31, Mr. Peter Boa, President, in the chair.

The minutes of the former meeting having been read and confirmed, the Chairman called upon Mr. J. R. Hill, Secretary to the Association, to read a paper on "The Manufacture of Sulphuric Acid."

In the introductory portion of this paper the properties and uses of sulphuric acid were fully treated, it being pointed out that nearly nine-tenths of the product is utilized by the manufacturers in the production of alkali, artificial manures, etc. The history of the acid from the time of Geber up to the present time was then given, the author incidentally noting the different methods of preparation used from time to time and the quantities and market value of acid so produced. He then proceeded to consider the composition, properties and sources of the raw materials employed. Regarding sulphur, it was mentioned that at one time Sicilian sulphur was the only body employed for the production of sulphur acids, but owing to the monopoly granted by the Sicilian Government its use for this purpose had now been almost superseded by pyrites. A full account of the methods employed in manufacturing acid from both materials was given, the description being rendered very interesting by means of a series of diagrams of furnaces, Gay Lussac and Glover towers and other plant employed, as well as by an enlarged plan of a sulphuric acid manufactory. The paper concluded with a summary of the theories advanced regarding the reactions which may take place during the chamber and denitrating stages, the author illustrating his statements by blackboard equations.

A discussion followed the reading of the paper, in which Messrs. Adamson, Boa, Hendry and MacEwan took part.

On the motion of the President, a hearty vote of thanks was accorded to Mr. Hill for his interesting communication.

A series of specimens illustrative of the paper will be shown at the next meeting of the Association.

After some other business had been disposed of, the President announced the next meeting for February 21, when a paper on "The Manufacture of Alcohol" will be read by Mr. James McGlashan.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on February 1. Dr. Gilbert, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The following certificates were read for the first time: G. Board, J. J. Knight, J. O'Sullivan, A. Vasey, T. D. Watson, R. M. Walmsley.

During the evening a ballot was held, and the following were declared by the Scrutators, Messrs. J. Spiller and W. Thorp, to be duly elected, as Foreign Members: F. Beilstein, D. T. Clève, H. Debray, E. Erlenmeyer, R. Fittig, H. Helmholtz, D. Mendelieff, Victor Meyer, Lothar Meyer; as ordinary Fellows, H. C. Bond, G. Chandra Basu, J. Brock, A. M. Chance, J. T. Donald, H. C. Foote, W. Fox, W. R. Flett, J. A. M. Fallon, E. C. Gill, F. Gothard, J. Hunter, H. Jones, R. B. Lee, A. H. Jackson, Joowansinghi, T. Jenner, J. E. Johnson, W. W. J. Nicol, F. W. Richardson, E. S. Spencer, C. A. Serré, T. Turner, J. E. Tuit.

Dr. Hodgkinson then communicated to the Society a paper—

On Derivatives of Fluorene. By W. R. E. Hodgkinson and T. E. Matthews.—Since Berthelot first isolated diphenylenmethane from coal tar oil, this body, termed fluorene from its supposed fluorescent properties, has been studied by several chemists. The object of the present investigation was to obtain a hydroxyl derivative. The fluorene was obtained in a state of approximate purity from Schuchardt and Kahlbaum. It was crystallized five or six times from hot alcohol, those crystals only being reserved which fell out between 25°–30°, and thus a pure product melting constantly at 113° and boiling 298°–305° was obtained. The slight fluorescence of this pure product can be entirely removed by sublimation over a little potassium carbonate. A dibromfluorene $C_{13}H_8Br_2$ and a monobromfluorene $C_{13}H_9Br$ were obtained; both these bodies yield on oxidation a substituted diphenylen ketone. The authors have also prepared fluorene sulphonic acid, $C_{13}H_9SO_3H$, by treating a chloroform solution of fluorene with SO_3HCl; the potassium, barium and cadmium salts were prepared and analysed. On heating the potassium sulphonate with potash to 400° C, acidifying the product and distilling in a current of steam, a white crystalline substance came over consisting of a substance melting at 205°, having the composition $C_{12}H_{10}O_3$, and a second substance much more soluble in water. This extraordinary result, the formation of trihydroxydiphenyl, can only be brought about by the splitting off of the methylen group in fluorene, and its replacement by two hydroxyl groups. By dropping the hydrocarbon into fused potash a dihydroxydiphenyl $C_{12}H_{10}O_2$, melting at 98°, was prepared. The authors shortly discuss the constitution of these bodies. The authors have also prepared dichlorfluorene $C_{13}H_8Cl_2$ by passing chlorine through a cold chloroform solution of fluorene. By using boiling chloroform a substance $C_{13}H_5Cl_7$ is obtained; a completely different action takes place when chlorine is passed into boiling fluorene. Fused potash acts energetically on these chloro-derivatives.

Mr. R. COWPER then read a paper—

On the Action of Chlorine on certain Metals.—As previously noticed by Wanklyn, dry chlorine is quite unable to act upon metallic sodium. The author finds that chlorine which has been perfectly dried by long contact with fused calcium chloride is without action on Dutch metal foil; on introducing a minute quantity of water the ordinary reaction ensues immediately. Similarly zinc foil and magnesium are not attacked. Silver and bismuth are tarnished very slowly. Tin foil, arsenic, and antimony are attacked immediately. The author remarks that these three metals all form chlorides which are liquid at ordinary temperatures. Chlorine, whether dry or moist, attacks mercury. If dried chlorine be passed over a piece of potassium the latter catches fire; this is probably caused by the envelope of hydrate. Potassium was sealed up in a tube containing dry air; the tube was then heated until all the oxygen was absorbed and a bright surface of potassium obtained; the tube was then filled with chlorine. The surface of the metal became slowly covered with a deep purple film, and the potassium finally ignited when heated considerably above its melting point.

Dr. Armstrong suggested that the author should dry the chlorine with phosphoric anhydride, and then try its action upon antimony; it was most important to settle the question whether two bodies could act upon each other without the presence of a third. Thus in most text-books it was stated that zinc dissolved in sulphuric acid; now, zinc is quite insoluble in sulphuric acid, and the presence of water is necessary to effect solution.

Mr. J. Spiller asked if the author had ascertained, in an alloy, whether chlorine attacked one metal leaving the other untouched, as, for instance, an alloy of zinc and tin.

Mr. Groves said that bromine when dry had no action upon zinc, but acted violently upon antimony and tin.

Dr. Hodgkinson mentioned that sulphur dioxide and sulphuretted hydrogen did not act upon each other if perfectly dry.

Professor McLeod said that similarly carbonic oxide and oxygen did not explode if free from moisture.

Mr. Cowper in reply said that he had not tried the action of chlorine upon an alloy of zinc and tin, nor upon phosphorus.

Mr. L. T. WRIGHT then read a paper entitled—

Some Notes on Hydrated Ferric Oxide and its Behaviour with Sulphuretted Hydrogen.—The author endeavoured to prepare hydrated ferric oxide by precipitating the chloride with ammonia, but could not succeed in preparing it free from basic chloride. In order to avoid the inconvenience of handling a bulky gelatinous precipitate the following method was tried:—Ferric chloride solution was added slowly to an excess of ammonia, and the whole evaporated to dryness at 100°. The reddish brown mass on treatment with water fell into an impalpable powder, which, for the most part, passed through many filter papers. The filtrates were turbid and of a bright red colour. In this condition the precipitate is probably similar to the so-called "colloidal ferric hydrate." The ferric hydrate in this condition is not blackened by sulphuretted hydrogen. Recently precipitated ferric hydrate is blackened at once by sulphuretted hydrogen, and the sulphide thus formed is completely soluble in excess of potassic cyanide

$$FeS + 6KCN = K_2S + K_4Fe(CN)_6.$$

Two equations are given in text-books to express the reaction of sulphuretted hydrogen upon hydrated ferric oxide,

$$(1)\ Fe_2O_3H_2O + 3H_2S = Fe_2S_3 + 4H_2O$$
$$(2)\ Fe_2O_3H_2O + 3H_2S = 2FeS + S + 4H_2O.$$

The author has studied the reaction, estimating the sulphur and the water formed.

Mr. Page suggested that it would be interesting to know whether the finely divided precipitate could be filtered off by sucking the fluid by a Sprengel pump through porous porcelain. Milk when thus filtered through the porous cell of a Daniell battery furnishes a perfectly transparent filtrate almost free from albuminous bodies and fats, but containing the sugar and salts.

The Secretary then read a paper—

On Alpha Cyano-naphthalene Sulphonic Acid. By U. K. DUTT.—The author first prepares naphthalene alpha sulphonic acid by treating naphthalene in carbon disulphide solution with sulphuric hydrochloride. The acid was converted into a potassium salt, which was distilled with an equal quantity of potassium ferrocyanide. The product was crystallized from light petroleum, and obtained as yellowish acicular crystals, melting at 36°. This α-cyano-naphthalene was dissolved in carbon disulphide and treated with sulphuric hydrochloride, and thus brilliant, colourless, laminar crystals of α-cyano-sulphonic acid were obtained; the barium salt was also prepared and analysed by the author.

M.P.S.—Syrup of white poppies.

An Assistant.—We do not think the subject can be discussed profitably in these columns, by persons unacquainted with all the circumstances of the case. Evidently there is some excuse for irritation.

R. B. Rees.—A recipe for ginger ale will be found in vol. xi., p. 588. As to "soluble essence of ginger," see Mr. Thresh's papers, vol. x., pp. 193 and 260.

Nemo.—A widow of a chemist and druggist, left sole executrix, may carry on the business with the aid of a qualified assistant, only during the time in which she is engaged in carrying out the duty of executrix.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Symes, Dr. Hesse, Messrs. Benjamin, Long, Martin, Symons, Smith, Forrest, Haydon, Wade, Laurie, Vincent, Evans, Pond, Williams, Hoult, Clagur, Cymro, Tinct. Gent. Co., A Forth Bank Assistant, One who Loves the Work, etc., B. J.

"THE MONTH."

Welcome signs of spring are already meeting the eye. The upper branches of the elm are bristling with flower-buds, the coltsfoot is decking favourite localities with its bright blossoms, and the catkins of the black poplar, the hazel and the willow are beginning to show traces of colour. An Isle of Wight correspondent remarks that compared with last year the flowers are running a neck-and-neck race. *Pulmonaria angustifolia* was observed in flower on February 7, and the Lent lily, true to its name, opened one day before Lent began. In the Royal Gardens, at Kew, the nutmeg is just coming into blossom.

In *Nature* (February 15, p. 365), Fritz Muller calls attention to some interesting facts with regard to plants which have differently coloured anthers or pollen in the same flower, or stamens of different length. Thus in *Heteranthera reniformis* insects visit the short stamens with yellow anthers, while fertilization is effected by the longer stamen with pale blue pollen. He suggests that the green colour of the anthers of the longer stamens of the mid-styled and shorter-styled flowers of *Lythrum Salicaria* may protect them against the attacks of pollen-eating insects. In a species of *Cassia* he has noticed that the humble bees which visit it gather the pollen of the four intermediate stamens, the three upper ones being pollenless, while the three lower ones, which are very long and curved, deposit their pollen on the back of the insects, whence it is taken by the similarly curved and elongated style.

At a meeting of the Linnean Society, January 20, Mr. H. Groves exhibited a specimen of *Ranunculus ophioglossifolius*, collected in the New Forest. In the British Islands this species has hitherto been found only in Jersey, and even there it is now practically extinct. The discovery of this plant and of *Eriophorum gracile*, *Orchis incarnata*, L., and of new localities for *Spiranthes æstivalis* and *Isnardia palustris*, indicate that there are probably parts of the grand old forest which may still repay careful exploration. A new British *Potamogeton* is also reported from North Wales, an account of which will appear in the March number of the *Journal of Botany*.

It is fortunate that fungological forays do not depend for their success on the edible properties of the species met with. One by one our edible species have been recently attacked. M. Dupetit has stated that *Agaricus campestris*, *Boletus edulis*, and three species of *Amanita* contain a poison, and now fresh *Helvella esculenta* is stated by Dr. Bostroem, of Freiburg (*Brit. Med. Journ.*, Jan. 27, p. 172), to also contain under all conditions a very active poison. Boiling and rejection of the water afterwards, prolonged washing, the addition of salt and any pickling process all fail to eliminate it. The fact, however, that this and other fungi have long been eaten with impunity, taken in conjunction with Bostroem's statement that the active principle is very soluble in hot water and is very unstable, and his denial that there is any form of the fungus but the typical one, as well as his affirmation that that one is poisonous, leads to the suspicion that it is probably only in cases of idiosyncrasy, or when the fungus is eaten raw, that there is any danger. *Lycoperdon giganteum* has been known to produce poisonous symptoms when eaten raw, but it is harmless and agreeable to eat when cooked.

The importance of a knowledge of the properties of the microscopic fungi with which we are surrounded is daily shown to be more and more important. A disease occasionally met with in France and occurring (*Lancet*, Jan. 27, p. 160), chiefly among labourers who manipulate the stems of the large reed, *Arundo Donax*, has recently been traced to the fungus *Sporotrichum dermatodes*, developed on the surface of the reeds under the influence of prolonged exposure to moisture. The symptoms produced are a painful irritation of the nose, eyes and throat, followed by erythematous swelling, which extends to others parts of the body. Acuminated pustules subsequently appear; inflammation of the eyes and a slight cough being also produced. Although usually trifling, the malady may sometimes assume a severe form, and has been known to cause death.

The *Brewers' Guardian* (Feb. 13, p. 47), calls attention to the fact that notwithstanding there was probably nearly 300,000 tons of dry yeast produced in the breweries of this country last year, six-sevenths of which was in excess of the requirements of the breweries, the imports of dried yeast from abroad during the same period amounted to nearly 30,000 tons. It is known that the bitterness of brewer's yeast is an obstacle in the way of its utilization by bakers, for whom the specially-prepared yeast is imported from abroad; but it would seem desirable that further investigation should be made as to the possibility of removing the objectionable bitterness and so to make another waste product available for economic purposes.

A few months since it was demonstrated by M. Gessard (*Pharm. Journ.*, [3], xii., 802) that the blue-green coloration sometimes noticed on the dressings of wounds is due to the development of minute organisms capable of separate cultivation. M. Rapin has now found that the analogous phenomenon of a black coloration occasionally occurring in toilet sponges is referable to a similar cause (*Lancet*, Feb. 17, p. 325). The blackness is attributed to the development of a minute fungus belonging to the genus *Torula*, and which he has named *T. spongicola*, in the chitinous fibres of the sponge, where it produces black spores and induces an alteration in the tissue of the sponge itself, which also becomes black. The fungus is communicable from one sponge to another; but it can be combated with the ordinary disinfectants or boiling water.

M. A. Bechamp, in the first number of Brown-Séquard's *Archives de Physiologie* for the present year (*Lancet*, January 27, p. 163), undertakes to show that the power possessed by the saliva of man of converting starch into sugar, which is not exerted by the saliva of the horse, dog or ox, is dependent upon a peculiar and special zymase which is the outcome of the action of microzymes peculiar to the salivary glands, of the microzymes of the anatomical elements which line the buccal cavity and the tongue, and of the microzymes and infusorial animalcules that accumulate in the interstices of the teeth. He found in the course of his experiment that a milligramme of the matter adherent to the free border of the gums of a healthy man, after being frequently washed with a weak solution of creasote, acted powerfully on starch paste. The parotidean saliva of the horse and dog do not saccharify boiled starch naturally, but acquire the power if placed in contact with the buccal organism of man.

Dr. C. Burger, of Bonn, describes in the *Berl.*

Med. Woch., No. 1, 1883 (*Med. Times and Gazette*, Feb. 3, p. 129), the bacterium of whooping cough. They are found most abundantly in the opaque white pellets of the early stage of the disease. With a magnifying power of 600 diameters the bacilli appear as small rods of different sizes, but of an attenuated ellipsoidal shape, the smaller being about twice as long as broad. With the aid of higher magnifying power and an Abbé condensing lens the larger rods are seen to have a constriction in the middle. These are quite distinct from those of *Leptothrix buccalis*, which are longer and thicker, and the spores and long threads of the leptothrix may always be discovered in close contiguity with them. Methyl-violet or fuchsin is used as the staining agent.

M. Vallin has lately (*Lancet*, Jan. 27, p. 161) communicated to the Académie de Médecine the results of a series of experiments on the disinfection of tubercle. He found that it was necessary in order to destroy the activity of tuberculous matter, spread on strips of paper in a chamber 50 cubic centimetres in area, to expose them to the fumes of burning sulphur for twenty-four hours, and that if less than 20 grams of sulphur was burnt animals subsequently inoculated with the matter died of tuberculous disease. He therefore deduces from his experiments the inference that it would be well every year to purify by sulphurous fumigation all prisons, barracks, hospitals and schools.

A paper, by Dr. Leistikow, is reported in the *Berliner Woch.*, No. 32, detailing the results of his researches on the bacterium of gonorrhœa. These are found in the pus cells, the locality distinguishing them from other bacteria, and whether found in the urethra or conjunctiva may be taken as proof of the disease, since they are not found in other secretions. Corrosive sublimate prevents their development, and Dr. Leistikow especially recommends its external use, in an exceedingly weak solution, such as 1 in 2000 or 3000, as the best treatment of gonorrhœa.

A novel dress, intended to protect nurses and others who have to enter the apartments of persons suffering from infectious disease, has recently been exhibited (*Med. Times and Gazette*, Jan. 27, p. 97) at the rooms of the National Health Society, Berners Street. The garment is of mackintosh, glazed inside and out, and made to completely envelop the wearer, with a hood to cover the head, only the hands and face remaining exposed. The garment is enclosed in a tight case when not in use, and can be cleansed by disinfectants as often as deemed necessary. By this means the danger of communicating diseases by garments is minimized. Further protection is given where necessary by a simple form of respirator, made of two folds of thin washing-net, between which is placed a thin layer of medicated cotton wool, which allows no germs to pass, while permitting the wearer to breathe. After use the wool is burnt and the net washed.

An account of the action of very dilute nitro-hydrochloric acid on meat and other animal substances has been recently published by Signor Pavesi, in the *Giorn. Farm. Chim.*, xxxi., 529 (*Nature*, February 8, p. 348). He finds that it is an excellent preserving agent. Meat in pieces of about 1 kilogramme kept in the liquid in wooden vessels remains unaltered and savoury for years. The meat so treated may also be dried at 15° to 20° C. without undergoing change, apart from a diminution of volume and the appearance of a brown colour; when placed for a few hours in water the meat regains its original softness and colour.

Professor Dianin records some observations on the use of trichlorophenol as a disinfectant, in the *St. Petersburg Med. Woch.*, 38, 1882 (*Practitioner*, Feb., p. 146). He considers it twenty-five times more powerful than carbolic acid, and that it deodorizes as well as disinfects. The solid substance is but very slightly, the solution not at all, irritating to the tissues. It is prepared by acting on carbolic acid with chloride of lime and the formula given is $C_6H_2Cl_3OH$. The compound with calcium is cheaper than carbolic acid, and that with sodium is inodorous, the properties of both being similar to those of trichlorophenol.

Dr. Gourges (*Jour. de Med. de Paris*, Sept. 22) recommends an ointment of 4 parts of finely powdered boracic acid, ½ part of benzoic acid and 20 parts of vaselin, in the treatment of boils. It promptly relieves pain, and causes the disappearance of the boil in three or four days.

L'Union Pharmaceutique proposes a method of applying chrysarobin to the skin, by which the staining of the clothes usually caused by it may be prevented. The chrysarobin is mixed with water so as to form a dough, and is applied carefully to the diseased spot, previously freed by warm water from adhering scales. As soon as it is dry, which will be in a few minutes, it is covered with a layer of collodion. After some days the whole may be soaked and washed off with warm water, when the application may be repeated (*New Remedies*, Jan., p. 20).

Iodide of barium has been used in France as an application to enlarged lymphatic glands, and more especially as a local application in chronic eczema. For this purpose it can be mixed with petrolatum. Iodide of barium is actively poisonous (*New Remedies*, Jan., p. 20).

Iodide of lithium is said to be the most useful of the lithium salts in the treatment of gout. It is serviceable in well developed cases and also in varieties of eczema and dyspepsia of gouty origin (*New Remedies*, Jan., p. 20).

Dr. W. H. Broadbent, commenting in the *Lancet* (Jan. 27, p. 166) on the use of manganese in amenorrhœa, points out that the use of the metal for this purpose was known as long ago as 1868, and quotes from the 'Transactions of the Clinical Society' (ii., 122) to show that it is there stated that in using certain metals as accessories to iron, manganese seemed to have a special influence in promoting the return of the catamenia, and nickel a special property in checking leucorrhœa. He attributes, however, the favourable effect of manganese to its effect on the general health and on the blood, since it does good in anæmia, whether associated with amenorrhœa or menorrhagia.

Dr. J. Mortimer Granville, in the *Brit. Med. Journ.*, p. 183, gives a prescription for acute gout, which he believes will give great relief. It is as follows:—"Ammonii chloridi, ʒij.; potassæ chloratis, ʒjss.; tincturæ iodi, ʒj.; glycerini, ʒvj.; aquam destillatam ad ℥vj. Misce fiat mistura cujus sumantur cochlearia duo magna quartâ (vel tertiâ) quaque hora. If there be much thirst it is well to give the dose of this mixture further diluted with water. In the interval of successive attacks of gout while the *malaise* lasts, great benefit is often derived from the use of a single dose freely diluted every morning before breakfast." If this prescription were correct, it would certainly be a heroic remedy, and one impossible to dispense as directed. But there can be no no doubt that ʒvj., as applied to distilled water, is a printer's error, probably for ℥vj.; at all events, chemists who may be called upon to dispense this prescription had better make inquiries on this point.

Dr. Quinlan, of Dublin, who last year read a paper at the British Pharmaceutical Conference, on the hæmostatic properties of the *Plantago lanceolata,* has recently investigated the properties of the common mullein, *Verbascum Thapsus* (*British Medical Journal,* January 27, p. 149). This plant has long been used in Ireland as a domestic remedy for consumptive cough, and Dr. Quinlan has made a series of experiments with a view to determine if it really possesses the valuable properties attributed to it. He finds that when boiled in milk the patient takes the decoction readily and experiences a physiological want when it is omitted. Its power of checking phthisical looseness of the bowels and the relief afforded to coughing were very marked, so that the patients took hardly any other cough mixture. In early stages it appears to have a distinct power of increasing weight, but in advanced cases, Dr. Quinlan remarks that he is not aware of anything that will do this except koumiss.

Dr. T. P. Kinnicutt has tried the oil of wintergreen, salicylate of methyl, in twelve cases of acute rheumatism, and considers that it possesses the following advantages (*Brit. Med. Journ.*, February 10, p. 243). Its use is unattended with the occasional toxic effects and frequent gastric disturbance produced by the acid or its sodium salt, while its agreeable taste and its comparative cheapness are also recommendations in favour of its employment. In controlling the disease, he considers that it at least ranks with any of the salicyl compounds, and that the best method of administration is in frequently repeated doses, diminished throughout the period of convalescence.

Paraldehyd has recently been introduced into medical practice as a new hypnotic, by Professor Morselli, of Turin (*Brit. Med. Journ.*, Feb. 3, p. 215). This body is a polymeric form of aldehyde and in its physiological action somewhat resembles chloral. Its formula is $C_6H_{12}O_3$. From chloral it differs in strengthening the action of the heart while diminishing its frequency. It also greatly increases the flow of urine, but does not affect the skin, and it does not give rise to digestive disturbance, headache or any other unpleasant symptom. Professor Morselli believes that it will to a large extent take the place of chloral. He has found it a valuable remedy in mania, melancholy and other nervous affections, as well as in the sleeplessness that accompanies acute bronchial catarrh, lobar pneumonia and heart disease. The action of paraldehyd was first studied by Dr. Cervello, of Palermo.

Dr. W. Soper, in the *Lancet* (Feb. 10, p. 262), recommends the use of a mixture of equal parts of glycerine and castor oil, slightly flavoured with oil of almonds or lemon, as an agreeable substitute for castor oil. He states that of this mixture a teaspoonful is an effective dose, and in cases of chronic constipation, hæmorrhoids and anæmia it has proved most useful. He has found half-teaspoonful doses useful in the early states of bronchitis, in which it seems to promote exudation from the bronchial tubes and is certainly expectorant. Dr. Soper having stated that there was some difficulty in making the two liquids mix, Mr. Brewis, a Portsmouth chemist, in the succeeding number (Feb. 10, p. 303), points out that if the glycerine be first poured into a mortar and the castor oil added very gradually, triturating thoroughly meanwhile, the result will be a perfectly homogeneous jelly-like emulsion, which, even after the lapse of twenty-four hours, shows no signs of separation, and in which the taste of the oil, if the finest Italian kind be used, is quite disguised.

M. Vigier, in the *Gaz. Hebd. de Méd.* (*Med. Press and Circ.*, Feb. 4, p. 149), states that any substance incorporated with glycerine is not absorbed when applied to the skin and does not produce constitutional effects. Hence he recommends the use of glycerine instead of lard in mercurial preparations for scabies, pediculi, etc. He states that even the following glycerite may be used without danger:—Hydrarg. bichlor. ʒiss., glycerine ℥iij.

Thanks to careful observations by scientific observers, the use of medicines is daily becoming less empirical and more dependent on actual knowledge based on experiments on animals. Professor Rossbach, of Wurtzburg, has recently added to our already increasing store, by experiments made as to the action of alkalies and other expectorants (*Brit. Med. Journ.*, Jan. 27, p. 165). It has generally been supposed that alkalies render the mucus of the air passages, etc., more soluble. Dr. Rossbach's observations, however, show that this is not the case, but that they cause a gradually increasing pallor and greenish-white appearance of the mucous membrane and ultimately a complete cessation of the mucous secretion.

As the results of other experiments, Dr. Rossbach strongly recommends oil of turpentine internally and locally in cases of chronic bronchial catarrh, especially where putrid expectoration is present. Apomorphia he considers to be the prototype of all expectorants, it giving in his hands most excellent results. He administers it in the form of hydrochlorate in doses of $\frac{1}{15}$ to $\frac{1}{7}$ of a grain thrice daily with a little dilute hydrochloric acid, the mixture containing no sugar and being kept in a dark bottle. Morphia possesses the advantage over atropine of diminishing secretion and lessening irritability without subsequent inflammation being produced. A mixture of morphia and apomorphia he has found extremely useful in difficult expectoration, while a combination of morphia and atropine has given excellent results in catarrh, emphysema and phthisis.

Two new anæsthetics, diethylacetate and dimethylacetate, have recently been experimented with by Dr. Mering (*New Remedies*, Feb., p. 51). The former has a burning pungent taste and the latter a disagreeable taste and smell. Both rapidly produced narcosis in frogs and rabbits, slowing the action of the heart, weakening the respiratory movements and acting, when inhaled, much like chloroform. The former was tried on criminals; it acted well, causing narcosis without bad after effects.

Dr. M. Czartoryski, writing to the *Lancet* (p. 261, Feb. 10), from California, states that the Chinese place great reliance on the internal use of fresh lime juice, and of the fruit itself, in diphtheria, and that the results are apparently most successful. Following their example, he has found the same advantages to accrue from its use even in the most desperate cases.

MM. Coninck and Pinet (*Comptes Rendus*, Jan. 15, p. 200) give an account of physiological experiments made on the frog, guinea-pig and dog, to determine the action of picoline and lutidine. They find that picoline abolishes the excito-motor power of the nervous system, thus approaching cicutine in its action. β-lutidine obtained from cinchonine has a similar effect, as also β-lutidine derived from brucine, but the latter acts more rapidly and diminishes muscular contractility, the hydrochlorate being still more active.

The recent introduction of a preparation of the seeds of *Abrus precatorius* (jequerity seeds) in the treatment of ophthalmia will lend interest to an investigation of them by Dr. Warden, of Calcutta. In a preliminary physiological experiment, half a seed, rubbed down with a small quantity of water, and injected into the thigh of a full-grown cat, produced fatal effects within twenty-four hours. This is in accordance with what is alleged to be a practice in some parts of India of using small spikes prepared by drying a paste of the powdered seeds for felonious cattle-poisoning, the spikes being fastened on to the end of a stick after the manner of a drover's goad. The only special principle which Dr. Warden has succeeded in isolating is an acid, which he represents by the formula $C_{21}H_{24}N_3O_4$, and has named "abric acid;" but this proved to be non-poisonous. There appears to be no question that a poisonous principle of considerable potency is present in the seeds, and Dr. Warden thinks his failure to isolate it may be due to its susceptibility to the action of reagents or heat, to its volatility, or that having a composition analogous to amygdalin, its poisonous properties require for their development the action of a principle allied to emulsin.

The composition of cacao butter has been engaging the attention of Herr Traub (*Archiv*, xxi., 19), who is, however, unable to confirm the experience of Mr. Kingzett (*Pharm. Journ.* [3], viii., 412), as to the presence in this fat of two new fatty acids, one of them, which he named "theobromic acid," having the formula $C_{64}H_{128}O_2$. The highest member of the $C_nH_{2n}O_2$ series recognized by Herr Traub was arachic acid, $C_{20}H_{40}O_2$, the other acids obtained being oleic, lauric, palmitic and stearic acids. He is of opinion that the solid consistence of cacao butter coincident with a low melting point is dependent upon the peculiar relative proportions in in which these acids are present.

Some experiments have been made by Herr Müller (*Pharm. Central.*, 1882, p. 581), having for their object to ascertain whether the composition of tamarinds is approximately constant. The pulp of nine specimens obtained from various sources, freed from seeds, showed the greatest variation in respect to citric acid, one specimen containing 3·95 per cent., and another only 0·64 per cent., and it may be remarked that Dr. Nessler has reported the presence of 13·5 per cent. in a specimen examined by him. The other constituents found were:—tartaric acid, ranging from 5·29 to 8·80 per cent.; potassium bitartrate, from 4·66 to 6·01 per cent.; water, from 21·92 to 32·58 per cent.; and vegetable fibre from 12·6 to 20·2 per cent. The relative proportion of the seeds varied enormously, one specimen containing 1·5 per cent. and another 38 per cent. It is evident that the proportion of this last constituent has an important bearing upon the value of the drug, and the author is of opinion that 10 per cent. should be the maximum of seeds allowed.

Mr. Martin, referring (*Druggists' Circular*, Feb., p. 17) to the coloration which takes place in a solution of salicylate of sodium, after being kept for a short time, says that it may be obviated by an addition of a small quantity of sodium hyposulphite. He prepares a solution which he finds to keep indefinitely, by rubbing 16 ounces of salicylic acid into a paste with 1 pint of boiling water, adding 1 drachm of sodium hyposulphite, and then gradually pouring upon it a solution of 9 ounces of sodium bicarbonate in $1\frac{1}{2}$ pint of boiling water. After filtration through paper sufficient water is added to make the product measure 4 pints.

According to some experiments recently described before the Société de Biologie, by Dr. Laborde, which were suggested by the recent disclosures as to the adulteration of the quinine supplied to the Paris hospitals, the physiological effects following the subcutaneous injection of quinine and cinchonine differ considerably. Two guinea-pigs were submitted to injections; one of them received twenty centigrams of the quinine adulterated with cinchonine, and the other twenty centigrams of pure quinine. The former was attacked almost immediately with violent convulsions and died in the course of twenty minutes; the other presented the well-known phenomena of quinism, collapse and ataxia, but did not die until after fifty or sixty minutes. Dr. Laborde pointed out, as a clinical fact of importance, that certain diseases, as for instance, typhoid fever, involve a predisposition to symptoms resembling those following the administration of cinchonine. If the observations of Dr. Laborde are confirmed in experience it is manifest that they will have an important bearing upon the use of preparations of red bark, such as the mixed alkaloids and those which have recently been made official in the United States Pharmacopœia.

A few months since Dr. Hesse stated (*Pharm. Journ.*, [3], xii., 517) that in a peculiar thin kind of cuprea bark, of a much paler colour than the ordinary bark of the *Remijia pedunculata*, he had found, in addition to cinchonine and a new alkaloid, a large quantity of aricine and cusconine. This "new alkaloid" he now believes (*Berichte*, xvi., 58) to be identical with the "hydrocinchonine" of Caventou and Willm, and the alkaloids he then regarded as aricine and cusconine, he now finds to consist of several new bodies. At present Dr. Hesse has separated an alkaloid which he calls "concusconine," as standing in the same relation to cusconine as quinidine to quinine; another which he has named "concusconidine," analogous to cusconidine, and a third, somewhat resembling aricine, which he believes may eventually prove to be identical with Arnaud's cinchonamine. Concusconine (m.p. 144°) gives $(\alpha)_D + 36·8$ (whilst cusconine melts at 110°, deflects the ray of polarized light (54·3° to the left), and crystallizes from alcohol with one molecule of water of crystallization. Concusconidine, $C_{23}H_{26}N_2O_4$, (m.p. 124°) is an amorphous yellowish white powder and gives a sulphate which gelatinizes from boiling water, but which soon becomes transformed into a mass of delicate needles. The alkaloid resembling aricine has the composition $C_{19}H_{24}N_2O$ (m.p. 184°), and gives a sulphate, $(C_{19}H_{24}N_2O)_2SO_4H_2$, which crystallizes from alcohol in colourless prisms, readily soluble in water. It is dextro-rotatory, whilst aricine is lævo-rotatory. As Dr. Hesse is extracting the alkaloids from about 100 kilos of this bark there is a possibility of the discovery of other alkaloids and an elucidation of the question as to the identity of cinchonamine. Diconchinine (diquinidine) and a small quantity of cincholine are also separable from the amorphous bases of cuprea bark, and more conviently than when dealing with cinchona bark.

In these days of unbelief it is satisfactory to learn (*Berichte*, xvi., 60) that Dr. Hesse has confirmed the independent statements of three sets of observers as to the existence of a peculiar alkaloid in cuprea bark,—"homoquinine," "ultraquinine" or "cupreine," —by an examination of a portion of the alkaloid obtained by Messrs. Paul and Cownley in their investigation. He states moreover that, although working with quinine and quinidine of absolute purity and prepared from cuprea bark, he has been unable to obtain the compound of quinine and quinidine which Messrs. C. H. Wood and Barrett stated they had prepared.

The observation that the essential oils of chamomile, wormwood, and millefolium, though varying in colour, when examined spectroscopically all give three absorption bands in the red and orange, led Herr Hock to suspect that there is a colouring matter common to them all (*Archiv*, xxi., 17). Upon submitting samples to distillation the first portion was obtained colourless; but on exceeding 150° C. greenish and blue-green portions passed over, and at 260° C. an intensely blue distillate, which showed the three absorption bands most distinctly. An examination of other similar oils led to the conclusion that although differing in chemical composition they all contained the same blue colouring matter (azulen). It would appear that this blue body is sometimes formed in the plant, and sometimes is first produced during distillation in the vapour of water, or at a higher temperature, as in the dry distillation of galbanum. The formation appears to be associated with the age of the oil, a somewhat resinified oil yielding a larger blue fraction than an equal quantity of a perfectly fresh sample.

Dr. H. P. Farnham, in a paper read before the Materia Medica Society of New York (*New Remedies*, February, p. 39), calls attention to the fact that the sulphocarbolates met with in commerce vary much in purity, some specimens that he had met with producing vomiting and prostration when taken internally. These specimens were not of English manufacture, the only satisfactory samples that he could obtain being prepared by one of the leading chemical firms in England. Dr. Farnham gives as a test for the purity and safety of the sulphocarbolates, that they should give off scarcely any odour of carbolic acid, should have a definite crystalline form, and should give no precipitate with chloride of barium. In other words, they should not contain free carbolic or sulphuric acid, and a preparation offered in the form of an amorphous powder should not be used. The pure salt also makes a perfectly clear solution in water, but the impure a muddy one.

Curious mistakes are sometimes made with regard to the names of drugs sent from foreign countries; thus safflower seed has been offered for sale as sunflower seed. Recently a fragrant commodity appeared in the market (*Gardeners' Chronicle*, Feb. 10, p. 184) under the name of safflower, which had not the least claim to the name, inasmuch as it was found to consist not of composite florets but of the finely broken leaves of a labiate plant, *Zataria multiflora*, a native of Persia, Beloochistan and Afghanistan. It was shipped to this country from Bombay, but with what object it is difficult to conceive. The odour of the leaves somewhat resembles that of thyme.

A new variety of aniseed has lately appeared in the market, imported from Chili. Eighty-six bags of this variety were offered at the London drug sales this month, but fetched a low price, being small and not so free from stalks, etc., as European aniseed.

In a paper read before the Institution of Mechanical Engineers "On the Molecular Rigidity of Tempered Steel," by Professor D. E. Hughes, (*Electrician*, Feb. 3), it is shown that there is experimental evidence for believing that tempered steel is a true alloy of carbon and iron. The author's experiments were made with a simple modification of his well-known "induction balance." One of the conclusions arrived at is that iron possesses more coercitive force than steel whenever the inducing force is limited, and within the range of iron. The author has remarked in this and previous researches on molecular magnetism that in all alloys of iron the molecules are far more rigid than in the pure metal; and further that, with steel, tempering adds greatly to this rigidity. He is now engaged upon the effect of different tempers on the same steel, and hopes in a future paper to bring the results before the Institution. Soft steel, when compared with hard drawn iron, shows that the mechanical hardening of iron has not in any great degree diminished its molecular freedom. Even the softest steel shows a high degree of molecular rigidity, as compared with the hardest iron, but far less than that of tempered steel. This would seem to indicate that steel in its softest state is still an alloy, though only feeble quantities of carbon may be held in that condition.

The same eminent experimenter has communicated a preliminary note to the Royal Society "On a Theory of Magnetism based upon New Experimental Researches." The following conclusions have been arrived at:—(1) That each molecule of a piece of iron, steel, or other magnetic metal is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism when noticed upon a steel bar-magnet. (2) That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress, or by physical forces such as magnetism and electricity. (3) That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can be neither augmented nor destroyed. (4) That when there is external neutrality, or no apparent magnetism, the molecules, or their polarities, arrange themselves so as to satisfy their mutual attraction by the shortest path, and thus form a complete closed circuit of attraction. (5) That when magnetism becomes evident, the molecules, or their polarities, have all rotated symetrically in a given direction, producing a north pole if rotated in this direction as regards the piece of steel, or a south pole if rotated in the opposite direction. Also, that in evident magnetism, there is still a symmetrical arrangement, but one whose circles of attraction are not completed except through an external armature jointing both poles. The experimental evidences of the above theory are said by the author to be so extremely numerous and conclusive that he has ventured upon formulating the results in the above manner.

In a paper read before the Royal Society on the 1st inst., "On the Electrical Resistance of Carbon Contacts" (*Electrician*, February 10), Mr. Shelford Bidwell has adduced some reasons for the superiority of carbon over metal in the microphone. He considers that the mere fact that a current causes delicately-adjusted metal contacts to adhere to each other (an observation previously made by Mr. Stroh) seems sufficient to account for the superior efficiency of carbon. In addition to this phenomenon of adhesion, and probably connected with it, are the facts that metallic contacts, unlike those of carbon, do not even approximately recover their original resistance when once it has been reduced by increased pressure or increased current; unless, indeed, complete reparation occurs; and even the initial effect of pressure upon resistance is in general much more marked with carbon than with metals. In the case of carbon, pressure and current act in consonance with each other; pressure diminishes the resistance, and in so doing increases the strength of the current, and the current thus strengthened effects a further diminution in the resistance. In the case of metals, on the other hand (or at least in the case of clean bismuth), pressure and current tend to produce opposite effects. The resistance is diminished by pressure, and the current consequently strengthened; but by reason of the increased strength of current the resistance is *higher* than it would have been if the current had remained unchanged. The effect of this antagonism is not very great, but it seems sufficient to give a material advantage to carbon.

According to a paragraph in the *Electrician* of the same date, Mr. R. Barker has patented a process for extracting gold from its ore, by causing it to be washed by a stream of water over an inclined table, in which are placed at intervals "riffles," or baths of mercury. The mercury is connected with the negative wire of a dynamo-machine, and the positive wire is led to the water. It is found that the mercury readily seizes on and holds the particles of gold, and never "sickens," as has hitherto been the case.

The electrical transmission of power is justly regarded as one of the greatest future possibilities of electricity, hence much interest has been manifested in some public experiments in this direction, made before a large number of scientific men and social and political notabilities, assembled at the Northern Station, Paris, on the 6th inst. According to *Nature* of the 15th inst. the energy was transmitted by an ordinary iron telegraph wire from Paris to Sevran, near Le Bourget, and returning to Paris, thus completing a distance of 20 kilometres. The primary engine was moved by a force of about 5 horse-power, and the force of the secondary was said to be 2½ horse-power. No precise measure was taken. The experiment was in continuation of the much spoken of Munich transmission of energy from Mierbach, according to the Marcel-Deprez system. It is not believed that this new experiment will put an end to the controversy, though many papers have reported enthusiastically on the proceedings, and letters have been written by electricians claiming to have executed more successful trials. It is stated that new experiments on the Marcel-Deprez system of transmission of energy will take place, under the superintendence of M. Tresca, with the same machines as on February 6. The *Lumière Electrique* states that the force transmitted is about 37½ per cent., and that the dynamometer for measuring the motive power of the primary machine was not in order at the time of the first experiment.

In a lecture on the "Progress of Telegraphy," which was the first of a series of six to be delivered before the Institution of Civil Engineers, Mr. W. H. Preece, last Thursday, presented to his hearers some interesting details. Premising that telegraphy is the oldest practical application of electricity, Mr. Preece remarked that electric currents for this purpose are, as a rule, maintained by the combustion of zinc in batteries of innumerable forms. In the British Post Office telegraph system three forms of batteries are used to the following extent—Daniell, 87,221 cells; Leclanché, 56,420 cells; and bichromate, 21,846 cells. Magneto-electricity is applied for some forms of apparatus and dynamo machines are sometimes employed to supplement batteries. Where the electric currents are conveyed from place to place overground the conducting wire used is almost exclusively of iron, but copper is much used in passing through smoky places. Phosphor-bronze wire is under trial, and appears to possess the conductivity of copper with the strength of iron. The quality of iron wire has been greatly improved, and it conducts now 50 per cent. better than it did a few years ago, whilst copper wire has improved in a still greater ratio. In towns the wires are carried underground; copper wire, insulated with gutta percha and encased in iron pipes, being the material used. There are now 12,000 miles of telegraph wire carried underground in the United Kingdom; to adopt the same course with respect to the whole of the Post Office system would involve an expenditure of £20,000,000, as the cost is fourfold, whilst the carrying power is reduced to one-fourth. Gutta percha still remains the best material for insulating purposes. Of submarine telegraphs there are now 80,000 miles of cable at work and a capital of £30,000,000 has been invested in them. A fleet of twenty-nine ships is employed in laying, watching and repairing the cables, and the Atlantic alone is spanned by nine cables in working order. The type of cable has been very little varied from the first laid between Dover and Calais, but the materials are better, the breaking strain of the homogeneous iron wire now reaching ninety tons to the square inch, whilst the machinery for laying has been so improved that a cable across the Atlantic was last year laid in twelve days, without hitch or stoppage. Of telegraph instruments the A B C is the simplest to read, and there are 4398 in use. Its mechanism is, however, complicated and expensive and it is being rapidly supplanted by the telephone. The needle instrument is the simplest in construction, but it requires training to read it; there are 3791 employed by the Post Office and 15,702 by various railway companies. The Morse instrument, of which the Post Office possesses 1330, records its letters in ink, in dots and dashes on paper tape, and also indicates the letters of the alphabet by sound. Sound reading is more rapid and accurate than any system of visual signals or permanent record and it is gaining ground with great rapidity, there being now about two thousand sound readers in England, while in 1869 there were none. Acoustic reading attains great perfection in Bright's bell instrument, where beats of different sound replace the dot and dash of Morse's system. In ordinary working only one message can be sent in one direction at one time; but by a simple and ingenious contrivance, by which the neutrality of opposite currents is utilized to convey signals, duplex telegraphy is rendered possible, so that two messages can be sent on the same wire at the same time; and, by a still further improvement, where currents of different strength are utilized, four messages are sent on one wire—two simultaneously in opposite directions—at the same time. There are in England 319 duplex and 13 quadruplex circuits at work. In the automatic system, manual labour is supplanted by mechanism in transmitting the messages. There are 71 circuits worked by these instruments, and 224 instruments in use, and a speed of working of 200 words per minute is easily maintained upon them. With the hand alone from 30 to 40 words per minute is the maximum rate attained. Since this system can be duplexed, and in many cases is so, 400 words per minute on one wire are easily sent. By the use of high-speed repeaters, the length of circuit for automatic working is scarcely limited; it would be easy to send 100 words per minute to India. The growth of business since the telegraphs have been acquired by the State is enormous: 126,000 messages per week have grown to an average of 603,000. In 1873, the average number of messages per mile of wire was 147, it is now 256. It is in press work that the greatest increase has taken place: 5000 words per day at the time of the Companies have grown to 934,154 words per day now. The growth of business is equally discernible in the great Cable Companies. In 1871, the number of messages dealt with by the Eastern Telegraph Company was 186,000; in 1881, it was 720,000.

NEW REMEDIES.*

BY WILLIAM ELBORNE.

Abrus precatorius. Nat. Ord., Leguminosæ.—This plant was originally a native of India, but is now found in the West Indies, the Mauritius, and most tropical regions. It is remarkable for its small nearly globose seeds, which are of a brilliant scarlet colour, with a black scar indicating the hilum or place of attachment to the pods. These seeds are much used in India in the arts, for necklaces and other ornamental purposes, and are employed as a standard of weight under the name of Rati. The weight of the famous Koh-i-noor diamond was ascertained in this way. From a medicinal point of view the roots are made use of in the same manner as the roots of the liquorice plant (Indian Pharm.). An infusion of the curious scarlet seeds has long been used in the interior of Brazil as a popular remedy in the treatment of ophthalmic disorders. In some experiments made by Dr. de Wecker to test the action of this remedy, he found that a weak cold infusion made from the powdered seeds, when applied as a lotion, rapidly produced a purulent ophthalmia, of intensity corresponding to the number of applications made. The factitious ophthalmia thus produced disappeared in the course of ten days or a fortnight without any therapeutic intervention or danger to the cornea, and Dr. de Wecker is of opinion that this property possessed by the seeds, of provoking a very intense ophthalmia of short duration, could be utilized in ocular therapeutics in the treatment of granulations and conjunctival diphtheria. M. Silva Aranjo having recently submitted to microscopical examination the infusion and maceration of the seed, together with the exudation produced by their use, attributes the cause of the inflammation and the purulent condition which follows the use of the drug, to the great number of gonidia contained in both preparations of the seed developing abundantly on the conjunctiva.

Adonis vernalis. Nat. Ord., Ranunculaceæ.—This plant is a showy perennial herb with large yellow flowers, finely divided leaves, and black fascicled roots. It has been recently introduced into medicine as a remedy in the treatment of certain forms of heart disease. Dr. Cervello, who has recently submitted the plant to a chemical investigation, finds that its active principle is a glucoside which he has named adonidin. It is described as being colourless, odourless, amorphous and very bitter.

Adonidin is prepared by precipitating a tincture of the plant, made with 50 per cent. alcohol, with basic acetate of lead, and decanting and evaporating the clear liquid to a syrup. This syrup is bitter and slightly acid, and after being made slightly alkaline with ammonia it is boiled with a strong solution of tannin, until a precipitate is no longer thrown down. The tannate of adonidin thus formed is difficultly soluble in water. The precipitate, after being washed, is decomposed with zinc oxide in presence of alcohol, the alcoholic solution evaporated to a small bulk, and colouring matter precipitated with ether. The clear solution on evaporation gives the adonidin in a pure state. It is then dried *in vacuo* over sulphuric acid.

The therapeutic effects are described as being identical with those of digitalin, with the exception that they are not accumulative, the administration of the drug during a considerable time being without danger.

Convallaria majalis. Nat. Ord., Liliaceæ.—The lily of the valley is a plant so well known that little need be said by way of description. A slender irregular stalk, a few inches high and slightly curved, bears from eight to twelve small bell-shaped white flowers, arranged one above the other, each on a pedicel of its own, elegantly bending towards the ground, and of a delicate perfume. The lily of the valley is an inhabitant of the woods in many parts of England, and has long been admitted into every garden. Notwithstanding the fragrance of the flowers, they have a narcotic odour when dried, and if reduced to powder excite sneezing.

The medicinal properties of the lily of the valley have been known as far back as the early portion of the seventeenth century, as having a peculiar action upon the heart. But this appears to have been lost sight of until a year or two ago, when the fact of the plant being used by the Russian peasants as a remedy for dropsy, attracted the attention of Messrs. Troitzky and Bojajawlensky. Two glucosides were obtained from this plant by Walzy in 1858, and were named convallarin and convallamarin. In 1865, Stanislas Martin isolated an alkaloid and an acid, which he named respectively maialine and maialic acid, finding at the same time an essential oil and a yellow colouring matter.

Convallarin is soluble in alcohol, but insoluble in water. Convallamarin is very soluble in water, alcohol, and methylated alcohol, but insoluble in ether, chloroform, and amylic alcohol. It has a bitter flavour, followed by a peculiar after-taste. The plant contains only a small quantity of this glucoside, 1000 parts (collected in August) yielding only 2 of convallamarin. It is best prepared as follows:—According to Tanret, a strong tincture of the whole plant is precipitated with subacetate of lead, filtered; the excess of lead removed by dilute sulphuric acid, carefully avoiding excess, neutralized, and the tincture distilled, the last portions being driven off in the open air. The cooled and filtered liquid is then precipitated by tannin, being at the same time kept neutral by very slight additions of dilute solution of sodium carbonate. The precipitated tannate of convallamarin is then washed, dissolved in 60 per cent. alcohol, the solution decolorized with animal charcoal

* The subject of a Report on Materia Medica read before the School of Pharmacy Students' Association, Jan. 18, 1883.

decomposed with oxide of zinc, filtered and evaporated to dryness. Thus prepared it is nearly white, and has the appearance of ordinary digitalin. To free it from salts sometimes carried down by the tannin, it may be advantageous to dissolve it in 60 per cent. alcohol, filter and evaporate.

Drs. Bojajawlensky and Troitzky found that in organic heart disease the effects of the plant taken in infusion were equal to those of digitalis; the urine being increased, serous deposits rapidly absorbed and nervousness diminished; while cumulative action was not observed. The irritability and resulting peevishness were lessened, the effect continuing for some days after the administration of the medicine; no dyspnœa or palpitation being experienced; the patients also were able to take boldly exercise without discomfort.

Lycoperdon giganteum (*The Giant Puff-ball*). —*Lycoperdon giganteum* is a fungus belonging to the Nat. Ord. *Trichogastres*. The peridium or outer coat which breaks up into warts or scales, is intimately connected with the inner coat, and the spores are mostly sessile. All the various species of *Lycoperdon* are produced abundantly in nearly every country, but are so variable both in character and properties that it is very difficult to distinguish them.

Dr. E. Thompson recalls attention in the *Lancet* to the use of this fungus as a local hæmostatic. He states that it forms a very soft and comfortable surgical dressing, and that the powder it contains seems to possess antiseptic and anodyne properties. The mature plant is used. At this period it is about the size of a child's head, and is covered with a thin skin; the latter is removed and the capillitium and spores, which form a dusty mass, are used. Mr. Fagan, a leading surgeon in Belfast, found that it at once restrained bleeding from arteries in the bone, in the neighbourhood of the orbit, after the failure of other means. The researches of Hagen, on the reason of the coagulation of the blood, show that the hæmostatic action of the puff-ball, as well as of all other spongy or powdery substances, depends upon the fact that healthy blood deposits hæmato-blasts or minute corpuscles on any foreign substance introduced into a vein, which become adhesive points for the subsequent attachment of particles of fibrin. This action, however, also takes place when the vessels themselves assume abnormal conditions, as when cut or altered by disease.

Pongamia glabra. Nat. Ord., Leguminosæ.—Pongamia glabra is a tree extensively diffused throughout Southern India, Malacca and the Indian Archipelago, and also found in Southern China and North Australia. It has smooth pinnate leaves, composed of five or seven egg-shaped or broadly elliptical leaflets, arranged in pairs with a terminal odd one; and loose axillary racemes of flowers. In India an oil, called pongamia or kurung oil, is expressed from the seeds, which is described in most works on Hindu Materia Medica as being a favourite remedy amongst the natives for various skin diseases. The oil is of a deep yellow colour, inclining to reddish-brown, and is fluid at temperatures above 60° F., but below that it becomes solid.

Surgeon-Major Dymock, of Bombay, has recently called attention to the use of pongamia oil in pityriasis versicolor. Having observed that the specific character of the diseases in which the oil had been used was not clearly defined in the descriptions given by Ainslie and other writers, he determined to make some experiments with the oil, and selected pityriasis versicolor, as a common and troublesome affection, for the first experiment.

Several cases occurring on the neck, face, and shoulders were cured in less than a fortnight by rubbing in the oil twice a day. He concludes, therefore, that this oil is likely to be of service in other skin diseases which, like pityriasis, are attended by the growth of a fungus. Dr. Dymock considers this oil much more effective than acetic acid; while it has the advantage over iodine and Goa powder of not discolouring the part (often the face) to which it is applied. Dr. Thin has recently stated that sulphur ointment is an admirable remedy for ringworm; but pongamia oil might be used in cases where the disease is of a recurrent character.

Sterculia acuminata.—Cola, Gourou or Ombéivé nuts are the seeds of the above plant, which belongs to the natural order, *Byttneriaceæ*, and are known to us by the accounts of West African travellers, who state that when chewed they possess the power of rendering the flavour of water, even if half putrid, agreeable and they were believed to contain caffeine.

Cola nuts have recently been submitted to a chemical investigation by Messrs. Haeckel and Schlagdenhauffen, who found that they contained more caffeine in an uncombined state than the best samples of coffee that could be procured; also theobromine, three times the quantity of starch that is found in cocoa, a considerable quantity of glucose, a small percentage of fat, a special tannin approaching caffeotannic acid in its composition, and a red colouring matter similar to cacao-red. Professor Attfield in a previous analysis found also a small quantity of volatile oil.

The physiological examination of this remedy has shown that its properties are essentially due to the caffeine and theobromine it contains. The seeds, it appears, have long been in use in Africa for the cure of diseases of the intestine or liver, and especially in cases of atony of the digestive tract, and also as a masticatory and tonic, like areca nuts, which are so much esteemed by the natives of India. Medically they may occupy a prominent place by the side of coca and other anti-metabolic remedies, to which they would probably prove superior in consequence of the tannin they contain.

EAU DE COLOGNE.*

A very pleasant and refreshing eau de Cologne, much resembling that sold with the trade-mark "Springbrunn," may be obtained as follows:—

Dissolve 15 parts of oil of orange-peel, 15 of oil of lemon, and 6 of oil of bergamot in 3000 parts of finest Cologne-spirit. (It is absolutely necessary that only the purest and finest oils and alcohol be used.)

Also dissolve 1 part of oil of neroli (pétale) and 1·5 parts of oil of orange (petits grains) in 1000 parts finest rectified rye-spirit.

After standing for five or ten days, both liquids are mixed. It is best to distil the mixture, since the odours are better blended thereby; but it may also be aged by allowing it to stand for a time.

To the distillate are added 2 parts of the finest oil of rosemary, and the liquid then put up in small well-corked vials, which must be kept in a cool, shady place.

TROPIC FRUIT LAXATIVE.†

Mr. Adam Conrath gives the following approximative formula for the preparation sold under the name of "Tropic Fruit Laxative":—Jalap tubers, powdered; senna leaves; sugar, of each 5 parts; pulp of East India tamarinds (of the consistence of a stiff extract), 30 parts.

Having rolled out the mass with a rolling-pin to a thickness of $\frac{1}{4}$ of an inch, it is to be cut with a tin mould to a size of one inch long by $\frac{7}{10}$ of an inch wide, to weigh 40 to 45 grains. The lozenges should be coated by a confectioner with chocolate and sugar, after which each one may be wrapped in thin tin foil. Mr. Conrath says that the objection to dispensing this form of a confection of senna is the liability of the laxative portion to become worm eaten, in which case, those who do not first remove the chocolate and examine the central mass are apt to swallow worms and all.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 24, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

THE BENEVOLENT FUND.

On subsequent pages will be found a list of the subscriptions and donations to the Benevolent Fund received during last year, which has been prepared in accordance with a resolution of the Council of the Pharmaceutical Society at its meeting in November that such a list should be printed in this Journal and a copy sent to every chemist and druggist whose name is on the Register. In thus carrying out the decision of the Council it has appeared to us that if the list were prefaced by a short statement as to the origin and past administration of the Fund it would enable some who receive it better to understand the nature and objects of the appeal which is to be made to them for help.

From the very inception of the Pharmaceutical Society, when in the year 1841 a few energetic spirits were endeavouring to give form to a belief that the permanent interests of chemists and druggists required the establishment of some organization for securing their common welfare, it was recognized that the "foundation of a fund for the relief of the distressed, the widow, and the orphan" would help to establish a substantial and permanent bond of union. Consequently, upon the establishment of the Pharmaceutical Society no time was lost in connecting with it the work of benevolence. In the first year only £37 17*s.* was received in donations; but in the first annual report the Council recommended that a sum of £500 from the funds of the Society should be invested in the names of trustees, as the nucleus of a fund, from which relief should be granted as soon as the annual income from investments should amount to £300. In the following year the Society obtained its Charter, in which the provision of a fund for the relief of distressed members and associates of the Society, and of their widows and orphans, was formally mentioned, and in "commemoration" of this, the Council in its second annual report recommended that another sum of £500 should be set apart for the Benevolent Fund. A similar course was taken in the following year, and again in 1870. In 1848, although the interest on investments had not yet reached the amount originally intended, it was decided to commence the granting of casual relief from the Fund; but it was not until the year 1865 that the first elections of annuitants took place.

Hitherto the Benevolent Fund, which had been formed mainly by successive grants from the General Fund of the Pharmaceutical Society and subscriptions and donations from its members and associates, had been administered solely in the interests of persons who were connected with the Society. But the area was to be now widened, for in the year 1868, when the accumulated investments amounted to nearly £10,000, the Council was empowered by the provisions of the Pharmacy Act to extend the benefits of the Fund in future to all persons "who may be, or have been, duly registered" as Chemists and Druggists. This permission has been fully utilized by the Council, and at the present time as many as eleven annuities, amounting altogether to £370 a year, are being paid from the Fund to registered chemists and druggists who have never been connected with the Society, or to the widows of such persons, whilst last year, besides this, the casual relief given in the same direction amounted to upwards of £160. It was justifiable to hope, therefore, that so catholic a dispensation of relief from the Fund would have been met by help, however small, from nearly every person whose name is on the Register, but, unfortunately, at present scarcely any advance has been made towards the realization of this hope. It is true there was some improvement manifest last year; though even then the total number of subscribers was only just over three thousand, so that there are *still more than ten thousand registered chemists and druggists who do not subscribe to the Benevolent Fund, or more than three-fourths of the whole!* It is impossible to believe that this is a fair indication of the measure of charitable feeling existing among the chemists and druggists of Great Britain, and the explanation is probably rather to be found in the absence of proper machinery for bringing the Fund, at stated intervals, under the notice especially of those who for various reasons have abstained from associating themselves with the Pharmaceutical Society. As an aid towards supplying this deficiency a copy of this number of the Pharmaceutical Journal will be sent to every chemist and druggist on the Register, and it is intended that this shall be supplemented in as many cases as possible by a visit to each recipient from the Local Secretary of the district, who will supply any other information about the Fund that may be desired and afford him an opportunity of satisfying his benevolent instincts with the least amount of trouble possible.

It would appear almost a work of supererogation to argue the necessity for the existence of some such organization. Every chemist and druggist must be cognizant more or less of the distress that exists among the unfortunate members of his craft or in families that have been bereft of the bread-winner, though few perhaps see it in the concentrated form in which month after month it comes under the observation of the Benevolent Fund Committee. It will be more to the purpose to mention a few simple facts to enforce the appeal now made on behalf of the Benevolent Fund which has been administered so successfully during a period of forty years by the Council of the Pharmaceutical Society. Last year twenty-one annuitants received from the Fund £35 each, one £32 10*s*., and fourteen £30 each, amounting altogether to £1187 10*s*.; besides which casual grants were made to the extent of £461, representing a total of £1648 10*s*. It may be desirable to explain that the variation in the amounts paid to different annuitants is in accordance with a resolution arrived at some years since, that annuitants above the age of sixty-five should henceforth receive £35 instead of £30 per annum. Towards meeting this outlay of £1648 10*s*. the dividends on invested capital only amounted to about £560, or less than half the sum required for annuities alone, leaving a sum of nearly £1100 to be made up by subscriptions and donations. Under the conditions which usually obtain in the administration of charitable funds this deficiency would have been largely increased by various expenses; but owing to the manner in which this Fund is administered, under the personal supervision and as part of the business of the Council of the Pharmaceutical Society, this large sum of money was collected and disbursed at a cost to the Fund of a little over ninety-five pounds. It is not likely that the calls upon the Fund during the present year will fall below those of last year; indeed the election of annuitants in December increased the responsibilities to the extent of at least £180 a year, and this did not represent all that might have been done with advantage in the same direction. Moreover, there is a constantly increasing necessity for casual relief, the sum granted this month,—namely, £150,—being larger than on almost any previous occasion. But if, as it is hoped, the present appeal is responded to favourably by even a moiety of the ten thousand registered chemists and druggists who are not at present subscribers, the anxiety of the Council will be removed, and it might become possible to dispense assistance more in accordance with the antecedent circumstances of those receiving it.

It only now remains to say that whilst the casual grants are made directly by the Council, upon the recommendation of its Benevolent Fund Committee, the election of Annuitants lies entirely with the Subscribers and Donors. Half-a-crown subscribed annually entitles the giver to one vote, but the number of votes is increased to five for each half-a-guinea. A contribution of five guineas constitutes a life subscriber, with five votes at each election for life, and an additional vote is accorded for each additional guinea. In the case of firms or corporations contributing five guineas, the right is acquired to a similar number of votes at each election for a period of ten years. We hope that the present special effort to increase the number of subscribers to the Fund, by bringing it under the immediate notice of every member of the body for whose benefit it is exclusively applicable, will be sufficiently successful to warrant the Council in repeating it annually. For it must be evident that, welcome as donations may be, the regular income from annual subscriptions is the only reliable basis upon which the Council can regulate the expenditure.

1843 AND 1883.

It is certainly a noteworthy, though an undesigned, coincidence that the resolution of the Council of the Pharmaceutical Society to send a copy of its Journal to every chemist and druggist on the Register should take effect in a week which marks the completion of a period of forty years since the granting of the Society's Charter of Incorporation on February 18th, 1843. The occasion will, therefore, not be an unsuitable one to take a retrospective glance and note some changes in the condition of the calling of a chemist and druggist which have occurred subsequently to, and we believe have been consequent upon, the establishment of the Pharmaceutical Society of Great Britain, of which this charter was the first official recognition.

It is in the power of only the older members of the body now to have a personal remembrance of the status—or more correctly the want of status—of chemists and druggists in Great Britain before the year 1840. The manor of pharmacy was then truly a "no man's land," and no restrictions were in existence as to qualification. Among those who in those days practised the art of pharmacy, it is true, were men equal in ability to any of their successors in the present day. But, on the other hand, the most ignorant of men was allowed, if he chose, to dub himself "chemist and druggist," and to carry on business as such with those members of the public whom he could induce to pin their faith to the colour of his carboys, the smartness of his shop or any other specious pretence that he might be able to put before them. Neither was there any bond of union between those who were more or less justified in assuming the name of "chemist and druggist." It was in this condition of affairs that a few of the more watchful members of the calling became aware, in the year 1841, that a Bill had been introduced into Parliament by Mr. Hawes, which, while affecting in its title only to amend the law relating to the medical profession, would have placed the whole body of chemists and druggists under the control, in respect to education and examinations, of a Medical Council in which they had no representative. The Bill would also, in Jacob Bell's words, have made a chemist and druggist "liable to a penalty of twenty pounds for recommending ten grains of rhubarb, strapping a cut finger, or explaining to a customer the usual mode of taking any medicine." Fortunately, through the vigorous opposition that was organized, though not without considerable difficulty, the danger was for the time averted. But it became evident to those who conducted the opposition that it was necessary to establish some permanent organization for promoting the interests of chemists and druggists, if their independence was not to be sacrificed and many existing privileges lost through the institution of an extraneous jurisdiction. Action trod upon the heels of conviction, and within six weeks of the first note of alarm, the memorable "pharmaceutical tea party" was held at 338, Oxford Street, which eventuated in the foundation of the Pharmaceutical Society of Great Britain. From that time, it may be fairly said there was little danger that chemists and druggists would be legislated for without knowing the reason why.

It was early recognized by the founders of the Pharmaceutical Society that a too plausible pretext for the harassing proceedings of ambitious medical reformers existed in the absence of any judicious regulations for connecting the welfare of chemists and druggists with the interests of the public. In a preliminary report it was therefore recommended that "education, examination, registration and representation" should form the basis of the new Society, and to these was afterwards added "benevolence." These objects have been steadily kept in view by successive Councils, and notwithstanding much apathy, or occasionally even opposition, the work has been steadily carried forward, so that although the measure of success has not been so full as might have been hoped, the progress that has been made is considerable. Pharmaceutical education, which was first treated with indifference, even when provided at the cost of the Society to its members and associates, is now eagerly sought for at various schools established as independent commercial speculations; examination and registration have, in presence of a rapidly increasing population, for a time rendered stationary the number of persons entitled to carry on business as "chemists and druggists," and have raised the body considerably in the estimation of the medical profession and the public; whilst benevolence has created a Fund from which a very large amount of assistance is distributed continually to distressed members of the calling. Moreover, instead of chemists and druggists being now harassed and worried by unexpected attempts at legislation, such is the confidence which the prudent conduct of the Council of the Pharmaceutical Society has established that it has been entrusted with important executive functions on behalf of the public, and it is now almost uniformly consulted by the various Government departments upon subjects which arise touching the interests of pharmacy.

Under these circumstances we think it is to be regretted that the roll of Members and Associates of the Pharmaceutical Society is not co-extensive with the Register of Chemists and Druggists. That the legislation obtained by the Society in 1868 was not more favourable was no fault of those who then conducted its affairs, but rather lay with those who stood aloof from or even opposed the efforts of the Society when all ought to have been united. Nevertheless, evidence that the legislation of 1868 had its value is to be found in the wide-spread complaints that it did not include a provision to meet a contingency which could not have been foreseen at the time it was passed. An effort is now, however, to be made to supply its shortcomings, and as almost all pharmacists are agreed that Parliament should be approached with an application for fresh legislation, it does seem very desirable that the Council of the Pharmaceutical Society should be actively supported at such a time by at least every chemist and druggist in business. We do not affect to ignore that many persons outside the Society,—and, indeed, some inside,—profess to be dissatisfied with the work done by the Society; but that is not, in our opinion, a sufficient reason for helping to neutralize, by simple abstention, the influence of the most powerful organization which chemists and druggists are likely to have at their disposal during the present century. Such a plea is deprived of any force it might have had by the fact that so fully has the principle of "representation" been carried out by the founders of the Society and their successors that it is in the power of the general body of chemists and druggists to mould its policy as they will; for all persons on the Register, whether examined or not, have the option of connecting themselves with the Society either as Members or Associates, and so to become entitled to take a part in controlling its operations. We may be pardoned, therefore, for expressing a hope that many under whose notice these lines will be brought through the extra issue of this Journal may be persuaded that such a step is in accordance with their true interests.

THE PROPOSED PHARMACY BILL.

It might naturally be expected that the publication of the Draft Pharmacy Bill adopted by the Council would give rise to considerable discussion. We have already evidence of this in the receipt of several instalments of correspondence upon the subject, which in consequence of the somewhat special character of this number of the Journal we think it desirable to defer dealing with until next week. A meeting of chemists and druggists has been held at Manchester, to discuss the subject, and has been adjourned for a month, and another one is being held in Edinburgh at the time of going to press.

SCHOOL OF PHARMACY.

As will be seen by the advertisement in the present number, the courses of lectures on "Chemistry and Pharmacy" and "Materia Medica and Botany," in connection with the Pharmaceutical Society's

School of Pharmacy, 17, Bloomsbury Square, will recommence on Thursday, March 1, at 9 a.m., when Professor Bentley will give his first lecture on Botany. Professor Redwood will commence his course on "Chemistry and Pharmacy" on Monday morning, March 5, at 9 o'clock.

Students will find the ensuing five months a favourable period for studying at the School, for between March 1 and the end of July they will have an opportunity of attending not only Practical Chemistry in the laboratories and the usual courses of lectures on Chemistry and Pharmacy and Materia Medica and Botany, but also the summer course on Practical Botany and the Classification of Plants, at the Royal Botanic Society's Gardens, in the Regent's Park, where every opportunity will be afforded to them of obtaining a practical acquaintance with medicinal plants.

In addition to the above courses of lectures and Practical Chemistry, there is also Mr. Dimmock's class for "Practical Instruction in Dispensing," which will recommence on Friday, March 2, at 5 p.m., and be continued until the end of July.

The preliminary matter of the newly published Medical Register for 1883, includes, in addition to reprints of the existing Medical Acts, some interesting statistics. From these it appears that the total number of registered medical practitioners in Great Britain and Ireland, at the commencement of the year, was 23,081, showing an increase of 525 as compared with the previous year. The number added by registration during the year 1882 was 1171, and the restorations were 199. On the other hand, there were 522 names removed upon ascertained evidence of death, 10 through ceasing to practise, and 311 through failure to respond to two registered letters.

* * *

It is interesting to notice, in the presence of this large influx into the medical profession, that there was a considerable falling off in the number of medical students registered during the year 1882, the number being 1862, against 2171 in 1881. Of these 853 were registered in England, 585 in Scotland, and 424 in Ireland The University of Cambridge had 72 entries, a larger number than any other place of medical study, and St. Bartholomew's Hospital, London, came next, with 69. It is significant of the great change that has taken place in the conditions of medical study in recent years, that out of the 1862 registrations, only 169 were in respect to pupilage with a registered practitioner.

* * *

From a similar table in *The Dentists' Register* for 1883, of which also we have received a copy, we learn that there are now 5252 registered dentists in the United Kingdom, of whom 759 are "licentiates in dental surgery" of various colleges. This shows a decrease of 93 registered dentists as compared with the previous year. Of registered dental students there are 166.

* * *

In reply to a question, Earl Granville stated, on Tuesday evening, that it is the intention of the Government to introduce into the House of Lords a Bill dealing with the subject of the Medical Council.

* * *

A Bill which has been introduced into the House of Commons, by Mr. A. Arnold, for the amendment of the Trade Marks Act, provides that after the expiration of five years from the date of registration of a trade mark, the original registered proprietor, or any subsequently registered proprietor lawfully claiming through him, shall have an absolute and unimpeachable right to the exclusive use of such trade mark.

* * *

A Partnerships Bill has been again introduced into the House of Commons, but it is devoid of the sections referring to the registration of firms and limited partnerships present in the Bill of last year, and to which we then called attention as being likely to affect the working of the Pharmacy Act.

* * *

A decision, given by the tribunal of the Seine, on the 3rd instant, has established that the French law regulating pharmacy does not allow of a pharmacy being carried on by any person who is not at the same time the real proprietor and a qualified pharmacist. The principle was distinctly laid down, that the responsibility of the proprietor of the pharmacy was the best guarantee to the public that the business should be efficiently carried on. The decision was given in connection with a prosecution of M. Bravais, formerly manager of the Company trading under the name of Bravais and Co., and M. Jolly, an unqualified man who was carrying on the business as liquidator of the Company.

* * *

A Pharmacy Bill has been introduced into the Nebraska Legislature which contains two novel definitions of classes of poisons. The first class is to include "any drug, chemical or preparation which according to standard works on medicine or materia medica is liable to be destructive to human life in quantities of 60 grains or less." These are to be labelled "poison," and are not to be delivered until the seller has satisfied himself that they are to be used for a legitimate purpose. The second class is to include "poisons" which are known to be destructive to adult human life in quantities of 5 grains or less, and sales of these are to be registered. Agricultural insecticides are to be excluded from the operation of the clause.

* * *

The Pharmaceutical Society of Victoria has just concluded the purchase from the Colonial Government of some premises now occupied as a County Court in Swanston Street, Melbourne.

* * *

Extra buildings are being erected adjoining the Imperial Museum, Calcutta, for the International Exhibition which is to be opened next December. Invitations have been sent throughout India to all the Rajahs and Princes, inviting them to contribute to the Indian display, which is to be on a very grand scale. It is to be hoped that a good descriptive catalogue of the exhibits will be prepared.

* * *

Many of our readers will have inferred from the frequent occurrence of German looking names at the head of articles quoted from transatlantic journals that the Teutonic element is pretty well represented among pharmacists in the United States. But few probably will learn without surprise that the New York German Pharmaceutical Association numbers 116 members.

* * *

A school of pharmacy has been organized in Louisville, Kentucky, for the education of women only. It is under the patronage of the local Polytechnic Society, and the members of the Board of Directors are all of the sterner sex.

* * *

According to the *Neue Dörptsche Zeitung*, the number of students in the Dorpat University in January, was 1431, of whom 610 were engaged specially in medical studies, and 103 in pharmaceutical studies.

* * *

A correspondent of the *Students' Journal* tells a good story about an accident that happened a few days ago in Kent, by which a carter's leg was broken. The man's companion ran off to the local practitioner for help, telling him that there was an "old cove" pulling his friend about, but, added he, "I can see he ain't up to much." When the local practitioner arrived on the scene he found that the "old cove" not "up to much" was Sir James Paget, who had in the meanwhile improvised some splints and bound up the leg with a copy of the *Times* newspaper.

* * *

We have received a circular announcing the commencement of the "Colchester Students' Association," which is worth referring to for the sake of mentioning a plan that might perhaps be followed with advantage in some other provincial localities. We are informed that the Association was mainly founded by chemists' apprentices, who at first intended to call it the "Colchester Chemists' Assistants and Apprentices' Association." Being doubtful, however, of their ability to stand alone, the title was altered so as to include other young men residing in the town; but the titles of the scientific papers read last year show that the original object of the founders has not been lost sight of.

* * *

According to *Nature*, the sulphuric acid works in connection with the Imperial Japanese Mint, at Osaka, are in active operation, nearly a million pounds of acid having been exported to China last year, besides supplying the home demand. Alkali manufacture also is being developed energetically.

* * *

At the meeting of the Chemical Society on Thursday next there will be a ballot for the election of Fellows, and a paper will be read on "Some Derivatives of the Isomeric $C_{10}H_{14}O$ Phenols," by Drs. Armstrong and Rennie.

* * *

The Chemists' Assistants' Association will meet at their rooms, 53, Conduit Street, on Wednesday evening next, when a paper on "Tobacco of Commerce" will be read by Mr. C. E. Palmer.

* * *

It may interest some of our readers to learn that on Monday next, the 26th instant, Professor Flower will commence, at the Royal College of Surgeons, a course of nine lectures upon the "Anatomy of the Horse and its Allies," which are to be free to all who take an interest in the subject. The lectures are to be delivered on Mondays, Wednesdays and Fridays.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The fourth Evening Meeting of this Session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Thursday, February 15, at 9 o'clock.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The Secretary to the Branch then announced the following donations.

To the Library:—

'New Commercial Plants and Drugs.' By Thomas Christy, F.L.S. (in six parts). From the AUTHOR.

To the Museum:—

Seeds of *Ptycholis Ajowan.*
From Mr. JOHN R. HILL, Edinburgh.

Resin of Scammony and Resin of Jalap.
From Messrs. T. and H. SMITH and Co., Edinburgh.

Large Crystals of Potash Alum, Bichromate of Potash, Sulphate of Copper and Yellow Prussiate of Potash.
From Mr. ALEXANDER NAPIER, Edinburgh.

Calumba Root Starch.
From Mr. JAMES MCGLASHAN, Edinburgh.

A vote of thanks having been accorded to the donors, the Chairman called upon Dr. Matthew Hay to deliver a lecture on "The Methods for the Separation of Alkaloids." This paper and the discussion thereon will be printed in next week's Journal.

Provincial Transactions.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday, February 12, at the rooms of the Association, the Church Institute, Oldham, the first lecture of the present session was delivered by Mr. A. Martin, the President, on "The way to prepare for the Minor."

The lecturer, who spoke for above an hour, dealt in turn with each of the six subjects of the Minor examination, and pointed out the work that should be done, and that which it would be as well to leave alone. He strongly insisted on the untrustworthiness of "cram," and the urgent necessity for honest systematic study.

The lecture was listened to with marked attention, and at its close a hearty vote of thanks was unanimously given.

Nearly all the members were present.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

THE PRIMÆVAL ANCESTORS OF EXISTING VEGETATION AND THEIR BEARING ON THE DOCTRINE OF EVOLUTION.

BY PROFESSOR C. W. WILLIAMSON.

The fourth lecture of this course was delivered on Tuesday, February 6. The following is an abstract:—

The alternation of sexual and spore-bearing generations already noticed in the Equisetums probably attains its most conspicuous manifestation, so far as the Cryptogams are concerned, in the Ferns. Yet the prothalloid or sexual condition in Ferns is a varied one. In the Hymenophyllums, or Filmy Ferns, in its development it rises but little above that of the Protonema of the Moss;

but in most other Ferns, or in the Polypodiaceæ, the Prothallus becomes a heart-shaped thalloid structure, even less like that of the mosses than in the diœcious form seen amongst the Equiseta. Another characteristic of the fern prothallus is its uniformly diœcious nature, as well as its commonly obcordate form; two features which cause this organism to be of little value in the distinction of genera and species. The classification of living Ferns mainly rests upon variations in the structure and arrangement of their spore-bearing organs. The spores are enclosed in "sporangia," or little cellular boxes. In most cases each of these sporangia is more or less surrounded by a linear series of large corner cells, which become elastic when ripe, and which are strong enough to tear open the sporangia and liberate the spores. Variations in the form and condition of this annulus characterize the primary groups. It is wanting in the Marattiaceæ; it is limited to a small localized cluster of cells in the Osmundæ, and whilst it is more complete in all the other types, peculiarities of its position distinguish them from one another. In like manner there are variations in the number and position of these sporangia upon the frond. Attached to the under surface of the frond they are more or less isolated in Mohria and various Lygodiæ, but gathered together in clusters called *sori* in various other tribes. The genera are characterized by the form and position of these sori on the frond.

Fossil plants on which these sori are preserved are very rare, hence paleo-botanists have been unable to make use of them when classifying the Fossil Ferns. The method of Brogniart, who trusted to the arrangement of the nervures of the leaves in constructing his genera groups, has from necessity been adopted by more recent observers, but this method proves to be an extremely defective one. The number of known examples retaining their sori has much increased of late, and their discovery has shown that Brogniart's method has brought together plants that differ widely and has separated others that should be more closely united. Hence the classification of Fossil Ferns now is and must for a long time to come be in a very unsatisfactory state. When endeavouring to learn what the Fossil Ferns teach in reference to the theory of evolution, it is important to ascertain which of the numerous living types of Ferns may be regarded as the highest and lowest representatives of the group. In determining this point their *general* organization must be considered rather than that of special organs. Thus viewed, the delicate Hymenophyllaceæ seem to claim the lowest rank, and to come nearest to the Mosses. Like the latter plants, their leaves consists of a single layer of cells which corresponds to the much thicker mesophyl of the other forms, whilst the latter are also furnished with an upper and a lower epidermal layer, which not only is absent from Mosses, but also from the Hymenophyllaceæ. These latter plants also have sporangia of a peculiar form. These project from the margin of the frond, each one being sustained by a prolongation of one of the nervures of the leaf. Then the "prothallus" developed from a spore approached much nearer to the filamentous "protonema" of the Moss than is the case with this organism in other Ferns. Examining the Fossil Ferns as they present themselves to us as we descend through the scale of strata, we discover that, whilst many of the common living genera, such as Polypodium, Asplenium, Pteris, Osmunda, Adiantum, and several others seen in a fossil state, they are confined to the Tertiary rocks. On the other hand, the semi-tropical genus Gleichenia descends through the Cretaceous age, and has two representatives in the Oolites, whilst though the true Osmundas are only seen in Tertiary beds, one of the Osmundaceæ, a Todea, has also been found in the Oolites; but whilst Oolitic Ferns are comparatively abundant, most of them assume generalized forms, incapable of being identified with special living genera. The large fossil genera Pecopteris, Neuropteris, Sphenopteris, are defined by peculiarities in the form of their nervures, but they may well be regarded as mixed and ill-determined groups, out of which many of the more specialized modern types have been developed, an opinion which obtains support from such examples as have already been met with in which traces of the reproductive sori are still preserved.

These remarks apply equally to numerous Fossil Ferns of yet older date. The three genera just named occur in considerable numbers both in the Carboniferous and Devonian strata.

On leaving the Oolitic rocks we find some special examples that demand more minute examination. Both the Permian and the upper and lower Carboniferous rocks furnish examples of true Tree-ferns. In the two former they have been obtained rather abundantly at Autun, in France, and in the latter from the neighbourhood of Oldham, in Lancashire; but since we only know their stems, it is impossible to say to what group of Ferns we ought to refer them. But it is otherwise with the very distinct group of the Marattiaceæ. The peculiar forms of the sporangia in this aberrant type of the Fern tribe are so distinctive, that it is impossible to mistake them. We have three principal modifications of this type living; the Angiopteris, the Marattia, and the Danæa. We find the Angiopterids represented in the Tertiary strata, in the Oolites and in the Keuper. The Marattiæ have only been discovered in the Tertiaries, whilst the Danæa is represented by two Oolitic species, the *Danæopsis marantacea* and *D. Rumphii*. But, besides these, some stems or very large petioles have been found at Autun, in France, and in the lower Carboniferous beds of Eastern Lancashire, which are certainly Marattiaceous, demonstrating the existence of this peculiar Cryptogam at that early date.

The greater number of the Carboniferous Ferns to which the organs of fructification are found attached belong to a peculiar and now extinct group to which the name of *Botryopterids* has been given; in which portions at least of the fertile fronds have been connected into branching masses of sporangia. But perhaps the most interesting feature connected with these Palæozoic Ferns is the discovery both in the Carboniferous and Devonian strata of representatives of the group of Hymenophyllaceæ or Filmy Ferns. The primitive organization of these Ferns has already been referred to; hence their prevalence in the oldest strata in which ferns have been discovered in any considerable quantities is what the doctrine of Evolution would lead us to expect were we to reason after the *à priori* fashion. There is evidently no reason for doubting that the fine *Palæopteris Hibernica* from the Devonian strata, not only occurs at Kiltorcan and some other places in Ireland, but also in Scotland and in North America. It may be observed that whilst both the Equisetaceæ and the Lycopods of the Palæozoic age became gigantic trees, and hence displayed in the interior of their stems a magnificent exogenous development of their vascular structures unknown amongst their living representatives, the Ferns of the same age, arborescent or otherwise, possessed no such growths. The genera and species are distinct from existing ones, but, except in detailed features of secondary importance, this important group has undergone but little change between the Devonian age and the present time. But that age was not the beginning of their existence. We have already obtained some fragments of Silurian Ferns, but they are too scanty and insignificant to throw much light on the true character of these plants in the Silurian age. A complete Silurian land-flora yet remains to be discovered.

CHEMICAL SOCIETY.

A meeting of this Society was held on February 15, Dr. Gilbert, President, in the chair.

It was announced that a ballot for the election of Fellows would be held at the next meeting (March 1).

The following certificate was read for the first time: W. H. Cameron.

The list of officers as proposed by the Council was read from the chair. Professor G. D. Liveing and Dr. A. Voelcker are proposed as Vice-Presidents instead of Professors J. Dewar and A. V. Harcourt, who retire; in the Council, Professor Dittmar, Dr. W. R. E. Hodgkinson, Messrs. D. Howard and R. Meldola replace Dr. T. E. Thorpe and Messrs. F. D. Brown, J. M. Thomson and W. Thorp.

Drs. Thorne and Hodgkinson and Mr. D. Howard were elected auditors.

The Secretary then read the following papers—

On some Derivatives of Diphenyleneketone Oxide. By A. G. Perkin.—While preparing the above substance from salicylic acid and acetic anhydride, the presence of a small quantity of another body was detected in the washings; this substance the author has separated as transparent satiny plates containing 75·2 per cent. C., 3·9 per cent. H; its formula has not yet been settled. By the action of a cold mixture of equal parts of nitric and sulphuric acids, and by the action of fuming nitric acid, a nitro body was formed, $C_{13}H_6(NO_2)O_2$; it is very slightly soluble in boiling alcohol and melts at 262° C. By the action of tin and hydrochloric acid on dinitrodiphenyleneketone oxide, suspended in alcohol, a diamido body is produced, $C_{13}H6(NH_2)_2O_2$; it was obtained in flat orange-coloured needles. This base forms a hydrochloride and a platinum salt, which were analysed. Diphenyleneketone oxide dissolves in cold Nordhausen acid unchanged, but on heating the solution and treating with barium carbonate a salt was obtained having the formula $C_{13}H_6O_2Ba(SO_3)_2$. Bromine, when heated in a sealed tube with diphenyleneketone oxide, forms a dibromobody, $C_{13}H_6Br_2O_2$.

On α-ethyl Valerolacton, α-ethyl-β-methyl Valerolacton, and on a Remarkable Decomposition of β-ethylacetosuccinic Ether. By S. Young.—Fittig and Krafft (*Ann.*, 208–71) prepared a heptolacton of unknown constitution. The author, at the suggestion of Professor Fittig, undertook the preparation of a heptolacton of known constitution. A mixture of 10 grams of sodium, 100 grams of alcohol, 58 grams of aceto-acetic ether and 87 grams of α-bromobutyric ether was heated in a water bath for two days. The author could not obtain a product of constant boiling point; about 12 grams of the portion, boiling at 250°–260°, was boiled with twice its weight of 33 per cent. hydrochloric acid. The resulting product was principally α-ethyl-β-acetopropionic acid, which was extracted with ether and the latter distilled off. The residue partially crystallized at low temperatures. A portion was warmed with sodium amalgam, acidified with sulphuric acid and boiled, made alkaline with potassium carbonate, and extracted with ether; the ether extract on distillation gave a residue which eventually, after fractionation, proved to be the lacton boiling at 219·5°. Analysis indicated the formula $C_7H_{12}O_2$, it did not solidify in a mixture of snow and salt. On dissolving this substance in the smallest possible quantity of ice-cold water a clear solution was obtained, which became turbid from 17° up to 90° C. By boiling the lacton with barium hydrate, barium and ethyloxyvalerate was prepared; the silver salt was also obtained and analysed. When either salt is decomposed by an acid a mixture of lacton and oxyacid is formed. On preparing larger quantities of the crystalline acid, which the author calls ketolactonic acid, the distillate at higher temperatures, above 265°, yielded proportionately more crystals than that between 250°–260°, so that the decomposition apparently takes place during distillation and not during saponification. The barium and silver salts of this ketolactonic acid were prepared and analysed. By the action of barium hydrate on ketolactonic acid a derived acid was prepared, the silver salt of which had the composition $C_8H_{10}O_5Ag_2$. Thorne obtained by the saponification of β-ethylacetosuccinic ether, α-ethyl β-acetopropionic acid and ethylsuccinic acid; the author separated in addition this new ketolactonic acid. α-ethyl-β-methylvalerolacton was also prepared by the distillation of β-ethyl acetomethylsuccinic ether. Thorne, by the distillation of α-ethyl-β-acetopropionic acid, obtained an anhydride, which he stated to be insoluble in water. The author has repeated these experiments and obtained the anhydride which is, however, slightly soluble in water. In conclusion, the constitution of ketolactonic acid is discussed.

Dr. Thorne said that he was able to distil the β-ethyl acetosuccinic ether *in vacuo* at 263°–264° without decomposition; as to the anhydride, he had since found that it was slightly soluble in water. At the time he first prepared the substance he had but a very small quantity at his disposal.

The Society then adjourned to March 1, when a ballot for the election of Fellows will be held and the following paper read, "On some Derivatives of the Isomeric $C_{10}H_{14}O$ Phenols," by Dr. Armstrong and E. H. Rennie.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A paper on "Glycerine and its Application to Pharmacy," was read by Mr. F. Harris Alcock, before the members of the above Association on Wednesday evening, January 31.

The author enumerated a long list of substances from the animal, vegetable and mineral world, which were soluble in glycerine. Popular pharmaceutical preparations into which glycerine largely entered were mentioned, and modes of preparation with formulæ given. The chief object of the paper was to bring forward a method of applying the wonderful solvent, antiseptic, preservative and anti-fermentive properties of glycerine, particularly with reference to the manufacture of glyceroles. The process recommended consists in the use of a menstruum of 1 part glycerine mixed with 4 parts distilled water, which has a sp. gr. 1·06. The properly comminuted drug is exhausted by the menstruum (1 oz. requiring 5 fl. ozs. of solvent as a rule) after maceration, by means of percolation, and the displacement fluid used being distilled water. The united products are then evaporated to 1 fluid ounce on the water-bath and the liquid preserved. One fluid drachm contains the soluble active ingredients from 1 drachm of solid. Experiments had been made with gentian, cinchona, sarsa, glycyrrhiza and pepsin, and the products were exhibited as clear, bright, thick, syrupy liquids having in each case the same odour, taste, appearance and general characters as other preparations of the same drugs prepared by the usual official processes.

An interesting and lively discussion followed, in which the President, Secretary, Messrs. W. T. Cooper, jun., Cox, Cracknell, Dodd, Fell, Parkinson and Ramble, took part.

A hearty vote of thanks, proposed by Mr. Packe and seconded by Mr. Winfrey, to the author for his valuable paper terminated a most enjoyable and profitably spent evening.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, February 1, 1883. Mr. R. H. Parker, Vice-President, in the chair.

The following "Dispensing Notes" were read by the Secretary in the absence of the author:—

Dispensing Notes.

BY WILLIAM JOHNSTON.

No. 1.

In the course of business, a few weeks ago, some—to me—rather remarkable results connected with the dispensing of the following prescription chanced to come under notice. I hope that the description of them may prove of some interest to the members of this Society.

The prescription was:—

Sulphate of Quinine	40 grains.
Tincture of Perchloride of Iron .	80 minims.
Dilute Phosphoric Acid	1 drachm.
Glycerine	4 drachms.
Water	to 8 ounces.

The quinine was shaken up with a little water as usual, and then dissolved by means of the phosphoric acid. On further dilution with water and addition of the tincture of iron, a copious whitish precipitate appeared. The first supposition was that it would be some compound of quinine, but after inquiry and a few experiments, it was found that there was no quinine in it, excepting, perhaps, a trace carried down mechanically.

When a little sulphate of quinine (a proportionate quantity) was dissolved in water by tincture of iron, and the phosphoric acid added last, precipitation did not take place so rapidly, though, after a time, quite as *completely*. In order to discover if the glycerine or spirit had any influence in the reaction, a small quantity of the mixture was prepared in several different ways.

First—Quinine, tincture of iron and phosphoric acid with glycerine; second—the first three with glycerine and spirit; third—with spirit; and fourth—without either glycerine or spirit. In a few days it was found that No. 1—*i.e.*, with glycerine only—had a trifle more precipitate than the others; No. 2 had next most, and so on; No. 4—without the alcohols—having slightly less than the others. The precipitate was thrown down as largely when one or other of the solvents was added to the quinine in solution *in the full quantity* of water.

It was noticed that, on adding either of the solvents in considerable excess of the proportions named, the precipitate was redissolved.

A portion of it was tested and found to be *phosphate of iron.*

An equation to represent the reaction would be:—

$$Fe_2Cl_6 + 2\,H_3PO_4 = Fe_2 2PO_4 + 6\,HCl.$$

Apparently, in that particular proportion, the quinine and, to a small extent, the two alcohols have the power of throwing the ferric phosphate out of solution. The quinine especially has that effect, as a subsequent experiment showed.

Three other mixtures were prepared.

The first containing 10 minims B.P. *solution* of ferric perchloride, 7½ minims dilute phosphoric acid, water to 1 ounce.

The second—Solution of perchloride of iron, dilute phosphoric acid, water, with 10 minims of rectified spirit added.

And the third—Solution of the perchloride, dilute phosphoric acid and water, with 5 grains sulphate of quinine added.

After standing a few days, No. 1 remained bright; No. 2 was decidedly cloudy; whilst No. 3 had in it a plentiful precipitate from the beginning, thus, I think, proving that the quinine and spirit have the power just ascribed to them.

The subject is capable of further development, but want of time compels me to abandon the investigation at present.

I may, however, add that of course the mixture was sent out with all the ferric phosphate in it,—the bottle bearing a "shake" label.

No. 2.

Another example of the power that spirit possesses of throwing throwing certain saline bodies out of solution, was observed a few days afterwards. There was brought to be refilled a bottle which had contained the following mixture:—

Phosphate of Soda	4 drachms.
Bicarbonate of Soda	2 drachms.
Aromatic Spirit of Ammonia,	
Comp. Tincture of Gentian, of each	4 drachms.
Water . . . . to	8 ounces.

When sent out the salts had been quite dissolved and the mixture bright, but now there was a lot of small crystals at the bottom of the bottle. The spirit was at once suspected of being the cause of this and an experiment undertaken in proof.

Four solutions were prepared.

The first had in it:—1 drachm phosphate of soda, ½ drachm bicarbonate of soda, 2 drachms spirit of wine, and water to 2 ounces.

The second—Phosphate of soda, spirit of wine and water.

The third—Phosphate of soda, bicarbonate of soda, and water.

And the fourth—Phosphate of soda and water.

After standing for three or four days in a cold place, Nos. 3 and 4 remained clear, but Nos. 1 and 2 had deposited a mass of oblique rhombic crystals of sodic phosphate, the former especially.

These facts speak for themselves and need little further comment. It cannot be fairly said that Nos. 1 and 2 deposited because there was *less water* in them, as the difference in that respect was only very slight; and, moreover, the ordinary solubility of the phosphate is one in four or five (Royle says *four* and Squire *five*), whereas, in this case there would be at least ten or twelve parts of water available.

This time, instead of fully dissolving the salts, they were reduced to fine powder, *partially* dissolved and the mixture sent with a "shake the bottle" label on. I may further state that, when the empty bottle was returned a second time, it was found that this plan of powdering and partial solution had been much more satisfactory, there being only a very few small crystals left at the bottom.

A vote of thanks was passed to Mr. Johnston.

In the discussion which followed the Chairman, Secretary, Messrs. Elworthy, Giles and Taylor took part.

The Reporter on Physics, Mr. H. Allen, B.Sc., then made a report upon "Secondary Batteries," which will be published in a future number of this Journal.

The Report was copiously illustrated by experiments, and several of the principal secondary batteries were exhibited, including the new Faure-Sellon-Volckmar accumulator, which was shown in working order.

A discussion followed the reading of the Report, in which the Chairman, Secretary, Messrs. Elworthy, Giles, Ince, MacDermott and Taylor took part, after which the meeting adjourned.

At a meeting held Thursday, February 15, the chair was occupied by Mr. H. G. Greenish, Vice-President.

Mr. W. E. Crow read a paper on "Linnæus," of which the following is an abstract:—

The author first alluded to the antecedents of Linnæus, observing that his predecessors had been peasants, although some of them early in the 17th century had followed literary pursuits. It was Nicholas, his father, who first adopted the name Linnæus, a remarkable linden tree, *Tilia Europæa*, growing near the place of their residence, having, it is said, given origin to this surname. After reviewing somewhat in detail the early life of this great naturalist, and pointing out that he had been intended by his parents for the church, Mr. Crow proceeded to mention the incidents connected with his meeting Rothman, Stobæus and others, men whose influence played no inconsiderable part in delineating a character which for ever would be regarded as one of the most remarkable in the annals of botany.

At the age of 22, Linnæus was eking out a most wretched existence, and it was related that he had to depend on chance generosity for a meal, and had even to repair his shoes with folded paper. The author here pointed out that in spite of all his troubles Linnæus still persevered with his studies, and shortly afterwards was discovered by Dr. Celsius, who took him under his protection and soon recommended him to pupils, by which means his finances were improved, and he was enabled thereby to assume a more creditable appearance. He then mentioned the many incidents connected with his stay at Upsala, his journey through Lapland, etc., and the steps taken by him to obtain his degree in medicine, which latter was effected at Harderwijk, in Holland. He then proceeded to notice the occasion when Linnæus convinced Professor Burman, of Amsterdam, that the cinnamon tree was a species of Laurus, and also alluded to a tradition connected with his visit to England, in which it is related that Linnæus fell on his knees in a rapture on observing the golden bloom of the furze (*Ulex Europæus*) growing on some of the commons near London, especially Putney Heath. After reviewing his visit to Paris and his meeting with Jussieu, the great French botanist, Mr. Crow proceeded to give a brief sketch of the Linnæan or Artificial System of classification.

A diagram was exhibited showing the whole of the twenty-four classes and some of the more important orders, comparing them at the same time with the Natural System. Special attention was called to the following classes:—Icosandria, Polyandria, Didynamia, Tetradynamia, Monadelphia, Syngenesia, Gynandria, Monœcia, Diœcia, etc., and the orders of the Natural System which corresponded with them.

A discussion followed in which the Chairman, Secretary, Messrs. Baily, Corder, Hamilton and Rees took part.

A vote of thanks was passed to Mr. Crow.

The Reporter upon Analytical Chemistry, Mr. C. Thompson, then made a Report upon two new methods for the separation of copper and cadmium. The first method depended upon the fact that copper is precipitated from solution as sulphide by boiling with milk of sulphur, while cadmium remains in solution, the second method depended upon a similar reaction but involved the use of sodium thiosulphate. Mr. Thompson was making experiments upon the processes and promised to give an account of his results at the next meeting.

After a short discussion the meeting adjourned.

SOCIETY OF CHEMICAL INDUSTRY.

The Present Condition of the Soda Industry.

BY WALTER WELDON, F.R.S.

(*Continued from page 638.*)

The other consideration to which I referred as having given comfort to the makers of Leblanc soda, and which constituted indeed their chief ground of hope for salvation against the ammonia process, was that the world requires chlorine as well as soda, and that while the chlorine of the salt decomposed by the Leblanc process is yielded as hydrochloric acid, from which free chlorine can be obtained readily, the chlorine of the salt decomposed by the ammonia process is yielded as a somewhat dilute solution of calcium chloride. It was thought that the ammonia process would eventually even help the existing Leblanc soda-makers, by preventing the further extension of the Leblanc process, and so restricting the production of hydrochloric acid, and thereby at length increasing the value of that body. The ammonia process, no doubt, would have produced that result, and would have produced it by this time, if the supply of hydrochloric acid in this country had not been already so largely in excess of the demand for chlorine products. That demand is always becoming larger, and within the last few years the production of hydrochloric acid has appreciably diminished; but in this country the constantly-increasing stringency of legislative enactments with respect to river and air pollution has compelled so many producers of hydrochloric acid, who would have preferred to throw their acid away, to employ it in the manufacture of chlorine, whether that manufacture were profitable or not, that the selling price of chlorine products has of late years been continually falling, until it is now at a point at which it barely pays their cost. No doubt, if all the other conditions of the problem were to remain as at present, the demand for chlorine products would in time overtake the supply of hydrochloric acid in this country, as it has long since done on the Continent, and the manufacture of chlorine in England would so again become profitable. But the other conditions of the problem are not likely to remain stationary, and both M. Solvay and myself are doing our best to change them.

M. Solvay is proposing to manufacture hydrochloric acid from the residual calcium chloride of the ammonia process. I imagine that he is urged to that course, not merely by a desire to turn that calcium chloride to account, but also by a desire to avoid making too much nuisance. For it must not be supposed that even the ammonia process, when practised on a large scale, is free from nuisance. It certainly does not send into the air any noxious vapours, but it sends into the water-courses very large quantities of calcium chloride, rarely accompanied by less, and often accompanied by much more, than an equivalent quantity of sodium chloride, and very apt to be accompanied also by both calcium carbonate and free lime. Neither calcium chloride nor sodium chloride will do much harm to a river, if sent into it in moderate quantities; but when it comes to sending into a comparatively small stream, far inland, 260 tons of calcium and sodium chlorides per twenty-four hours,—say, about ten tons per hour, night and day, all the year through: and M. Solvay must be doing something very like that at Dombasle,—the matter assumes quite another aspect. I am not myself an angler, but, if I were, I do not think that I should seek for sport immediately below Dombasle.

Be all that, however, as it may, M. Solvay is now erecting at Dombasle apparatus for an industrial trial of a process for obtaining hydrochloric acid from calcium chloride, at which he has been working for many years. The process in question consists in first concentrating by evaporation the mixed solution of calcium and sodium chlorides which is the residual product of the ammonia process; then mixing the concentrated solution with clay, making the mixture into balls and drying those balls: and then heating these balls to redness in a current of steam. This process certainly works, on condition that the temperature employed be sufficiently high, and that the quantity of steam used be largely in excess of the quantity necessary to react upon the calcium chloride. As the resulting mixture of vapour of water and vapour of hydrochloric acid would otherwise give an extremely dilute aqueous acid, M. Solvay proposes to separate from it most of its vapour of water, before condensing its hydrochloric acid, by passing the mixture of the two vapours through a very strong solution of $CaCl_2$, which he finds will absorb most of the steam from such a mixture, allowing the HCl to pass on alone, so that it can afterwards be condensed in the usual way. All this is ingenious, but it can hardly be cheap. Firstly, a solution containing only about 8 per cent. of calcium chloride has to be evaporated, we may say to dryness; then the mixture of $CaCl_2$ and clay has to be maintained at a red heat for a considerable time, in a current of steam; and then the solution of calcium chloride used to separate steam from the resulting mixture of steam and HCl has to be prepared for use again by having all the water which it has absorbed evaporated off from it. To English manufacturers who have more hydrochloric acid than they can use, this process of M. Solvay's will seem little less than ridiculous; but one must remember that it is intended for countries in which the demand for hydrochloric acid exceeds the supply, and in which countries, moreover, chlorine products are protected by import duties. In such countries, one can quite conceive its being commercially practicable; in which case the exportation of chlorine products from England to the Continent is doomed. I ought to add that M. Solvay expects that the silico-aluminate of calcium which remains after the chlorine of his mixture of calcium chloride and clay has been driven off by steam will be useful as a cement, and will thus help to pay the cost of his hydrochloric acid.

The exportation of chlorine products from England to the Continent is, moreover, threatened in another way. The Continental manufacturers of Leblanc soda, unlike the English manufacturers of Leblanc soda, do not produce enough hydrochloric acid to meet the demand of their respective countries for that acid itself and the products which are made from it. This is partly due to the production of ammonia soda, proportionately to the total production of soda, being so much greater in France and Germany than in this country; and partly to hydrochloric acid being required in those countries for industries which in this country do not exist. Large quantities of chlorine products consequently go to the Continent from this country: our production of hydrochloric acid being still sufficient to enable us to supply not only the total English demand for chlorine, and the total American demand for chlorine, but also an appreciable proportion of the Continental demand for chlorine, and, in addition to all that, to throw a large residue of hydrochloric acid into the North Sea. The Continental Leblanc soda-makers do not like this importation into their respective countries of chlorine products from England; but they can prevent it only in one or other of two ways: either by increasing their production of hydrochloric acid, or by becoming enabled to obtain from a given quantity of hydrochloric acid a larger proportion of free chlorine than is yielded by the process at present in use. Personally, I have for the process at present in use that respect which one always feels for the bridge which has carried one over, but I am well aware that it can by no means be regarded as final. It yields chlorine cheaply; but it yields only one-third of the total chlorine contained in the acid employed, the other two-thirds being lost as calcium chloride. English chlorine manufacturers will regard almost with horror the idea of a new chlorine process, which shall yield in the free state practically the whole of the chlorine contained in the acid employed; but on the Continent there is a demand for such a process,—a demand which will no doubt be lessened, but will by no means be destroyed, by what is being done in France by the Compagnie d'Exploitation,—and I am one of those who have been called upon to endeavour to supply that demand. M. Pechiney is now preparing to make at Salindres a trial on an industrial scale of a process which, I think, will supply it; and by the end of this year he will probably have obtained decisive results.

As regards the English chlorine industry, however, I do not think that its prospects are by any means so gloomy as, from what I have said so far, might at first blush appear. But I think that its salvation will come from an unexpected quarter. I think that our English manufacturers of Leblanc soda will have to cease to devote their hydrochloric acid,—when they do not throw it away,—exclusively to chlorine making. They would, of course, be only too glad to do so, if a means could be furnished them of turning it to account otherwise; but the difficulty hitherto has been as to how to turn it to account otherwise. I believe that that difficulty is about to disappear. I am not free to enter into that matter now, and, indeed, it is not yet ripe for discussion; but I have very great confidence that new applications of hydrochloric acid, admitting of being applied very extensively, at comparatively small expense, are among the things of the immediate future.

As regards soda, the position of the English Leblanc soda-makers is this. They are now working, when not actually at a loss, at least without profit. Until comparatively recently, they supplied the whole of the English demand for soda, the whole of the American demand for soda, and a large part of the Continental demand for soda. Both their home market, however, and their American market have been recently invaded by English-made ammonia soda, and now the manufacture of ammonia soda has begun in the United States themselves, and will have reached there, before the expiration of this year, a scale of 20,000 tons per annum, while a little later on that Belgian soda and copper work of which I spoke will not only have put an end to all export of English soda to Belgium, but will, doubtless, also be sending Leblanc soda to America: as will also, no doubt, the great work which is being built at Marseilles, and, eventually, those other works which are about to be built at others of the French sea-ports. The exportation of English soda to Austria, which has already dwindled to little more than 8000 tons per annum, is expected to cease entirely before the end of the present year, by reason of the increased quantity of ammonia soda which will soon be made in Austria. An increased production of ammonia soda is similarly expected to put an end, almost immediately, to the importation of English soda into Germany, which importation in 1881 was already only two-thirds of what it was in 1879. Russia, moreover, will soon be making for herself at least a portion of the soda she consumes; and France, which country has hitherto been entirely dependent upon England for her supplies of caustic soda, though she has long ceased to take from us any form of soda, will soon be making herself all the caustic soda she requires; for, apart from what may be done by the new company of which I have spoken, M. Solvay is just beginning to make caustic soda at Dombasle, and contemplates making it there on a very extensive scale.

In face of all this, how are the English Leblanc soda-makers to continue to live? For one thing, it is quite certain that they must have cheaper pyrites. The present price of 6*d.* per unit is an artificial price, entirely due to a trade combination; and that price will certainly have to be reduced by at least 50 per cent. That it can be reduced to 3*d.* per unit, and yet leave a very fair profit to the pyrites sellers, I believe there can be no doubt. At the present price of copper, and at 3*d.* per unit for sulphur, pyrites showing 2½ per cent. of copper by Swansea assay would sell for 39*s.* per ton; and, that Spanish pyrites can be delivered to English ports at that price at a fair profit, is, I believe, unquestionable. If, therefore, the existing companies refuse to supply pyrites at that price, they will simply call into existence other companies which will supply it at that price. That the Leblanc soda-makers will thus get their sulphur at a price not exceeding 3*d.* per unit, after the end of next year, when the present combination between the pyrites companies will expire, may be regarded as quite certain.

Pyrites at 3*d.* per unit, however, would by no means bring down the cost of Leblanc soda to that of ammonia soda. Without using any figures which have been given to me privately, there is no difficulty in arriving, very approximately, at the difference between the cost of ammonia soda and that of Leblanc soda, from what is matter of public knowledge with respect to the dividends paid by joint stock companies which make ammonia soda and publish balance-sheets. We learn in this way that, when Leblanc soda is yielding no profit at all, ammonia-soda is yielding fully £1 per ton. As to make a ton of actual sodium carbonate by the Leblanc process does not require more than about 13·5 cwt. of pyrites, reduction of the price of pyrites to 3*d.* per unit would thus reduce the cost of Leblanc soda only by about 7*s.* 9*d.* per ton of actual sodium carbonate.

Seven shillings and ninepence, however, is something; and, as regards the balance of the pound, there are two resources, which together will, I think, be sufficient to turn the tables upon the ammonia process, and make the good old Leblanc process the cheaper of the two.

One of these two resources consists, of course, in sulphur recovery. If sulphur recovery were the only resource,—which, however, happily it is not,—I think it not impossible that the required 12*s.* 3*d.* per ton of sodium carbonate could be gained by it alone. To this end, except in localities in which there is a demand for sulphuric acid free from arsenic, the sulphur must be recovered, not as sulphuric acid for use again, but as free sulphur, for sale as such. At the general meeting of our Society at Manchester, last July, I explained that, while the Schaffner and Helbig process would yield as sulphuric acid practically the whole of the sulphur of the calcium sulphide contained in the waste treated by it, it would probably yield as free sulphur only four-fifths of the total sulphur contained in the waste as calcium sulphide. Since then, reason has arisen for a very confident hope that the whole of the sulphur of the calcium sulphide contained in the waste may be obtained in the free state: in which case the yield will be almost exactly 6 cwt. of free sulphur per ton of actual sodium carbonate manufactured. If, therefore, one were dependent for that 12*s.* 6*s.* on sulphur recovery alone, the problem would be narrowed to this: Can free sulphur be obtained from alkali-waste at such a cost, and is there a sufficient demand for free sulphur at such a price, that it shall be possible to sell recovered sulphur, in sufficient quantity, at 2*s.* 0½*d.* per cwt., or say 41*s.* per ton, more than the cost of producing it?

To be continued.)

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act, 1868.

At the Borough Police Court, Nottingham, on Tuesday, February 6, before Mr. F. Parsons and Captain Starey, John Alfred Bailey, of 220, Alfred Street Central, was charged with having sold to Alfred Short Wright, Assistant Secretary of the Chemists and Druggists' Trade Association of Great Britain, a certain poison, to wit, "laudanum," the same being a preparation of opium, not labelled with the name of the article, or with the name and address of the seller of the same, contrary to the statute in such case made and provided.

Mr. Henry Glaisyer, solicitor, Birmingham, appeared on behalf of the Chemists and Druggists' Trade Association of Great Britain, and Mr. F. Lees, solicitor, Nottingham, conducted the defence.

Mr. Glaisyer, in opening the case, said this was a summons issued under the 17th section of the Pharmacy Act, 1868, 31 and 32 Vict., chap. 121, which stated "that it shall be unlawful to sell any poison, either by wholesale or retail, unless the box, bottle, vessel, wrapper or cover in which the poison is contained be distinctly labelled with the name of the article, the word 'poison,' and with the name and address of the seller of the poison." The section then proceeded to lay down that any person selling poison otherwise than is herein provided shall, upon a summary conviction before two justices of the peace in England or the sheriff in Scotland, be liable to a penalty not exceeding £5 for the first offence, and £10 for the second or any subsequent offence, and for the purposes of this section, the person on whose behalf any sale is made shall be deemed to be the seller. Mr. Glaisyer further stated that on January 30 last Mr. Alfred Short Wright went to Nottingham, and visited the shop of the defendant at 220, Alfred Street Central, where he purchased a quarter of a pound of linseed meal and one pennyworth of laudanum. The laudanum, on being tested by the purchaser, was found to be a preparation of opium. There could be no doubt whatever that the defendant was the person carrying on the business at the address he had given, as he should be prepared to prove, if necessary, that the defendant paid the rates and taxes of the said premises.

Alfred Short Wright, Assistant Secretary of the Chemists and Druggists' Trade Association of Great Britain, gave evidence as to the purchase of the laudanum, which he said had been supplied to him by a woman. He had examined the contents of the bottle and found it to be a preparation of opium.

William Pilgrim said he was rate collector for the Borough of Nottingham, and produced his rate book, in which the name of John Alfred Bailey appeared as occupier of the premises 220, Alfred Street Central, and that he paid him the rates.

This was the case for the prosecution.

Mr. Lees said he was quite prepared to admit the offence on behalf of his client, and addressed the Bench for mitigation of the fine, admitting that the laudanum had been sold, but not by the defendant. Defendant was preparing to undergo an examination which would enable him to be qualified as a dealer in such drugs. After taking these facts into consideration he trusted the Bench would only inflict a nominal penalty.

The Magistrates said they had carefully considered the matter and thought it was a case that had been taken up very properly for the protection of the public and they had decided to convict defendant in a penalty of £1 11*s.* 6*d.* including costs.

Prosecution of a "Herbalist" under the 17th Section of the Pharmacy Act.

At the Hanley Borough Police Court, on Monday, the 12th inst., John Wheatcroft, carrying on business as a herbalist in Parliament Row, Hanley, was summoned to answer a charge of selling poison without labelling the same, and Edward Davis was summoned that he being in the employ of Wheatcroft did vend the same on the 25th January last.

It appeared that on the day named Mrs. Bratt, a widow, went to the defendant's shop for some burdock root. The defendant Davis was in the shop, and said in reply to a question by Mrs. Bratt that burdock would do a deal of good if mixed with some other herb roots, namely, mezereum, gentian and dandelion. He gave her a paper which he said contained these roots, but on Mrs. Bratt taking a wineglassful of a decoction made from them she became black in the face and delirious.

Evidence was given to the effect that belladonna had been given instead of burdock.

Mrs. Bratt's daughter, who also took two tablespoonfuls of the decoction, became very ill, and was almost blind when she went for the doctor, and was obliged to turn back to get a drink, so great was her thirst.

Wheatcroft was fined £5 and costs, the summons against Davis being dismissed.—*Staffordshire Sentinel.*

Alleged Poisoning by a Patent Medicine.

An adjourned inquest has been held at the Stowmarket County Hall, on the body of Sarah Scurrah, before Mr. A. F. Vulliamy, Coroner.

Dr. W. G. Groome said that he had made a *post-mortem* examination of the deceased and could find no cause of death. Deceased was suffering from no disease that would rapidly cause death. His opinion was that she died from opium poisoning.

Edward Richard Gibbs said he bought the bottle of balsam produced, at his aunt's request, for her at Mr. Martin's shop in the Edgware Road, about four years ago. It was not opened till January 9, last. His aunt wished him to buy it for her, because she had previously found it beneficial. She on that occasion took a teaspoonful of the mixture three times a day. She took three doses of it. This was rather more than four years ago. He did not remember that she felt drowsy on that occasion.

Mr. A. H. Martin, chemist, of South Hampstead, described the constituents of the pectoral balsam. It contained, amongst other things, ½ ounce of crude opium in every 100 ounces. He had been very careful to keep within the limits of the dose ordered by the Pharmacopœia, which gave ½ a grain to 2 grains of opium as the maximum dose. Crude opium was not so strong as powdered opium, because the latter was deprived of the moisture. He should think one teaspoonful, which contained 6 minims of laudanum, would be absorbed as soon as taken, more especially as it is taken in combination with an alkali. He had sold hundreds of bottles, and had never had an accident. He did not believe that the dose deceased took of his mixture would have caused death.

A verdict of "Accidental death from opium poisoning" was returned.

Charge against an Assistant.

At the Southampton Petty Sessions, Charles Baker was charged on remand with stealing two florins, the property of his employers, the Southampton Drug Company, of 153, High Street.

Mr. William Day, director and secretary of the Company, stated that on January 16, defendant, who was a managing chemist in their employ, was engaged in the shop, his duty being amongst other things to serve customers, and when he took cash over the counter it was his duty to enter it in a book which duplicated the entry by means of a carbon sheet placed between the leaves. He then had to tear out two leaves, and hand one with a billhead to the customer, and the other with the carbon impression to the cashier with the money. This it was alleged he had not done in a case where a purchase had been made with marked money, which was afterwards found in his possession. The prisoner was committed for trial, but was liberated on bail, himself in £100 and two sureties in £50 each.

Charge of Theft against a Chemist's Assistant.

At the Liverpool Police Court, on Wednesday, January 31, Francis Edward Twemlow, was charged with having stolen drugs and chemicals to the value of £150, the property of the Liverpool Apothecaries' Company, Limited, Colquit Street, Liverpool. According to the evidence it appeared that the prisoner had been three months in the service of the prosecutors, and that after he had left their suspicions were excited by information that he had been advertising drugs, etc., for sale at reduced prices. Upon inquiries being made it was found that the prisoner had received two cheques, and when he was arrested drugs were found in his boxes which were identified as the property of the Company. The prisoner was committed for trial, bail being refused. —*Manchester Guardian.*

Obituary.

Notice has been received of the death of the following:—

On the 6th of January, Mr. Albert Charles Muskett, Chemist and Druggist, Park Street, Southwark. Aged 56 years.

On the 20th of January, Mr. John Hawkin, Chemist and Druggist, Bedale, Yorkshire. Aged 78 years.

On the 22nd of January, Mr. James William Barnes, Pharmaceutical Chemist, Spalding, formerly of Oxford Street. Aged 27 years. Mr. Barnes had been a Member of the Pharmaceutical Society since 1881.

On the 25th of January, Mr. Frederick Finney Flint, Chemist and Druggist, Prebend Street, Islington. Aged 44 years.

On the 25th of January, Mr. William Saxe Pearson, Chemist and Druggist, Kidsgrove, Staffordshire. Aged 67 years.

On the 27th of January, Mr. Stephen Bloxwich, Chemist and Druggist, Bloomsbury Street, Birmingham. Aged 65 years.

On the 28th of January, Mr. Charles Patrick Baker, Pharmaceutical Chemist, High Street, Chelmsford. Aged 63 years. Mr. Baker had been a Member of the Pharmaceutical Society since 1850.

On the 2nd of February, Mr. Edwin Pomeroy Webster, Pharmaceutical Chemist, Newcastle-on-Tyne. Aged 60 years. Mr. Webster had been a Member of the Pharmaceutical Society since 1853.

On the 4th of February, Mr. Joseph Dixon, Chemist and Druggist, Whitefriar Gate, Hull. Aged 62 years.

On the 6th of February, Mr. Benjamin Matthew Tippett, Pharmaceutical Chemist, Sloane Street, London. Age 71 years. Mr. Tippett was one of the Founders of the Pharmaceutical Society.

On the 8th of February, Mr. John Martin, Pharmamaceutical Chemist, Cleveden, Somerset. Aged 67 years. Mr. Martin also was one of the Founders of the Pharmaceutical Society.

On the 12th of February, Mr. Edward Bruce Oddie Chemist and Druggist, High Street, Bristol. Aged 34 years.

On the 13th of February, Mr. Alexander Maunder, Chemist and Druggist, Weston-super-Mare. Aged 66 years.

Aromatic Spirits of Ammonia.

Sir,—Kindly allow me space to point out an error into which Mr. Martindale fell in criticizing my paper on sal volatile.

To make 7 pints of the official compound without distillation, the 8 oz. amm. carb. must be dissolved in a mixture of 4 oz. liq. amm. ft. and 10 ozs. of water. Mr. Martindale, to disprove my statement that the amm. carb. would not dissolve in the requisite quantity of water, showed an experiment in which he used double this proportion of water.

As for Mr. Schacht's reiterated statement, that after addition of the spirit, in my process "a solution could be obtained without the aid of heat," I do not find in the paper any assertion to the contrary.

The application of heat is recommended because sal volatile made with such a solution does not deposit crystals, even at 0° C., whereas when prepared with a solution effected in the cold, a deposit forms at low temperatures.

Buxton. J. C. Thresh.

Only a Junior.—The answer to your question may be obtained by drying the extracts and observing the reduction in weight through loss of moisture. The equivalent of the dry extract is then ascertainable by calculation.

T. H. Dodd.—Your letter was not published because it did not appear to us that it threw any fresh light upon the subject.

Vibgyor.—There is no contradiction between the two statements. For an account of the ammonia process, see before, p. 455.

E. J.—Your communication was sent to the wrong address. It has now been received.

J. F. L.—(1) A candidate for a Bell Scholarship must be a Registered Student or Apprentice of the Society. (2) No. (3 and 4) No single book would be sufficient for the purpose. (5) We cannot say.

Communications, Letters, etc., have been received from Messrs. Burgoyne, Burbidge and Co., Baldock, Jones, Shirivell, Ince, Pollard, Rouch, Young, Wilkinson, Wade, Hay, Hart, W. Robert, Local Secretary, Only a Junior, Hospital Dispenser, Assistant, Asinus, Minor Associate in Business, Pestle, Nemo, Publishers of *El Sentido Catolico.*

ANNUITANTS.

There are at present *forty-one* annuitants, receiving £1350 per annum, and casual relief is also granted, involving a total annual expenditure of upwards of £1800.

The scale of pensions is £30 per annum to pensioners under 65 years of age, and £35 per annum to pensioners 65 years of age and upwards.

ABSTRACT OF RULES IN REFERENCE TO VOTES AT THE ELECTIONS OF ANNUITANTS.

Annual Subscribers of—Half-a-crown are entitled at each election of Annuitants to ONE Vote.
Five Shillings ... ... TWO Votes.
Half-a-guinea ... ... FIVE Votes.
One Guinea ... ... TEN Votes.
And to increase in the same proportion.
Five Guineas are entitled to ... ... FIVE Votes for life.
Ten Guineas ... ... TEN Votes for life.
And to increase in the same proportion.

Should any Subscriber or Donor, or the widow of any Subscriber or Donor, become a Candidate for an annuity, such number of votes shall be placed to his or her credit, at the first succeeding election, as shall be represented by the whole amount of subscriptions or donations to the Benevolent Fund he or she (or, in the case of a widow, her husband) may have contributed.

Cheques and post office orders to be made payable to Elias Bremridge.

FORM OF BEQUEST TO THE BENEVOLENT FUND.

"*I give and bequeath the sum of* *unto the* Pharmaceutical Society of Great Britain, *the same to be paid out of my pure personal estate, and to be applied for the purposes of the* Benevolent Fund *of the said Society.*"

N.B.—Devises of land and bequests of money savouring of realty, or, in other words connected in any way with land, will be void.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 623.)

ELATERINUM, U.S.P.—The unequal strength of commercial elaterium led some years ago to the introduction of a standard dilution of the active principle, elaterin, which was subsequently adopted in the public hospitals of New York under the name of "lactosum elaterini." The strength of this was one part in 100, and the dose about 10 grains (*New Remedies*, Jan., 1883, p. 28). The "trituratio elaterini" is the only preparation now official, and although the dose is not mentioned, it is probably understood to be one grain, since it is ten times the strength of the lactosum. Although a more convenient preparation, inasmuch as the bulk of the powder is smaller, the thoughtless substitution of the one preparation for the other in dispensing might lead to dangerous results. The lactosum will therefore now probably drop out of use in view of this possible risk. The non-precipitation of elaterin by tannic acid, salts of mercury and platinum is given as a test for the absence of, and difference from, alkaloids.

ERYTHROXYLON, U.S.P.—The consistence of the leaf is not mentioned. The "curved line running from base to apex" of the leaf, and formed by the vernation of the leaf is not always discernible, nor, at least as met with in this country, would the leaf be called somewhat aromatic and bitter.

EUCALYPTUS GLOBULUS, U.S.P. — The leaves should be "lanceolately scythe-shaped, 6 to 12 inches long, and "collected from rather old trees."

EUONYMUS, U.S.P.—Removed from the secondary list, probably in consequence of the discovery of the cholagogue property of euonymin by Rutherford. An alcoholic extract is the only preparation. It is probably intended to be the official representative of "euonymin."

FARFARÆ FOLIA, P.G.—The date for collection (May), and the warning against confounding the leaves of *Petasites officinalis*, Mœnch, and *P. tomentosus*, with those of coltsfoot, are now omitted; and the measurement of the leaf is given as being frequently a decimetre in length and breadth.

FEL BOVIS, U.S.P.—The sp. gr. should be 1·018 to 1·028. It is to be evaporated at a temperature of 176° F., to form *Fel Bovis Inspissatum*.

The mode of preparation of *Fel Bovis Purificatum* differs from that adopted in the B.P. in the use of only 1 part of alcohol to 3 parts of fresh ox-gall, and in the mixture being allowed to stand for twenty-four hours before evaporation.

FŒNICULUM, U.S.P.; FRUCTUS FŒNICULI, P.G.—The U.S.P. now mentions *F. vulgare*, Gærtn., and the P.G. *F. capillaceum* as the official source of the fruit. The U.S.P. permits the use of seed from 4 to 8 millimetres long, and by this measurement, as well as by simply stating "odour and taste aromatic, anise-like," without mentioning sweetness, it evidently allows the use of different varieties. The P.G. now requires fennel fruit to be 8 millimetres long and 3 broad, and to have a sweet taste, indicating probably the Maltese rather than the German fennel.

FRANGULA, U.S.P.; CORTEX FRANGULÆ, P.G.—The U.S.P. directs that the bark should be collected at least one year before being used. The P.G. does not make any such provision, although it was stated several years ago by Fristedt that the fresh bark produces colic and vomiting; and by Lamm that it is less active as an aperient than after it has been kept for a year or more (*Pharm. Journ.*, [3], vii., 102), owing possibly to changes taking place in the bark, when kept, which cause the formation of emodin, and possibly other substances (*Pharm. Journ.*, [3], vii., 616). The thickness of the bark is limited in the U.S.P. to 1 millimetre, and in the P.G. to 1½ millimetre, probably to prevent the use of the thicker stem bark, which, according to Baildon, gives a nauseous decoction (*Pharm. Journ.*, [3], iv., 889).

FUNGUS CHIRURGORUM, P.G.—This name replaces that of *Fungus igniarius præparatus*. As there is a *Polyporus igniarius*, Fr., as well as a *Polyporus fomentarius*, Fr., and the latter only is official, it is well that the name of *Fungus igniarius* is dropped. It should consist, as seen under the microscope, only of filiform cells and should quickly absorb twice its weight of water, which when expressed from it and evaporated should leave but very little residue. Amadou impregnated with nitrate of potassium or other salts is to be rejected.

GALBANUM, U.S.P. and P.G.—In the U.S.P. *Ferula galbaniflua*, Boiss. et Buhse, is alone given as the source of the drug. In the P.G. both *Ferula galbaniflua* and *F. rubricaulis* are mentioned. The U.S.P. remarks that when moistened with alcohol galbanum acquires a purple colour on the addition of a little hydrochloric acid. The P.G. states that hydrochloric acid which has been poured on galbanum becomes of a fine red colour in the course of an hour, which, on the gradual addition of spirit, if heated to 60°, becomes of an intense violet colour.

GALLÆ, U.S.P.; GALLÆ, P.G.—In the P.G. the tree yielding the official galls is stated to be *Quercus Lusitanica;* and in the U.S.P. *Q. Lusitanica*, Webb, *var. infectoria*, D.C. In the former the limit of diameter of the official galls is given as ¾ inch, and in the latter as 25 millimetres, thus excluding the large Algerian and Bussorah and other galls. The U.S.P. directs that light, spongy and whitish nutgalls should be rejected.

GELSEMIUM, U.S.P.—The rhizome and rootlets are now official. This description is more suitable to the commercial article, which usually consists in larger proportion of the rhizome. It is rarely seen in this country of the size mentioned, viz., "occasionally an inch and a quarter thick."

GENTIAN, U.S.P.; RADIX GENTIANÆ, P.G.—In the P.G. the other official species besides *G. lutea* are now mentioned. These are *G. Pannonica*, *G. purpurea*, and *G. punctata*, the roots of which are said to be more slender than that of *G. lutea*, the size of which is given as longer than 6 decimetres, and about 4 centimetres thick in the upper portion. Gentian roots should not contain starch. The roots are more correctly described than in the B.P., as transversely annulate in *the upper portion*.

GERANIUM, U.S.P.—A description of the rhizome of *G. maculatum* is now given.

GLYCYRRHIZA, U.S.P.; RADIX LIQUIRITIÆ, P.G.—The root of *G. glabra*, L., only is official in the U.S.P. "The underground stem, which is often present, has the same appearance, but contains a thin pith." In the P.G. the stolons, which have "the pith a little darker, often angular, and the cambial ring distinctly marked," are official; but both roots and stolons of Russian liquorice (*Radix Liquiritiæ mundata*) are official, and should be derived from "*Glycyrrhiza glabra* (*Glycyrrhiza glandulifera*)."

Gossypium, U.S.P.; Gossypium depuratum, P.G. —Absorbent cotton is now official. When thrown upon water it should immediately absorb the latter and sink (U.S.P.), and the water should not acquire either an acid or an alkaline reaction. On combustion it should not leave more than 0·8 (0·6 to 0·8 P.G.) per cent of ash.

Granatum, U.S.P.; Cortex Granati, P.G.—In the U.S.P. the root bark only, but in the P.G. the bark of the stem as well as that of the root is official. Under these circumstances there seems no necessity for giving in the latter the names of lichens found on pomegranate stem bark as a means of distinguishing it from that of the root, especially as *Arthonea astroidea* and *A. punctiformis* are by no means confined to the pomegranate. The stem and root bark almost always occur mixed in commerce, and as they both possess the same properties, and are not easily separated, the recognition of the fact in the P.G. is an advantage.

Grindelia, U.S.P.—The description is sufficiently indefinite to allow the use of *G. squarrosa*, although *G. robusta* is the only official species.

Guaiaci lignum, U.S.P.—The heartwood of *G. sanctum* is now official in addition to that of *G. officinale*, although "guiaci resina" is to be obtained only from the last-named species. Guaiacum wood should be a greenish-brown, containing few particles of a whitish colour, and should acquire a dark blue-green colour on the addition of nitric acid. The water test to ascertain how much alburnum is present is not given.

Hamamelis, U.S.P.—The leaves collected in autumn are official for the preparation of a fluid extract. This will hardly replace the preparations in common use, which are mostly distilled, and appear to contain comparatively little extractive matter.

Humulus, U.S.P.—The strobiles should be about 1¼ in. long, and the scales of a greenish colour.

Hyoscyamus, U.S.P.; Herba Hyoscyami, P.G. —In the U.S.P. the leaves collected from plants of the second year's growth are now official. No test for distinguishing the leaves from those of the first year's growth is given, the size of the leaf, "sometimes ten inches long and four broad," being a not uncommon size for the autumn leaves of the first year's growth of the biennial plant. This character would be almost useless as applied to the broken-up leaves met with in commerce. There are, however, good tests for distinguishing the annual from the biennial plant. See *Pharm. Journ.*, [3], i., 907, 921; and [2], xi., 134. In the P.G. the leaves and flowering stalks are official, the limit of size of the basal leaves being given as 3 decimetres long and 1 broad. The maximum dose of the leaves is 0·3 gram.

Icthyocolla, U.S.P.—The solution in 24 parts of boiling water should form on cooling a transparent jelly.

Illicium, U.S.P.—A warning is given against the use of the very similar but poisonous fruit of *Illicium religiosum*, Siebold. These are to be distinguished by the more woody shrivelled carpels, having a thin, mostly curved beak, a faint clove-like odour, and an unpleasant taste.

Inula, U.S.P.; Radix Helenii, P.G.—The root is official in the U.S.P. in the form of transverse, concave slices or longitudinal sections, and in the P.G. the rhizome and branches of the root. The P.G. observes that *Radix Helenii* does not contain starch, without alluding to its being replaced by inulin. The directions for time of collection are now omitted.

Ipecacuanha, U.S.P.; Radix Ipecacuanhæ, P.G. —The P.G. mentions *Psychotria Ipecacuanha* (*Cephaëlis Ipecacuanha*) as the source of the drug. The aqueous infusion of the root should give a copious amorphous white precipitate with solution of iodohydrargyrate of potassium. Iodine water should give a blue colour to a filtered solution, made by agitating 0·2 gram of the root with 10 grams of hydrochloric acid, and with chloride of lime a colour described as "igneum." Mr. L. R. Power has mentioned (*Pharm. Journ.*, [3], viii., p. 344) as a distinctive test for emetine the production of a *bright orange* or *lemon yellow* colour with chloride of lime, most other alkaloids being found to assume a reddish coloration with the same reagent. It would have been an improvement if directions had been given for using a weighed quantity of the bark separated from the root by bruising it, the stem, which has a very thin bark, being often present in considerable quantity in the commercial article, whereby considerable variation is liable to occur inthe official preparation.

Iridis Rhizoma, P.G., may now be obtained from *Iris Germanica* and *I. pallida*, as well as *I. Florentina*.

Iris versicolor, U.S.P.—Retained from the secondary list; it is official in the preparation of an alcoholic extract and fluid extract, the former of which would appear to be the official representative of irisin or iridin. The activity and acridity are said to be impaired by age (U.S. Dispens., 14th ed., p. 520); but the U.S.P. does not impose any limit as to the age of the root. A description of the root is given in the U.S.P., but is not sufficiently definite to distinguish the rhizome from that of other species which, in this country at least, are sometimes substituted for it.

Jaborandi Folia, P.G.—The leaves should be the produce of *Pilocarpus pennatifolius*, and their size is given as 16 centimetres long by 4 to 7 broad. In the drug market there are two varieties of jaborandi, one of which contains more alkaloid than the other, and is distinguishable by the greater prominence of the veinlets on the upper surface of the leaf, and its firmer consistence, features which may be worthy of notice in future Pharmacopœias.

Jalapa, U.S.P.; Tubera Jalapæ, P.G.—The name *Ipomœa purga* is now adopted by the P.G. while that of *Exogonium purga*, Benth., is retained by the U.S.P. According to the latter 100 parts of jalap should yield not less than 12 parts of resin, of which not over 10 per cent. should be soluble in ether. The P.G. directs that jalap should yield not less than 10 per cent. of resin, easily soluble in spirit, but not in bisulphide of carbon; also that the resin should be soluble in 5 parts of warm solution of caustic ammonia, forming a solution which should not gelatinize on cooling and should remain clear when supersaturated with acid, the residue of the liquid when evaporated being soluble in water.

Juglans, U.S.P.—The bark of *Juglans cinerea*, L. (butternut), should now be collected in autumn, and should be free from soft cork.

Juglandis Folia, P.G.—The leaves of *Juglans regia* (walnut). The date of collection (June) is now omitted; the leaves should not be of a blackish colour.

Kamala, U.S.P., P.G.—The U.S.P. defines this drug as consisting of the glands and hairs from the capsules of *Mallotus Philippinensis*, but the P.G. evidently holds that the powder cannot properly be placed under "Glandulæ" with lupulin, since it is given under the name of "Kamala," and is described as "indumentum fructuum." The U.S.P. gives the percentage of ash as not more than 8 per cent.; the P.G. as not more than 6 per cent. The pure drug, according to 'Pharmacographia,' yields only about 1·37 per cent. of a grey ash. Kamala not unfrequently gives as much as 15 per cent. of ash and has been known to yield 50 per cent. A process directing its purification would therefore be an advantage.

Kino, U.S.P.—The official kino is now restricted to the inspissated juice of *Pterocarpus Marsupium*, Roxb. The inspissated juice of some species of *Eucalyptus* might perhaps yield a more satisfactory tincture (*Pharm. Journ.*, [3], ii., p. 102.

(*To be continued.*)

VEGETABLE ALKALOIDS, AND THE METHODS FOR THEIR SEPARATION.*

BY MATTHEW HAY, M.D., DEMONSTRATOR OF MATERIA MEDICA, UNIVERSITY OF EDINBURGH.

Historical and Introductory.—The alkaloids are among the most important of all the substances of the materia medica, either from a pharmaceutical or from a therapeutical aspect, for it is to their presence that a very large number, and, in many instances, the most valuable, of the natural organic drugs owe their remedial activity. That many plants possessed a highly poisonous action, and that this action when moderated might be utilized in the treatment of disease, has been known from time immemorial; but that the activity of the plant was in the majority of cases confined, and in a highly concentrated form, to a separable alkaloidal constituent of the plant, was not anticipated until shortly after the beginning of the present century, when Sertürner, Derosne and Seguin, working each apart from the other, shared the honour of preparing in a tolerably pure state the main active principle of opium, and to which the name of morphium (Gr. μορφή, *form*,—on account of its crystalline form) was given by Sertürner. Sertürner was an apothecary of Hamelin, and Derosne an apothecary of Paris. It was the former who first clearly recognized the basic or alkaline qualities of the newly found active principle; but, although he observed in his first communication, published in 1806, that the morphium possessed an alkaline reaction, yet it was not until eleven years later, in his classic work, 'Ueber das Morphium, eine neue salzfähige Grundlage, und das Mekonsäure, als Hauptbestandtheile des Opiums," that he could write with perfect confidence as to the morphium possessing the character of a base. For his further examination of it had shown that in addition to possessing a well-marked alkaline reaction it was capable of uniting with acids to form salts. He even hazarded the opinion that in many respects it was closely related to ammonia, an opinion the correctness of which has since been amply verified, not only for morphia but for all other alkaloids.

The discovery of morphia, and the observation that it possessed the action of opium in a highly concentrated form, most naturally suggested to the minds of chemists and physicians the probability of other vegetable drugs besides opium containing an alkaloidal principle, to whose presence the activity of the drug was to be ascribed. The better known of the toxic and medicinal plants were accordingly, one after another, submitted to chemical analysis, and not without much persevering and ingenious labour were their active principles brought to light. The discovery of strychnine, brucine, quinine and cinchonine by Pelletier and his associate Caventou, of narcotine and codeine by Robiquet, of veratrine by Meissner, of caffeine by Runge, of coniine by Giesecke, of atropine by Mein, of nicotine by Reimann and Posselt, and of aconitine and hyoscyamine by Geiger and Hesse, and of several other less important alkaloids, followed in rapid succession within the sixteen years subsequent to the publication of Sertürner's completed work. Since then, almost every year has furnished its quota of separated alkaloids until at the present day their number is beyond being readily computed, and the chemistry of the alkaloids now claims for itself almost a special department in the broad and ever extending domain of organic chemistry. But, numerous as are the alkaloids which have already been separated and the plants that have been analysed for their presence, there yet remain many plants of considerable toxic activity, and presumably of some medicinal value, whose active principles have not yet been determined. Travellers and explorers, but more particularly our colonists, are bringing year after year such plants to our knowledge. And not only in newly discovered drugs is there much room for future chemical research, but even in the very drugs which have been longest known and are most used the labours of the chemist in his search for their active principles have not yet been brought to a close. For earlier investigators have sometimes failed to separate the principles in a perfectly pure state, or in certain cases to recognize that the product obtained was a mixture of various alkaloids, necessitating the separation of the one alkaloid from the other; and in other cases the drug is so rich in alkaloids, as, for example, opium, that chemists are by no means certain, when now and again we hear of the discovery of an additional alkaloid, that all the alkaloids which the drug actually contains have as yet been recognized and separated. It is not by any means Utopian to expect that the time is not far distant when our present organic materia medica, in so far as it consists of substances of highly complex and of very variable and in some instances of unknown composition, will give place to bodies with constant characters and a definite chemical constitution, the nature and extent of whose activity is to be relied upon with the greatest exactitude. We all of us can do a little to help towards the attainment of this most desirable end; and it is because I think that all of you, as chemists, would find it both pleasurable and profitable to be engaged in so laudable a work, that I have chosen in quite a general manner to place before you, for the instruction more particularly of the younger members of your Society, an outline of the processes most commonly employed for the separation of these basic bodies which are destined to occupy a very important position in a pure organic materia medica such as I speak of. This instruction might have been unnecessary, were a description of such methods to be obtained from any of our ordinary text-books, or from other readily accessible works; indeed they are in great part to be met with only in original and separate memoirs.

The method used for the separation of each alkaloid, it is true, is fully stated in most works on materia medica; but the operations required in the one case differ so widely in appearance from those required in the next, that, in the event of your meditating the separation of an unknown alkaloid you are quite at a loss which of the various methods to adopt; and the probability is, even did you select one of the methods given, that it is so specially adapted for the particular alkaloid which it is designed to separate that it may absolutely fail when applied to the drug you are investigating. And here lies the difficulty in the task I have assigned to myself. For to provide you with a method, or methods, absolutely comprehensive in application, is, and probably always will be, practically an impossibility. Some alkaloids are so erratic in their chemical deportment that specially devised methods are

---

* Read by request before the North British Branch of the Pharmaceutical Society, Feb. 15, 1883.

necessary for their separation. I have not, however, permitted this consideration to deter me from presenting to you the principles which in all cases should guide us, and from detailing a few of the methods of most general application, in the search for an unknown alkaloid.

CHARACTERS OF ALKALOIDS.—In order that we may clearly understand these general principles and the methods based on them, it is necessary that we first consider the characters of the alkaloids. They are all of them nitrogenous organic bases; and, although the name "alkaloid" is usually applied only to such bases obtainable from plants, yet they do not differ materially from other nitrogenous organic bases which have been artificially prepared in large number during recent years, as ethylamine, aniline, pyridine and picoline; nor from the similarly constituted bodies which are met with in animals, as choline and kreatine, and the recently discovered bases of dead bodies, the so-called ptomaines. Until lately, one distinction between the artificial bases and the natural bases or alkaloids was, that the latter, in addition to possessing a more powerful and more subtle physiological action, were incapable of being prepared artificially. This distinction has failed us since Hugo Schiff, in 1870, prepared coniine synthetically from butylaldehyde, and Schmiedeberg and Harnack, six years later, obtained muscarine by the oxidation of hydroxylentrimethylammonium (neurine), and Ladenburg has all but accomplished the synthesis of atropine. The alkaloids are not, therefore, to be chemically distinguished from other nitrogenous organic bases, although the exact constitution or intra-molecular arrangement is known for only a very few of them. Much work has been done in order to determine the constitution of alkaloids, and the conclusions arrived at all agree in this, that the alkaloids are to be regarded as substitution or other products of ammonia. For our present purpose it is unnecessary to consider more fully their constitution, except to remind you of the elementary fact that, whilst the alkaloids, as a rule, contain oxygen in addition to carbon, hydrogen and nitrogen, yet a very few of them are non-oxygenated. With the exception of the latter, which, until recently, were only three in number, namely, coniine, nicotine and sparteine, but whose number has been extended to four by the discovery of piturine, all the known alkaloids are solid, and, unless under special circumstances, non-volatile bodies. The oxygen-free alkaloids are, on the other hand, volatile liquids, a character, which by enabling us to adopt the method of distillation, renders their separation a matter of easy accomplishment. The solid alkaloids are generally colourless, odourless, bitter to the taste, and, in most cases, crystallizable.

Solvents.—A knowledge of their relation to solvents is of the greatest importance in their separation. With a few exceptions (colchicine, curarine), they are either insoluble or difficultly soluble in water. In alcohol they are almost without exception, and, in most cases, tolerably freely, soluble. Ether is for many alkaloids the most active solvent we possess, but there are others which it hardly at all acts on (cinchonine, morphine, strychnine). Amylic alcohol is a very general and very capable solvent, and so also are chloroform, benzol, acetic ether and petroleum ether, although there are a very few alkaloids which are not acted on by these solvents. In fatty oils they are soluble only to a very small extent, but with the help of oleic acid they can be mixed in nearly every proportion with oils, a fact of pharmaceutical value. The solutions of the alkaloids in the various menstrua have generally a strong alkaline reaction, but in certain cases (*e. g.*, colchicine, narcotine), the reaction is extremely feeble.

Chemical relations.—Besides the action of solvents on the alkaloids, it is not of less importance, before we proceed to undertake the separation of an alkaloid, to know something of the chemical relations of the alkaloids, and more particularly of their behaviour towards acids. They comport themselves very like ammonia in most of their combinations with acids, for being bases they readily unite with acids to form salts; but, unlike ammonia, do not, as a rule, form salts with carbonic acid. If an alkaline carbonate be added to a solution of the salt of an alkaloid, the alkaloid is liberated, and carbonic acid evolved. This fact is of importance, because it enables us, when we so desire it, to set free the alkaloids by means of an alkaline carbonate, instead of employing the alkali itself, which, as in the case of atropia, may decompose the liberated base.

The salts formed with the mineral acids, as with sulphuric, hydrochloric, and nitric acids, and with the more simple of the organic acids, as acetic, tartaric, citric, oxalic, and malic acids, are highly crystalline, and are, as a rule, freely soluble in water, and still more soluble in alcohol. On the contrary, in ether, acetic ether, chloroform, amyl alcohol, benzol, and petroleum ether, they are, for the most part, completely, or almost completely insoluble. In those cases where the alkaloid *e. g.*, quinine) unites with the acid in more than one proportion, the salt containing the highest proportion of acid is, as a rule, much the most soluble. Ammonia and the alkaline bases and the alkaline earths liberate the alkaloid from its combinations with acids, and the alkaloid, if insoluble in water, is precipitated; but this precipitation may be prevented if excess of the alkali be used, as several of the alkaloids (*e. g.*, morphine) are soluble in excess of alkali, whilst all of them, with only one or two exceptions, are soluble in excess of ammonia.

It is of great service in the separation of the alkaloids that they practically, without exception, form insoluble salts with tannic acid, picric acid, the double iodide of potassium and mercury, the double iodide of potassium and cadmium, the double iodide of potassium and bismuth, iodine dissolved in iodide of potassium or in alcohol, phospho-molybdic acid, metawolframic acid, phospho-wolframic acid, and with a mixture of chloride of antimony and phosphoric acid. Further, with the double cyanide of potassium and platinum, with the chlorides of gold, platinum, iridium, palladium, and mercury, and with nitro-prusside of sodium, nearly all the alkaloids form more or less insoluble salts.

Decomposition.—It is important also to remember that the alkaloids are not as a rule very stable bodies, so that when exposed in solution to the sunlight many of them undergo gradual decomposition. Similar and other decompositions of alkaloids are more readily effected if a solution of an alkaloid is boiled for some time or is kept for too long a period at a high temperature, as is apt to occur whilst evaporating the various extracts in the processes sometimes employed for the separation of the alkaloid. Decomposition is still more liable to occur if the alkaloid be heated along with dilute mineral acids, as with hydrochloric acid; and in some instances the decomposition results in the formation of a new alkaloid more or less different in its properties and action from the original alkaloid. Solanidine is such a decomposition product of solanine, ecgonine of cocaine, tropine of atropine or hyoscyamine. In the presence of nitric acid decomposition usually occurs to a still greater extent, resulting often in the formation of reddish resinoid substances. The oxidizing action of nitric acid may exhibit itself in the production of well-characterized oxidation bodies, as cinchonic acid from cinchonine, and nicotic acid from nicotine.

Similarly, if a solution of an alkaloid be heated for some time in the presence of an alkali, the alkaloid is apt to undergo decomposition, forming in many cases methyl-, dimethyl-, and trimethylamine, and bases belonging to the pyridine and chinoline series. A few alkaloids, as atropine, are very readily decomposed in contact with alkalies even without the application of heat, so that in the course of their separation the use of free alkali, and, especially, prolonged contact of the alkaloid with the alkali, is as far as possible to be avoided.

(To be continued.)

The Pharmaceutical Journal.

SATURDAY, MARCH 3, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACY ACTS AMENDMENT BILL.

THE copious correspondence which we publish this week, on the subject of the Pharmacy Acts Amendment Bill, may fairly be taken as evidence of wholesome interest in the work that has so long engaged the attention of the Society's Council, and the discussions that have taken place at the several meetings reported in the present number also point in the same direction. It would perhaps be expecting too much if we sought in the various comments on the Bill for unqualified and general concurrence with all its details, and, highly as we estimate the importance of eventual agreement as to the fitness of any measure of this kind, we cannot ignore the probability of adverse opinions being formed at the outset in regard to some of the provisions contained in the Bill. The state of pharmacy in this country is still so far from being perfect, and the conditions under which the trade bearing that designation is carried on are so diverse, that these circumstances alone would insure difference of opinion as to details, and if such difference were not expressed the fact would only be indicative of an apathetic feeling in regard to the interests of the business which would be far more deplorable.

But after considering the various criticisms passed on certain clauses of the Bill there seem to be scarcely any which are radically antagonistic to the measure as a whole, while many of the objections that are apparently most cogent rest on misconception of the objects and intentions of its framers or upon misinterpretation of the scope and bearing of particular clauses. Under these circumstances, therefore, we may reasonably anticipate that when these misconceptions are corrected, and when the contemplated operation of the Bill shall be more thoroughly appreciated, there will be a very general concurrence of opinion that, if it does not secure all that might be desired, it is at least a measure which adapts itself to existing conditions, and provides as far as practicable for that advancement of pharmacy which it has always been the aim of the Pharmaceutical Society to promote.

It would be impossible within the limits of a single article to deal with all the points referred to in the discussion of the Bill by our correspondents, and we shall, therefore, on the present occasion confine our remarks to some general considerations respecting the circumstances which gave rise to the drawing up of the Bill, the extent to which there is a probability of obtaining an amendment of the law relating to pharmacy, and the expediency of conceding individual opinion for the sake of obtaining some modicum of improvement in the present position of affairs.

In the first place we will refer to the objections which have been raised to clause 2, objections which have found expression not only from members of the trade but also from some of those who took part in the framing of the Bill. It will be in the recollection of our readers that some months ago the Council of the Society submitted to the Privy Council a recommendation that certain articles should be added to the schedule of poisons and sold only in conformity with the provisions of the existing Act as regards the sale of poisons. It will also be remembered that the Privy Council refused to endorse this recommendation and that as a result of subsequent communications upon the subject the Council of the Society was requested to prepare and submit a Draft Bill for the amendment of the Pharmacy Acts. This request, while furnishing an opportunity for seeking that amendment of the law which has been so long felt necessary, was, however, associated with the proviso that the Council should, in the interests of the public, devise safeguards applicable to the sale of certain articles without interference with general trade, such as it was considered by the Privy Council would result from the addition of those articles to the Poison Schedule of the existing Act. It was simply upon this point and the restriction of sales of patent medicines containing poison that the Privy Council insisted. It was only in this light, and to this extent, that amendment of the Pharmacy Act presented itself to the consideration of the Privy Council as being desirable, and the Council of the Society, in availing itself of this opportunity for introducing a Bill for the general amendment of the law, was constrained to acquiesce in the conditions thus laid down. It will be seen, therefore, that the requirements on the part of the Government in regard to this matter were precisely such as Mr. HARRISON said he would submit to, when he moved, at the Meeting of the Executive Committee of the Trade Association, that clause 2 should be expunged from the Bill, and we venture to think that this position of the matter might have been perceived if the antecedent circumstances and the previous action of the Council of the Society had been duly considered.

It follows, therefore, from what we have above stated that any objection to clause 2 based upon the assumption that its provisions were independently originated by the Council of the Society falls to the ground, and that this clause must be regarded with tolerance, if not with entire approval, as being the pathway by which the entire Bill was to find its way into the Legislature and furnish opportunity for removing more serious difficulties.

Having so far given an explanation of the *raison d'être* of clause 2 of the Bill, let us consider the objection that its provisions involve a breach of the principle laid down in the preamble of the Pharmacy Act, and upon which the Society has always acted since its origin. With all respect to those who hold this opinion, we look upon the objection to clause 2 on this ground as having a merely sentimental foundation. The principle recited in the preamble to the Pharmacy Act is a good and laudable one, and from the point of view of the Council of the Pharmaceutical Society it—and the means by which it is to be maintained—cannot be too constantly borne in mind; but it would be quixotic to endeavour to enforce that principle at the present time by legislative enactments interfering with general trade and with the convenience of the public, which will certainly be considered by the public itself quite as much as the Legislature will be disposed to consider its safety. We have here practical limitations beyond which it would be imprudent to attempt to enforce consideration for the sound principles of the Pharmaceutical Society.

But we will even go further than this and deal with the precise details to which the provisions of clause 2 relate. We contend that the sale of such articles as are referred to in that clause do not constitute a part of the true business of pharmacy, regarded from that abstract point of view from which it is fitting the Council of the Pharmaceutical Society should regard it. From that point of view it is not admissible that consideration for the safety of the public should be made use of as a pretext for seeking to obtain trade monopoly, and if it be insisted upon at all, as within the province of the Council representing the Society, it must be only for the purpose of imposing such restriction upon general trade as may be evidently conducive to that end. It is, we think, a total mistake to take exception to clause 2 as involving a departure from what we may call the fundamental principle of the Society. The trade in the articles referred to in clause 2 is not to be conceded to persons outside the pharmaceutical body, for they already possess the right to it, and the provisions of the clause simply limit the exercise of that right by imposing restrictions as to the future, which are all that the Government is disposed to sanction.

When the clause of the Bill now referred to is considered in this light, and with regard to the circumstances under which the Bill was proposed, there will be, we think, a great modification of the adverse opinions that have been expressed, and it must moreover be remembered that continued opposition to it might have the effect of seriously damaging the prospect of amending the Pharmacy Act altogether. If it should appear that dissension prevails within the body which seeks to obtain amended legislation, there would be the danger that the Government might confine its attention solely to that portion of the Bill which is considered to affect the interests of the general public and abandon those parts which are more essential to the pharmaceutical body as a bone of contention to be disputed over at its leisure. We trust that no such contingency is in store for the proposed Bill, but that, in accordance with the wishes expressed by many of our correspondents, its really important recommendations as a means of promoting the advance of pharmacy will be recognized so far as to ensure its being passed with the general conviction that it will do something in that direction, if not all that might be desired.

THE VALUE OF ANALYTICAL RESULTS AS INDICATIVE OF THE QUALITY OF POTABLE WATER.

From the very important annual report presented by Dr. Buchanan as Medical Officer to the Local Government Board, which has been issued within the last few days, it appears that among the auxiliary scientific investigations that have been carried on under the superintendence of the Medical Department, is one that was prompted by the observation that on many occasions sanitary authorities and their advisers had shown a tendency to estimate unduly the value of chemical analysis as a means of demonstrating the wholesomeness of drinking waters. The investigation, which was conducted by Dr. Cory, whose report is printed *in extenso* in an an appendix, had for its main object therefore to test the nature of the evidence derivable from chemical analysis, by adding various polluting matters, to a series of samples of known waters and submitting them, together with samples of the original waters, to experts for chemical examination. In a large number of the experiments the polluting material used consisted of the stools of enteric fever patients, this disease having manifested a special faculty of spreading by means of drinking water, and Dr. Buchanan selects these for the purposes of his report as conveniently showing some of the results obtained in the investigation. In the first place, as might have been expected, it was found that the customary methods of chemical analysis do not furnish any evidence to distinguish enteric fever pollution from any other form of excremental pollution, and, indeed, up to the present time chemistry fails to give any indication which will help in deciding whether such pollutions have had their source in a healthy or a diseased body. This remark applies equally to the permanganate test, and the "albumenoid ammonia" and the "combustion" processes, all of which were used. But Dr. Buchanan restricts his comments to the results obtained by the "process which is most "popularly trusted for the recognition of animal "impurity, the amount of albumenoid ammonia "yielded by the water." A water was purposely polluted with enteric fever stool in the proportion of one grain to a gallon, and after the coarser particles had been allowed to deposit, the water was decanted and sent to Dr. DUPRÉ for analysis. Dr. DUPRÉ'S analyses showed that the resulting increment of albumenoid ammonia amounted in an average of experiments to only one-thousandth part of a grain in a gallon, or fourteen thousandths of a part per million parts. Another sample of water was purposely polluted with 3·5 grains of fever stool to the gallon and sent, with a sample of the original water, to Mr. WANKLYN, who found the yield of albumenoid ammonia to have been increased in the proportion of twenty thousandths of a part per million parts for the entire 3·5 grains, or fifty-seven ten thousandths of a part per million parts for each grain of the contaminating stool added to the gallon of water.

Of course some scepticism may be felt as to the possible influence of so minute a contamination as one grain in a gallon of water, and Dr. BUCHANAN quotes, as bearing upon this point, some figures, which though evidently liable to be affected in their meaning by many possible contingencies, have a certain value in the absence of more precise data. In an outbreak of enteric fever at Caterham, in the year 1880, nearly two hundred of the earlier attacks were traced to the use, during a fortnight, of water that had been pumped from a well in which a man had been at work while suffering from enteric fever. During this particular fortnight as much as 1,861,000 gallons of water was pumped from the well, and to have infected this quantity of water to the extent of one grain per gallon would have required the addition of 19 lbs. of excremental matter to each day's supply. Of course under the conditions stated this would have been impossible, while on the other hand, it would not follow, and indeed it is not likely, that the pollution was equally diffused throughout the whole of the water. But Dr. BUCHANAN considers the evidence is sufficient to show that one grain in the gallon is a very large amount of polluting matter to be present in a gallon of water, and one that is not likely to have been exceeded in the particular samples of Caterham water that did actually produce disease in the individuals who drank it. Since, therefore, the chemical evidence of this dangerous proportion of pollution is expressed in terms of albumenoid ammonia as low as ·014 part per million parts of water, Dr. BUCHANAN is of opinion that it is not permissible to accept the doctrines that have been formulated as to the significance of a particular amount of albumenoid ammonia present in an otherwise unknown water. With an evident reference to Mr. WANKLYN'S classification of waters, he remarks that polluting matter potent for harm might be present in a water "yielding from 0·0 up to 0·05 parts of albumenoid ammonia per million" without removing it from the rank of waters of "extraordinary organic purity;" and he denies that there is evidence that an unknown water showing from 0·05 to 0·10 parts of albumenoid ammonia per million may be assumed to be "safe organically."

The lesson which Dr. BUCHANAN believes to be taught afresh and significantly by this investigation is that whilst it is desirable to be ever on the watch for any indications that chemistry may afford of the access of contaminations to drinking waters, it is at present necessary to go beyond the laboratory for evidence that any water is free from dangerous organic pollution. In the words of Dr. BUCHANAN, "Unless the chemist is well acquainted with the "origin and liabilities of the water he is examining, "he is not justified in speaking of a water as 'safe' "or 'wholesome,' if it contains any trace whatever of "organic matter; hardly, indeed, even if it contain "absolutely none of such matter appreciable by his "very delicate methods. The chemist can, in brief, "tell us of impurity and hazard, but not of purity "and safety."

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, at half-past eight o'clock, when a paper will be read, on "Uranium Oleate," by Mr. Walter Gibbons, and another on "Liquid Extract of Cinchona, with Data illustrating the Results obtained in its Preparation by the Process of the British Pharmacopœia," by Dr. B. H. Paul. There will also be a Note read descriptive of an important series of Cinchona specimens recently received by the Pharmaceutical Society from the Government Plantations, Jamaica.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Tuesday, the 6th inst., when a paper on "Photography" will be read by Mr. C. F. Wyatt.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, March 8, at 8.30 p.m., when a "Note on Dried Alum" will be read by Mr. E. Baily, and a Report on "Two New Methods for the Separation of Cadmium and Copper" will be made by Mr. C. Thompson. There will also be a Report upon "Inorganic Chemistry," made by Mr. F. W. Short.

* * *

At a meeting of the House Committee and Medical Council of the London Hospital last week a resolution was passed declaring that it was expedient that a suitable resident college for students should be established in connection with the hospital, and a Committee was appointed to consider and report on the best method for giving effect to the resolution.

* * *

Arkansas is now to add another to the numerous organizations of pharmacists already in existence in the United States. At a recent meeting it was decided to form a pharmaceutical association for the State, the head quarters being fixed at Little Rock.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

February 21, 22 *and* 23, 1883.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

MAJOR EXAMINATION.

21*st.*—*Three* candidates were examined. *One* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Ball, Henry ....Southport.
Dangerfield, William Henry ...Devizes.

22*nd.*—*Four* candidates were examined. *Three* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Deeks, William Thomas ....Shanklin.

23*rd.*—*Four* candidates were examined. *Two* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Prosser, Frank Henry ....Birmingham.
Wilson, Joseph.....................Chislehurst.

MINOR EXAMINATION.

21*st.*—*Twenty-nine* candidates were examined. *Twenty two* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barlow, Arthur.....................Hull.
Boyden, John Augustus C.......Wisbeach.
Caffyn, Ernest John ....Crawley.
Capper, Fred. William Noad ...Tetbury.
Ensor, John Thomas ....Birmingham.
Foster, Henry Simpson ....Rotherham.
Gill, Reginald ....Yeovil.

22*nd.*—*Twenty-seven* candidates were examined. *Nineteen* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Davies, William ....Newcastle Emlyn.
Hadfield, James Havelock......Manchester.
Heyes, Thomas Harry............Bolton.
Laverty, Joshua ... .Jersey.
Lockyer, Joseph Ernest ....Deptford.
Marten, John Reed ....Brighton.
Mason, Hubert Huxley ....Clevedon.
Smith, Harry James ....Speenhamland.

23*rd.*—*Twenty-eight* candidates were examined. *Fifteen* failed. The undermentioned *thirteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Corder, Edward ....Norwich.
Passmore, Arthur Bradshaw ...Bristol.
Ranken, Charles ... .Sunderland.
Rees, David ....Newcastle Emlyn.
Robinson, Richard Fredk. Wm.Manchester.
Rye, Frank ....Northampton.
Sewell, Edward Ernest ....Whitby.
Stacey, Frederick Charles ......London.
Thomas, Daniel Griffith ....Cardigan.
Thompson, Frederic...............Scarborough.
Tilley, Joseph ....Chelmsford.
Wall, Edward John................Peckham.
Woolliscroft, Henry...............Wrexham.

PRELIMINARY EXAMINATION.

The following certificates were received in lieu of the Society's Preliminary examination:—

Certificate of the College of Preceptors.

Widgery, John.......................South Molton.

Certificates of the University of Cambridge.

Day, John Thomas ....London.
Griffith, Martin Luther ....Weston-super-Mare.
Harrison, George William ......Reading.
Payne, William ....Wendover.
Sloan, William G. ....Barking.
Spyer, George Nathan............London.
Thompson, Herbert ....Manchester.

Certificate of the University of Oxford.

Dorning, Herbert Rigby.........Chorley.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on February 19, 1883, at 12·45 p.m. Mr. Robert Hampson (London), President, in the chair. Mr. John Harrison (Sunderland), Vice-President.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Barclay (Birmingham), Bell (Hull), Churchill (Birmingham), Cross (Shrewsbury), Davis (Leamington), Jervis (Sheffield), Jones (Llanrwst), Laird (Edinburgh), Mason (Liverpool), Parker (Nottingham), Paterson (Aberdeen), and the Solicitor of the Association.

The minutes of the previous meeting of the Executive were read and confirmed.

The report of the Law and Parliamentary Committee was then read. The report stated that the Committee had considered the case of a member of the Association, residing at Longton, who had been summoned under the Sale of Food and Drugs Act for having sold lime water alleged to be not of the nature, substance, and quality of the article demanded by the purchaser. The Secretary had investigated the case on the spot and explained the means by which the lime water was made, and other facts incidental to the sale of the same. A sealed sample of the lime water left by the inspector with the defendant had been analysed by the Analytical Referee of the Association, who had reported that he found that 10 fluid ounces contained 2 grains of lime, whereas the same quantity of the official B.P. lime water should contain 5·6 grains of lime, and that he could not recommend defence. The Committee consequently decided not to defend. The Committee had authorized the Assistant Secretary to investigate several cases of illegal trading in poisonous sheep dips in Scotland when the sheep dipping season again commenced. The appointment of Local Secretaries in Scotland had been considered and postponed until the Committee of the Scotch Branch had made recommendations for those posts. The appointment of Local Secretaries for London had been relegated to the London Committee, the President and Mr. Andrews being empowered to take all necessary steps in the matter. The Committee had appointed the members who had been acting as correspondents to the Association in all towns in England and Wales containing six or more chemists, Local Secretaries of the Association. The Committee had considered the advisability of instituting proceedings under the 17th section of the Pharmacy Act against two companies registered under the Limited Liability Companies Acts, and the Assistant Secretary had made purchases of poisons for that purpose, but the Committee had decided to take no further action in the matter at that time. The Committee had passed the following resolution:—"That this Committee, on behalf of the Association, beg to express their deep regret at the loss they have sustained by the death of Mr. Stead, who was a firm supporter and friend of the Association; they likewise desire to record their sympathy with his bereaved family." A considerable amount of the business of the

Association had been conducted by the Sub-Committee appointed by the Law and Parliamentary Committee to deal with urgent cases. A report of the proceedings of that Committee stated that it had held five meetings. It had considered the case of a member of the Association, against whom an action had been brought by a farmer for having sold to him a certain sheep dipping composition, which it was alleged had caused the death of several of his sheep and serious injury to others. The solicitor had expressed as his opinion that the case appeared to raise a question between the two parties themselves, not affecting the trade generally; he considered that the defendant had grounds for defence, but that the Association would not be warranted in undertaking it. The Sub-Committee had consequently decided not to defend. The Sub-Committee had considered the case of a member of the Association against whom proceedings had been taken by the Inspector of Weights and Measures, he having had in his possession certain weights which were found to be below the standard. The defendant stated that the last occasion on which he had received notice to have his weights examined was some two years previous, when he sent them for adjustment; he was quite sure he had not since that time received any notice from the inspector to have his weights examined; had he received such a notice, he would have sent them as usual. It was customary in the locality in which he resided for the inspectors to give notice of their intention to examine weights. The Sub-Committee decided that a grant of a guinea should be made to meet the law costs of the case, in preference to expending a larger sum in ordering their solicitor to watch the case for the Association. The Sub-Committee had considered the case of a member of the Association, who was threatened with an action for damages for having unskilfully and improperly treated the finger of a child in June last, and decided that the solicitor should see the plaintiff's solicitors, make further inquiries in the matter and report to them in due course.

Mr. Paterson said that with reference to the case under the Weights and Measures Act, he thought chemists should see that their weights were examined; he did not think the inspector was bound to see that chemists sent their weights to be examined.

Mr. Barclay said that the inspector had previously given the member notice that on a certain day he, the inspector, would examine the weights of traders residing in the district. He thought it was economical as well as politic on the part of the Sub-Committee to vote a guinea to meet the member's defence, because had it not done so it would have instructed the solicitor to attend the hearing for the purpose of watching the case.

It was moved by Mr. Cross, seconded by Mr. Andrews, and unanimously resolved:—"That the report now read be received, adopted, and entered on the minutes."

The Executive then went into committee to consider the case of a member of the Association, against whom proceedings were threatened for having unskilfully treated the finger of a child who was brought to him with a cut finger. It was eventually resolved:—"That the solicitor be instructed to defend a member of the Association in the event of proceedings being commenced against him for the recovery of damages for having treated a child's finger."

The report of the Finance Committee was then read.

It was moved by Mr. Andrews, seconded by Mr. Davis, and unanimously resolved:—"That the report now read be received, adopted, and entered on the minutes."

The report of the London Committee was then read. The principal portion referred to a meeting of the trade which was held at the Inns of Court Hotel in December last, the proceedings at which have already been reported in this Journal.

It was moved by Mr. Harrison, seconded by Mr. Mason and unanimously resolved:—"That the report now read be received, adopted and entered on the minutes."

It was moved by Mr. Harrison, seconded by Mr. Arblaster and unanimously resolved:—"That the following members be appointed Local Secretaries of the Association for the towns in which they reside, viz., H. Allenby (St. Albans, Herts), W. F. Chave (Hereford), J. C. Cossey (Ipswich), and A. T. Watson (Jarrow).

On the motion of Mr. Barclay, seconded by Mr. Andrews, it was unanimously resolved:—"That Mr. Alfred Wright be appointed Assistant-Secretary to the Association, *vice* Mr. G. R. Templeman."

The Draft Pharmacy Bill.

The Executive then proceeded to consider the Pharmacy Act Amendment Bill, 1883.

On the suggestion of the President it was decided to consider the Bill clause by clause.

In reply to a question from Mr. Paterson, the Secretary said the Bill made a clear distinction between scheduled poisons of the existing Pharmacy Act and certain poisonous articles to be scheduled under the amended Act.

The preamble was read and agreed to.

Clause 1 was then read.

The Solicitor said he thought it required enlarging.

The President said he thought the members should consider the principle rather than the phraseology of the Bill, which had been drafted by a very eminent authority.

Clause 1 was then agreed to.

Clause 2 was read.

Mr. Harrison said the clause just read provided an entirely new schedule of poisons, or, in the words of the Bill, "poisonous articles;" it also provided for the sale of such articles by persons not registered as chemists and druggists. It was therefore his intention to propose an amendment, because he believed that the principle enunciated by this clause was diametrically opposed to that laid down in the existing Pharmacy Acts. It had been urged in certain quarters that the sale of these so-called poisonous articles should not be restricted to chemists and druggists, because they were articles of daily use and sold in large quantities, but he thought that a poison was none the less poisonous or dangerous to the public because it was sold in considerable quantities. It would appear that a chemist might introduce a poisonous article into commerce and so long as the sale was small the trade alone would be allowed to sell it; but if the sale increased and it became of commercial importance, and consequently of some value to the trade to have the sale restricted to them, then it ceased to be a poison, and became a "poisonous article" and could be sold by anyone. Again it had been urged as a reason for the Pharmaceutical Council proposing to introduce a schedule for so-called "poisonous articles," that if they had not done so the Government would. Now if the Government had made such a proposal he would submit to it; but he would be no party to informing the Government that it might simply allow such poisons to be sold by unqualified persons on being placed in a schedule of so-called poisonous articles. The distinction which the Bill proposed to set up between "poisons" and "poisonous articles" was altogether misleading. Oxalic acid was to be treated as a poison, and could be sold by qualified persons only. Sulphuric acid, which was a stronger poison, was to be treated as a "poisonous article," and might be sold by unqualified persons. He therefore moved:—"That in the opinion of this Committee the principle laid down in clause 2 of the Pharmacy Acts Amendment Bill is so entirely contrary to the principle recited in the preamble of the Pharmacy Act, 1868, of which this Bill claims to be an amendment, that it recommends the Council of the Pharmaceutical Society to expunge the clause and schedule relating thereto from the draft copy proposed to be submitted to the Privy Council."

Mr. Cross, in seconding the amendment, said that he thought the introduction of the third schedule of so-called "poisonous articles," which might be sold by unqualified persons, would be decidedly disadvantageous to the safety of the public and the interests of the trade.

Mr. Barclay proposed as a further amendment:—"That the articles in the special schedule, referred to in clause 2, be added to part 2 of schedule A to the Pharmacy Act, 1868."

Mr. Harrison said he would, with the permission of his seconder, readily accept Mr. Barclay's suggestion, adding words to his own amendment.

Mr. Cross consented to this arrangement.

Mr. Andrews said that some time ago the Pharmaceutical Council asked the Privy Council to add the articles contained in the special schedule under consideration to the poison schedule in the existing Act, and that it positively refused to do so.

Mr. Paterson said he thought the Pharmaceutical Council should give the trade some notice of its intention to approach the Privy Council, so that chemists might, if they thought proper, object to the proposal about to be made by the Pharmaceutical Council.

Mr. Churchill said he considered it would have been more satisfactory to the trade if the strong acids, etc., under discussion could be placed in the schedule to the existing Act. That course, however, as Mr. Andrews had stated, had been suggested to the Privy Council some months since, but the Privy Council declined to do anything of the kind, and he did not think the House of Commons would be likely to take a contrary view of the matter.

The President said that having had an opportunity of considering the matter under discussion from various points of view, he thought it desirable to support the clause, although it appeared to be an infraction of a just principle as laid down in the Pharmacy Act of 1868. It must be remembered that that Act was but a compromise: there was a flaw in every Act of Parliament, and he thought it would be to the interest of both the public and the trade to accept clause 2 of the proposed Bill as a compromise in the present position. He did not think there was any chance whatever of either Parliament or the Privy Council adopting the proposal contained in the amendment.

Mr. Arblaster moved as a further amendment:—"That clause 2 and the schedule referred to therein be expunged from the Bill."

This amendment was not seconded.

The following amendment was then put to the meeting by the President:—"That in the opinion of this Committee the principle laid down in clause 2 of the Pharmacy Acts Amendment Bill is so entirely contrary to the principle recited in the preamble of the Pharmacy Act, 1868, of which this Bill claims to be an amendment, that it recommends the Council of the Pharmaceutical Society to expunge the clause and schedule relating thereto from the draft copy proposed to be submitted to the Privy Council, and that the articles in the special schedule, referred to in clause 2, be added to part 2 of schedule A to the Pharmacy Act."

Seven voted for and 5 against the amendment. It was then put as a substantive resolution and carried.

Clause 3 was then read and agreed to.

Clause 4 was then read.

Mr. Harrison moved as an amendment:—"That the word 'and' should be inserted after the word 'contained' in the 28th line, and the words 'the name of the poison contained therein' after the word 'medicine' in the 31st line."

Mr. Mason seconded the amendment.

Mr. Paterson moved as a further amendment:—"That on and after January 1, 1885, every person manufacturing a patent medicine shall lodge with the distributor of stamps in the town or district where such patent medicine is manufactured, the name, or names, and addresses of the proprietors or of such person as shall have acquired the proprietary right in the medicine and shall cause the same to be printed on the label or wrapper of the medicine, and such persons shall be held to be liable directly and immediately for any fine that may be exigible for any infringement of the Pharmacy Acts. And in the case of foreign patent medicines it shall not be lawful to sell them until an agent shall be appointed who will accept responsibility and whose name is printed on the label in case of any infringement of the Pharmacy Act."

Mr. Laird, in seconding the amendment, said that if clause 4 of the Bill were accepted, it would involve the principle of selling poisons under the guise of patent medicines. He would accept no responsibility whatever in respect to the patent medicine question.

Mr. Paterson's amendment was then put to the meeting and lost; 2 voting for, and 8 against it.

Mr. Harrison's amendment was then put and carried.

Clauses 5, 6, and 7, were read and agreed to.

Clause 8 was then read.

Mr. Paterson moved—"That this clause be deleted." He said the Aberdeen chemists objected to being compelled to have qualified assistants, unless they were to be made responsible for the conduct of the business. It was going too far, unless the qualified man was made responsible for his own mistakes and the master relieved of responsibility.

The President said the proprietors were always the responsible persons.

The amendment was not seconded. The clause was then agree to.

Clause 9 was then read, upon which the following amendment was moved by Mr. Barclay, seconded by Mr. Harrison and carried:—"That the following words be inserted at end of the clause, viz.:—'Notwithstanding the provisions of section 16 of the Pharmacy Act, 1868, or of this Act, it shall not be lawful for any executors, administrators or trustees of a deceased pharmaceutical chemist or chemist and druggist to continue the business of such pharmaceutical chemist or chemist and druggist for a longer period than three years, unless by permission of the Council of the Pharmaceutical Society of Great Britain.'"

Clauses 10 and 11 were then read and agreed to.

Clause 12 was then read.

Mr. Paterson said it was desirable that an opportunity should be given to students and apprentices to pass their examinations as near their residences as possible. Considering that the Privy Council gave grants in aid of technical education, an effort should be made to induce them to give similar grants for special pharmaceutical education. Where schools were established and examinations held, the Pharmaceutical Society should accept the first-class certificates as sufficient evidence of the proficiency of such candidates in the branch of education for which they had obtained the certificate. The Pharmaceutical Society ought, he maintained, to examine in pharmacy and dispensing once a year at the various centres throughout the country where technical schools were established, providing a sufficient number of persons came forward for examination. He therefore moved:—"That this clause be erased from the Bill."

The amendment was seconded by Mr. Laird, and on being put to the meeting, 2 voted for and 8 against it. The clause was consequently agreed to.

Clause 13 was then read.

Mr. Paterson said that although he thought that there were few chemists who took apprentices who were not capable of passing the Preliminary examination, yet he thought it was very undesirable that they should be compelled, under the penalty of a fine, not to take an apprentice unless he has passed. He moved:—"That clause 13 be deleted from the Bill."

The amendment was seconded by Mr. Davis, and on being put to the meeting, 3 voted for and 8 against it.

The clause was consequently agreed to.

Clauses 14 and 15 were read, and amendments moved by Mr. Paterson to both, which not being seconded, the clauses were agreed to.

Clauses 16, 17, 18, 19, 20, 21, 22 and 23, were then read and agreed to.

It was moved by Mr. Harrison, seconded by Mr. Jones, and resolved, that a clause to the following effect be inserted in the Bill:—"Every person registered, or who shall be registered under the provisions of the Pharmacy Act, 1852, or of the Pharmacy Act, 1868, as a chemist and druggist, and who shall be in business on his own account, shall be exempt from serving on all juries and inquests whatsoever."

It was moved by Mr. Andrews, seconded by Mr. Mason, and resolved:—"That the officers of the Association, together with Messrs. Barclay, Jones, Mason and Paterson, be appointed a Committee to take such steps as they may deem desirable to carry out the wishes of the Executive in amending the Pharmacy Acts Amendment Bill, 1883."

It was moved by the President, seconded by Mr. Jervis, and unanimously resolved:—"That the seventh annual general meeting of the members of the Association be held in London, on Tuesday, May 22 next, and that the arrangements for the same be left in the hands of the London Committee."

It was decided to report to the Pharmaceutical Council particulars of several cases of illegal trading in which the Assistant-Secretary of the Association had collected evidence of infringements of the 15th section of the Pharmacy Act, the Association not having power to sue under that section.

THE PHARMACY ACT AMENDMENT BILL. MEETING OF CHEMISTS AND DRUGGISTS IN EDINBURGH.

A meeting of the chemists and druggists of Edinburgh and neighbourhood was held on Thursday evening, February 22, to consider the Pharmacy Act Amendment Bill. There was a large attendance. Mr. J. R. Young was requested to preside and Mr. P. MacEwan to act as clerk of the meeting.

Mr. Young, having taken the chair, explained the steps which the Council of the Pharmaceutical Society had taken in promoting legislation for the trade. The Council, he remarked, had long been of opinion that the Pharmacy Act, 1868, had not came up to the expectations which had been formed respecting it, and two years ago it had made an endeavour to amend that Act, but owing to the condition of parliamentary affairs at that time, the Council had been unable to get the last draft Bill introduced into the House of Commons. Latterly, however, circumstances favourable to immediate legislation had arisen, and in the drafting of the new Bill the Society had been largely indebted to the efficient Committee of the Council and to the energy of the President of the Society. Regarding the sale of the "poisonous articles" contained in the schedule to this Bill, he remarked, that the Council had endeavoured to get these articles added to Schedule A, Part 2, of the Pharmacy Act, 1868; but the Privy Council was of opinion that this procedure would impose an unnecessary restriction on certain dealers. He thought that the new proposal was the best one that could be made in the circumstances, and he commended it to the favourable consideration of the meeting. He would ask the clerk to read each clause separately, so that an expression of opinion might be had on each principle involved,

On the reading of the preamble, Mr. Young explained, in reply to Mr. Noble and others, that the word "poisonous" was used to distinguish the articles contained in the schedule from "poisons" so called in the Pharmacy Act, 1868; it was not implied, however, that the ordinary poison label could not be used for "poisonous articles."

Clause 1 was read and agreed to without any discussion.

On clause 2 a long discussion took place, in which Messrs. Gilmour, Leitch Mackenzie, Napier, Nesbit, Noble and others took part. Objections to the principle of the clause were freely made; but after explanations had been made by Mr. Young, the clause was agreed to with the reservation, proposed by Mr. Laird and seconded by Mr. Buchanan, "That advertisements mentioned in the clause be inserted in the *Edinburgh* as well as the *London Gazette*."

On clause 3 being read, Mr. Pinkerton asked the Chairman if the record to be kept would require to correspond with that required in sales by retail. Wholesale houses, he remarked, generally had at least three records, namely, the written order of the purchaser, the entry in the day-book and that in the ledger. Either of these might be held to be sufficient evidence of the sale, and he thought that the keeping of a sale of poisons book by wholesale houses would be an unnecessary hardship.

Mr. Raimes, jun., having made similar comment, Mr. Young stated in reply that all that would be required was such a record as would enable the authorities to trace the sale in any criminal case. This would not alter the customs of wholesale houses, further than it would ensure that cash sales by wholesale should be properly recorded. The clause was agreed to.

Considerable discussion took place on clause 4, particularly regarding the size of the type in which the word "poison" should be printed. No amendment was, however, proposed, and the clause with the one following it were agreed to.

When clause 6 was read, Mr. Mackenzie said that he entirely disagreed with it, because it would impose a great hardship on the retailer, involving him in undesirable litigation. He, therefore, moved as an amendment "That the party to be prosecuted be the maker and not the retailer of the patent medicine."

Mr. Billing seconded the amendment.

Mr. Nesbit moved and Mr. McLaren seconded that the clause be agreed to. After a long discussion a vote was taken, when it was found that Mr. Nesbit's motion was carried.

Clauses 7 and 8 were agreed to, and on clauses 9 and 10 being read, Mr. Mackenzie moved, "That medical practitioners should not be allowed to keep open shop unless they passed the qualifying examination of the Pharmaceutical Society." The motion not being seconded the clauses were agreed to, as were also the two clauses following.

Clauses 13 and 14 having been read, Mr. Young said that clause 13 would ensure that persons entering the trade had a proper education, while the three years' pupilage necessary for the qualifying examination would thus require to be served subsequent to registration as apprentice or student.

Mr. Mackenzie objected to the principle of the clause and held that it was inapplicable to Scotland and unjust to employers. He therefore moved "That clause 13 should stop short of the penalty provision." Mr. Leitch seconded.

Mr. Stephenson argued strongly for the insertion of the clause, which he said was framed entirely in the interests of apprentices, and would not at all militate against the interests of employers. He felt that the framers of the Bill were conferring a benefit on the trade by ensuring that persons entering it had a proper elementary education. He accordingly moved "That the support of the meeting be given to the clause." Mr. McLaren seconded.

On being put to the vote it was found that Mr. Stephenson's motion was carried by a very large majority.

The remaining clauses of the Bill were afterwards discussed and unanimously agreed to.

Subsequently a long discussion took place regarding exemption of chemists and druggists from service on juries and after the sense of the meeting had been determined, the following resolution was moved by Mr

Stephenson and unanimously agreed to:—"Resolved that this meeting give its cordial support to the Pharmacy Acts Amendment Bill as approved by the Council of the Pharmaceutical Society, but suggests to that Council that the advertisements referred to in clause 2 o e Bill should be inserted in the *Edinburgh* a well n the *London Gazette*."

Mr. Napier then opened a discussion on the exemption of chemists and druggists from jury service, and after many of those present had spoken on the subject, it appeared that the opinion was unanimous in favour of the extension of the present exemption to all persons qualified under the Pharmacy Acts and who are carrying on business.

Mr. Buchanan then moved a vote of thanks to Mr. Young for presiding and for so ably explaining the several points which had been under discussion. The motion being heartily responded to, the meeting separated.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual supper of this Association was held in the Alexandra Hotel, 148, Bath Street, on Wednesday evening, January 24, when about seventy gentlemen sat down to supper. Mr. Robert McAdam, of the Glasgow Apothecaries' Company, occupied the chair.

Mr. J. R. Young, in giving the toast of the evening, "The Glasgow Chemists and Druggists' Association," said that the duty could hardly have fallen into more incompetent hands, for he was altogether ignorant of the history of the Society. He had, it was true, received from the Secretary a copy of the constitution, but that document was without date, and he was left to infer that the institution might date back to the time of Melchisedec, and might be intended to last for all time. From that constitution he found that one of the objects of the Society was to promote, by lectures, essays and debates, the attainment of the abridgment of the hours of labour. If that was meant to be a continuous process, he supposed that by-and-by the profession of a druggist would mean all play and no work. Speaking without the book, however, and drawing on his own personal knowledge, he knew their society was doing a great deal of good, and its efficiency was due in no small measure to the many excellent men who had, within the last thirty or forty years, filled the President's chair. It was quite right and proper that a society such as this should exist in a city like Glasgow, and there was plenty of work for it to do. They had most exceptional facilities here for the acquirement of a knowledge of chemistry, and he had often been struck by the number of young men he had met hailing from the West of Scotland, who, though they had no connection with pharmacy, had still a very useful knowledge of the science of chemistry. Such an acquaintance was of the utmost service to any young man, for it developed in him a healthy curiosity to know as much as he could about most things, and he had no doubt that such attainment had contributed in no small degree to the accumulation of the great wealth which was in Glasgow. Mr. Young then gave a few words of advice to the younger members of the Association, and asked the company to drink the toast with all the honours, coupling it with the name of Mr. Alexander Kinninmont.

The toast was most enthusiastically pledged.

Mr. Kinninmont, in replying, gave a most interesting historical sketch of the Association and the good work it had done, and pointed out that it had still much to do. He earnestly appealed to those present to join together in keeping the Association in a thorough state of organization.

Mr. John Currie (Eglinton Street) proposed "The Medical Profession" in a felicitous speech, and coupled the toast with the name of Dr. A. M. Robertson, who replied, thanking the company for the manner in which the toast had been received.

Mr. John Walker (Glasgow Apothecaries' Company) proposed "The Pharmaceutical Society," to which toast Mr. Alexander Napier, President of the North British Branch, replied.

Mr. David Lees gave "The Edinburgh Chemists' Assistants' Association," coupling it with the name of Mr. Boa.

Mr. J. L. Hatrick, in proposing "The Visitors," gave them a hearty welcome in name of the Association, and coupled the toast with the name of Mr. Borland, of Kilmarnock, who, in reply, likewise expressed the pleasure he had in being present on such an occasion.

Mr. A. Paterson, in a few remarks, proposed "The Chairman," whose health was drunk with acclamation.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at the Mechanics' Institute, on Tuesday, February 20, the President, Mr. R. Fitzhugh, F.C.S., in the chair. There was a good attendance.

Mr. F. H. Spenser was the lecturer for the evening and gave an interesting lecture upon the "Sun and Earth." He commenced by giving a brief description of the Ptolemaic theory, pointing out that although Pythagoras and other Greek philosophers had expounded more correct notions, it was not until the teaching of Copernicus in the 15th century that the present system was thoroughly recognized. The Copernican system was explained and the planets briefly described. The enormous size of the sun, the source of our light and heat, rendered him a suitable centre of the system, his weight being 750 times that of all the planets together, his diameter one hundred times greater than the diameter of the earth, and a train running at the rate of forty miles an hour would take seven years to perform a journey round him. Supposing a ball six feet in diameter were taken to represent the sun, a pea would suitably represent the earth. He rotated on his axis in about twenty-five and a quarter of our days. The spots on the disc found in bands on either side of his equator were mentioned and the probable eleven-yearly changes pointed out. Bode's and Kepler's laws were explained, and the lecturer showed how the investigation of the latter led to the discovery of most important scientific truths by Sir I. Newton. A brief, but clear account of the Newtonian theory and the nebular hypothesis was given, showing their strong points and failings. The excentricity of the earth's orbit, the change extending over a period of 25,868 years, was mentioned. How celestial distances could be measured was explained and the methods by which the sun's distance had been determined shown. In conclusion, the lecturer remarked that our solar system does but form one star in the host of heaven, and that the universe is governed by laws so far-seeing and perfect that we must admit with the Psalmist "the heavens declare the glory of God and the firmament showeth His handiwork."

A hearty vote of thanks was accorded to Mr. Spenser on the proposition of Mr. Fitzhugh, seconded by Mr. Wilford.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held on Tuesday, February 6, the President, Mr. W. A. Wrenn, in the chair. A paper was read by Mr. W. Temple Cooper, jun., entitled "Practical Hints on the Examination of Urine."

The author began by alluding to the importance of the subject which formed the title of his paper, and gave it as an example of the uses to which the work of a student, when preparing for examination, could, in after life, be applied. Reference was made to urine in its normal state, its appearance, colour, sp. gr. and composition per thousand parts, and the fermentation it undergoes with the production of ammoniacal compounds when allowed to stand. The chief normal constituents, organic and inorganic, were mentioned and described, amongst which were urea, uric acid, hippuric acid, creatine, creatinine, phosphates, chlorides, etc., in combination with magnesium, calcium and sodium, etc., and specimens were shown of the organic portion.

Methods for estimating urea by Dr. Russell and Mr. West, by Dupré, and others, were cited, the two former being practically demonstrated before the audience. The apparatus for the first method was kindly lent by Messrs. Cetti, Brook Street, Holborn.

Of abnormal constituents the author mentioned albumen and its tests; special reference being made to nitric acid, metaphosphoric acid and ferrocyanide of potassium in conjunction with acetic or citric acids (this forming a very delicate test).

Sugar and its qualitative and quantitative tests were described; of the former, potassic hydrate (Moore's), molybdate of ammonium with nitric acid, nitrate of silver and the fermentation process were spoken of; and of the latter Fehling's method, as recommended by Dr. Pavy, which was specially dealt with, and specimens of the reagents, both before and after the addition of the saccharine urine, were shown. The method consists in the use of the following solution:—The usual quantities of cupric sulphate, Rochelle salt and sodic hydrate per litre are taken, and of the above Fehling's solution 120 c.c. are added to—

Strong solution of ammonia (sp. gr. ·880) .	300 c.c.
Solution of sodic hydrate (sp. gr. 1·14) . .	400 c.c.
Distilled water	to 1 litre.

100 c.c. of this solution = ·05 glucose.

The ammonia prevents the precipitation of the well-known red-coloured cuprous oxide, the mixture being kept at a boiling temperature, while the urine is gradually run in until the blue colour disappears.

Amongst the precautions to be observed in the application of this test are—

(1). To use right proportions of the test reagents.

(2). To use a correctly standardized copper solution.

(3). To operate quickly; as the blue colour returns when oxygen is absorbed.

(4) To maintain ebullition from beginning to end of experiment.

(5) And performing the experiment in a flask having a cork with two glass tubes, one to emit steam and ammonia, and the other connected with the burette containing the urine to be examined by means of india-rubber tubing, dilution of urine, 1 in 10, rendering reaction more delicate.

A gravimetric method was also described, which consists of solution of the cuprous oxide in hydrochloric acid, addition of solution of ammonia in excess, and precipitation of metallic silver on addition of nitrate of silver, which is estimated as metal, 509·6 grams of which have been proved by experiment to be equivalent to 100 grams of glucose.

For the examination of bile, another abnormal constituent, the author recommended a modification of the one given in the B.P. for oleum morrhuæ.

For blood in urine, the special characters of urine thus contaminated were described, the methods adopted being microscopic and Day's tests.

The cause of urinary sediments was described, and methods given for the examination of them chemically and microscopically. A chart was shown, on which were drawn the commoner kinds of sediments, illustrating their microscopic shape and character.

In conclusion, the author alluded to such substances as rhubarb, gamboge, logwood, etc., the colouring matters of which were imparted to urine when patients were taking these medicines.

A lively discussion followed, in which the President, Messrs. Alcock, Dangerfield, Park, Parkinson, Roper, Woods and Millhouse took part.

A vote of thanks, proposed by Mr. Parkinson and seconded by Mr. Townsend, was accorded the author for his valuable paper.

The Draft Pharmacy Act Amendment Bill.

Sir,—Salvation by Act of Parliament has a limited value, though it may be one difficult to define. I had almost made up my mind to shirk the somewhat hazardous task of expressing an opinion upon the probable benefits of a prospective law; but several friends have suggested that the action of the Council would be strengthened by the expressions of approbation from men of various shades of colour. I am ready to admit that my colour is a very shady one in the eyes of those who look to Acts of Parliament to help them out of pecuniary troubles. It may be that my approbation will attach to itself just that value which commonly belongs to the praise of a fool. If so, my friends are to be thanked.

I do not look for any other object in Government than the general weal; that individual is to suffer for the class, and the class for the community; that poison regulations and Pharmacy Acts should be, and must be, constructed upon such plans as facilitate the public getting their wants supplied with the least cost, the least inconvenience, and the least danger. Happy is the man who has learned that his interests lie in meeting the public requirements, and has learned how to meet those requirements in a way that is advantageous to himself at the same time. The law may compel him to learn the first of these two lessons; his own necessities and his ingenuity must teach the second. If we could clear from our minds the craving for somebody to do something for us, I think we should see that the Bill under consideration is fairly planned for its legitimate work.

It endeavours to provide that dangerous articles should be sold under such regulations as diminish the danger of their sale, and when the restriction is not carried to the point of attaining the greatest possible safety it is because the additional safety would be purchased at the cost of disproportionate inconvenience or pecuniary outlay.

I should rather have seen the dealing in "poisonous" materials limited to the hands of the educated tradesman, who would know the effects of a dose of the poisonous matter he might be selling, and the appropriate remedy to use in case of an accident; but my experience would not allow of my strongly urging this point, seeing that I have been nearly forty years behind the counter and cannot call to mind more than two or three cases when this kind of knowledge has been called into request. So insignificant a protection as my knowledge has in these cases afforded will not weigh with the public against paying 10 per cent. more for their soldering solutions or sheep dip, and when the pharmacist or other educated man does not allow his knowledge to stand in the way of his doing business in fair commercial competition with other tradesmen, the probability is that the "poisonous" goods will as effectually fall into his hands as if Parliament had decreed that no other class of traders should be allowed the privilege of such sales.

In some other points I think the Bill falls short of providing, it may be at the expense of the trader, some points of protection which I think the public might reasonably demand.

Take clause 8, which provides if a man has a branch shop he shall have a qualified assistant there. If a pharmacist in Holborn opens branch shops at Bayswater, Islington and Mile End, how many branches has he? If he has three and keeps a qualified assistant at each, he may be so much taken up with looking after the branches that his root becomes a source of danger, and it may become necessary for the botanical examiner to prove that a root is a branch also, and that a pharmacist who opens three branch shops has four branches. The clause would be improved by striking out the word "branch" before the word "shop" in the sixth line.

In the fourth clause the requirement that a nostrum containing a poison shall be labelled with the name of the patent medicine and the word poison will afford some protection against the careless use of such medicines, but does not afford information on one important point which might in public interest have been reasonably required. That is, that it should bear the name of the poison which it contains, so that in event of an overdose having been taken the medical attendant might know with what poison he had to deal. It is true that most of the poisoning cases occurring through the use of patent medicines have been caused by the presence of opiates of some description, but it is not improbable that the acknowledgment of the presence of the opium or other articles on the poison schedule would be a reasonable requirement.

I think the clauses attempting to fix upon the true proprietors of businesses the responsibilities which rightly belong to them are good in principle and probably advantageous in their results, as much upon the pharmacists as upon the public. They would tend to facilitate the spotting of a transgressor. I see no reason why the President of the Pharmaceutical Society should blush to see his name in print upon his labels, or painted over his shop door in letters as large as "Dinneford." I say this with some feeling and full knowledge of the great amount of inertia that would have to be overcome before we could educate ourselves up to this point, for, however well my name may be known to readers of the *Pharmaceutical Journal*, I am best known in my own town as W. Proctor and Son.

Now, having spoken my approbation of some clauses and my partial approbation of others, I have only to add my hope that the trade may have unity enough to sink little differences and support any measure which moves them one step in advance.

11, *Grey Street, Newcastle.* BARNARD S. PROCTOR.

Sir,—Actively engaged as I was with my fellow members of Council in framing the Pharmacy Act of 1868, and promoting its passage through Parliament, you will not be surprised at my watching with much interest the proceedings of each succeeding Council, more especially as to future legislation, and you will, I am sure, grant me space for some remarks on the proposed Pharmacy Bill adopted recently by the Council, and published in the Journal of February 10.

You say that this Bill is the outcome of six years' deliberation. During the earlier portion of that period I sat on the various committees in which the subject was discussed, and remember well the arguments produced for and against certain propositions as they arose.

While I recognize much in the Bill calculated to increase the public safety, and rejoice in the evident desire of my successors in the Council to advance the education and qualification of future pharmacists, I regret to say that I think the means proposed quite inadequate for the former purpose. The public safety is the only plea on which we can go to Parliament with any hope of a favourable response. Now we all know that the trial of Lamson brought vividly before the public the lamentable case with which a man being, or even pretending to be, a medical man could obtain the most deadly poisons, and created a demand for greater restriction on such sales. Clause 3 of the new Bill is evidently intended as an answer to that demand; but how far, I would ask, would it effect the object? It might possibly help in some rare cases to convict a murderer; but it would not prevent murder. I take prevention in this case to be the object demanded, and justly demanded, by the public. Surely Parliament would never be satisfied with so inefficient a provision! Much greater safety may be attained by more precise restrictions, and that without inconvenience to anybody—except would-be murderers! At present a stranger applies to a chemist for (say) aconitine. He writes a prescription in due form—perhaps points to the name of "Dash Blank" on the Medical Register, and says it is his name. The chemist does not know that he is "Dash Blank," or even a medical man at all, still does not like to express a doubt.

I think it would be an advantage to the chemist to have some authoritative reason for refusing the supply. Certainly it would be an advantage to the public. Let it be at once enacted that in all such sales there must be personal knowledge of the applicant, or that he must be introduced to the seller by some person known to both parties. Record of sale and signature to be kept as provided in the present Pharmacy Act. Mind, I am not speaking of the ordinary supply of such articles in the proper course of wholesale dealing, nor would I have on the special list of prohibitions any but the most intense poisons which science has of late eliminated. The prohibition would only extend to what may be called casual cases. I believe I may, in support of my opinion, say that such a proposition has been approved by the College of Physicians.

One other point I must mention on behalf of the public. Clause 8 provides that persons keeping more than one open shop shall employ a qualified assistant in "each branch shop." I think it should be in each shop, leaving no question as to "branch" or principal.

We want to encourage young men to pass our examinations; it would be wise therefore to give them every opportunity of profiting by having done so.

So much for the public. Now I must direct the attention of my brethren in the trade to a most unjust and unnecessary hardship which this Bill will inflict on us. Clause 4 throws the penalty for insufficient labelling of poisonous patent medicines on the retailer. It is very well known that the retailer has no knowledge or power in this matter. He can only sell a patent medicine wrapped up as he buys it; if he open the package he renders it unsaleable. How then can he say whether the bottle is marked "poison"? If it be not, he is liable to a fine of £5 for a first offence, or £10 for a second. It is true that Clause 6 gives him power of recovery from his wholesale dealer, but it is ten to one he will never get it; he may have great difficulty in proving that the particular article on which he was fined was supplied to him by a particular wholesale house. Even if he obtain reimbursement of the money penalty, he will still labour under the stigma of the prosecution. This recovery clause is framed evidently for the multiplication of law-suits; five or six may be carried through before the real offender is reached.

The first action should lie against the proprietor of the medicine, and this would be easy enough.

Again, I will suppose a case in which a retailer is fined £5 for a first offence in selling a bottle of Hunter's Chloral. He offends a second time by selling a bottle of Bunter's Nervine, and is fined £10. Can he recover the £10 from Bunter, who was in no way implicated in the first offence?

Piccadilly. GEORGE W. SANDFORD.

Sir,—At a meeting of our local Association, rather more than two years ago, I read a short paper, giving my opinion as to the direction in which the Pharmacy Act should be amended, and as the amended Bill now before us coincides in many points with the views then expressed, I feel bound to give my tribute of approval to the Council for the care it has taken to bring forward a measure at once reasonable and practicable.

Whatever may be thought of the effect of the Pharmacy Act, 1868, in elevating the status of the druggist, there can be no doubt that the safety of the public is now much better ensured than was the case before it became law, and the amendments proposed, being calculated to assure that safety in still greater degree, should meet with a favourable reception from the public and the Legislature.

It would occupy too much space to comment on every section of the Bill proposed, but perhaps the following brief remarks may be worthy of attention.

Section 2 grapples successfully with a serious difficulty, and as no claim to the exclusive sale of the articles specified is put forward, no charge of attempted monopoly can be made, whilst the danger of accidental poisoning is lessened, as far as is possible, by the use of the "poisonous" label being made imperative.

Section 3 provides for such cases as that of Dr. Lamson, and will ensure the registration of cash sales by wholesale houses.

With respect to section 4 and others concerning patent medicines, I have held that section 17 of the Act of 1868 was applicable to them. As no decision, however, has been given on this point, it is as well to settle the question definitely, as is now done.

The regulation as to branch shops is necessary, and will not infringe on the just rights of anyone, whilst the powers asked for under section 10 will render it easier to find out the real proprietor of a shop, which is at present a matter of some difficulty.

Section 12 and following relate more to the internal constitution of the Society and seem calculated to strengthen it and increase its usefulness.

In conclusion, I consider that the Council has acted wisely in asking for amendments which are really measures conducive to increasing the safety of the public, and in avoiding everything which might have the appearance of grasping at a monopoly.

Let us hope that its efforts will be crowned with success.

Glasgow. ALEX. KINNINMONT.

Sir,—This Bill defines the undefined, and where it departs from the original position taken up by the Pharmaceutical Society I fail to see.

Sharp tools which leave their mark need little legislation, and knives, razors, oil of vitriol, muriatic and nitric acid, chloride of antimony, carbolic acid and pistols belong to the same category. It is far different with the occult poisons scientific resarch has lately given, and will continue to give us, which require skill in their use, discretion to prevent abuse, and registration to detect misuse. Parliament, in the interests of the State, cannot guard these too vigorously; careful thought marks this, the cardinal point of the Bill. Poison and its distribution will be placed in the hands of responsible skilled persons. This done the necessity for legislation ceases; all the other clauses are subsidiary, regulating the machinery in the best possible manner for the time being.

Few of us would care to give the great and sustained attention our Council has given to this matter to steer the pharmaceutical barque safely between the Scylla of trades unionism and the Charybdis of vested interests. I therefore ask my fellow members and chemists generally to look back on the last twenty or thirty years with unprejudiced eye to our business and its prospects in their youth, and see, if they can, the step ladder of progress, for every step is a firm footing. We have not finished, but let us with a firm will and glad hope take this one with confidence, for the future is bright for us; but let each of us remember that the strength of a chain is that of its weakest link, and that of a society to some extent of its weakest member. We must not move too quickly nor ask for too much.

GEORGE MEE.

Sir,—Having carefully watched the progress of pharmaceutical legislation for many years, I cannot, at this point, refrain from raising a jubilant note in praise of the last effort made by the Council to provide something as nearly like a perfect Pharmacy Act as the times and circumstances will permit. I am not so childish as to believe the Act will satisfy all men, but I believe it will be received with approval by a large majority, and that it will go far to meet more than one evil left untouched by the Act now in force.

That the present Act is imperfect everybody admits. It supposes that no life may be endangered except by the most potent poisons, and throws open the right to dispense medicines to the most ignorant so long as those medicines are not included in the existing poison schedule. The new Act, in providing that all persons who dispense prescriptions shall show that they are able and fit to do so, makes a wise provision which will be appreciated by all but the incompetent and unreasonable. If skill is required in the dispensing of a medicine which kills with a dose of 20 minims, precisely the same skill and knowledge are requisite for the dispensing of one which is left untouched by the schedules because it reserves its potency for a larger dose. The dispenser should be responsible, no matter what the medicine may be. In any case his concern with human health and life is equally strict.

I would fain omit allusion to the vexed question of patent medicines, but it is evident enough that the only difference between dispensing a prescription and selling a patent medicine lies in the fact that the dispenser is in one case preparing a medicine of which he, the prescriber, and probably the patient, have an accurate knowledge, while in the other all parties, excepting the proprietor of the patent, are in utter darkness, and may be running their barque on the frowning rocks of death without a warning. Surely a man who dispenses poisons, the strength of which is wrapped in the impenetrable gloom of a private formula, should be one who is responsible in the strongest sense of the word, and it appears to me that the only man who can be so responsible is he who is registered as possessing qualifications for the work he undertakes. Unfortunately, even then, he takes the responsibility without the knowledge the physician imparts on his slip of paper; that, however, he must risk. He is at least one to whom the public may refer to deliver them from the many uncertainties belonging to proprietary physic.

Heaven forbid that I should appear to come between the desolate widow and the means for her subsistence provided by her inheriting the business her husband leaves behind. I think her true interests lie not in trying to carry on a business (even with the aid of a qualified assistant), which in actual practice has so seldom proved a success in the hands of a widow. I take it to be a cruel kindness to encourage it. How many a sad story could I relate of women left stranded by a receding business, which, if disposed of when necessity came, would have made a decent provision for them. Nor must we forget that the Pharmacy Act will be sufficiently like the Medical Act to make it as absurd for an irresponsible widow to carry on the responsibilities of a pharmacy, as for the widow of a surgeon to run the risks and hazards of a medical practice. But this is my opinion only, and I am quite prepared to follow in the steps of the Council by conceding this point in favour of those who hold a different opinion. The wisdom of the Council is shown in straining a point, where no great interests are involved, and where many diverse opinions have to be conciliated.

It is a step in the right direction to put a stumbling block before those who would carry on business at several places under different names. The honest man is provided for, if he please to open a dozen shops, so long as he takes care a qualified man stands behind each counter. The public is protected and the pharmacist obtains his hardly-earned profits. But where it is needed to show who is the responsible man, so that, dispensing physic being a matter of life and death, there shall be no doubt about it, then the Act will provide that this shall be settled once for all, without resort to practices which make it as difficult to identify the owner of a business as to discover that arch-conspirator, "No. 1."

For the education clauses I thank the Council. The system of education should either be entirely "as you like it," or it should be as complete as it can be made without being positively irksome.

The late Jacob Bell, were he to revisit earth, would see in this Bill the realization of more than one of his dearest hopes, and I cannot but think that it affords many a despairing pharmacist a sight of a clear and straight way out of difficulties, which now are a source of danger and discontent.

Liverpool. JOSEPH HALLAWELL.

Sir,—The long-expected Pharmacy Amendment Bill as proposed by the Council of the Pharmaceutical Society has now appeared. Naturally, much criticism of its provisions will reach you. Our immediate private interests colour our views respecting it, but I hope that we shall be able to take an "all-round" view and recognize facts, whether they be pleasant or otherwise. Compromise seems a necessary characteristic of legislation. There as elsewhere, not being able to get all we would like to have, we take what we can get, and concede as little to the other side as we can help without exciting doubts of our own good intentions.

Now, I take it that the Government, and influential persons and associations, were determined upon two things, viz., that dangerous articles should not be sold without the purchaser being informed of their potent nature for evil as well as for all the good that their makers claimed for them. The fact that we sell so many preparations that may produce, and have produced, fatal results, yet called by the most innocent names, is certainly an anomaly in our business, where accuracy of definition and practice is matter of something like boast amongst us. Imagine our calling paragoric elixir "balsam of aniseed," or chlorodyne "concentrated cordial peppermint." Hence the need for clause 4.

With regard to the proposed schedule of "poisonous articles," we know that a monopoly of their retail sale has been decidedly refused to us, and I daresay most of us do not wish to have it. Then surely the next best thing is to compel all sellers of these to adopt precautions similar to those that we use ourselves and comply with the requirements of clause 2.

Although in the strictly logical use of words "poisonous" may be better than "poison," yet as everybody is familiar with the latter in the practice of labelling, I should prefer that the word "poison" should serve all round. We know the difficulty of making and teaching such nice distinctions. Is this one worth the trouble even of the extra specified labels? As there are already two grades of "poisons" recognized, why not have a third? I throw out this idea with all deference, for I feel that the result of so much deliberation amongst the picked men of our body is not to be lightly esteemed.

Concerning clause 8, I fear that there are vested interests, which have been to some extent overlooked. Whilst we have been prepared for a time when none might own a business unless upon the Register, I think it would be a terrible surprise to some good business men to find that unless they pass their examination by January 1, next year, they must leave their present employment where they are giving satisfaction to their employers.

On the whole the Bill is one that I think the trade might receive with favour. It has reasonable claims and reasonable concessions, and provides, wisely, I think, for the educational needs of the future. If there seems to any to be room for cynical criticism and suggestions of unfairly interested motives, let them show "a more excellent way."

221, *West Derby Road, Liverpool.* B. DICKINS.

Sir,—The mountain in labour, after much commotion, brought forth a mouse. The Council of the Society, after six years of Herculean effort, has produced some patent fetters, not of a velvety character, but real golden manacles, in the shape of £5 and £10 penalties, and exults as much over its achievement, judging by its self-adulation at the last meeting, as a hen after depositing an addled egg. The members of the Society have never claimed to be a mutual admiration society, but rather a combination in defence of trade rights and interests.

It is expected, now that the "memorable epoch in pharmacy" has arrived, that individual members should express their very grateful thanks to the Committee for the great boon bestowed upon them, unless there are some who, like myself, fail to see any important advantages in the Bill, and not being able to comprehend, respectfully ask, What benefit of any consequence will the passing of this Act be to the trade? Without wishing to depreciate the "gigantic labour" of our much-esteemed and energetic President and those who aided him in the work, it appears to me that their labour has been entirely on behalf of the public, and of very little service to the chemist.

If the Council has been deputed by the Lord President of the Privy Council to act as a sub-committee for that department of Government which protects the people from harm arising from the slovenly sale of oil of vitriol, etc., then has it performed its duties admirably to the best of its judgment; but why the trade in the "north" or any other quarter is likely to receive the Bill with "acclamation" is beyond my understanding. In my opinion it will be regarded with indifference and general apathy, if the contemptuous comparison is not suggested. as a "much ado about nothing."

The Bill is divided into three subjects, trade, education, and the improvement in the funds of the Society. I scarcely believe our members will be much interested in others, not registered chemists, being compelled to label half a dozen acids "Poisonous." Neither do I believe that placing a poison label on all proprietary articles containing any portion of the scheduled drugs will be a wise act or a safeguard, but, on the contrary, it will increase the evil it is intended to prevent.

In most cases of injury or death from patent medicines, negligence on the part of the public, in failing to observe the printed directions and dose, are the causes of the evil, and fifty poison labels would not engage their attention, or be the safety it is assumed. Accidents will happen, in spite of every precaution the chemist may take, if the public will not look after itself. Not long since, I dispensed a cough mixture and a gargle for a gentleman of education and good position. Different shaped bottles were used and a coloured label, headed, "Not to be taken," placed on the bottle containing the gargle, and yet this intellectual person poured out his gargle and swallowed it instead of his medicine; fortunately, without any serious effects. In such cases, what is the use of a label? Negligence and failing to find relief from the dose ordered, people wilfully take more than the directions permit. Then who is to blame? The same danger attends the ordinary medicines, especially drops, prescribed daily by the physician, and carefully dispensed by the pharmacist, but on which a poison label is not allowed. If the public will not take care of itself then no Act of Parliament of this nature will succour it. How often is it the case that medicine bottles are returned without having had the demy wrapper removed, the tops only torn off to permit of the removal of the corks, the label never having been disclosed or uncovered. Many will exclaim daily it is so. People who are now unaware that certain proprietary medicines contain poison in excess doses, will by the required label have an instrument brought neatly to their hands, to carry out any nefarious act they may contemplate, whereas before and now they are entirely ignorant that such an innocent article, in one sense, can be rendered so dangerous in another.

A very important question, never yet satisfactorily defined, is, What constitutes a poison? A man may have a good proprietary article, which for half a century has been sold without a single accident arising therefrom, containing a harmless dose of nux vomica, opium, or some other narcotic, which, in itself, is not only innocuous, but highly beneficial, and therefore not a poison, but only made a poison by larger doses being taken than directed. Why not compel the licensed victualler to label every bottle of spirit he sells over his counter "Poison?" A glass of brandy or whisky many people think nutritious, but the contents of a bottle, if taken, would make a human being dead drunk. Where is the difference? Why should the minor dose of nux vomica be considered and proclaimed a poison to the injury of the proprietors of an old-established property by shaking the faith and shaking the nerves of many constant purchasers?

If man or woman be intent upon committing murder, or suicide, no label will prevent it. But the proposed increase in the number of poisonous articles to be brought before the public will add to the mischief already deplored. The Council may well leave the Government to look after the public interest, whilst they study chemists' wants, and if Government will not place these articles in the hands of men competent to distribute them, it is no fault of ours.

Phosphorus paste has for some time past been employed to destroy life. Why is not that scheduled?

Mr. Hampson gives a reason why we should support this Bill. If the Society does not introduce a clause to regulate the sale of acids, Government will. But when the educational drift is considered, I cannot see what the future pharmacist will care, any more than those of the present day, who it is that regulates the acids scheduled "poisonous."

The branch shop clause need not excite the chemists. So long as co-operative stores and corporate bodies are permitted to carry on dispensing and chemists' retail business by engaging men on the register, I see no reason why orthodox pharmacists, having capital to invest, should not embark in that they most understand, especially as they are now to be held responsible for the sins of their managers.

The most important clause affecting the future existence of the Society is undoubtedly No. 17. This arrangement I persistently advocated at the time of the incorporation, which, if then carried, would by this time have made the Society a representative institution of the whole body of chemists instead of the fragmentary part now belonging to it. To become effectual, the bye-law requiring a two guinea entrance fee for registration will have to be repealed, or the proposal will meet with few acceptances by the future pharmacist. This short-sighted policy, when insisted upon, has prevented the Society from becoming the grand institution it ought to be.

I confess myself disappointed with the Bill. Not because I have Quixotic notions, or expected any endeavour to secure a monopoly, for that cannot be; but because I see no particular good in it for the trade, and I am quite unable to understand why "nine tenths of the Council" are so unanimous and enthusiastic over it.

I had looked forward with much interest to its publication, fully expecting, with the incessant cry for education, curriculum, higher and stiffer examinations, "no cram," that some attempt would have been made to bring a more refined business to the chemist of the future, as well as to place us of to-day on more favourable terms with the medical profession, and instead of wasting time over acids and colourmen, that our Council had endeavoured to bring dispensing to the counter of its pupils. Then might we have had reason for receiving the Bill with "acclamation." Then we might have argued, with Mr. Young, that it is one of the "best Bills which had been passed by the Council," but as it is, I cannot see how it "deals practically with all those matters which were the peculiarly crying evils of the present time." Unless the Council make some effort to provide pharmacy proper as the work for the future chemist, it is only a mockery to entice educated youths to pass through high class examinations, and a delusion to bring them to the classes, without providing for them at its close an employment suitable to their attainments.

I expected some endeavour would have been made in any new Bill to legally divide prescribing and dispensing, so that each branch of medicine should have recognized duties. For the regular trade of the chemist having hopelessly departed to the grocery and other stores, there is nothing left for the chemist but to relieve the medical men of dispensing. His only hope in the future is pure pharmacy.

This should be the aim of our examining body and Council to enable the qualified man to enter an employment befitting his past preparations, instead of launching him forth into a general dealer's, to employ his talents and highly paid for education in the sale of pennyworths of hair oil and poisonous acids.

174, *Warwick Street, Pimlico, S.W.* JOHN WADE.

Sir,—Though the "Amended Pharmacy Act" may be, and I believe is, thoroughly sound and wise in its general object and conception, yet it contains that which cannot fail to provoke adverse criticism and dissent. I allude particularly to clause No. 16, which provides that after a given date, the "Major" shall be practically "abolished." This appears to me most unwarrantable and unfair as well as unnecessary. Mr. Hampson evidently had some misgivings on this point, since he anticipates that this proposal will raise opposition on the part of some pharmaceutical chemists, and Mr. Gostling is not unconscious that "some pharmacists may feel aggrieved." My own impression is that the vast majority will feel very indignant and greatly aggrieved. Just imagine the "Royal College of Surgeons" seeking to abolish their Fellowship, simply because not one in a dozen of its members proceed to the higher diploma, and yet such a course is contemplated in the Bill just produced. Because the majority of chemists have seen fit, for their own reasons, or more probably for the want of them, to remain outside the paternal care of the Society, they must needs be promoted to the title of "pharmaceutical chemist," just when the distinction is at last beginning to be appreciated by a slowly discerning public. The qualification is to be shorn of its value by being literally thrust upon a class of druggists who never earned it, and who content themselves with the easiest attainable ingress into the trade that the law permits.

Surely this is a singular manner in which to reward apathy and unreasoning discontent! If those that were bidden persistently decline the pharmaceutic feast, it is no part for the Council to hunt up the halt and the lame. If it is really necessary for the existence of the Society that its membership should be increased, why not adopt the system that obtains in the various medical licensing bodies, increase the examination fee by such a sum as would confer life membership upon the candidate passing? This would augment our numbers; numerical augmentation, however, by no means implies increased interest. It is worthy of note that indifference and apathy are characteristic features inside as well as outside the Society. Very few, comparatively, attend the annual meetings; very few indeed appear to take any interest in the proceedings at Bloomsbury Square; and at the last election of Council, not more than a third of the members even took the trouble to fill in their voting papers. The fact is, causes quite beyond the control of the Council are operating to decrease and weaken our ranks. Competition is taking from us a variety of trade that never really pertained to our calling. A process of natural selection is going on; some of us will inevitably fall victims to the law "Survival of the fittest." It is no use blinking the fact, though it is far from delectable. One chemist will find it difficult to exist where two flourished before (Proctor). I utterly fail to see how the wholesale manufacture of pharmaceutical chemists can in any way mitigate the troubles that so unfortunately beset the business, whilst such procedure would inflict gross injustice on those who, though deriving no apparent benefit therefrom, have obtained the qualification in a proper and legitimate way.

Warrington. J. RYMER YOUNG.

Sir,—That the intended new Pharmacy Act should meet with such unanimous support in the Council augurs well; that it should meet with no criticism (friendly or otherwise) from the trade at large would indicate a supineness on the part of those for whom it is intended that might dishearten the boldest of those who for the past twelve months have laboured so earnestly and with such a splendid result to bring this Bill into shape. It is therefore with this idea that I presume upon your courtesy to allow me to lay before your readers a few friendly remarks.

In the first place, clause No. 2 seems to me the weakest part of the Bill, and were it not evident that it is a compromise between the Privy Council and our Council, I should say "leave it out altogether," since I think it is very apparent that it may create confusion and do more harm than good. For the future (if this clause pass) those of us who have been in the habit of putting a bold red poison label on carbolic acid, for instance, must label it "poisonous,"* and the public will naturally come to the conclusion that after all it cannot be so very dangerous, for whilst oxalic acid is labelled "poison," this is only poisonous, and will gradually come to treat the whole system of poison labelling with contempt. Would it not be much better to stick to the old definition of poison?

Clause 4 seems also to require a slight addition or alteration. Would it not be better to leave out the reference to the outer wrapper, and make it imperative that the inner label should indicate poison; of course, it would be much safer that both should say "poison," but if only one, then most decidedly the inner one. In many cases the outer wrapper is torn off without being looked at, whilst the inner one must remain an indication of danger (and labelled "poison"), so long as the bottle, etc., lasts. Clause 17 will no doubt meet with considerable criticism by "Minor men," who will fear being thus debarred after 1886 from qualifying as Majors. But no injustice can accrue under this clause, for whilst those who wish to become Major men can present themselves for the Minor up to July, 1886, and then pass the Major in December, 1886, those who are anxious to be enrolled under the new Act have simply to defer this examination until the first one in 1887. Those of my Major brethren who feel their dignity and title touched by this clause, I would urge to read it in conjunction with clause 12, and to rest assured the present Board will not lower the standard; therefore, let us swallow our pride and present an united front on this question, having this consolation that if we suffer, or fancy we suffer, an injury ourselves, the "future of pharmacy" will have a brighter look out. And let us recollect that the men who propose this are the very men whose names give honour to our title and who have most to lose, if any loss there can be. But in pharmaceutical politics where a Carteighe, a Hills, a Williams, a Symes, or a Schacht lead, not a shadow of discredit can fall on those who follow.

131, *Embden Street, Manchester.* J. HART.

Sir,—Mr. Schacht's objection to the second clause is intelligible and relevant. He thinks it marks a new departure, for we not only give up the privilege of being the exclusive vendors of poisons, but what is apparently a more serious concession, we recognize the right of

* The obligation upon general traders to use the label "poisonous" would not in any way interfere with the use of the "poison" label, as at present.—ED. PH. J.

outsiders to sell them. It is discouraging that after all our efforts to raise ourselves, we should be obliged to follow what appears to be a retrogressive policy, and to ask the Legislature to distinguish between "poison" and "poisonous"—between a noun and an adjective, or as some might say, between tweedledum and tweedledee.

As a question of abstract principle, Mr. Schacht's view is the correct one, and if we had more legislators, as thoughtful and pharmaceutical as that gentleman, his opinions would be in the ascendant.

But unfortunately, what is right in the abstract is not always expedient, and now that the principles of free trade are so firmly imbedded in our legislation it is hopeless to pass any measure having even the appearance of exclusive dealing. I, therefore, think that the Council in inserting that clause has, however reluctantly, been obliged to yield to the remorseless logic of facts. At the same time the boon is of questionable value to the grocer and drysalter, clogged as it is by the irksome condition of labelling those "poisonous substances" which are to be elevated to the dignity of legislative recognition. Perhaps these "poisonous substances" will burn their fingers in more senses than one.

Sydney Smith once said that railway travelling never would be safe until a bishop was crushed in a collision; perhaps we too may say our true position will never be clearly defined until a dyspeptic Cabinet Minister takes a wrong dose.

A great noise is made when an unlucky mistake occurs in dispensing; but if a record could be obtained of the number of lives and the amount of suffering saved by the watchfulness and skill of the dispenser, the public might then appreciate our services, and generously second our attempts to improve our condition. In my time I have seen prescriptions ordering 7 drachms of prussic acid in a 3 ounce mixture instead of 72 minims; tinct. opii instead of tinct. camph. c. opio; aq. ammon. instead of aq. ammon. acetat., and many such like, which, if literally dispensed would have been mischievous, if not fatal. I am sure thousands could adduce similar testimony to the anxious supervision we all must and do exercise.

I do not see much force in Mr. Schacht's objection to clause 8. It is a just concession to qualified assistants, which I doubt not they will appreciate.

The Bill on the whole I would support with the exception of the 13th clause, compelling the Preliminary examination antecedent to apprenticeship. If the intention be to limit the number of apprentices, it will succeed; but it may put those in country districts and provincial towns to great inconvenience. I think a discretionary power on that point should have been left to us. I believe a large proportion of our best assistants come from those districts, and if they are not so apt to run to brains as town apprentices, they are thoroughly trained in all the manipulative parts of the business. If many, or the most of such are legislated out of existence, I suspect the larger towns will be the losers.

Montrose. GEO. BURRELL.

Sir,—It seems to me that the distinction, in the new draft of a Pharmacy Bill, between substances that are "poisons" and "poisonous," is too fine for Parliament or the public to appreciate. That which has poisonous properties is popularly regarded as a "poison." Should the proposed Bill become law, chemists would continue to label oil of vitriol, for example, "poison," while the huckster would label it "poisonous," and the whole affair would look like a distinction without a difference. If "dangerous" is too general a term, which might be applied to gunpowder, benzoline, and acids alike, they might be severally labelled "explosive!" "highly inflammable!" and "powerfully corrosive!" which would sufficiently warn the public, while the terms "poison" and "poisonous" were reserved for such commodities as are included in the schedules. Some amendment in this direction is desirable.

Ryde. HENRY H. POLLARD.

Sir,—I should feel obliged to be allowed a small space in your pages to express my gratitude to our worthy President and the members of the Council who have devoted so much time and consideration to the Draft Bill, recently presented to us in the *Pharmaceutical Journal.* I feel sure that the same feeling of gratitude will find an echo in the breasts of the majority of country chemists, and it cannot fail to produce an almost unanimous wish that the Bill will be successfully carried through Parliament during the present year. But while I feel grateful for the Bill as at present, I cannot help sympathizing with Mr. Schacht as to clause 2. Those fortunate enough to be situated in towns where medical men do not dispense can scarcely feel on this matter like the chemist whose lot is cast in less pleasant places, and who gets comparatively very little dispensing, but has to contend against drysalters and herbalists, who, in many instances, carry on, to all intents and purposes, a chemist's business, with the exception of the sale of the present scheduled poisons. I feel strongly on this point, because of late we have had many instances in this town where patent medicines have been retailed by the above tradesmen with serious results.

I beg to enclose you a report of a case which came before our magistrates lately, in which a herbalist of this town supplied belladonna root among other things, the result proving almost a fatal one. One of the magistrates himself, in this case, told me shortly after the trial, that the sale of such powerful medicines by incompetent persons must be discouraged.

In another case, a customer of mine assures me that another herbalist in the town "nearly did for his wife a short time ago."

These are doubtless only a few of thousands of cases which occur, and which point to the necessity for more stringent regulations regarding not only "poisonous" articles, but other powerful medicines of the Pharmacopœia. In fact I should wish myself to see the sale of all B.P. preparations reserved to the chemist; but unfortunately chemists cannot always have what they like, and we should feel thankful if we succeed in passing th present proposed amendments.

21, *High Street, Hanley.* EDMUND JONES.

Sir,—I venture to remark on the Bill, printed on pp. 644–646 of the *Pharmaceutical Journal.* Paragraph 4 contains the words "unles sthe box, bottle, package or vessel in which the same is contained, the wrapper, if there be only one, or the outermost wrapper, if there be more than one, be labelled," etc.

Now, I presume that one object sought is to have introduced a higher degree of safety than now obtains, by the addition of the word "poison" to the "vessel," etc., containing such poison so long as any of the poison remains in it. This will not be effected if the immediately containing vessel be not also labelled "poison," as outermost wrappers are commonly destroyed.

The remedy: *after* "is contained" *insert* "and."

Paragraph 2 contains an annoying alteration of terms in use by the introduction of the term "poisonous." Most of us are provided with labels for the five drugs named, *e.g.*, "Nitric Acid, Poison." Why compel us to procure a fresh stock of labels, which are only too seldom used by small men like myself?* And why compel me to label a belladonna plaster "poison" (affixing name and address, that I may be found in case some cuddie's sweetheart be driven by hunger to eat shoeleather), yet oblige me to use the diminutive "poisonous" to the deadly carbolic acid?

Lastly, I should like to see introduced the compulsory prosecution of the unqualified men who sell poisons and poisonous preparations without hindrance under the labels of registered men, with their own labels (and more frequently), with a false one, or none at all.

Farnworth, Bolton. D. OGILVIE EVANS.

Sir,—I wish briefly to mention a few considerations on clause 8, to which I fancy the Council have not given sufficient weight.

Branch businesses, whether defensible or not, abound in some towns, notably here in Liverpool, where there are to my knowledge sixty-seven.

It may be taken for granted, I think, that in a large majority of cases, unqualified men (using the term in a legal sense) have charge of them. Some of these are of middle age, and some married. If this clause comes into force on January 1, 1884, I can foresee that it will produce quite a revolution of the trade here as well as in some other towns.

First. There could hardly be the requisite number of

* See the footnote on p. 733.

"qualified" men ready by that time to take charge of those numerous businesses; and secondly a large number of men would be thrown out of employ, and to some, I fear, it would mean actual ruin, *e.g.*, married men, for the latter would not be required in businesses under the principal.

For my part, I wish branch businesses were not legal; but, seeing that the evil exists, I must go with the majority in the Council in believing that they ought to be regulated. But I differ with them as to the date from which such a great change should commence.

For the sake of the men employed and for the sake of the public, who might be seriously inconvenienced by the sudden closing of some businesses useful to the community, I should advise that another year at least should elapse before that clause is allowed to operate.

Walton, Liverpool. JOHN J. SMITH.

Sir,—The promotion of a new Pharmacy Bill by the Pharmaceutical Society, which is intended to be the consummation of the policy of the last forty years, is an occasion which calls above everything for the loyalty of the pharmaceutical body. No doubt this will be generally felt, but pharmacists will be asking themselves to whom or to what is their loyalty due; and as a looker-on is proverbially best able to see the points of the game, I beg your permission to propose an answer.

The loyalty in question must not be claimed for the Society by reason of anything it has done in the past, though that is the best reason for trusting (or mis-trusting as the case may be) its present action, nor for the memory of those honoured men who guided it through its earlier difficulties, nor for those who preside over it now, except in so far as their administration can be shown to be contributory to the permanent advancement of pharmacy. Sentiment which relates exclusively backward is out of place. Forty years' experience should have taught us something, and may have untaught us some pardonable preconceptions in which it would be culpable to persevere. But whatever has come down to us unaltered through that long array of years brings with it the impress of permanence, and should not be lightly cast aside. It is in behalf of the future interests and permanent credit of pharmacy that the loyalty of pharmacists must be appealed to, to put an end to a vicious anomaly hostile to the welfare and dignity of pharmacy, and to place it in a position as favourable as that which pharmacy has long occupied in other countries which are not more advanced in the arts and resources of civilization than our own. It may be that some surrender of distinctions, laudably earned and honestly prized, must be the cost of this great gain. Happily that sacrifice will be claimed of those from whom the greatest liberality of sentiment and the clearest foresight may be expected, who will not too critically weigh an individual privilege against a collective advantage, and who will respond with the same alacrity as they did on a former occasion to a similar appeal when the equivalent was less attractive.

Has this Bill the sanction of a long and unbroken approval? Is it any better than those that have gone before? These questions involve a review of the past history of pharmacy, and as there is no such history outside the annals of the Pharmaceutical Society, we must be content to go to that source for our facts.

In 1841, preliminary to the formation of the Pharmaceutical Society, the following resolution was adopted by a representative committee of chemists and druggists, viz.:—"That the objects of the Society be (1) to benefit the public, and (2) elevate the profession of pharmacy by furnishing the means of proper instruction; (3) to protect the collective and individual interests and privileges of its members in the event of any hostile attack in Parliament or otherwise; (4) to establish a club for the relief of decayed or distressed members." The Society was founded upon this basis in the same year, and received its first recognition in the form of a Royal Charter of Incorporation in 1843.

The Charter defined its constitution and objects strictly in accordance with the resolution just quoted. In 1852, the Society obtained its first Act of Parliament, which, besides confirming the Charter generally, created a privileged class of registered pharmaceutical chemists who were declared in the preamble to be needful for the safety of the public, but were not endowed with any exclusive rights beyond that of using the name and title of pharmaceutical chemists, so that, as Professor Attfield well said in his address to the Pharmaceutical Conference, the Act of Parliament declared it to be necessary that pharmacists should be qualified, but did not prohibit unqualified persons from acting as pharmacists. Although this Act was passed on the petition of the Pharmaceutical Society, it did not express the views of its promoters. They had submitted a Bill to restrict the practice of pharmacy to duly qualified men; but Parliament could not then be induced to accept such a radical reform, and the Society wisely took what they could get, well knowing how ineffectual it must prove, but knowing also that it carried with it the important element of legislative recognition which gave the Society a *locus standi* for future operations.

The Society promoted another Bill in 1865, in which it was again proposed (this time in pursuance with a suggestion made to the Government by the Medical Council) to restrict the compounding of the prescriptions of duly qualified medical practitioners to registered pharmacists; but that proposition proved fatal to the Bill.

The next and last Pharmacy Act was passed in 1868;* it created a second grade of pharmacists, to be registered as chemists and druggists, and prohibited all other persons than those registered under the Act from using that title. But its really operative clauses are mere regulations for restricting the sale, etc., of certain poisons scheduled to the Act, clauses which reflect the views of the Government of the day rather than those of the pharmaceutical body. It was important as restricting the selling, retailing, dispensing or compounding of these poisons to the persons registered under the Act, which restriction practically, though not expressly, limited the practice of pharmacy to those persons. The provisions are, however, too incomplete to be satisfactory and are not a sufficient security against interloping, the worst of all forms of competition.

The essential feature of the present Bill is the express restriction of "retailing, dispensing and compounding medical prescriptions," that is to say of the practice of pharmacy, to qualified pharmacists. This is a distinctive characteristic of professional status. The Bill also provides for the ultimate extinction of the secondary grade of registered chemists and druggists, and the consolidation of all who practise pharmacy into one class of "registered pharmaceutical chemists," who alone will be authorized in future to carry on the business of pharmacy. These provisions must have the effect of raising the standard of pharmacy, and the status and estimation of those who practise it.

There are other provisions relating to the sale of "poisonous articles" as distinguished from the "poisons" provided for by the Act of 1868. These provisions are more a matter of police than of pharmaceutical politics. There are also provisions for placing the sale of patent medicines under the operation of the poisons law, and certain needful powers for the readjustment of examinations. These clauses do not raise important issues, and those which relate to "poisonous articles" have rather been thrust upon than sought by the promoters of the Bill.

Finally, by comparing these historic events with the manifesto of the embryo Society—its promises and its performances—we shall see how far the quality of permanence attaches to the principles so early propounded.

(1). "The benefit to the public," which occupied the post of honour in the resolution, has continued to appear in slightly modified phrase in the preamble of both Acts and in that of the proposed Bill, viz.:—"Whereas it is expedient for the safety of the public." It is important to bear in mind that the public benefit is the only motive that will induce Parliament to legislate in the affairs of any corporation.

(2). "The elevation of the profession of pharmacy by furnishing the means of proper instruction" has been steadily kept in view. A school and lectures were established as speedily as practicable and have been maintained in full efficiency from 1844 to the present time, not without occasional protest by malcontent members. The

* The amending Act of 1869 is a mere supplement to this Act, too unimportant to be enumerated separately.

Society's laboratory has the proud distinction of being the earliest public laboratory for chemical instruction in this country. Examinations were organized and have been expressly sanctioned by the Charter, and by the Acts of 1852 and 1868, and it is intended to make them still more effectual by further provisions inserted in the present Bill. The way in which the Society has fulfilled its pledge to provide suitable pharmaceutical education and has by various facilities encouraged scientific pharmacy is the chief means by which it has established its claim to public respect and confidence, and has acquired an authority which enables it to exercise a beneficial influence upon legislation.

(3). "The protection of the collective and individual interests and privileges of its members in the event of hostile attacks in Parliament or otherwise" has been fulfilled by the prevention of hasty and impractical legislation, and by the defence of individual chemists oppressed by unjust and vexatious prosecutions. This intervention has not been confined to the protection of its own members, but has been exercised in a catholic spirit on behalf of chemists who do not belong to the Society or contribute to its funds. In addition to this, whatever privileges or exemptions pharmacists enjoy (what they enjoyed when the resolution was formulated it would be hard to say, except the privilege of being let alone) have been secured to them by the vigilance of the Society. Nor will it escape observation that the new Bill aims a more direct blow at unlicensed competition than it has hitherto been possible to deliver.

(4). "The establishment of a club for the relief of decayed or distressed members" has been more than realized by the foundation and consolidation of the Benevolent Fund, which distributes its charity over a wider area than was originally contemplated, under powers introduced into the Act of 1868.

It seems, therefore, that nothing remains to be done of the objects proposed by the founders of the Society, nor so far as I know anything else which has ever been generally accepted by the pharmaceutical body, with the one serious exception of restricting the practice of pharmacy to those whom the law has required to qualify themselves for it. Powers to this effect were sought for in the first application to Parliament in 1852. The application was renewed in 1865, it was unwillingly abandoned after much deliberation in 1868, as being then impracticable, and it now forms the salient feature of the Bill of 1883. Nor has the Society voluntarily introduced new objects which are not fairly accessory to the old,—the poisons clauses, as already stated, having been originated in a quarter too powerful to be resisted.

I submit that the restriction of the practice of pharmacy to qualified pharmacists is a principle which comprehends the whole *raison d'être* of the Pharmaceutical Society, that it is the kernel of the policy which its founders and their successors have been labouring to consolidate for the last forty years, and that, in virtue of these qualities, it demands and deserves the loyal support of all classes of the pharmaceutical body, whether associated with the Society or not. If they give that support cordially and unanimously it is my hope and belief that the present effort will be successful; but if there is a large amount of schism amongst those whom a common interest should unite, it is to be feared that the present favourable opportunity will be lost and that the "elevation of the profession of pharmacy" in England to its rightful position will again be indefinitely postponed.

EX-PHARMACIST.

John Laurie, W. T. Hicks, Associate, Minor Associate in Business and Excelsior.—We believe that in the event of the Bill passing into law it is intended by the Council to propose a bye-law admitting "Minors" to the examination enforced after 1887 under the same regulations as are now in force, and in that way all ground for the objections you raise would be removed.

Henry Long.—We appreciate your remarks on the mischief produced by want of union in the pharmaceutical body on previous occasions, and think you cannot do better than act in the spirit of your remarks by giving the Council credit for having taken into consideration the various points you refer to.

R. Martin.—We do not think that in the present day there is any ground for hoping that the Legislature would entertain proposals for creating an exclusive monopoly, even in the trade in drugs, or that it would consider such a measure desirable for protecting the interests of the public.

One who loves the work but not the pay.—It does not appear to be feasible to attempt to prohibit the establishment of branch shops, though it is eminently necessary to establish regulations as to the mode in which they are carried on.

Local Secretary.—Lozenges and other medicines must contain a deadly dose of poison to bring them within the provisions as to labelling.

Hospital Dispenser.—The class that you refer to is outside the limits of pharmaceutical legislation.

Asinus post prand.—The proposed Pharmacy Bill would not give grocers and others any right other than they now possess of selling the articles you mention; but it provides that they shall not continue to do so without observing certain formalities deemed to be necessary in the interests of the public.

J. Thompson.—With regard to your first two questions, we can only suggest that it has been deemed desirable in the interests of the body to adopt the provisions referred to. With regard to the other point we do not think there is any probability of the Legislature entertaining a proposal to prohibit the sale of patent medicines by tradesmen who are not pharmacists.

E. E. c. R. R.—If you refer to the Bill you will see that it does propose to restrict dispensing in the way you think desirable.

W. T. Hicks.—We fail to perceive any such inconsistency as you suggest. The sale of one article you mention by a grocer or an oilman is illegal, the sale of the other is not, and the provisions of the Bill with regard to the sale of the latter are simply a limitation of existing rights.

J. C. Meacher, Devoniensis and J. D.—These three correspondents, who write to point out the hardships that would be inflicted upon unqualified managers of branch shops, if clause 8 of the Pharmacy Bill were to become law, are reminded that such persons ought to have no great difficulty in acquiring a right to registration by passing the Modified examination, unless they have ignored the provision made in their behalf in the Pharmacy Act, 1868.

A. P. S. (Eng.).—Thanks for your letter, and the information it contains, which we will take care shall be brought under the notice of those whose conduct you approve.

A. B. C.—(1) Syrupus violæ, P.L.: Fresh petals of *Viola odorata*, ℥ix.; boiling distilled water, Oj.; macerate for twelve hours, express and strain. Let the dregs subside and dissolve in the clear liquor by the aid of a gentle heat twice its weight of sugar; when the syrup has cooled add f℥ss. of rectified spirit to each f℥j. of syrup. (2) See papers on pill coating in vol. iv., p. 953, vol. viii., p. 461, and many other places.

T. H. North.—The formula for the preparation mentioned has not been published.

URANIUM OLEATE.*

BY WALTER GIBBONS.

The oleates of the alkalies and those of many other metals are well known to us, but, as far as I have been able to search, an oleate of uranium has not as yet been prepared, nor have I been able to find any mention or suggestion of the same in Watts's Dictionary or similar standard works.

As oleic acid has a great tendency to attach itself to bases, one might expect that it would form a compound with uranium, and I bring this subject before you more with the object of explaining how I have been able to make it in a pure state (by a most simple method) than to claim any particular merit for having been the first to point out, by experiment, that it can be prepared.

The common method of preparing such a compound, would be to make pure barium oleate, add to this the sulphate of the metal, and purify by crystallization from alcohol. This process I found inapplicable in the case of uranium, and therefore tried the following method, with a successful result:—

I prepared pure oleic acid, and to this added in excess uranic oxide (about twice the quantity). This formed a semi-liquid, which, after standing in an atmosphere of hydrogen for twelve hours, solidified. The solid mass, after standing six days, was dissolved in ether and decanted from excess of uranic oxide. The resulting oleate was crystallized from alcohol and dried *in vacuo.*

By this plan a pure oleate was obtained which probably is, like other uranic compounds, an oleate of uranyl (UO_2); thus—

$$UO_2.2C_{18}H_{33}O_2$$

This formula appears to be the correct one from the following figures obtained by combustion:—

	Took of substance.	CO_2 obtained.
(A).	·2046	·385
(B).	·3101	·586
(C).	·3253	·6131

giving an average of ·428 of carbon, the calculated quantity being ·432 for the preceding formula.

The residues from the above three combustions, properly estimated for uranium (see Fresenius's first process), gave respectively the following numbers for uranium:—

Uranium (calculated from oxide obtained)—

(A). ·0582.
(B). ·0885.
(C). ·0931.

Here, again, we have an average of 238, whereas the calculated quantity of uranium is 240.

Taking these two numbers, I think we shall be quite justified in accepting the formula given.

The sp. gr. when freshly prepared is 1·13, but this soon changes owing to the rapid alteration of the compound, which is most unstable. I found that almost immediately on having free access to the air change commenced; therefore it was absolutely necessary for me to keep the compound in an atmosphere of hydrogen. It softens at about 85° C., passing gradually to a liquid of the consistence of treacle, so remaining until a temperature be reached at which it is decomposed.

As yet I know of no medicinal use to which it can be applied; but if in future it be required for outward use, I can recommend it to be prepared by mixing calculated quantities of uranic oxide and oleic acid (using slight excess of the former), and heating on a water-bath for about half to one hour. This will produce a moderately good preparation which should be mixed with some preparation like vaseline or ozokerine to exclude it from oxidizing influences.

[*The discussion on this paper is printed at p.* 752.]

* Read at an Evening Meeting of the Pharmaceutical Society, March 7, 1883.

LIQUID EXTRACT OF CINCHONA,*

WITH DATA ILLUSTRATING THE RESULTS OBTAINED IN ITS PREPARATION BY THE PROCESS OF THE B.P.

BY B. H. PAUL, PH.D.

Some months ago I had occasion to examine a sample of the British Pharmacopœia liquid extract of cinchona and was particularly struck by the fact that it contained only a very small amount of quinine. Provided the liquid extract fully represents the medicinal properties of the bark, as it has had the credit of doing, 35 grains of quinine to the fluid ounce is the proportion that should be present in this preparation when made from bark satisfying the requirements of the Pharmacopœia in regard to percentage of quinine. Instead of this amount, however, I found that in the sample I examined there was less than 2 grains of quinine in the fluid ounce. So great a deviation from what might have been expected in this respect seemed to merit further inquiry, for notwithstanding the fact that the medicinal efficacy of this preparation is not considered to depend exclusively upon the quinine it contains, still quinine is so important a constituent of cinchona bark that it may reasonably be assumed any pharmaceutical preparation claiming to represent this drug ought to contain the quinine as well as the other constituents of the bark from which it is made. I therefore examined several other samples of liquid extract, collected from different sources, and finding that they all agreed in containing but very small proportions of quinine, varying from mere traces up to 2 grains per fluid ounce, I determined to make some further experiments with the object of ascertaining the cause of the deficiency in the amount of quinine. Among the circumstances possibly giving rise to this deficiency there were two which might be anticipated at the outset. First, the well known deterioration in the quality of the "flat calisaya" oryellow bark ordered to be used for the purpose of making liquid extract of cinchona bark by the Pharmacopœia, which has been so great within the last few years that it is now very unusual to meet with a sample of that kind of bark containing anything like the amount of quinine indicated in the Pharmacopœia. Secondly, it has been frequently stated that the process of manufacture ordered in the Pharmacopœia is itself defective, inasmuch as it fails to yield a liquid extract fully representing the medicinal properties of the bark operated upon.

Upon reference to papers in which this subject had been treated of I did not find any precise evidence of the grounds upon which the process of the Pharmacopœia was objected to, beyond general statements of the result of experience, and I therefore determined to put the matter to the test by preparing liquid extract according to the directions of the Pharmacopœia, from bark of known composition, analysing the product obtained as well as

* Read at an Evening Meeting of the Pharmaceutical Society, March 7, 1883.

the residual bark. For this purpose two kinds of bark were operated upon, one an ordinary sample of "flat calisaya," such as is now commonly met with, the other a sample of bark from the Government plantations in India. The following tabular statement of the results thus obtained shows first the amount of alkaloid contained in the bark operated upon, then the calculated proportions of alkaloid which a fluid ounce of the liquid extract made from it ought to contain in order to represent the whole of the medicinal properties of the bark, and lastly, the quantities of alkaloid actually present in the fluid ounce of the product obtained:—

CALISAYA BARK.

1 *lb. containing*—

Quinine	5·50 grains.
Cinchonidine	19·50 „
Cinchonine	101·50 „
Amorphous	21·75 „
	148·25 grains.

Liquid Extract prepared from the above according to the B.P.

	Should contain grains per fl. oz.:—	Found grains per fl. oz.:—
Quinine, Cinchonidine, Cinchonine, Amorphous	37·0	8·6
Quinic and cinchotannic acids, etc.		169·6
Total solid contents (Over 10 per cent. of the bark		178·2

Although the bark here referred to cannot be said to have corresponded with the requirements of the Pharmacopœia, either in the amount of quinine it contained or in being true yellow bark, still the amount of total alkaloid present was quite equal to that indicated in the Pharmacopœia as the proper amount of quinine. But the liquid extract made from it did not contain much more than one-fourth as much total alkaloids as it should have contained if the alkaloids had been perfectly extracted from the bark, and it must therefore be concluded that the deficiency is to a considerable extent due to some defect in the process of preparation as well as to the present inferior character of calisaya bark.

In the case of the Indian bark operated upon in the other experiment, the amount of quinine was nearly as great as the Pharmacopœia requires, while the total alkaloids present amounted to nearly three times as much; but still it will be seen from the following table that even in the liquid extract made from this bark, the proportion of total alkaloids, as well as that of quinine, fell far short of what should have been present if the preparation was to represent the whole of the medicinal properties of the bark, for while a fluid ounce of the liquid extract contained only one-eighth as much quinine as it should do, the total alkaloid did not even equal the half of that quantity, and actually amounted to only one-seventh part of the alkaloid present in the bark used in preparing the extract:—

INDIAN BARK.

1 *lb. containing*—

Quinine	135 grains.
Cinchonidine	134 „
Cinchonine	84 „
Amorphous	44 „
	397 „

Liquid Extract prepared from the above according to the B.P.

	Should contain grains per fl. oz.:—		Found grains per fl. oz.:—	
Quinine	35·75		4·39	
Cinchonidine	33·50		3·50	
Cinchonine	21·00		2·62	
Amorphous	11·00		3·81	
Total alkaloids		99·25		14·32
Quinic acid				46·58
Cinchotannic acid, etc.				134·85
Total solid contents (Nearly 12 per cent. of the bark)				195·75
Deposit after adding spirit				39·70

In order to check these results the residual extracted bark used in the two experiments was examined, and in both cases it was found to contain a large amount of alkaloids, not quite equal, however, to the difference between that in the original bark and that in the liquid extract, the reason for this being that the deposit formed during the concentration of the large volume of liquid percolate was also found to contain a considerable quantity of quinine and other alkaloids, the general result being, as shown below, in the case of the Indian bark.

	Quinine.	Cinchonidine.	Cinchonine.	Amorphous.
Present in 1 fl. oz. liquid extract	4·39	3·50	2·62	3·81
Present in deposit	1·32	1·68	0·91	0·27
Residual bark contained	28·04	28·32	17·47	6·92
Total in 4 ozs. bark	33·75	33·50	21·00	11·00

These results show conclusively that if quinine and the other alkaloids of cinchona bark are to be regarded as constituting an essential factor of the medicinal properties of this drug, the process ordered by the British Pharmacopœia for the preparation of liquid extract fails in a very important particular to furnish a product that can be relied upon as fully representing those properties.

It would seem that the same failure obtains in the case of liquid extract made by other processes, if such there be, for on examining a number of samples obtained from different makers it was found that they all agreed in containing but little quinine or other cinchona alkaloids, as will be seen from the following tabular statement of the results of analysis:—

Grains per fluid ounce.

No.	Dry extract.	Quinine.	Cinchonidine.	Cinchonine.	Amorphous.
1	330	2·81	1·93	1·76	1·49
2	221	1·37	1·71	0·68	4·27
3	192	1·93	1 67	0·35	4·14
4	133	2·73	0·53	0·26	2·11
5	188	0·27	0·44	2·55	6·68
6	236	1·05	0·70	0·53	1·85
7	179	1·90	2·20	1·02	3·66
8	171	0·63	0·18	0·18	0·79
9	48	0·59	0·14	0·29	1·32

It is now nearly half a century since it was laid down as a desideratum in regard to the pharmaceutical treatment of certain drugs, of which cinchona bark was one, that while their medicinal constituents were left unchanged in their natural state of combination, they should be as far as possible separated and removed from every part not possessing remedial virtue. More recently this has been expressed in regard to cinchona bark as the production of some preparation which might justly be regarded as "bark minus woody fibre;" but it is evident from the results above stated that treatment with cold water for extraction, as directed in the preparation of liquid extract, is quite inadequate to attain the object in view, so far as one very important part of the medicinal virtue of cinchona bark is concerned. From a chemical point of view, moreover, it is at the present day easy to perceive why this should be the the case, since there is good reason for believing that only small fractions of the alkaloids in cinchona bark exist in such a state of combination with quinic acid that by reason of the free solubility of the quinates of the alkaloids they can be extracted on treating the bark with cold water. By far the greater part of the alkaloids, probably at least four-fifths, is combined with the cinchotannic acid of the bark, forming salts that are but very sparingly soluble in water, even with the aid of heat.

If, therefore, it be desirable from a medical point of view to unite in a concentrated form—such as the liquid extract purports to be—the several medicinal constituents of cinchona bark, alkaloids as well as others, recourse must be had to improved chemical knowledge of bark for the purpose of devising a method by which this pharmaceutical desideratum may be made practicable.

In order to furnish some basis for a comparative estimate of the merits of the liquid extract and other Pharmacopœia preparations of cinchona bark, it will, perhaps, be useful to show what relation they bear to each other from a chemical point of view. For this purpose an infusion and a decoction were prepared according to the directions of the Pharmacopœia from the Indian bark above referred to.

One pint of infusion (made from 1 ounce of bark containing 25 grains total alkaloids) was found to yield, on evaporation, dry residue amounting to 74·5 grains, and containing 4 grains of total alkaloids, or rather more than one-sixth part of the alkaloids in the bark used.

One pint of decoction (made from 1·25 ounces of bark containing 31·17 grains total alkaloids) was found to yield, on evaporation, dry residue amounting to 174 grains, and containing 7·70 grains of total alkaloids, or nearly one-fourth part of the alkaloids in the bark used.

These results are of such a nature as to justify the conclusion that both the infusion and the decoction are, pharmaceutically, better preparations than the liquid extract, which, as shown above, renders available only one-seventh part of the alkaloids in cinchona bark, and, as usually met with, contains only a very small proportion of quinine or other alkaloid.

[*The discussion on this paper is printed at p.* 753.]

MICROCHEMICAL REACTION METHODS.*

BY A. TSCHIRCH.

The author describes the great advantages of the microscope in technical chemistry, especially in the examination of food, and expresses regret that many chemists consider their laboratories complete without such an instrument: he enumerates many examples of its usefulness, such as starches, textile materials, etc.; even in the domain of pure chemistry, its application is necessary in the hæmatin reaction for the detection of blood stains, the composition of urinary deposits, the search for strychnine, atropine, etc.

These advantages led to its more extensive employment in pure chemistry, and the name of microchemistry was given to it by Döbereiner. The author thinks that microchemistry must always be distinguished by a series of colour reactions; that in the same manner as the changes of colour, etc., in experiments on the large scale are examined in the test tube, so must they be similarly observed on the slide of the microscope. The actual process is simple. The objects to be examined must be either in thin sections, fine powder, or as fibres; a drop of the reagent is placed on a slide and allowed to flow slowly towards the object, the operator observing through the instrument. Many physical as well as chemical changes may thus be detected: expansion or contraction, refractive changes, commencement of coloration, evolution of gas bubbles, solution, etc. The iodine starch reaction of Stromeyer was the first to be employed with the microscope; from it is learned the topography and division of starch in plants, the way it is stored up, and the process of its conversion; this reaction has also taught the difference between pure cellulose and woody fibre and the nature of intercellular substance. The reactions with zinc chloride and iodine, and with sulphuric acid and iodine, are also striking instances of the value of microchemistry, affording an easy method of distinguishing vegetable from animal fibres, the first colouring pure cellulose violet, and the second dissolving it with an intensely blue colour, the lignin encrusting the fibres having been previously removed by maceration in nitric acid, alkalies, or Schultze's maceration fluid. Thus sulphuric acid and iodine stain cork dark-yellow, thereby affording a trustworthy test for all membranes or sections containing suberin. The solubility of pure cellulose in "cuoxam" discovered by Schweitzer is also credited to microchemistry; the reagent may be prepared by digesting copper turnings in concentrated ammonia, or by decomposing a concentrated solution of copper sulphate with ammonia until the precipitated hydroxide is redissolved.

The maceration process of Schultze is a valuable aid to operations in microchemistry; the substance is treated with nitric acid and potassium chlorate either in the cold, or in cases of obstinate samples, is boiled for a short time, when the cells are isolated by the solution of the intermediate lamellæ. Amongst the instances given of its utility in food analysis is the separation of those peculiar cells of radiating branchial form which exist in the tea leaf, and are not found in other leaves used for its adulteration (they are, however, found in some of the camellia family).

This treatment has also the advantage of dissolving the coloured incrustations of cinnamon, roasted coffee, etc., and leaving the substances ready for further examination. Potash plays an important part in microchemistry, as it renders many objects transparent which are not made so by other reagents; it was by successive treatment with potash solution, acetic acid, and iodine that Böhm was able to perceive in chlorophyll the small particles of starch which had hitherto escaped observation. The most striking success in the science is that of Sachs with Trommer's sugar test which, with slight modifications, enables the microscopist to identify, and even estimate quantitatively, cane- and grape-sugar, dextrin, gums, and albuminous substances in single cells.

The author alludes to the tinctorial methods which are employed in the examination of microbes, but which do not come under the strict domain of chemistry; he urges more extensive use of the microscope, together with the micropolariscope and spectroscope, and the study of botany and physics amongst chemists.

The Pharmaceutical Journal.

SATURDAY, MARCH 10, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACY ACTS AMENDMENT BILL.

ALTHOUGH we were unable in the previous article to do more than refer to certain general considerations respecting the Pharmacy Acts Amendment Bill, it must not be inferred that there were not other features of the Bill which would admit of being recommended to the favourable consideration of our readers. But we do not consider that the work which has been the result of long and laborious deliberation on the part of the Council is really in any need of such recommendation to the favourable consideration of thinking members of the trade. We still continue to receive evidence in support of this view, and though the demands upon our available space this week do not admit of our inserting more than one of the letters we have received on the subject, endorsing the work that the Council has done, that one comes from a source that will generally be admitted to be so deserving of respect,—and, we may say obedience to its dictates,—that we have considerable confidence in referring to it as a guide by which intending critics of the Bill may do well to gauge the desirability of their indulgence in adverse comments.

So far we may, without much danger of refutation, assume that the expressions of opinion upon the Bill are decidedly in its favour. The objections that have been raised are either based upon misconception, or upon a too ardent desire to have things as it may be contended they should be rather than in accordance with what can be at the present time. If the letter of Mr. WADE be taken, as we think it fairly may be, to represent the extreme of opposition to the Bill, we fail to perceive in it any adequate ground for the position he takes. In the first place he objects to the result of the Council's labours, because they appear to him to have been entirely on behalf of the public. On what other base, we might ask Mr. WADE, does he believe an amendment of the Pharmacy Act could be reasonably sought for? So far from such a motive and recommendation being decried, is it not to be regarded as the only feasible consideration under which a claim for legislative consideration can be urged by pharmacists? We have already said enough upon the circumstances which have led to the drafting of the Bill to make it evident that this feature of it cannot be ignored. Whether members of the Society will be materially interested or not by an enactment which would compel others not being registered chemists to label half a dozen articles "poisonous" is not the question; but it will be important, in the event of the Bill becoming law, to know that the Society has contributed to bring into operation outside the drug trade an observance of such regulations and precautions in the dealing with dangerous articles as chemists observe themselves and consider to be essential. In regard to patent medicines again, will not the use of poison labels in necessary cases contribute to relieve the registered chemist of responsibilities that are sometimes cast upon him now without reason? Absolute prevention of fatal accidents from negligence cannot perhaps be secured by any systematic observance of precautionary measures, but much of the personal inconvenience arising from incidental connection with such accidents may be thus avoided.

Mr. WADE's objection to the clause relating to branch shops involves the erroneous assumption that co-operative stores and other corporate bodies would be at liberty to carry on dispensing and chemists' retail business by engaging men on the register to conduct their business, and on that ground alone it fails to have any validity. But what is more to the point, Mr. WADE seems to forget that so long as a chemist's branch business can be carried on by an unregistered assistant there is no ground for objecting to the kind of business he deprecates. If it be made compulsory for the continuance of a branch business that it shall be under the control of a legally qualified assistant, the state of the case, so far as the public are concerned, would be no different from that which would obtain if that legally qualified assistant were in business on his own account, while at the same time there would be the further guarantee of public safety that the actual proprietor of the business was himself a qualified and competent man, who in his own interest would take care that the business was properly conducted.

Lastly, Mr. WADE's objection to the Bill because it does not provide for a legal division of prescribing and dispensing is one that indicates such a flagrant disregard of legislative possibilities as scarcely to merit serious comment. Such a division of labour between medical practitioners and pharmacists may indeed be wished for, but not by any sensible man otherwise than as a dream of the future for the ultimate achievement of which much yet remains to be done.

In satisfactory contrast to Mr. WADE's objection, are the communications addressed to the Council by the Committee of the Liverpool Registered Chemists' Trade Association and by the North

British Branch of the Society, which may be referred to as manifesting a more reasonable view of the measure intended to be presented to Parliament for the amendment of the Pharmacy Acts, and, as we believe, a better appreciation of what can be done for the advancement of pharmacy. We trust that the disposition to support the Council thus shown will be still more generally expressed, and that on the present occasion there may not again be reason to lament a want of unity, such as led to the partial failure of former efforts.

TELEPHONES.

In the second of the series of lectures on the applications of electricity, organized by the Institution of Civil Engineers, Sir Frederick Bramwell gave a most interesting account of the invention and development of the telephone and allied instruments. Prior to the invention of the telephone it was known that by making and breaking circuit at a transmitting station sounds, such as the striking of bells, could be produced at a receiving station; but these effects were independent of any corresponding sound at the transmitting station, and were analogous to those now utilized in audible telegraphy. It was also known that in a similar way the note given forth by a musical instrument could be transmitted; but it was only the note corresponding to the number of vibrations making and breaking contact within a certain time that was heard at the receiving station, and the sound was the same whether the note was derived from a tuning fork, a violin string or a clarionette. In 1862, Mr. Reiss succeeded in reproducing tones, and it is said even words, and in 1874 Mr. Barlow exhibited to the Royal Society his "logograph," by means of which he was able to depict upon a travelling band of paper the motions derived from the vibrations of a membrane under the influence of speech, but, unfortunately, the vibrations for the same syllable were found to vary with the speaker and circumstances.

The goal came in view when Professor Graham Bell, having demonstrated that the variations in the electric current, either direct or reversed, caused by break and make, are too abrupt for the reproduction of articulate speech, proposed to attain his object by keeping the circuit closed, and causing rises and falls, or reversals, as the case might be, of electricity, which should be made gradually, instead of abruptly. In one of the earlier forms of the "Bell transmitter," this was effected by placing in the neighbourhood of a permanent magnet, surrounded by a coil of insulated wire, an iron or steel diaphragm, which upon being set in vibration by the voice should induce in the coil reversed currents of electricity that could travel along a wire connecting it with the coil of a similar instrument at the receiving station, and by varying the power of the magnet there set up similar vibrations in the corresponding metal disk, which being communicated to the air should reproduce a *fac simile* of the original sound. Other modes were also devised by Professor Bell, such as the use of a battery in the line wire, and the use of two local batteries to send the current to a primary coil round a core, the line wire being connected with secondary coils acting by induced electricity. But as transmitters these instruments were necessarily somewhat feeble, since the operative electricity was dependent upon the microscopic movements of the disk set up by the sound waves produced by the speaker. The instrument most in use at the present day is the carbon transmitter devised by Mr. Edison, in which the vibrations of the disk—not necessarily metallic—are caused to operate upon a small block of carbon introduced into the circuit of a battery. The almost inappreciable variation in pressure due to the vibration of the disk is sufficient to alter the conducting power of the carbon and to cause varying currents to be transmitted along the wire to "Bell receiver" at the opposite end. Mr. Edison has also invented a "chalk receiver," in which he utilizes the fact that the friction produced by rotating a cylinder of chalk, adjusted so that its periphery presses against the edge of a stem attached to the centre of the disk, varies with the electric current passing through the cylinder. As in this case power is derived, not from the electricity, but from the hand of the operator turning the cylinder, considerable loudness is obtained. Other instruments referred to by the lecturer were Professor Hughes's "microphone," by which the most minute sounds are rendered audible; Mr. Edison's "phonograph," which records the vibrations produced in a disk under the influence of speech on tinfoil, in such a way that they can be reproduced at pleasure; and Professor Bell's "photophone," in which the variations produced in the conductivity of a selenium cell through vibrations set up in a beam of light by sounds received on a disk in connection with a mirror allow of the sounds being reproduced without the intervention of any wire between the transmitter and the receiver.

In the United States the telephone is used more freely than in this country, the city of Washington, with 120,000 white inhabitants, having 800 telephones. In England the spread of the telephone has been retarded to some extent by legal disputes, but it is now making considerable progress. On the 28th of February, 1881, there were, independently of private lines, 845 subscribers to the London Exchange of the United Telephones Company; on the same day in 1882 this number had increased to 1505, and in the present year to 2541. The use of the telephone by each subscriber has also augmented, until it now averages 7½ calls per subscriber daily, which for a subscription of £20 per year represents a cost of 2*d.* per call, usually involving a message each way.

On Thursday evening Lord Carlingford introduced into the House of Lords a "Bill for the Consolidation and Amendment of the Law relating to Medical Practitioners," which was read a first time and ordered to be printed. The second reading is fixed for Thursday next, but up to the time of going to press the Bill had not been issued.

* * *

Recently allusion was made to the omission from the Partnerships Bill of the clauses in which last year it was proposed to deal with the Registration of Firms. These have now been introduced separately as a "Bill for the Registration of Firms and of Persons carrying on Business under Names or Styles other than their own." It contains a provision that "every firm carrying on business or having any place of business in the United Kingdom, under a firm name which does not consist of the full or the usual names of all the partners or all the acting partners without any addition" shall effect registration under the Act, and among the particulars to be supplied to the Registrar are "the full name, usual residence, and other occupation, if any, of the person or persons carrying on the business."

* * *

A similar course has been taken with respect to the provisions for the establishment of limited partnerships, which have now been brought in as a separate Bill. The limited partnership proposed would necessarily contain one or more persons, called "general partners," who would be jointly liable for all the debts and obligations of the firm, and one or more persons to be called "limited partners," who would only be liable to a certain specified extent. Under these conditions it is satisfactory to find that the Bill would render compulsory the registration of such firms with the names, residences, and usual occupations of all the partners, both "general" and "limited."

* * *

By the courtesy of the Registrar we have received a copy of the Calendar of the Pharmaceutical Society of Ireland for 1883, and we regret to observe that although the number of Pharmaceutical Chemists in Ireland is 219, or 18 in excess of that of last year, the number of members of the Irish Society is only 81, showing a decrease of 11. Of these 81, 18 were named in the Act, 2 are Life Members, and 61 are Subscribing Members.

* * *

According to some statistics published in the *Journal de Pharmacie*, 200 first class students in the Superior School of Pharmacy, Paris, went up at the conclusion of last term for the final examination at the end of their studies; of these 161 passed, and 39, or 19·5 per cent., failed. There were also 204 second class candidates, of whom 93, or 45·4 per cent., were rejected.

* * *

The Committee which has been nominated to report upon the Bill for the amendment of the law regulating the practice of pharmacy in France, recently introduced into the Legislative Assembly by M. Faure, consists of two medical men, two pharmacists, one druggist, a literary professor, and five lawyers.

* * *

According to the *Lancet*, a recently issued 'Additamentum ad Pharmakopœam Hungaricam' includes carbolized catgut, carbolized silk, salicylic gauze, salicylic wool, and carbolized drainage tubes.

* * *

In bringing the subject of the new United States Pharmacopœia before the Boston Society for Medical Observation, at a recent meeting, Dr. B. F. Davenport made some pertinent remarks upon the practice of prescribing proprietary preparations, for which he said physicians in the United States had now no excuse. "What encouragement," he asked, "is there to pharmacists to become skilful and expert if the physicians make no demand upon them, but oblige them to send to a distance for preparations which they could make as well or better themselves? Any apprentice could pass over the counter and take pay for ready-made preparations. The pharmacist thus defrauded of his proper functions . . . . is degraded to the vocation of a mere shopkeeper."

* * *

Dr. Davenport further referred to the injury resulting to medical practitioners themselves through their thus promoting the keeping in stock of the very medicines they are accustomed to prescribe, done up in convenient packages, accompanied with full particulars as to the diseases they are supposed to cure, the doses, and method of administration. He pointed out that the druggist has the opportunity of becoming just as familiar with such medicines as the physician, since both get all their information from the printed wrappers, and he asked why a patient should go to a physician when a druggist can show him his own physician's printed certificate that the contents of a certain bottle are the best cure for the disease from which he is suffering.

* * *

An Evening Meeting of the North British Branch will be held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday next, the 14th inst. The papers announced are a "Descriptive Note of a New Form of Hot Air Chamber, suitable for Pharmaceutical Purposes," by Mr. Thomas Maber; and "An Examination into the Acetic Ether of Commerce, with Suggestions for the Improved Manufacture thereof," by Dr. Inglis Clark.

* * *

The Anniversary Meeting of the Chemical Society is to be held on Friday, the 30th inst., at 8.30 p.m. At the ordinary meeting on Thursday next a paper will be read on "Some Condensation Products of Aldehydes with Acetoacetic Ether and Substituted Acetoacetic Derivatives," by Mr. F. E. Matthews.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, the 14th inst., when a paper on "Porcelain, its Manufacture and Composition," will be read by Mr. Herbert Cracknell.

* * *

At a preliminary meeting held on Monday last, the students attending the School of Pharmacy decided to attempt the formation of a Cricket Club. With this object an adjourned meeting will be held in the Society's house on Tuesday next, at 8.30 p.m., at which students and assistants desirous of joining the club are invited to attend.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, March 7, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Ball, Henry.
Dangerfield, William Henry.
Deeks, William Thomas.
Prosser, Frank Henry.
Wilson, Joseph.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Cherrington, Geo. Widdowson...Newark-on-Trent.
Dangerfield, William Henry ...London.
Nicholson, Richard ....Darlington.
Prosser, Frank Henry ....Coleshill.

Chemist and Druggist.

The following registered chemist and druggist, who was in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society:—
Paterson, James ....Aberdeen.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Adams, Benjamin..................Mansfield.
Bainbridge, Arthur ....Acton.
Beall, Samuel Smart ....Cambridge.
Bostock, Samuel Pass ....Hyde.
Clarke, Ethelbert...................Forest Hill.
Davies, John Myrddin ....Swansea.
Fletcher, Ellis ....Atherton.
Freeman, John Henry............Lower Tooting.
Gardner, Charles Edward ....Colesberg.
Hill, Francis.........................Macclesfield.
Moore, Frank Philip ....Dumfries.
Morgan, Alfred William.........Chatham.
Pritchard, Lewis T. Richard ...Aberavon.
Wood, William Arlington ......Bradford.

Modified.

Garrett, Thomas Philip ....Newport (Mon.).
Steeper, Samuel ....Swineshead.

ASSOCIATES.

The following, having passed the Minor examination and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Barlow, Arthur.......................Hull.
Boyd, Alexander ....Glasgow.
Caffyn, Ernest John...............Crawley.
Clague, Thomas Maltby ....Douglas.
Corder, Edward ....Norwich.
Doo, James Emile ....Atherstone.
Hadfield, James Havelock ......Manchester.
Heyes, Thomas Harry ....Bolton.
Houfe, Robert William ....York.
Jenkins, Thomas ....Swansea.
Lockyer, Joseph Ernest ....Deptford.
Mason, Hubert Huxley ....Clevedon.
Mitten, Flora ....Hurstpierpoint.
Neve, Annie ....London.
Ranken, Charles ....Sunderland.
Rees, David ....Newcastle Emlyn.
Sewell, Edward Ernest ....Whitby.
Smith, William Thomas ....Bath.
Stacey, Frederick Charles ......London.
Thompson, Charles Letchford...London.
Thompson, Frederic...............Scarborough.
Turner, Alexander ....Dumfries.
Woolliscroft, Henry...............Wrexham.
Young, Robert John ....Bideford.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Abbott, Herbert Edw. Tripp ...Lowestoft.
Arthur, John.........................Chesterfield.
Atherton, Albert George.........Tunbridge Wells.
Badcock, Henry Southgate R...South Petherton.
Barrett, Arthur Albert ....London.
Benjamin, John Blake............Brecon.
Bishop, Cecil.........................Brading.
Chattaway, William...............Leicester.
Cuff, Joshua Harcombe ....London.
Davis, Francis M. ....Leominster.
Deck, Arthur Albert ....London.
Dorning, Herbert Rigby ....Chorley.
Fletcher, Francis Round.........Netherton.
Hacon, Elizabeth Constance ...London.
Hayton, William Pattinson......Wigton.
Henderson, John George.........Middlesboro'.
Jackson, Albert Ernest ....Ipswich.
Jones, James ....Newcastle Emlyn.
Jones, Richard Alan ....Holyhead.
Kingston, William Richard .. London.
Lane, Henry ....Wednesfield.
Livesey, William Forrest ......Preston.
May, Samuel Augustus ....Jersey.
Owen, David James...............Swansea.
Parkinson, Joseph, jun. ....Preston.
Payne, William ....Wendover.
Perkins, Frank ....Newcastle-under-Lyme.
Price, Charles Cleaver............Bristol.
Riddiough, Fred. .. ..Leeds.
Rutter, William ....Masham.
Smith, Edwin ....Pendleton.
Somerville, Wm. Alexander ...Chorley.
Spyer, George Nathan............London.
Stevenson, Geo. S. Cartwright...Portobello.
Steward, Josiah William.........Bridgnorth.
Wallbridge, John George ......Liverpool.
Widgery, John ....South Molton.
Wokes, Thomas Siminson ......Hull.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restorations to the Register.

The following persons having severally made the required declarations and paid a fine of one guinea, their names were restored to the Register of Chemists and Druggists:—

David Lindsay Macfarland, 503, Lawnmarket, Edinburgh.
William Rangeley Radford, 4, Enfield Road, South Kingsland, London, E.

ADDITIONS TO THE REGISTER.

The Registrar reported that—
William Adams, 19, Dudley Road, Birmingham; and
Edward W. Lane, Dameagnes Street, Nottingham;
having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been duly supported by qualified persons, their names had been placed on the Register.

LOCAL SECRETARY.

Mr. Garrad Baker was appointed Local Secretary at Chelmsford, in place of Mr. C. P. Baker, deceased.

AUDITOR'S REPORT.

The Secretary laid on the table the Auditor's Report for the financial year ending, December 31, 1882.

Several remarks were made upon the figures, the Council going into committee for the purpose.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee recommended the payment of several accounts; that £800 be invested in Consols on account of the Benevolent Fund; and that £3000 New Two and a Half per Cent. Stock be purchased on account of the General Fund. It also stated that the Committee had considered the desirability of changing the mode of investment of the Society's funds, and recommended that a portion, not exceeding three-fourths of the invested capital of the Society, be re-invested as occasion might offer in freehold ground rents or freehold land, and that the President, Vice-President and Treasurer for the time being should be constituted a committee to watch such opportunities as may appear to them desirable to secure investments for the Society either in freehold ground rents or freehold land.

The PRESIDENT explained that the Committee had thought it desirable to purchase New 2½ per Cent. stock, instead of Consols or New 3 per Cents., because while the return per cent. was only 1*s.* 3*d.* less there was a probability of this Stock rising in the market, and it was considered likely by financiers that the Three per Cents might be paid off at par at no distant date, and this would entail a loss. The main point, however, in the report was that which recommended the investment of a portion of the funds in ground rents or suitable freehold land. The Society was authorized by the Charter to invest in such securities, though not in debentures, and the high price of Consols and New Three per Cents had led the Committee to think that it would be desirable to invest some of the Society's property in freehold ground rents, which would yield an interest approximate to that which was now received, with a possibility and probability of getting a greatly increased income at a future time. The question had been discussed on several previous occasions, but Government Stocks had then always been at a much lower price than now, and the advantage attending investments in them of being realizable at any moment had hitherto led the Council not to entertain the proposal. But now that the property of the Society was considerable, about £20,000 on the General Fund Account, and a similar amount on that of the Benevolent Fund, the question whether some portion of it could not be so dealt with as to give a prospect of greatly increased benefit in the future was of considerable importance. Freehold ground rents were not unfrequently in the market; they paid in some cases 3 per cent. only, in others as much as 4 per cent., the rate varying according to the time at which the reversion would fall in. The Committee was of opinion that, with regard to the General Fund, if an investment could be obtained which would return even only 3 per cent. it would be wise to take it, looking to the probability of a much larger return in future. Freehold ground rents were generally secured by property of an annual value of at least five times the amount of the ground rent. By purchasing ground rents which had fifty or sixty years to run the Council would be investing in a way which need not diminish the present income, and at the same time would be providing increased means for carrying on the Society by its successors in future years. With regard to the General Fund, as it was not absolutely necessary that the whole of the interest now received should be maintained, it was suggested that the endeavour should be to select for investment ground rents which would fall in at an early date rather than to obtain the highest rate of interest; but with regard to the Benevolent Fund, it would be desirable to buy ground rents having a long term to run, in order to obtain as large a present income as possible. Nearly all the Consols now standing in the name of the Society had been purchased at about 90, so that at the present price a considerable profit would be obtained on the sale, for re-investment. As to the purchase of land, it was not intended to buy large pieces of land, and cut it up in building lots, or to speculate in land in any way; but if it happened to come to the knowledge of the Committee that there was a field on the outskirts of town, on which there was a moral certainty that buildings must be erected sooner or later, the land might be purchased and let for building purposes. It could not be expected that such opportunities of investment would be found every day, and, therefore, the Council was asked to authorize the immediate investment of cash in hand as stated in the report, and that the President, Vice-President and Treasurer should have power to look out for opportunities for re-investment in ground rents or land to the extent of not more than three-fourths of the total amount of invested capital. By this means it was hoped that the present income for benevolent purposes would be secured, and that in thirty or forty years' time the Society would be placed in a much better financial position than anyone could now contemplate.

The Council went into committee to discuss this matter. On resuming, it was moved by Mr. GREENISH and seconded by Mr. SYMES—

"That the report and recommendations of the Finance Committee be received and adopted."

An amendment was moved by Mr. WILLIAMS—

"That the report and recommendations of the Finance Committee be received and adopted, with the exception of that portion which recommends the re-investment of part of the Society's funded capital."

Mr. RICHARDSON seconded the amendment, which was put to the vote with the following result:—

For the Amendment.—Messrs. Bottle, Richardson and Williams.

Against:—Messrs. Andrews, Atkins, Borland, Butt, Carteighe, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Robbins, Savage, Schacht, Squire, Symes, Woolley and Young.

Mr. HAMPSON then moved another amendment, which was seconded by Mr. RADLEY—

"That the report and recommendations of the Finance Committee be received and adopted, with the exception of the recommendation to re-invest a part of the Society's funded capital in freehold land."

The Council divided, with the following result—

For the Amendment:—Messrs. Atkins, Borland, Bottle, Gostling, Hampson, Radley, Savage and Squire.

Against:—Messrs. Andrews, Butt, Carteighe, Churchill, Greenish, Hills, Robbins, Schacht, Symes, Woolley and Young.

Mr. Williams and Mr. Richardson were present, but did not vote.

The original motion was then put and carried.

EDUCATION AND EXAMINATION.

The following report was presented:—

Report of a Committee consisting of the President, Vice-President, Messrs. Bottle, Greenish, Hills, Schacht and Symes, appointed by the Council in July, 1882, (*Pharm. Journ., July* 8, 1882, *p.* 35), *for the purpose of considering the best method of giving effect to the resolutions of the Council of April* 5 (*Pharm. Journ., April* 15, 1882, *p.* 845), *upon the report of the Special Committee appointed to inquire into the relation to each other of Pharmaceutical Education and the Pharmaceutical Examinations,—and of reporting thereon to the Council; together with any suggestions it may desire to advance as the result of its deliberations.*

The Committee considers it unnecessary to recapitulate the various steps by which the subject of its report has reached its present position. It has nevertheless endeavoured to weigh with due care every fact and consideration that has arisen throughout the investigation; and it now desires to present a series of recommendations, which to some extent modify and amplify those previously presented to the Council.

Recommendations.

The Committee recommends the following as the course to be required of every candidate for qualification to practise pharmacy.

1st. The candidate must pass the Preliminary examination of the Pharmaceutical Society, or one of the examinations the certificates of which are accepted in lieu thereof, and be registered as a Pharmaceutical Student.

2nd. The pharmaceutical student must then enter the pharmacy of a pharmaceutical chemist, or a registered chemist and druggist who keeps an open shop, as apprentice or pupil, or in some other capacity as a learner; and be so employed for three years.

Note.—During these three years he may or may not, at discretion, attend one or more of the courses of lectures that form part of the "curriculum" approved by the Council in April, 1882 (*Pharm. Journ.*, April 15, 1882, p. 846).

3rd. After the expiration of the three years shop experience, the pharmaceutical student is eligible to offer himself for the *first portion* of the qualifying examination on production of evidence of registration as a pharmaceutical student and of having been employed for three years subsequent to such registration in the shop of a pharmaceutical chemist or a registered chemist and druggist.

This *first portion* of the qualifying examination to be a written one and to include the following subjects:—Prescriptions, Pharmacy and Theoretical Chemistry.

This *first portion* of the qualifying examination to be conducted in London, Edinburgh, and such a number of centres in the provinces as will allow the superintendence of each examination by a member of the Board of Examiners.

4th. An interval of not less than *one year* must elapse between the date of passing the *first portion* of the qualifying examination and the date of entering for the *second portion* of that examination. During that interval the above-named "curriculum" *must be completed.*

5th. On entering for the *second and final portion* of the qualifying examination, the pharmaceutical student must produce evidence of being twenty-one years of age and of having fulfilled the conditions mentioned in the previous paragraph.

This *second and final portion* of the qualifying examination to be practical and "*vivâ voce*," and to include the following subjects:—Practical Dispensing, Botany, Materia Medica, and Chemistry.

This *second and final portion* of the qualifying examination to be conducted in London and Edinburgh only.

With respect to the "Curriculum" of study already approved by the Council (*Pharm. Journ.*, April 15, 1882, p. 846), the Committee recommends that in the announcement with respect to the time to be occupied in the suggested course of Practical Chemistry the following modification be made.

Instead of—

"*Time*: 5 months, 3 hours daily,
or
3 months, 5 hours daily,"

Read—

"*Time*: 10 months, 2 hours daily,
5 months, 3 hours daily,
or
3 months, 5 hours daily."

And in the foot-note that accompanies the above notice

Instead of—

"A modification of the time to be occupied in this course would be accepted provided such modified course extend over a period of not less than three months, and that not more than five hours in any single day are occupied in its work."

Read—

"A modification of the time to be occupied in this course will be accepted provided such modified course extend over a period of not less than three months, and not more than twelve months, and that not more than five hours in any single day be devoted to practical work."

The Committee further recommends that these recommendations and those previously adopted by the Council be incorporated into the bye-laws, according to existing regulation, and that they be announced to come into force on and after December 31st, 1887.

NOTE.—The effect of this will be that all candidates who shall pass the Preliminary examination AFTER December 31, 1883, will NOT be eligible to present themselves for the first portion of the qualifying examination until the expiration of a period of three years from the date of their having been registered as having passed the said Preliminary examination. During these three years they must be engaged in acquiring shop experience. They will also be required to produce certificates of having passed through the curriculum of study already adopted by the Council before presenting themselves for the final portion of the qualifying examination.

Candidates who shall have been registered as having passed the Preliminary examination BEFORE December 31, 1883, will be eligible to present themselves for the Minor examination, under the regulations now in force, during and up to the end of the year 1887.

———

Mr. SCHACHT moved:—

"That the report and recommendations of the Education and Examination Committee be received and adopted."

He said he should not trouble the Council with any remarks, the report having been in the hands of the members for nearly a month, and he hoped that it had received thorough attention. It would be recollected that at the date named in the preamble a series of resolutions was adopted by the Council. On that occasion he found himself, with some other gentlemen, in a minority on certain points, but they thought it was possible that further consideration might alter the opinions of some of the Council, and it was fair to state that some of the recommendations contained in their report did refer to some of those points about which there was then a difference of opinion. The considerations which then led the minority to certain conclusions had been amplified and extended in certain directions, by which he ventured to hope that the matter being broadened over they might find themselves on more common ground. Those points referred to what was called clause 4 in the old recommendations; he would simply say that in the recommendations now presented, the whole process by which the student should accomplish his qualification was tabulated in a manner which was thought to be the most easy way of suggesting improvements for the future. With reference to the differences between these recommendations and those adopted by the Council last April, there was the division of the final technical examination into two portions, one of which was to be as it were preliminary, and the other final. The Committee thought that the first portion might fairly be conducted in the provinces, notwithstanding there would be many who would be tempted to dissent from that if it were the final and qualifying examination, but as it was simply preliminary to the final, the Committee thought the objections were not such as to over-ride the advantages which would attend such a division. In addition to that it was thought that the ease with which the whole business of the examination could be conducted was such as would justify its adoption; the comfort to the candidate, and the absolute certainty with which it could be conducted would overbalance any disadvantages. It would also be noticed that the final portion was distinctly declared only to be capable of being conducted in London and Edinburgh at present. The further alteration was that the time to be occupied in one portion of the curriculum, that which applied to practical pharmacy, should be capable of extension to a longer period, the purpose being to permit those who had the opportunity of taking up their practical chemistry during the time of pupilage to do so, so that they might devote more time afterwards to other portions of their work. He must say with regard to this ideal scheme of training, that on considering it very carefully, he had failed to detect any spot in it. It seemed to him to be the most exactly correct process by which it could be hoped to train the future pharmacist which his mind could conceive. It might, perhaps, present certain difficulties, but the whole result would be so great a gain on the system which at present existed, that he most sincerely hoped that his colleagues would see their way to its adoption.

Mr. Symes seconded the motion.

Mr. Hampson said he wished to move an amendment, but it must not be supposed that because he did so he had an antagonistic feeling towards any sound educational scheme. He believed in education all round, and, therefore, it was with considerable diffidence that he took exception to certain parts of the report. He did, however, take exception to the third, fourth and fifth recommendations and would move as an amendment that those be omitted. About twelve months ago he felt it necessary to retire from the Committee, when the first report was presented to the Council, and a vote taken with the result that the fourth recommendation was eliminated. He still held the same views as he did then, and he would briefly state his reasons for so doing. He must first go back to the time when this educational inquiry took place, and if he went far enough it would be found that the inquiry merely sprang out of the astute brain of one of their professors. No doubt he represented a certain amount of professorial opinion; he represented the impression that there was a great deal of cramming going on and this was really a sort of anti-cram inquiry. So far so good, and he admitted that inquiry was perhaps necessary, and it resulted in the proposal of a curriculum. With that he agreed most heartily, because he believed it was to the interest of the student, and it had a special charm to him, because it would have the effect, if brought into operation, of establishing sound educational centres, which would be the backbone of any educational system. But he hesitated to go further; he believed the imposition of the curriculum was a sufficient guarantee for sound education. The fact that a number of candidates were regularly rejected was a security that only capable men were admitted to practise pharmacy. But if all these arbitrary conditions were instituted, the possibility of cramming would still continue. If there were a regular course of education provided it would remove any obstacle which arose from imperfect education. He might be old fashioned, nevertheless his impression was that the training of pharmacists in the present day was quite equal to the demands of the public. There had been no outside demand made by the public, and the Government officials who attended the examinations had not represented that they were insufficient or ineffective. He heartily agreed with the plan of insisting on the apprentice passing the Preliminary examination before he was articled, and also in insisting upon apprenticeship, and that there should be a curriculum, but he objected to imposing other conditions beyond that, which he thought objectionable and entirely unnecessary. Then the question arose, whether the Council had power to introduce these changes. He believed the Act of Parliament had been unduly stretched already, in imposing the condition that a candidate should be twenty-one, which was distinctly illegal in his opinion, and the division of the examination into two parts, as now proposed, he believed was utterly beyond the powers the Society now possessed. It would appear from the report that even according to the present state of the law an endeavour was to be made to stretch the Act of Parliament still further. What would be the effect of this scheme on the country? It would be a very long time before it could possibly come into operation, for certain educational centres would have to be established, and he would recommend the Council rather to defer the discussion than to come to a hasty conclusion upon it. He objected to dividing the examination into two parts and making the candidate wait twelve months between. It was all very well to style the first examination a preliminary part, but it was nothing of the sort, it was a distinct examination. It would be really establishing two examinations. That might be a good thing, though he did not believe it was, but it was illegal. The tendency would be if this scheme came into operation for the two distinct examinations to become stricter and stricter, as all examinations did. He wished the state of pharmacy were such that such a scheme could be justly established, but it was not so. If chemists had real pharmaceutical work to do in their various businesses the whole thing would be a bagatelle; everyone would take an interest in the movement and education would become more perfect. But he maintained that the men who passed already, the average men, were, as a rule, quite equal to the demands of the occasion, and equal to the safety of the public. The man who passed his examination went back to his business and found that his learning was useless except as a mental exercise. If the Council accepted the curriculum and left out the other portions it would meet all the necessities of the case. He would move—

"That the report and recommendations of the Education Committee be received, with the exception of the recommendations numbered 3, 4 and 5."

Mr. Williams seconded the amendment and said he should have been prepared to go even further. He should like to speak at some length on this question, but was not well enough to do so. He agreed with what Mr. Hampson had said, and, of course, he agreed that an apprentice or pupil should pass the Preliminary examination before entering the trade, and also that he should pass a certain time in the actual practice of the business, as an apprentice or student, because that was the real mode of education. He was quite aware that in practice it was often very deficient, because in many cases there was not the means for apprentices to acquire a knowledge of their business properly, but at any rate the shop experience he looked upon as an essential point. There was no doubt a curriculum of some sort was also essential to the education of the chemists of the present day. They had to occupy a somewhat scientific position before the public, and he believed they had in the past lost a good deal of what would have been a legitimate source of profit through want of the scientific acquirements they ought to possess, and which he trusted the curriculum would tend to give them. But to draw a hard and fast line and to say exactly what the curriculum should be, and to leave no elasticity in these regulations, was in his opinion a mistake. It seemed to him an arbitrary condition to say that there must be twelve months between the two portions of the examination, and he should be sorry to accept it, especially as he understood the whole of the curriculum must be gone through in that year.

The PRESIDENT said what was intended was that a man might begin his curriculum during the period of his apprenticeship; but if after passing the first examination he had not completed the curriculum, then he must complete it before passing the second portion.

Mr. WILLIAMS said the objection remained, as Mr. Hampson had stated, that the examination was divided into two, and he believed that to be objectionable and illegal. Probably certain clauses had been put into the new draft Bill which had been submitted for the approval of the Council at their last meeeting with the view of enabling the Council to alter the examinations in the way here indicated, but at present he was quite clear the Council had no legal power to do so, and on that ground alone he should feel bound to vote against those recommendations. The curriculum, as here laid down, was simply a copy of the ordinary curriculum of the Pharmaceutical Society's School, which some thought had not proved in practice as satisfactory as could have been desired. It might possess many merits, but he did think it would be wiser to leave the new curriculum more elastic. Another point he had remarked was the recommendation that this scheme should come into operation on and after December 31, 1887, and it seemed to him an absurdity to give a date to a thing which the Council had no legal power to carry out.

Mr. WOOLLEY was much disappointed to find Mr. Hampson opposing this scheme, which he considered a distinct advance in the educational progress of the Society. Mr. Hampson's last objection was that the position of pharmacy was not what it ought to be; in fact, he brought forward the old objection, which they were getting rather tried of in the country, that the game was not worth the candle. As long as men were found who would take up that position, the game never would be worth the candle, because they were not the proper men to play the game. Then he went on to say that the pharmacists of the present day were equal to the demands of the occasion, and no doubt there were a great many men who were equal to the occasion; but taking the whole body of pharmacists throughout the country, he thought they were not equal to the occasion. Only the other day a meeting of pharmacists was summoned in Manchester to consider the Pharmacy Bill, but only six persons were present; that showed that the men were not equal to the occasion. It would be a great advantage to every young man about to engage in pharmacy, to have his whole career before him and to know what he would have to do, which up to the present time had not been the case. There were many cases of disaster, men presenting themselves several times for examination and being rejected; all that would be done away with in future to the benefit of every one. Mr. Hampson doubted the examinations being inefficient; but it had been shown repeatedly that the results had not been what they might be, and the only way of overcoming the difficulty was to have a certain curriculum which the young men must follow, and be able to show that they had given a certain amount of solid study to their profession. Mr. Hampson deprecated coming to a hasty decision, but how long was it necessary to consider this. Had they not all had time to make up their minds? Dividing the examination into two parts was to his mind the greatest boon; he should have been only too glad if his examination had been divided into two parts, and he could have gone through the theoretical portion of it in the country and come up to London afterwards to complete his qualification.

Mr. HAMPSON wished to explain that his reference to the efficacy of the education and examination was simply this, that there was no proof of any complaint on the part of the Government assessors that the examination was inefficient. Unqualified men had been turned back invariably and efficient men had passed.

The VICE-PRESIDENT said that all he had to say had been said before. There were certain propositions of Mr. Hampson he did not for a moment dispute, but he could not agree with his last remark, because it was not a question of the efficacy of examinations but of education; it was there where the deficiency lay. Notwithstanding the supineness of Manchester, which might be taken as typical of the state of feeling in the country generally, he was disposed to go largely with him, that, taking the average of the men passed through the mill and receiving the stamp of authority, they were men fairly up to the mark; but the special object of promoting this educational measure was to promote the benefit of the students. He had been deeply impressed with the fact during the twelve months he had been in the examination room, that many men came up unprepared. He had letters in his possession bearing out the conclusion that there had been in early days scarcely any advantages in the country for education, and many of these men had trusted to get up what was required by three, four or five months' study, and he had even known of a man coming up for only a fortnight's training and expecting to pass. They all agreed as to the advisability of a curriculum, and with regard to the division of the examination he agreed with Mr. Woolley that it would be an immense advantage to the student. The theoretical portion he could acquire from books in the country and his mind would then be relieved of a large amount of anxiety when he came up to London. With a limited area for investigation, he would be able to concentrate his attention on that, and would consequently be in much better form for passing the test which was required. He was convinced that the written portion of the examination might be conducted with perfect integrity in the country. In the main he agreed with the statements of Mr. Schacht that this scheme had a great many merits, that there were very few spots about it, and he hoped it would be carried by a large majority, and go forth to be tested by experience, because he was satisfied it was in the interests of the students, the masters and the public.

Mr. BORLAND said, according to the opinion expressed by Mr. Hampson, the attempt to impose a curriculum under the existing Act was illegal; but he had always been of opinion that the endeavour to enforce this curriculum would be carried out in conjunction with the proposed Act of Parliament. The discussion had hitherto failed to a considerable extent to take into consideration some of the practical results which would follow from this proposed curriculum. In the discussion last year he remembered bringing forward an objection to the botanical part, and he was then asked to ascertain the conditions which prevailed in Scotland. He had done so, and he had found that in the three Universities in Scotland the time devoted to botany was only three months, and the curriculum here imposed a term of five months, so that students, if that were insisted upon, would have to devote two years to botany, unless special arrangements were made for their benefit. Otherwise they would have to study at inferior schools, where the very system of cramming, which was so much objected to, might very likely be carried out. He did not say there were not schools in Scotland capable of teaching that science; at the same time it would be greatly to the benefit of young men coming into their ranks if they were induced to attend the Universities. With regard to the fourth clause, providing for an interval of not less than one year between the two portions of the examination, he should have preferred it to be six months, because he thought a young man who had passed his college curriculum, if he were willing to present himself, should be allowed to do so, providing he were twenty-one years of age. As he could complete his curriculum in five months if he chose, there did not seem to be any necessity for forcing him to take an interval of seven months. It had been stated over and over again that when a boy left school he should present himself for the Preliminary, and, on the same grounds, when a man left the University he ought to be able to present himself for the final examination. He also agreed with Mr. Williams that the clause fixing a time for the scheme to come into operation should be omitted.

Mr. Symes said the most potent objection to this scheme was that it was beyond the powers of the Council to carry out; but the members of the Council were not solicitors and were not going to discuss the power they had under the Act. When the motion came before the Council on a previous occasion, and a large portion of the recommendations were adopted, this question was not raised, and the sole question before them was whether these changes were desirable. He should rather see the whole of the recommendations rejected than that the scheme should be adopted piecemeal. This was not done in the interest of the Council, but principally in the interest of students, though perhaps they would be the last persons to think they were considered. They might think there was some little hardship upon them, but he was satisfied that anyone who would carefully go into the matter would conclude that it was in their interest, without being against the interest of anyone else, that this was proposed. Mr. Hampson asked for evidence that this improvement was necessary, and he had made a note at the time that most of the evidence was of a negative character; pharmacists had not that social position that they would have if they were, as a whole, educated up to the point they ought to be for the requirements of their class. But Mr. Hampson himself supplied a much better answer later on to the effect that the business was in a most unsatisfactory condition. That, in itself, was evidence that improvement was necessary. It was an old remark, that so long as men grumbled at their position and objected to do anything for the advancement of pharmacy, so long would it be where it was now. Mr. Williams had referred to the curriculum in force at the Society's school, which he said had not answered very well; but he must say he had been in the laboratory a short time that morning and he was pleased to find it so full and working so satisfactorily. Mr. Hampson had not ventured on one statement which he had pressed strongly on a previous occasion, and that was the objection he made to having any portion of the examination conducted in the provinces. He had thought a great deal over that objection when put forward originally, and came to the conclusion that it was entirely groundless. He was quite satisfied that if in a centre like Liverpool there were twelve candidates, who, if they had to come to London, would have to expend some £30 or £40, the whole thing could be done by the Society quite as efficiently for as many shillings. If these young men paid their fees they were entitled to be examined at the expense of the Society and not at an increased expense to themselves. It was a different thing to the final examination which gave them their qualification, and the Committee had been very particular in stating that this first portion of the examination is not to entitle the candidate to any kind of document whatever; his name would simply be recorded as having passed and that would entitle him to come up for the final and qualifying examination. He did not believe in any scheme being perfect, but this having anticipated almost every objection which could be raised to it he hoped it would receive the unanimous support of the Council.

Mr. Savage said there was a feeling in the country that the present educational arrangements were more than sufficient to qualify a man for the position which he afterwards occupied. The evidence brought forward was the large number who failed to get through the examination, but it seemed to him that that led to the directly opposite conclusion. Only last week he had a communication from a gentleman, formerly a member of the Council, objecting to the curriculum on the ground that it would entail greater expense on the candidate; but he felt convinced that the curriculum was necessary, for the large number of failures indicated that the Preliminary examination had not been sufficient.

Mr. Greenish agreed in the main with the report of the Committee, and being a member of it perhaps some apology was necessary for repeating his objection on the present occasion. It could not be said that he was an opponent of systematic education, for long before the curriculum became a pass-word he had published one or two papers in the Journal advocating a course of study similar to that required in North and South Germany, or as near to it as could be attained in this country. He could not go quite so far as Mr. Hampson's amendment; but he still held the same objections to the scheme which he mentioned twelve months ago, and he had remained on the Committee when he thought he ought perhaps to have retired, with a view of having his errors pointed out and acquiring some information which might enable him to change his opinion. At the last moment, however, he was obliged to say that he was not convinced on one point, and that was the very important point of the division of the examination, which involved one portion being a written one. Mr. Symes had just stated that the first portion was not a part of the qualifying examination; but seeing that it included prescriptions, pharmacy and theoretical chemistry, he (Mr. Greenish) could not agree to that, and he also took it that as a man could not enter for the second portion until he had passed the first, that first part must form a part of the qualifying examination. He also objected to the division. The three technical subjects of the present examination were reading prescriptions, pharmacy, and dispensing, and they formed the real portion of the examination on which the safety of the public mainly depended. After a candidate had passed the examination room his botany might get rusty, and even his materia medica, and also his chemistry, and in seven cases out of ten they did; but if he were to be a pharmacist at all, and if the safety of the public were at all considered, accurate dispensing, correct reading of prescriptions, and pharmacy must remain to him. Whether it was conducted in town or country he must express his conscientious conviction that an examination in prescriptions and pharmacy could not be so well conducted by written examinations as personally when the examiners sat by the side of the student. It seemed to him that the three technical subjects on which the safety of the public mainly depended were in this arrangement completely frittered away.

Mr. Young agreed very much with what Mr. Greenish had said with regard to the division, and should have preferred subjects which an apprentice could learn during his three years' term, such as practical dispensing, being included rather than theoretical chemistry; but he could not throw away the scheme because this change had been made. At one time he believed that no curriculum or anything else was necessary, and that if a man had knowledge sufficient to enable him to pass the examinations it was enough; but after some years' consideration he had come to the conclusion that a curriculum would really be advantageous to the student, and therefore in his interest he should vote for this scheme. He knew nothing about the legality of the movement, but did not see that there could be much difficulty about it. It was much easier for a student to come up prepared with three subjects than to come up stuffed with half a dozen, and he had, again and again, in his own neighbourhood, pressed the propriety of doing something to get rid of this concentration which seemed required at a particular time. He rather approved of the interval of twelve months between the two portions of the examination. Under the present system, when a young man passed the Minor he rushed into business at once, before he had gained much experience; but under the new system he would have to wait twelve months and probably most men would take longer, and it would be good for them in the end to do so.

Mr. RADLEY asked if it was intended to do away with what was called the Minor and constitute this the one examination.

The PRESIDENT said that was rather a question of the new Bill. That would be the effect if that Bill passed.

Mr. RADLEY said he was favourable to one examination rather than to two.

Mr. BOTTLE, as a member of the Committee, should have preferred to have given a silent vote and simply endorsed the views of the majority; but as several other members of the Committee had already spoken, he might say a word with regard to his own views. As he had remarked before, he looked upon all legislation as a compromise, and he regarded this scheme in the same light. He regretted that Mr. Hampson had not moved to reject the entire scheme, because if the third, fourth and fifth recommendations were taken out there would be nothing worth having left. With regard to the division of the examinations, one portion was as much qualifying as the other, and he considered it advantageous in this way, that many men at present did not attempt to take up the theoretical portion of their studies during their apprenticeship, thinking that they could get it up in a few weeks afterwards. Under this system a young man might, if he liked to be a little studious during his apprenticeship, get up enough of these three subjects to pass in at a centre convenient to himself. To some extent he shared Mr. Young's regret that practical dispensing was not a portion of the first examination; but that could not be dealt with by a written examination, and, therefore, it was deferred to the final portion.

Mr. HILLS did not think Mr. Bottle's remarks entirely explained the reason for this division of subjects. If the dispensing formed part of the first portion of the examination, he suspected that a cry would be raised that it would be quite sufficient for the needs of the public if a man were fairly up in prescriptions, pharmacy, and practical dispensing. It had been one of the objects of the Committee to impress on the pharmaceutical student that he should be working up some of the scientific subjects quietly in the country while engaged in practical work, and that theoretical chemistry should not be something he could put off until he had passed the first portion—that in fact it should be the basis on which he was undertaking his daily duty. Mr. Borland seemed to think there would be some disadvantages to the student in having a year's interval between the first and second part, and that thus considerable time might be wasted; but the candidate might pass the first portion of his examination whilst still in a situation, and not commence certain parts of his curriculum for five or six months subsequently. There seemed to be a little difference of opinion between the mover and seconder of the amendment, for whilst Mr. Hampson said pharmacists at the present time were equal to the occasion, Mr. Williams said they had lost in times past many advantages that they might have had, because they were not up to the mark.

Mr. WILLIAMS said he did not see where the contradiction was.

Mr. HAMPSON asked if the opinion of the Solicitor had been obtained on the legal aspect of the proposal; and supposing the new Bill did not pass, was it contemplated to put this scheme into force.

The PRESIDENT said the opinion of the Committee was that, substantially, these recommendations could be carried out under the existing law; but if they could not in their integrity, it was desirable they should be as far as practicable.

Mr. HAMPSON wished to know whether the Solicitor's opinion had been obtained.

The PRESIDENT said the Solicitor had often expressed some doubts as to the expediency of dividing the examination; but the Committee believed that the Council had as much power to divide the Minor into two parts as it had to have the Preliminary separated from the other portion.

Mr. WILLIAMS said there were many minor points, such as conducting the examinations in the country, which, he thought involved legal questions, and he should like to know whether the Solicitor had been consulted or whether the Committee had acted simply on its own judgment.

The PRESIDENT said the Solicitor had only been consulted as to the division of the examination. As to conducting a part of it in the country that was a question of bye-law. The whole of these matters would have to be incorporated into bye-laws approved by the Council and by the Society at a special general meeting, and then approved by the Privy Council in the ordinary way.

Mr. WILLIAMS said bye-laws could only be made within the limits of the Act of Parliament. It must be obvious to everyone who read the Act of Parliament and the bye-laws that the Council had not power under the present Act to carry out this scheme.

Mr. SCHACHT, in reply, said it did not appear to him that the adoption of the report involved the question of the possibility of carrying it out under the present law or another law. The first thing to arrive at was the course which it was desirable to adopt, and that was the only subject at present before the Council.

Mr. HAMPSON took exception to that view. Part of the report mentioned a time when the scheme was to come into operation, and that was as much a portion of it as any other.

Mr. SCHACHT said he asked the approval of that recommendation. If it were approved, the Council would of course take the best means possible for carrying it out. He had his own opinions about the matter, but did not think it desirable to intrude them on the Council now. The present question was simply whether those were the right principles to adopt in the training of young men for the future, and on that he should have but few words to say in reply, for looking carefully into the objections raised they resolved themselves into a very few points. He did not wish to undervalue their importance, but now and then points had been touched upon which had been already decided in past times. He would therefore not enter into any consideration of the question whether it was desirable that the system of education should be reorganized. The question whether men came up fit or unfit had, in his opinion, been settled. The new points for consideration that day he had before referred to, and on those he would once more say a word, because they had been to some extent attacked. In the first place he would refer to the criticism that any division of the examination was to be estimated as a separation into two examinations. That seemed to him a point not of any great importance, but seeing that it was not so considered in many other cases it might be fairly taken in their own case as a portion of one examination. Many medical examinations consisted of two portions, and some of three. A man studying medicine had to pass two or three examinations, but he did not get the smallest advantage outside the effect on his own training by having passed the first or second; it was not until he passed the final portion that he was credited with being anything else than a student. The advantage of dividing the examination was not only that it cleared away a certain portion of the student's work, but it was calculated to be of the greatest importance in the student's own career it brought him up at intervals to the position that he was being looked after by a central body and was required from time to time to show he was doing some work, and work which would ultimately qualify him for a vocation in life. At a recent meeting in his own neighbourhood one very sagacious man suggested that it would be extremely useful if the Society could institute an annual examination for all pupils. He did not suggest that it was practicable, but that it would do an immense deal of good to the students. That might be an extreme view, but it was quite correct, and this intermediate or first portion of the examination would have the same effect. It put before a man a point that was not too far off which he had to reach, and then he went on again to a further point, and this would help to keep him systematically and carefully to his work. Supposing the division were admitted, there was an important objection made to the special division proposed, and it had been urged very strongly by Mr. Greenish that the practical subjects should form the first part and the three scientific subjects the last. To that he had always felt the gravest objection. In the first place, if the objection took place at all, the first portion must consist of those subjects in which a student could be examined by a written process, and a man could not be examined as to his capability in dispensing by any written process. A still more important reason in his opinion was, that when a man declared himself, or aspired to be a real dispenser he should not be able simply to put so much into a mortar and make a good pill of it, but that he should know how, from a knowledge of chemical principles, to manipulate properly the materials he was called upon to dispense. He did not think much of a man who was simply capable of mechanically fulfilling the instructions on a bit of paper and sending the result out either as pills or mixtures. If dispensing meant anything, it meant bringing to the compounding of medicine all the intelligence it was capable of, and he would, therefore, take that as the culminating point of the examination. If a man could dispense well, according to his interpretation he could do all the rest, and might pass with the best hall-mark that could be given him. The division he proposed was open to one serious objection, no doubt; they were obliged to include pharmacy. But it only meant a portion of pharmacy, because there were many points of pharmacy about which a candidate should be examined, which could not be well done by a written process, and those he hoped the examiners would see they could take under the heading of materia medica. A great deal, however, could be done in writing, and such portions could fairly be taken in the first part of the examination. The division was, after all, a sort of compromise, the endeavour being to get that portion which could be done by a written process in order that it might be conducted in the country. The scheme now suggested was one which guarded against any possibility of immorality; that was a strong word, but not too strong, for it would be most decidedly immoral to allow anything which could compromise in the slightest degree the absolute *bona fides* of any examination. It was proposed that a member of the Board of Examiners should be present at each examination, the number of centres being limited accordingly, and under that condition he did not see that there could be any objection. With regard to the point raised by Mr. Borland as to the course of five months for botany, that was a point which might be modified at any time. The great point was the security the Council must have that a full and complete system of botanical study should be undertaken by those who taught the students. If the peculiarity of any district, like Scotland, prevented it being carried out in a particular form, he saw no reason why the matter should not be met by special regulation. Again, with regard to the interval between the two portions of the examination, he should be quite willing that the interval should be six months if the model system of training could be secured in all cases, namely, that during the three years' training certain work should be carried on, and then six months should be devoted to practical work in the laboratory. That would be sufficient, and he should be glad to find that that was the course practically adopted in the future. But it must happen that in a great number of cases a small portion of the curriculum only could be fulfilled during the first three years of pupilage; many pupils would be in localities where they could not obtain the instruction required, and then it would be necessary for them to take the whole of their lecture teaching after they passed through their pupilage. In such cases it would be a great misfortune to say it could be done in six months, because it would be nothing less than recommending a system of cram of the worst order. It was from that point of view the Committee said the only escape was to make the interval longer. He regretted that there was not perfect unanimity on this point, and that Mr. Hampson had not continued on the Committee. What was aimed at was nothing but a more complete training of the pharmacist for the future, the difference of opinion being only a question of degree, and he was happy to think the degree was becoming more and more limited in scope.

Mr. Borland wished to explain with regard to the courses of botany in Scotland, that there were quite forty-eight lectures given, but they were given in three months instead of in five.

The President said it would be quite open to introduce a modification of the regulations to meet such cases at any future time.

The amendment was then put, with the following result:—

For—Messrs. Hampson and Williams.

Against—Messrs. Andrews, Atkins, Borland, Bottle, Butt, Carteighe, Churchill, Gostling, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, and Young.

Mr. Greenish was present but did not vote.

Mr. Williams then moved a second amendment to the effect that the paragraph in the report fixing the time when the regulations should come into force should not be adopted.

The amendment not being seconded fell to the ground.

The original motion for the adoption of the report was then put and carried.

The Pharmacy Acts Amendment Bill.

The Secretary then read the following communications:—

From the Council of the North British Branch containing certain suggestions with regard to the draft Bill, to which it gave a general support.

From Edinburgh, enclosing a resolution passed at a meeting of chemists and druggists held in that city on February 22, to consider the Pharmacy Acts Amendment Bill, to the effect that that meeting gave its cordial support to the Bill. The meeting also recommended that the exemption from jury service should be extended to all persons qualified under the Pharmacy Act who were engaged in business.

From the Chemists and Druggists' Trade Association of Great Britain, dated Birmingham, February 28, enclosing a series of suggested amendments to the draft Pharmacy Bill which were adopted at a meeting of the Executive of that Association held on February 19. The principal recommendation was that the whole of clause 2 should be expunged and that the articles in the special schedule referred to in that clause be added to Part 2, Schedule A, of the Pharmacy Act, 1868. Another suggested amendment was the exemption from jury service of all registered chemists and druggists.

From the Committee of the Registered Chemists' Trade Association of Liverpool, expressing a general approval of the Bill. The Committee suggested that the new technical term "poisonous articles" was calculated to cause confusion and recommended that the articles comprised under it should be put in a third part of the poison schedule of the Act of 1868 or a "poison schedule" of this Act; also that the usual consideration of existing vested interests should be granted to assistants who have been acting as managers of branch shops for a term of not less than three years previous to the passing of the Act, or who may pass a Modified examination provided for them as "existing managers."

It was resolved that the communications now received respecting the new Pharmacy Bill be referred to the Law and Parliamentary Committee.

REPORTS OF COMMITTEES—*continued.*

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former member, aged 76.

£10 to the widow of a member who has had two previous grants.

£5 to the widow of an associate.

£10 to the widow of a registered chemist and druggist, who has had two previous grants.

£21 to be placed in the Secretary's hands to be expended at his discretion in getting an orphan into an asylum.

£10 to a fund being raised for the seven orphan children of a registered chemist and druggist.

The death of two of the annuitants was reported.

The report and recommendations were received and adopted.

Junior Pharmacy Ball.

The SECRETARY announced the receipt of twenty guineas for the Fund from the Committee of the Junior Pharmacy Ball.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
January	Day . . .	572	33	7	27
	Evening . .	157	20	3	7

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
January	184	137	321

Carriage paid, £1 14*s.* 10*d.*

The undermentioned Donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Papers relating to the administration of the Dentists' Act. From the BRITISH DENTAL ASSOCIATION.

Parey (A.), Workes, 1649. From Mr. W. V. RADLEY.

Plugge (P. C.), Über Andromedotoxin, den giftigen Bestandtheil der Andromeda Japonica, 1883.
From the AUTHOR.

The Committee recommended that the undermentioned work be purchased for six months:

Knowledge, conducted by Richard A. Proctor. 2*d.* weekly.

The Committee recommended that certain volumes and numbers of the *Pharmaceutical Journal*, to complete the set belonging to the Chicago College of Pharmacy, be presented to the College.

Curator's Report.

The Curator had reported the attendance in the Museum during January to have been:—

	Total.	Highest.	Lowest.	Average.
Morning .	445	34	3	17
Evening .	104	14	0	5

The following Donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Leaves of *Eucalyptus globulus*, from the plant which yielded the oil previously presented
From Messrs. WARRICK BROTHERS.

Seeds of *Pterocarpus Guianensis.*
From Dr. H. E. CAUTY, Liverpool.

Roots of *Tephrosia macropoda*, *Sium Thunbergii*, *Chlorocodon Whitei*, Bark of Isibaha, and three bottles of Aloe Juice obtained from African species cultivated in the Botanic Gardens at Natal.
From the Curator, Mr. J. M. WOOD.

Specimens of Naphthaline and Naphthol.
From Messrs. DOMEIER and Co.

Specimens of *Casca amarga* Bark, and of the Barks of *Croton Pseudo-china*, and of an unnamed species of Croton. From Messrs. CURLING and Co.

Specimen of the Bark of *Vateria Indica.*
From Dr. ONDAATJE, Ceylon.

Herbarium Specimens of Damiana.
From Messrs. PARKE DAVIS and Co.

The following letter had been received:

"Botanical Department,
"Gordon Town, P.O.,
"Jamaica, 22 *January*, 1883.

"Sir,—In accordance with the request received from the Pharmaceutical Society of Great Britain for specimens of Cinchona under cultivation on the Government Plantations in Jamaica, I have pleasure in forwarding a set as described on the accompanying notes, which leave by this mail to the care of J. F. Obree and Co., Southampton.

"Messrs. Obree and Co. are instructed to forward the box containing the specimens addressed to the Curator of the Museum of the Pharmaceutical Society, together with a memorandum of expenses incurred in transit.

"I may mention that the specimens are presented to the Pharmaceutical Society by the Government of Jamaica, and they have been prepared and packed with great care. All the specimens of leaves, flowers, fruit and bark of each kind are taken from one tree, so that the sets are complete in themselves and thoroughly representative of the plants under cultivation in this Island.

"I have the honour to be, Sir,
"Your obedient servant,
(Signed) "D. MORRIS.
"Director, Public Gardens and Plantations.

"The Secretary,
"Pharmaceutical Society of Great Britain,
17, Bloomsbury Square, W.C."

The Curator had reported that the specimens referred to had arrived in excellent preservation, and were all that could be desired. Each species was represented by specimens of the root, trunk, branch, and twig bark taken from the same tree as the herbarium specimen. The latter showed the fruit and flower in each stage, and the whole formed a most valuable and instructive series.

The PRESIDENT had reported that on consultation with the Solicitor and several members of the Council, it appeared that in order to give the Council power to elect Corresponding Members of the Society the bye-laws would have to be amended; and it was recommended that a suitable bye-law should be drafted for the purpose at the earliest opportunity.

The Professors had attended and reported satisfactorily of their respective classes.

It was recommended that the front of the house be painted with one coat, and that the second-floor windows in Great Russell Street be made to correspond in appearance with those facing Bloomsbury Square.

The report and recommendations of the Committee were unanimously adopted.

THE CONVERSAZIONE.

This Committee reported that similar arrangements were being made to those of former years. The report was received and adopted.

SPURIOUS AND WORTHLESS DRUGS.

This Committee presented the following report:—

Report of the Committee on the Sale by Auction of Spurious and Worthless Drugs,

Consisting of the President, Vice-President, Messrs. Greenish, Hampson, Richardson, Symes, Williams, Woolley, Young (*Members of Council*), and Messrs. Fredk. Barron, Richd. B. Barron, T. Farries, G. Bult Francis, J. B. Herring, Wm. Hodgkinson, E. M. Holmes, Edw. Horner, C. Umney, F. Yates, Professor Bentley and Dr. Paul.

Your Committee has had several prolonged meetings and obtained much information on the subject from various sources. It has also received many suggestions from other members of the wholesale and export trade.

Your Committee begs to report the following general conclusions which have been arrived at after much careful consideration of the facts brought before them and mature deliberation thereon.

1. The importation and sale of adulterated as well as spurious and worthless drugs does not appear to be on the increase. This fact is probably in part due to the greater skill now possessed by wholesale dealers and pharmacists as a result of the advances made during recent years in the physical, chemical and microscopical examination of many drugs. Effectual means of detecting sophistication and distinguishing the genuine from the spurious have been thereby placed at the disposal of importers and wholesale and retail dealers of drugs.
2. That a few adulterated and spurious drugs, belonging to a small class not easily assayed or tested by chemical methods, occasionally find their way into commerce is undeniable; but occurrences of this kind do not appear to be so frequent as to require special powers to deal with them, beyond those already to be found in the existing law.
3. With a view of preventing as far as possible the importation and distribution of adulterated, sophisticated and spurious drugs, it seems desirable that the Council should annually appoint a standing committee, whose special duty it should be to receive information regarding such drugs, collect specimens and have them carefully examined. A report of the results of its labours should be published periodically in the pharmaceutical press.

The report was unanimously received and adopted.

Appointment of a Standing Committee.

The PRESIDENT moved that the Standing Committee referred to in the third paragraph consist of the present members of the Council acting on the Committee, and that at their first meeting they proceed to elect some members of the wholesale trade to act with them.

Mr. WILLIAMS thought it would be more satisfactory to the members of the wholesale trade if they were invited to assist the Committee in rotation, not limiting it to any one section, but appointing four or six members year by year.

The PRESIDENT said he thought the best way would be to move that the members of Council now on the Committee be reappointed a standing committee with power to add to their number. They would, no doubt, bear in mind what had been suggested.

This was agreed to.

GENERAL PURPOSES.

The report of this Committee mainly consisted of the Solicitor's report as to cases which had been placed in his hands. From this it appeared that—

Mr. Hustwit, 19 and 20, Market Street, Darwen;
R. Newman, jun., and Co., 13, Market St, Darwen;
E. C. Lewin, 7, Whimple Street, Plymouth; and
H. W. J. Ince and Co., Market Place, Dudley,
had severally paid £5 penalty and costs.

Several cases of alleged infringement of the Act had been considered by the Committee, and in some of them it was recommended that proceedings be taken.

The report and recommendations of the Committee were unanimously adopted.

REPORT OF EXAMINATIONS.

February, 1883.

ENGLAND AND WALES.

	Candidates.		
	Examined.	Passed.	Failed.
Major (21st)	3	2	1
„ (22nd)	4	1	3
„ (23rd)	4	2	2
	— 11	— 5	— 6
Minor (21st)	29	7	22
„ (22nd)	27	8	19
„ (23rd)	28	13	15
	— 84	—28	—56
	95	33	62

Preliminary Examination.

Nine certificates had been received in lieu of the Society's examination:—

1 College of Preceptors.
7 University of Cambridge.
1 „ Oxford.

THE ANNUAL REPORT.

It was resolved that the preparation of the Annual Report be referred to the Library, Museum and Laboratory Committee.

EVENING MEETING.

Wednesday, March 7, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Pharmaceutical Society was held on Wednesday last, March 7. The chair was taken at half-past eight o'clock.

The minutes of the previous meeting having been read and confirmed, the President read a paper on—

OLEATE OF URANIUM.

BY WALTER GIBBONS.

The paper is printed on p. 737, and gave rise to the following discussion:—

The PRESIDENT said that although oleate of uranium was not a sufficiently stable compound to come into use to any great extent, still it was interesting to find that such compounds could be prepared; and it was gratifying to find that one of the members of the Society took sufficient interest in the subject to make a complete analysis of this body.

Mr. POSTANS said that if Mr. Gibbons could have produced a stable preparation there would have been some chance of its being tried for medical purposes. He believed that if the salts of uranium were brought into use, the nitrate of uranium would be the best and most easy of manipulation, and he had found it perfectly soluble in almost all proportions in glycerine. Probably the solution in glycerine would keep exceedingly well. It was opportune that Mr. Gibbons should have brought this subject before the Society at the present moment, there being a paper which seemed to run almost concurrently with his note, and which was published in the current number of the *Journal of the Chemical Society*. It contained investigations which Dr. Arthur Smithells had undertaken at the suggestion of Professor Roscoe. At present there was no medical evidence as to the usefulness of salts of uranium.

A vote of thanks was accorded to the author of the paper.

The next paper read was on—

Liquid Extract of Cinchona.

BY B. H. PAUL, PH.D.

Dr. Paul introduced the paper by remarking that the liquid extracts constitute a class of preparations which have found especial favour with medical men in America, and that the new edition of the United States Pharmacopœia contained formulæ for no less than seventy-seven liquid extracts, or nearly double the number that were contained in the previous edition. The advantages claimed for these preparations were, first, that they present the active constituents of drugs in that particular state of combination and association in which they occur naturally; secondly, that they ensure complete exhaustion of the active principles of drugs by the selection of menstrua suitable for holding them in permanent solution and presenting them in a concentrated form. Among the defects of these preparations, one of the principal, which they shared with other galenical preparations, was variation in strength, consequent upon the variability of the crude drugs used in making them, and though in British pharmacy they were less numerous than on the other side of the Atlantic, some of them would admit of being considered from this point of view.

The paper is printed on p. 737, and gave rise to the following discussion:—

The President said that the paper was essentially a practical one, and it had both a pharmaceutical and a medical aspect. Some advanced pharmacists and young medical practitioners thought that preparations of bark were a mistake, and that it was better to use the active principles in definite proportions. On the other hand there was, perhaps, a larger number of medical men who had to think of the best way of curing disease, and who did not set about it with any preconceived theory, but who looked to results. These men alleged that certain good results followed from the use of preparations of the crude drugs. Certainly when Mr. Battley introduced fluid extract of cinchona his intention was to place in the hands of medical men a preparation which should contain the active principles as they existed in the drug.

At the invitation of the President to address the meeting—

Dr. Duckworth said that he had been very much enlightened by the paper. He must at once acknowledge that he had always conceived the Pharmacopœia preparation to be a very good one, and he believed that it took the place of one that was once largely used, namely, the liquor cinchonæ, which he confessed he had not prescribed ten times in his life. But he was bound to say that he had not used the Pharmacopœia preparation as much as he had used two other preparations of bark, namely, tincture of yellow bark and the old compound tincture of bark. He always made use largely of decoction of cinchona. One came to know the tools with which he worked from day to day, although some persons scoffed at experience which was gained in that way. He did not decry the methods of investigation employed in the physiological laboratory, but he believed in the correct observations of the effects of what he was not ashamed to call empirical preparations. He was bound to say that he should, in future, think much less of the preparation to which the paper related than he had thought of it hitherto. His dear old master, Sir George Burrows, taught him to use this preparation in conjunction with quinine, and defined very clearly the cases in which one or other or both of these medicines should be employed. In certain cases of disease of the throat, Sir George Burrows held that a mixture of the two was more useful than either given alone. He was sure that the medical profession was very much indebted to Dr. Paul for enlightening them on the subject of the preparation in question. Medical men would be willing to attribute to quinine all the credit which belonged to it, and to allow that it would do work which no other preparation would accomplish; but yet in the preparations of bark there were virtues which they might suppose to be due to other substances which were present in those preparations in addition to quinine. He thought that it might be said that there were forms of pernicious malarial fever which even that grand alkaloid quinine was not of itself able to meet, and in which the preparations of bark would produce good results. He was sure that the profession would continue to use the preparation of the crude drugs, and would refuse to be tied up to the use of the pure alkaloids.

The President said that it would be fitting that he should ask Professor Redwood to give them his views of the *raison d'être* of the process given in the Pharmacopœia and to state how it came to pass that a preparation of the kind in question should have become official.

Professor Redwood stated that the introduction of fluid extract of bark into the Pharmacopœia did not originate with him, and he thought that he might fairly say that the preparation did not originate even with the pharmacists or the medical men of this country. Sixty years ago he was practically engaged in pharmacy, and he could remember a preparation of cinchona bark which was in use at that time, and which bore a very close resemblance to that which was under discussion. It was a preparation made in accordance with the French Codex. It was employed under the name of "essential salt of bark," and was prepared by making a cold infusion of bark and evaporating it, filtering towards the end of the process, and then spreading the filtrate out on plates of glass, upon which it scaled somewhat like ordinary scale preparations. It was perfectly soluble in water and was an approved article in medicine. Similar preparations had been introduced since. One was included in the London Pharmacopœia in 1851, and it passed from the London Pharmacopœia to the British Pharmacopœia. It was a preparation which was also recognized in the Pharmacopœia Germanica. It was obvious that there had been for a great length of time a belief in the efficacy of an aqueous extract of bark. It was true that extracts of bark in a concentrated form had varied in their nature from time to time, but all the authorities that he had referred to had ordered very concentrated preparations, the essential salt of bark being in the solid state. The exhaustion of the bark was effected by water, though in some cases, as in the process given in the British Pharmacopœia, a little spirit was added at the end of the process after concentration. He looked upon the communication which had been read by Dr. Paul as a very important and very valuable one, and having been brought forward by a gentleman so competent as Dr. Paul it necessarily called for a great deal of investigation; but still he must say that he was disappointed at the manner in which the author had treated the subject. The paper contained too many assumptions, some of which were obviously erroneous. This very much damaged the value which the paper would in other respects possess. The first assumption was that flat calisaya bark was ordered by the British Pharmacopœia in the preparation of the liquid extract. He would ask Dr. Paul where he found anything to that effect in the Pharmacopœia. At the time the Pharmacopœia was published, flat calisaya bark, which readily yielded 2 per cent. of quinine without other alkaloids, was an article of commerce which could be easily obtained. The Pharmacopœia in defining the yellow calisaya bark said that it was "in flat pieces, uncoated, rarely in coated quills." It was true that calisaya bark was ordered, but flat calisaya bark was not exclusively ordered; and he gathered from Dr. Paul that flat calisaya bark was an article rarely met with in commerce now. There was an article which resembled it, and which perhaps Mr. Holmes could hardly distinguish, but that was not the article of the Pharmacopœia. Dr. Paul stated, however, that quilled calisaya bark, which was equally the article ordered in the Pharmacopœia, could be obtained of good quality and in any quantity. The second assumption made by the author was that the efficiency of the process of the Pharmacopœia might be tested and judged of by referring to something which had been produced by materials such as were not ordered in the Pharmacopœia. The material used by Dr. Paul in making the extract in one set of experiments was a spurious bark which was obviously not calisaya bark at all, for it contained scarcely any quinine, and it contained an abundance of alkaloids which were not present in the true calisaya bark. The other set of experiments was made with a bark which the Pharmacopœia did not order, namely, Indian bark, which he believed differed from calisaya bark in an essential feature, namely, the proportion of cinchotannic acid which was present in it, and which rendered the quinine and the alkaloids in the bark less easily extracted, and less soluble in water than they would be otherwise. The third assumption of which he complained was that the preparation in question, and perhaps other preparations also, were intended fully to represent the medicinal properties of the drugs from which they were prepared. This was expressed or implied in different terms in different parts of the paper. He was quite prepared to hear that those who had written upon the subject—Mr. Battley, for instance—had said something to the effect that the preparation in question was bark, minus woody fibre, and that it might be looked upon as containing all the medicinal value of the bark. He asked what ground there was for assuming that the authors of the Pharmacopœia adopted any such view. Perhaps there would be no difficulty in showing that in scarcely any of the preparations of the Pharmacopœia were the drugs completely exhausted of their active principles, and perhaps in a great number of instances the very object was to take out only a small quantity of these principles. Taking, for instance, such a preparation as infusion of chamomile, who in his senses would think of objecting to that infusion because it did not fully represent all that was active and efficacious in the chamomile? In his opinion the objection that extract of bark did not fully represent the whole of the active matters contained in the bark was a very weak objection to urge against it. Twenty years ago he sat upon a Committee of the Society for the revision of the London Pharmacopœia, and at that time he made some experiments at the request of the Committee with reference to some of the preparations of bark, especially decoction. Dr. Paul stated in his paper that a decoction of Indian bark contained no more than one-fourth or one-fifth of the alkaloids of the drug. He (Professor Redwood) made his experiments, not with Indian bark, but with the bark ordered in the Pharmacopœia, namely, calisaya bark, and he found that a decoction made strictly as the Pharmacopœia indicated contained nearly one-half of the alkaloid. A pint of the decoction made from 1¼ ounces of the bark contained 6·25 grains of quinine, and in the residue of the bark 7·8 grains of quinine could be subsequently taken out. A ¼ of a grain of the quinine in the decoction deposited with the precipitate, which formed as the decoction cooled. This instance went to show the weakness of that mode of judging the efficacy of the Pharmacopœia preparations which was founded upon experiments with materials which were not ordered in the Pharmacopœia. Good calisaya bark was a quinine bark containing a certain quantity of cinchotannic acid, which rendered the quinine only slightly soluble, but it contained other substances, such as kinic acid, in combination with which quinine was soluble. It yielded by decoction or infusion a larger quantity of quinine than the Indian bark such as Dr. Paul had used. Although the Indian bark contained the same proportion of quinine, yet there was something present in it—probably a larger proportion of the astringent matter or cinchontannic acid—which rendered the quinine less soluble in that kind of solvent. In answer to the President, Professor Redwood added that he had not determined the amount of total alkaloids in the fluid extract. He was prepared to find that there was some deficiency as regarded the alkaloids, but he and the medical men with whom he had had the honour of acting in connection with the British Pharmacopœia considered that there was great efficacy in the extract independently of the alkaloids. Probably there were aromatic and resinous matters taken up and retained in the aqueous preparations.

Mr. Umney said that he had always looked upon the fluid extract of cinchona contained in the Pharmacopœia as a continuation of a preparation which was originally brought before the College of Physicians by Richard Battley, about the year 1830. In the London Pharmacopœia of 1851 there were preparations known as infusum cinchonæ spissatum, made from both loxa and calisaya barks; that from calisaya bark was continued in the British Pharmacopœias. He considered that the pharmacy of cinchona bark at the present day was in a great muddle. He was aware that quilled calisaya bark could be obtained, but it certainly did not come up to the standard of former years either in quality, as far as its quinine assay was concerned, or in quantity. Flat calisaya bark was offered weekly at public auctions which did not contain a trace of quinine. He did not know what would happen one day with respect to this substance when druggists found themselves face to face with the Sale of Food and Drugs Act. Every one knew calisaya bark was a very difficult thing to even partially exhaust with water. He generally employed a series of percolators, each of which contained a certain amount of bark, and he was in the habit of passing the percolate from one to the other. The Pharmacopœia was in fault with regard to the specific gravity of the preparation, which instead of being 1·100 was 1·120, provided the proportion of spirit directed was added to the evaporated extractive having a specific gravity of 1·200. The yield of fluid extract also was somewhat overrated in the Pharmacopœia. His own experience was that one could never get more than about 20 per cent. of completed fluid extract from flat calisaya bark or more than 22 per cent. from quilled calisaya bark. He had not used either flat or quilled calisaya bark for the Pharmacopœia preparation for years. He had used Indian *Cinchona officinalis*, containing probably 3 to 5 per cent. of quinine, and this bark would yield sometimes upwards of 40 per cent. of completed extract. A very good bark which came into commerce in enormous quantities was known as soft Columbian bark. Although it contained fully the quantity of quinine ordered in the Pharmacopœia, namely 2 per cent., still it contained no extractive matter at all, and was ill adapted for the preparation of liquid extract.

Mr. Ekin said that in a paper which he had read before the Pharmaceutical Conference some years ago, he went over somewhat the same ground as Dr. Paul. He took a bark sold as flat calisaya bark which contained about 2 per cent. of quinine and made the preparations with it. The bark was almost entirely exhausted by the tincture. The infusion was next richest, and then came the decoction, which so far as he could remember contained about half the total alkaloids contained in the bark. With regard to the inspissated infusion it was quite possible to follow the directions of the Pharmacopœia and yet not get more than 20 per cent. of fluid extract; but sometimes more was obtained, for if the bark was very rich in quinovic acid an infusion would be obtained which when concentrated would give a much larger yield, sometimes as much as 50 per cent. of a fluid extract having the required specific gravity and which of course would be to a corresponding extent poor in alkaloids; yet, in a case of this sort if it were attempted to concentrate the infusion from a pound of bark to 3 ounces as ordered by the Pharmacopœia, they would get an almost solid extract. Dr. Paul, in his paper, had omitted any mention of the way in which he estimated the alkaloids. It would be interesting if he would give the details of his method, as some present might like to repeat his experiments.

The PRESIDENT said that, with all respect to what Professor Redwood had said, it appeared to him that the object of the paper was to show the action of water upon such cinchona barks as were now commonly met with in commerce. It was no answer to the paper to say that if they took such barks as were obtained many years ago different results would be obtained. The paper showed the action of water upon two very well known specimens of bark, namely, flat calisaya bark so-called, which was rather poor in alkaloids, and Indian bark, which was rather rich. Pharmacists had imagined that they had a very potent preparation of cinchona bark in the fluid extract, and the paper seemed to him to prove that such was not the case.

Dr. PAUL, in reply, said that his object in appearing before them with the paper was not to speak as a pharmaceutical professor and ask them *ex cathedrâ* to accept assumptions of any kind, whether well or ill founded. The main object of the paper was to raise a question as to what was required in a preparation of bark such as the liquid extract, so that, having arrived at a knowledge of what was desired from a medical point of view, chemical and pharmaceutical skill might be applied in obtaining it. He had, however, been charged by Professor Redwood with venturing upon assumptions which were entirely erroneous, and he would, therefore, address himself to answering that charge. First he was said to be wrong in assuming that the bark known as "flat calisaya" was the bark of the Pharmacopœia. In reply to that, he would only refer to the description given in the Pharmacopœia in the following words:—"Characters: In flat pieces uncoated or deprived of the periderm, *rarely in coated quills.*" If that did not mean that the flat bark was essentially the bark to be used for pharmaceutical purposes, he did not understand the English language. As regarded the second alleged assumption, it was true that the experiments in the paper referred to bark which was not official, but in the one case he had operated upon such a bark as was obtainable under the name of "flat calisaya" at the present time, and in the other case upon one which contained the same amount of quinine as the official bark should do. He had shown that the process given in the Pharmacopœia failed to extract the alkaloids in both cases, and that was precisely the point which raised the question as to what was the object of the liquid extract. Was it to represent cinchona bark in reality, or was it to be merely an astringent preparation with the cinchona alkaloids left out? He had certainly adopted the view that this preparation ought to represent the whole of the medicinal properties of cinchona bark in a concentrated form, but was that an erroneous assumption, as Professor Redwood contended? In order to justify himself on this point, so far as pharmaceutical opinion was concerned, he would refer to the original paper read in the year 1838 before the College of Physicians by Mr. Battley, who said, "I have arrived at the conclusion that the desideratum in pharmaceutical chemistry is to leave unchanged the medicinal qualities of the substance acted upon, separating and removing therefrom, as far as may be possible, every matter not possessing remedial virtue." Then Mr. Battley went on further to say, with special reference to liquid extract of cinchona bark, that his process had the effect of separating and securing nearly the whole of the medicinal properties of the bark. There was, indeed, no doubt that was the object which Mr. Battley had in view, and according to the light of the chemistry of that day Mr. Battley supposed he had attained it. He (Dr. Paul) believed that he had shown conclusively that, whatever kind of bark was used, the result of operating upon it with cold water was that material, time and labour were wasted, and the result arrived at was a fiasco. The data given in the paper showed that the poorer the bark the better, proportionately, was the result. He found it to be a notorious reproach that the process given in the Pharmacopœia for making liquid extract of cinchona was utterly bad. He read in one place that the process was "exceedingly wasteful," and that the bark after being operated upon was as good for quinine making as it was before. Another writer said that there was "no efficient formula in existence" to represent cinchona bark, though that was a great desideratum, and that some means of arriving at a preparation which should be justly represented as "bark minus the woody fibre" had yet to be attained. He therefore thought that the meeting would absolve him from having been regardless of pharmaceutical authority and pharmaceutical considerations and admit that he had been guided at any rate by common sense, if not by such long experience as Professor Redwood was able to command. In regard to the results he had obtained in making the decoction and the infusion of cinchona, referred to incidentally for the purpose of comparison with the liquid extract, Professor Redwood's objection that they had been obtained by operating upon Indian bark did not hold good; for he had not only used for this purpose Indian bark, and such as was to be had under the designation of "flat calisaya" bark of the Pharmacopœia, but he had prepared the decoction and liquid extract from the quilled calisaya, which was the exceptional kind of the Pharmacopœia, and he found the results just the same as those obtained with other kinds of bark. The decoction contained about $\frac{1}{4}$, and the liquid extract $\frac{1}{7}$ of the alkaloid present in the bark. The exhaustion was only very partial. He did not think that it was possible to exhaust the bark thoroughly with cold water; and he regarded the indication afforded by the specific gravity of liquid extract, which was stated in the Pharmacopœia to be a guide as to the volume to which the extract was to be brought, as fallacious in so far as it was used to judge of the extent to which a liquid extract really represented the bark it was made from. Specific gravity was no indication of what was present in solution. That might be gum or starch, or cinchotannic acid or anything. What he considered to be required was a knowledge that the preparation contained a definite and uniform proportion of medicinal constituents. Mr. Ekin's reference to the paper he had read before the Pharmaceutical Conference led him (Dr. Paul) to say that he had not been able to confirm the results which Mr. Ekin obtained. Mr. Ekin represented that he obtained from a bark containing nearly 2 per cent. of quinine a tincture equivalent to 100 grains, which contained nearly $1\frac{9}{10}$ths of a grain. He had not been able to obtain such a degree of extraction in making tincture of Cinchona, but, on the contrary, had found that when he repeated the Pharmacopœia process on the same bark, he got a result nearly as good the second time as the first in regard to the proportion of alkaloids. With regard to the liquid extract he found a certain amount of agreement between Mr. Ekin's results and his own, but Mr. Ekin's results were somewhat less favourable to the liquid extract.

The PRESIDENT, in closing the discussion, said that the meeting would, he was sure, accord a hearty vote of thanks to Dr. Paul for his valuable paper.

A note by Mr. Morris on "The Cultivation of Cinchona in Jamaica" was submitted by Mr. Holmes. The paper, which will be printed in a future number, was accompanied by a considerable collection of illustrative specimens.

Mr. HOLMES called attention to some other specimens which were exhibited on the table. Among these were naphthaline and naphthol, new remedies recently introduced in the treatment of skin diseases. There was also a specimen of the very curious body known as paraldehyde, which had lately been described in the *British Medical Journal* (February 3, p. 215) as a new hypnotic, possessing the advantage over chloral of strengthening the action of the heart. The specimens of pure aldehyde, aldehyde ammonia and aldehyde resin had been sent at the same time by Mr. Williams to illustrate some remarks which he had intended to make, but he was unable to be present. In his absence, he might say that paraldehyde had the formula $C_6H_{12}O_3$, and might be regarded as three molecules of aldehyde grouped into one, the formula of aldehyde being C_2H_4O. The vapour density of paraldehyde was three times greater and the boiling point more than three times higher than that of aldehyde. It was very remarkable, therefore, that this body differed entirely in its chemical, physical and therapeutical properties from aldehyde. Thus aldehyde formed with ammoniacal gas the crystalline compound aldehyde ammonia, and when mixed with alcohol and heated with caustic potash formed aldehyde resin; but neither of these substances was formed by paraldehyde, nor had it the power of reducing nitrate of silver like aldehyde. Paraldehyde had an odour resembling that of acetal, and was soluble in about 8 parts of cold and less of hot water, while aldehyde possessed a very suffocating odour, and was freely miscible with water and alcohol in all proportions. Yet the same substances which cause the molecular changes by which paraldehyde is produced will, at a lower temperature, give rise to the very different crystalline body, metaldehyde. The difference in therapeutical properties caused by slight molecular changes must be a subject of great interest to medical men. The group of aldehydes also possessed a considerable importance from the point of view of botany and materia medica, since they were intimately connected, as recently shown by Messrs. Cross and Bevan, with the formation of vegetable products and with the changes that take place in the tissues of plants, which appear to be largely due to the facility with which aldehyde forms polymeric bodies, the ease with which they are decomposed and the readiness with which they form compounds with other bodies. There was also a specimen of the cayenne pepper pods from Natal, which produced the bright red cayenne pepper so much prized in commerce.

The PRESIDENT said that the specimens of cinchona from Jamaica were sent, in answer to an application made by the Society to the Colonial Office, by the director of public gardens and plantations in Jamaica.

After the conclusion of the business Mr. J. C. Shenstone exhibited a new arrangement for securing the stoppers of poison bottles.

The meeting was adjourned to Wednesday, April 4.

Errata.

Page 724, col. 1, line 32 from top,—

For Capper, Fred. William Noad,
Read Clark, Fred. William Noad.

In the Local List of Subscriptions to the Benevolent Fund, published in the Journal for February 24, the name of Mr. T. D. Walker, of Dresden, Staffordshire, should have been included under "Longton," instead of under "Stoke-on-Trent."

In the same List, on p. 715, under "Walton-on-Thames," *for* "Power, Edward, 5*s*.," *read* "Power, Edward, 10*s*."

Asinus post prand.—We hope that in reading the Bill carefully through you will be able to find an answer to your question.

F. A. Barritt.—We would suggest your further consideration of the clause referred to, and have no doubt you will then perceive that it gives no such permission as that you deprecate.

Cyrmo.—(1) The quinine is soluble in the quantity of dilute sulphuric acid ordered, and will not crystallize out. The solution being a clear one a "shake the bottle" label is not required. (2) Certainly, but the phosphate of iron must be recently precipitated and moist. (3) Dissolve the ammon. hydrochlor. in water to saturation, add a little mucilage, and then the tinct. guaiac. vol. so as to form an emulsion.

Correspondence.

THE DRAFT PHARMACY ACTS AMENDMENT BILL.

Sir,—*Post tenebras lux.* At last, the forced inaction which has been our lot in relation to pharmaceutical politics may be thrown off. Our leaders have sounded the note to prepare for an immediate advance, and we cannot too soon make up our minds to take a share in the work that has to be done.

But, is this work laudable? Personally, I can offer the most cordial approval to the new Pharmacy Bill, now sanctioned by the Council of the Pharmaceutical Society. If it has been laid down upon lines consistent with its greatest chance of "viability," and if it will ameliorate several of the anomalies of the existing Act, giving greater effect to the contract made by the State in 1868, so that unqualified persons shall not usurp the functions of those who have complied with the law, then, on all the principles by which prudent men regulate their actions, we shall give the new Bill a hearty support.

The "heckling" to which the Bill has been subjected should largely increase the confidence of its authors in its soundness. And it is a hopeful circumstance that the public criticism of the measure has been generally conceived in a friendly spirit. Any faults of the Bill are now known, and since the explanations which have been given of the "necessity which has no law," I believe that very little adverse criticism will be accepted as having hit the mark. There is wisdom in the proverb that "Bad wine makes good vinegar." Judging by the quality of the adverse critics' vinegar, I feel that they have not operated on bad wine in dealing with this Bill.

Some of the suggestions thrown out will undoubtedly prove useful contributions to the finished measure. I will venture to add one for what it may be worth, viz., that articles in clause 2 should be labelled either "poisonous" or "poison." As "the greater includes the less," the pharmacist would find it more convenient to fulfil his duty by using the label which at present covers the sale of scheduled "poisons."

Mr. Sandford's remarks upon clause 4, making the retailer of patent medicines responsible for proper labelling in case of their containing a legal poison, will be sure to receive careful attention. But, so far as the labelling of the outer wrapper is concerned, the retailer can be in no difficulty as to what he is selling, for the presence or absence of the poison label will be literally "patent" to his vision.

The Council have deserved our hearty support. Let them have it ungrudgingly.

Leeds. RICHARD REYNOLDS.

B.—The main decomposition results in the formation of iodide of ammonium, and if the iodine be in excess iodide of mercury is also formed.

O. M., Honiton.—The iodide of iron should be dry and the carbolic acid in crystals; crumb of bread will then do as an excipient.

T. Martin.—A dispenser may amend the excipient to retain in their integrity the remedial agents of the prescription. Cacao butter is a good excipient for permanganate of potash; if the mass be too crumbly, add a little vaseline to it.

Joseph.—It was correct to use the ol. junip. pyrolig., which is synonymous with "huile de cade." It is usually a dark empyreumatic oil, but samples may differ.

Pharmacien.—The difficulty in filtration sometimes arises from the rhubarb being powdered, instead of being sliced or bruised, as directed in the B.P.

F. W. W.—As the properties of the ingredients in the mixture are well known, there ought to be little difficulty in devising a scheme for separating them.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Kingzett, Allen, Forrest, Wilkinson, Wells, Southwell, Hocken, MacEwan, Hicks, Tanner, Fowler, Gibbons, Page, Newsholme, Lacy, Hannah, Coates, Lloyd, Devoniensis, Labiatæ.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 719.)

KRAMERIA, U.S.P.; RADIX RATANHIÆ P.G.—In the U.S.P. the root of *Krameria Tomentosa*, St. Hil., is now official, in addition to that of *K. triandra.* From the description of the latter given in the text, it would appear that *K. argentea* is intended, as the root is described as having a *dark* purplish brown bark, whereas that of Savanilla rhatany (*K. tomentosa*) is of a dull or *pale* purplish brown. As yielding a larger proportion of bark as compared with the almost tasteless woody centre, the roots of Savanilla or Pará rhatany are both preferable to the Payta rhatany, the knotted upper portion of which is difficult to powder or contuse. Moreover, the Savanilla rhatany is richer in soluble matter. In the P.G. the root of *K. triandra* is still the only official kind, probably on account of the colour of the tincture, which is redder than that of either Savanilla or Pará rhatany (*Pharm. Journal*, [3], vi., p. 21). Tests are given which preclude the use of either of the two varieties last mentioned (*Pharm. Journ.*, [3], i., p. 84). The woody portion being practically useless, and forming a large portion of the crude Peruvian drug, a weighed portion of the root bark would give a more uniform preparation.

LACTUCARIUM, U.S.P. and P.G.—The P.G. now directs that the liquid obtained by pouring boiling water on it should not, after filtration, become turbid when cold, nor become coloured if shaken with powdered iodine; the spirituous solution should not be changed by sesquichloride of iron. It should not yield more than 10 per cent. of ash.

LAPPA, U.S.P.—Retained from the secondary list, and a description added. It is referred to *Lappa officinalis*, Allioni.

LAVANDULA, U.S.P.; FLORES LAVANDULÆ, P.G. —According to the P.G. the calyx should be "coloris ferruginei." The greyish-blue calyx is here evidently confounded with the brown bracts.

MALVÆ, FLORES, P.G.—The flowers of *Malva sylvestris* only are now official. Under the name of "mallow flowers," both those of this species and of *Malva arborea* (*Althæa rosea*, Cav.) are popularly used in Germany, and the restriction to one species is likely to cause some inconvenience in certain districts.

MALVÆ, FOLIA, P.G., are obtained from *M. vulgaris* and *M. sylvestris.* It is difficult to understand why one species is not sufficient in this case. The ambiguity which results from the omission of the name of the botanical authority after the Latin name of a plant is well illustrated in this case. *Malva vulgaris*, Tenor, is identical with *Malva sylvestris*, L., and it is only by putting the name of Fries after *Malva vulgaris* that it is possible to know that *Malva rotundifolia* is intended by that name.

LIMONIS SUCCUS, U.S.P.—The sp. gr. should be not less than 1·030; and the juice evaporated to dryness and the residue ignited should not give more than 0·5 per cent. of ash. Fresh lemon juice should contain about 7 per cent. of citric acid.

LOBELIA, U.S.P.; HERBA LOBELIÆ, P.G.—The U.S.P. now directs the plant to be collected after a portion of the capsules have become inflated.

LUPULINUM, U.S.P.; GLANDULÆ LUPULI, P.G.—The U.S.P. directs that when agitated with water and allowed to stand no considerable sediment (sand, etc.) should be deposited. When ignited lupulin should not leave more than 8 per cent. of ash. The P.G. permits 10 per cent. of ash, and the glands when exhausted by ether should not leave more than 30 per cent. of insoluble matter, the ethereal solution on evaporation leaving a residue which should smell strongly of the hop. It should be kept from the light and not held in stock longer than a year. Owing to the great demand for hops, lupulin is at present scarcer and more adulterated than usual, vegetable matter which can only be detected by the microscope or by the ether test given in the P.G. being frequently mixed with it.

LYCOPODIUM, U.S.P., P.G.—It should be free from pollen, starch, sand and other impurities. The distinguishing features of lycopodium under the miscroscope are given. Dextrin and talc, which have also been found in lycopodium, are easily detected by means of the same instrument. The P.G. states that it should float on water or chloroform and leave no deposit in those liquids when shaken with them. It should not yield more than 5 per cent. of ash.

MALTUM, U.S.P.—It should be fresh, and not darker in colour than pale amber. Extract of malt is the only preparation.

MANNA, U.S.P., P.G.—The U.S.P. gives the specific gravity as 0·834. It should be slowly but almost completely soluble in 15 parts of boiling alcohol. The P.G., in which both *Manna cannulata* and *Manna communis* are still official, gives as a test of its purity that 5 parts boiled with 100 parts of spirit should leave about 1 part of insoluble but not viscid matter, and that 100 parts dried in a water-bath should not lose more than 10 parts of moisture.

MATICO, U.S.P.—The leaves are described as "oblong-lanceolate, pointed, unequally heart-shaped, very finely crenulate." The words "at the base" after the words "heart-shaped" are evidently wanting to complete the sense and the description.

MEL, U.S.P.—When diluted with 2 parts of water the resulting liquid should be almost clear, not stringy; it should have a specific gravity of 1·101 to 1·115 and a brownish or yellowish colour. If a small portion be diluted with 1 volume of water, then gradually mixed with 5 volumes of absolute alcohol, it should become only faintly opalescent, but not opaque, nor should it deposit a slimy substance at the bottom and along the sides of the test tube. When incinerated in small portions at a time in a platinum crucible it should not leave more than 0·2 per cent. of ash. It should not give evidence of the presence of starch, nor more than traces of chlorides and sulphates.

MEL DESPUMATUM, U.S.P.; MEL DEPURATUM, P.G. The U.S.P. preparation is made by merely heating the honey in a water-bath and straining off the scum which rises. The P.G. now omits the directions for preparing it, but gives the specific gravity as 1·30, and as tests of purity, that it should not change colour when mixed with an equal quantity of liquor ammoniæ nor be rendered turbid when a double quantity of spirit is added to it.

MELILOTI, HERBA, P.G.—This may now consist of *Melilotus altissimus*, as well as *M. officinalis*; the former is distinguished by the pods being distinctly acuminated and furnished with blackish hairs.

MEZEREUM, U.S.P.—The bark of *D. Mezereum* and of other species of *Daphne* is official. The bark is described as having the "outer surface yellowish or brownish yellow," a description which scarcely applies to the stem bark of *D. Mezereum*; indeed it is difficult to understand how it is possible to give a detailed description which shall equally apply to "other species."

MOSCHUS, U.S.P. and P.G.—According to the P.G. it should not afford an ammoniacal odour, a remark apparently intended to exclude Russian or Cabardine musk. It should be dried over sulphuric acid until it ceases to lose weight and should not afford more than 8 per cent. of ash when incinerated. The U.S.P. describes musk as contained in oval or roundish sacs about 1½ to 2 inches in diameter, apparently permitting the use of the Russian (oval) as well as Chinese musk, but excluding that of Assam. About 10 per cent. should be soluble in alcohol and 50 per cent. in water.

MYRRHA, U.S.P. and P.G.—The U.S.P. requires that the brownish yellow alcoholic tincture should acquire a purple hue when nitric acid is added. Pieces of gum which do not answer to this test, and others which dissolve entirely in water, or merely swell up in it, should be rejected, tests which are evidently taken from the last P.G. The P.G. now refers it to *Balsamea Myrrha*, and states that 30 per cent. of the gum resin should be soluble in spirit and the residue left on evaporation of the alcoholic solution, when dissolved in ether, should on the addition of bromine vapour give a red or violet colour.

NUX VOMICA, U.S.P.; SEMEN STRYCHNI, P.G.—In the U.S.P. the seeds are described as having a silky lustre, but nothing is said concerning the margin. The P.G., however, points out that when the seeds are softened in water the subacute marginal line becomes more visible. The diameter in both Pharmacopœias is given as 25 millimetres. It was pointed out some time since in Bentley and Trimen's 'Medicinal Plants' that some specimens of the seeds contain more alkaloid than others. It is well known that the large seeds are more active than the smaller ones, hence a limit of size is of some importance. Another point, however, does not seem to be so generally recognized, viz., that the Bombay seeds, with a subacute margin and more silky lustre, contain much more alkaloid than those from Madras and Cochin China. In future Pharmacopœias this point will be worth attention, as a variation of strength in preparations made from so potent a drug might lead to dangerous results.

OLEUM ADIPIS, U.S.P.—It should become opaque at or below 0° C., and the sp. gr. should be 0·900 to 0·920.

(To be continued.)

VEGETABLE ALKALOIDS, AND THE METHODS FOR THEIR SEPARATION.*

BY MATTHEW HAY, M.D., DEMONSTRATOR OF MATERIA MEDICA, UNIVERSITY OF EDINBURGH.

(Concluded from page 720.)

SEPARATION OF ALKALOIDS.—Without being intelligently acquainted with these various physical and chemical qualities of alkaloids it is impossible that any one can competently undertake their separation. And it is based almost entirely upon the qualities I have briefly sketched, especially upon the relation of the alkaloids to solvents and precipitants, that the various methods for the separation of alkaloids have been devised.

Assuming that we are all more or less familiar with these characters of alkaloids, let us proceed to inquire in as plain and as practical a manner as is consistent with accuracy how we are to set about the separation of an unknown alkaloid. A plant is brought to us with reputed toxic powers, and we are desirous of isolating the alkaloid to which we suppose that the activity of the plant is due. We are not at once to assume that because the plant possesses a considerable degree of activity that its active principle is necessarily an alkaloid. It may belong to that important class of active principles, whose exact chemical constitution and position, with the exception of the glucosides, is so little understood that they are known by the very negative name of "neutral" principles. These bodies behave in relation to the various solvents I have already enumerated much in the same manner as alkaloids, and are often thus to be obtained by such methods employed for the separation of alkaloids as do not involve the use of precipitants. The activity of the plant may reside in a resin, as is the case with several plants possessing a cathartic action (*e.g.*, podophyllum), in a volatile oil (as in copaifera), or in a fixed oil (as in ricinus), or in some other constituent of the plant possessing no alkaloidal characters whatever. It is almost impossible to predict from the nature of the action of the plant whether its activity is dependent on the presence of an alkaloid or upon some other of the constituents. But as a rough guide in the expectation of the presence of one or other kind of active principle, it may be remembered that all poisonous plants which primarily act on the nervous system, producing tetanus, paralysis or narcotism, generally possess alkaloids as their active principles. On the other hand, if the action of the plant is primarily on the muscular system, as, for example, the large class of plants possessing the action of digitalis, then expect to find a neutral principle. It is a rule without exception that all pure simple bitter tonic plants possess as their active ingredient, likewise, a neutral principle. Further, if the action of the plant be cathartic, emetic, or purely astringent, then again there is probably no alkaloid present, but merely a neutral principle, or, perhaps, a resin.

If, from a consideration of these and other points, we become tolerably assured of the presence of an alkaloid, we can the more confidently proceed to lay down our plans for its separation. It is always advisable, before beginning what may prove a long and tedious analysis of some imperfectly known plant, to ensure, by the administration of a small quantity of it to one of the lower animals—a frog, a rabbit, a cat, or a dog—that the specimen of the plant or drug about to be examined really possesses the action ascribed to it. There is another reason why it is desirable to make one, and, it may be, several such preliminary experiments, and it is, that we render ourselves familiar with the nature of the action of the plant, and therefore with that of the alkaloid we desire to separate; and, accordingly, by making a similar experiment with our successive extracts, solutions or precipitates, we are enabled readily to ascertain in which of them the alkaloid is present. This form of physiological testing is most conveniently made with frogs, and best by subcutaneous injection; but, unfortunately, under the Vivisection Act we are not permitted to practise even so small an operation as a subcutaneous injection without a licence from the Home Office, which is not always easily obtainable.

Preliminary Extraction.—This experiment having been made, and having selected for that purpose the portion of the plant (seed, bark, root, etc.) which we believe, or may have proved, to contain the active principle, we take for our analysis the same portion of the plant, and begin by having it well comminuted or pulverized.

Now, let us consider for a moment in what chemical

---

* Read by request before the North British Branch of the Pharmaceutical Society, Feb. 15, 1883.

form or combination the alkaloid exists in the plant or in the powder, and what is the nature of the substances with which it is mixed and from which it is to be separated. The alkaloid never exists in the plant in the free state but is invariably combined in the form of a salt, and oftentimes as an acid salt, with one or other of the organic acids which are found so generally in plants, particularly malic acid and the varieties of tannic acid. Sometimes the acid with which it is combined is, like the alkaloid, peculiar to the plant in which it is found, as meconic acid in opium, quinic acid in cinchona; and occasionally the acid may be even inorganic, as, for example, the sulphuric acid with which some of the opium bases appear to be united. To whatever acid the alkaloid may be joined it almost invariably forms a salt which is readily soluble in water or in alcohol, and which therefore can be extracted by either of these menstrua.

The various substances with which the alkaloidal salt is mixed is dependent, of course, upon the nature of the plant, and may be thus arranged, and at the same time their solubility in the three most common menstrua represented:—

	Water.	Alcohol.	Ether.
Cellulose . . .	insol.	insol.	insol.
Starch	insol. in cold. sol. in hot.	insol.	insol.
Gums and pectose.	sol.	partly sol.	insol.
Sugars	sol.	sol.	insol.
Fixed oils . . .	insol.	partly sol.	sol.
Volatile oils . .	slightly sol.	sol.	sol.
Resins	insol.	partly sol.	partly sol.
Albuminoids, incl. mucus. . . .	sol.	insol.	insol.
Neutral principles.	partly sol.	partly sol.	partly sol.
Colouring matters.	sol.	sol.	partly sol.
Organic acids and salts	sol.	sol.	partly sol.
Other organic matter	partly sol.	partly sol.	partly sol.
Inorganic salts .	mostly sol.	mostly insol.	insol.

It can be perceived at a glance what portions of the plant, in addition to the alkaloidal salt, are likely to be met with in extracts made with water, alcohol, or ether.

Continuing the examination of our plant, we now make choice of what solvent or menstruum will most readily dissolve the alkaloidal salt out of the plant, and at the same time carry into solution as few and as little as possible of the other constituents of the plant. Were the natural alkaloidal salt freely soluble in ether, which it is not, and did the ether penetrate readily the particles of the pulverized drug, we would feel inclined on account of its dissolving so few of the other vegetable substances to adopt it as an extractive solvent. As, however, a perfect extraction of the alkaloid is the primary object, we commonly find it advisable to use water or alcohol in preference to ether. Pure hot water is in nearly every case the best extractive solvent, and, after the plant has been repeatedly exhausted with water, the solvent power of the water in the final extraction may be increased by the addition of a small quantity of sulphuric acid or of tartaric acid. Even when alcohol is used it is sometimes advantageous to add a little acid. But on the whole it is advisable to use as little acid as possible. It is well not to employ too large a bulk of the solvent, for it may necessitate prolonged evaporation in order to remove a portion of the alcohol or the water at a later stage of the process. The extraction may be made by mixing the powdered plant with three or four successive portions of the solvent and allowing each mixture to stand for some hours, then draining and pressing; or the extraction may be made with the help of a percolator, particularly if the drug at our disposal is small in quantity or if alcohol is employed as the solvent.

Methods for Separation of Alkaloid.—We have now obtained a fluid extract of the plant, either watery or alcoholic, and its treatment for the separation of the alkaloid may take one of two different directions. We may endeavour to separate the alkaloid by precipitating it in the form of an insoluble salt, or we may remove it from the extract by means of solvents. The former method yields, as a rule, better results than the latter in respect both of the purity and the amount of the product, although it is not generally so well adapted for the separation and detection of small quantities of alkaloids in chemico-legal investigations, where often the absolute purity of the product is of less account, provided it satisfies the tests and possesses the physiological action of the alkaloid sought for. As the more important, therefore, for our purpose let us first consider in what manner the method by precipitation is to be followed.

A. Methods by Precipitation.—*Purification of Extract.*—The watery extract, or the alcoholic extract deprived of its alcohol by evaporation and the residue exhausted with water, if it has been prepared from a portion of the plant, as, for example certain woods and barks which yield to the water not much else than extractive matter besides the alkaloidal salt, may at once be treated with the precipitant; and this is also in many cases the course pursued if the alkaloid is present in large quantity, and can, on account of its insolubility in water, be precipitated in an uncombined form by the addition of an alkali (*e.g.*, morphine). If, on the other hand, the precipitation of the alkaloid, on account of the solubility of the alkaloid in water, or its presence in small quantity, requires the use of some of the more complex but more effective reagents, as phospho-molybdic acid or the double iodide of potassium and mercury, it is always necessary to previously remove from the extract as much of its inert organic matter as possible. For this purpose nothing surpasses a combination of basic acetate of lead and of ammonia. The basic acetate can of itself form insoluble precipitates with most of the organic acids, as malic acid; with many glucosides, as tannin, and with all albuminoids, starches, and gums. It can also very effectually remove the colouring matter; but the presence of free ammonia is essential to its completely precipitating dextrine and the various sugars. The ammonia may be added either immediately after the addition of the basic acetate of lead without previous filtration; or the precipitated lead compounds may be first removed by draining or filtration, and the ammonia mixed with the filtrate which should contain an excess of the basic acetate. The ammonia is added until the fluid, after stirring, begins to smell distinctly of ammonia; no alkaloid is known to be precipitated by basic acetate of lead and ammonia. The fluid having been again filtered is now evaporated at a moderate heat over the water-bath to drive off the excess of ammonia and to diminish the bulk of the fluid, which may with advantage be reduced until the fluid becomes of a syrupy consistence, so that the ammonia may be almost completely removed. The partially evaporated fluid is, if syrupy, diluted with some water, and now treated with dilute sulphuric acid in sufficient quantity to precipitate all the lead in the form of the insoluble sulphate of lead, and the fluid is once more filtered. The fluid will generally at this stage be found pure enough to permit of the precipitation of the alkaloid by means of any form of precipitant. If it is still highly coloured and evidently contains a large proportion of extraneous organic matter, the process of precipitation with the basic acetate of lead and with ammonia may be repeated; but, generally, this is not needed.

Precipitants.—The stage has now been reached when we must select an alkaloidal precipitant. If the alkaloid be insoluble in water, a solution of any one of the alkalies or alkaline carbonates, or of the alkaline earths, will prove the most ready and effectual precipitant. But if, as it far oftener occurs. the alkaloid is soluble to some extent in water—and, indeed, whether soluble or not—we must resort to the use of some of those acids or salts, which have already been mentioned as forming insoluble precipitates with practically every alkaloid. These precipitants may be divided into four classes :—

(1.) Some *simple organic acids,* as tannic acid (Berzelius) and picric acid (Hager).

(2.) Some *compound inorganic acids,* as phospho-wolframic acid (Scheibler), phospho-molybdic acid (De Vrij, Sonnenschein), and phospho-antimonic acid (Schulze).

(3.) The *chlorides of the heavier metals,* as those of platinum (Dragendorff), gold, iridium, and palladium (V. Planta).

(4.) Certain *double metallic iodides,* as those of potassium and mercury (V. Planta, Mayer), potassium and bismuth (Dragendorff), and potassium and cadmium (Marmé).

The cost of the third group precludes their general use, but each of the precipitants of the other groups has its advocates. The best of them are probably phospho-wolframic acid, phospho-molybdic acid, the double iodide of potassium and mercury, the double iodide of potassium and bismuth, and tannic acid.

Precipitation.—Each precipitant, except the last, acts most effectually in the presence of dilute mineral acid; and the acid most commonly used is sulphuric, which is at any rate present in excess in the extract, on account of its having been used to remove the lead. Tannic acid must be added in a neutral or faintly acid solution, and sometimes, owing to the acid which is being set free from the precipitated alkaloid being large in amount and rendering the fluid too acid, a little alkali or alkaline carbonate may require to be added before complete precipitation can be secured. In the use of the other precipitants, no precaution is, as a rule, necessary, unless it is to take care that the fluid has a well-marked acid reaction, and that previous to filtering the fluid is allowed to stand for a day or so, in order to ensure the complete precipitation of the alkaloidal compound. It is important, as Schmiedeberg has remarked for the double iodide of potassium and mercury, that the solutions of the double iodides do not contain any more iodide of potassium than is sufficient for the solution of the heavier iodide, otherwise the excess of the iodide of potassium may, in certain cases, dissolve the alkaloidal precipitate. To avoid this, the solution should be made by adding excess of the heavier iodide to a solution of the iodide of the alkali, allowing the latter to dissolve as much of the former as it can, then filtering, to remove the undissolved iodide, and observing that the filtrate does not give a precipitate on dilution; if it does, dilute and again filter. The alkaloidal precipitate obtained by the use of tannic acid, or of one of the composite organic acids, or of one of the double iodides, is now separated by filtration. The tannic acid precipitate may be washed with a little water; the others must be washed with dilute sulphuric acid, as water alone is apt to decompose and dissolve them. The precipitate is then dried in the usual way by pressure between several folds of filter paper, and is transferred to a beaker and mixed with a little water.

Liberation of Alkaloid from Precipitate.—The means necessary for the liberation of the alkaloid from its insoluble salt varies with the nature of the precipitant, but is the same for the members of each of the different kinds or groups of precipitants; that is, there is one method to be followed in the treatment of the precipitate with tannin, another for all the precipitates with the double iodides, and a third for all those with the composite acids.

a. From Tannic Acid Precipitate.—The treatment of the precipitate with tannic acid is simple, and consists in gently digesting it for some time with moist and freshly precipitated oxide of lead, until a portion of the supernatant fluid or filtrate is no longer darkened by the addition of ferric chloride. If the alkaloid which has been set free is soluble in water, then it will all be contained in the filtrate, from which any trace of lead is removed by passing sulphuretted hydrogen through it, and again filtering. The filtrate, if gently heated for a short time over the water-bath, will have the excess of sulphuretted hydrogen readily dissipated. By continued slow evaporation, crystals of the alkaloid may be got; or it may be exactly neutralized with a dilute mineral acid, and a crystalline salt obtained by evaporation. The further steps necessary for the perfect purification of the alkaloid or of its salt, I shall immediately come to.

If the liberated alkaloid be insoluble, it remains mixed with the precipitated tannate of lead, and with the excess of lead oxide, and requires to be extracted with alcohol. The alcoholic extract is evaporated almost to dryness and dissolved in dilute sulphuric acid, any trace of lead remaining undissolved as sulphate of lead. The acid solution of the sulphate of the alkaloid is then treated with carbonate of barium to remove the acid, but of course at the expense of the precipitation of the alkaloid (as the carbonates of the alkalies or alkaline earths behave as bases towards solutions of alkaloidal salts). The mixture is filtered, and the alkaloid once more extracted with alcohol. Slow evaporation of the alcohol will, under favourable circumstances, yield crystals of the alkaloid.

b. From Double Iodide Precipitate.—If one of the double iodides has been employed for the original precipitation of the alkaloid, then the precipitate, which is a double iodide of the alkaloid and the heavier metal, requires a different process for the recovery of the alkaloid. It is mixed with a little water and with an equal volume of the moist hydrated oxide of barium, and a stream of sulphuretted hydrogen gas is passed through the mixture until the fluid, after being shaken, smells strongly of the gas, when the double iodide will have become completely decomposed, forming an insoluble sulphide of the heavy metal—mercury, bismuth or cadmium, as the case may be—the alkaloid being dissolved in the form of the simple iodide. The previous addition of the baryta facilitates the decomposing action of the sulphuretted hydrogen. The fluid is filtered to remove the insoluble sulphide, and the filtrate which contains the iodide of the alkaloid, and the iodide and the sulphide of barium, is treated with excess, either of moist and freshly prepared oxide of lead, or of sulphate of silver. The latter precipitates the hydriodic acid in the form of iodide of silver, the sulphuretted hydrogen in the form of sulphide of silver, and the barium as sulphate of barium, and leaves the alkaloid in the form of a soluble sulphate; whereas, the oxide of lead, whilst it precipitates with equal effectiveness the hydriodic acid and the sulphuretted hydrogen, and the barium as oxide of barium, yet it sets free the alkaloid in an uncombined state; and if the alkaloid be insoluble in water, it remains mixed with the precipitates.

Where the sulphate of silver has been employed, the filtrate, after the addition of this reagent, contains the unused excess of the reagent as well as the sulphate of the alkaloid. To remove the silver, the fluid is treated with an excess of barium hydrate, and sulphate of barium and oxide of silver are formed and the alkaloid is liberated, which, according as it is soluble or insoluble in water, is dissolved in the filtrate or remains precipitated with the barium and the silver. If it is dissolved in the filtrate, the small excess of barium hydrate is removed by a stream of carbonic acid gas, and the barium carbonate is then got rid of by filtration, and the filtrate gently evaporated, when the alkaloid will be obtained. If the alkaloid is insoluble in water and remains mixed with the precipitates, then, after filtration, the residue is exhausted with alcohol, and the alcoholic solution treated in the same manner as that obtained from the tannate of lead in the previous process.

If oxide of lead has been used for the precipitation of the iodine, it is advisable to previously render the fluid slightly acid with sulphuric acid, so as to precipitate the barium as sulphate of barium. The oxide should then be digested with the fluid, until the fluid has an alkaline reaction. The precipitate from the oxide of lead may, as already mentioned, contain the alkaloid, if it be insoluble. If it be soluble, it will be met with in the filtrate, which, in order to deprive it entirely of its lead, is treated with a little sulphuretted hydrogen and again filtered. The filtrate then requires the same treatment, in order to isolate the alkaloid, as was described in connection with the filtrate obtained at the same stage of the tannin method. The alkaloid if insoluble in water is also obtained from the mixed precipitate in the same manner as previously described.

c. *From Precipitate with Composite Inorganic Acid.*—The process required for the separation of the alkaloid from its precipitate with the composite inorganic acids is simpler than the preceding; and to that extent is one or other of these acids to be preferred for the precipitation of the alkaloid. The precipitate, after being pressed, is thoroughly mixed by frequent stirring with a little water and more than an equal volume of pure barium hydrate, until it is completely decomposed, which is readily indicated by the excess of the dissolved barium hydrate forming with the carbonic acid of the atmosphere an insoluble scum of carbonate on the surface of the fluid. The mixture is now filtered, and the alkaloid, if it be soluble in water, passes through in the filtrate mixed only with a little barium hydrate, which can be readily removed by precipitation with a stream of carbonic acid gas. The filtrate on gentle evaporation will yield the alkaloid; or, if it be previously neutralized with dilute sulphuric acid, or other simple acid, crystals of a salt of the alkaloid may be obtained. If the alkaloid be insoluble in water, it remains mixed with the insoluble wolframate of barium and with the excess of baryta, and can be removed by alcohol, and the alcoholic solution treated in the usual way.

Purification of Alkaloid.—By these various methods of precipitation it is possible to obtain, and in the manner described, a tolerably pure alkaloidal product. For its more complete purification it is sometimes necessary to make a solution of it in water and a little acid, and to repeat the process of precipitation and isolation; and, whether it be reprecipitated or not, if it possesses a tinge of colour it is often advantageous to treat its solution in water or in alcohol, or the solution of its salt in one of these menstrua, with pure animal charcoal, remembering that the charcoal is apt to remove a portion of the alkaloid, which can, however, be re-obtained by treating the charcoal with boiling alcohol. Also, repeated crystallization of the alkaloid or its salt from a solution in alcohol or in water may be required to furnish a perfectly pure product. The *technique* of the methods employed for this purpose is quite familiar in every department of chemistry, and, therefore, requires no further mention.

When it is desired to procure a very pure salt of the alkaloid of definite composition and of good crystalline form for the purpose of an elementary analysis, the double salt obtained by the addition of chloride of platinum or chloride of gold to a solution of the alkaloid, will generally be found to best meet the requirements.

These, then, are, quickly stated, the most reliable methods for the separation of the alkaloid by precipitation, and important modifications may be necessitated in each individual practical application of the methods, which can only be suggested in the course of the analytical investigation. For example, other solvents than alcohol may be required for the extraction of the alkaloid from the mixed precipitates, and it is an easy matter to try one after another until the most efficient is obtained.

Separation of Volatile Alkaloids.—I have described these methods as if the alkaloid were non-volatile, which in the great majority of instances it is; but there are exceptions, as I formerly mentioned. In such cases the separation of the alkaloid is generally most easily accomplished, often even without making a preliminary extract with alcohol or water, merely by mixing the drug with a little water and alkali or alkaline earth, and distilling, neutralizing the distillate, and again distilling to remove other volatile substances, the alkaloid remaining in the retort in the form of a non-volatile salt. This can be dissolved in water or alcohol and purified by crystallization, etc., in the usual way, and a perfectly pure alkaloid obtained from the salt by a final distillation with an alkali. The presence of a volatile alkaloid is generally to be perceived by its odour at that stage of the operations required for the separation of an alkaloid by precipitation, where oxide of lead or barium hydrate is being employed for the decomposition of the precipitated compound of the alkaloid, on the alkaloid being set free. If so, it is advisable to add excess of barium oxide and distil. A tolerably pure alkaloid will in this manner be obtained.

B. METHODS BY SOLUTION.—The other series of methods for the separation of alkaloids, and which mainly involves the use of solvents, without precipitants, is that which, as I have already mentioned, is in one form or other most frequently employed for the medico-legal isolation of alkaloids. They were formerly the only methods used, but at the present time the precipitation methods are considered more serviceable in pharmaceutical research. These methods mainly depend on the following facts:—(1) When an acid solution of the alkaloid is shaken with ether, chloroform, amylic alcohol, benzol, acetic ether or petroleum ether, the alkaloid is not removed by these solvents; but, (2) When the solution is alkaline, the alkaloid is readily taken up by one or other of these solvents. In short, these methods rely on the solubility of the free alkaloid and the insolubility of its salts, in certain menstrua which are nonmiscible with water.

Purification of Extract.—When it is desired to separate an alkaloid by means of solvents, an extract of the plant is made with acidulated water or alcohol just as when precipitants are intended to be employed. The watery extract, which is the more preferable, is neutralized with carbonate of soda, and cautiously evaporated almost to dryness, and the residue is treated with acidulated absolute alcohol, which dissolves the alkaloid and leaves some albuminous and other matter. The filtrate is again neutralized with carbonate of soda and evaporated to dryness, and the residue dissolved in water. It is always strongly advisable never to evaporate fluids containing alkaloids without previously neutralizing them, otherwise the alkaloids are very prone to suffer decomposition.

Separation of Alkaloid.—The aqueous solution is now rendered acid with a little sulphuric acid or other simple acid, and is well shaken with successive portions of ether to remove fats and resins, and the ether poured off. The ether, as a rule, in the presence of acid dissolves none of the alkaloid; but there are one or two exceptions where a small portion of the alkaloidal salt is removed by the ether. If any of the alkaloid should chance to be thus removed, evaporate the ether and treat the residue with water. The watery extract will contain the alkaloid. But, if, as almost invariably happens, the ether has removed none of the alkaloid, the acidified aqueous solution is now rendered alkaline by means of carbonate of soda or a little caustic soda, and is again well shaken with successive quantities of ether, which, in the great majority of cases, will completely dissolve out the alkaloid. Should the alkaloid prove to be insoluble in ether, it is necessary after pouring off the ether to neutralize the aqueous fluid and heat to drive off the ether, and again render it alkaline, and shake it with another of the alkaloidal solvents enumerated, as chloroform, or amylic alcohol, or benzol, or with a succession of them. The ethereal or other solution of the alkaloid, in order to purify it, is then shaken with an equal volume of slightly alkaline water. Sometimes, to ensure a still greater degree of purity, the ethereal or other solution is next shaken with water containing a little sulphuric or hydrochloric acid, which transfers the alkaloid to the water, and this may now be shaken with successive portions of pure ether, or whatever solvent has been previously used, to completely remove from it all substances soluble in the ethereal menstruum in the presence of acid. On adding an alkali or alkaline carbonate to the water, it readily gives up the alkaloid to a fresh portion of the ethereal solvent when shaken with it. Evaporation of this purified ethereal solution will generally yield the alkaloid in a tolerably pure condition. For its further purification, digestion with charcoal and crystallization of the alkaloid or its salts from their solution in water or alcohol may be necessary.

This is merely an illustrative outline of a process embodying the principles involved in the method of separating alkaloids by means of solvents. As this method is very largely employed in medico-legal investigations, several more detailed descriptions of processes will be found in the numerous works on toxicology (Husemann, Otto, Dragendorff, Taylor, etc.). Of these, the process or method of Stas, as improved by Otto, is the oldest and the best known, and, perhaps, still the most frequently employed. In it ether and amylic alcohol are successively employed as solvents. The method of Erdmann and Uslar, in which amylic alcohol is the main solvent employed, has been also favourably received. Dragendorff's method is, perhaps, of all the most thorough, and involves the use of nearly all the important alkaloidal solvents.

Separation of Alkaloids from one another.—In the processes which I have described as being used for the separation of alkaloids, I have nearly always spoken as if but one alkaloid were to be met with in each plant. But, as a matter of fact, many plants, perhaps, it will be eventually found, most toxic plants, contain more than one alkaloid. The product obtained by the methods described may, therefore, consist of a mixture of alkaloids. If so, the alkaloids are to be separated from each other by taking advantage of the differences in the degree of the solubility of themselves or their salts in the various solvents mentioned, water included.

Recognition of Alkaloid.—When once the substance is supposed to have been isolated in a pure form, it is necessary to make certain that it is in reality alkaloidal. If it be an alkaloid or alkaloidal salt it will when heated to redness, like all organic matter, completely burn away. Mixed and heated with soda-lime (a mixture of caustic soda and lime) it will, unlike neutral active principles and other nitrogen-free organic substances, evolve the odour of ammonia. Further, a solution of the alkaloid or of its soluble salts, will give a precipitate with nearly all the substances already mentioned as generally forming insoluble salts with alkaloids. The physiological action of the separated product will also sometimes be of help in determining whether it is alkaloidal or not. One must guard against mistaking a salt of ammonia for a salt of an alkaloid, as the former behaves chemically in almost every respect quite like an alkaloid.

Conclusion.—These, then, are, briefly stated, the various processes or methods employed for the separation of alkaloids. It is impossible in the present state of our knowledge to lay down any single general method which will suffice for the separation of any alkaloid. It will therefore rest with each chemist to choose the method that may appear to him the most suitable for the plant he is about to examine, and to use his own discretion and ingenuity in modifying it when necessary. It has been mainly my aim in the present communication to lay before you the general principles which guide us in the separation of alkaloids.

In conclusion, allow me to say that, whilst only a few of you may have the opportunity of discovering an unknown alkaloid, yet many of you may be able to improve and cheapen the processes by which we at present obtain known alkaloids. Pure alkaloids of definite composition, and, therefore, of unvarying action, are what the therapeutist requires; and the chemist who can furnish him with these, and by the readiest and cheapest methods, benefits both therapeutics and pharmacy as much as he who brings to light a new alkaloid. For all new alkaloids are not of value medicinally.

To those who are proficient scientific chemists, and who devote themselves in great part to pharmaceutical research, there lies open the almost untrodden field of the artificial production of both known and unknown alkaloids. The syntheses of Schiff and Schmiedeberg cannot surely remain solitary. The capability of the artificial formation of all alkaloids is in the highest degree probable. And what synthetical chemistry is now in certain instances doing for the arts, we are all hopeful, and even confident, will soon be accomplished for the materia medica.

During the course of the lecture Dr. Hay very successfully demonstrated the practicability of the various methods of separation to which he referred. He also showed a collection of rare active principles, as well as the more important bodies existing in vegetable tissue and from which alkaloids are separated.

The President, in moving a vote of thanks to the lecturer, said that he was sure that those present would join with him in admiration of the manner in which the interesting subject had been treated. It was a subject of great pharmaceutical importance, and he was sure that the younger members, who had the opportunity before them, would receive from the lecture a stimulus for research, since Dr. Hay had made each stage of investigation appear so simple. He had much pleasure in proposing a cordial vote of thanks to Dr. Hay.

Mr. Dott, in supporting the motion, said that although there were some points on which he differed from what had been said, yet, generally his experience would lead him to agree with the principles laid down. It should not be forgotten that a process which might be applicable in a chemico-legal investigation, for instance, might not, for economical grounds, be suitable on the manufacturing scale. There were at least two general laws to be observed in all cases, namely, *low temperature* and *neutrality*. It was commonly stated that all alkaloids were soluble in alcohol. This was not universally so,—pseudo-morphine and rhœadine forming striking exceptions to the rule. Regarding the greater solubility of acid salts of alkaloids, he mentioned that the acid tartrate of morphia was an exception, the neutral tartrate in this case being more soluble. There was a process recommended for the elimination of alkaloids, in which a solution of oxalic acid was employed for exhausting the drug. He thought that this was probably the worst acid which could be used as a solvent, because oxalates were the most insoluble salts of alkaloids, and, moreover, alkaloids in combination with organic acids were far more liable to be decomposed on evaporation than when they were in combination with inorganic acids. For these reasons he thought that acids of the latter class ought always to be used.

Mr. Stephenson having made a few remarks in support of the motion,

Dr. Hay thanked the meeting for the manner in which his communication had been received. Referring to Mr. Dott's remarks, he said that the methods which he had proposed were such as were best adapted for the purposes of investigation; they were well-tried methods, and in his own hands they had been very satisfactory, the only trouble he had had being in the separation of one alkaloid from another in a good crystalline form. Regarding the solubility of acid salts, he said that the exception which had been referred to was worthy of note, since it was another indication of the brotherhood existing between alkaloids and ammonia—the acid tartrate of ammonia being less soluble than the neutral tartrate.

The Pharmaceutical Journal.

SATURDAY, MARCH 17, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL EDUCATION AND EXAMINATION.

THE adoption by the Council, at its last meeting, of the whole of the recommendations contained in the report of the Committee to which the subject of the relation to each other of pharmaceutical education and pharmaceutical examinations had been referred for reconsideration, closes the history of the first stage in a praiseworthy attempt to prevent failures in passing the pharmaceutical examinations by ensuring that candidates shall have gone through a systematic course of study before presenting themselves. At present it is proposed to bring the new regulations into force on and after December 31, 1887, and although it is not certain whether this will be effected under the powers of the Pharmacy Act, 1868, or of the legislation which it is hoped will take place during the present session of Parliament, it should be noted that if this arrangement be carried out it will have a retrospective effect reaching back to the end of the present year. The whole subject is of the greatest importance to persons who contemplate becoming qualified pharmacists and their friends, by whom the new scheme should be carefully considered, and to facilitate this it may be as well to give a *résumé* of the principal features of the proposed regulations, as now adopted, especially as they have only appeared in a fragmentary form in the official report.

The first step to be taken by a candidate for qualification to practise pharmacy will be to become registered as a "pharmaceutical student," either by passing the Preliminary examination of the Pharmaceutical Society, or by presenting to the Board of Examiners evidence that he has passed one of the examinations the certificates of which are accepted in its stead. A list of these latter examinations will be found in the *Pharmaceutical Journal* for March 5, 1881, or may be obtained upon application to the Registrar. Between the date of effecting this registration and that of the candidate presenting himself for the final portion of the qualifying examination at least four years will necessarily have to elapse in order to comply with the following requirements. Three of these years will have to be spent in practical employment as an apprentice or pupil in the pharmacy of a pharmaceutical chemist or registered chemist and druggist, after which the pharmaceutical student will be eligible to present himself for the first portion of the qualifying examination. In the event of the student passing this, he will have to pursue his studies, and at the end of another year he will be entitled to present himself for the second and final portion of the qualifying examination. That the provision as to the regulations coming into force at the end of the year 1887 is intended to have a retrospective effect in regard to these four years is shown by a special note, appended to the report, in which it is stated that the effect will be that "all candidates who shall "pass the Preliminary examination after December "31, 1883, will not be eligible to present them- "selves for the first portion of the qualifying "examination until the expiration of a period of "three years from the date of their having been "registered as having passed the said Preliminary "examination."

As to the range of studies to be undertaken by the pupil during these four years, it may be stated that besides such practical training as he may obtain during his stay of three years in a pharmacy, he will have to attend at some school recognized by the Council, and at some period between the date of his registration as a "pharmaceutical student" and the time when he presents himself for the second portion of his qualifying examination, three courses of lectures, of a defined scope and character, one on Chemistry, one on Botany, and one on Materia Medica, as well as a course of instruction in Practical Chemistry. The course on Chemistry will have to comprise not less than eighty lectures, that on Botany not less than forty-eight lectures, and that on Materia Medica not less than forty lectures, at least four-fifths of which must be attended by the student; each lecture is to be the length of at least one hour, and each course is to extend over at least five months. The course of instruction in Practical Chemistry is to extend to two hours daily for ten months, three hours daily for five months, five hours daily for three months, or some modification in which the course shall not extend over a period of less than three months or more than twelve months, or exceed five hours in any single day.

It will be apparent from the foregoing that the qualifying examination is to be divided into two portions. The first portion, for which the "pharmaceutical student" will be eligible as soon as he can present evidence that he has passed the prescribed three years in a pharmacy since his first registration, will include Prescriptions, Pharmacy, and Theoretical Chemistry. This will be entirely in writing, and will be conducted in London, Edinburgh, and other centres in the provinces, under the superintendence of members of the Board of Examiners. The second portion, upon entering for which the candidate will have to produce evidence that he has passed the first portion at least a year, has completed the "curriculum," and is twenty-one years of age, will be practical and *vivâ voce*. It will include Practical Dispensing, Botany, Materia Medica and Chemistry.

No argument is needed to enforce the probability that the carrying out of a scheme of systematic training for the calling of a pharmacist, such as that described above, will contribute materially to reduce the proportion of rejections in the examination rooms; as to this all are agreed, and objections that have been raised against the scheme have been based on other considerations. But just a reference may be made to the statistics contained in one of the short notes published in the Journal for last week, as bearing upon this point. It appears from these that at the end of the last term of the Paris School of Pharmacy nearly an equal number of candidates presented themselves for their final examination as pharmaciens in each grade. But whilst only 19·5 per cent. of the candidates for the first class failed to pass, those for the second class, from whom the requirements as to preliminary education are less stringent, suffered 45·4 per cent. of rejections.

MEDICAL ACTS AMENDMENT BILL.

Since the publication of our last number, a Bill has been introduced into the House of Lords by the Lord Privy Seal for the consolidation and amendment of the law relating to medical practitioners. This Bill is based upon the report of the Royal Commission on the Medical Acts, a *résumé* of which appeared in this Journal last July. Conformably with the recommendations contained in that report it is proposed in the present Bill to establish three Medical Boards for England, Scotland and Ireland respectively, consisting, in the case of England, of members chosen by the Universities of Oxford, Cambridge, London, Durham and the Victoria University, the Royal College of Physicians of London, the Royal College of Surgeons of England and the Apothecaries Society of London. The Scotch Board is to consist of members chosen by the Universities of Edinburgh, Glasgow, Aberdeen and St. Andrew's, the College of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. The Irish Board is to consist of members chosen by the Universities of Dublin and Irelond, the King's and Queen's College of Physicians, the Royal College of Surgeons and the Apothecaries' Hall.

These Medical Boards are to be renewed every five years by election, the retiring members being eligible for re-election, and casual vacancies by death or resignation meanwhile are to be filled up by the choice of fresh members by the constituent authorities which returned the members who caused the vacancies. The Privy Council is to have power to extend or withdraw the privilege of returning members to a Medical Board. The functions of these Boards are to regulate examinations, appoint examiners, and as far as possible establish uniformity of standard in the qualifying examinations, subject to the control of the Medical Council and the Privy Council.

For the reconstitution of the Medical Council it is proposed that it shall consist of eighteen members, six of them nominated by the Crown, with the advice of the Privy Council, two elected by registered medical practitioners resident in England, one by registered practitioners in Scotland, and one in like manner for Ireland, four by the English Medical Board, two by the Scotch and two by the Irish Boards. The Crown nominees need not be members of the medical profession. The duties of the Medical Council are to comprise visitations of the examinations conducted for the purposes of the Act, inquiry into their efficiency and regulation of the duties to be performed by the Medical Boards.

The course of medical education is to be prescribed and regulated by the respective Medical Boards, and the sufficiency of the education provided at recognized schools is to be ascertained periodically by inspection carried out by the Medical Boards.

In regard to the regulation of medical practice the Bill indirectly recognizes the existence of unqualified practitioners and does not impose penalties upon them unless they use medical titles to which they have no right, or represent themselves to be legally qualified, or use designations or descriptions denoting that they are qualified by law to practice. Consistently with the provisions of the Bill in this respect it proposes to repeal so much of the "Apothecaries Act, 1815," as confers any privileges or enacts any restrictions inconsistent with the provisions of the present Bill.

Lastly, the provisions for the publication of the British Pharmacopœia are in effect the same as those in the Medical Act, 1858, namely, that the Medical Council shall, from time to time, cause the Pharmacopœia to be published under its direction. Among the saving clauses it is provided that nothing in the Act shall in any way prejudice or affect the lawful occupation or business of chemists or druggists, nor the rights, privileges or employment of duly licensed apothecaries in Ireland, so far as relates to selling, compounding or dispensing medicines.

PROPOSED INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

We have been favoured by the Executive Committee with a copy of the arrangements that have been made for carrying out this exhibition, which promises to be one of remarkable interest to pharmacists. From this we learn that the enterprise is to be under the auspices of the Allgemeine oesterreichische Apothekerverein and the Oesterreichische pharmaceutische Gesellschaft of Vienna, the Apotheker-Hauptgremien of Vienna, Gratz and Troppau, and the Lower Austrian Apotheker-Gremien of Fünfhaus and Melk, so that the entire empire is well represented. The exhibition, which is to be held in the rooms of the Imperial Horticultural Society, in the Park Ring, Vienna, will open on the 11th of August and close on the 27th, and will be divided into five "groups." Group 1 will consist of scientific instruments and contrivances used for pharmaceutical purposes; Group 2, of literature of pharmacy and the allied sciences; Group 3, of apparatus and machinery for the preparation of medicinal products; Group 4, of apparatus and utensils necessary or useful in pharmacy; Group 5, of drugs, chemical products, pharmaceutical preparations and articles intended for medicinal purposes; and Group 6, of contributions to the history of pharmacy. All medicinal specialties, of which the composition and manner of preparation are not based upon recognized rational and scientific principles, are to be excluded, as well as all nostrums without distinction, whether their composition is known or not.

For the management of the exhibition a large Executive Committee is formed, consisting of representatives from the above-mentioned Societies, and from manufacturing and commercial firms. Of this Committee, Herr A. von Waldheim is President, and Dr. A. P. Hellmann, Vice-President, the Secretaries being Dr. Hans Heger and Herr F. Kwisda. The distinctions which it is proposed to award in recognition of special merit in the exhibits are—diplomas of honour, gold medal diplomas and silver medal diplomas.

A charge will be made for space according to the following scale:—Per square metre, having a metre or a portion of a metre, of frontage, 16*s.* 8*d.* Per square metre in the open room, or portion of a metre, £1 13*s.* 4*d.* Per metre of wall surface, 8*s.* 4*d.* A reduction of 20 per cent. will be made in cases where at least ten square metres are taken. All expenses connected with an exhibit will fall upon the exhibitor, the Committee only promising to exercise careful supervision. The articles will have to be in place before the 6th of August and removed by the 31st. Applications for space or for further information should be addressed to Dr. Hans Heger, 22, Berggasse, Vienna, IX.

We regret to have to report the death, on Sunday week, of two Benevolent Fund annuitants, Mr. George Godden, in the 87th year of his age, and Mrs. Ellen Parkes, in her 64th year. Mrs. Parkes was elected in December, 1878, and as the only annuitant who previous to the last election came within the requirement of having been "a subscriber or the widow of a subscriber," received the £5 "Robbins Gift." Mr. Godden was elected in 1881.

On Wednesday next, at noon, a meeting will be held at 17, Bloomsbury Square, with the object of making preliminary arrangements for the usual Dinner of the Members of the Pharmaceutical Society and their friends in connection with the Annual Meeting in May. For obvious reasons it is desirable that the company at the Dinner should this year be numerous and representative, and it is hoped that with a view of attaining this end many of our readers will make a point of being present at the meeting on Wednesday.

* * *

Just before going to press we have received a telegram from Leeds stating that a good meeting of the trade was held there on Wednesday for the purpose of considering the Draft Bill for the Amendment of the Pharmacy Acts. The result was a unanimous expression of cordial approval of the Bill, the only addition suggested being an extension of the present exemption from jury service, which it was decided to ask the Council to endeavour to obtain.

* * *

In the House of Commons, on Friday the 9th inst., in reply to a question put by Mr. Warton, Mr. Mundella stated that it is the intention of the Government to introduce into the House of Lords a Bill for the further regulation of the sale of poisons, which will include provisions respecting the sale of so-called patent medicines of a poisonous character.

* * *

A Bill to amend the law governing the sale of drugs and poisons in the County of Kings, State of New York, has been drawn up by the local pharmaceutical association, which proposes to make it illegal for any but registered pharmacists to "open or conduct any store or place for retailing, compounding or dispensing drugs, medicines or poisons, or to practise pharmacy within the county." The Bill would create two grades of qualification: one for "registered pharmacists," who are to be persons whom the examiners may deem competent to act independently as principals or to be entrusted with the sole charge of pharmacies, the other for "assistant pharmacists," who will only be entitled to act under the direction of registered pharmacists. It would also make it unlawful to employ in a pharmacy any person who is not either a registered pharmacist or an assistant pharmacist or a student, apprentice or aid acting under the immediate supervision of such a person.

* * *

Special committees have been appointed by the College of Pharmacy of the City of New York and the New York Deutschen Apotheker-Verein to act jointly in taking steps to induce physicians to refrain from prescribing "ready made identical specialties of rival manufacturers," and to omit from their prescriptions the names of makers of such preparations.

* * *

According to the *British Medical Journal* the Upper Sanitary Council of Italy has just passed an important resolution regulating the importation of patent medicines into the kingdom. A list of the foreign patent medicines admissible was drawn up, which showed that they were all French but two; to these a few more English articles have now been added. The subject is said to be engaging the attention of the British Embassy and we gather that further modifications in the regulation are probable.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, March 7, in the College of Physicians, Dublin, at three o'clock.

The President, Dr. Tichborne, in the chair.

The other members of the Council present were the Vice-President, Dr. Aquilla Smith, Dr. Montgomery, Dr. Collins, Messrs. Allen, Bennett, Brunker, Grindley, Hayes, Hodgson, Pring, Simpson and Wells.

The President said a letter had been received from Mr. Middleton, dated March 2, reminding the Council that he had not up to that date, received any answer to his communication of December 19, 1882, asking that a declaration should be accepted in lieu of a certificate. He (the President) had a visit, two or three days ago, from Mr. Middleton, who wanted to know why he had not received a reply.

The Registrar, Mr. Fennell, said he laid the matter before the Certificate Committee.

Mr. Hayes: The Certificate Committee only meets immediately before the examinations for the purpose of examining the certificates.

The President said a reply ought to have been sent to Mr. Middleton.

Mr. Allen: Mr. Fennell brought the matter before some members of the Committee informally assembled and it was arranged that I should speak to Mr. Grindley about giving him a certificate. I did so, and the certificate has since been handed to Mr. Middleton. Nothing more can be done until he sends that certificate before us.

It was resolved that Mr. Fennell should write to Mr. Middleton stating that the Certificate Committee had not met since the receipt of his letter in December, 1882; but that it would meet before the next examination, when his case would be considered; and that in the meantime he should send in any further documents relating to his qualification.

A letter was read from Mr. E. Worth, of Bournemouth, presenting some prescriptions to the Society.

On the motion of Mr. Hayes, seconded by Dr. Collins, thanks were voted to the donor.

A letter was read from Dr. A. N. Montgomery, Secretary of the Medical Section of the Academy of Medicine in Ireland, requesting the use of the Council room on an evening in each month to exhibit specimens in.

On the motion of Mr. Hayes, seconded by Mr. Brunker, a resolution was passed granting the use of the Council room on an evening in each month, provided it did not interfere with the examinations or meetings of the Society, and also provided the sanction of the College of Physicians was obtained.

A letter was read from Mr. G. T. Dobson, of 1, Gilbert Road, Kennington Road, London, stating that he proposed taking a chemist's business in Ireland, and asking for a syllabus of the subjects required in the examination of the Society; and also asking whether the licence of the Society of Apothecaries, London, would be accepted in lieu of the final examination of the Society.

The President: It does for the Preliminary examination of our Society, but that is all.

The Registrar was directed to inform Mr. Dobson that the licence of the Society of Apothecaries, London, could not, under the Act, be accepted by the Pharmaceutical Society of Ireland in lieu of its final examination.

A letter, dated March 3, was read from Dr. J. W. Moore, Registrar of the College of Physicians, Ireland, stating that a communication had been received from the Privy Council, asking whether the provisions of the Sale of Poisons (Ireland) Act, 1870, as far as regarded the sale of poisons to persons unknown to the seller, were generally observed in Ireland, and if so, whether any inconvenience had been caused thereby; and that he had been directed to ask the Council of the Pharmaceutical Society whether it would inform the College of the results of the inquiry which it was making on the subject.

The President: The way to meet that would be to send a copy of the report of our Pharmacy Act Amendment Committee.

Mr. Brunker submitted a report from the Pharmacy Act Amendment Committee of the Society. It stated that in reply to the queries addressed to licentiates as directed at the last committee meeting thirty replies had been received from twenty different localities. The answers to the first query were nearly unanimous as to qualified persons observing the provisions of the Poisons Act. The answers to the second query unanimously were that no inconvenience arose to the public from the restrictions being observed by qualified persons. The answers to the third and fourth queries showed that the sale of scheduled poisons was largely carried on by persons describing themselves as chemists and druggists, ironmongers, grocers, seedsmen and small huxters. Replies to those queries had been received from seventeen towns. Two or three of the replies stated that no such sales took place in Dublin; and a negative reply had been received from Warrenpoint. The towns from which the answers had been received included such important places as Dublin, Belfast, Limerick, Omagh, Monaghan, Mullingar and Athlone. Replies to the fifth query mentioned only three fatal cases resulting from unqualified persons selling poison, but stated that numerous serious mistakes were reported. Replies to the sixth query went to show that the police had taken some action towards seeing the provisions of the Act carried out in Dublin, Blessington and Naas, but not elsewhere.

The President: I do not think the police have taken any action, except so far as making inquiries. We know of no prosecutions for illegal sales.

Mr. Brunker: They have issued circulars and called at some places to see if poison books were kept.

Mr. Wells said that in one instance two detectives called at an establishment in Sackville Street and asked to see the poison book, and they also called at a number of other houses; but the object of their inquiries was to ascertain where the poison had come from in connection with a recent case of poisoning that had occurred.

Mr. Brunker said that since the report was drawn up a reply had come from Ballymoney stating that some action was being taken by the police there. The report concluded as follows:—

"The Committee then took up the consideration of the Poisons Act (Ireland), 1870, with the view to amend same, and suggest that the sale of proprietary or patent medicines, containing scheduled poisons, should be subjected to the following restrictions:—

"(*a*). A specification of the poisonous contents, and the quantity of same to be printed on label or wrapper.

"(*b*). The word 'poison' to be printed on the various labels or wrappers of the article, together with the name and address of the first seller.

"(*c*). The sale of such articles to be confined to persons legally qualified to sell scheduled poisons.

"The Committee also recommend the addition to Schedule II., Poison Act (Ireland), 1870, of sulphuric acid, hydrochloric acid, nitric acid, solution of chloride of antimony, and carbolic acid.

"In addition to the amendments already adopted by the Council of the Pharmaceutical Society of Ireland to the Pharmacy Act (Ireland), 1875, Committee suggest that Clause 10 of the draft Bill, proposed by the Pharmaceutical Society of Great Britain, should be adopted, with the addition 'that delivery of such notice by registered letter shall be deemed good service,' after the words 'notice signed by him.'"

The object of inserting that clause was to provide means for discovering who were the actual owners of establishments about the ownership of which there was a doubt.

The Committee had been instructed to draft a letter to Dr. Kaye, and had prepared the following:—

"Pharmaceutical Society of Ireland.
"Kildare Street, Dublin,
"*7th March*, 1883.

"W. S. B. Kaye, Esq., LL.D.,
"Clerk to the Privy Council,
"Dublin Castle.

"Sir,—In reply to your letter of 29th January, 1883, I am directed by the President and Council of the Pharmaceutical Society of Ireland to state, for the information of the Lords of the Privy Council in England, that they have carefully considered the queries contained therein, and, having instituted inquiries among the Licentiates of the Society residing in various parts of Ireland, have to convey the following replies to those queries:—

"I. (1). The provisions of the Sale of Poisons (Ireland) Act, 1870, with regard to the sale of poisons to persons unknown to the seller, are pretty generally observed by duly qualified pharmaceutical chemists and apothecaries.

"(2). The observance of these provisions has not caused any inconvenience to the public.

"(3). But the sale of poisons is largely carried on throughout the country by general traders, such as chemists and druggists (not holding the licence of the Pharmaceutical Society), grocers, ironmongers, seedsmen, huxters, etc., and by this class of persons the provisions of this Act are generally ignored.

"This is the case in seventeen towns from which returns have been received, including Dublin, Belfast, Limerick, Omagh, Dungannon, Monaghan, Maryborough, Mullingar and Athlone —all large centres of population.

"(4). Though few fatal accidents have occurred through this indiscriminate dealing in poisons, numerous serious mistakes have been made by ignorant persons.

"(5). The returns show that in no towns, except Dublin, Naas and Blessington, have any steps been taken by the police authorities to ascertain whether the provisions of the Act are observed or not; and that no prosecutions have been instituted by them in any part of the country.

"II. In reference to the second query contained in your letter, I am to state that the President and Council recommend, for the consideration of the Privy Council, the following additional provisions for the better regulating the sale of poisons in this country:—

"(1). That the sale of proprietary or patent medicines containing scheduled poisons should be subject to the following restrictions:—

"A. A specification of the poisonous contents, and the quantity of same to be printed on the label or wrapper.

"B. The word *Poison* to be printed on the various labels and wrappers of the article, together with the name and address of the first seller.

"C. The sale of such articles to be confined to those legally qualified to sell the scheduled poisons.

(2). That the following substances be added to schedule II. of the existing Act:—sulphuric acid, nitric acid, hydrochloric acid, carbolic acid and solution of chloride of antimony.

"III. I have also to state that some difficulties and deficiencies have been experienced by this Council in the working of the Pharmacy Act (Ireland), 1875, since its enactment; and I am to bring under your notice the following considerations, with recommendations based thereon:—

"The Act conferred upon the Licentiates of this Society—

"(1). The right formerly enjoyed in Ireland by Apothecaries only, to compound medical prescriptions (sec. 30).

"(2). The right—confined to them and to Apothecaries —to retail the poisons scheduled under the Poisons Act (33 and 34 Vict. cap. 26).

"(1). The former privilege was opened up to chemists and druggists who were in business at the time of the passing of the Act; but only on their submitting themselves for examination, in accordance with the regulations of the Society.

"(2). By section 31 of the Act, such persons had reserved to them the right to sell poisons, without any restriction as to any qualification by examination, if they were engaged in that trade at the time of the passing of the Act.

"No machinery was adopted or laid down under the Act whereby such persons should be registered, nor was any line of demarcation drawn between them and others, who at some subsequent date might choose to enter upon that trade. The consequence is that the sale of poisons throughout the country is carried on without hindrance by any person who cares to engage in it.

"The Council, feeling that such a state of things should not, in the interests of the public, be allowed to continue, have adopted the following resolutions:—

"1. That it is desirable that the Council of the Pharmaceutical Society should seek powers which will enable them to compel all chemists and druggists actually engaged in the sale of poisons and poisonous drugs at the time of the passing of the Pharmacy Act (1875), on making a declaration to that effect, and giving reasonable proof thereof, to register their names, paying a fee of three guineas for same; such persons to be styled 'Registered Druggists.'

"Since these resolutions were adopted, nearly three years have elapsed, rendering the enforcement of amendment No. 1, even if it were now passed into law, much more difficult. The Council therefore think that it would be satisfactory if the privilege of registering were extended to those engaged *bonâ fide* in the sale of poisons at the present date.

"That a list of 'registered druggists' for the sale of poisons shall be published from time to time by the Council of the Pharmaceutical Society, containing the names and addresses of all persons entitled to be placed thereon.

"3. That it shall be illegal for any person to sell poisons or poisonous drugs, or to style himself a 'registered druggist,' except he shall be so registered, save and except he be a registered medical practitioner, or duly registered by the Pharmaceutical Society of Ireland, or otherwise qualified under the provisions of the Pharmacy Act.

"4. That it shall be unlawful for any registered druggist, or other person, to keep open shop for retailing, dispensing, or compounding medical prescriptions, unless he be registered as a pharmaceutical chemist, or apothecary.

"5. That the penalties for infringement of this Act shall be the same as provided in the Pharmacy Act.

"6. That all bye-laws or rules for registration shall be approved of by the Privy Council prior to their adoption.

"Some inconvenience has arisen under Clause 11 of the Act, from the short interval allowed for filling occasional vacancies on the Council, to meet which the following amendment is suggested:—

"After the word 'Society' (line 3) read:—'Such day not to be later than the next monthly meeting after the vacancy has been notified to the said President.'

"The following amendments have also been adopted by the Council, and I am to recommend them for the consideration of the Privy Council:—

"That in reference to the Pharmacy Act (Ireland), 38 and 39 Vict. cap. 57, and more especially in reference to Clause 30 of same, the word *person* shall be held to mean and imply any association of persons, whether as a partnership, society, or company (limited or otherwise), of which one or more members shall not be qualified under the provisions of the Act.

"That the Society shall have powers to institute an Examination for Assistants to Pharmaceutical Chemists.

"That no pharmaceutical chemist shall legally hold any establishment for the retail of poisons, or compounding of medical prescriptions, except under the responsible management of a duly qualified pharmacist.

"This Council further recommend the extension to Ireland of Clause 10 of the draft Amendment Bill proposed by the Pharmaceutical Society of Great Britain, adding after the words 'notice signed by him,' 'the delivery of such notice by registered letter to be held sufficient service.'

"I have the honour to be, sir,
"Your obedient servant,
"H. J. Fennell,
"*Registrar.*"

On the motion of the Vice-President, seconded by Mr. Pring, the report was adopted.

On the motion of Mr. Bennett, seconded by Mr. Grindley, it was ordered that fifty copies of the draft letter to Dr. Kaye be printed, and that a copy of it be sent to the College of Physicians of Ireland.

On the motion of Mr. Allen, seconded by Mr. Grindley, it was ordered that all the replies received to the queries which had been addressed to licentiates should also be sent to the College of Physicians.

Mr. Henry Forewell, of 53, Lower Sackville Street, Dublin, was elected a member of the Society.

The following donations were announced:—

The Year-Book of Pharmacy for 1882.
From the British Pharmaceutical Conference.

The Calendar of the Pharmaceutical Society of Great Britain for 1883.
Presented by that Society.

Fourteen volumes of Curtis's 'Botanical Magazine.'
Presented by the Registrar, Mr. Fennell.

The thanks of the Council were voted to the donors.

The Council then adjourned.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

Discussion on "The Pharmacy Acts Amendment Bill."

In response to an invitation from the Council of the Sheffield Pharmaceutical and Chemical Association, a meeting of members and the trade was held in the Society's rooms, Market Place, Sheffield, on Wednesday, March 7, to discuss "The Pharmacy Acts Amendment Bill now or about to be introduced into the House of Commons." Mr. J. Preston (President of the Society) occupied the chair.

The President said that the meeting had been called at the instigation of the Council, and said there had been meetings held in other towns in connection with the question which would form the subject of discussion that afternoon. It was proposed that the preamble of the Bill as published in the *Pharmaceutical Journal* of February 10 should be read, and the clauses discussed one by one. He would ask them to consider the Bill broadly, remembering that Acts of Parliament were not made for individuals, but for communities, and he trusted that they might have a wise and fair discussion of the several points in the Bill.

Mr. Newsholme (Hon. Sec.) then read the preamble of the Bill.

Mr. J. M. Furness rose to move that the word "poisonous" in the second line of the preamble should be omitted, remarking that clause 2, specifying the "regulations to be observed in the sale of poisonous articles," appeared to him to be the most objectionable in the whole Bill.

Mr. W. Ward asked if Mr. Furness proposed to leave out the word "poisonous" and substitute some other word.

Mr. Furness said he proposed to omit the word "poisonous" and put the word "dangerous" in its place. He then moved to that effect.

Mr. Learoyd seconded the motion.

Mr. Ward moved as an amendment that the word "poisonous" should remain in the preamble.

The President stated that a simple negative would suffice, and he then put the resolution moved by Mr. Furness, which was carried, 8 voting for and 3 against it.

The preamble was adopted with the alteration.

Clause 1, as simply a definition clause, was agreed to without discussion.

Clause 2. *Regulations to be observed in the sale of poisonous articles.*

Mr. E. R. Learoyd remarked that clause 2 referred to a number of articles to which for the first time since the passing of the Pharmacy Act a condition had been provided for the sale of articles which were no doubt poisonous, but which should be sold by others than registered chemists. The reason that clause had been introduced into the Draft Pharmacy Bill was this. Some time ago a number of men interested in agriculture and in the keeping of horses,—such men as stud farmers and stud keepers,—found great injury done to their stock by maladministration of those very deleterious and injurious bodies which were easily obtained by horse-keepers and grooms. It was felt that this was a great injustice, and it was suggested by the Pharmaceutical Society that these poisons should be added to the second part of Schedule A in the Pharmacy Act of 1868, which would render their sale liable only by registered chemists, who would have to label them "poison" in the ordinary way. When the Pharmaceutical Society represented this to the Privy Council it was clearly shown that the Government would not entertain that suggestion, as these drugs were largely used in manufactures. They would not entertain the idea of restricting the sale to chemists alone. In the Draft Pharmacy Bill, therefore, in order to cover and protect the people injured thereby, this clause had been inserted as a sort of compromise, and it had become necessary in the opinion of the Pharmaceutical Society instead of having them placed on the list of poisons that they should be marked "poisonous," as they could be sold by any dealer. The resolution he should propose referred to the last article in the schedule of poisonous articles; he spoke more particularly of carbolic acid. So far as they had any information with regard to this particular drug it was not used in manufactures. He also believed he was correct in stating that this article was largely used for medicinal purposes and appliances, and he did think that when the Pharmaceutical Society considered it necessary to have these things labelled "poisonous" it would be wise to place carbolic acid in the list of "poisons" to be marked with the name of the seller, and sold by chemists only. Numerous mistakes had occurred in hospitals and elsewhere in applying the article, and he moved that the second clause be adopted with the exception of the article carbolic acid, recommending that it should be placed in the second part of the Schedule A of the Pharmacy Act of 1868, to be sold by chemists only.

Mr. A. Archer, in seconding the motion, said that in his opinion carbolic acid should be placed in the list of poisons only to be sold by registered chemists and druggists. It was, he said, a mistake to include it in the list of "poisonous" articles.

Mr. H. E. Ibbitt said he should like to ask if there was any legal distinction between a poisonous article and a poison. He could not conceive of any. He had looked in Taylor's 'Medical Jurisprudence,' and there he found only poison defined. If the word "poisonous" had any use at all it meant a minor form of poison. The articles proposed to be included in the schedule were not minor forms of poison, though they were deadly, if he might use such a word. If the Act was passed it would place them in this position, that suppose a customer came for a pennyworth of paregoric in half a pint of vinegar they must put "poison" on it, but if he wanted oil of vitriol or nitric acid they must label it "poisonous," which meant that it was not a strong poison. It might come to a question as to which were "poisons" and which were "poisonous" articles.

Mr. Learoyd said he thought he should be able to show that the Act of 1868 very clearly defined what were "poisons," and that the present clause defined what were "poisonous."

Mr. Ibbitt thought the word "poisonous" should be left out altogether.

Mr. W. Ward said it was quite well known, and had been clearly explained, that the Council was not able to add to the schedule of poisons the acids mentioned along with carbolic acid. The Privy Council rejected them, and no doubt they had strong reason for putting carbolic acid along with the other acids. He thought they should give the Council credit for what was no doubt a judicious plan. On that ground he was not prepared to support Mr. Learoyd's motion.

Mr. J. M. Furness said he was prepared to move that the whole of clause 2 be expunged from the Bill. They had been told by Mr. Ibbitt that the articles proposed to be added to the schedule were not merely "poisonous" but poisons. The Pharmaceutical Society itself, when asked to represent their opinions to the Government, said these very articles should be placed in the second section of Schedule A of the Act of 1868; yet it was now proposed they should be labelled "poisonous." Were they to understand that this very objectionable clause was to be a sop for the whole Bill. If they voted now that those articles should be labelled "poisonous" they would stultify their opinions of last year, and he maintained that if the Privy Council wanted this clause let it have it on its own responsibility. No chemist sold those articles without labelling them poison, and the public was safe if they were exclusively in the hands of the chemist. Therefore he asked why they should bind themselves to the Privy Council in order to do objectionable work which was against their own opinions of last year.

Mr. J. Ellison said that he objected to other people besides chemists and druggists selling poisons, and he thought the Privy Council ought to restrict the sale of them.

The motion, upon being put, was carried, 10 voting for, and 4 against it.

Clause 3.—*Regulations on sales by wholesale of poisons in part* 1 *of Schedule A to the Pharmacy Act of* 1868.

Mr. Ellinor said he thought the wholesale houses should be registered as wholesale dealers, that there should be a register of wholesale druggists.

No other remarks were made on this clause, which was agreed to.

Clause 4.—*Labelling of patent medicines being or containing a poison.*

Mr. Learoyd said he should be sorry indeed if they, as representing in some slight degree a branch of the Pharmaceutical Society, let it go forth to the public that they were at all selfish in their views. It was the greatest mistake in the world to suppose that they, as a branch of the Society, or that the Pharmaceutical Council representing the great mass of pharmacists, wished to legislate with any selfish views whatever. The principle they desired to lay down and promulgate was that they as a society were bound to legislate for the public good, and in taking that view they were bound as a body to protect the public from the use of articles people did not quite understand. The word "poison" was distinctly placed here with the object of stating most clearly that the "poison" meant one of those articles contained in Schedule A of the Pharmacy Act of 1868, in distinction from other things which the Privy Council said had a right to be sold to the public at large, but which by improper use would be dangerous. He moved that the clause be adopted.

Mr. Ward seconded the motion.

Mr. Furness moved as an amendment that the inside should be labelled "poison," as well as the outside, believing that this was necessary for the public safety.

Mr. Learoyd said the clause took that precaution, and he read a portion of it, pointing out that it would be unlawful to sell "unless the box, bottle, package or vessel in which the same is contained, the wrapper, if there be only one, or the outermost wrapper, if there be more than one, be labelled."

The President said the clause seemed a little ambiguous on the point, but he thought so long as the word "poison" was placed on the outside wrapper there need be no other label, because the word "or" instead of "and" was used in the clause.

Mr. Ellinor considered that the clause should be more definite, and suggested that the part should read "unless the box, bottle, package or vessel in which the same is contained, *and* the wrapper, if there be only one, or the outermost wrapper, if there be more than one, be labelled."

Mr. Learoyd thought the word was quite unnecessary.

The clause was agreed to, with the addition of the conjunction suggested.

Clause 5, which provides *Penalties for certain offences*, was agreed to.

Clause 6.—*Duly qualified keepers of open shops entitled to remedies in certain cases.*

The President said this was a very important clause, rendering, as it did, chemists liable for things over which they had little or no control.

Mr. Ward remarked that in his opinion this clause contained a very mischievous principle. He should have been much better pleased to see the fine made on the manufacturer, or the proprietors of the article. It seemed to him that if the seller, through no fault of his own, was to be continually dragged up before the justices for selling these articles, of the non-labelling of which he might be perfectly ignorant, he was likely to get into litigation most damaging to his reputation. He therefore moved —"That the manufacturer be sued for the fine, and not the seller."

Mr. Ellinor was much surprised that Mr. Ward should oppose this principle in the clause. It was the very principle upon which the life and existence of the Adulteration Act depended. They could not go to the proprietor in the first case; they must go to the seller, as in the Adulteration Act. They would never be able to get a conviction if they went to the proprietor first; indeed they might not know who he was for long enough.

Mr. Learoyd wished to support Mr. Ward in his idea, but not in the method in which he proposed his resolution. They had, he contended, quite hardships enough to suffer in the present exigencies of their condition, without having them amplified. Perhaps it might meet Mr. Ward's view if he put the matter in this way,—"That in case a seller is summoned for selling poisons not duly labelled, on his showing that he obtained them direct from the manufacturer or wholesale dealer, the manufacturer or wholesale dealer shall be rendered liable to this penalty and costs."

Mr. Ward expressed his willingness to accept this resolution, which he moved.

Mr. Furness pointed out that the seller frequently did not know the contents of the patent medicines he had for sale, and said he could only make himself safe by labelling every patent medicine in his shop "poison."

The President observed that under the Adulteration Act, the retailer was always summoned, and power given into his hands to deal with persons from whom he obtained the article. But supposing a bottle of chlorodyne came from the manufacturer. It was quite possible the label might fall off in the chemist's shop. Now was the manufacturer of that article to be summoned because it had not the word "poison" upon it?

Mr. Ward said the bottle would have the word "poison" upon it beneath the wrapper.

Mr. Hall presumed that if the bottle were wrapped up the label could not fall off.

Mr. Ward maintained that it would be exceedingly annoying for the vendor to be in fear of being dragged up before the magistrates, of being fined, and having his name made prominent. He might be subjected to this annoyance frequently, and that was his objection to the seller being made liable.

Mr. Hall had pleasure in supporting Mr. Ward on that point, at any rate.

Mr. Archer asked one question as to the liability of the manufacturer and wholesale dealer, how they were to get their penalties in the case of patent medicines imported from abroad—from France and America.

Mr. Learoyd pointed out that the wholesale dealer would be liable.

Mr. Ellinor asked if they got these medicines direct from the foreign makers how they were to manage about getting the penalty. Were they to go abroad to prosecute? In his opinion they would get no conviction at all. Would not the clause as it stood make those who dealt in patent medicines more careful what they supplied?

Mr. Ward's motion, having been seconded, was put to the meeting, and carried, 9 voting for it, and 4 for the clause as it stood.

Clause 7.—*Persons keeping open shops to be liable for their assistants, apprentices and servants.*

Mr. Learoyd asked whether it was fair in clause 7 to say the master was to be rendered liable for any accident or mistake of his assistants, and in the next breath, in clause 8, to say the chemist was compelled to employ a qualified man, and yet, although employing a qualified man, he himself was to be liable to the penalties. He moved that clause 7 be struck out, thinking it a hardship that chemists should be trammelled with this liability for the accidents and mistakes of their *employés.*

Mr. Ward said they would like the clause to be expunged, but it was impracticable.

Mr. Ellinor believed the clause was a greater gain than a loss.

Mr. Furness suggested an addition to the effect that the qualified assistant at the branch shop should be answerable for his own doings.

Mr. Archer considered this a proper suggestion.

Mr. Fox seconded Mr. Learoyd's motion.

Mr. Ellinor moved as an amendment that the clause be retained in its entirety. They could not, he remarked, do away with their responsibility, whether the clause was expunged or not; but seeing that the latter part of the clause would be of great service in administering the Act, he thought they had better retain the clause as it stood.

Mr. Ward seconded Mr. Ellinor's amendment.

The voting was then taken, with the following result:—For Mr. Ellinor's amendment, 11; against, 2.

Mr. Learoyd's motion was therefore declared lost.

Clause 8.—*Regulation for conducting branch businesses.*

Mr. Learoyd then moved that clause 8 be struck out. He did so, he said, because it was perfectly clear that the object of the clause was to make the proprietor of the shop responsible for acts committed in that shop, and it said nothing about how many branch shops he had. According to the clause if he had a qualified assistant in each he would still be liable. There might be some other meaning hidden in the clause, something they did not understand; but if the hidden meaning was one relating to the question of co-operative stores, and to meet that part of the question, he maintained that it was perfectly absurd to suppose it did anything of the kind. When clause 10 came on he should submit that that met the case of the co-operative societies quite fully, and that clause 8 was a great hardship.

The President said this was a very important clause, and he hoped somebody would be found to second the motion, so that there might be some discussion. There were a lot of people in the business who were not registered chemists and druggists; it was true they had the privilege of becoming registered, and of passing the Modified examination. Still, there were a number of older people who had not been registered, and to them he was afraid this clause would be rather a hardship.

Mr. Fox seconded the motion in order to facilitate discussion.

Mr. Ellinor thought they had in this clause a great provision of safety. Of course, if a person took fifty branch shops he took fifty responsibilities. He believed if the clause was expunged they would have a lot of difficulty. If a man wished to have an open shop he must have a qualification, and for every branch shop he must have a qualified assistant. It was so in the Irish Pharmacy Act and he did not see why they should not have it with the English Pharmacy Act. If men would take these extra responsibilities they must be prepared for the consequences or responsibilities they assumed. By the Act of 1868 everybody had an opportunity of becoming registered; people were crammed like turkeys, and put through their examinations like wildfire. He saw no hardship in retaining the clause, and moved that it stood in its entirety.

After some further remarks from Mr Learoyd and Mr. Ellinor, the discussion was continued by Mr. Ward, who said with respect to the question of the proprietor of a shop and a co-operative store, there was a marked difference. The proprietor of the chemist's shop was a registered pharmacist, and must be a registered man; the members of a co-operative store were not registered men. And there was a difference between the registered man employing a qualified assistant, and a co-operative store, not registered, employing a qualified man. The owner of the branch shop having a qualified man should be held responsible for his assistant, and he therefore supported the clause as it stood, believing it was one of the most sensible and best calculated to benefit not only the cause of pharmacy, but to protect the public.

The President then put the question to the meeting. Only 2 gentlemen voted for Mr. Learoyd's motion, and 11 against it.

Clause 9.—*Duly qualified persons to sell medical prescriptions and sell poisons.*

Mr. Learoyd pointed out that the Pharmacy Act of 1868 referred to the poison clauses, and the amendment to that Act merely related to additions to those clauses.

Mr. Archer, quoting a portion of the clause, "provided nevertheless that nothing in this section shall extend to or interefere with the business of wholesale dealing in patent medicines," said Messrs. Birks, of that town, were wholesale dealers in patent medicines. Would the clause extend to them?

Mr. Learoyd said the clause referred to selling by retail, and he was not aware that wholesale dealers were supposed to sell retail.

Mr. Furness suggested an addition to the clause to the effect that all dealers, wholesale and retail, in any of the poisons in the schedules of 1868, should be qualified as registered chemists and druggists.

Mr. Ward was afraid that would never be carried.

Mr. Ellinor said he would have them all registered if he possibly could, but there was a great doubt about it.

Mr. Furness thought not with regard to poisons.

Mr. Ellinor remarked that they could not have all the wholesale druggists registered and he did not see how they could go on with the suggestion.

The clause was then agree to.

Clause 10.—*Persons having open shop must, on application, inform the Registrar of the name or names of proprietor or proprietors.*

Mr. Learoyd said that this clause was one with which he had a great deal of sympathy. It met the case clearly and comprehensively. If it became an Act of Parliament it would settle the store question finally. At the same time he must say this was the clause on which he should have relied if they had expunged clauses 7 and 8. If this clause 10 became law and they were subjected to its restrictions, he could not help thinking that in years to come some of them would arrive at the conclusion that it would have been better to take his advice with regard to clause 7.

The President said they knew the difficulty the Pharmaceutical Society had experienced in ascertaining the names of proprietors of shops where nefarious practices had been carried on. He supposed it was to meet these cases that the clause had been framed.

Mr. Ellinor said if Parliament would only adopt it, the Society would no doubt make great use of the power given by the clause.

The clause was then agreed to.

Clause 11.—This clause was agreed to without discussion.

Clause 12.—*Regulations may be made by bye-law to subdivide examinations, etc.*

The President observed that this was the educational part of the Bill. They had, as a local association, given their opinion on the question a little time since.

There was no discussion, and the clause was adopted.

Clause 13.—*Certificates of having passed Preliminary examination requisite to apprenticeship.*

Mr. Archer remarked that this clause said that no pharmaceutical chemist should take as an apprentice any person who had not obtained a certificate. Assuming that any chemist took a youth who was not legally bound, he contended that youth was not an apprentice. Apprenticeships were getting shorter, and the time might come when they would be materially altered. Now they heard of people who had passed no examination, served no time, never been bound to a master. It ought to be absolutely defined that youths entering the trade in this way were not apprentices.

Mr. Ward asked how he would define it.

Mr. Archer, continuing, said he might find a youth who was suitable and take him on verbal conditions, but he would not be an apprentice. He might remain to the end of four years, and yet he would not be an apprentice. In such a case the matter would be left open.

The President remarked that it would be an evasion.

Mr. Archer, continuing, observed that the word "apprentice" would have to be defined. Then there was another matter. In clause 8 were the words "a duly qualified keeper of an open shop." Any shopkeeper who was not a chemist and druggist might say he was "a qualified keeper."

The President said a definition of "a qualified keeper of an open shop" was given in the former Bill. Certainly no person was "duly qualified" unless he had passed.

Mr. Archer admitted that in that case it was all right, but with regard to the word "apprentice" they should have it defined.

Mr. Learoyd said there was a clause in the bye-laws which set forth distinctly that no person was eligible for examination until he had served three years with a qualified chemist.

Mr. Archer remarked that if that was so they were all right.

Mr. Ellinor said Mr. Archer was probably not aware that each student must have a certificate showing that he had served three years, and that the youth would have to serve three years after he was registered before he could present himself for examination.

Mr. Fox asserted that the clause would not interfere with a chemist having a boy in his shop. It was merely that the apprentice must pass his Preliminary examination before he stayed three years for the Minor examination.

Mr. Ward pointed out that the youth would have to stay three years between passing the Preliminary and passing his Minor examination.

The President, by way of illustration, said if he took a boy for two years and gave a certificate that the lad had been three years as an apprentice, then he should render himself liable to the extent of £5 or £10; but if he took a youth who was not apprenticed, but was merely serving his time as a porter or servant, not wishing to enter the trade, he could not give that youth a certificate.

Mr. Learoyd said the word in the clause was "previously," meaning that a man should not take an apprentice until he, prior to the commencement of his apprenticeship, passed this Preliminary examination.

The clause was adopted without further discussion.

Clause 14.—*Certificates may be accepted in lieu of Preliminary examination.*

The President said he only wished other bodies would imitate the Pharmaceutical Society with regard to the liberality shown in that clause.

The clause was agreed to.

Clause 15.—*Certificates of death and expense of same.*

This clause was adopted without discussion.

Clause 16.—*Certain persons to be registered as Pharmaceutical Chemists and eligible for membership.*

The President said he took it that this clause was a position taken up by the Pharmaceutical Society with the object of continuing its existence. It was a lengthening of its stakes, and a strengthening of its cords.

Mr. Ellinor observed that this was not the time when he should take strenuous opposition to this clause, although he did not see there was any advantage to be gained. It seemed as if the assistant qualification of the Society qualified a person as a chemist, and the Minor examination qualified for a pharmaceutical chemist. But the Society had not provided anything for those who had borne the heat and burden of the day. Nothing was said for those who had worked for progress. He thought it was wrong to take away the title of pharmaceutical chemist without giving him, who had passed all the examinations, another title. He thought there should be some distinction for those who had worked upward in this way. This clause had a double action, and referred to attendance on juries. The chemists and druggists were desirous of getting rid of this jury service if they possibly could, and this section would give the means to every chemist and druggist who qualified after the time named to get rid of the jury service. But those who were chemists and druggists under the present Act would have to remain on juries. What he objected to was that nothing was being done for those who had passed the examinations. He thought a time would come when they would have to have a fellowship.

Mr. Ward thought Mr. Ellinor was mistaken. That gentleman referred to the Minor examination as qualifying for a pharmaceutical chemist, but the clause did not say so.

Mr. Ellinor read the clause, and believed he had interpreted it rightly.

Mr. Ward said it did not necessarily follow that the Minor examination was meant; indeed, he did not think the Council had the remotest idea of making the Minor examination an entrance for the degree of pharmaceutical chemist. Looking at the matter from a broader standpoint, he was bound to confess that it would be a wise and judicious course to take. At present it was confusing to the public, who were not able to distinguish between the Minor and Major examinations. Mr. Ellinor had referred to the Irish Pharmacy Act. They had two examinations—a Preliminary, and a Pharmaceutical; and he thought the proposed change would not only advance the cause of pharmacy amongst themselves, but in the eyes of the public. He was glad they were going to show a liberal spirit and admit all as pharmaceutical chemists.

Mr. Learoyd said those who were aware of the inner working of the Pharmaceutical Society were prepared to see a very amended scheme of examinations, and he believed the examination of "chemists and druggists" would not be the examination chemists would have to undergo to be placed on the Register of Pharmaceutical Chemists.

Mr. Furness was certain the Minor examination was stiff enough for chemists to pass at any time. He felt inclined to move that these examinations should be placed under the authority of the Privy Council. The Pharmaceutical Society were a very go-a-head people. They had an idea that everything was to be tested by examinations; but the Minor examination was strict enough for anyone to pass who wished to qualify as a chemist and druggist. The objection he had was that the people who passed the Minor were to be raised to be members of the Pharmaceutical Society. If the Bill became law those who passed the Minor examination would be pharmaceutical chemists and those who had passed it previously would be simply chemists and druggists. It was manifestly unjust that the man who passed the Minor examination before the Act came into force should be in an inferior position to the person who passed the examination after it came into force. It was also unjust to the Major men who had qualified as pharmaceutical chemists that the persons who only passed the qualifying examination should be able to assume their title.

Mr. Ellinor also thought it would be a great injustice.

Mr. Archer thought all who passed the Minor were going to be pharmaceutical chemists and that they were going to abolish the Major. If that was the case, he considered it would be quite as fair to take them all in.

Mr. Ibbitt asked what would happen to those who were in business before 1868?

It was pointed out that the next clause dealt with such chemists, and clause 16 was then agreed to.

Clause 17.—*Certain persons to be eligible for membership.*

Mr. Learoyd moved the adoption of this clause, and said that from 1841, when the first Act passed, until 1852 the method of obtaining entrance to the Pharmaceutical Society was not by examination but by subscription only. And although that had been the foundation of the great success of pharmacy in these dominions, they must consider that those gentlemen who had by reason of examinations become chemists and druggists were to be placed on a par with gentlemen who passed none at all. Those who commenced this great work were already passing away, their subscriptions were ceasing, and it would be necessary from a pecuniary point of view that somebody should step in their shoes and support the Society. He thought it a very proper thing that this clause should take effect, and he also thought there would be a sufficient distinction that these chemists would only become members of the Society while the pharmaceutical chemists, attaining the high position to which Mr. Ellinor had referred, might obtain a fellowship.

The clause was agreed to.

Clause 18.—*Certain claims for registration not valid unless made before January* 1, 1885.

This clause was agreed to without comment.

Clause 19.—*Repeal of Section XI. of Pharmacy Act,* 1852, *and Section XX. of Pharmacy Act,* 1868.

Mr. Learoyd stated that in 1869 an amended clause was inserted by which any medical man could commence business and be registered under the Act if he had passed the pharmaceutical examination in conjunction with his medical examination.

The clause was adopted without further remark.

Clause 20.—*Penalties under Act not to exempt from other penalties*;

Clause 21.—*Penalty for wilful falsification of register, or for obtaining registration by false representation*; and

Clause 22.—*This Act shall not extend to Ireland*;—were agreed to without discussion.

Clause 23.—*Commencement of Act.*

Mr. Learoyd said he rose to propose a resolution. The spirit of the clause was perfect with one exception. It was intended the Act should come into force on January 1, 1884. In clause 8 they had already decided that no person should have a branch shop without having a qualified assistant. In many cases throughout England and Wales chemists had not only one but several shops, and the question arose whether in the time stated they would be able to get a sufficient supply of qualified assistants. It would be an unaccountable hardship, and he was sure one never intended by the Pharmaceutical Society, if chemists were liable to a penalty, although it might be impossible to obtain a qualified assistant in the time specified. He therefore moved that the Act should come into force as stated, with the exception of clause 8, which should come into force on and after January 1, 1886.

Mr. Furness submitted that the resolution was out of order, and that it should have been proposed previously.

Mr. Learoyd said this was a question of date, and he could not see why it was not applicable to the question of date in the Bill.

The President thought it would be in order to consider the question of date.

Mr. Archer seconded the amendment, saying he was not personally interested in branch shops, and did not wish to be, but he thought the suggestion thrown out was quite to the point. It did not seem quite fair that people having branch shops should be expected to get qualified assistants in such a short time, and he was in favour of the period being extended to January 1, 1886.

Mr. Ward moved—"That the clause remain as it is."

Mr. Ellinor seconded the amendment, remarking that the Pharmaceutical Society would not draw a hard and fast line, or begin to take proceedings against persons without giving them an opportunity to get qualified assistants.

Mr. Learoyd said the Pharmaceutical Society were expected to be guided by the Act of Parliament. Even though they were as lenient as possible other persons might take action, and he looked upon this short period as a serious objection.

The amendment was put—4 voting for it, and 8 against it.

The discussion on the Bill being concluded, Mr. Learoyd said he rose to express the gratification he felt at the very able manner in which the President had conducted the business. He then moved a vote of thanks to the President.

The resolution was seconded by Mr. Hall, and supported by Mr. Ellinor, and carried.

The President, in acknowledging the vote, complimented the meeting on the celerity and thoroughness with which it had dealt with the various clauses, and the proceedings concluded.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The eighth meeting of the session was held on Wednesday, February 21, in the rooms of the North British Branch. Mr. William Aitken in the chair.

The minutes of the last meeting having been read and adopted, the Chairman called upon Mr. J. MacGlashan to read a paper on "The Manufacture of Alcohol."

The paper was illustrated by an interesting series of specimens showing the stages in the process of manufacturing alcohol from grain, and a microscopic slide showing the yeast plant (*Torula cerevisiæ*).

On the motion of the Chairman, seconded by Mr. MacEwan, a cordial vote of thanks was awarded to Mr. MacGlashan.

The discussion which followed was taken part in by Messrs. Crowder, Fraser, MacEwan and Hill.

The ninth meeting of the session was held on Wednesday, March 7, in the rooms, 119A, George Street. Mr. P. Boa, President, in the chair.

The minutes of last meeting having been read and confirmed, the Chairman called upon Mr. W. Pirie to read a paper on "Chloral."

The paper will be published in a future number.

Mr. Pirie exhibited specimens of chloral, chloral hydrate, chloral alcoholate and chloral sulphydrate, and on the motion of the Chairman, seconded by Mr. J. D. Robertson, he was awarded a hearty vote of thanks.

A discussion followed, in which Messrs. Boa, Crowden, Henry, MacEwan, Robertson and Hill took part, the latter giving a practical illustration of Ogston's ammonium sulphydrate test for the detection of chloral, butylchloral and croton chloral.

Mr. W. S. Turnbull then started a discussion on the new Pharmacy Act Amendment Bill, and gave notice of the following motion for the next meeting, which was fixed for Wednesday, March 21, viz.:—"That this Association, while giving its cordial support to the larger portion of the Pharmacy Acts Amendment Bill, cannot overlook the desirability of having a common title for all who have or may become qualified by examination prior to and after 1886, and would respectfully urge upon the Pharmaceutical Council the necessity for deleting the following from clause 17:—'But no person shall in right of membership acquired pursuant to this clause be placed on the Register of Pharmaceutical Chemists,' and the following words be added:—'And shall be entitled to be placed on the Register of Pharmaceutical Chemists.'"

The Chairman having intimated that at the same meeting a paper would also be read on "The Alimentary Canal," the meeting was closed.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 8, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. E. Baily read a "Note on Dried Alum," which will be published in a future number of this Journal.

A discussion followed the reading of the paper, in which the Chairman, Secretary, and Messrs. Crow, Corder, Parker, Thompson and Short took part.

A vote of thanks was passed to Mr. Baily for his paper, which had been worked out with the aid of a grant from the Research Fund.

The Reporter upon Analytical Chemistry, Mr. C. Thompson, then made a report upon the "Separation of Cadmium and Copper."

A discussion followed the reading of the report, in which the Chairman, Secretary, Messrs. Crow, Parker, Ransom, Rees and Short took part, after which—

Mr. F. W. Short, the Reporter upon Inorganic Chemistry, made a report upon "The Alkali Manufacture." Various processes were described for converting NaCl into Na_2CO_3, but those chiefly dwelt upon were the Leblanc and ammonia processes. Special attention was devoted to the reactions which occur in the intermediate stages of the Leblanc process, with regard to some of which there is a difference of opinion among various authorities. The different methods proposed from time to time for the recovery of sulphur from the bye-products, or for their utilization in other ways, were reviewed, and the most important of them, including the Schaffner and Helbig process for recovering sulphur, were fully described. The report concluded with a description of the ammonia process, and details of the most recently published modifications and improvements.

In the discussion that followed the Chairman, Secretary, Messrs. Crow, Parker, Ransom and Thompson took part.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Association on Wednesday, February 21, Mr. C. Thompson read a paper on "Lithiæ Citras," which will be published in a future number.

After a discussion, in which several members took part, a vote of thanks, proposed by Mr. Cracknell, and seconded by Mr. Billson, was given Mr. Thompson for his valuable paper.

Another meeting of the Association was held on Wednesday, February 28, Mr. W. A. Wrenn in the chair, when a paper on "Tobacco of Commerce" was read by Mr. C. E. Palmer.

Mr. Palmer divided his subject into two divisions, viz., unmanufactured and manufactured tobacco. Under the first division he gave a brief description of the most important species of the tobacco plant, including *N. tobacum*, *N. rustica* and *N. repanda*, pointing out that *N. repanda* is not now to be found either wild or cultivated in Manilla. He then proceeded to give the history of the tobacco plant and of smoking, referring to Sir Walter Raleigh and his companions as being the first to introduce the practice of smoking into England in 1586. The collection of the leaf and preparation of it for the market was next spoken of. Lastly, its chemical composition and medicinal uses were treated, Mr. Palmer saying that he thought the use of tobacco as a medicine was nearly obsolete, for having been for ten years actively engaged in dispensing, he had only had occasion to dispense any preparation of tobacco three times. Under the division of manufactured tobacco, the laws regulating the manufacture and sale of tobacco were enumerated, and the operation of cutting tobacco, making cigars and snuff were fully explained. The enormous revenue derived from tobacco and snuff was stated, also the adulteration to which tobacco is subject, the latter being illustrated by drawings.

A lively discussion followed, in which the President, Messrs. Alcock, Braithwaite, Coe, Cracknell, Kerr, Park, Parkinson, Thompson, Woods and Millhouse took part.

A vote of thanks to the author was proposed by Mr. Winfrey and seconded by Mr. W. T. Cooper, jun.

A meeting of the above Association was held at the rooms, on Tuesday, March 6, when a paper, on "Photography," was read by Mr. C. F. Wyatt, who commenced by giving the history of the early processes which led to the practice of photography in its present form, with a short description of the more important ones, including those of Wedgwood, Niépce and Daguerre. The more recent wet-plate process was described, and the difficulties met with by the wet-plate worker mentioned, after which, the different dry-plate collodion and gelatine processes were described, and details given of the manufacture and use of gelatine dry plates. Printing and toning were described, and the precautions necessary in order to obtain permanent pictures commented upon.

The paper was illustrated by specimens taken by different processes, and after a lengthy discussion, in which the President, Messrs. Crow, Fell, Glow, Thompson, Millhouse and others took part, a vote of thanks, proposed by Mr. W. E. Crow and seconded by Mr. Palmer, was given to Mr. Wyatt.

Parliamentary and Law Proceedings.

Alleged Poisoning by a Cough Mixture.

Mr. F. Price, district coroner, has held an inquiry at the Murraytown Liberal Club, Cheetham, respecting the death of a child named Minnie Rendle Wilson, three months old. The evidence of the mother and grandmother showed that the child was a full-grown and healthy one up to Friday, when it caught cold and commenced to cough very badly. Mrs. Wilson applied bran poultices to its chest, which gave the child temporary relief. On Saturday afternoon, however, the mother went to the shop of Mr. C. G. Breadnor, chemist, 256, Waterloo Road, Cheetham, where she purchased a small bottle of "Breadnor's celebrated cough mixture." The deceased was given half a teaspoonful in a little warm water about half-past 10 o'clock, another dose was administered at half-past 2, another about half-past 5, and a fourth about half-past 8 on Saturday evening. The child slept all the following day till about half-past 11, when it became very bad, and Dr. Husband was sent for. On arriving at midnight the doctor found that the deceased had died a few minutes previously.

Dr. W. E. Husband said he examined the child, and there were no marks of violence upon the body, but the appearance of the eyes showed symptoms of poisoning. He took the medicine bottle with a portion of the medicine in it to Mr. Breadnor, and asked him what it contained. Mr. Breadnor showed him the prescription from which the mixture was made, and from that it appeared that it contained morphia. The bottle would hold about sixteen doses, and the child had had doses which would have about the 1-32nd part of a grain of morphia, which would be more than sufficient to cause the death of a child of that age.

The Coroner: Have you any doubt that the death of this child has been accelerated by the taking of this mixture?

Dr. Husband: I have no doubt whatever.

The Coroner: And in fact had not this mixture been taken and the child been properly treated it might probably have been alive?

The Doctor: Yes.

In answer to a juryman, the Coroner stated that the description on the label of the bottle stated that the mixture was "for children under six months old; half a teaspoonful in the same quantity of warm water every three hours."

Mr. Price said there could scarcely be any doubt that the child had died from an overdose of this medicine, which had been administered innocently enough on the part of the mother and grandmother. Mr. Breadnor had sold it in the ordinary course of his business, and he (the Coroner) did not know that any fault could be found with him, for if people would purchase these medicines and administer them indiscriminately it could not be helped. He thought, as the doctor had said, that it was a dangerous practice to give narcotics to very young children.

The Jury returned a verdict that the deceased had died from an overdose of cough mixture containing morphia inadvertently administered.

Prosecutions under the 17th Section of the Pharmacy Act.

At Mansfield Petty Sessions, last week, before Mr. Oakes, Captain Need, R.N., and Captain Salmond, John Davidson, grocer, Kirkby-in-Ashfield, was summoned for selling a packet containing poison, to wit, strychnine, in the form of vermin-killer, without registering the transaction, on the 6th ult.

Police constable Cuckson said on the day in question he called at defendant's shop in plain clothes and bought the packet of vermin-killer produced from defendant's wife, who asked no question whatever.

Police constable Blackburn said he took the packet to Mr. Cutts, Mansfield, for analysis.

Mr. Cutts, Mansfield, said he had examined the contents of the packet, and it contained strychnine.

Defendant pleaded ignorance.

Fined £2, Captain Need saying that it was a very dangerous practice, which must be stopped.

Ann Wharmby, shopkeeper, Kirkby, was similarly charged. She failed to appear. She had been previously cautioned.

Mr. Cutts, in speaking to the analysis of the contents of this packet, said it was a 6*d.* one, and he calculated that there was sufficient strychnine in it to poison fifty people.

Fined £2.

The Draft Pharmacy Acts Amendment Bill.

Sir,—The nature and amount of correspondence which appears in the Journal of the 3rd inst. is alone a sufficient index of the very widespread interest which has been awakened by the publication of the Pharmacy Acts Amendment Bill, and it will probably assure the Council —if such assurance were needed—that whatever may be the ultimate fate of this Bill, to the production of which so much time and ability have been given, it will scarcely be opposed by that weight of apathy, or absolute indifference, which has been the chief factor of opposition to all similar efforts in former years.

In all parts of the country the want of legislation in some shape or form, connected with things pharmaceutical, has long been plainly manifest, and, in many cases, the more remote the district from London, the more urgent the necessity. Points of divergence in opinion have latterly occurred only in the expression of ideas as to the exact nature of the change desirable, and whilst most of us are agreed upon broad principles, it can scarcely be expected that the present Bill will exactly adapt itself to the want and wish of every individual. However, it seems already to be very generally regarded as a reasonable demand for that which undoubtedly the interest of the public requires at the hand of pharmacy; and if, with this, is preferred a moderate request for certain clauses which may react to the benefit of her devotees, it must be extremely necessary that our desires for the latter may not be accompanied by too much commotion about the former, or both will surely suffer.

As in the Council itself, so amongst your correspondents, clause 2 aroused the greatest amount of controversy, and that part of your leading article which refers to this subject is of particular interest. Upon reading the clause in question, and its discussion by the Council, it appeared to me that so far from being a departure from any of the recognized principles of the Society, it rather tended towards an extension of power. And were it not for your history of its origin, it would be hard to realize that such a demand could by any possibility be accorded. If the Society acquires the right to go outside its own community and insist upon certain restrictions in the sale of dangerous articles which it may from time to time schedule, a vast accession of influence must result, and such increase cannot be reflected, to the detriment of individual members. Hitherto the complaint has been, that the Council of the Pharmaceutical Society was not sufficiently active in comprehending the extent to which general traders encroached upon the border land of pharmacy; it is now asserting its right to interfere with the manner of conducting business in these self-same establishments, and thus claiming universal recognition as the guardian of public safety.

I have always held that two degrees of qualification, the higher being purely optional, constitute a source of weakness; our spheres of labour are, to a certain extent, far too contracted to admit of such distinction, and it would be better for the public, the Society, and ourselves if in this respect at least we were upon terms of equality.

The matters connected with the educational clauses have been thoroughly discussed by the Council, and particularly agreed upon by the trade at large before their appearance in the Bill. Clause No. 13, to which Mr. Burrell takes exception, has for its object the protection of the pharmacists of the future. Many young men have entered upon their apprenticeship with very ill-defined notions of what is expected of them in the matter of preliminary education, or even of the examinations which await them at the expiration of their pupilage, whilst parents or guardians have totally ignored their responsibility upon this point. That the result has been deplorable the periodical pass list affords almost certain proof.

Every pharmacist, who is actually engaged in business, hears from time to time expressions of opinion upon the part of the outside public as to his position in comparison with other members of the trading community; almost every one of the educated public admits readily, with but little argument, that the pharmacist has rights for consideration and emolument which no other individual who keeps an open shop can urge. I cannot hesitate in believing that members of Parliament, differing in no great degree from the general public, would willingly admit such rights to a lawful recognition if only they were properly represented to them. In order to ensure an efficient representation I would suggest that a copy of the Bill should be sent by every Local Secretary, or other person appointed or approved by the Society, to all the members of Parliament in their district, together with a personal request for its consideration and support when the proper time came. By this means it would be possible to reach every member of Parliament from the most accessible quarter and perhaps do much to secure an easy passage for the Bill.

Meanwhile, every pharmacist can do much to this end, by lending hearty support and losing no opportunity of giving a *résumé* of the proposition to all those of influence who are willing to listen.

Kilburn, N.W. CHARLES B. ALLEN.

Sir,—The draft Pharmacy Bill, which has so anxiously been waited for, and which for such a length of time has engaged the attention of the Pharmaceutical Council, is at length in the hands of those who cannot but be deeply interested in its provisions. To those amongst us who have been cherishing utopian ideas of legislative enactments which should secure to the chemist a monopoly of the sale of all poisonous substances, to say nothing of an exclusive right in the retailing of drugs and pharmacopœial preparations, the Pharmacy Acts Amendment Bill will doubtless be a sore disappointment. The general favour, however, with which the Bill seems to be regarded, judging from the correspondence which has appeared in the Journal, must be a source of gratification to its promoters. That it should be perfection in all its details is more than would be reasonably expected. A generous expression of opinion with regard to the Bill by the members of the trade generally will, doubtless, be the means of removing anything which is objectionable in its provisions.

Mr. Sandford has done good service by pointing out the injustice and unnecessary hardship which will be inflicted upon the retailer of an insufficiently labelled patent medicine by clause 4, and I think his suggestion that the first action should lie against the proprietor of the medicine is an exceedingly wise one. With regard to the labelling of patent medicines containing poisons, I think both the inner and outer label should bear the word "poison."

The regulation concerning branch businesses will remove one of the most glaring inconsistencies of the existing law, and will operate beneficially alike in the interest of the pharmacist and in the protection of the public.

The distinction between pharmaceutical chemist and chemist and druggist is one which is not well understood by the public, and under the special circumstances of the case I do not see how any one can seriously object to that distinction being removed.

Considering the difficulties which surround the subject of pharmaceutical legislation I think the Council are to be congratulated upon the result of their labours, and I sincerely hope that their exertions many meet with that success which all who are interested in the progress of pharmacy must desire.

72, *Lancashire Hill, Stockport.* THOMAS HART.

Sir,—Although I have nothing much to add to what has already been said concerning the proposed "new Pharmacy Bill," it may, perhaps, be desirable that the views of those engaged in business in various parts should be made known.

In the Journal of the 3rd inst., Mr. Wade compares the result of the deliberations of the Society to the oft repeated quotation, "The mountain in labour after much commotion brought forth a mouse."

Certainly, the proposed Bill at first sight appears a simple measure, but inasmuch as it deals with most of the difficulties which have filled chemists' minds during late years, therein lies its merit.

It is clear that chemists now in business cannot expect much if any individual benefit from the Bill; but I cannot find any fault on that account, for the sooner we make up our minds to the fact that we must depend entirely upon our own individual energy for success, both monetary and social, the better for the business and all connected with it.

If we expect that the Pharmaceutical Society or the Government will make laws which will, in any sense, create a monopoly, or limit the number which enter our ranks, we shall expect that which, under the existing order of events, is impossible, for neither the Pharmaceutical Society nor the Government can improve our social position or our incomes by making laws. On the other hand, it must be evident that had not the Pharmaceutical Society always shown itself ready to take the initiative in regulating the sale of poisons, laws would have been passed by bodies outside our ranks to accomplish the same purpose, and taking into consideration the peculiar nature of our calling, harassing laws they would have been. Hence I maintain that we have much to thank the Councils (both past and present) of our Society for in so carefully looking to our interests. We are apt to overlook the fact that the Council is a representative body of ourselves. If the Council is not composed of such men as are best able to look after our interests, then we have ourselves to blame; in fact, in attempting to fling mud at the Pharmaceutical Council most of it must come back upon ourselves. I make these remarks knowing how deeply rooted among some in our ranks is the idea that the Council, in not providing us all with profitable businesses, has neglected its duty.

And now a few remarks concerning the Bill itself. With regard to clause 2, I cannot help recognizing that there are many articles requiring to be labelled "poisonous," which belong more properly to the business of the oil and colourman, and the sale of which cannot well be confined to chemists, without imposing a hardship upon the former tradesman. Moreover, dealing in such articles does not well assort with the chemist's business, now that the oil and colourman's business has become separated in towns of any size. On the other hand those chemists whose businesses partake of the nature of the oil and colourman's will not be at all injured by the clause.

I think that clause 4 will be found to require modification before the Bill is finally accepted. The large vested interests it will affect are well known, and the clause will undoubtedly meet with great opposition, unless care is taken to make it applicable only to those patents which strictly require to be labelled "poisonous." Undoubtedly it is a great anomaly that at present patent poisons can be sold without any restrictions; on the other hand, many patents, although they contain poison, contain it in such small quantities as to be harmless.

My own cough lozenges contain a poison. On one occasion a customer ate a whole box-full at one sitting, but suffered no greater harm than an attack of sickness. He might, indeed, have increased the dose without more injury. There are probably many patents similarly constituted, and it would be objectionable to label them "poison," as to do so would either unnecessarily injure their sale, or educate the public to regard the word "poison" as of little importance. I would suggest that all patents containing poison should be registered by the Pharmaceutical

Council, and the nature and proportion of the poison being known the Council shall decide upon the necessity for labelling them as poisons.

I would endorse the remarks made by Mr. Proctor on clause 4, and the remarks made by Mr. Sandford upon clauses 3, 4, and 8.

Undoubtedly clause 6 will press heavily on many unqualified managers, but to produce a Bill which would be hard on no one is a practical impossibility, and to as far as possible expunge all inconsistencies from the pharmacy laws will be a great point gained.

Mr. Burrell anticipates that inconvenience will be caused by clause 3. I do not myself think that a chemist, as the law now stands, can honourably have an apprentice bound before he passes his Preliminary, as there must be a great chance of his not passing it at all, and consequently he would waste his time during his apprenticeship, in learning a trade which he would not be able to follow up afterwards. I make it an absolute rule not to accept an apprentice until he has passed his Preliminary, and I find no inconvenience in carrying out that rule.

I am aware that the members of the Council have probably, in framing the proposed new Bill, been guided by considerations which, were they known to me, might change my views upon some of the above points.

Colchester. J. C. SHENSTONE.

Sir,—I am sure that all who have the true interests of the body at heart will be rejoiced to see the steps the Council has taken, both in adopting the recommendations of the Educational Committee and with regard to the amended Pharmacy Bill.

There can be no doubt that both these will tend to considerably elevate the position of pharmacy in this country.

But I certainly think, if it is thought advisable to admit the "Minor" men as members of the Society, that a fellowship should be formed by the Council for those who have taken the Major qualification. If this is done I am quite sure there will be a great increase of candidates for the Major examination.

I do hope the Council will not let this matter pass, but carefully consider it for the interests of pharmacists.

Bentley Road, Princes Park, Liverpool. C. J. S. THOMPSON.

Sir,—The admission of my letter, representing, perhaps, the extreme of opposition, must convince members of your impartiality and desire to have all opinions represented. I should not have trespassed on your indulgence again had you not in your last leader on the Pharmacy Act, by some mistake, misinterpreted one portion of my letter, and made me express the very opposite opinion to that I put forth on the clause relating to branch shops.

I have no objection whatever to clause 8. I contended that if co-operative stores and corporate bodies could become proprietors, having qualified chemists to conduct their business, that orthodox chemists should enjoy the same privilege upon condition that their managers were qualified men.

I fail to perceive any clause in the Bill which will prevent corporate bodies dispensing and retailing poisons—and if there were, I should consider the passing of it through the Legislature highly improbable after the decision of the highest Court of Appeal in their favour. At present, I appear to be the only "adverse critic." Although holding so unenviable a position, I must, in justice to myself, ask you to allow me to say that I am hopeful that the weak "vinegar" I have been able to distil out of the Bill may be beneficial in cooling the imagination of those pharmacists who seem to indulge too hopefully in the remedial effects of the pharmaceutical wine.

174, *Warwick Street, Pimlico, S.W.* JOHN WADE.

THE COMPOSITION OF CACAO BUTTER.

Sir,—In "The Month" article published in your issue of February 24, attention is called to some experiments of Herr Traub, from which I gather that he has been unable to confirm the existence of my theobromic acid, $C_{64}H_{12}O_{28}$ and did not suceed in obtaining a higher fatty acid than arachic acid, $C_{20}H_{40}O_2$.

I have not been able to consult the original paper by Herr Traub, but as I did obtain an acid of the composition here given, and have a quantity still in my possession, I can only conclude that his investigation was not conducted with the same patience and pains with which I worked, and that he too soon grew tired of fractionations, which, if steadily pursued, would, in all probability, have resulted in obtaining the acid.

As I wish to stand well with your readers, I will add that I entirely adhere to the results of my original investigation (*Journ. Chem. Soc.*, January, 1878) and have no doubt that Herr Traub's arachic acid was a mixture of lower and higher fatty acids. I obtained such a mixture as an intermediate product, and if he had gone on fractionating this, his highest product, again and again, he would have been better advised than in committing himself to a gratuitous assumption and a pointless criticism.

	Kingzett's Theobromic Acid. Theory.	Obtained.	Kingzett's Intermediate product.	Composition of Arachic Acid.
C.	82·75	82·62	76·81	76·92
H.	13·79	13·92	13·14	12·82
O.	3·46	3·46	10·05	10·24

There could be no confusion of such widely differing substances as are here indicated.

Further, in spite of Herr Traub's statement to the contrary, no proof has yet been afforded that either palmitic acid or stearic acid is obtainable from cacao butter.

In conclusion, should any reader of this protest wish to investigate the matter, I will gladly place in his hands such products as I have preserved, for analysis, and I extend the offer to Herr Traub.

C. T. KINGZETT, F.I.C., F.C.S.

SPIRITUS AMMONIÆ AROMATICUS.

Sir,—I should like to point out a slight inaccuracy into which Dr. Thresh has fallen, in his paper on the above subject, published in the Journal of February 17. He says, "Taking the official quantities, the ammoniæ carbonas refuses to dissolve in the requisite amount of water and solution of ammonia without the aid of heat." The "requisite" amount of water I take to be about 10 ozs., and I find that using this quantity complete solution takes place at ordinary temperature in about one hour, provided that the ammon. carb. be powdered and the mixture be continuously agitated. Mr. Martindale attempted to demonstrate this, but failed in not carrying out the conditions as to the "requisite" quantity of water, as pointed out by Dr. Thresh in the ensuing number of the Journal.

ACETIC ETHER.*

ITS TRADE COMPOSITION, MANUFACTURE AND SPECIFIC GRAVITY.

BY WILLIAM INGLIS CLARK, D.SC.,

Pharmaceutical Chemist.

In the spring of 1882, while working with a sample of acetic ether, supplied by an eminent London firm, I was surprised to find that the addition of dry potassium carbonate to it resulted in the production of a lower layer of solution, and I arrived at the conclusion that the so-called acetic ether contained a certain amount of water. Further investigation led me to examine the acetic ether supplied by other makers, with the result that in only one case did I find the commercial article to resemble what it professed to be. I may mention that I have not examined any samples guaranteed chemically pure, but have confined myself to the samples known as pure acetic ether in the London and other markets. Before giving you the results of this examination, I propose to explain the analytical methods adopted in estimating the acetic ether and alcohol present.

1. *Estimation of Real Acetic Ether.*—In this I followed the method recommended in Allen's 'Organic Analysis,' vol. i., p. 141. A solution of caustic potash in pure rectified spirit (free from aldehyde, the presence of which, by the formation of aldehyde resin, renders titration very difficult), of the strength of about 8 per cent. real KOH is prepared, and its alkalinity accurately determined by standard sulphuric acid; 50 c.c. of this solution are transferred to a strong glass flask, and to this are added 5 c.c. or a weighed quantity of the sample of acetic ether under examination. The flask may be either closed with a rubber stopper, securely tied down, or connected with an inverted Liebig's condenser, and it is then heated in a water-bath for three hours. Having allowed the flask to cool, the contents are carefully washed into a beaker, and the alkalinity determined. The loss of alkalinity evidently represents the amount of acetic or other acid which has been present in the ether, either free or in combination. "Each c.c. of *difference* between the normal sulphuric acid *originally* and *ultimately* employed represents one equivalent in milligrammes (·088 grms.) of the ether present."

The reaction corresponds to the following equation:—

$$C_2H_5C_2H_3O_2 + KOH = KC_2H_3O_2 + C_2H_5OH$$

the resulting products being potassium acetate and ethyl alcohol. To reduce the *weight* of acetic ether obtained to *volumes* it is only necessary to divide by ·901 the specific gravity of acetic ether (·898 according to Allen).

It is, of course, necessary to determine the percentage of free acid present in the acetic ether. This is easily obtained by dissolving 5 c.c. of the ether in proof spirit and titrating with standard alkali. I may here call attention to the necessity of previously neutralizing the acid present in the proof spirit or taking it into account in the estimation. The following example is taken from my note book:—

Sample A. 5 c.c. ether taken.
50 c.c. sol. KOH alcoholic neutralized . . . . . 52 c.c. standard H_2SO_4.
Free acid in 5 c.c. acetic ether . . . . = 5·1 c.c. standard alkali.

Alkalinity before action = 46·9 c.c. standard H_2SO_4.
Alkalinity after action = 9·1 c.c. standard H_2SO_4.

Loss . . . . = 37·8 c.c. standard H_2SO_4.
Acetic ether = 37·8 × ·088 = 3·3264 grams.
3·70 c.c.
74 per cent.

2. *Estimation of Alcohol.*—Having first ascertained the percentage of acetic ether present, the amount of alcohol is determined by taking advantage of the reaction between acetic ether and caustic potash, for which I have already given an explanatory equation in reference to the estimation of acetic ether. We saw that the final products were potassium acetate and ethyl alcohol, and if we can determine the total amount of alcohol after the action is complete, we have a ready means of knowing how much was present originally in the free state. You will of course understand that any ether (sulphuric), aldehyde, or other volatile substances present in the acetic ether will prevent the process being absolutely accurate, unless these are estimated and allowed for; but as these do not occur to any great extent, the process is sufficiently accurate for ordinary purposes.

The "*modus operandi*" is as follows:—

In a flask connected with inverted Liebig's condenser, place 200 c.c. of the ether under examination (or any less quantity) along with 200 c.c. of water and about 120 grams caustic potash in sticks. In a short time reaction spontaneously occurs, but to complete this the flask is heated on a water-bath for two hours and allowed to cool. Another 200 c.c. of water are now added, and distillation carried on till 500 c.c. in all have passed over. This contains all the alcohol and it may be readily estimated by the Sikes hydrometer, or the careful determination of specific gravity. By subtracting the amount corresponding to the acetic ether known to be present, we know how much was present as alcohol.

In giving the approximate composition of trade samples, I regret that I have only been able to procure eight of these, representing, however, most of the makers (two from scotch houses, one of German manufacture, the others, believed to be of English manufacture, from London), acetic ether not being an article of large consumption.

From a glance at the accompanying table it will be seen that of these only one contains over 75 per cent. of real acetic ether, while in one case only 30·6 per cent. were present.

Table showing Approximate Percentage Composition of Acetic Ether (1882).

Parts by Volume.	A.	B.	C.	D.	E.	F.	G.	H.
Acetic ether ($C_2H_5C_2H_3O_2$)	90·14	74·8	67·02	60·0	46·1	41·7	31·4	30·6
Alcohol absol. (C_2H_5OH) .	7·2	22·8	21·93	24·3	37·4	33·4	48·0	32·8
Ac. acetic glac. ($HC_2H_3O_2$) .	trace	·9	·30	·4	trace	2·0	1·1	7·0
Water, ether, etc.	2·66	1·5	10·75	15·3	16·5	22·9	19·5	29·6

In order to see whether the large percentage of free alcohol and the water had been added intentionally or were the result of careless manufacture,

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, March 14, 1883.

I have made an extensive examination of the more commonly accepted processes, and present the more important results to you now. These processes may be at once divided into two classes, viz., those in which acetic acid is made to act in the free state on alcohol in presence of sulphuric acid, and those in which it is liberated from an acetate in presence of alcohol.

No. 1. In the 'Year-Book of Pharmacy' for 1881, p. 68, a modification of the first of these is given, which resembles the continuous process in ether making, and is highly recommended. Equal parts of sulphuric acid and alcohol are placed in a retort, heated to 140° C., and a mixture of equivalent parts of acetic acid and alcohol run in, the temperature being kept nearly stationary. It is stated that 90 per cent. of the theoretical yield of ethyl acetate may be obtained. I made several trials of this process and give below the results of one operation taken more in detail. I regret that I did not accurately estimate the yield of acetic ether, but the specific gravity indicates the composition to some extent.

Forty-five ounces each of sulphuric acid and s. v. rect. were heated to 140° C. and into this was slowly run a mixture of—

Glacial acetic acid (6 lbs.)	91 fl. oz.
Alcohol, 56 o. p.	104 fl. oz.

The following fractions were obtained:—

275 c.c.	sp. gr. 766
235 c.c.	sp. gr. 807
900 c.c.	sp. gr. 837-883
505 c.c.	sp. gr. 890–900
985 c.c.	sp. gr. 907-917
1475 c.c.	sp. gr. 925–935
1365 c.c.	sp. gr. 940

i.e. 1915 c.c. below sp. gr. 900.
985 c.c. below sp. gr. 907–919.
2840 c.c. above sp. gr. 925.

From these figures it will be apparent that at first a large amount of ethyl oxide was produced, while during the last half of the operation combination took place very imperfectly. Were the process of any practical value I would give details as to the purification of this sample, but the large amount of ethyl oxide, free alcohol and free acetic acid at once shuts out this method of manufacture.

The other similar plans in which the acetic and sulphuric acids along with the alcohol are distilled together are open to the same objections, though to a less degree.

No. 2. *Action of Carbonic Acid on Potassium Acetate.*—In Allen's 'Organic Analysis,' reference is made to this little known process. Potassium acetate is dissolved in absolute alcohol and carbonic acid passed through. The potassium carbonate being insoluble, is supposed to be precipitated, and only acetic ether remains. I was unable to detect a trace of acetic ether when absolute alcohol was used, even after passing carbonic acid (dry) through for twenty-four hours, but by adding water till solution of the acetate was obtained a slight action took place, but not to any practical extent.

Thus:—Potassium acetate	13½ ounces.
Rectified spirit	283 c.c.
Water	57 c.c.

when treated with CO_2 for twenty-four hours and distilled, gave—

275 c.c. containing 1 per cent. ethyl acetate.

No. 3. *Action of Sulphuric Acid on Acetates.*—A. *The B.P. Process.*—As in other cases, where chemical substances of definite composition are in the Pharmacopœia, the directions do not bind us to any special method of manufacture, the ultimate purity of the product being secured by the tests appended. So it is in this case, the formula being given and the specific gravity and boiling point almost coinciding with those of the pure substance. The specific gravity is given as about 900, practically agreeing with that of the pure article, sp. gr. 901, as obtained by myself. There is much confusion in text books as to the real specific gravity.

Thus:—Bache says	·866	at 15° C.
Cooley and 'Dict. Chem. Manuf.'	·890	
U. S. Pharm.	·889-897	
Gmelin (authorities) . . .	·812-930	
Squire	·900	
Mendelejef	·8981	
Gössman	·932	at 20° C.
Kopp	·9104	at 0° C.

In any case there can be no doubt that a pure article was intended, and not such an one as would include the samples, the composition of which I have already referred to. Indeed, in their case the sp. gr. (which at any rate is no evidence of purity), differed widely from that of the B.P. The numbers obtained were 892, 910, 912, 894, 904, 908.

The B.P. says it may be obtained by distilling a mixture of dry acetate of soda, 8 parts; rectified spirit, 5 parts; sulphuric acid, 10 parts, adding the distilled product to half its weight of chloride of calcium in a stoppered bottle; letting them remain together for twenty-four hours, and then decanting and rectifying the ethereal liquid.

I accordingly took—

Alcohol, 56 o.p.	283 c.c.
Sulphuric acid	566 c.c.
Mixed, cooled, and added,	
Sodium acetate, dried	453·6 grams.

After thorough mixing, the flask was heated on a water-bath with inverted condenser for two hours to ensure complete reaction, and the contents distilled. Let me here give a warning with regard to the addition of the sodium acetate. Unless great care be taken, loss of ether will occur from the sudden heat evolved, and an efficient condenser should be at once attached. A still more important point is to ensure thorough decomposition of the acetate before beginning to distil off the ether. Should this be overlooked and the mass gather into knots, as soon as nearly all the ether (and of course along with it the uncombined alcohol) has passed over, the sodium sulphate will melt, and, along with the sulphuric acid, form a viscid liquid, which acting on the knots of acetate of sodium gives rise to sudden and violent frothing, which may readily burst the flask. When the mixing has been carefully attended to the distillation goes on quietly till the end. In the B.P. process, in which, as we shall afterwards see, large excess of sulphuric acid and sodium acetate are added, the action is specially violent and knots form readily, with the result that frothing is very persistent and commences early in the distillation.

To return to the operation: 372 c.c. of distillate were obtained, sp. gr. ·9185, which on analysis showed 88·18 per cent. ethyl acetate, =294·6 grams, =328 c.c. in all. Following out the directions, I macerated with 171 grams fused chloride of calcium for twenty-four hours and decanted. I only obtained—

134 c.c., sp. gr. ·930,

and on distillation obtained the greater part, say 130 c.c., sp. gr. ·9024, and containing 91·6 per cent. ethyl acetate, the total yield being thus 119 c.c. I shall again refer to the method of purification later on, but at present I would just call your attention to the extravagance of the B.P. process.

The reaction which goes on may be represented by the equation—

$$NaC_2H_3O_2 + H_2SO_4 + C_2H_5OH = C_2H_5C_2H_3O_2 + NaHSO_4 + H_2O,$$

and the proportions therein indicated correspond closely to—

Rectified spirit	283 c.c.
Sulphuric acid	230 c.c.
Sodium acetate, dried	351 grams,

while in the B.P. an excess of 336 c.c. sulphuric acid and 102 grams sodium acetate are ordered.

We have above assumed an equation representing the action of sulphuric acid on acetate of soda and alcohol; but there is still another equation which might be adduced, in which neutral instead of the acid sodium sulphate is obtained, only half of the sulphuric acid being required.

This is—

$$2NaC_2H_3O_2 + H_2SO_4 + 2C_2H_5OH = 2C_2H_5C_2H_3O_2 + Na_2SO_4 + 2H_2O.$$

Which is correct? To decide this I prepared some acetic ether with the above proportions.

No. 4.	Sodium acetate (dry)	351 grams.
	Sulphuric acid	120 c.c.
	S. v. rect.	283 c.c.

The acid and alcohol were mixed and cooled, thoroughly mixed with the acetate, heated with inverted condenser for one hour, and distilled. This was a matter of difficulty, for owing to the absence of excess of sulphuric acid, the contents of the flask remained unmelted or undissolved, and distillation proceeded but slowly.

400 c.c., sp. gr. ·928, were obtained, which, on analysis gave—

Acetic ether 173·18 grams 192·8 c.c.
Acetic acid $HC_2H_3O_2$ 53·28 grams.
Alcohol and water, the remainder.

The 283 c.c. s. v. rect. = 357 grams acetic ether
The 351 grams sod. acet. = 376 grams acetic ether.

The sulphuric acid is also slightly in excess of what is necessary for the alcohol, and we see that—

If $H_2SO_4 = C_2H_5C_2H_3O_2$, yield should be 178·5 grams
$= 2C_2H_5C_2H_3O_2$, yield should be 357 grams.
Yield actually obtained 173·18 grams,

so that the first given equation is the correct one.

Action of Sulphuric Acid on Acetic Ether.—When sulphuric acid is heated with acetic ether it decomposes it into ethyl oxide and acetic acid, with the formation of numerous compounds dissolved in the sulphuric acid. It will be probable, if this statement be correct, that the effect of using excess of sulphuric acid in the preparation of acetic ether must be to decompose some of it as soon as formed and to lessen the yield. In order to examine this more closely,

I mixed

Acetic ether 200 c.c. (90·14 per cent. by volume)
Acid sulphuric 100 c.c.,

allowed to lie for two days and distilled.

Much sulphurous acid was given off and a treacly residue was left in the flask. The distillate 140 c.c. sp. gr. 925 contained now only 81·32 per cent. of acetic ether, giving the following result:—

	Acetic Ether.	Acetic Acid.
Before . . .	161·92 grams	None.
After . . .	102·25 grams	16·63 grams.
Loss	58·67 grams.	

This fact determined me in examining the production of acetic ether when the theoretical amount of sulphuric acid was used. It will be observed from the equations already given that water is set free in the reaction, and on this account it might be supposed that a slight excess of sulphuric acid would be useful in absorbing this, thus preventing formation of aqueous acetic acid. It is to avoid this that it is recommended to dry the sodium acetate before adding it to the sulphuric acid and alcohol. For this reason also Frankland and Duppa have recommended the use of absolute alcohol, although others have pointed out that a trace of moisture seems to assist etherification. I have accordingly, in dealing with this matter of excess of sulphuric acid, used absolute alcohol, rectified spirit, and crystallized as well as dried acetate of soda.

No. 5. *With Crystallized Sodium Acetate and S. V. Rect.*—

Sod. acet. cryst. 582 grams

Sod. acet. sic. + s. v. rect .	173·1	318·9	318·5	294·6
Sod. acet. sic. + alc. absol. .		310·2	325·7	

From these we see (1) that the water in the crystallized salt should be removed; (2) that great excess of sulphuric acid (as in the B.P. process) or deficiency are equally to be avoided; (3) that any advantage gained by using absolute alcohol instead of s. v. rect. is very small and not worth the extra expense; (4) that a slight excess of sulphuric acid is advantageous, and (5) that in no case have I obtained more than 91·2 per cent. of the theoretical yield. This last is to some extent accounted for by loss from evaporation, etc., etc., as I purposly omitted to pass the uncondensed vapours from the flask through absorbing bulbs; but in every case secondary actions took place between the acetic ether or alcohol and the sulphuric acid which no doubt reduced the yield.

Effects of Delay on the Yield.—Frankland and Duppa recommend that the mixture of alcohol and acid be allowed to lie for some time before addition of the sodium acetate, and that thereafter it is advisable to leave the mixture for some time before distillation. The latter proposal is probably intended to ensure complete decomposition of the acetate, and, in my experience, this is necessary, unless great care be taken in thoroughly mixing the acetate, in which case it can be dispensed with. Before the action of sulphuric acid on ethyl acetate had been satisfactorily made out, I thought that the complete decomposition of the acetate could be most easily effected by heating the flask with inverted condenser for an hour, and all the already detailed experiments were made under this condition. A little reflection will, however, show that if excess of sulphuric acid be present an undesirable opportunity is afforded for the subsequent decomposition of the already formed acetic ether, and I found, by mixing thoroughly in the cold, and immediately heating rapidly and distilling (as described in my "model process" later on), a still larger yield was obtainable.

Thus:—

		Heated for one hour before distilling	Mixed in cold and distilled.
S. v. r. 283 c.c. . . H_2SO_4 280 c.c. . . Sod. acet. sic. 351 grms.	yields	318·5 grams	338·7 grams

The object of the former, *i.e.*, delay before addition of the acetate, as stated in their paper, was to favour the formation of sulphovinic acid, but in the six annexed experiments on the point I find it to be undesirable; not only is there a smaller yield, but there is a greater residuum of secondary products in the flask, when delay occurs before addition of the sodium acetate.

Table showing Effect of Delay on the Yield.

Average results.	Acetic ether.	Acetic acid.
No delay (av. of 3) . .	318·9 grams	7·1 grams.
18 hours (one trial) . .	301·6 „	6·7 „
48 „ (av. of 2) . .	295·9 „	7·6 „

We have now examined pretty fully the various processes of manufacture (I may mention that my experiments have included the acetates of potash and lead) and it is evident that whether we use the B.P. process or any one of the modifications of it, using rectified spirit, absolute alcohol, dried or even crystallized sodium acetate, in every case *even without purification*, we at once get a distillate purer, stronger and better than any of the commercial articles obtainable, and we are forced to one of two conclusions, either that a wilful adulteration has been practised or that the manufacture has been accomplished in a careless manner, by the distillation of free acetic acid, sulphuric acid and alcohol. It may be asserted that as acetic ether gradually decomposes in presence of moisture into acetic acid and alcohol, the samples under discussion were at first of greater strength and had deteriorated by keeping; but this is inadmissible, for in the first place, the free acetic acid is, after all, so small, that were it in combination the composition would be but slightly altered, and, secondly, I have again estimated the free acid after keeping the samples from one to nine months and find no great change, as shown in the following table:—

Table showing Increase in Free Acid by Keeping.

	Free acetic acid in 100 c.c. acetic ether. At first.	After keeping.		Increase.
A . .	Only two days in possession.			
B . .	·998 gms.	9 months.	3·484 gms.	2·486 gms.
C . .	Only one day in possession.			
D . .	·442 „	3 „	·422 „	None.
E . .	None kept.			
F . .	2·121 gms.	9 „	3·168 „	1·047 „
G . .	1·248 „	9 „	1·742 „	·494 „
H . .	7·440 „	1 „	7·440 „	None.

Up to this point we have dealt only with the subject of manufacture, and the purification of the acetic ether must now receive our attention. You may perhaps think it sufficient if I say how to purify it; but the right understanding of this depends so much on knowing how not to purify it, that I make no apology for dwelling on this point at length, and bringing in some experiments which have at first sight little to do with the main question.

From a careful study of the subject of manufacture we learn what are the impurities to be removed from the acetic ether. These are ether, products resulting from the secondary action of sulphuric acid, acetic acid, alcohol and water. Of these, the first two can be most easily removed by distillation; but the ether, at least, is only present in a badly manufactured preparation, and I therefore shall not refer to it again.

The acetic acid is present in all samples of crude acetic ether, though in some cases to a very slight extent, and is most easily removed by agitating the ether with a solution of an alkaline carbonate. If the sample is free from water the acetic acid is not readily removed by dry potassium carbonate, but the addition of a few drops of water facilitates the absorption of the acid.

The removal of alcohol is not so easily effected, and although, as I shall afterwards show, it is quite easy to obtain an article, at the first distillation, free from alcohol, yet the examination of the methods usually employed have, in my hand, yielded such interesting results that I must refer to these more fully.

It will be remembered that in the B.P. process a large excess of sodium acetate and sulphuric acid are employed, with the evident intention of ensuring the absence of alcohol in the resulting product, and I find that this object is attained; but we also noticed that it is directed to add to the distillate half its weight of chloride of calcium (fused); allow to stand for a night, decant and distil. The chloride of calcium is added to remove alcohol or water, and the use of it has been advocated or objected to by various writers. Chloride of calcium forms with acetic ether a crystalline compound, and in the B.P. process so large a proportion is absorbed by it that only a very small amount (174 c.c. out of 372 c.c.) is separable by decantation. The addition of water separates the acetic ether, but at the same time destroys any advantage that had been gained by the use of the calcium chloride. In this dilemma some have adopted distillation from fused calcium chloride, a plan which others have objected to on account of the bumping which occurs during the distillation, owing to the solubility of the chloride in acetic ether. In my opinion a much more serious objection (and one which I nowhere find alluded to) lies in the decomposition which occurs. Fused calcium chloride is always alkaline, and the free lime decomposes acetic ether with the production of alcohol and calcium acetate. In addition to this the distillate has a somewhat pungent smell, the cause of which I have not determined, and after all it is not even comparatively pure acetic ether. Thus in the B.P. process, ·372 c.c. containing 88·18 per cent. of acetic ether, when treated with calcium chloride, decanted and distilled, gave only 130 c.c. containing 91·9 per cent.; an enormous loss with only an impure product.

The solubility of calcium chloride in acetic ether is not great, and I have determined it by estimating the chlorine in a given volume of the ether after digestion with the chloride.

At 0° C.—100 c.c. acetic ether dissolve ·3688 gram $CaCl_2$.

At 15° C.—100 c.c. acetic ether dissolve ·15008 gram $CaCl_2$.

Use of Solution of Calcium Chloride.—Saturated solution of this salt has the property of absorbing water and alcohol, while it does not, to any great extent, dissolve acetic ether.

In 'Year-Book of Pharmacy,' 1881, p. 68, M. Pabst is represented as affirming "pure ethyl acetate is insoluble in a solution of calcium chloride; but if it contains 30 per cent. alcohol, calcium chloride solution dissolves appreciable quantities. A mixture of 1 volume ethyl acetate and 1 volume alcohol forms a homogeneous mixture with 2 volumes of a solution of calcium chloride."

This statement I believe to be incorrect, and in support of this I adduce the following experiments made with an acetic ether 96·36 per cent.

Five c.c. acetic ether were placed in a burette and sol. $CaCl_2$ saturat. added to it in successive quantities of 10 c.c. When 40 c.c. in all were added the acetic ether measured only 4·15 c.c. showing a loss of ·85 c.c. We therefore find—

1 c.c. acetic ether (99·36 per cent.) soluble in 47 c.c. sol. calc. chlorid. sat. at 15° C.

and *very slightly more soluble at* 0° C.

The second part of the statement I find to be also incorrect, as will be seen from the following table, and this seems accounted for by the evident fact that M. Pabst, by his own process (which I previously discussed), had obtained and was using an impure acetic ether. I have already shown that acetic ether is slightly soluble in solution of chloride of calcium, and I have also determined the amount of absorption which takes place when acetic ether diluted with alcohol, water, or both together, is shaken with an equal volume of the saturated solution, and on this, at first sight, untrustworthy basis I have worked out a rapid process of examining acetic ether, which gives fairly approximate results.

Table showing the Action of Sol. Calc. Chlor. Sat. on Acetic Ether (99·36 *per cent.*) *at* 15° *C.*

A. Diluted in Absolute Alcohol.

Equal parts of Dilute Acetic Ether and Calcium Chloride solution.

Acetic ether (99·36 p.c.). Parts.	Alcohol. Parts.	Ether separated. Parts.	Error. Per cent.
100 . . .		97	– ·3
90·9 . . .	91·1	91·1	+ ·2
83·4 . . .	16·6	83·75	+ ·35
71·5 . . .	28·5	68·5	– ·3
62·5 . . .	37·5	52·8	– 9·7
55·6 . . .	44·4	38·9	– 16·7
50·0 . . .	50·0	26·7	– 23·3
45·5 . . .	54·5	16·1	– 29·4
41·7 . . .	58·3	7·5	– 34·2
38·5 . . .	61·5	None separated.	

B. Diluted with Alcohol and Water.

Acetic ether (99·36 p.c.). Parts.	Alcohol. Parts.	Water. Parts.	Ether separated. Parts.	Error. Per cent.
100			97	–3
90·9		9·1	87·2	–3·2
83·4	8·3	8·3	82·3	–1·1
76·9	15·4	7·7	77·6	+ ·7
66·8	26·6	6·6	66·5	– ·3
58·9	35·2	5·9	53·2	–5·7
47·7	38·0	14·3	41·8	–5·9
40·0	40·0	20·0	33·4	–6·6
37·2	37·0	25·8	32·4	–4·8

From these tables it will be seen that as long as the percentage of acetic ether ranges between 75 per cent. and 90 per cent., the amount of separable ether fairly agrees with that known to be present, but as the percentage becomes less and less the ether separated varies according as the diluting agent is alcohol alone or along with water. It would have been easy to construct a table which would apply to all mixtures of acetic ether and absolute alcohol, but as water is constantly present we must resort to a very simple device. In the first place, we must have some pure acetic ether as a standard, and having shaken up 10 c.c. of the sample under examination with 10 c.c. solution calcium chloride, note how much ether separates. If this amount be more than 75 per cent. the result may be taken as nearly correct, but if less, we must add pure acetic ether to the sample in such proportion as will ensure the final per cent. reaching 75 per cent. Thus, if only 30 per cent. separated we know from the tables that the sample must contain something between 30 and 55 per cent., and we therefore add to it twice its volume of pure acetic ether (the per cent. then being at least 76 per cent.) and taking 10 c.c. of the mixed sample again shake with 10 c.c of the chloride solution and note how much separates. If, say 8·0 c.c. separate, subtract 6·5 c.c. (the amount corresponding to the two volumes of pure ether added) and we have 1·5 c.c. as the ether from 3·33 c.c. of the sample = about 45 per cent. It is of course desirable to work with, say 20 c.c. or 30 c.c. when the sample is very impure; but it must be remembered that the results are not within 1 per cent. of the truth, and this method should not be resorted to when the method first described is applicable.

It may be said that in this discussion we have lost sight of the purification of the acetic ether from alcohol, but it will be noticed that in the solution of calcium chloride we have an excellent means of removing any alcohol present. If the percentage be but small, a single washing with an equal volume will practically effect separation, and we may now therefore consider—

2. *Removal of Water from Acetic Ether.—To what extent is Water Soluble in Acetic Ether?*—I do not find this question answered in references to this ether, and I have accordingly determined not only this point, but the converse, viz., the solubility of acetic ether in water. These two inquiries have

brought out a most instructive lesson, one which shows forcibly how easy it is to fall into error in deductions from a few experiments. When (about) 34 c.c. of acetic ether and 10 c.c. of water are shaken together in a stoppered burette (temperature 15° C.), on standing exactly 34 c.c. of acetic ether and 10 c.c. of water separate again, and shall we therefore say that the liquids are non-miscible? At first we might think so; but a little reflection will show that if they are not, they must be reciprocally soluble in the proportions we have alluded to, *i.e.*, that the ether must have dissolved exactly as much water as the water dissolved ether; and that this is the true explanation is evident from the appended tables.

Table shoowing the Addition of Water to Acetic Ether at 50° *F.*

	Water.	
10 c.c. acetic ether +	10 c.c. = 9	c.c. ether undissolved.
10 c.c. acetic ether +	20 c.c. = 8	c.c. ether undissolved.
10 c.c. acetic ether +	30 c.c. = 7	c.c. ether undissolved.
10 c.c. acetic ether +	50 c.c. = 4·7	c.c. ether undissolved.
10 c.c. acetic ether +	70 c.c. = 2·2	c.c. ether undissolved.
10 c c. acetic ether +	80 c.c. = 1	c.c. ether undissolved.

On cooling now to 0° C., the whole of the ether dissolved after standing, while on heating to 15° C., 1·8 c.c. separated again. From these and duplicate experiments, I find—

Solubility of acetic ether in water = 1 c.c. in 8 c.c. at 0° C.
Solubility of acetic ether in water = 1 c.c. in 9 c.c. at 15° C.

Table showing Addition of Acetic Ether to Water at 15° *C.*

		Water.
10 c.c. water +	50 c.c. acetic ether =	7·5 c.c. undissolved.
10 c.c. water +	100 c.c. acetic ether =	5·5 c.c. undissolved.
10 c.c. water +	150 c.c. acetic ether =	3·5 c.c. undissolved.
10 c.c. water +	200 c.c. acetic ether =	1·5 c.c. undissolved.
10 c.c. water +	250 c.c. acetic ether =	all dissolved.

When cooled to 0° C., about ·05° c.c. separated again.

Solubility of water in acetic ether = about 1 c.c. in 26 c.c. at 0° C.

Solubility of water in acetic ether = about 1 c.c. in 24 c.c. at 15° C.

We have thus the following curious results:—

Calcium chloride more soluble in acetic ether at 0° C. than 15° C.
Water less soluble in acetic ether at 0° C. than 15° C.
Acetic ether more soluble in sol. calc. chlorid. at 0° C. than 15° C.
Acetic ether more soluble in water at 0° C. than 15° C.

Dried potassium carbonate is usually employed to dry the acetic ether, and Berthelot has recommended that it should be finally distilled off this salt; but I have found this to decompose the ether. In preparing a pure sample for examination I distilled it, after digestion, with potassium carbonate and found—

Before distillation 93·48 per cent. $C_2H_5C_2H_3O_2$.
After distillation 90·14 per cent. $C_2H_5C_2H_3O_2$.

I therefore again heated the 90·14 per cent. lot with potassium carbonate in a water-bath for one hour. A green colour was developed along with a disagreeable odour, and on distillation the product only contained 86·22 per cent. $C_2H_5C_2H_3O_2$. Digestion with the carbonate, however, does not decompose acetic ether, and in the course of a few days it will be found practically dehydrated.

I have also made use of dried sodium acetate, which on the large scale is undoubtedly the best to use, since distillation over this has no decomposing effect, and after drying, the acetate may be again used in preparing acetic ether.

We are now in a position to decide on a process to be adopted, and I would therefore propose that in the next Pharmacopœia the following or a modification of it should be adopted:—

Rectified spirit . . .	283 c.c. = 10 oz.
Sulphuric acid . . .	283 c.c. = 10 oz. fluid.
Dried sodium acetate .	351 grams = 12⅜ oz.

Place the alcohol in a copper or glass flask, and into it pour the sulphuric acid, adopting means to keep it cool. Allow to stand, and when the temperature has fallen to about 60° F., gradually add the sodium acetate with constant agitation, to insure thorough mixture, keeping the flask as cool as possible, and connecting it with an inverted condenser to avoid loss. When all has been added, connect with a condenser, and distil the contents by means of a naked flame or sand-bath till 400 c.c. (about 14 fl. oz.) have passed. Digest the distillate for three days with 2 ounces of freshly dried potassium carbonate. Filter and distil the filtrate by the aid of a water-bath, stopping the distillation before the last ounce has passed over.

I have already discussed the process of manufacture so fully that I need hardly say more with reference to the one just detailed; but a few points merit attention. By the excess of sulphuric acid ordered, the absence of alcohol in the distillate is secured, while the action of this excess on the newly formed acetic ether is minimized by the directions to secure thorough mixture before applying heat. Alcohol being absent in the distillate it is only necessary to neutralize and free the ether of water. I recommend for this purpose the potassium carbonate, as most convenient on the small scale, but the sodium acetate is equally efficient.

As an example of the operation of this process I give the following details:—

Using the quantities above mentioned I distilled off—

375 c.c., sp. gr. ·912, containing 94·06 per cent. acetic ether.
30 c.c., sp. gr. ·912, containing 81·42 per cent. acetic ether.

The 375 c.c. contained	316·8	grams or	352·7	c.c. acetic ether
30 c.c. „	21·9	„	24·4	„
	338·7		377·1	„

After washing with water, and digestion with potassium carbonate, the sp. gr. was found slowly to diminish—

After eighteen hours	·904
After thirty hours	·9023

when it contained 99·36 per cent. real acetic ether.

I must here enter a protest against some of the characters of acetic ether given in the B.P., and also in the new United States Pharmacopœia.

The solubility in water is given as—

B.P.	1 in 12 parts (vol. or weight?)
New U.S.P. . . .	1 in 17 parts by weight.
While I find it to be	1 in 9 parts by vol.

Again, as regards specific gravity, I have already pointed out the great diversity among observers as to the real sp. gr. of pure acetic ether; and this, no doubt, arises from the impurity of the article examined; but looking to the latest authorities only we find—

B.P., corrected addendum	·900.
U.S.P. (1883)	·889 to ·897.
Mendelejef and Allen	·898.

After much work on the subject I am convinced that in all these cases the acetic ether contained alcohol or some other light liquid, and the following are my grounds. I took two samples of acetic ether, one known to contain alcohol (A), the other known to contain water (B). I distilled A, dividing the distillate into fractions, and by analysis having selected the purest of these, sp. gr. about 890, I twice shook up with an equal volume of calcium chloride solution, digested with excess of potassium carbonate, filtered, distilled, rejected the first portions and selected the middle portion. On analysis it showed 95·04 per cent. ethyl acetate. After prolonged digestion with pot. carb. sic., and afterwards with cupri sulph. sic. for ten days, it was sp. gr. 9004 and contained 98·76 per cent. ethyl acetate. I now washed it with water to remove any trace of alcohol still remaining. The watery acetic ether was now sp. gr. ·909 at 60° F., I divided it into two portions (1 and 2), and set aside—

1. 100 c.c. + 20 grams . . . Sod. acet. fused.
2. 100 c.c. + 20 „ . . . Pot. carb. sic.

and noted the lowering of the sp. gr.—

	In 48 hours.	In 72 hours.
1.	·90191	·9014.
2.	·90205	·9018.

I then mixed them (170 c.c. in all) distilled off 40 c.c., which I rejected, and retained the next 75 c.c., sp. gr. 9015 and containing about 99·4 per cent. ethyl acetate.

On the other hand, I took sample B containing water, but no alcohol, and digested it for some weeks with pot. carb. and cupri sulph. sic. and finally distilled, selecting fractions by analysis as before, and obtained—

Sp. gr. ·902	= 99·36 per cent.
Sp. gr. ·9015	= 99·58 „
Sp. gr. ·9012	= 99·70 „

To sum up: we see that it is exceedingly difficult to obtain anhydrous acetic ether, the last traces of water obstinately adhering, and we can have no doubt as to the accuracy of the determination (oxalic acid from methyl oxalate having been used in the preparation of the standard solution). In the absence then, of an absolutely pure sample we may reason as follows. Sample A after purification, but before treatment with water, was—

Sp. gr. ·9004 and 98·76 per cent. ethyl acetate
B = sp. gr. ·9012 and 99·7 per cent. ethyl acetate,

and as A originally contained alcohol, while B contained water, it would seem most likely that the sp. gr. of the former would be too low while that of the latter would be too high. But by purifying A so as to remove the alcohol the sp. gr. was raised to

Sp. gr. ·9015 and it then contained about 99·4 per cent.

so that on all grounds the sp. gr. must be higher than ·9004 and lower than ·9012.

It is of course not to be expected that such purity will be met with, but I see no reason why 95 per cent. or even higher should not be insisted on in the Pharmacopœia.

In closing this discussion, I am aware that some, perhaps many, of my deductions may hereafter be proved to be incorrect, and it is in order that subsequent experimenters may know the grounds on which these were based that I have troubled you with such complexity and detail.

Postscript.—Since writing the foregoing it has been suggested to me that the *parts* in the B.P. formula may be intended to be taken by weight. When working on the subject the question as to what was meant came up, there being an undesirable ambiguity in the wording of the process. Opinions of those consulted agreed in giving the solids by weight, liquids by measure. This view was also confirmed by the statement in the text that "1 part dissolves in 11 or 12 parts of water at 60°," which was understood by all to mean parts by volume. On consulting Squire on the subject, I found "solids by weight, liquids by measure," at the top of the page, showing that according to English usage the sulphuric acid and alcohol were understood generally to be parts by measure. On this ground I examined the process, and founded the objections above detailed, the more serious of which, as will be seen, lie, not so much in the formula, as in the method of purification. If we, however, calculate out the proportions as represented by weight as well as by measure, it seems probable that all the parts are intended to be taken by weight, and that if this be so, the proportions in themselves are satisfactory enough. The following figures indicate this:—

1st. *Liquids and Solid by Weight.*

500 grams s. v. rect. . . = 420 grams absolute alcohol.
1000 grams sulphuric acid = 960 grams H_2SO_4.
800 grams sod. acetate.

But 420 grams alcohol require 895 grams sulphuric acid and 748 grams dried sodium acetate, showing in this case a slight excess of these bodies.

2nd. *Liquids by Measure, Solid by Weight.*

500 c.c. or 419 grams s. v. rect. . = 352 grams C_2H_6O.
1000 c.c. or 1843 grams sulphuric acid . . . . = 1769 grams H_2SO_4.
800 grams acetate of soda,
But 352 grams C_2H_6O require 750 grams H_2SO_4.
352 grams C_2H_6O require 627 grams $NaC_2H_3O_2$.

So that in this case the proportions are very much further, than in the former case, from the theoretical. It is to be regretted, therefore, that if the former be the correct reading, the wording is not so framed as to avoid all doubt, and I would suggest that in that case the solubility should be expressed in similar terms.

LITHIÆ CITRAS.*

BY C. THOMPSON.

It is very difficult to say when this salt was first used in medicine. Dr. Ure, in 1843, introduced the carbonate as a specific for gout, pointing out the remarkable solvent power of lithia over uric acid compared with the other alkalies, hence its great use in cases of gout. The urate of sodium with which gouty patients all seem charged, is converted into the more soluble lithia salt, and so washed out of the system.

In 1857, Drs. Garrod and Ringer mention using strong lotions of lithia salts to disperse gouty swellings. Lithium citrate was not officially recognized until 1864, when it appeared in the new British Pharmacopœia of that date. It appeared in the United States Pharmacopœia of 1870, also in the revised edition lately published, and these are the only two Pharmacopœias in which it is recognized.

* Read before the Chemists' Assistants' Association, February 21, 1883.

The German Pharmacopœias of 1872 and 1882 have the carbonate, but not the citrate, and the same is the case with the French Codex.

The instructions for making this salt are different in each Pharmacopœia.

In the British of 1864, the directions are—

Take:—

Carbonate of lithia	50 grs.
Citric acid in crystals	90 grs.
Warm distilled water	1 fl. oz.

Dissolve the citric acid in the water and add the carbonate in successive portions, applying heat until effervescence ceases, and a perfect solution is obtained. Evaporate by a steam or sand bath until water ceases to escape, and the residue is converted into a viscid liquid. This should then be dried in an air oven at about 240° F., then rapidly pulverized, and enclosed in a stoppered bottle. The process in the British Pharmacopœia for 1867 is exactly the same.

In the United States Pharmacopœia for 1870, we find:—

Take of—

Lithium carbonate	100 grs.
Citric acids in crystals	200 grs.
Distilled water	2 fl. ozs.

Dissolve the citric acid in the water, gently heated, and to the solution gradually add the carbonate until perfectly dissolved, heating the mixture, so long as effervescence is produced. Evaporate by means of a steam or sand bath to a viscid consistence, dry the residue in an oven, at a temperature of about 240° F., then rapidly pulverize, and preserve in a stoppered bottle.

In the revised Pharmacopœia of the United States, lately issued, no process is in accordance with the decision to omit processes except where necessary to ensure a particular result.

Neither the proportions of the British Pharmacopœia nor that of the United States Pharmacopœia are correct, for the former having an excess of carbonate gives an alkaline product, whereas the latter, having an excess of citric acid gives an acid product.

As Mr. Umney pointed out in a paper read at the Pharmaceutical Conference of 1875, if the formula—

$$3Li_2CO_3 + 2(H_3C_6H_5O_7,H_2O) = 2Li_3C_6H_5O_7 + 5H_2O + 3CO_2$$

be accepted as correct, then 100 parts of carbonate of lithium will be required to neutralize 189·2 parts of citric acid, the product of anhydrous lithium citrate being identical with the amount of citric acid originally employed in the operation. But as the best commercial carbonate of lithium does not contain more than 98·5 per cent. of real carbonate, the proportion will be 100 parts of carbonate to 186·5 parts of citric acid.*

Lithium citrate, according to Mr. Umney, when prepared from these proportions and dried until anhydrous, is neutral to test paper.

According to the 1864 Pharmacopœia, lithium citrate is a white, amorphous powder, *deliquescent*, and soluble in water without leaving any residue. Heated to redness it blackens, evolving inflammable gases, and the residue, neutralized by hydrochloric acid, yields with rectified spirit a solution which burns with a crimson flame. Twenty grains of the salt burned at a low red heat, with free access of air, leave 10·6 grains of white residue.

The U.S.P. of 1870 gives the following characters and tests by which this salt may be recognized:—

"A white powder, *deliquescent* and soluble in 25 parts of water; upon ignition it leaves a residue which if dissolved in dilute muriatic acid gives a solution, which burns with a crimson flame, showing the presence of lithium. The citric acid is indicated by the solution becoming turbid when heated with lime-water and clear again on cooling. Twenty grs. of this salt burned at a low red heat, with free access of air, should leave $10\frac{6}{10}$ grs. of white residue. The revised edition, before alluded to, gives a much fuller account of the characters and tests.

"A white powder, *deliquescent* on exposure to air, odourless, having a slight cooling, faintly alkaline taste, and of a neutral reaction, soluble in 5·5 parts of water at 15° C. and in 2·5 parts boiling water; only slightly soluble in alcohol. When exposed to a red heat, the salt chars, emits inflammable vapours, and finally leaves a black residue having an alkaline reaction, which imparts a crimson colour to a non-luminous flame. The aqueous solution of the salt mixed with test solution of calcium chloride deposits a white precipitate on boiling. On dissolving the residue left on ignition in diluted hydrochloric acid, and evaporating the filtered residue to dryness, 1 part of the residue should be completely soluble in 3 parts of absolute alcohol, which when ignited, should burn with a crimson flame, and the addition of an equal volume of stronger ether to the alcoholic solution should produce no precipitate (salts of alkalies absent). On dissolving another portion of the residue in a small quantity of water, the solution should produce no precipitate with the test solution of ammonium oxalate (salts of alkaline earths). The aqueous solution should remain unaffected by sulphuretted hydrogen or ammonium sulphide (absence of metals)."

Lithium citrate, as Squire remarks, is not deliquescent. It appears in commerce either as a crystalline or pulverulent substance. When crystalline its composition is exceedingly uniform; when in powder its composition is rather apt to vary, and does not resemble the citrate of lithium of the B. P., which is anhydrous; whereas Mr. Umney found, in an examination of some ten different samples, in no case more than 84 per cent., while most were about 74 per cent. of anhydrous salt.

Mr. Umney dried the specimens examined first at 100° C., and then finished at 115° C., or so as to produce the official article; the difference between the two dryings is about* 5 per cent., corresponding to about 1 molecule of water, so that, if the formula $Li_3C_6H_5O_7.4H_2O$ be accepted, then the salt dried at 100° will lose three of these four molecules of water. This was the composition of some crystals of pure lithium citrate, made by Mr. Sandford and presented to Mr. Umney, which contained about 73 per cent. anhydrous citrate.

Out of four samples examined by me, one contained 86 per cent., another 83·5 per cent., and the other two 75·2 per cent. of anhydrous citrate of lithium.

But not only does the commercial article contain water of crystallization, but other substances, distinct impurities,† the most common of which are calcium, magnesium, potassium and sodium, and sometimes traces of the heavier metals. Occasionally the citrate is found adulterated with powdered petalite, bitartrate of potassium, etc. Before proceeding to discuss the methods of detecting and estimating these impurities it will be as well to see how they get into the citrate.

There are two sources:—

1st. The carbonate of lithium.

2nd. The citric acid.

The chief impurities in the carbonate are calcium, potassium and sodium chlorides.

The citric acid may contain tartaric acid, salts of potassium and calcium, together with iron, lead and copper.‡

The mineral lepidolite, a silicate of aluminium, potassium and lithium.

Petalite, a silicate of aluminium, sodium and lithium.

* In some formulæ for new medicaments adopted by the Paris Pharmaceutical Society, it is recommended to use 100 parts carbonate of lithium to 186 parts citric acid (*Pharm. Journ.*, July 21, 1877).

* Since writing the above, Mr. Umney has found that this varies considerably.

† Mr. W. L. Scott, out of twenty-seven samples of lithium salts, found sixteen pure, six fair, and five adulterated with Na_2CO_3, $KHC_4H_4O_6$, powdered petalite, etc., etc. ('Year-Book of Pharmacy,' 1870, p. 452).

‡ A. H. Allen, *Chem. News*, xxxi., 277.

Triphyline, a phosphate of iron, manganese, sodium and lithium, and

Spodumene, another silicate of aluminium, sodium and lithium, are the principal sources whence the lithium carbonate of commerce is derived.

A description of two of the processes by which the carbonate of lithium is prepared from lepidolite, etc., may be interesting, as showing how the impurities before alluded to come to be present in the carbonate.

1. Schering's process for obtaining lithium carbonate from lepidolite, which is the greatest source of the lithium.—The lepidolite is ground up, treated with strong sulphuric acid. It is heated with constant stirring until it gains consistency enough to be made into balls, which are then introduced into a reverberatory furnace. The slight excess of sulphuric acid is driven off at a gentle heat, the temperature is then raised, and the pieces, while still hot, are treated with water in vessels lined with lead. Silica is then removed by filtration, and to the lye sufficient carbonate of potassium is added to convert all the alumina present into alum, as lithium does not replace potassium in alum. The alum meal separating on boiling is removed, and the small remaining quantity of alum is precipitated by milk of lime; all the lyes are united, the salts converted into chlorides by treatment with barium chloride, the liquid is evaporated to dryness, and the lithium and calcium chlorides are extracted with absolute alcohol in order to separate them from the barium, sodium and potassium chlorides present. The calcium is separated by ammonium oxalate. Any heavy metals which may happen to be present are got rid of by ammonium sulphide. The lithium chloride is evaporated to dryness in a large silver vessel, treated with ammonia and ammonia carbonate and the resulting lithium carbonate washed to free it from chlorides.

2. Frost's method, for obtaining lithium carbonate from lepidolite.—Fuse together lepidolite, well powdered, 10 parts; barium carbonate, 10 parts; barium sulphate, 5 parts; potassium sulphate, 3 parts. The heavy silicate and sulphate of barium sink to the bottom, whilst a layer of sulphates of potassium and lithium floats on the surface of the fused mass. These are then extracted by lixiviation, and the sulphates are converted into chlorides by precipitation with chloride of barium. The liquid is evaporated to dryness and the potassium and lithium chlorides are separated by treatment with a mixture of absolute alcohol and ether, which dissolves the lithium and leaves the potassium. Ammonia and ammonium carbonate are then added and the carbonate of lithium is collected and well washed. It will be seen that the impurities, *i.e.*, the calcium, potassium and sodium chlorides, are very difficult to separate entirely from the lithium, owing to the partial solubility of potassium and sodium chloride in alcohol.

Both the B.P. and the U.S.P. recommend, as a means for the quantitative estimation of the citrate, incineration, at a red heat, and weighing the residue as carbonate, when 53 per cent. (52·8 per cent.) should be obtained.

This method is useless as a means of estimation of the amount of lithium present, for the carbon cannot be entirely got rid of without very prolonged heating, by which means the carbonate becomes caustic; the resulting greyish-white mass is very deliquescent, thus introducing another source of error.

An improvement on this method is given in the 'U.S. Dispensatory,' where it is directed to incinerate and treat the mass with sulphuric acid, and weigh the resulting sulphate of lithium.

100 grains citrate should yield 22·3 grains of sulphate.

In making an analysis of lithium citrate, the probable impurities and adulterations to look for are powdered petalite or lepidolite, salts of calcium, potassium and sodium.

First as regards powdered petalite or lepidolite. Take a weighed quantity (1 to 2 grams.), and treat with boiling water; if any of the powder remains insoluble, this must be collected, washed, incinerated and weighed. For calcium:—Take about 5 grams, dissolve in water, add ammonium oxalate, collect, wash, incinerate and weigh as $CaCO_3$.

The real difficulty is when it comes to the estimation of the potassium, sodium and of the lithium present in the samples. There are four processes for this, all starting with the salts as chlorides; therefore, a weighed quantity of the citrate is to be taken, incinerated in a platinum crucible, and the greyish-white mass dissolved up in as small a quantity as possible of dilute hydrochloric acid, and then having the salts present as chlorides, either one of the following four processes may be proceeded with.

1. Kobell separates the potassium by precipitation as platino-potassium chloride, and separates the sodium and lithium by heating the mixed chlorides to incipient fusion in a platinum crucible (care must be taken not to raise the temperature too high, or else some of the sodium chloride will be volatilized), then weighs the residue; he leaves it exposed for twenty-four hours to an atmosphere not moist enough to attack the sodium chloride, till the lithium chloride, which is very deliquescent, has absorbed water, drenches the partly deliquesced mass with alcohol, decants carefully, repeats the washing and decantation a second time and weighs the residual sodium chloride.

According to the author this process gives exact results.

2. Mayer's process, as given by Fresenius. Add to the solution (of the chlorides before mentioned) a sufficient quantity of sodium phosphate (which must be perfectly free from phosphates of the alkaline earths—this is very important), and enough soda, either carbonate or hydrate, to keep the solution alkaline; evaporate the mixture to dryness, pour water over the residue, in a sufficient quantity to dissolve the soluble salts by the aid of a gentle heat. Add an equal volume of a solution of ammonia, digest at a gentle heat, filter after standing for twelve hours, and wash the precipitate with a mixture of equal volumes water and ammonia. Evaporate filtrate and first and second washing to dryness, and treat the residue the same way as before. If any phosphate is obtained add it to that previously obtained. The phosphate is then dried and weighed.

The formula of the phosphate is Li_3PO_4 Rammelsberg asserted that a variable quantity of lithium sodium phosphate was formed. Fresenius, however, confirmed Mayer's work, and showed that no double phosphate was formed.

According to Mayer this process gives 99·61 for every 100 of lithium, and Fresenius obtained 99·8 per cent. The phosphate is not a very soluble body, 1 part dissolving in 2539 parts of pure, and 3920 parts of ammoniated water. This is the best and surest method of estimating the lithium.

Another process is to separate the potassium as platino-potassium chloride, then shake the mixed chlorides of sodium and lithium, dried at 120° C., with a mixture of ether and absolute alcohol for twenty-four hours, until the salts are disintegrated, decant on to filter, and treat the residue again with several smaller portions of alcohol and ether. It is best, in order to be as accurate as possible, to distil off the alcohol and ether, and again treat the impure lithium salt with alcohol and ether, a drop of hydrochloric acid being added. This method is not a very reliable one, however.

Bunsen, seeing the difficulty of separating the lithium and sodium by the alcohol treatment, devised an indirect method of determining the potassium, sodium and lithium.*

The solution of the chlorides of potassium, sodium and lithium is treated with nitrate of silver and the total

* Watts's 'Dictionary,' vol. iii.

amount of chlorine present determined; the filtrate is freed from excess of silver nitrate by hydrochloric acid, and the potassium contained in the filtrate determined by platinic chloride. The potassium thus determined, gives, when subtracted from the total chlorides, a remainder:—

$$A = x(LiCl) + y(NaCl)$$

and the quantity of silver chloride equivalent to a known weight of potassium chloride gives, when subtracted from the total weight of silver chloride, a weight B., whence quantity of lithium chloride is calculated by the formula:—

$$x = 1{\cdot}0823\ B - 2{\cdot}6525\ A.$$

As the citrate of lithium in crystals has been shown to be a non-deliquescent body, and all manufacturers now acknowledge that they can make it, although when the Pharmacopœia of 1867 was brought out they were dead against the crystalline article, it is to be hoped that in the Pharmacopœia of the future there will be found the crystalline body as the official citrate.

If this be the case, there will not be much fear of so great a dissimilarity between the commercial article and the official article.

I cannot close my paper better than by giving Mr. Umney's opinion on the crystalline body*:—

"The crystals are quite definite and reliable, and if indeed it were thought necessary to have a citrate containing less water, then let it be dried at 100°, which will be quite enough.

"I suppose the reason why the 1864 Pharmacopœia orders the anhydrous citrate, was to lessen the objections to the salt on account of its supposed deliquescence."

COSMETIC PREPARATIONS.†

Rose-Bandoline.—Digest 800 grains of tragacanth with 1 quart of rose-water for two days at a gentle heat in a closed vessel. Strain the mixture, and perfume it with oil of rose.

Or, macerate 1 part of quince seed with 40 parts of rose-water for several hours, repeatedly agitating; strain the mixture, and perfume it with oil of rose.

Almond-Bandoline.—Prepared like the preceding, except that oil of bitter almonds is used for scenting.

If either of the above are wanted coloured, an ammoniacal solution of carmine may be used.

Brilliantine.—Mix 1 part of glycerin with 3 parts of castor oil and 60 parts of alcohol.

Perfume according to taste.

Crême de Mauve.—Mix 1 part of glycerin with 1 part of alcoholic extract of jasmin, and colour with a little fuchsine.

Used to impart gloss to the hair.

Oleolisse Tonique (de Piver).—Dissolve 5 parts of castor oil in 15 parts of alcohol, and flavour with oil of bergamot or oil of Portugal.

Hungarian Cosmetic.—Melt 30 parts of white wax on a water-bath, and add 20 parts of powdered almond soap, and 20 parts of a solution of 1 part of gum arabic in 60 parts of rose-water. Stir the mixture until it cools, and perfume it with 1 part of oil of bergamot, or $\frac{1}{5}$ part of oil of rose.

By adding umber or lamp-black, the mass may be coloured brown or black.

Bay Rum (artificial):—

Tincture of bay leaves (1 of bay leaves, 10 of alcohol.)	6 ozs.
Oil of bay	60 grains.
Borax	1 oz.
Carbonate of ammonium	1 oz.
Rose-water	1 quart.

* 'Year-Book of Pharmacy,' 1875, page 559.
† From *New Remedies*, February, 1883.

Extrait Végétal:—

Essence of vanilla (1 of vanilla, 30 of alcohol.)	2 parts.
Extract of orange flowers	1 part.
„ jasmine	1 „
„ rose	1 „
„ tuberose	1 „
Alcohol	16 parts.
Rose-water	20 „

Amandine (for softening and beautifying the skin).—Make a syrup from 1 part of sugar and $\frac{1}{2}$ part of water. Mix 8 parts of the syrup with 2 parts of almond soap cream, until a homogeneous mass is obtained, to which is to be added, under constant stirring, 200 parts of almond oil, previously perfumed with 2 parts of oil of bitter almonds, 2 parts of oil of bergamot and 1 part of oil of cloves.

The mixture of the almond oil with the syrupy mass requires some practice and, particularly towards the end, when the mass becomes stiffer, a considerable expenditure of force.

Almond Soap Cream is prepared by melting 250 parts of pure lard and mixing with the melted fat 100 parts of solution containing 25 per cent. of caustic potash. The latter must be added very slowly, and under constant stirring. When all is added it is gradually allowed to cool, the stirring being continued. It is then transferred to a mortar, and triturated with addition of 6 parts of alcohol and $\frac{1}{2}$ part of oil of bitter almonds, until it is creamy and homogeneous.

Olivine.—4 parts of powdered gum arabic and 12 parts of honey are intimately mixed, and the mixture triturated with 6 parts of Castile soap and with two yolks of egg for every ounce of gum arabic used. To this is gradually added, under continued trituration, a previously prepared mixture of 60 parts of finest olive oil, 2 parts of oil of sesame, 2 parts of oil of bergamot, 2 parts of oil of lemon, 1 of oil of cloves, $\frac{1}{5}$ of oil of thyme and $\frac{1}{5}$ of oil of cinnamon, and the whole thoroughly triturated until a homogeneous mass results.

Almond Paste.—16 parts of blanched bitter almonds are rubbed to a fine paste, and this is gradually added to an intimate mixture of 30 parts of honey, 15 parts of yolk of egg, 30 parts of almond oil, $\frac{1}{2}$ part of oil of bergamot and $\frac{1}{2}$ part of oil of cloves.

Rose Milk (Lait de Rose).—1 part of finely rasped Castile soap is dissolved, with a very gentle heat, in 4 parts of rose-water; 1 part of white wax and 1 part of spermaceti are next added and, when they are melted, a strained almond mixture is added, prepared from 16 parts of blanched sweet almonds and 1000 parts of water. The addition must be made gradually and under continuous stirring. Finally, 150 parts of alcohol and 8 parts of oil of rose are thoroughly incorporated with the mixture.

Frangipanni Sachet Powder.

Orris root, powdered	1500 parts.
Vetiver, powdered	120 „
Sandal wood, powdered	120 „
Oil of neroli	2 „
„ rose	2 „
„ sandal wood	2 „
Musk bag, powdered	20 „
Civet	5 „

Heliotrope Sachet Powder.

Orris root, powdered	1000 parts.
Rose leaves, powdered	500 „
Tonka bean, powdered	250 „
Vanilla, powdered	120 „
Musk	4 „
Oil of bitter almond	3 „

The Pharmaceutical Journal.

THE DRAFT PHARMACY BILL.

IN the discussion of the Pharmacy Act Amendment Bill by several correspondents and at the various meetings which have been held throughout the country, it appears that there is a tendency to dwell upon the desirability of having the articles proposed to be sold with the label "poisonous" added to the second part of the existing schedule of poisons, rather than dealt with as is proposed in the Bill. Those who advocate this course seem, however, to overlook the circumstance that a special recommendation to that effect has already been made by the Council of the Pharmaceutical Society and that the Privy Council has distinctly refused to sanction such a step. To repeat such a recommendation would, therefore, be futile in itself and calculated, moreover, to injure the prospect of obtaining an amendment of the Act in other respects, since the Government is not inclined to look with favour upon any measure which comprises interference with general trade.

In regard to the particular article which Mr. LEAROYD referred to at the Sheffield meeting, as belonging more properly to the schedule of poisons, we have reason for stating that it was precisely the one which the advisers of the Privy Council most strongly objected to interfering with. It is true that numerous accidents have happened with carbolic acid, in consequence of its misuse or from carelessness, and this has been the case even in hospitals. But with all due regard for the desirability of preventing such accidents as far as possible, it must also be remembered that carbolic acid is an article of great utility as a disinfectant and in constant demand for some purpose connected with sanitation. It is for this reason considered to be unwise to place restrictions upon the supply of this article which would make the procuring of it in some cases difficult or impossible.

Though we have already explained the circumstances which led to the introduction of the second clause of the Bill, and have pointed out that from the view taken by the Privy Council it is an essential feature of the Bill, it is evident that this aspect of the matter has not met with that attention which it demands; for, if that were the case, we should not hear so much of resolutions to expunge this clause from the Bill. As it is probable that members of local associations may exert themselves by communication on the subject with their parliamentary representatives, it seems very necessary to point out the danger that might be incurred if they were solicited to use their influence in a direction at variance with the views of the Government, and also if they were called upon to use that influence in such a way as to show that there was a serious want of agreement among the members of the class seeking amendment of the law.

Another point, in regard to which some difference of opinion exists, is the provision that the seller of a patent medicine insufficiently labelled is to be liable to a penalty, and it has been urged that the manufacturer should more justly be sued in the first instance. Whatever plausibility there may be in this view at first sight, it will we think be found to disappear very completely on further consideration, and especially if it be attempted to formulate the means by which the manufacturer is to be reached. Moreover, some regard must be had to the fact that the chemist is not to be looked upon as selling, like the grocer or oilman, articles of whose nature he does not pretend to have any knowledge. Just as the propriety of limiting to the chemist the sale of patent medicines containing poison can be advocated on the ground that he possesses higher qualifications than the general dealer, so can the duty of carefulness in regard to the sale of such articles be expected from him no less for his own protection than for the public safety. It would be within his power to insist upon a proper observance of the law, and as he would be the only legitimate vendor of such articles there would be little difficulty in securing the observance of it by the manufacturers whose goods he sold. We are glad to observe that these considerations met with recognition at the meetings held at Sheffield and Leeds and that the general result in both cases was approval of the Bill as a useful and desirable means of satisfying public demands and promoting the advancement of pharmacy.

ELECTRICAL TRANSMISSION AND STORAGE OF POWER.

ANOTHER of the very interesting series of lectures on the applications of electricity, now in course of delivery at the Institute of Civil Engineers, was given on the 15th inst., by Dr. C. W. SIEMENS, who took for his subject the "Electrical Transmission and Storage of Power." Referring to the previous lectures, wherein electricity had appeared as a swift and subtle agency by which signals produced by mechanical means or the voice are flashed almost instantaneously to great distances, Dr. SIEMENS said he now introduced electric energy under another aspect, in which it proved capable of rivalling the steam engine in the accomplishment of actual work. After tracing the steps by which the present methods of converting mechanical power into electric energy have been developed, Dr. Siemens proceeded to describe the conditions upon which the working of a well-conceived dynamo machine must depend, and demonstrated that when losses through unnecessary wire resistance, Foucault currents, and induced currents in the rotating armature, are avoided, at least 90 per cent. of the power communicated to the machine could be realized in the form of electric energy, and that this electric energy could be reconverted into mechanical energy with a similarly small loss. By means of two such machines, therefore, at a moderate distance apart, nearly 80 per cent. of the power imparted to the one machine could be again yielded by the other in the mechanical form. Practically the best condition of working consists in giving to the primary machine such conditions as to produce a current of the same magnitude, but of 50 per cent. greater electromotive force than the secondary, and with such an arrangement as much as 50 per cent. of the power imparted to the primary machine can be practically received from the secondary one at a distance of several miles.

But besides the means for converting mechanical power into electric energy, and reconverting it after transmission, the medium for conducting it from one place to another with the least amount of loss has been the subject of much patient investigation. Six years ago Dr. Siemens expressed an opinion that a copper rod six inches in diameter would be found capable of transmitting through a distance of thirty miles 1000 horse-power, or an amount sufficient to supply one quarter of a million candle-power, which would suffice to light a moderately-sized town. This suggestion was much criticized at the time, but it bears the test of recent results; for M. Marcel Deprez has lately succeeded in transmitting 3 horse-power a distance of twenty-five miles through a pair of ordinary telegraph wires, 4 mm. in diameter, and calculating from the relative conductivity of this iron wire and the 6-inch copper wire proposed by Dr. Siemens, the amount of power that could be transmitted through the latter would be 4000 horse-power. Moreover, M. Deprez employed a motor-dynamo of 2000 volts, and was contented with a yield of 32 per cent. of the power imparted to the primary machine, whilst Dr. Siemens had calculated upon an electromotive force of only 500 volts, with a return of at least 40 per cent. of the energy imparted. By 1878 Dr. Siemens had conceived the possibility of employing a current of at least 1000 volts, and then expressed an opinion that a 2-inch copper rod could be made to accomplish the object intended, whilst Sir William Thomson, enlarging on this idea, soon afterwards told the Parliamentary Committee on Electric Lighting that through a copper wire of only ½-inch diameter, 21,000 horse-power might be conveyed to a distance of three hundred miles with a current of an intensity of 80,000 volts. But Dr. Siemens is of opinion that although the time may come when such a current, having a striking distance of about two feet in air, can be dealt with, a fundamental law as to the economical transmission of electricity will probably then be violated, and he is on the whole inclined to abide by his original choice of a 3-inch copper wire.

The application of the electrical transmission of power to railways is perhaps the form in which it has created most public interest. This was first accomplished by Dr. Werner Siemens in 1879, in connection with the Berlin Exhibition, and led to the opening of the Lichterfelde line, 2500 yards in length, which has been in daily operation since May, 1881, and is worked by two dynamos, developing an aggregate of 9000 Watts, or equal to 12 horse-power. In 1881, too, Dr. C. W. Siemens established a short line, in connection with the Electric Exhibition in Paris, on which 95,000 passengers were carried within seven weeks. An electric tramway, six miles in length, has just been opened in the north of Ireland, connecting Portrush with Bush Mills. This is at present worked by power produced by a steam engine at Portrush, giving motion to a shunt-wound dynamo of 15,000 Watts (=12 horse-power); but turbines are in course of erection at Bush Mills for the utilization of a waterfall of sufficient power. In the opinion of the lecturer, the electric system of propulsion is already sufficiently advanced to assure practical success under suitable circumstances, as, for instance, suburban tramways, elevated lines, and especially lines through tunnels, such as the Metropolitan and District Railways, the advantages being the saving of the weight of the engine and perfect freedom from products of combustion. For tramways within populous districts the insulated conductor would involve a serious difficulty, and for these it would be more advantageous to resort to secondary batteries carried in the car itself.

The subject of secondary batteries was treated much less fully by the lecturer, who, however, pointed out that it is only since the dynamo machine has become an accomplished fact that this mode of storing energy has become of practical importance, and he gave great credit to Messrs. Faure, Sellon and Volckman for putting this valuable addition to practical science into available forms. Fears have been expressed that the permanence of secondary batteries will be affected by their active surfaces becoming coated with sulphate of lead; but the investigations of Mesrs. Frankland, Gladstone and Tribe have shown that the action of the secondary battery depends essentially upon the alternate formation and decomposition of sulphate of lead, and that, therefore, this compound is not an enemy, but the best friend to its continued action.

THE ANNUAL DINNER.

THE meeting referred to last week was held at the Society's house, on Wednesday, when a considerable number of gentlemen having expressed their willingness to become Stewards, it was resolved that the Twelfth Annual Dinner of the Members of the Pharmaceutical Society and their friends shall be held at WILLIS's Rooms, on Tuesday, May 22, and that the price of the tickets, which are to be obtainable only from the Honorary Secretary, shall be one guinea each. It will be remembered that for the past few years the extra expenses in connection with the Dinner have been met by charging the higher sum of thirty shillings for each ticket; but it having been now determined to revert to the earlier charge of one guinea, the extra expenses will this year be defrayed by the Stewards, as formerly. This alteration is calculated to meet the views of many who have objected to the higher charge, and it is to be hoped that in view of the present necessity for exchange of opinions in respect to prospective legislation this opportunity for personal intercourse will not be neglected.

A Committee, consisting of the President, Vice-President and Treasurer of the Pharmaceutical Society, and Messrs. ATTFIELD, F. BARRON, BUTT, GREENISH, W. HILLS and PAUL, was requested by the meeting to carry out the necessary arrangements, and Mr. RICHARD BREMRIDGE was appointed Honorary Secretary. As, probably, many gentlemen who would like to support the Committee have not yet sent in their names, it has been decided not to close the list of Stewards for publication until Wednesday, the 4th of April. All communications upon the subject should be addressed to the Honorary Secretary, Mr. RICHARD BREMRIDGE, 17, Bloomsbury Square, W.C.

The last number of *L'Orosi* contains an interesting statistical table, based upon the last census, showing the relative proportion of pharmacists to the population in the different provinces in Italy. From this we learn that with a gross population of 28,951,374, the number of pharmacists in Italy is 11,572 or 1 in 2502. The proportion of pharmacists is, however, by no means constant in respect to the different provinces, since it ranges from 1 in 1396 in Avellino to 1 in 7241 in Cagliari.

*   *   *

According to the Pharmaceutical Register of New Zealand, a copy of which has just been received, there were at the commencement of the year 256 "pharmaceutical chemists" in virtue of registration effected under the Colonial Act of 1880.

*   *   *

According to Consul-General Blunt the cultivation of the poppy in Macedonia, where it was introduced from Asia Minor in 1866, is being carried on most successfully. The yield of opium in 1881 amounted to 135,000 lbs., most of which was exported to this country at prices ranging from 12*s*. 6*d*. to 14*s*. per lb. The Macedonian opium, especially that produced in the district of Istip, is said to be of very good quality and to contain about 11 per cent. of morphia.

*   *   *

The *Utica Herald* reports the proceedings in an action in which a physician sought to recover damages from a chemist for having dispensed a drachm of podophyllin instead of a grain, and thereby endangered the life of a patient. The defence was that "one drachm" was the quantity ordered in the prescription; but the doctor averred that he wrote "one grain," and that an alteration had been made by the chemist to cover his mistake. The prescription was submitted for examination to two experts, who reported that no alteration had been made, and the jury returned a verdict for the defendant. Incidentally, the question was raised whether a chemist is justified in putting up a prescription ordering a dangerous excess of any ingredient, concerning which the judge ruled that if the prescription of a regular practising physician is dispensed as written the dispenser is not responsible.

*   *   *

According to a recent decision of the Appeal Court at Poitiers, the law which in France prevents pharmaceutical compounds, or remedies of any kind, from becoming the subjects of letters patent extends also to such preparations when intended solely for veterinary purposes.

*   *   *

A weekly contemporary has furnished a good specimen of "penny-a-lining" *à propos* of the recent explosion. It gravely informs its readers of the remarkable coincidence that Sir Frederick Bramwell was lecturing at the Institute of Civil Engineers upon "the powerful effect of dynamite and the dynamo machine," and had just explained that "so many pounds of zinc would, under certain conditions, produce an explosion of terrific magnitude," when his audience was startled and panic stricken by the effects of the explosion at the offices of the Local Government Board. In the presence of so much that is "remarkable," the fact that Sir Frederick Bramwell was not lecturing at the Institute on that evening is, perhaps, hardly worth mentioning.

*   *   *

A "Bill for better securing the purity of Beer," which has been brought into the House of Commons, provides that every person who sells or exposes for sale, by wholesale or retail, any beer brewed from or containing any ingredients other than hops and malt from barley, shall post conspicuously in the same place a legible notice stating what other ingredients are contained in it, under a penalty of twenty pounds for a first offence. "Beer" is defined as "beer (other than black or spruce beer), ale and porter."

*   *   *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, March 29, when a paper will be read on "Vortmann's Method for the Separation of Chlorides, Bromides and Iodides," by Mr. J. B. Barnes. A Report on Botany will be made by Mr. J. O. Braithwaite, the subject being "Plant Movement."

*   *   *

A paper on "Phosphorus, and a new Method of Exhibiting it in Pill Form," by Mr. Millhouse, will be read at the next meeting of the Chemists' Assistants' Association, on Wednesday the 28th inst.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A meeting of the above Association was held at Burlington Chambers, New Street, Birmingham, on Wednesday evening, March 14, Mr. Joseph Lucas, President, in the chair.

A paper was read by Mr. David Hooper, F.C.S., on the "Chemistry of British Coinage." The author introduced the subject by remarking on the necessity for a chemical knowledge in the art of fabricating money, and gave some interesting particulars, under the head of "Historical Remarks," of the composition and the fluctuation in the composition of the British coinage from an early period. In dealing with the Mint processes some peculiarities connected with the melting and annealing were referred to and explained, and some of the methods adopted for refining standard gold and silver were discussed, especially the removal of arsenic and antimony by the chlorine process. The parting assays of gold and silver were then described, and the operations of "quartation" and "cupellation" were explained in detail. Some interesting reference was made on the subject of counterfeit coining and methods for its detection were shown. The paper was illustrated throughout by diagrams, specimens of fraudulent coinage, and several tests and experiments.

After a discussion, in which most of the members present joined, a vote of thanks to Mr. Hooper for his interesting and instructive paper was proposed by Mr. Barclay and seconded by Mr. Charles Thompson.

It was then moved that arrangements should be made for monthly meetings of the Association, when papers could be read, and matters of pharmaceutical interest could be brought forward and discussed.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The Annual General Meeting was held in the Society's Rooms, on Wednesday evening, February 21. Mr. Preston, the President, in the chair.

The Secretary, having read the minutes of the previous meeting, which were confirmed, announced that the following donations had been received during the year:—The *Pharmaceutical Journal*, 'The Calendar of the Pharmaceutical Society,' 'The Register of Chemists and Druggists,' from the Pharmaceutical Society of Great Britain; 'The Year-Book of Pharmacy,' from the British Pharmaceutical Conference; and the *Chemists' Journal*, from the Editor.

It was moved by Mr. Ward, and seconded by Mr. Fox, that the best thanks of the Society be given to the respective donors for their kindness in forwarding the same, which was carried unanimously.

The Annual Report was then read by the Secretary. It stated that during the year ten general meetings and seven Council meetings had been held to further the interests of the Society, and for the benefit of the trade generally. The financial condition of the Society was as follows: — Receipts for the current year had been £10 11*s.* 11*d.* This, with the balance in hand of £29 6*s.* 8*d.* from last year, made a total of £39 18*s.* 7*d.* The expenditure for the year had been—Donation to the Trade Association, £10; Rent, £5 10*s.*; Secretarial expenses, £6 0*s.* 5*d.*, making a total of £21 10*s.* 5*d.*, thus leaving a balance in hand at the present moment of £18 8*s.* 2*d.* This showed that the expenditure had been a little in excess of the income, which was accounted for by the cost incurred in removal from one room to another. The Council confidently trusted that the funds of the Society would be augmented by a still further increase in the number of members and associates. The election of delegates to the Trade Association had resulted in Messrs. Jervis and Ellinor being sent to represent their district. In the early part of the year a "Question Box" had been inaugurated, which had proved a source of pleasure and instruction to many members and associates. During the year several papers had been read, and discussions held thereon, on various matters connected with the trade. The Council had pleasure in stating that its efforts in this direction had met with success, the attendance at the meetings having been fairly good. The curriculum as proposed by the Pharmaceutical Society had been discussed at one meeting, and a resolution had been passed supporting the action of the Society. The Council had held a meeting to discuss the proceedings of a person representing a Copying Apparatus Company—the result being that notices were sent out cautioning the trade to be on their guard. It had reason to think that this action in the matter prevented many vexatious proceedings, not only in Sheffield, but throughout the country. The subject of education had not been overlooked during the past year, but as yet nothing definite has been arranged. It was, however, hoped that during the coming year some arrangement might be made with the Firth College authorities as to a course of lectures on Chemistry, Botany, Pharmacy, etc.

It was unanimously resolved—"That the report be adopted and that it be printed and copies be sent to the members of the Society."

The election of officers then took place, the following being elected for the ensuing year:—President; Mr. J. Preston (re-elected); Vice-Presidents, Mr. G. Carr (re-elected), and Mr. J. M. Turner; Hon. Secretary, Mr. G. T. W. Newsholme (re-elected); Treasurer, Mr. W. Jervis; Auditor, Mr. G. A. Cubley; Council, Messrs. Cubley, Ellinor, Fox, Jepson, Learoyd, Mayor, W. Ward, F.C.S., and Watts. Mr. R. Watts was appointed Librarian *pro tem.*

Mr. Ward, in proposing that Mr. Preston be again elected to the Presidential Chair, referred in eulogistic terms to the manner in which he had filled the chair during the past year and said he thought no one was more fit to occupy it during the coming year, when so many matters of importance would come before the Society. Mr. E. R. Learoyd seconded the motion and it was carried unanimously.

Mr. Preston, in thanking the members for the honour they had done him in again electing him President, mentioned several of the more important matters which would come before the Society during the coming year, and said that he felt sure that he should have the support of the members during his second year of office.

The other officers having returned thanks for their election, and votes of thanks having been passed to the retiring officers for their services during the past year, the proceedings terminated.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A very interesting paper was read before the members of the above Association, on Thursday evening, March 8, 1883, by Mr. Smith, on the subject of "Light." The lecturer spoke of reflection and refraction of light, described the eye and the manner in which sight was produced, and explained other phenomena pertaining to the subject.

A vote of thanks to the essayist brought the meeting to a close.

Mr. A. E. Martin, President, occupied the chair.

ABERDEEN CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual assembly of the chemists and druggists in this neighbourhood was held in St. Katherine's Hall, on Friday, February 9, 1883.

The attendance of the local chemists and their friends was, as hitherto, of the most gratifying nature. This social gathering has now taken root from the oldest member in the trade to the youngest apprentice, and is looked upon by all as the social desideratum of the season.

LEEDS CHEMISTS' ASSOCIATION.

A lecture was delivered before the members and associates of the Leeds Chemists' Association, on Tuesday evening, February 27, by Mr. Alfred Denny, of the Yorkshire College, "On the Chemistry of Plant Life." The President, Mr. S. Taylor, in the chair.

The lecturer first dealt with the primary elements which chemical analysis shows to exist in every vegetable structure hitherto investigated, and which are absolutely necessary for the life and growth of plants. Of the first importance amongst these indispensable food materials are the elements, carbon, hydrogen, oxygen, nitrogen and sulphur, which the plant obtains from various sources, and by a process of synthesis converts into organic matter. The elements, potassium, calcium, magnesium, iron and phosphorus are also invariably present, and all investigations on the nutrition of plants have established the fact that if one of these substances is absent growth is impossible. The presence of chlorine has been shown to be essential for nutrition in one instance, the buckwheat. Sodium, manganese, silicon are often present in the ash, and in marine plants iodine and bromine. Other elements as aluminium, copper, zinc, barium, etc., are found in rare cases, but their absence does not appear to impair the nourishment of the plant, and it is therefore inferred that they are present rather by accident than otherwise. The sources of the essential food elements, and the mode by which the plant obtains them were next considered. The most important is carbon, which is a constituent of every organic compound and forms nearly one-half of the dry weight of the entire mass of vegetation which clothes our planet. Up to a recent period it was the opinion of botanists that plants obtained their carbon from the carbonaceous substances in the soil, *i.e.*, vegetable mould or humus, etc.; this theory was exploded about forty years ago, when the subject was taken up by agricultural chemists both in this country and on the continent. Many striking arguments were put forward against this theory, perhaps one of the most conclusive being from experiments of Messrs. Lawes and Gilbert, which proved that soil after producing crops for twenty successive years showed little or no decrease of carbon, a fact which alone was enough to crush the humus theory; for in such a case, where the crops were removed as produced, a very inconsiderable amount of carbon could be returned to the soil in the form of decaying tissues as is the case in a state of nature. The carbon dioxide of the atmosphere was next thought of as a possible source of the carbon of vegetable structures, and all investigations from that time to the present have proved beyond all doubt that this is the case. This property of obtaining carbon from the carbon dioxide of the air is possessed by plants only, and only by such plants as contain chlorophyll, the substance which gives to all green plants their colour; chlorophyll only has this power of decomposing carbon dioxide in presence of sunlight. Fungi, and all other plants which do not contain chlorophyll, in common with all animals, are thus unable to appropriate the carbon of the atmosphere and on this account are quite dependent, either directly or indirectly, on green plants for their food, being incapable of producing organic matter from inorganic substances for themselves. Plants obtain their nitrogen from ammonia and certain nitrates in the soil, having no power whatever of making use of the free nitrogen of the atmosphere. Mayer has shown that plants absorb ammonia from the atmosphere, but still if the root supply is cut off they do not thrive. Insectivorous plants obtain nitrogen from animal substances by a process of digestion, similar to digestion in the bodies of animals. Hydrogen and oxygen are obtained chiefly by the decomposition of water absorbed by the roots. Hydrogen may also be appropriated from ammonia and a certain amount of the oxygen resulting from the decomposition of carbon dioxide by the green leaves is also retained for the use of the plant. A small quantity of iron in the soil is indespensable for the production of chlorophyll in exposed parts, and potassium is as essential for the activity of chlorophyll as iron is for its production. The sources of the other materials were also considered. The transformation of these inorganic materials into organic substances is termed assimilation and this property is possessed only by green plants. Starch is usually the first product of assimilation, and is the raw material from which the other organic substances are produced, Starch appears as grains in the chlorophyll corpuscles, but is only formed under the influence of light and within certain limits of temperature. All the after processes which result in the transformation of the products of assimilation, are termed products of "metastasis" or "metabolism." The chief products of metastasis were then considered and also certain bye-products of metastatis termed "products of degradation" which appear to originate as the inevitable results of certain processes, but which have generally no further use in the economy of the plant. The various gums and resins, tannin, colouring matters, alkaloids, acids, volatile oils, etc., and almost all vegetable products that are most useful to man are degradation products.

The Draft Pharmacy Bill.

A meeting of members of the Leeds Chemists' Association and other registered chemists and druggists of Leeds was held at the Church Institute, on Wednesday, March 14, 1883. There was an attendance of between twenty and thirty members of the trade. Mr. Samuel Taylor, President of the Association, was called to the chair.

The Chairman explained that the Committee of the Chemists' Association had felt that the issue by the Council of the Pharmaceutical Society of a draft Pharmacy Act Amendment Bill was a matter of so great interest to all chemists and druggists that it was desirable to take this opportunity for considering and expressing any opinions which might be the result of such consideration. He thought it would be most consistent with the position in which they had been pleased to put him as Chairman of the meeting, that he should not at that time offer his own opinions upon the subject. He would therefore ask Mr. Reynolds to introduce the question by an explanatory statement.

Mr. R. Reynolds then gave an account of the origin of the present measure in the appointment some years since by the Council of the Pharmaceutical Society of a Committee entrusted with the duty of preparing amendments to the existing Pharmacy Act. The communications which have taken place with the Medical Department of the Privy Council were alluded to, and the interchange of views on the subject of regulating the sale of certain poisonous articles, notably the strong mineral acids, which the Privy Council refused to add to the existing Poisons Schedule, but which they regarded as demanding cautionary labels. The numerous accidents which have followed the incautious or ignorant use of patent medicines containing powerful remedies, as morphia and chloral hydrate, had clearly produced an impression on the mind of the Government that something should be done to check the evil. The draft Bill dealt with both these questions in a manner which it was believed had the approval of the Government, and in its whole scope it was calculated to stay those infringements of the intentions of the Act of 1868 which unqualified men acting as companies had been able to commit with impunity. It would have been seen in the newspapers that Mr. Mundella, replying to a question from Mr. Warton, had informed the House of Commons that the

Government would introduce a Bill this session to amend the law on the sale of poisons and also dealing with the question of patent medicines. Hence legislation was imminent, and as practical men they had to consider how far they could agree with the proposals which might commend themselves to the Government, and which evidently had the best chance of being carried.

The clauses of the draft Bill were then considered.

Clause 2 was fully debated.

Some members expressed a wish to see the "poisonous" articles of the Schedule dealt with by the Schedule of the existing Act, the Chairman stating his feeling in favour of such a course, if practicable. Some members thought that the proposed Bill would encourage the public idea that the sale of "poisons" was not confined to registered chemists. It was replied that this could not enable them to make purchases of scheduled "poisons" otherwise than at present, provided the existing Act was enforced, and the recent prosecutions and convictions for breaches of this enactment were cited in proof of the vigilance of those entrusted with the working of the Pharmacy Act.

In the discussion on clause 4, Mr. James Abbott objected strongly to the responsibility placed upon a retailer of any patent medicine found to contain a legal poison, and urged that the maker alone should be responsible. In reply, it was shown that the act of sale was that which constituted an offence, and that the responsibility of the retailer was the principle of existing legislation of an analogous kind, as in the Food and Drugs Act. The power of claiming indemnity from the wholesale dealer was contended to be a very solid protection to the retailer.

At the conclusion of the consideration of the clauses the following resolution was proposed by Mr. Reynolds, seconded by Mr. Smeeton, and carried unanimously:—"That this meeting of members of the Leeds Chemists' Association and other registered chemists and druggists of Leeds has considered the draft Pharmacy Acts Amendment Bill proposed by the Council of the Pharmaceutical Society, and records its cordial approval of the same; those present will use their best endeavours to promote the passing of the Bill by Parliament."

It was then moved by Mr. Chadwick, seconded by Mr. Fawcett, and carried unanimously:—"That the Council of the Pharmaceutical Society be requested to use its best efforts to extend to all chemists and druggists exemption from jury service."

A vote of thanks to the Chairman brought the proceedings to a close.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting of the above Association, was held at the Royal Institution, on Thursday, February 15.

The Secretary announced that he had received a letter from the President, in which that gentleman expressed his regret that he would, owing to illness, be unable to preside. In the absence of the Vice-President, Dr. Symes was, on the motion of Mr. M. Conroy, seconded by Mr. A. H. Samuel, voted to the chair.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal*, from the Society; the *Canadian Pharmaceutical Journal*, from the Editor; the 'Calendar of the Pharmaceutical Society,' from the Society.

Mr. T. F. Abraham then moved that, as owing to the unavoidable absence of several gentlemen, the meeting was unusually small, it be adjourned until a more favourable opportunity.

This arrangement being agreeable to the members present and to Mr. Samuel, the proceedings terminated.

The tenth general meeting was held at the Royal Institution, on Thursday, March 1.

In the absence of the President through illness, and in the absence of the Vice-President and Treasurer, Dr. Symes moved that Mr. John Shaw do take the chair. This was carried.

The minutes of the previous meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal* and specimens of the following drugs, from the Pharmaceutical Society:—*Ammomum aromaticum*, *Scopolia japonica*, Caramana gum, *Aconitum Fischeri*, *Empleurum serrulatum*, *Pimpinella anisatum*, Calumba wood, *Illicium religiosum.*

Dr. Symes showed some new filter papers from which the ash is removed by means of hydrochloric and hydrofluoric acids, the smallest size containing only $\frac{1}{25}$ of a milligram of ash.

Mr. Astrup Carus was then called upon to read a paper upon "Contrivances for the Economy of Fuel and the Abatement of Smoke."

The author, after dealing with the mischief caused by smoke and the great quantity of so-called ashes which the authorities of such a town as Liverpool had annually to remove, showed how both nuisances might be very considerably abated.

A discussion ensued and a vote of thanks having been passed to Mr. Carus, the proceedings terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on March 1, Dr. Gilbert, President, in the chair.

The following certificates were read for the first time:—J. A. Baxter, E. C. Hemming, J. B. Coleman.

The full list of Officers and Council was read from the chair. The changes contemplated are given in the report of the meeting on February 15; in that report the name of Professor Dittmar was, however, inserted instead of H. T. Brown, as a proposed member of the Council.

During the evening a ballot was held, and the Scrutators, Dr. Hodgkinson and Mr. Howard, declared the following gentlemen duly elected Fellows:—A. C. Abraham, G. Board, C. N. Betts, E. Bevan, F. J. Cox, A. Collenette, S. Dyson, W. T. Elliott, H. B. Fulton, C. G. Grenfell, B. F. Halford, W. D. Hogg, D. Hooper, J. J. Knight, H. F. Lowe, T. H. Leeming, J. E. Marsh, W. Newton, C. Rumble, F. Scudder, J. O'Sullivan, S. A. Vasey, T. D. Watson, R. M. Walmsley, C. S. S. Webster, F. Watts.

The following papers were read:—

On some Derivatives of the Isomeric $C_{10}H_{14}O_7$ Phenols. By H. E. Armstrong and E. H. Rennie.—Lallemand stated (*Ann. Chem. Ph.*, 101, 119) that by the action of a mixture of strong nitric and sulphuric acids on dinitrothymol a trinitrothymol was obtained. The authors have repeated this reaction and find that a trinitro body is produced, but that it is trinitrometacresol, the propyl group being displaced. The authors were unable to trace this reaction. On comparing carvacrol with thymol it is seen that the only difference is in the relative positions of the methyl and propyl groups. Only a dinitro derivative could be obtained from carvacrol; no trinitro body could be formed. An attempt was made to introduce the NO_2 group into the unoccupied ortho-position in thymol sulphonic acid, but without success, as the sulpho-group is displaced by NO_2, and paranitrothymol is formed. When bromothymol sulphonic acid is oxidized by chromic acid a quinone is formed; with permanganate no formation of quinone takes place, but some amorphous, probably condensation products are produced. Dibromthymol with cold nitric acid forms a colourless substance, probably a nitroso body. The authors have also investigated the nitro bodies formed from isobutyl phenol.

Dr. Japp suggested that the propyl group which was displaced by NO_2 might be eliminated as propylen, which was then polymerized by sulphuric acid.

The Secretary then read a paper entitled—

Chemico-Microscopical Researches on the Cell-contents of Certain Plants. By A. B. GRIFFITHS.—The author has contrasted the growth of some savoy cabbages grown in a soil to which no iron was added with that of plants grown with the addition of ferrous sulphate. The weight of the latter plants was about twice that of the former, and the ash contained notable quantities of iron; in one case the stalk contained 3·521 per cent. Fe_2O_3 and the leaves 12·29 per cent. Fe_2O_3. Microscopical sections of the leaves exhibited minute crystals in some of the cells. On running potassium ferricyanide under the cover glass, these crystals became blue, and after the addition of barium chloride a cloudiness was observed; the crystals also were monoclinic, so the author concludes that they were crystals of $FeSO_4 + 7H_2O$.

The following communication was read by the Secretary:—

The Phenates of Amidobases. By R. S. DALE and C. SCHORLEMMER.—The authors could not isolate any compounds intermediate between aurin and pararosanilin, and have concluded, after many experiments, that when aurin is heated with aqueous or alcoholic ammonia, the action proceeds at once to the formation of rosanilin. When equal molecules of aurin and common rosanilin were heated with alcohol, a solution was soon formed and on concentration a crystalline powder, with dark-green lustre, separated, which proved to be rosanilin aurinate. Similarly, when equal molecules of anilin and phenol were heated for some hours to the boiling point, anilin phenate C_6H_7N,C_6H_6O was obtained in glistening plates, melting at 29·5°, boiling at 184·5°; this substance has a faint phenol-like odour. A rosanilin phenate has been prepared by Mr. G. Dyson. Red alkaline solutions of aurin sometimes turn brown. On acidifying such a brown solution a smeary mass is precipitated from which a body was isolated in colourless crystals; it proved to be dioxyphenylketone $CO(C_6H_4OH)_2$.

The Society then adjourned to March 15.

A meeting of this Society was held on March 15, Dr. Gilbert, President, in the chair.

The following certificates were read for the first time: —T. L. Briggs, E. C. Conrad, C. Gillett, L. Levy, A. Ness, V. S. Schopoff and A. E. Wilson.

Dr. Gilbert announced that the anniversary meeting would take place on Friday, March 30, and that he had decided, after much deliberation, to resign the office of President; the Council proposed that Dr. W. H. Perkin should fill the vacancy thus created, and that Mr. J. Millar Thomson should be Secretary.

Mr. MATTHEWS then read a paper—

On some Condensation Products of Aldehydes with Aceto-Acetic Ether, and with substituted Aceto-Acetic Ethers.—The author has studied the following reactions, condensations of acetic ether with isobutylic aldehydes, with valeric aldehyde, with chloral, with furfurol and with acrolein; benzoic aldehyde with acetodiethyl acetic ether, with acetodichloracetic ether, with acetobenzylidenacetic ether, and with acetomonoethylacetic ether. He concludes that acetoacetic ether is capable of condensing with aldehydes of all descriptions, and that the condensation takes place only in the methylene group, but with the greatest ease; that mono and disubstituted acetoacetic ethers, with the exception of the dichlor ether, are capable of condensing with benzoic aldehyde, but the condensation is very much more difficult to effect and it takes place only in the methyl group.

Mr. R. Warington communicated a paper entitled—

Contribution to the Chemistry of "Fairy Rings." By Sir J. B. LAWES, J. H. GILBERT and R. WARINGTON.—The circles of dark-green grass which frequently occur on pasture land, and which have been long known by the name of "fairy rings," have attracted much attention from botanists and vegetable physiologists. Professor Way, in 1846, explained this phenomenon as follows:—"A fungus is developed on a single spot of ground, sheds its seed and dies. On the spot where it grew it leaves a valuable manuring of phosphoric acid and alkalies, etc., the ground then becomes occupied by a vigorous crop of grass rising like a phœnix on the ashes of its predecessor; the grass crop is then removed and with it the greater part of the inorganic materials the fungus had collected." Professor Way, therefore, attributed the effect chiefly to the inorganic elements. Many experiments were made on the subject at Rothamsted, and in 1851 (*Journ. Royal Agricultural Society*, vol. xii., 32), it was stated that the manuring action was due to the nitrogen collected by the fungus rather than to the ash constituents. The source of the nitrogen was at that time supposed to be the atmosphere. Since that time, however, much evidence has been acquired as to the sources of the nitrogen of green-leaved plants, and grave doubts have arisen as to the nitrogen being derived from the atmosphere. In 1874 an attempt was made to obtain direct experimental data on the subject. Samples of soil were taken, of the soil inside a fairy ring, from the ring and outside. The quantity of organic carbon and nitrogen was carefully estimated; the mean results obtained were nitrogen within the ring 0·247 per cent., on the ring 0·266 per cent., outside 0·281 per cent.; carbon within 2·78 per cent., on the ring 2·99 per cent., outside 3·30 per cent. The percentage of nitrogen and carbon is therefore highest in the soil outside the ring and lowest within the ring, whilst the quantities found in the soil from the ring have an intermediate value. It is obvious, therefore, that the growth of the fungus and the subsequent increased growth and removal of the associated herbage are accompanied by a considerable reduction in the amount of the organic carbon and nitrogen in the soil, and that fungi have taken up organic carbon and nitrogen from the soil which was not available to the previously established vegetation. Five series of experiments were made and the investigation would have been continued, but owing probably to the late wet seasons the fairy rings have disappeared from Rothamsted. The soil of the ring always contained more nitrates than the soil either within or without.

Dr. Gilbert said that the point of interest in the paper was the source of the nitrogen. These rings usually occurred on very poor pastures, and it was at first natural to suppose that the fungi must draw the nitrogen from another source, as the previous vegetation could not obtain it from the soil, and although we have no evidence that green-leaved plants can obtain nitrogen from the atmosphere it was thought that with fungi, of which the growth is so different, it might be otherwise. Direct evidence that the nitrogen comes from the soil is still wanting, but there is a great deal less evidence that the nitrogen is furnished by the atmosphere, so that on the whole the balance of evidence points to the soil as the source of the nitrogen.

The Secretary then read a paper—

On Lines of no Chemical Change. By E. J. MILLS and W. Mc. D. MACKEY.—The authors considered it of great interest to determine in certain cases the origin of chemical change, such origin being obviously identifiable in many instances with a line of no chemical change. In the present paper they have studied the reaction between sulphuric acid and zinc brought into contact under definite conditions as regards temperature, strength of acid, etc. The hydrogen evolved was taken as the index of the extent of the reaction. The results are represented in tables, and are plotted on a curve. The nature of the reaction is shown to be of a very complicated character. The law of the relation of temperature to chemical change requires an equation of the second degree. The authors state that their investigations place temperature on the footing of an ordinary chemical reagent. They intend to resume this investigation.

The Secretary then read a paper—

On Homologous Spectra. By W. N. HARTLEY.—In June, 1881, the author published (*Chem. Soc. Journ.*, 134

84) a note on certain photographs of the ultra-violet spectra of elementary bodies, and attention was directed to the extraordinary similarity between the groupings of lines in the spectra of magnesium, zinc and cadmium, copper and silver, iron, cobalt and nickel. It was thus made evident that the spectra of elements of the same homologous series present either homologous spectra or homologous groups of lines in their spectra; but it was remarked "it will be hopeless to determine whether there are numerical relations between the wave lengths of different groups of lines until the spectra have been reproduced on an enlarged scale, and the wave lengths for the principal lines of the different elements calculated." Ciamician has remarked that almost every element has a number of feeble lines which bear the same relation to the chief line or lines that the overtones in music bear to the fundamental note. These observations, however, refer only to the visible rays or about one octave of the spectrum; photographs of the ultra-violet region can easily be extended to more than two octaves. The conclusions of Ciamician are completely confirmed by such extended photographs. The three hydrogen lines N, F and C have been shown to be the thirty-second, twenty-seventh and twentieth harmonies of a fundamental vibration whose wave length is 0·01313 mm. There is evidently a harmonic relation between the lines in the spectra of magnesium, zinc, cadmium, aluminium and in those of calcium, strontium and barium when two octaves of the spectra are examined. The fundamental vibrations appear to be all in the infra-red region. The author originally intended to bring forward an extended series of observations on the constitution of the spectra of the elements, but as it appears that Liveing and Dewar are engaged in a similar research, the author wishes to publish such facts as he has already obtained. In order that harmonic relations between lines and groups of lines may be rendered apparent it is necessary to map spectra according to their "oscillation frequencies," instead of wave lengths. The author has thus mapped the wave frequencies in one millimetre of the chief rays in the spectra of magnesium, zinc, cadmium, copper, silver, silicon, boron and aluminium. The data thus obtained present a considerable addition to the body of evidence in support of the view that elements whose atomic weights differ by a constant quantity and whose chemical character is similar are truly homologues, or in other words are the same kind of matter in different states of condensation. The probability of the fundamental vibrations of the simpler elements being found in the infra-red region will doubtless be soon tested, since Captain Abney has enabled us to photograph this region, and with the help of Rowland's exquisite concave ruled specula, etc., has now a range of four octaves of the spectrum.

The Society then adjourned to April 5, when a paper, "On the Estimation of Hydrogen Sulphide and Carbonic Anhydride in Coal Gas," by L. T. Wright, will be read. The anniversary meeting is on Friday, March 30.

ROYAL INSTITUTION.

The Primæval Ancestors of Existing Vegetation and their Bearing on the Doctrine of Evolution.

BY PROFESSOR C. W. WILLIAMSON.

The fifth lecture of this course was delivered on Tuesday, February 6. The following is an abstract:—

The Cellular Cryptogams, as their name implies, are wholly devoid of fibro-vascular bundles, though in some forms, as in some seaweeds, the fronds appear to have a district midrib which, on a superficial glance, might be supposed to be a vascular bundle, but more minute examination shows to be merely composed of one or more linear series of elongated, square-ended cells. The most highly differentiated of these cryptogams are probably the mosses of which the spores develop a branching creeping Prothallus, called the Protonema, that gives off root hairs, and seeds that develop into the aerial shoots. Some of these latter bear the sexual reproductive organs in the shape of Antheridia and Archegonia; the entire vegetative organism may be regarded as a Prothallus. The Anatheridia and Archegonia are sometimes found on the same and sometimes on different plants; functionally these organs correspond with those seen on the vascular cryptogams. The fertilized cell occupying the base of the Archegonium develops into a Sporogonium or spore-bearing structure. The most important part in this structure, which consists of several parts, is the Theca or urn; a hollow capsule, supported on a slender stalk, within which the spores are found and from which they are liberated, when ripe, by the detachment of a small lid, or aperculum. Though this sporogonium remains attached to the vegetative portions of the moss, it nevertheless represents a distinct generation; since, though supported by the leaf-bearing Prothallus, it has no true organic connection with it. Hence, even in these mosses we have a distinct alteration of generation, a sexual, followed by a non-sexual one.

Though at the present day mosses are so numerous and widely distributed over the earth, from the Tropics to the Artic circle and from the Equatorial sea-level to the snow-line of our mountain ranges, we find no traces of them in a fossil state in rocks older than the Tertiary strata. That they are capable of fossilization is shown by the circumstance that a considerable number of such have been preserved in these more recent beds and in the amber met with in many localities. But no trace of an indisputable moss has been met with in the Cretaceous or more ancient strata,—a remarkable fact suggesting a modern origin of the entire group. These remarks apply equally to the nearly allied group of the Jungermanniæ. Many of these have a very moss-like habit, but differ chiefly from the mosses in the characteristic features of their Sporogonia, of which the organization is much simpler than is the case with those of the mosses. They are yet further distinguished by the mechanism by which the spore-containing capsule is burst open to liberate the spores. This capsule is only partially filled with spores, which have intermingled with them a number of cells, each of which contains a spiral thread. Non-elastic so long as not ripe, when it becomes so it is highly elastic; reaching this state it expands the cell in which it is contained, all acting more or less simultaneously. These "Elaters" burst the capsule, separating it into four valves, and thus setting the spores free. In the lower true Jungermanniæ and the Marchantiæ, or Liver-worts, the vegetative structure is less moss-like, and assumes much of the appearance of a gigantic fern—Prothallus; the resemblance being made the more obvious by the fact that this Prothalloid organism bears the Antheridia and Archegonia, from the latter of which are developed sporangia containing spores, and which represent a simple form of sporogonial generation. These Jungermanniæ and Marchantiæ also occur in a fossil state in the Tertiary rocks. The Characeæ constitutes another highly distinct group of cellular plants of aquatic habits, remarkable for the large size of their elongated cells. Here, again, we find Antheridia and Archegonia assuming very distinctive forms, these being severally known by the names of *Globule* and *Nucule*. The latter, also known as the Carpogonium, is the female organism, and is readily distinguished by five broad and distinct bands wound spirally around the central cavity containing the spore. These carpogonia, the fossil states of which have long been known as Gyrogonites, are found abundantly, not only in the Tertiary strata of Fresh-water origin, but also in the Cretaceous and Oolitic rocks, and, according to Schimper, they have also been discovered near Moscow in the bed of Triassic age, known as the Keuper. Hence these plants have evidently not only existed at an early period of the world's history, but have undergone but little change between what seems to have been the age in which they originated and the present time.

There can be no doubt but that some forms of marine vegetation must have existed at least as far back as the period when animal life first made its appearance on the earth; since plants alone have the power of converting mineral matter into an organic form, and the earliest animals must have required pre-existing vegetable matter on which to subsist. But the identification of these Protophytes is not easy. Myriads of objects exist in a fossil state, which have been called "Fucoids"; but many of these have been portions of plants of higher organization, all details of which have disappeared. Some of these have been identified as belonging even to the Conifers; others to Ferns, etc. Then, again, M. Natharst, of Stockholm, has shown that many supposed marine plants are merely casts of the tracks left by marine animals when crawling over a muddy sea-bottom. There is, however, no question respecting the *Fucoid* character of many forms existing in the Tertiary and Oolitic strata, whilst resemblances of form suggest that yet older and less distinct objects may have been of the same nature. But in most cases proofs that such has been the case are unattainable; hence these objects cannot be relied upon in framing a genealogical tree of vegetable life. On the other hand the group of Fungi is represented in strata of various ages, and very distinctly so in some of the older Carboniferous rocks. The latter consist wholly of some of those lower Fungoid forms known as moulds, five examples of which have been found in the Lower Coal Measures of Halifax, in Yorkshire.

Having thus, in this course of lectures, reviewed some of the more distinctive types of vegetable life found in the Palæozoic rocks, and endeavoured to trace the links connecting these ancient types with their living representatives, we may ask, how far does the order of their succession correspond with what the doctrine of Evolution would presuppose to be probable.

If we examine the living plants only, we have no difficulty in following a succession of graduated forms which might well suggest a continuous line of descent from the simplest to the most highly organized types of Plant-life; but such would not necessarily be the actual ancestral line. We have seen how long the Cryptogams and Gymnosperms existed before any of the Angiosperms or higher flowering plants made their appearance. Dealing with special types, we have seen that the lowly organized Hymenophylloid Ferns were amongst the earliest of which traces have been discovered. In the same way the most ancient cone-bearing plants, as the Cycads and Conifers, but especially the latter, only assumed their modern characteristics by slow degrees and after long periods of time; yet testing these Gymnosperms by their flowers we see that the most ancient ones belonged to the least complex of known groups, whilst the higher types came into existence during more recent times. On the other hand the most ancient Lycopods and Equisetums burst upon us in the Devonian age, almost, if not absolutely, in the state of their most glorious culmination whether of size or organization. They did so in contemporary association with Conifers (Dadoxylons), which occupy a high rank even compared with the vascular Cryptograms along with which they grew; how much higher therefore are they than the simple unicellular specks of Protoplasm from which we assume them all to have primarily originated. It is obvious from these and numerous similar facts that whilst the study of fossil plants gives a general support to the Doctrine of Evolution, that support does not and cannot at present extend beyond a limited measure. There must have been a protracted duration of time antecedent to that of the Devonian rocks, during which vegetation developed from its lowest and simplest state to that of the noblest Dadoxylons, Lepidodendra, Calamites and Tree ferns which existed in the Devonian and Carboniferous ages. Of that Predevonian vegetation we have yet obtained but the faintest glimpses. We can only hope that ere long more will be discovered, but until such discoveries are made all attempts to frame a genealogical tree of the vegetable world must be useless and vain.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Association held on Wednesday, March 14, Mr. W. A. Wrenn in the chair, a paper on "Porcelain, its Manufacture and Composition," was read by Mr. H. Cracknell.

Mr. Cracknell first alluded to the antiquity of the potter's art. He mentioned that the Portuguese were the first to import Chinese porcelain into Europe about 1518, but it was not for more than two hundred years after that soft porcelain was manufactured in France. He then alluded to Böttcher as being one of the first to investigate the subject of porcelain manufacture. Next he pointed out the difficulties met with in early days, due principally to the want of a knowledge of chemical analysis and mineralogy. The author then proceeded to describe the difference between hard and soft porcelain, and the glazes used for them, and gave a short account of the manufacture of true hard porcelain, Sèvres porcelain and Viennese porcelain. Lastly he gave a detailed account of the manufacture of porcelain at Worcester, dealing especially with fine porcelain, mentioning the grinding of the materials, and the kneading and beating required to make the paste tough; after which he proceeded to describe the potter's wheel and its use. The process of firing and glazing having been fully dealt with, an account was given of painting and gilding on porcelain, mentioning the salts used for the colours and also describing the preparation of the gold for the workmen. He then mentioned a few of the marks which appear on Worcester porcelain, but he cautioned those who might be collectors not to be led astray, inasmuch as marks which were considered valuable and much sought after were freely manufactured both at home and abroad. The paper was illustrated with diagrams, and tables of the composition of the various clays used in the manufacture of porcelain, as well as of the composition of the various glazes, were also shown.

A discussion took place in which the President, Messrs Alcock, Cooper, Millhouse and Woods took part.

Obituary.

Notice has been received of the death of the following:—

On the 31st of January, Mr. Charles Farrant Webber, Chemist and Druggist, Market Place, Sidmouth. Aged 41 years.

On the 4th of February, Mr. William Bray, Chemist and Druggist, Buntingford, Herts. Aged 55 years.

On the 17th of February, Mr. Paris Anderson Huggard, Chemist and Druggist, Church Street, Alpha Road, London. Aged 73 years.

On the 22nd of February, at Bishop's Castle, Shropshire, Mr. Albert Brown Hollway, Chemist and Druggist, Aged 44 years. Mr. Hollway had been an Associate in Business of the Pharmaceutical Society since 1869, and was formerly Local Secretary for Cardiff.

On the 25th of February, Mr. Lewis Michael Wibmer, Pharmaceutical Chemist, Tunbridge. Aged 70 years. Mr. Wibmer had been a Member of the Pharmaceutical Society since 1853.

On the 28th of February, Mr. Charles Edmund Hitchcock, Pharmaceutical Chemist, High Street, Oxford. Aged 66 years. Mr. Hitchcock had been a Member of the Pharmaceutical Society since 1842.

On the 1st of March, Mr. Matthew Pound, Pharmaceutical Chemist, Leather Lane, London. Aged 71 years. Mr. Pound was one of the Founders of the Pharmaceutical Society.

On the 3rd of March, Mr. William Field, Pharmaceutical Chemist, Brompton Road, London. Aged 82 years. Mr. Field also was one of the Founders of the Pharmaceutical Society.

On the 3rd of March, Mr. Henry Woodhead Hewitt, Chemist and Druggist, Wood Bank, Sheffield. Aged 65 years.

On the 3rd of March, Mr. George Godden, Chemist and Druggist, Plumstead. Aged 87 years.

On the 6th of March, Mr. John Woodman Bowring, Pharmaceutical Chemist, Ringwood, Hants. Aged 63 years. Mr. Bowring was one of the Founders of the Pharmaceutical Society.

On the 9th of March, at Glasgow, Mr. William Hatrick, Pharmaceutical Chemist, Gilmour Street, Paisley. Mr. Hatrick had been a Member of the Pharmaceutical Society since 1853, and at the time of his death was Local Secretary for Paisley.

On the 12th of March, Mr. John Davies, Chemist and Druggist, Pontypridd. Aged 44 years.

On the 13th of March, Mr. George Jarman, Chemist and Druggist, Bolton Street, Bury, Lancs. Aged 76 years.

On the 16th of March, Mr. Joshua Henthorn, Pharmaceutical Chemist, Lees Road, Oldham. Aged 57 years. Mr. Henthorn had been a Member of the Pharmaceutical Society since 1853.

BOOKS RECEIVED.

Physical Optics. By R. T. Glazebrook, M.A., F.R.S. London: Longmans, Green and Co. 1883. [Text-Books of Science.] From the Publishers.

The Intermediate Text-Book of Physical Science. By F. H. Bowman, D.Sc., etc. London: Cassell, Petter, Galpin and Co. 1882. From the Publishers.

Photometry and Gas Analysis. Compiled and Edited by J. T. Brown, F.C.S. London: The Scientific Publishing Company. From the Publishers.

A Pharmacopœia of Selected Remedies, with Therapeutic Annotations. By Edmund A. Kirby, M.D., etc. Sixth Edition. London: H. K. Lewis. 1883. From the Author.

Syllabus of Materia Medica for the Use of Students, Teachers and Practitioners. By Alexander Harvey, M.D., and Alexander Dyce Davidson, M.D. Sixth Edition. London: H. K. Lewis. 1882. From the Publisher.

St. Bartholomew's Hospital Reports. Edited by W. S. Church, M.D., and John Langton, F.R.C.S. Vol. XVIII. London: Smith, Elder and Co. 1882.

The Philosophy of Advertising and Newspaper Register. By Henry Sell. London: H. Sell. 1883.

Dental Vade Mecum. Concise Notes on Anatomy, Physiology, Surgery and Chemistry. Fourth Edition. By James Hardie. Glasgow: W. Collins and Co. 1882. From the Author.

Sid Evans.—Such an appointment would be outside the scope of the Bill.

A. J. W.—See the Preface to the British Pharmacopœia, p. xiii.

Botanist.—The Editor of the *Journal of Botany* is Mr. James Britten, 3, Gumley Row, Isleworth.

Major.—The circumstance you mention has not been overlooked, and on reference to the terms of the clause in question, you will find that they are not by any means one-sided. The consideration of the claims of existing managers may well be deferred until the occasion for it is more pressing.

A.P.S.—An answer to your question was given on p. 660, under the initials *F.S.S.* An examination of the compound there referred to would probably well repay the trouble.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Fertilization of the Papaveraceæ.

Sir,—When reading over the order Papaveraceæ I came across a statement that some inquisitive botanist had amused himself in counting the number of seeds contained in the capsule of a poppy, viz., 32,000. A question occurred to me at the time, I having been previously reading the subject of "Fertilization." A pollen grain falling on the apex of the ovary (stigma) forms a long tube which penetrates the style when present, enters through the micropyle to the oosphere, which is in consequence fertilized. Now the question is, "Does it require a pollen grain for each of the seeds produced?" If so, no less than 32,000 pollen grains would have to fall on the stigmas of one poppy, and the same number of tubes to penetrate the ovary. If not, then each pollen grain can form more than one embryo and be the father of many plants. From analogy we find that it requires in mammalia a spermatozoa for the fertilization of each ovum; if two enter the same ovum and each thrives, then a monster is the product, and it is impossible for one spermatozoa to enter more than one ovum. Will some reader kindly throw light on it, giving quotation of authors. If not explained anywhere I think it is a worthy subject for investigation.

Morris J. Williams.

St. Bartholomew's Hospital, E.C.

Aromatic Spirit of Ammonia.

Sir,—In reply to Dr. Thresh and Mr. Tanner (pp. 700 and 776 of this volume), allow me to refute the error imputed to me and to quote Dr. Thresh again:—"Taking the official quantities, the ammoniæ carbonas refuses to dissolve in the requisite amount of water and solution of ammonia without the aid of heat." The plain-English of the requisite amount of water, I take to be the quantity required to make the preparation. Dr. Thresh now says, he means the quantity contained in the finished product. I respectfully submit the above quotation will not bear this construction, although Mr. Tanner goes further than I did, and says, that a solution can be made in the cold even with this quantity of water, which is one-sixth the requisite amount of the B.P. process.

10, *New Cavendish Street, London, W.* Wm. Martindale.

[*** As it is evident that our correspondents hold distinctly different opinions as to what should be understood as the meaning of the words "requisite amount of water," it will serve no useful purpose to continue the correspondence.—Ed. Ph. Journ.]

T. Evans.—Godfrey's 'Diseases of the Hair' (Churchills).

W. D. Haydon.—We have received your circular, but cannot perceive that it contains anything of sufficient interest to call for its publication.

Country Major.—You appear to have overlooked the fact that the recommendation you suggest has been submitted and has met with a distinct refusal. We do not think that further recommendations of the same nature are likely to meet with a satisfactory reception.

Wanting Help (who should have sent his name and address).—We think enough has been said for the present upon the subject of "golden ointment."

Novice.—No special qualification is necessary. See a communication on "Pharmacy in South Africa" in the *Pharm. Journal* for July 2, 1881, p. 19.

T. D.—The case you refer to is provided for in the Bill.

Troubadour.—Your letter has been received, but the immunity spoken of is certainly not in accord with our own experience.

Communications, Letters, etc., have been received from Dr. Mallez, Messrs. Illingworth, Brown, Long, J. O. Smith, Storey, Evans, R. H., Veritas Vincit, Outon.

"THE MONTH."

The cold blustering north-east winds have not been without their effect on vegetation, the season, in spite of the sunshine, being more backward than last year. Even in the sunny South, icicles two feet long were observed on Good Friday in the Isle of Wight, although in warm nooks the *Arum maculatum* and *Sarothamnus Scoparius* were met with in flower, and in sheltered spots, the cherry laurel, *Prunus Lauro-Cerasus*, and the true laurel of the ancients, *Laurus nobilis*, were seen covered with bursting flower-buds. The pretty little *Corydalis claviculata* and *Adoxa moschatellina* were observed in blossom, but the *Oxalis Acetosella* had not opened its delicate pencilled and pensile flowers. In cottage gardens the rosemary is coming into blossom, and on chalk downs the Pasque flower, *Anemone Pulsatilla*, is raising its dull bluish bells among the short grass. The yew, the elm, the dandelion and scurvy grass may be found in bloom in the country, and the almond will soon be in full beauty in the London gardens. Several rare British plants also flower at this time of year. *Trichonema columnæ*, at Dawlish Warren, and *Knappia agrostidea*, near Llyn Coron, in Anglesea, are probably often missed by botanists through flowering so early. *Carex ericetorum*, *C. clandestina* and *Lathræa squamaria* may also usually be found in blossom about Eastertide.

According to the *Gardeners' Chronicle* (March 3, p. 282), the cultivation of the rose-leaf geranium (*Pelargonium capitatum*) has been attempted in this country, and it is said with some success. From plants grown in the open air an essential oil has been obtained, which has been reported equal, if not superior, to the oils imported into this country under the name of geranium oils. It is said that with proper care plants, grown at the rate of about 3000 to an acre, will yield sufficient oil during their free growth in the summer, so that, after cuttings are taken (in September), the ground can be utilized with vegetables or other profitable crops. The statements, however, that rose-leaf geranium is grown to a large extent in Turkey is open to question, as is also the remark that oil of genuine rose-leaf geranium fetches about 3*s.* per ounce, while that of andropogon, with which it is often adulterated, is not worth more than that sum per pound.

At a meeting of the Edinburgh Botanical Society on February 8, Professor Dickson called attention to a donation to the Museum of the Royal Botanical Gardens of a foxglove, 10 feet high, and of another from the Bridge of Allan, 8 feet 1 inch high. A branch of the *Eucalyptus globulus* grown in a cool conservatory at Carlowrie, Linlithgowshire, was also shown, taken from a tree which grew at the rate of 4 feet in a year, being now nine years old (*Gardeners' Chronicle*, Feb. 26, p. 255).

The pretty yellow fungus, *Æthalium septicum*, commonly called flowers of tan, and which sometimes does much mischief where that substance is used in propagating houses, has been analysed by M. Bergmann and found to contain acetic and formic acids (*Gard. Chron.*, March 7, p. 344). This fact suggests the possibility that the fungus might be utilized as a ferment in promoting certain chemical changes.

Messrs. Dehérain and Breal, following up the researches of M. Bœhm, have ascertained that the presence of lime is beneficial in germinating seeds, and particularly when combined with ulmic acid (*Gard. Chron.*, March 7, p. 344), especially as regards the development of the root.

In the *Répertoire de Pharmacie* (p. 112), M. Stanislas Martin gives an account of the seeds of *Dolichos urens*, commonly known as the ass's eye bean, which is used in medicine in Tropical America in the form of a decoction, to alleviate the pain of hæmorrhoids; the pulp of the seed being employed as a topical application for cleansing and healing wounds. M. Martin found the seed to contain tannin, fixed and volatile oils, and mucilage like that of *Plantago Psyllium* and a brown extractive matter. He attributes the effect of the drug to the tannin and mucilage, the former of which is present in considerable quantity. As, however, the bean is used as a diuretic in the West Indies it seems probable that it may contain some other active principle.

Dr. J. M. Gibbs, New Zealand, recommends (*Lancet*, February 24, p. 316) the use in diphtheria of an inhalation of steam impregnated with *Eucalyptus globulus*. In thirty-seven cases, in which the treatment was carried out, the patients recovered without a bad symptom. He found it especially useful in those cases in which the larynx was affected and where the patches in consequence could only be reached by steam. In influenza and laryngeal phthisis it was found equally useful. His mode of procedure is to pour boiling water on blue gum leaves and change the infusion every half hour. The leaves as procurable in this country would doubtless be less rich in volatile oil and the substitution of the oil would therefore be likely to prove more generally useful.

In the *British Medical Journal* (March 10, p. 449) Dr. Marion Sims gives an interesting account of the permanent cure of syphilis by the native Indians, the chief agent in the remedy being *Stillingia sylvatica*. The formula recommended is:—Fl. ext. *Smilax sarsaparilla*; fl. ext. *Lappa minor*; fl. ext. *Phytolacca decandra*, āā ℥ij; tincture of *Xanthoxylon Carolinianum*, ℥j; M. Take a teaspoonful three times a day before meals and gradually increase the quantity to a tablespoonful. The *Stillingia* root is said to lose much of its activity when kept for a long time.

In the *Medical Record* (Feb. 3, 1883) Dr. C. J. Macguire states that he has found subnitrate of bismuth very valuable in cancrum oris, curing the disease in twenty out of twenty-four cases. The powder was topically applied every three hours, after cleansing the mouth with a disinfecting solution.

Dr. E. A. Whiteley, of Duffield, points out (*Lancet*, March 10, p. 437) that the external application of salicylate of soda affords speedy relief when applied to painful joints in cases of acute rheumatism. The strength of solution used is 20 grains to the ounce of water.

As the result of an experimental investigation into the action of opium, chloral and bromide of potassium, Drs. Ringer and Sainsbury (*Brit. Med. Journ.*, March 24, p. 556) express the opinion that a salt now used rather extensively in America, viz., bromide of sodium, might probably be substituted with advantage for the last two, the salts of potassium being about ten times as poisonous as those of sodium, with regard to their action on the heart, and the bromide of sodium ranking far ahead of bromide of potassium, chloral or opium, as to innocuousness.

A substance called ichthyol, obtained by R. Schroter, by the distillation of bituminous substances and treatment with concentrated sulphuric acid, has been recently experimented with by Dr. P. G. Unna, of Hamburg. It is tarlike in appearance and has a peculiar and disagreeable odour, but does not resemble any known wood or coal tar in its chemical and physical properties. In consistence it resembles vaseline, and its emulsion with water is easily washed off the skin, whilst it may be mixed in any proportions with lard, oil or vaseline. Ichthyol is said to contain about 10 per cent. of sulphur and a small quantity of phosphorus, as well as carbon, hydrogen and oxygen, the sulphur, however, being in a state of combination which is not decomposed by preparations of lead and mercury. It is alleged to soothe pain and itching, and is considered a fairly good remedy in psoriasis and acne, and is useful as a parasiticide. In eczema it has been used with great benefit, the plan found most successful being to begin with a moderately strong preparation, or to reduce the strength gradually. For moist eczema 20 to 30 per cent. preparations reduced to 10 per cent., and for the papular condition 50 per cent. reduced to 20 per cent., are used. For obstinate eczema of the hand, the following formula has been found very efficacious:—Litharge, 10 parts, boiled with 30 parts of vinegar, to 20 parts; olive oil or lard, 10 parts; ichthyol, 10 parts. Any strength from a 5 per cent. to a 40 or 50 per cent. preparation may be used with safety undiluted. A stronger application may be used to the hands than to the face and stronger for children than adults.

At a meeting of the Medical Society of London on March 12 (*Lancet*, March 24, p. 500), a case of poisoning by citrate of caffeine was mentioned by Dr. Routh, in which the drug had been prescribed in drachm doses three times a day for the relief of severe headache in a man under treatment for debility. The report states that Bishop's effervescing preparation was intended, but the pure salt was sent. The difference in dose of an effervescent preparation and of the pure drug, which it is intended to exhibit in this way, should be more widely known than would seem to be the case, if one may judge from this instance.

Professor J. F. Eykman, in his research on the poisonous and other constituents of *Andromeda japonica*, Thunb., has found in the residuary liquid left after the separation of asebotoxin a crystalline substance which he calls "asebotin" (*New Rem.*, March, p. 66). It forms colourless needles easily soluble in hot or boiling water, but only slightly soluble in cold water, the solution having a very bitter taste. It is also soluble in dilute alkalies, the solution acquiring a brownish-yellow colour on exposure to the air. It has a neutral reaction and does not appear to be poisonous when injected hypodermically in doses of $\frac{1}{12}$ grain. When boiled with a dilute mineral acid asebotin splits up into asebogenin and apparently glucose. Asebogenin forms fine colourless needles, insoluble, or nearly so, in both cold and hot water; in absolute alcohol and ether and also in alkalies it is quite soluble. Asebotin differs from arbutin merely by the elements of water H_2O, its formula being $C_{24}H_{28}O_{12}$, but the two substances are not identical, the crystals of asebotin assuming a red-brown colour in a moist ammoniacal atmosphere, while those of arbutin assume a sky-blue colour under similar circumstances.

In Brazil the root and leaves of *Franciscea uniflora*, a scrophulariaceous plant, popularly known as "manaca," have long had a reputation in the treatment of syphilitic complaints, and have been called for this reason "vegetable mercury." Under the name of "manaca," the drug has been introduced in the United States as an alterative and as useful in the treatment of rheumatism. A specimen having been submitted to Professor Dragendorff for examination he reports (*Ther. Ger.*, iv., 63) that the presence of an alkaloid has been recognized, which acts energetically upon frogs in milligram doses, the respiration being at first accelerated, then retarded, followed still later by gradual diminution of the activity of the heart. The separation of the alkaloid in perfect purity is attended with great difficulty, since it cannot be isolated by shaking it out of aqueous solutions, neither can it be separated undecomposed by precipitation with potassio-mercuric iodide. It is worth mentioning that another drug had been previously received at Dorpat under the same name, which had decidedly different external characters and apparently had had another botanical origin.

"Jamaica dogwood" (*Piscidia erythrina*) is another "new remedy" that has been put forward in the United States, it being recommended as "a positive anodyne in the more purely idiopathic neuralgic affections," and a narcotic and calmative in insomnia arising from mental worry. A liquid extract of this drug has been recently examined by Dr. E. Hart, of the Chemical Department, Lafayette College, who reports (*Ther. Gaz.*, iv., 97) that he has isolated the active principle, which he has named "piscidin," by intimately mixing the liquid with a milk of lime, allowing the mixture to stand half-an-hour in a warm place, filtering and pressing, and adding water to the filtrate until it becomes slightly turbid. After standing a few days the piscidin crystallized out in prisms, and were obtained pure by recrystallization from alcohol. Piscidin is represented by the formula $C_{29}H_{24}O_8$. It is described as being insoluble in water, slightly soluble in cold alcohol and ether, much more soluble in hot alcohol, and freely soluble in petroleum spirit and chloroform. The alcoholic solution is neutral to test paper, and no separation of sugar is caused by boiling with dilute or strong acids. It does not appear what part was used in the preparation of this liquid extract; but according to some notes appended to the paper, the bark, when examined in the laboratory of Messrs. Parke, Davis and Co. yielded two resins, one acid and the other indifferent, minute quantities of a volatile oil, and indications of a volatile alkaloid.

The leaves of *Myrtus Chekan*, which were recommended some two years since by Dr. Murrell as a remedy in winter cough, have been submitted to analysis by Mr. J. Hoehn, who reports (*Weekly Drug News and Am. Pharm.*, vi., 238) that he has recognized the presence of three kinds of glucosides, (1) soluble in benzol and not in water, (2) soluble in benzol and in water, and (3) insoluble in benzol and soluble in alcohol. The leaves also yielded 4·2 per cent. of a tannic acid, and 3·7 per cent. of the volatile oil resembling oil of bay, first noticed by Mr. Hutchinson (*Pharm. Journ.*, [3], ix., 653).

In a recent trade circular, Herr Haensel, of Pirna, mentions that he had received from a mercantile house in Columbia, South America, a quantity of dried flowers derived from a plant described under the name "*Sulamita vitulus*," which grows abundantly on the eastern spurs of the Cordilleras and is used as a remedy in neuralgic affections. The flowers are said to possess in the fresh state a delicious aroma of such intensity that a single fresh flower laid amongst clothes is sufficient to impart to them a permanent perfume. Distillation of the dried flowers did not give results so favourable as was expected, the yield in essential oil not exceeding one-half per cent., which may have been due to loss occurring during the long journey. The oil was heavier than water, and in its odour markedly resembled salicylate of methyl, which is the principal constituent of oil of wintergreen and also sinks in water. The flowers sent, however, came from a Melastomaceous and not an Ericaceous plant.

At the suggestion of Professor Hegen, of Freiburg, Herr Merck has prepared a phosphate of codeine, which is believed to obviate the difficulty attending the use subcutaneously of the sulphate and hydrochlorate of this alkaloid, in consequence of their comparative insolubility. The phosphate of codeine is described as being soluble in 4 parts of water and containing 70 per cent. of codeine. The same firm prepares a hydrochlorate of cocaine (the alkaloid of *Erythroxylon Coca*), which is soluble in water in all proportions, whilst pure cocaine is only soluble with difficulty in water.

Mr. R. S. Christiani, in the *Oil, Paint and Drug Reporter,* gives a further account of "American musk." He remarks that for soaps and sachets and even for the musk lozenges sold by confectioners it answers well, but that for toilet waters and perfumes its use will be limited, for the odour, though strong, is not sufficiently delicate for a refined taste. The removal of the fatty matter, which seems to be liable to become rancid, would probably render the odour more agreeable. In consequence of the present scarcity of good musk and the consequent high price and scarcity of *Abelmoschus moschatus* it seems probable that the American musk may find a market here, especially as the musk rat (*Fiber zibethicus*), from which it is derived, frequents the marshes of most of the States of North America.

Ten samples of willow bark examined by Mr. Gessler (*Weekl. Dr. News,* vi., 182), with the object of ascertaining the yield of salicin, gave results varying from 1·06 to 3·13 per cent., but usually lying between 2·2 and 2·5 per cent.

It is well known that occasionally very unpleasant results follow the use of a preparation of arnica, which have been sometimes attributed to idiosyncrasy. So far as the tincture of the flowers is concerned Dr. Stieren is of opinion (*Ther. Gaz.*, iv., 9) that the inflammation noticed occurs only when a defective preparation is used, it being due to the non-removal by filtration of minute hooks, derived from the disk florets, which become imbedded in the flesh and cause irritation.

Various samples of commercial "veratrine," entirely soluble in ether and corresponding with the requirements of the German Pharmacopœia, have been the subject of an investigation by Herr E. Bosetti (*Archiv*, xxi., 81). They proved to consist of a very intimate apparently amorphous mixture of two probably isomeric alkaloids, represented by the formula $C_{32}H_{49}NO_9$, one of which is crystallizable and almost insoluble in water ("crystalline veratrine," the "cevadin" of Wright and Luff), whilst the other is not crystallizable, but is soluble in water ("veratridine," the "soluble veratrine" of Weigelin, Schmidt and Köppen). Relatively small quantities of the former suffice to render the latter insoluble in water, whilst a small proportion of the latter will prevent the crystallization of the former. When boiled with an alcoholic solution of barium hydrate, crystallizable veratrine splits up into amorphous "cevidin" ($C_{27}H_{45}NO_9$) and angelic acid; whilst the amorphous "veratridine" splits up into another amorphous base, veratroïne ($C_{55}H_{92}N_2O_{16}$) and veratric acid.

Dr. S. Zeisel reports (*Monatshefte*, iv., 162) that he has obtained from a solution of colchicine in chloroform a well-crystallized compound; but at present he is uncertain whether some chloroform, which persistently clings to the crystals, is only mechanically adherent or in chemical combination. The chloroform can, however, be easily removed by dissolving the crystals in water, and the aqueous solution gives all the essential reactions of colchicine. He also states that in converting colchicine into colchiceine by the action of very dilute sulphuric or hydrochloric acid he obtains as a bye-product the hydrochlorate or sulphate of a new votatile base, which he has named "apocolchiceine," and which is produced in larger quantity, together with methyl chloride, upon heating colchiceine with hydrochloric acid. If this heating of colchiceine be prolonged the apocolchiceine at first formed is converted into another substance, which has the properties of an acid. Colchicine, colchiceine and apocolchiceine are all altered by nascent hydrogen.

In the United States Pharmacopœia both strychnine and the sulphate of that alkaloid are official, the sulphate being described as a neutral salt, containing seven molecules of water of crystallization, and soluble in ten parts of water at 15° C. It having been recently stated (*Berichte*, xv., 1231) that strychnine sulphate of German manufacture, as met with in commerce, is an acid salt with only two molecules of water, Mr. Coleman has examined samples of the commercial salt of American manufacture in order to see how far they correspond with the official description. He reports (*Amer. Journ. Phar.*, xiii., 113) that as manufactured in the United States strychnine sulphate corresponds with the Pharmacopœia requirements in being a neutral salt,—or distrychnine sulphate,—but that it contains only six molecules of water of crystallization, and requires for its solution from 42 to 43 parts of water at 15° C.

In a note read recently before the Philadelphia Society (*Amer. Journ. Phar.*, xiii., 145) Mr. Lehman stated that in preparing the United States official tincture of iodine, which is a solution of 8 parts of iodine in 92 parts of 94 per cent. alcohol, the iodine can be rendered readily soluble, without trituration, by the addition of a little sodium chloride. Professor Maisch pointed out that considering the slight solubility of sodium chloride in strong alcohol this action was rather remarkable.

The *Pistia Stratiotes*, or "tropical duckweed," is a common tropical water-weed, occurring on pools of stagnant water in most parts of India, and having much the appearance of half-grown lettuce plants, to which it owes its West Indian name of "water lettuce." In some parts of India the mature plant is dried, incinerated, and lixiviated, and under the name of "páná salt" the saline product is used for medicinal purposes as a domestic remedy. Specimens of the plant and of the "salt" have been examined by Surgeon-Major Warden, who reports (*Chem. News*, March 23, p. 133) that the weed dried at 130° C. and carbonized yielded 31 per cent. of total ash, of which 6 per cent. was soluble. The sample of "salt" was slightly deliquescent, alkaline in reaction, and had the appearance of dirty common salt. Dried at 130° it yielded 73 per cent. of potassic chloride, 22·6 per cent. of potassic sulphate, and minute quantities of potassic carbonate, sodic chloride, calcic sulphate, magnesic sulphate, and ferric, aluminic and silicic oxides. According to Colonel Drury ('Useful Plants of India,' p. 34) the plant is cooling and demulcent and is given in dysuria, whilst poultices of the leaves are applied to hæmorrhoids. In Jamaica, in the hot dry weather, the *Pistia Stratiotes* is said to impregnate the water in which it grows with its particles to such an extent as to give rise to the bloody flux.

In an account of an investigation into the manner of formation of compound ethers, which was recently laid before the Société Industrielle de Mulhouse (*Chem. Zeit.*, vii., 321), Herr Pabst states that when alcohol, sulphuric acid and acetic acid are heated together, the formation of acetic ether takes place in three stages in a manner analogous to the formation of ordinary ether. In the first place there is a production of ethylsulphuric acid and water:—

$$C_2H_5OH + HO{\cdot}SO_2OH = C_2H_5O{\cdot}SO_2OH + H_2O.$$

In the second stage ethyl acetate is formed, whilst sulphuric acid is reformed and acts upon a fresh quantity of alcohol to convert it into ethylsulphuric acid:—

$$C_2H_5O{\cdot}SO_2OH + C_2H_3O{\cdot}OH = C_2H_5O{\cdot}C_2H_3O + HO{\cdot}SO_2OH.$$

Herr Pabst confirmed this by allowing methylsulphuric acid to act upon a mixture of acetic acid and ethylic alcohol, when he obtained methyl acetate and ethylsulphuric acid, the latter reacting with the remaining alcohol and acetic acid, yielding ethyl acetate; upon suspending the operation scarcely any methylsulphuric acid was found. Herr Pabst recommends as a practical method of preparing acetic ether the addition of equal molecules of strong alcohol and glacial acetic acid to ethylsulphuric acid heated to 135° to 140° C.

Herr Rammelsberg (*Ber.*, xvi., 273) describes a sesquicarbonate of potassium which had been produced by the evaporation of a large quantity of solution of bicarbonate of potassium in Struve's mineral water manufactory. The crystals, which belonged to the rhombic system, were represented by the formula ($2K_2CO_3,H_2CO_3.3H_2O$). The conditions under which they were formed are not understood, as all attempts at their reproduction failed. When a solution of potassium bicarbonate was exposed for a fortnight over caustic potash and sulphuric acid, so that half the carbonic acid was withdrawn, potassium carbonate was formed. By heating a solution of potassium bicarbonate until half the carbonic acid has been expelled, potassium carbonate was formed in the solution, whereas in order to obtain the sesquicarbonate it is theoretically necessary to expel three-fourths of the carbonic acid.

In the same number of the *Berichte*, Professor Spring describes some more chemical compounds which he has produced by submitting the elements in a fine state of division to a pressure of 6500 atmospheres. In this way the arsenides of zinc, lead, tin, cadmium, copper and silver were obtained and behaved normally under the influence of chemical reagents.

Messrs. Kelbe and Lwoff (*Ber.*, xvi., 351) have found methyl alcohol among the numerous products yielded by the destructive distillation of resin (colophony). It occurs in the aqueous portion of the distillate, together with acetic acid and the higher acids of the same series. One hundred and fifty kilograms of the commercial product yielded about 50 grams of pure methyl alcohol.

The recently issued Report by the Medical Officer to the Local Government Board contains an account of some observations of Dr. Klein upon septic bacteria, which have an interesting bearing upon the "attenuation" theories of M. Pasteur. Dr. Klein finds that the specific bacillus of a disease, such as anthrax, undergoes in the course of its own proper life remarkable changes in its powers. For instance, as a consequence of the formation of spores in the bacilli the material containing them appears to acquire a new virulence; it is, therefore, important to know that the formation or non-formation of these spores is largely a matter of definable circumstance and condition. Further, after several weeks of growth in any of the cultivation materials used by Dr. Klein the anthrax bacillus was found to undergo degeneration, but apparently through exhaustion of pabulum. This alteration, however, was not of the nature of "attenuation," since, if any effects were produced by inoculation with the liquid they were of the same fatal nature as before the alteration, and the change was in the number of active bacilli and not in the potency of those who remained active. Dr. Klein has not been able to discover any indication of such a loss of intensity during successive cultivations as would allow of the material of a late cultivation being introduced into the body of an animal as a protection against the disease, or without killing or doing the animal serious injury. Therefore, whilst Dr. Klein guards himself from throwing doubt on the discovery by M. Pasteur of a material protective against fatal anthrax in sheep, he says that something more is required for the production of an "attenuated" virus than the recognized method of successive cultivations in organic liquids at 42° C., and that these conditions have not transpired from M. Pasteur's laboratory.

Professors Liveing and Dewar have been working on the reversal of the principal lines of hydrogen, and their results are embodied in a paper read before the Royal Society on March 8, entitled "Spectroscopic Experiments with the Arc." They find that when a short induction spark is taken between electrodes of aluminium or magnesium in hydrogen at atmospheric pressure, a large leyden jar being in the secondary circuit, no reversal is obtained; but on increasing the pressure by half an atmosphere, the lines expand, and a fine dark line may be seen in the middle of the F line. As the pressure is increased the dark line becomes stronger, so that at two atmospheres it is very decided. As the F line expands the dark line expands too and becomes a band. It is best seen when the pressure is between two and three atmospheres; at higher pressures it becomes diffuse and at five atmospheres it can hardly be traced. No definite reversal of the C line is observed with the dispersion of a one-prism spectroscope. By using greater dispersion than this, however, the reversal of both C and F lines was observed at lower pressures. The authors find that both the C and F lines of hydrogen are visible in the arc of a De Meritens machine taken in hydrogen, but in the arc of a Siemens machine the C line can only be detected at the moment of breaking the arc, the F line hardly at all. If instead of taking the arc in hydrogen, small drops of water are allowed to fall from a fine pipette into the arc taken in air inside a lime crucible, each drop, as it falls into the arc, produces an explosive outburst of the hydrogen lines. Generally the outburst is only momentary, but occasionally a sort of flickering arc is maintained for a second or two and the hydrogen line C is visible all the time. The lines C and F are usually much expanded, but are frequently very unequally wide in different parts of the line. F is weaker, more diffuse, and more difficult to see than C and is visible for a shorter time. There is no sign of reversal. In the explosive character of the outburst and the irregularity in the width of the lines, the effect resembles that of an outburst of hydrogen in the solar atmosphere.

Mr. W. H. Preece has contributed an elaborate and valuable paper to the Royal Society on "The Effects of Temperature on the Electromotive Force and Resistance of Batteries." The author concludes from his very numerous experiments that changes of temperature do not practically affect electromotive force, but that they materially affect the internal resistance of cells; also, that of the various forms of batteries in practical use, the Daniel is the most seriously influenced by variations of temperature, and that in all experiments with that battery, either the temperature must be kept constant or frequent measurements should be taken of its internal resistance, and allowances made for the variation.

It is reported that a test of a telephone between New York and Chicago, a distance of one thousand miles, has proved a great success. The result is attributed principally to a novelty in the conductor, which consisted of a steel wire core, copper plated, the electrical resistance of which through this distance was only 1522 ohms, instead of upwards of 15,000 ohms, which would represent the average resistance of ordinary telephonic wire.

Herr Pringsheim has contributed (*Annalen*, 1883, No. 1, *Phil. Mag.*, Feb.) an exhaustive paper detailing experiments made to exactly determine the cause of radiometer motion. In a perfectly simple radiometer, freed from needless complications of technical construction, there are three essential parts, all or each of which might conceivably affect motion: the glass case, the enclosed gas, and the vanes. A radiometer was therefore constructed which excluded as far as possible the introduction of conditions other than these. It consisted of a tube having a bulb at one end and a stopper fitting airtight at the other; on the end of a long glass thread suspended from the stopper was cemented a very thin microscope covering glass, silvered at the back, which thus formed a mirror; to the back of this was affixed one side of a small rectangular disk of mica, which acted the part of the vane in an ordinary radiometer. The apparatus was then exhausted by means of parallel arms let in just below the stopper. The readings were taken in the ordinary way by reflection to a graduated scale. The first experiments were made to determine the part played by the glass case. To eliminate the difference in temperature of the two sides of the vane, which occurs when one side of a thick plate is heated, an extremely thin mica plate was used, and thus also the absorptive power was reduced to a minimum. When the glass case was heated by a Bunsen burner upon that side which was nearest to the vane, powerful repulsion occurred; that is to say, the mica plate receded from the source of heat. If it be assumed that the sides of the mica vane are of the same temperature, this effect would be due to the heating of the glass tube. This was actually proved by a later experiment, when the side of the glass case which was farthest from the vane was heated, the vane itself being at the same time shaded so that it was outside the cone of heat, and yet repulsion occurred, though, of course, not to the same extent as in the first experiment. In fact, it was subsequently shown that the whole of the repulsive effect was produced by the heating of the portion of the glass case immediately opposite the mica vane. Under the above conditions, where the vane is not directly heated, the result is unaffected by the nature of the vane; a mica vane, blackened on one side and hence possessing absorptive power in the highest degree, gave practically the same result, when each side was alternately shaded and the glass case alone heated, both sides of the vane being repelled to the same extent. Hence the repulsion is a direct effect of the heat communicated by the glass case through the particles of residual gas to the vane suspended in front, and not a secondary one due to the absorption by the vane of heat radiated from the case; thus the amount of this motion is not affected by the nature of the vane. Having thus determined the action of the glass case, it remained to investigate that of the residual gas and of the vanes. The residual gas was found in no way to directly concern the phenomena. When the vanes were made of different substances and directly heated some interesting facts were observed. When a mica plate was blackened on one side and heated on the clear side, first attraction occurred, then oscillation, followed by repulsion. This was due to the conduction of the heat through the thin mica plate to the lampblack, hence the apparent attraction; then the slow heating of the mica plate, when the normal repulsion occurred. The results of these experiments and of others with metallic vanes showed that conduction of heat from one side of the vane to the other is one of the most important factors in radiometric motion. The results of all the experiments upon radiometer motion are summed up in the following general statement or law. A surface element (vane) at which heat enters or leaves the rarefied air undergoes a repulsion of which the amount is proportional to the intensity of the heat current. The author adopts the kinetic theory to explain radiometer motion; the air molecules are heated by the glass case and then rebound to the vane and thus repulsion occurs.

The increased range of rifled arms, involving the exposure of troops to the effects of firing at greater distances, has rendered it very important that for active service, at least, a uniform should be adopted which is as little conspicuous as possible, and a "Colour Committee" appointed to experiment and advise the Government as to the comparative visibility of different colours suitable for military uniform has just presented its report on the subject. The experiments, which were under the immediate superintendence of Professors Abel and Stokes, were carried out under varying conditions of weather, atmosphere, surroundings and background, and the general result was to eliminate all the colours at present used in the dress of the regular army. It is reported that under ordinary circumstances white is much the most conspicuous, and black, with which the dark green and dark blue of the service are practically identical, is also extremely conspicuous. The scarlet of the service is, as might be expected, very conspicuous, but its relative rank depends upon the amount of light; in a bright light it is more conspicuous than black, though not equal to white, but on a dull day and at a considerable distance scarlet and black are almost equal, whilst in a failing light black would be the more conspicuous. Red and crimson are a little less conspicuous than scarlet. The nearest approach to invisibility is attained by the use of neutral or nearly neutral tints, such as are met with among the service colours of the volunteers, and it depends far more on a proper depth of shade than on what the tint may be. Of course the conditions of invisibility on the sky line are very different.

CULTIVATION OF CINCHONA IN JAMAICA.*

Notes on Specimens of Cinchona sent to the Pharmaceutical Society of Great Britain from the Government Plantations.

BY D. MORRIS, M.A.,

Director of Public Gardens and Plantations in Jamaica.

No. 1. *Cinchona officinalis*, of the ordinary type of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit and seed. Three kinds of bark, viz., root, stem and twigs. All the specimens with the exception of the seeds (in a separate packet) have been taken from the same tree, so that botanical specimens as well as samples of bark, are exactly identical.

With reference to this species of cinchona in Jamaica the following extract from official reports and letters from Mr. John Eliot Howard, F.R.S., on similar specimens will be of interest.

"*Cinchona officinalis* of the Jamaica plantations.—The average price per pound on all qualities, viz.: root, stem and branch bark, 6*s*. 7*d*.; highest price realized, 10*s*. 1*d*. per pound for root bark; lowest price realized, 2*s*. 3*d*. per pound for twig bark."

The tree from which the specimens were taken was about nine years old, and growing at an elevation of 5500 feet. Mr. Howard's analysis of the trunk bark is as follows:—

Quinine alkaloid	5·18	= Quinine Sulphate	6·95
Cinchonidine	0·22		
Cinchonine	0·01		
Quinidine	0·15		

Mr. Howard adds:—"This bark does not require many observations, as the price per pound agrees with the appearance of the bark and with the analysis in showing that it is good *Cinchona officinalis*, perhaps of slightly varying forms."

No. 2. *Cinchona succirubra*, of the ordinary type of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs; all the specimens have been taken from the same tree.

"*Cinchona succirubra* of Jamaica plantations. Average price per pound on all qualities, viz., root, stem, and branch bark, 4*s*.; highest price realized 5*s*. 7*d*. per pound for root bark; lowest price realized 1*s*. 3*d*. per pound for twig bark." Specimens sent from trees nine years old, growing at an elevation of 5000 feet. Mr. Howard reports on this bark as follows:—"Very good and true *Cinchona succirubra*, agreeing well with my specimens from South America. It is a *sub-pubescent* form."

No. 3. *Cinchona hybrid* of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs. All the specimens have been taken from the same tree. Supposed to be a hybrid form between *Cinchona succirubra* and *Cinchona officinalis*. Up to 1879 it was considered by Mr. Thompson to be *Cinchona Calisaya*. Average price per pound on all qualities, viz., root, stem and branch bark, 6*s*. 1⅝*d*.; highest price realized 7*s*. 9*d*. per pound for trunk bark; lowest price realized 4*s*. 6*d*. per pound also for trunk bark. The specimens taken from a tree nine years old, growing at an elevation of 5300 feet. Mr. Howard's analysis of trunk bark is as follows:—

Quinine alkaloid	6·00	= Quinine sulphate	8·00
Cinchonidine	0·73		
Cinchonine	0·10		
Quinidine	0·03		

Mr. Howard adds "What proof is there that this is a hybrid? What connection with Calisaya? It is an excellent bark, resembles true *Cinchona officinalis*, var. *Uritusinga*." In another communication Mr. Howard remarks, "It is evident that the so-called 'hybrid' No. 4, if only it is a free grower, must be about the most valuable of all the sorts. The price obtained in commerce does not seem proportional to its value; but possibly, as remarked before, it may be an exceptionally fine specimen. So far as I can judge by the botanical specimens it is a true form of *Cinchona officinalis*."

With regard to the above remarks on this "hybrid" form, I would mention that although in single specimens of leaves, flowers, etc., it is almost impossible to decide its hybridity, yet on the plantations, where all gradations may be distinguished from among these trees, from almost the pure *succirubra* type to almost the pure *officinalis*, there can be no doubt of their origin. Again, when seed of this kind was sent to Kew the seedlings and plants were pronounced of a decidedly "hybrid" character; and, lastly, although following Mr. Thompson's classification, I shipped the bark at first to the London market as "Calisaya?", the brokers in their report drew my attention to it and remarked, "It is not pure yellow bark, but supposed to be a hybrid with *succirubra*." It is nevertheless gratifying to find that this bark is of so valuable a character, and as it is a free grower at lower elevations, steps are being taken to propagate it for general distribution. According to the analysis of the specimen bark sent to Mr. Howard its market value would not fall far short of 14*s*. per pound.

No. 4. *Cinchona Calisaya* of the Government

* Read at an Evening Meeting of the Pharmaceutical Society, March 7, 1883.

Plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs. All the specimens have been taken from the same tree. These trees are about 9 or 10 feet high at five or six years old; they were formerly included under *Cinchona officinalis.* Their compact hardy habit and early maturing render them very suitable for steep slopes. Mr. Howard's analysis of trunk bark is as follows:—

Quinine alkaloid	3·70 =	Quinine sulphate	4·93
Cinchonidine	0·60		
Cinchonine	·35		
Quinidine	·05		

Mr. Howard adds "these trees appear to me to be true to the Calisaya type and form a valuable portion of the plantations. I should not think they belong to either the Josephiana or the Ledgeriana form, but that the exact variety is perhaps not yet published. In the meantime it might be well to call them *Cinchona Calisaya* simply. There is no appearance of 'hybridity' nor any resemblance to the Loxa (officinalis) barks."

No. 5. *Cinchona Ledgeriana.* Specimens of the leaves and flowers from one of three plants (the broad leaved form) of this species sent out by Mr. John Eliot Howard, F.R.S., through the Royal Gardens, Kew, in 1880. For description and plate of the original of these plants, see *Gardeners' Chronicle*, 1880, vol. 12, p. 457. The plant from which the specimens were taken was 6 feet high: some trunk bark is sent herewith.

No. 6. Specimens of leaves and flowers of a tree supposed to be *Cinchona micrantha*, not determined.

SECONDARY BATTERIES.*

BY H. ALLEN, B.SC.

I have thought that a brief account of the latest improvements in secondary batteries, accumulators, or storage cells, as they are variously called, as well as of recent investigations touching the chemistry and general behaviour of the same, might be of interest to the members of this Association. And since the ideas of the general public, and even of students, on the subject of electricity are apt to be more extended than precise, I propose to introduce the subject by a few remarks on the nature of the voltaic cell, and of storage cells in particular.

The voltaic cell may be defined as an arrangement for transforming chemical energy into a current of electricity. To produce a current of given energy for a given time a definite amount of chemical energy has to disappear. The energy of such current can be stored up, or converted into motion, or may pass immediately into the form of heat and its availability be thereby diminished or lost.

The materials generally used in the cell for the production of the current are two different elementary solids and one or more compound bodies, one at least liquid, separating them.

When a plate of copper and a plate of zinc are placed in contact, a difference of potential or electro-motive force is produced, the zinc becoming positive and the copper negative. This difference of potential corresponds to difference of level in the case of water or to difference of pressure in the case of gases. Suppose two such plates touching at two points, a current tends to flow in the copper towards both points of contact, but such tendency is at one and the same time in opposite directions so that no actual current is produced, but only a certain amount of something analogous to strain. If, now the plates still touching at one point be separated at the other by a liquid, such as dilute sulphuric acid, this "strain" is relieved by the chemical action of the acid upon the zinc and the current is free to flow throughout the circuit from copper to zinc through the external contact and from zinc to copper within the liquid, or electrolyte, and this current will continue as long as the requisite energy is supplied by the combustion of the zinc.

The strength of the current (C) in any circuit varies (1) directly as the electro-motive force (E) of the producing cell, which depends solely upon the materials employed, and (2) inversely as the total resistance (R) of the circuit and cell, that of cell depending on the size of the plates, their distance apart and the nature of the electrolyte separating them. If then E and R be known, C is immediately determined without any reference to what is vaguely known as the size of the cell. *The size does not enter as a separate factor into the determination of the current producible by any cell,* any more than the quantity of water in an elevated cistern determines the rate at which it can be drawn off by a given pipe or the pressure which it is capable of exerting.

The energy of the current, *i.e*, the work it is capable of doing, is equal to the product of E and C. If E be expressed in volts and C in ampères and t be put for time of duration of current in minutes, then work done by cell $= E \times C \times t \times 44{\cdot}25$ foot lbs. This energy may be spent entirely in heating the cell and circuit, the heating effect in any part varying with its resistance, or it can be stored up or converted into motion.

A simple analogy may be of use in explaining what has been stated. Suppose a closed circuit of water pipes with a force-pump at some point of it worked by a spring. The pump will produce a continuous current in the circuit, the amount of water circulating in a given time depending partly on the pressure of the pump-piston, and partly on the size of the pump and pipes. The energy imparted to the water may be spent entirely in friction against the pump and pipes, the friction and consequent heating effect being greatest where there is the greatest resistance to the flow. But the water might be made to work a second pump and thereby wind up a second spring. In this case the energy of one spring is transferred by means of the water to the other spring, but of course there is no storage of water. Lastly, if water were continually supplied to the pump from a cistern, it could be raised to a higher cistern and there stored up.

The energy of the voltaic cell can be stored up in two ways somewhat analogous to the above. The electricity produced by chemical action in the cell can be stored up *as such* in a Leyden jar, just as the water in the pump just mentioned might be stored in a cistern. But it can also be transformed again into chemical energy and retained as such for future use, the current being merely used as a carrier of the energy, just as the water was the means used for transferring energy from one spring to the other. An arrangement for effecting this object is called a secondary battery, or a storage cell. *Such cell does not store electricity.* In fact there is no more electricity in it than in a pound of zinc or a quart of acid, but it contains bodies capable of acting chemically on each other and thus supplying the requisite energy for the production of a current of electricity. It differs from an ordinary cell merely in the fact that the materials used are manufactured in the cell itself instead of being put in ready made.

A storage cell, then, may be defined as an arrangement for transforming the energy of a current of electricity into chemical energy and retaining the same available for the reproduction of the current. The following experiment illustrates the mode of action. One form of Daniell's cell consists of a plate of copper immersed in

* Paper read before the School of Pharmacy Students' Association.

solution of copper sulphate and a zinc plate immersed in solution of zinc sulphate, the direction of the current being from zinc to copper within the cell. The energy of the current is supplied by the combustion of the zinc, $ZnZnZnSO_4CuSO_4Cu$ becoming $ZnZnSO_4ZnSO_4CuCu$. If a current from two such cells be sent through a third cell consisting of two copper plates immersed in solution of zinc sulphate, zinc is deposited on one plate and copper taken off the other, $CuZnSO_4ZnSO_4CuCu$ becoming $CuZnZnSO_4CuSO_4Cu$. The current flows through this cell from copper to zinc, *i.e.*, to the plate which has become coated with zinc, and the cell has become, in fact, a Daniell's cell ready to produce a current in the direction opposite to that of the forming current.

If the above be clearly understood, the theory of the storage cell is known It will be at once seen that the E. M. F. of the charging battery or machine must exceed that of the cell to be charged, but it is not necessary or desirable that it should exceed it by a large amount. The strength of the charging current will generally exercise an effect on the nature of the products formed, and, therefore on the E. M. F. of the cell. Thus the E. M. F. of a gas battery (a form of secondary battery) varies from 1·49 to 3·57, according to the mode of formation.

Various forms of storage cells have been devised since the original cell of M. Planté. Planté's battery and Faure's accumulator are well known. Cells embodying the latest improvements in the latter of these are now being supplied, under the name of Faure-Sellon-Volckmar accumulators, by the Electrical Power Storage Co., Limited, of Great Winchester Buildings, E.C., who have kindly sent a few of these cells for exhibition and have supplied me with information as to their construction, etc. Each cell consists of a number of lead plates cast in the form of window frames, the apertures being square of about ¼ inch side. The positive plate, corresponding to the zinc plate of a Daniell's cell, has its apertures filled up with litharge made into a paste with dilute sulphuric acid, and the negative plate is filled in with a paste of red lead and acid. There is no felt or other such material to separate the plates, but they are just kept apart by india-rubber bands. The advantages of this arrangement are—(1) that the red lead is prevented from falling away from the plates; (2) that there is less chance of short circuiting than where felt or canvas is employed.

The plates, alternately + and –, are immersed in sulphuric acid of sp. gr. 1·25 (about 27 per cent.). The resistance of the small cells is about ·003 ohm and the E. M. F. 2·15 volts.

Sutton's cell has been already described in these pages, but I not aware that it possesses any particular advantages. Swan has found that a pair of lead plates that have been used as negative plates in a Sutton's cell can be advantageously employed in the construction of a Planté cell.

A storage-cell when made has to be "formed," *i.e.*, got into working condition. This, which was a most tedious process in Planté's cell, is accomplished in Faure's cell by one charging with a powerful current, and occupies fewer hours than the former required weeks.

For a particular cell there will be an economic rate of charge and discharge; thus, for what is termed a 1 horse-power cell (weighing about 30 lbs.), *i.e.*, a cell that will yield as much energy as a horse-power or 33,000 foot lbs. per minute continued for one hour, that is 1,980,000 foot lbs., the rate of charge recommended is 20 to 25 ampères, and that of discharge is 30 to 40 ampères. If these conditions be observed the cell should yield over 90 per cent. of the energy put into it, the loss being due to the heating of the cell during charge and discharge, which heating it is impossible altogether to avoid, though it may be diminished indefinitely by keeping the E. M. F. of the charging battery or machine as little as possible above that of the storage-cell. By so doing, however, the rate of charging is diminished, so that practically a sensible amount of loss must be submitted to. If E, R, be the E. M. F. and resistance of the charging cell and e, r, that of the storage cell—

the total work spent in charging $= \dfrac{(E-e)E}{R+r}$

the loss by heat in both cells $= \dfrac{(E-e)r}{R+r}$

the energy stored $= \dfrac{(E-e)e}{R+r}$

Hence it follows that the greatest economy is obtained by increasing both E and e, while their difference is kept as small as practicable, *i.e.*, a number of cells should be charged in series from a powerful machine, with just sufficient E. M. F. to send a current through them.

In conclusion, I wish to call your attention to a few points connected with the chemistry of the cell, with especial reference to the investigations of Messrs. Gladstone and Tribe, published in *Nature* last year. When dilute sulphuric acid is electrolysed between lead plates by a powerful current, the oxygen formed becomes partially ozonized and forms peroxide of lead on the plate at which the current enters, the first action being $PbH_2SO_4PbPb = PbH_2PbSO_4Pb$; then the ozone formed by further action attacks the sulphate which adheres to the plate, forming peroxide of lead (PbO_2) and reproducing the acid. This action occurs in Planté's cell. When the cell is at rest after charging, the lead with its coat of peroxide is gradually attacked by the acid, hydrogen is evolved and lead sulphate formed again. This local action, as it is termed, is well known in other cases, particularly in the zinc and copper couple, which is capable of decomposing water, and is violently attacked by dilute acid. In the case of lead, however, the action is delayed by the insoluble nature of the sulphate formed, and to this insolubility is probably due the practicability of the Faure cells. In Planté's cell, after a rest, the current was reversed, when the peroxide or sulphate previously formed became reduced to spongy metal and the other plate in turn became peroxidized. By repeating this process, both plates became coated more and more thickly, the one with spongy metal, the other with peroxide.

Let us now consider the case of the latest modification of the Faure cell. Here starting with $Pb3PbO\ Pb_3O_4$ Pb, neglecting the acid, we obtain by charging $Pb3Pb$ $3PbO_2Pb + O$; in the presence of acid part of both oxides is converted into sulphate, forming $Pb,3PbSO_4$ $2PbSO_4,PbO_2,Pb$, and the sulphate is reduced and oxidized in the same way as the oxide. The reduction of the latter part of the sulphate appears to be effected with considerable difficulty, hence the oxidizing action is completed first, unless the quantity of litharge used be proportionally less than that of the red lead. During the charging the local action above referred to occurs continuously, so that the oxidation of the sulphate will never be quite complete. In the discharge reverse actions occur, the spongy lead being oxidized and the peroxide reduced, but as there is always a considerable quantity of each of these left, mixed with the sulphate, the appearance of a discharged cell differs little from that of a charged one. If discharged very rapidly the E. M. F. sinks almost to *nil*, and the current falls off. This, according to Messrs. Gladstone and Tribe, is due to the formation of a film of peroxide on the spongy metal of the positive plate, whereby both plates become alike. On leaving the cell at rest for a short time this peroxide is reduced, and the E. M. F. and current rise to their previous amount. This action is of the same nature as that which occurs in ordinary single fluid cells, and is known as polarization.

When a storage cell is at rest the local action above-mentioned goes on continuously, and hence the energy of the cell gradually runs down.

The Pharmaceutical Journal.

SATURDAY, MARCH 31, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CULTIVATION OF CINCHONAS.

THE very interesting series of Jamaica cinchona barks, accompanied by leaves, flowers, fruits and seeds of the plants from which they had been taken, which attracted the attention of visitors to the last Evening Meeting of the Pharmaceutical Society, supplemented as it has since been by an even more extensive series from the Indian Government plantations at Ootacamund, which will be shown on Wednesday evening next, will contribute to a realization of the great importance that the experiments in cinchona cultivation in different parts of the world are now assuming towards pharmacists or consumers of bark. It is indeed a matter for congratulation that the authorities at the Indian and Colonial Offices have complied so liberally with the request of the Council of the Pharmaceutical Society, that typical specimens grown in the Government plantations should be made accessible to the inspection of British pharmacists by being placed in the Society's Museum, especially as they are accompanied by useful information as to their history and characters, such as has been furnished by Mr. MORRIS, and appears on another page of this number of the Journal. Whilst the subject is thus somewhat prominently under notice, it will be opportune to quote from two official reports that have just been issued some statements bearing upon cinchona cultivation in India and Jamaica.

From the new Report on the Trade of British India we learn that the exports of cinchona bark from that country during the year 1881–82 showed a considerable decline as compared with the previous year, the quantity being only 428,497 pounds against 699,258 pounds in the previous year, the fall in value being from Rs. 7,24,705 to Rs. 4,58,340. This decline, however, does not appear to be attributable to any decrease in the production of the plantations, but to the fall of price in the European market caused by the enormous importations of cuprea bark from South America. Indeed the Collector of Customs at Calcutta expressly states that, if necessary, there could have been larger shipments made than in the preceding year, the trees not having been barked in consequence of the lowness of price. It must not be assumed, however, that the figure reached was therefore one below the point at which cinchona cultivation can be carried on in India profitably; for the bark was simply withheld in expectation of a rise in the market. But should the decline in value prove permanent, the Report says there can be no reason to doubt that the industry is one which has a very hopeful future, notwithstanding it may have to compete with importations from South America. The bark is exported almost exclusively from Calcutta and Madras, a very small quantity being sent from British Burmah. The quantity exported from Calcutta, which is said to represent almost entirely the exports of one company in the Darjeeling district, amounted in 1881–82 to 249,694 pounds, valued at Rs. 1,86,795; the exports from Madras amounted to 178,467 pounds, valued at Rs. 2,71,195. These figures show that the average price of the bark shipped from Calcutta was very much below that shipped from Madras.

It is interesting to observe in the face of the foregoing figures, suggesting an accumulation of bark in the country, that the imports of quinine rose during the same time enormously, having amounted to 10,615 pounds, valued at Rs. 9,98,631, in 1881–82, against 3964 pounds, valued at Rs. 4,29,515, in 1880–81. As these figures show that the large increase in the quantity of quinine imported was accompanied by a considerable fall in price, it is probable that both the decrease in exports of bark and the increase in imports of quinine were to a considerable extent due to the disturbing influence of the enormous supply of cuprea bark thrown upon the market as raw material. The figures, however, have a further significance, since they show that a low-priced quinine is capable of driving all its competitors out of the field. In the previous report it had been remarked that the "cinchona alkaloid" had been largely used in preference to quinine, and to this preference was attributed some falling off in the imports of quinine; but the larger consumption of the mixed alkaloids would now appear to have been based rather upon economical considerations. The increased demand for quinine may, however, have been due to some extent to the fact that although the general health of the country was fairly good during the year, there were severe outbreaks of malarious fever in certain districts in Bengal; whilst in parts of Northern India also fever was more than usually prevalent.

A Supplement to the *Jamaica Gazette* of the 22nd ult. contains the report of the Director of Public Gardens and Plantations in Jamaica for the year ending September 30, 1882. In this Report Mr. MORRIS states definitely that the purpose of the Government in establishing cinchona plantations in Jamaica,—namely, to show that cinchona barks of good quality could be produced in the island, and that cinchona planting, as an enterprise in private hands, possesses all the elements of a remunerative industry,—has been attained, these points having been demonstrated by the returns from the sale of Jamaica-grown barks during the last three years. It is therefore proposed henceforth to devote the chief attention in the Government plantations to the introduction and cultivation, on a small scale, of all new and rich kinds of cinchonas, with a view to establishing them as far as possible in the island, and to carrying on experimental and scientific work in connection with the industry, such as is not likely at present to be undertaken by private individuals. The extent to which Mr. Morris has succeeded in impressing upon others his conviction as to the remunerativeness of cinchona cultivation is shown by the fact that during the year the sales from the Government nurseries to private planters amounted to 372 ounces of seeds, 77,961 plants and 362,250 seedlings of various species of cinchona, *C. officinalis* appearing to be the one most in demand. One shipment only of bark to Europe was made during the year, and this consisted for the most part of "thinnings" or "prunings" from two plantations, rendered necessary by the too abundant growth of established trees and self-sown seedlings. Notwithstanding, however, that the consignment, amounting to 21,512 pounds, consisted consequently principally of twig and broken bark, and the somewhat unfavourable condition of the market, the results were very satisfactory, the net amount realized being £2419 5*s.* 7*d.*, the prospective estimate having only been £2000. As compared with consignments from other countries the prices obtained for this Jamaica-grown bark were very encouraging. The highest price, 8*s.* per pound, was paid for 248 pounds of root bark of *C. officinalis*, taken from trees eight or nine years old, whilst a large package of stem bark realized 4*s.* 11*d.* per pound. The largest parcels were 7844 pounds of "small branch" bark which fetched 3*s.* per pound, and 6151 pounds of twig bark, derived from young shoots and saplings, probably not more than a year and a half old, which realized 1*s.* 5*d.* per pound. Since the actual cost of barking, curing and shipping amounted to only about 7½*d.* per pound, it is evident that even these young growths yielded a fair margin of profit.

PHARMACY IN VICTORIA.

The receipt of the Second Triennial Report of the Pharmacy Board of Victoria enables us to take a brief glance at the results following legislation in restriction of the practice of pharmacy in one of the most important of British colonies. At the end of six years after the passing of the colonial Act, the Pharmaceutical Register of Victoria contains 669 names, showing an increase of 62 during the period covered by the Report. Registration is obtainable as a "pharmaceutical chemist" under this Act either in virtue of having had a certain status at the time of the passing of the Act, possessing the qualification of the Pharmaceutical Society of Great Britain or some recognized examining board, or passing one of two examinations—the Major or the Modified—before the Victoria Pharmacy Board. It will, therefore, be interesting to notice to what extent a qualification which it has been suggested should be made interchangeable with the English one is being conferred as the result of passing an examination test. The Major examination is open only to persons who have served not less than four years' apprenticeship and attended one course of lectures and passed an examination at a recognized school in materia medica and medical botany, and in practical chemistry, besides having passed an examination before the Board in practical pharmacy. Three of these examinations have been held in the three years, at which there have been five candidates, all of whom passed. The Modified examination is open to persons who have served more than three years' apprenticeship, the apprenticeship having commenced three months before the passing of the Act. There have been twelve of these examinations held in the course of the three years, at which there have been 36 candidates, of whom 26 passed. As during the same period there were 99 registrations effected, it follows that 58 persons became entitled to call themselves "pharmaceutical chemists" without having undergone examination, against 41 who passed either the Major or the Modified.

The Preliminary examinations appear to give promise of a larger number of candidates for the Major in future years, twelve examinations having been held, at which there were 112 candidates, of whom 68 passed. We notice with satisfaction that, in virtue of powers conferred upon the Board, a regulation has been passed making it compulsory for every person, before entering into articles of agreement to be an apprentice within the meaning of the Act, to pass the Preliminary examination. A further provision also makes it compulsory to register the apprenticeship indentures within three months of their execution.

A number of prosecutions under the Victoria Pharmacy Act have been instituted during the last three years, and one of them deserves especial mention. It was in respect to a "pharmaceutical chemist" who had been tried and convicted for manslaughter. The Board thereupon took proceedings against him under the section of the Act relating to erasure for improper conduct, on the charge of "practising surgery other than in accordance with the rights and privileges of chemists and druggists in their open shops." The defendant, being convicted, was sentenced to three months' imprisonment and fined one shilling, and on the recommendation of the Board, his Excellency the Governor in Council approved of his name being erased from the Register.

The Pharmacy Board of Victoria is also entrusted with the administration of the colonial "Sale and

Use of Poisons Act," and upon urgent representations that "poisons" were being sold by grocers, ironmongers, and others, as "vermin killers," without restriction, it took action and instituted prosecutions in upwards of fifty cases. The results were, however, hardly satisfactory, since although convictions were obtained the penalties imposed by the magistrates were not such as to warrant the Board in continuing to bring forward fresh cases. In concluding its Report the Board expresses an opinion that the Act at present in operation regulating the sale of poisons is imperfect in many respects, and a hope that at no distant date an amendment of the Act may be brought under the consideration of the colonial legislature.

EVENING MEETING.

THE last Evening Meeting of the Pharmaceutical Society for the present session will be held on Wednesday evening next, at half-past Eight o'clock, when the following papers will be read:—"The Bitter Principle of *Hymenodictyon excelsum*," by W. A H. NAYLOR, F.C.S.; and "Remarks on Medicinal Plants of Ceylon," by W. C. ONDAATJE, F.L.S., Colonial Surgeon of Ceylon. As mentioned on another page, a complete series of barks and herbarium specimens, illustrating the varieties of cinchona plants cultivated at Ootacamund, have been received for the Society's Museum through the Secretary of State for India. These will be placed on the table and will no doubt add greatly to the interest of the meeting.

If original research is really to be fostered by subsidies, sanitary science ought to make considerable progress under the influence of the liberality of the Grocers' Company. This guild has announced its intention to establish three Research Scholarships, each of £250 a year, the holders of which are to devote themselves to researches as to the causes of important diseases and the means by which these causes may be prevented or obviated. Besides these Scholarships there is to be a Discovery Prize of £1000, to be awarded once in four years as a reward for original investigation that shall have resulted in important additions to exact knowledge in specified sections of sanitary science. Two of the appointments to Scholarships are to be made and the first subject for the Discovery Prize is to be announced in the coming month of May, and the third Scholarship is to be filled in May, 1884.

* * *

In an interesting report on the petroleum trade of Báku, on the Caspian, Mr. Consul Lovett mentions that in the refineries the distillation of the crude product is now carried on with plant of the most approved construction, under the superintendence of trained chemists (mostly Germans), who receive about £25 per month. The Consul speaks of as many as 115 separate products being obtained from the Báku oil, and it is claimed that although its illuminating power does not equal that of American oil, the value of the residuum is greater.

* * *

In the same report it is mentioned incidentally, that in the year 1858 the Russian Government farmed the monopoly of salt and naphtha at Báku for £300 a year, whilst it is estimated that the yield of oil alone last year brought the pit-owners and refiners a clear profit of £500,000.

Some time since reference was made in "The Month" to the "extra strong essential oils," which Mr. Heansel, of Pirna, prepares by fractional distillation, and which he claims to consist of the finest and most aromatic parts of the ordinary oil. These oils have given rise to a law suit in the United States, the customs officials having insisted upon collecting a duty of 50 per cent. *ad valorem* upon them, as artificial oils, instead of 50 cents per lb., the duty leviable upon essential oils. The sum in dispute was about one thousand dollars, and judgment was given against the customs authorities.

* * *

The *Tropical Agriculturist* states that a beetle which infests *Cinchona succirubra* trees in Ceylon that have been "shaved" has been identified as the male of a species of *Lucanus*, greatly resembling the common European stag beetle. The insect appears to pierce the new bark and feed upon the resinous juice which exudes through the wound.

* * *

The results of some agricultural experiments made on the Shevaroy Hills have been communicated to the *Madras Times*, from which it appears that a plot of ground 22½ by 32 feet planted with *Maranta arundinacea* produced 430 lbs. of corms, yielding 65 lbs. of "arrow root;" and another plot, 29 by 43 feet, planted with 145 plants of *Jatropha Manihot*, produced 255 lbs. of roots yielding 30 lbs. of tapioca.

* * *

According to the *St. Louis Druggist*, an Illinois "doctor," having sent a bottle to a patient labelled "Calmel—pizen," has been cited to appear before the County Medical Society to show cause why he should not be expelled.

* * *

The present arrangements for the Friday evening discourses at the Royal Institution include the following subjects:—April 20, "The Island of Socotra and its Recent Revelations," by Professor Bayley Balfour; April 27, "Some of the Questions involved in Solar Physics," by Dr. C. W. Siemens; May 4, "Weather Knowledge in 1883," by Mr. Robert H. Scott; May 11, "Oysters and the Oyster Question," by Professsor Huxley; May 25, "Whales, Present and Past, and their Probable Origin," by Professor Flower; and June 8, a discourse by Professor Dewar.

* * *

On Tuesday next, at the Royal Institution, Professor J. G. McKendrick will commence a course of ten lectures on "Physiological Discovery," in which the progress of physiological research will be traced from the beginning of the sixteenth century, with the aim of showing how physiology has attempted to solve some of its problems by the methods of physics and chemistry and has thus become a branch of experimental science.

* * *

At the meeting of the Chemical Society, on Thursday next, April 5, a paper will be read on "The Elimination of Hydrogen Sulphide and Carbonic Anhydride in Coal Gas," by Mr. Lewis Wright.

* * *

On Tuesday next, April 3, at 8.30, Mr. R. W. Giles will read a paper on "Pharmaceutical Politics," before the Chemists' Assistants' Association, at the rooms, University Chambers, Conduit Street.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.
EVENING MEETING.

The fifth meeting of the present session was held in the rooms of the Society, George Street, Edinburgh, on Wednesday, March 14, at 9 p.m.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The following donations to the museum were then intimated:—

Specimen of Fresh Bael Fruit.
From Messrs. W. and F. FERGUSSON, Liverpool.

Hyracium (large piece.)
From Mr. ALEXANDER CLEGHORN, Cape Town.

Fine Crystals of Piperin.
From Messrs. T. and H. SMITH and Co., Edinburgh.

Cinnamic Acid, prepared from Tolu Balsam.
From Mr. D. GORRIE, Edinburgh.

Specimens of Malted and Unmalted Grain, and of Impure and Rectified Spirit.
From Mr. JAMES McGLASHAN, Edinburgh.

Specimens illustrating Pyrites roasting and the manufacture of Sulphuric Acid.
From Mr. JOHN R. HILL, Edinburgh.

Pure Chloral. From Mr. WILLIAM PIRIE, Edinburgh.

The Secretary of the Branch having made a few remarks on the specimens, the President moved a vote of thanks to the donors, which was cordially responded to.

The Secretary then read a—

DESCRIPTIVE NOTE OF A NEW HOT-AIR CHAMBER SUITABLE FOR PHARMACEUTICAL PURPOSES.

BY THOMAS MABEN.

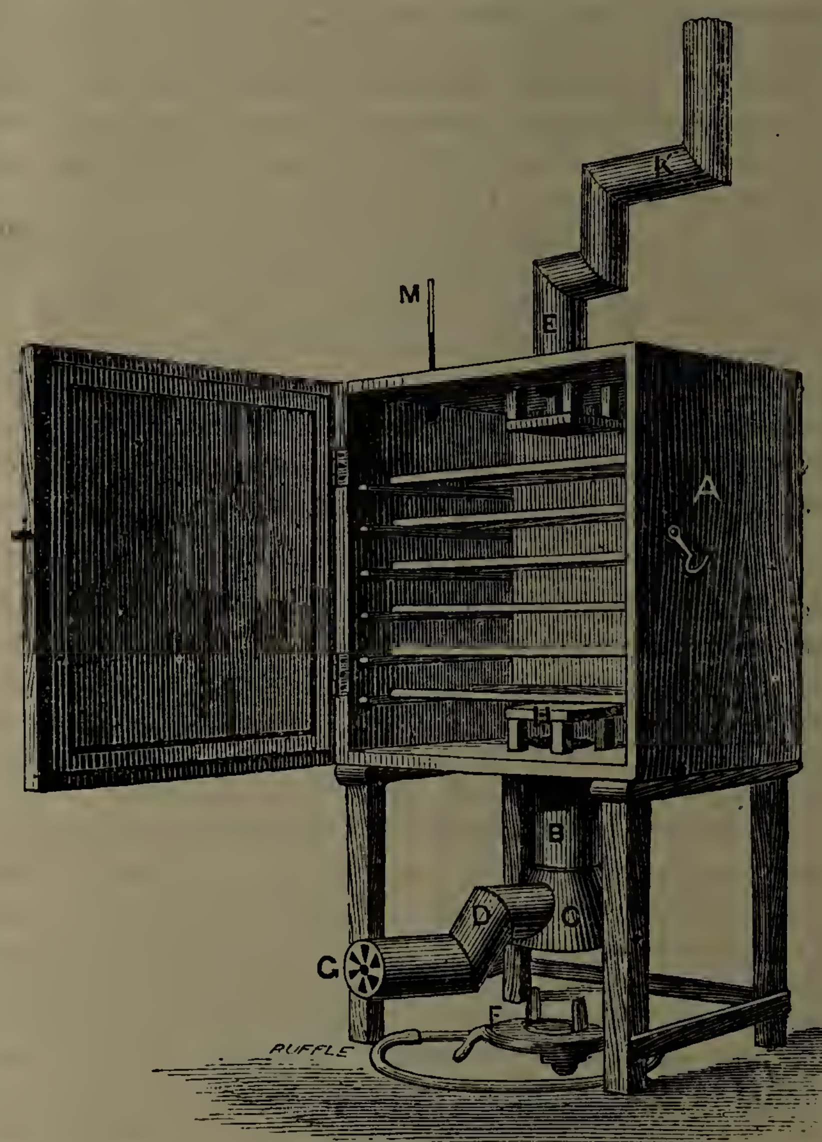
The ordinary steam or hot-air chambers for laboratory use, although meeting the most of the requirements for which they are designed, have the disadvantage of being more adapted for experimental than manufacturing purposes, and are, moreover, of such a price as to exclude their use in small pharmacies. The want of a cheap and convenient apparatus has induced me to bring under your notice the one on the table. I may remark that the design is due to Mr. Hislop, one of my apprentices, who intended it for drying photographic gelatine plates, but by slight modifications of the interior I find it perfectly adapted for the purposes of my own laboratory.

The chamber consists of a strong wooden box (A), 18 inches high by 18 inches wide, and 14 inches deep. To the front a door is attached, hinged in this instance, but a vertical sliding movement would be more convenient. To the two sides of the box are fixed wooden supports which serve to receive teak spars for supporting drying trays or evaporating dishes. The bottom of the box has a perforation of 3 inches diameter into which a zinc cylinder (B) is securely fitted and to this is soldered the upper end of a copper cone (C) with a flat bottom, while into this latter a bent tube (D), diameter $2\frac{1}{2}$ inches, and 9 inches total length, is securely inserted in the manner shown. A corresponding perforation is made in the top for receiving a tube to answer the purposes of a chimney.

Using a Bunsen burner or a spirit lamp as the source of heat, the flame is directed to the bottom of the cone (C) with the result that the heated air ascends into the chamber, being diffused by means of a dispersion board (H) about 4 inches square, which is placed over the orifice. At the end of the tube (D) there is fitted a "hit and miss" regulator (G), which consists of a series of triangle-shaped holes with a revolving disc behind so that the size of the apertures can be increased or diminished, thus enabling the amount of air entering to be under partial control. The highest temperature to which the air in the chamber has been raised is 180° F., which is sufficiently high for most pharmaceutical operations. If a uniform temperature of say 100° F. be required, the admission of air must be regulated accordingly by means of the regulator (G), accuracy being ensured by the insertion of a thermometer (M) into a perforated cork fitted into a half-inch aperture on the top of the chamber. By this means there is no difficulty in keeping within 2·5 degrees less or more of the desired temperature.

If a rapid current of warm air is desired, this can be had by placing an angular tube (K) on the top of the chimney (E), and by heating the angle of the tube a draught is quickly created.

It is desirable in some cases to filter the admitted air; this can be done by stretching a piece of lint or other suitable material between the regulator (G) and the tube (D) by which means dust particles are effectually excluded.



Maben's Hot-Air Chamber.

The metal parts of the apparatus being made to screw off and on, they can be detached at will, so that we can thus have a series of wooden chambers suited to different purposes. In this instance, the chamber being intended for drying gelatine plates, it was of course constructed so that the light would be effectually shut out, but it is obvious that a small glass window would add greatly to its value for laboratory purposes.

The advantages of this chamber are its simplicity, its perfect security against over heating and its small cost,—it can be made for a few shillings. It is light and easily handled and is always ready for work, a current of pure hot air being obtained in a very few minutes after the application of the Bunsen flame.

I find it specially adaptable in the preparation of granular and scale compounds, for drying precipitates, hardening pills previous to coating, and in other operations requiring a current of hot air.

The President in moving a vote of thanks to Mr.

Maben, for bringing the design under the notice of the meeting, said that the chamber seemed to be well adapted to the purposes for which it was intended. It was certainly very commodious, and the readiness with which it could be rendered available for use was a strong argument in its favour.

Mr. Gilmour supported the motion. He did not think that the chamber would be suitable for all purposes for which such apparatus was required, but when a current of hot air was desired it certainly would give that very readily. Several remarks regarding the apparatus having been replied to, a paper was read on—

"Acetic Ether: its Trade Composition, Manufacture and Specific Gravity."

BY WILLIAM INGLIS CLARK, D.SC.

The paper was printed in last week's issue, p. 777.

Upon proceeding to read the paper the author asked the indulgence of the meeting for presenting a communication of so great length and so much complexity on an article which could scarcely be said to be in common use. The subject had grown in his hands, and he preferred to detail the various steps taken, so that the audience might follow the line of argument, and this he hoped to make more clear by reference to the series of diagrams which had been prepared for him.

The President of the Branch in returning the thanks of the meeting to the author of the paper said that the investigations detailed were beyond all praise as mere investigations in themselves, while the communication was an example of thoroughness of work which would not be lost on young investigators. The substance was not extensively used in medicine, but it had been proposed as a solvent in the preparation of certain alkaloids; for this reason it was desirable that the commercial articles should be as pure as possible, and, moreover, it was highly necessary that the pharmacopœial formula should be accurate: this it did not appear to be so far as the purification was concerned. On this point he might remark that magnesia had been recommended as a desiccator, and he might ask Dr. Clark if he had any experience of its use.

Dr. Clark: Magnesia is open to the same objections as caustic lime.

Continuing, the President said that he was sure that the meeting would join with him in admiration of the manner in which the subject had been presented to them.

Mr. Gilmour said that he had great pleasure in seconding the vote of thanks. Owing to the lateness of the hour he would not venture upon any detailed comment on the subject, but he might remark that he was not prepared to find so much and so serious variation in the commercial article as had been pointed out. A more serious matter was the unsatisfactory product obtained by the Pharmacopœia process; if there were an official process at all it certainly should be a perfect process. On this point future compilers should be careful to ensure correctness, and Dr. Clark's work would favour this greatly.

Mr. Dott said, that on the spur of the moment, he would not attempt anything like a complete criticism of such an exhaustive paper. There were one or two points which were referred to, which brought to his recollection something connected with his own work two or three years ago. At that time he was engaged in the same work, and he remembered that he found the gravity given in some text books to be quite different from anything he could prepare, which as far as he could recollect was very near ·900. Regarding the use of chloride of calcium as a dehydrating agent, it ought of course to be neutral, that was to say, the granular and not the fused salt should be used. With reference to the greater solubility of ethyl acetate in water at zero than at 15° C., and the reverse in the case of water in ethyl acetate, it was not really understood why it should be so; water had a greater attraction for itself at a low temperature than at a higher, while the reverse was the case with acetic ether. Probably this would explain the circumstance. He might ask Dr. Clark if anhydrous sulphate of copper would not have been admissible in getting rid of the water from the acetic ether.

Mr. MacEwan then said that the presence of water in commercial acetic ether was easily detected, and in most cases indicated the presence of impurity; but of course a sample containing only alcohol might be very impure and yet contain no water. However it was apparent from Dr Clark's statements that in most cases water was present, and there was a ready means of detecting its presence in anhydrous copper sulphate, which became blue when hydrated, while carbonate of potash shaken up with a portion of a suspected sample would become pasty or syrupy according as the quantity was small or great. Hitherto some reliance had been placed on the specific gravity of the compound, and should a sample be within a few units of ·900 it was considered a fair sample; but Dr Clark stated that this was not at all a reliable basis. Now on that point as well as on others which had been treated, there was at least one pharmacist, Mr. Umney, who had made investigations and got results differing somewhat from Dr. Clark's. Mr. Umney's results were given in an article on the Pharmacopœia "Additions;" in it he stated that the official process was satisfactory, and in a subsequent discussion recommended purification with chloride of calcium and free alkali, the resulting product having a lower specific gravity than that given by Dr. Clark. Knowing the important work which had been done by Mr. Umney, he (the speaker) would like to ask Dr. Clark if he had read Mr. Umney's paper, and if so, it would be satisfactory to hear from him any comment he had to make thereon.

Mr. Young said that he did not rise to criticize the excellent paper to which they had all listened, he was sure, with pleasure. Acetic ether was not an article of great importance, but it might be by-and-by. It was a curious circumstance that recent investigators had differed so much, and this would lead him to expect that Dr. Clark's paper would not be allowed to pass without outside criticism, which he felt that he (the author) would be perfectly prepared to meet.

Mr. Stephenson said that he was unwilling to let the discussion close without supporting what had been said regarding the merit of the paper. On one point he differed from Dr. Clark, namely in the "parts" of sulphuric acid and alcohol being taken by measure. Probably, the writer of the formula had the continental system in his mind's eye when writing the vague formula; however that might be, if the sulphuric acid were taken by weight, it would very nearly approach the theoretical quantity stated in the "model formula."

Mr. Gorrie having made some remarks regarding the specific heat of acetic ether, and several questions having been asked —

Dr. Clark said, in reply, that many of the points which had been referred to were already fully treated in the paper, so that he would only refer to the more important objections and statements. With reference to Mr. Dott's remark, regarding the use of chloride of calcium, he had no doubt that the use of the neutral salt would obviate decomposition of the ethyl acetate; but there was still the fact remaining that the salt absorbs more than one-half of the ether, so that no advantage was to be gained by its use. He then repeated his remarks on the use of anhydrous copper sulphate as a dehydrating agent and afterwards answered Mr. Stephenson's remarks on the meaning of "parts" in the Pharmacopœia directions. (See postscript). Reference had been made to Mr. Umney's paper on "Acetic Ether." He had read the article, and regarding the statements contained therein he had to say that if the parts in the B.P. were all to be taken by weight, then Mr. Umney's statement that the process was satisfactory could not be gainsayed, and it seemed probable that Mr. Umney had adopted this view. He (the speaker) had already shown that if a different interpretation of the B.P. were taken then the process was utterly faulty. Mr. Umney only took exception to the B.P. process because it did not include rectification over carbonated alkali, or some provision for neutralizing the free acid, and he suspected that a sample rectified in the B.P. manner would contain much acetic acid. In the subsequent discussion he (Mr. Umney) again referred to this, but in his (Dr. Clark's) own experiments the pure acetic acid (after treatment with calcium chloride) only amounted to 1·56 per cent, not a large quantity but one which he quite agreed should be removed. The main objection, namely, the enormous loss, was never referred to in the aforesaid discussion. Mr. Umney had said that the more anhydrous the materials the better the yield. This was certainly the case as far as the acetate of soda was concerned, but Putullo and others have shown that a little water rather assists in etherification, and he (Dr. Clark) had already shown that absolute alcohol is unnecessary. He did not think that the boiling point could be used as a certain indication of purity, since alcohol and water raised it. The sample prepared by himself (99·7 per cent. ethyl acetate) boiled at 74·3–74·80 C. with barometer about 29·7 inches.

Mr. Gilmour here remarked that Mr. Williams, as well as Mr. Umney, had experimented with acetic ether and found the specific gravity to be ·880. Considering the care which Mr. Williams had always shown in his work, he thought that some regard should be shown for his results.

Dr. Clark, continuing, said that on the specific gravity he could place no reliance, for, although he believed the pure article, on the ground previously given, to be sp. gr. ·9004 to ·9012 at 60° F., it was no proof of purity that a sample agreed with this. It must be remembered that a mere mixture of alcohol and water could be made to give the same specific gravity. If the boiling point remained practically constant, if the specific gravity were about ·901, and, on analysis, the liquid contained 99 per cent. of ethyl acetate, then, he thought, some reliance might be placed on the sample; but Messrs. Williams and Umney did not publish any such statements; on the contrary Mr. Umney prepared his sample, which he considered to be very nearly pure, sp. gr. ·8956, by digestion with chloride of calcium and a small quantity of caustic lime, the latter would undoubtedly cause decomposition. Mr. Williams, on the other hand, believed ·890 to be correct.

The President then closed the discussion, and the meeting adjourned.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The tenth meeting of this Association was held in the Pharmaceutical Society's rooms, on the evening of the 21st instant. Mr. Peter Boa, President, in the chair.

The minutes of the previous meeting having been read and confirmed, the President called upon Mr. W. Scott Turnbull, to read a paper on the "Alimentary Canal."

The author began by giving a brief outline of the course and structure of the alimentary canal and the position occupied by the various organs in connection with it. He then took up the consideration of these organs separately so as to bring out clearly the several processes of digestion and described the constituents of saliva, gastric, pancreatic, and intestinal juices, and bile, the action of these upon amyloids, fats and proteids being shown. He then entered into the consideration of the pharmaceutical aspect of the subject, alluding to the artificially prepared digestive fluids and their method of preparation; thus the methods for preparing vinum pepsinæ, liquor pepticus, liquor pancreaticus, pepsin, and other medicaments of a like nature were given and the extent of their action discussed. Finally he showed how the digested food is carried into the blood circulation, and how the various kinds of food influence the growth of the body.

The paper was a highly interesting one and was well received by a good audience, and on the motion of the President a hearty vote of thanks was accorded to Mr. Turnbull.

A discussion followed the reading of the paper.

Thereafter, Mr. Turnbull initiated a discussion on the motion of which he had given notice at the previous meeting, held on March 7, and already printed in this Journal. In a short speech he endeavoured to prove that a universal title is desirable for all who carry on the practice of pharmacy; this title he thought should be "Pharmaceutical Chemist" as being the most appropriate, while those who had already acquired that title by examination should receive a purely honorary title, showing that it was one of distinction.

Mr. J. D. Robertson seconded the motion.

Mr. Peter MacEwan then proposed as an amendment, the following counter-resolution:—"Resolved that this Association give its cordial support to the Pharmacy Acts Amendment Bill, and in the event of the measure being enacted, respectfully urge the Council of the Pharmaceutical Society to make provision whereby the present Major examination may be continued for a reasonable time after 1886, so that those who may at that time be qualified by the Minor examination may have an opportunity of becoming pharmaceutical chemists if they so desire."

Mr. Robertson objected to the counter-resolution as not being a direct amendment to the motion; but the President ruled that the amendment was in order.

Mr. MacEwan then replied to the remarks of Messrs. Turnbull and Robertson and showed how the counter-resolution would meet any apparent hardships which might arise.

Mr. John R. Hill seconded the amendment and criticized the unjust principle of the motion; and he was supported by Messrs. Adamson, Aitkin, Crowden and Henry.

Mr. Turnbull having replied, the amendment was put to the meeting when 16 voted for it. Three afterwards voted for the motion. The counter-resolution was therefore adopted.

The President then intimated that the last scientific meeting of the session would be held on March 28, when a paper on "Photography—Dry Process," would be read by Mr. William Aitkin.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting was held on Wednesday evening, March 21, at the George Hotel, when opportunity was taken to present a handsome testimonial to the President, Mr. R. Fitzhugh, consisting of a case of silver dessert knives and forks, a liquor stand, and a beautifully illuminated address, which ran as follows:—"Presented to Richard Fitzhugh, F.C.S., by the members of the Nottingham and Notts Chemists' Association, together with a liquor stand and a case of dessert knives and forks, as a mark of the high personal esteem and respect in which he is held by them, and in recognition of his energetic and valuable services to the Association since its foundation, during which time he has successively filled the offices of Hon. Secretary, Vice-President, and for seven years that of President, with unvarying courtesy and kindness. They sincerely hope he may be blessed with happiness and prosperity, and that he may for many years continue to preside over the Association for which he has laboured so long and with so much success. Signed on behalf of the Association, Roberts Jackson, Vice-President; W. H. Parker, Treasurer; C. W. Warriner, Hon. Secretary."

The presentation was made by the Vice-President, who occupied the chair for the time, in a brief speech, in which he referred to the work done by the President, and the esteem and respect in which he is held by the whole trade.

Mr. Fitzhugh responded in a feeling manner, thanking the members for their most unexpected and handsome present, and assuring them that the sight of it would be an incentive to greater personal interest and work, if it were possible.

The healths of the Vice-President, Treasurer, and Honorary Secretary were drunk, and the remainder of the evening was spent in a social manner.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

The Present Condition of the Soda Industry.

BY WALTER WELDON, F.R.S.

(*Concluded from page* 699.)

As regards the demand for free sulphur, the latest returns published by the Italian Government show that the average annual production of sulphur in Sicily and Italy, during the five years, 1875 to 1879 inclusive, was 282,000 tons, of which 216,000 tons were exported. The total quantity of sulphur that could be produced from English alkali-waste does not exceed two-thirds of this latter quantity. The world thus consumes much more sulphur than the English alkali-makers could produce, and although to sell all that they could produce they must drive much of the Sicilian sulphur out of the market, in the present "struggle for existence" somebody must go down, and English Leblanc soda-makers may be pardoned for preferring that it should be producers of Sicilian sulphur who have to do so, rather than themselves.

The actual cost of Sicilian sulphur, delivered at Marseilles,—transported in the cheapest way, in bulk, at the purchasers' risk,—is about £5 per ton. To become masters of the sulphur market, and at the same time to gain by recovered sulphur the required 2*s*. per cwt., English soda-makers must thus be able to recover sulphur at a cost not exceeding, say, about £2 per ton. They will hardly be able to do that at first, but I think that eventually they will be able to do it. If so, and if chlorine products should again command, as I think they will again command, a reasonable price,—for a price which scarcely pays their cost is, of course, not a reasonable price,—the Leblanc process will at least be able to hold its own, even without that other resource to which I have referred, and which I will now proceed to indicate.

There has come to me from Newcastle a very bold but, I venture to think, quite practical suggestion, the result of which can hardly fail to be of enormous importance, not only to the soda industry, but to almost all industries whatever. That suggestion is that the soda-maker should entirely cease to use raw coal as fuel, but should convert all his coal into coke, collecting for sale the oil and ammonia evolved during its conversion into coke, and himself using for heating purposes the gases evolved during the coking operation and the coke itself. It is believed that, in the Newcastle district at any rate, by this mode of proceeding the soda-maker would obtain his fuel virtually for nothing. In that district there is produced per annum some 2,000,000 of tons of very small coal or "duff," which is almost a waste product, and which, singularly enough, yields more oil than the more costly kinds of Newcastle coal, while at the same time yielding a very fair coke, sufficiently good, at any rate, for use in the furnaces of chemical works, especially when its combustion is assisted by that of the gases from the ovens in which the coke is produced; and the value of the oil and ammonia obtained when this "duff" is coked in ovens to which the Jameson system is applied is greater than the cost of the "duff," *plus* the cost of coking it. And it is probable that improved condensing arrangements will render the yield, if not of oil, at any rate of ammonia, so much greater than the yield hitherto actually realized as to enable the same result to be obtained in the case of ordinary steam coal, not only in the Newcastle district, but in the Lancashire district also. If so, the cost of producing Leblanc soda in both districts will be diminished by almost the total amount of the present cost of Leblanc soda for fuel. I say "almost," because, so far as one can see, the use of raw coal for "mixing" in the black-ash process must still be continued.

And it seems to me that this idea cannot but be as applicable to almost all other industries as to the soda industry: while the result to the material well-being of mankind of its general application, it is utterly beyond the power of any imagination adequately to conceive. This idea means, among other things, cheaper fuel for all purposes, an enormously increased supply of agricultural produce, and the entire suppression of smoke even in the busiest centres of industry. It means that manufacturing towns, by-and-by, shall no longer deserve such names as that which Mr. Matthew Arnold recently applied to St. Helens, and may even become tolerable in the sight of Mr. Ruskin.

And for my own part I venture to think that the same idea might be applied even to the fuel required for domestic purposes, rendering London absolutely free from smoke, and pea-soup fogs things only of tradition. I think that the time will come when our gasworks will be replaced, at least to a large extent, by establishments in which coal will be treated for the production of coke, illuminating oils, ammonia, and heating gases: the coke to be burnt in our domestic fire-places, the oils to be used for lighting the interiors of our houses, the ammonia to be employed in agriculture, to cheapen and render more abundant our supplies of food, and the gases to be burnt for raising steam for driving dynamos for lighting our streets by the electric arc.

Coming back to soda: if the suggestion in question will enable makers of Leblanc soda in certain districts to obtain their fuel for nothing, it will, of course, enable makers of ammonia soda, in similar districts, to do the same. How, then, will it help the Leblanc soda makers? While the quantity of fuel consumed in the ammonia process is only 150 per cent. on the soda produced, the quantity consumed in the Leblanc process is about 350 per cent. on the soda produced. This lower consumption of coal in the ammonia process than in the Leblanc process has hitherto been one of the chief advantages of the ammonia process; but fuel for nothing will so far convert this advantage into a disadvantage, that it will reduce the cost of ammonia soda per ton only by the cost of one and a half tons of fuel, while it will reduce the cost of Leblanc soda, per ton, by the cost of fully twice that quantity of fuel. No doubt, this result will be accompanied by some diminution in that heavy item in the cost of ammonia soda which is due to loss of ammonia; but still I think that the balance of advantage will be on the side of the Leblanc process. It can only fail to be so by reason of ammonia falling to one-half of its present price. The price of ammonia unquestionably will fall; but I think that increased use of ammonia in agriculture will prevent its price falling to anything like that extent.

Besides, then, being certain of getting his sulphur, by-and-by, at half its present price, the English Leblanc soda-maker has thus before him the proverbial "three courses": only, he must not choose between them, but must adopt them all. He must turn his hydrochloric acid to more uses than he does at present; he must recover and sell his sulphur; and he must distil most of his coal. He will then, I believe, be able, not only to hold his own against the ammonia process, but even to incline the balance in his favour.

It is said that "sweet are the uses of adversity;" and those uses, if not "sweet" in any ordinary sense, are at least usually wholesome. One of the results of the conditions under which Leblanc soda-makers have had to work of late years has been to lead them to do their utmost to economize fuel and labour in all possible ways, and of the extent to which this has been done some figures which have been supplied to me by one our leading English manufacturers afford a striking example. They are figures for the ten years, 1872 to 1882. In 1872, in the work to which these figures refer, per 100 tons of total products manufactured, 336 tons of coals were consumed and £256 paid in wages; while in 1882, per 100 tons of total products manufactured, only 216 tons of coals were consumed, and only £144 paid in wages: the coal consumption in 1882 being thus only 64 per cent., and the wages in 1882 only 56 per cent., of what they were, upon the same quantity of total products, in 1872. How much more it may yet be possible to do in the way of economizing fuel, and in adopting labour-saving machinery, I cannot judge; but I venture to think that there are a number of little ways in which economies remain to be effected, and of these I will ask permission to give just one example.

I would venture to suggest that the English Leblanc soda-maker, who has taught the Continental Leblanc soda-maker so very much, might, in return, learn just one or two things from the latter. There can be no doubt that on the Continent, as a rule, and especially in Germany, the Leblanc soda-maker performs to a far less extent than the English Leblanc soda-maker usually does, that useless and costly series of operations which consists in buying salt, transforming it into sodium sulphate, converting that sodium sulphate into carbonate, then converting that carbonate back again into sulphate, and finally giving the sulphate away to his customers, and paying out of his own pocket for casks to put it in. Without entering on the question of the relative proportions of sodium sulphide in English and in German vat-liquors respectively, the ordinary English method of evaporating the vat-liquors and treating the resulting "salts" obviously involves losses of soda which the method of procedure now adopted by all the best German makers wholly avoids. In England, not invariably, but for the most part, the soda-liquors are evaporated by products of combustion passing over their surface, and the resulting "black salts," as they are called, are then "calcined" by products of combustion playing upon and through them. Alike during the evaporation of the liquors, and during the subsequent calcination of the "salts," SO_2 from the products of combustion is absorbed, with the ultimate result that an equivalent of what was soda in the liquors becomes in the final product sodium sulphate. How much soda is habitually lost in this way in England I do not know; but the only careful experiment on the subject with which I am acquainted brought out the loss due to this cause as over 2 per cent. I cannot think that it averages so much as that; but even if it averages only 1 per cent., it would be worth avoiding, providing that the cost of avoiding it were not greater than the value of the soda saved. The best German makers do now avoid all loss of soda from absorption of SO_2, and they believe that they gain other important advantages at the same time. They evaporate their soda liquors in pans heated from below; from these pans they fish by automatic mechanical means perfectly white salts; and then, instead of calcining these salts, either in contact with products of combustion or otherwise, they simply dry them in closed iron vessels heated externally, and now usually furnished with mechanical appliances for crushing the soda as it dries, and automatically feeding it into casks. They believe that by these means they effect an appreciable economy, not only of soda, but of fuel and labour too. The mechanical evaporating and fishing pan which they employ,—known, from the name of its inventor, as the Thelen pan,—has been adopted in one work in this country, by Messrs. J. C. Gamble and Sons, of St. Helens; but the Thelen apparatus for drying fished salts and delivering the products into casks has not yet been tried in this country at all.

Of course, the product obtained by merely drying fished salts has not the crystalline brilliancy of soda ash which has been calcined at a high temperature, and is, moreover, probably slightly more bulky that the latter. Bulkiness is objectionable, because it means more casks; but a preference for mere appearance, apart from actual quality, I think consumers could, if it were worth while, be easily educated out of. When the late Karl von Kulmitz founded the chemical works of Saarau, in Silesia, he did so with a view to supplying soda to the soap-makers of Breslau, who at that time were getting all their soda from England. The soda they were supplied with from England was very red, and the first soda made at Saarau was nice and white. When, however, samples of this white soda were sent to Breslau, the soap-makers there would have nothing to do with it. They said that to make good soap they must have *red* soda ash; and, for a time, Herr Kulmitz was obliged, in order to make his soda saleable, to mix with it a little oxide of iron. He managed after a while to educate his customers out of the habit of requiring that their soda should be red, just as some Continental makers of ammonia soda have had to educate many of their customers out of requiring that their soda should be very weak. A little similar education of some of the clients of some of the English Leblanc soda-makers might perhaps put an end to the irrational custom of the latter of adding salt to their soda after they have made it. They have to pay for that salt, they get nothing for it (the mixture being sold at so much per alkali metric degree), and it increases the cost of their product both for casks and for carriage. As in Lancashire, where this custom of reducing by salt chiefly prevails, a hundredweight of salt costs only about 5*d.*,—though extra cost for casks and carriage raise that 5*d.* to at least 1*s.*, or to fully 1 per cent. on the present selling price of 48 per cent. ash,—the matter may be considered too small to be worthy of mention; but in the alkali trade the present is a day of small things, when even pence per ton must be economized at every possible point, and when 1*s.* a ton may mean all the difference between an actual loss and a small profit. Moreover, it so happens that it is my lot nowadays to visit Continental alkali works much oftener than English alkali works, and when I have made a round among the former, and have found every foreign manufacturer whom I have visited eagerly intent, not only on economizing to the uttermost fuel, labour, and raw materials, but also upon making his soda as rich and as pure as possible, in order that it may compete with ammonia soda, and when I then, on getting home, write to an English alkali-maker to ask what a ton of soda now costs him, in order that I may compare his figures with figures which have been given me abroad, and on receipt of his figures I find that he charges each ton of soda with "1 cwt. of salt for reducing,"—while I know that in some sense or other it must be all right, since my friend of course knows his business very much better than I do, I nevertheless cannot help feeling that there is something here which is behind the times—I cannot help feeling that that ignorance on the part of the customer which makes dilution with salt all right for the moment is not going to last, and that if I were an alkali-maker I should do my best to become one of the first in the new state of things which is fast coming, by beginning at once to take such steps as I have seen Continental ammonia soda-makers take to persuade my customers to take my soda as rich as I make it, and not to require me to increase its cost by adding to it what is of no advantage to them.

Here the present paper might very well have ended, but I know that it is expected by some of the members present that I should say something on the present state of the sulphur recovery question; and I have, therefore, to ask permission to go on a little longer, in order to do so.

The question of the cost of sulphur recovery is one which I do not propose to go into, for the reason, among others, that Mr. Alexander Chance will before long deal with that question before the Liverpool section of our Society. The experimental plant for the Schaffner and Helbig process which Messrs. Chance Brothers had in operation at their works at Oldbury this time last year, and which continued in operation till June or July, was then stopped, in order to the erection of a new plant, intended to deal with 300 tons of waste per week. This new plant has been recently got to work, and a little later on Mr. Alexander Chance intends to give at Liverpool a full account of its results, and especially of those of them bearing on the commercial aspect of the process. All I will say of it now, therefore, is, that into this new plant the Messrs. Chance have introduced several important improvements which greatly facilitate the working of the process, and that with the results yielded by it, so far, they are perfectly content.

In order to render intelligible some interesting results, relating in some degree to the commercial side of the Schaffner and Helbig process, which were obtained at Oldbury in the autumn, and which I have permission to report this evening, allow me to remind you that the two main operations of that process consist: firstly, in decomposing the calcium sulphide contained in alkali-waste by heating the waste with solution of magnesium chloride, whereby there is obtained, on the one hand, H_2S, and, on the other, solution of calcium chloride holding magnesium hydrate in suspension; and, secondly, in regenerating magnesium chloride for use again by treating that mixture of magnesium hydrate and solution of chloride of calcium by CO_2:—

First Operation.

$$CaS + MgCl_2 + 2H_2O = H_2S + CaCl_2 + MgH_2O_2.$$

Second Operation.

$$CaCl_2 + MgH_2O_2 + CO_2 = MgCl_2 + CaCO_3 + H_2O.$$

During the construction of their new plant, Messrs. Chance Brothers made a series of quantitative experiments, upon a scale of half a ton of waste per operation, mainly with a view to determining quantitatively the loss of magnesia involved in the process. These experiments were conducted by Mr. Frederick Chance,—a young member of the firm, who has only to fulfil the promise of his youth to take a very high rank among industrial chemists,—and their results are interesting and to a certain extent important. By making a number of successive operations without adding any fresh magnesia or magnesium chloride, and comparing the quantity of magnesium chloride which he had at the end of the series of operations with the quantity which he had at the beginning, Mr. Frederick Chance found that the average loss of magnesia corresponded to 1·05 parts of MgO per 100 parts of waste treated. Now, while in the waste produced at Oldbury there is no magnesia to speak of, a very pure limestone being used there for making black-ash, there is reason to believe that the waste produced in the Newcastle district,—the limestone of which district is all more or less magnesian,—contains fully enough magnesia to make up this amount of loss, without the addition of any magnesium compound specially for that purpose. All that should be needed, therefore, in the case of Newcastle waste, should be to add from time to time the quantity of calcium chloride necessary to convert into magnesium chloride, by the aid of CO_2, the magnesia actually existing in the waste itself. In other cases, the loss of magnesia in the Schaffner and Helbig process might be made up by replacing 2 or 3 per cent. of the limestone used for making black-ash by dolomite. This is supposing, of course, that the calcium carbonate recovered in the process is not used again in black-ash making. In proportion as this recovered carbonate can be used again for making black-ash, there will be no loss of magnesia, the magnesia "lost" in one operation coming round again in the next.

The experiments of Mr. Frederick Chance further brought out the important fact that the reaction by which magnesium chloride and calcium carbonate are recovered takes place,—at any rate under the conditions under which he operated, *i.e.*, under a pressure of 20 pounds per square inch,—quite as readily when the mixture treated by CO_2 is hot as when that mixture is cold. It has been supposed that that reaction depends upon the formation of bicarbonate of magnesia, in which case the mixture in question would have required to be cooled before being treated by CO_2, and so to cool it would have been at least troublesome. It seems, however, that the reaction in question is really a reaction between $CaCl_2$ and $MgCO_3$. This result is confirmed by the result obtained by Dr. Hewitt by simply mixing with solution of $CaCl_2$ an equivalent of the carbonate of magnesia of the shops. He obtained in that way a decomposition of about 80 per cent. of his calcium chloride, and it is probable that the carbonate of magnesia he employed did not contain more than that percentage of $MgCO_3$.

Mr. Frederick Chance further lighted upon a very curious fact, which is valuable as affording to the workmen a simple and ready indication of the moment at which the regeneration of the magnesium chloride has become complete. In the mixture operated upon there is always a little ferrous sulphide. This ferrous sulphide is not acted upon by CO_2 so long as there is any free magnesia present, but it is attacked so soon as all magnesia present has become carbonated, with the result of sending iron into solution as acid ferrous carbonate. The presence of the iron which thus comes into solution can be very readily detected, and the moment it appears the workmen in charge know that it is time to stop injecting CO_2.

In the South of France, experiments are now being made, at my instance, with a modification of the Schaffner and Helbig process. The first time I visited Cornwall, now very many years ago, I was on one occasion at a dinner-table at which I was asked to name "the four Cornish minerals." To name two of them was not difficult, but my endeavours to name the other two only created most Homeric laughter. At length I was informed that "the four Cornish minerals" are "fish, copper, potatoes, and tin." Cornwall being a mining county, for a Cornishman every natural production which he turns to useful account is a "mineral." At a banquet given by him at Giraud, in May last, to the members of the "Société de l'Industrie Minérale,"—the French "Iron and Steel Institute,"—M. Pechiney, addressing miners and metallurgists, similarly spoke of sea-water as "notre minérai à nous;" and the object of the modification in question is to turn to account in two ways one of the constituents of that extremely complex liquid ore, namely, its magnesium chloride. Most of those in France who make salt from sea-water content themselves with obtaining therefrom only common salt, but M. Pechiney treats the mother-liquors from which as much NaCl as possible has been crystallized out for the further obtainment from them of sodium sulphate, magnesium sulphate, and potassium chloride, and his final residue is a saturated solution of magnesium chloride, containing no other body except magnesium bromide. It has seemed to me that this magnesium chloride might be utilized at once for the recovery of sulphur from soda-waste, and as a source of magnesia for sale as such. When alkali-waste, however, is treated directly by solution of magnesium chloride, the magnesium hydrate, which is one of the products of the reaction which takes place, is obtained in admixture with all the numerous bodies other than calcium sulphide which were contained in the waste treated. When the magnesium hydrate is to be employed for the regeneration of magnesium chloride, this presence with it of foreign bodies does not matter; but in cases in which regeneration of the magnesium chloride used is not necessary, while it is desired to obtain magnesium hydrate for sale, the presence of foreign bodies with the magnesium hydrate must be avoided. I propose to avoid it by taking advantage of a reaction which is known as Kraushaar's, from its having been first published, in *Dingler's Journal* for 1877, by Dr. Kraushaar, of Thann, but which was really first discovered by Mr. Helbig, at Aussig, and turned by him to practical account there as early as 1874. This is the reaction which takes place when alkali waste is heated with water under pressure. It is a reaction of two of water upon two of calcium sulphide, giving one of calcium hydrate and one of calcium sulphydrate. The calcium sulphydrate is obtained in solution, and if this solution be separated from the calcium hydrate and other bodies which it at first holds in suspension, on then running into it solution of magnesium chloride there is obtained, on the one hand, H_2S, and on the other, magnesium hydrate, almost chemically pure. And it is to be noted that, whereas when alkali-waste is treated directly with solution of magnesium chloride only one of H_2S is obtained for each equivalent of $MgCl_2$ which enters into reaction, by first getting the sulphur of the waste into the state of calcium sulphydrate two equivalents of H_2S are obtained for each equivalent of magnesium chloride decomposed.

At one time I had some hope that one might take advantage in England of this reaction of two of water upon two of waste, to the end of reducing by one-half the quantity of magnesium chloride to be employed, and consequently the quantity of that body to be recovered, per given quantity of alkali-waste treated. Mr. Chance was so obliging as to make some experiments on this point at Oldbury, and Mr. Helbig made others at Aussig, and the result of both series of experiments went to show that the idea is not applicable, or at any rate not applicable with any great advantage, when the magnesium chloride employed has to be regenerated. The reason is that the whole of the sulphur of the calcium sulphide of the waste which is heated with water under pressure does not come into solution unless a certain minimum quantity of water be used. This quantity of water is not too great to permit of the method being employed with advantage when the magnesium chloride has not to be recovered. But, when it has to be recovered, all this water would have afterwards to be driven off by evaporation, or the regenerated magnesium chloride would be impracticably dilute; and the cost of this additional evaporation would probably balance the economy due to halving the quantity of magnesium chloride to be dealt with.

Some attention has been drawn recently to a second Austrian method of recovering sulphur from alkali-waste: a method proposed by Herr Opl, of the chemical works of Hruschau, in Moravia. This gentleman proposes to mix waste with water, to treat the mixture with CO_2 and so drive off H_2S from it, and then to pass this H_2S into more mixture of waste with water, in order that it shall be absorbed by the calcium sulphide of this second quantity of waste with formation of solution of calcium sulphydrate, which could then be treated in any one of several ways. This proposal seems to me defective, for the reason, among others, that I do not see how it would be practicable to avoid sending an excess of CO_2 into the second quantity of mixture of waste and water, which excess of CO_2 would react on some of the calcium sulphydrate formed in that second quantity of such mixture, driving off H_2S, and so occasioning both loss of sulphur and nuisance. Certainly, Herr Opl's method of getting the sulphur of alkali-waste into solution as calcium sulphydrate cannot, I think, compete with the simpler method of heating the waste with water under pressure.

Here, at last, I draw this too long paper to a close. I have had to show in it that the immediate future of the English Leblanc soda industry is somewhat gloomy; but I trust that I have shown also reason to believe that sufficient attention to the complete utilization of all raw materials is yet capable of saving it. Very much has yet to be done before it will be placed once more on a satisfactory basis; but *nil desperandum!* Patient courage and wisely-directed labour will bring all right again in time. A French Leblanc soda-maker, discussing in Paris, a few weeks ago, "l'affaire de Rio Tinto," spoke very hopelessly at first, but suddenly his countenance brightened, and he said "*Mais, courage!* This is not the first time, nor the second, since I have been in the trade, that we have been menaced with apparently unavoidable ruin; but we have always pulled through before, and we will pull through again." That is a spirit on which we in England specially pride ourselves; and in whatever "pluck," combined with intelligence, can do,—and in this case I believe that they can do all that is required,—I am confident that my countrymen will not be left behind.

Parliamentary and Law Proceedings.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* LEWIN.

At the Stonehouse County Court, before S. S. Underhay, Esq., deputy judge, on Monday, March 19, the Council of the Pharmaceutical Society sued Mr. E. C. Lewin, carrying on business as a chemist, at Whimple Street, Plymouth, at the Stonehouse County Court, to recover two penalties of £5 each; first, for that he styled himself as "chemist" and carried on business as a chemist without having duly qualified himself; and, second, that not being a duly qualified person he sold a poison scheduled in the Act.

Mr. F. R. Stanbury (instructed by Messrs. Flux, Son and Co.) represented the Society.

The defendant did not appear.

Mr. Stanbury explained the nature of the action, and said Mr. Lewin's name did not appear on the Register of Chemists, which he produced, and which could be accepted as evidence by the Court. The defendant was well aware that he was infringing the law, because he had previously paid fines to the solicitors of the Pharmaceutical Society (Messrs. Flux, Son and Co.) for similar offences, and he (Mr. Stanbury) had served notice on Mr. Lewin to produce the letters he had received in relation thereto. Of course it was for the protection of the public that gentlemen who entered into business as chemists and dispensed drugs and poisons should thoroughly understand that business. On February 16, last, his (Mr. Stanbury's) clerk went to defendant's shop and purchased of him a packet marked "oxalic acid," the label on the paper in which the poison was wrapped was endorsed, "Poison.—Lewin, chemist." Oxalic acid was one of the poisons coming under the schedule, and it was mentioned in the Act referred to, that any person not duly qualified selling "oxalic acid" should be liable to a fine of £5. The Act went on to say further, that any person who exhibited or used the name or title of "chemist" and at the same time not being a duly registered person should be liable thereby to a penalty of £5. That defendant had infringed the law was plain as he had sold "oxalic acid" and had styled himself "chemist" having no authority to do so. When his (Mr. Stanbury's) clerk served a notice on defendant, he admitted that he had infringed the Act, but said that he hoped to have been able to set the matter right before it came into court.

Howard Stanley Walter, a clerk in Mr. Stanbury's employ, proved purchasing a packet of "oxalic acid" from defendant and handing it over that morning, unopened, to Mr. Codd, for analysis.

Mr. F. Codd, chemist, stated that he had analysed a portion of the contents of the packet produced, and proved it by four tests to be oxalic acid, a poison included in schedule 2 to the Act.

Mr. Stanbury: Mr. Codd is Local Secretary of the Pharmaceutical Society and I think it right to say that he knew nothing about this prosecution when the packet of poison was taken to him.

Robert Ellis, clerk to Mr. Stanbury, said he served notices on Mr. Lewin and asked him if he had received the letters, copies of which he showed him, relating to a fine of £5 which he had already paid to the solicitors of the Pharmaceutical Society. Mr. Lewin admitted having received the letters.

Mr. Stanbury said, that as the case had been one that had entailed a certain amount of labour he asked his Honour to pass judgment with costs on the higher scale, as was allowable by the recent County Court Act.

His Honour gave judgment for the full amount of penalties, £10, with costs on the higher scale, £8 7s. 10*d*.

Poisoning by Prussic Acid.

An inquest was held at Christchurch, on Tuesday, March 13, before Mr. Druitt, Coroner, to inquire into the cause of the death of Mrs. Eliza Louisa Broadway.

According to the evidence of the husband the deceased had been in the habit of taking occasionally, before going to bed, some warm ale containing a few drops of laudanum and sal volatile. These preparations were contained in bottles usually kept in a cellaret, and in the same place was a bottle containing prussic acid which had been obtained for the purpose of poisoning a dog, but not used. The prussic acid was originally supplied in a bottle with three poison labels on it, but this having been broken deceased had placed it in another one, transferring to it one of the poison labels. On the previous night he had found his wife dead in bed by his side.

Dr. Henry W. Hartford deposed that just before Christmas he let Mr. Broadway have about 60 drops of Scheele's prussic acid to poison a dog the next morning. He wrote "Prussic Acid" on the bottle with a red "poison" label underneath it; put "poison" two or three times on the back, and gave him strict injunctions not to let it go out of his possession, and that he was to break the bottle as soon as he had used it. On the previous night Mr. Broadway came to his house and stated that he had found his wife lying dead in bed by his side; the room smelt of prussic acid, and that he feared that she had taken it in mistake for sal volatile, which she kept in the same place. Witness examined the place where the bottles were kept, and found four bottles in a division of the drawer, one contained about three teaspoonfuls of sal volatile; a small one was nearly full of laudanum; one labelled "prussic acid—poison" was empty; and there was one of olive oil. The opium and sal volatile were inside, and the oil and prussic acid outside.

As the result of a *post-mortem* examination medical evidence was given that deceased met her death through poisoning by prussic acid, and the jury returned an open verdict to that effect, and censured the husband for his carelessness in keeping so dangerous a poison.

Obituary.

RALPH DAVISON.

It is with great regret that we announce the death on Saturday last, the 24th inst., of Mr. Ralph Davison, Pharmaceutical Chemist, of Haysthorpe, Holgate Hill, York, in the 61st year of his age. Mr. Davison joined the Pharmaceutical Society in 1845, and for the last sixteen years has filled the post of Local Secretary, having continued his services in that office and as Local Superintendent of Examinations even after his retirement from business a few years ago. In 1881 Mr. Davison presided over the Local Committee which entertained the British Pharmaceutical Conference during its visit to York. During more than twenty years Mr. Davison held the position of Councillor in the city of York, and in this and many other ways rendered good and much appreciated service to his fellow citizens.

Notice has also been received of the death of the following:—

On the 2nd of February, Mr. James Rowell Rickard, Chemist and Druggist, Wadebridge, Cornwall. Aged 69 years.

On the 11th of March, Mr. Alfred Hodder, Pharmaceutical Chemist, High Street, Camden Town. Aged 42 years. Mr. Hodder had been a Member of the Pharmaceutical Society since 1864.

On the 15th of March, Mr. Ralph Robert Warrior, Chemist and Druggist, Edge Hill, Liverpool. Aged 55 years.

On the 16th of March, Mr. William Matthias Rackham, Chemist and Druggist, Upper Market, Norwich. Aged 51 years.

On the 26th of March, Mr. Francis Staveley, Chemist and Druggist, Park Lane, Liverpool. Aged 64 years.

Correspondence.

Acetic Ether.

Sir,—It appears from the very able and complete investigation which Dr. W. Inglis Clark has made of the various processes which have been suggested for the production of acetic ether, as reported in your last number, that the process yielding the best result is that of the British Pharmacopœia. And this has been demonstrated notwithstanding the disadvantage resulting from larger proportions of sulphuric acid and acetate of soda having been used in the experiments than the Pharmacopœia process was intended to indicate.

I cannot understand how Dr. Clark could have inferred that the term "parts," when used in describing a process, without further explanation, should mean one thing as applied to a solid and another as applied to a liquid. The term is very commonly employed in describing chemical processes, and I have never seen it used otherwise than to represent parts by weight, unless accompanied by an explicit representation of its having a different meaning, as in the case of Squire's 'Companion to the Pharmacopœia,' where the explanation is given at the head of every page, clearly indicating what would be inferred in the absence of such explanation.

The postscript to Dr. Clark's paper seems to show that he had become sensible of having incorrectly interpreted the Pharmacopœia process, for he says:—"If we, however, calculate out the proportions as represented by weight as well as by measure, it seems probable that all the parts are intended to be taken by weight, and if this be so, the proportions in themselves are satisfactory enough."

The following figures will serve to show how well the proportions given in the Pharmacopœia accord with those which Dr. Clark has deduced theoretically and practically.

The theoretical quantities of the ingredients as given by Dr. Clark, if reduced to parts by weight, will be—

Rectified spirit	237·1	or 5	parts.
Sulphuric acid	423·8	,, 8·9	,,
Sodium acetate	351·0	,, 7·4	,,

Practically, however, it was found desirable to have excess, but not much excess, of sulphuric acid present, and the proportions suggested by Dr. Clark, when reduced to parts by weight, are as follows:—

Rectified spirit	237·1	or 5	parts.
Sulphuric acid	521·5	,, 11	,,
Sodium acetate	351·0	,, 7·4	,,

The Pharmacopœia proportions, similarly expressed, would be—

Rectified spirit	237·0	or 5	parts.
Sulphuric acid	474·0	,, 10	,,
Sodium acetate	379·2	,, 8	,,

As I had originally devoted considerable attention to this process, I should have been surprised to find that it required the alteration suggested, and, in fact, it will be found that the proportions indicated in the Pharmocopœia are all that can be desired, as also are the properties assigned to the finished product.

The value of Dr. Clark's paper will scarcely be lessened by withdrawing the requirement for any alteration of the simple and sufficiently exact statement of proportions in the Pharmacopœia process. The chief merit of the paper consists in the elaboration of important details relating to the production of acetic ether, the determination of its right specific gravity and solubility in water, and the best means of purifying the first crude product of the Pharmacopœia process. With regard to the last-named object, the author has suggested a mode of operating which is obviously a great improvement upon that described in the Pharmacopœia.

T. Redwood.

Sir,—Ladies are said to put the most important part of their communications in the P.S., and as far as the British Pharmacopœia is concerned Dr. Clark seems to have followed their example.

That a gentleman of Dr. Clark's attainments should have made such an assumption as that the Pharmacopœia meant solids by weight, liquids by measure, seems to me most extraordinary.

I must protest against the assumption that such a method of stating formulæ (not physicians' prescriptions) is according to English usage. On the contrary, except in Squire's 'Companion,' I have, as far as my memory serves, seen it used only once.

In this case it was quoted as a "Pharmacopœial dictum" by a gentleman who recently read a paper before the North British Branch, where this heresy seems to have found a home. The B.P., on almost every page, refutes such a supposition, as far as it is concerned, by using the terms fluid drachm and fluid ounce; and even Squire's 'Companion,' although written for the use of medical men, prints the statement, "Solids by weight, liquids by measure," on every page, which, to my mind, is conclusive evidence (if such were required) that such a rendering of formulæ is not according to "English usage," but an exception requiring specially to be noted.

But, respecting Dr. Clark's valuable and exhaustive paper, it may be well to compare the quantities required by theory, the B.P. and Dr. Clark for the production of acetic ether:—

	Theory (roughly).	B.P.*	Clark.
Alcohol ·838	50	50	50
Dry acetate of soda . . .	74	80	62
Sulphuric acid, B.P. . . .	91	100	92

Now these three proportions are not so very dissimilar, and I have no doubt that all would produce a satisfactory result, although perhaps Dr. Clark's may be the best. The latter does not seem, however, to be remarkable so much for the excess of sulphuric acid as for the deficiency of acetate.

I have myself only worked with the theoretical proportions and have found no difficulty (using chloride of calcium and carbonate of potash for purification) in obtaining a product of a pretty constant composition, and one having the same specific gravity as that of the best makers, viz., about ·891.

A preparation of this gravity is evidently easily obtained, as many writers give figures very closely approximating to it. I have no doubt, however, after reading an account of Dr. Clark's very careful experiments, that he is right, and that a sample of ·890 specific gravity does contain a certain amount of alcohol or common ether.

Doubtless acetic acid is not a desirable impurity, but ethyl ether or even alcohol in small quantities are, I should imagine, harmless, and it would seem desirable to adopt a gravity which is easily attainable. Perhaps, however, Dr. Clark's process may be found to be worked with almost as great facility and constancy.

87, *Bold Road, Liverpool.* Alfred C. Abraham.

The Pharmacy Act Amendment Bill.

Sir,—Your article in last week's Journal calls our attention once again to the draft Pharmacy Bill. Without going fully into the merits or demerits of this proposed Bill, there is one part which strikes my mind as pre-eminently objectionable, and which it is to be hoped the trade at large will by no means quietly allow to pass into law. I refer to clauses 4 to 6, touching the penalties attached to the sale of patent or proprietary medicines, in the event of such containing a poison within the meaning of the Pharmacy Act, 1868.

In your remarks upon this point you state "That the chemist is not to be looked upon as selling, like the grocer or oilman, articles of whose nature he does not pretend to have any knowledge," etc., etc. Now, unfortunately, I must venture to differ from you in this assertion, so far as regards the sale of proprietary medicines sold as patents, and I think the experience of the trade at large will support the statement, that as a rule we are practically excluded from the possibility of knowing the contents of the majority of the nostrums with which the market is flooded under the protection of the patent medicine stamp; and yet by these clauses we are to be held responsible, and subject to penalties for not knowing that which the proprietors take every precaution against our knowing.

But again in clause 4, the name and address of the first seller is required. Who can be the first seller but the person by whom the preparation is actually made and sent forth into the market? Whereas clause 6 again throws the entire responsibility, with all the accompanying annoyances, upon the retail dealer, notwithstanding the possibility that the article may have previously passed through three or four intermediate hands. In the event of such becoming law, I can see no alternative other than the abandonment of the sale of all patents, unless we are prepared to risk the continual annoyance of actions, fines and visionary prospects of indemnification from unknown parties, possibly men of straw.

Another serious difficulty is one which comes home to our own preparations in common with others, viz.:—How far is it necessary or desirable to label every proprietary article "poison" in which a possible infinitesimally small dose of opium, morphia, etc., is introduced? That protection against the unguarded sale of poisons is desirable is not questioned, but whether the existing law, if properly carried out, together with an extension of the schedules of poisons, is not in itself sufficient, I think very doubtful.

Without going into other points which this Bill is supposed to remedy, but which I fear in practice will prove lamentably wanting, I would ask the Council to consider whether much difficulty might not be removed by, among other alterations, the addition of another clause requiring the registration of all proprietary preparations containing poisons, with the name and quantity of such poison contained in each bottle, box or packet. The number of such registration to be distinctly printed upon the labels, and outside the wrapper. And further, whether some scale might not be devised, beyond which alone it might be deemed necessary to require the poisons caution to be affixed.

I hope that some such material alterations may yet be introduced into the Bill.

Belgravia House, West Brighton. Edwin B. Vizer.

Weight.—According to section 45 of the Weights and Measures Act, a weight or measure duly stamped by an inspector under the Act is a legal weight or measure throughout the United Kingdom, unless found to be false or unjust, and is not liable to be restamped because used in any place other than that in which it was originally stamped.

D. M. L.—Such persons would stand in the same position as others who have not passed the Preliminary examination.

Herbalist.—(1) *Berberis Darwinii*, probably; (2) *Luzula sylvatica*; (3) *Dicranum majus*; (4) *Hypnum rutabulum*; (5) *Thuidium tamariscinum*; (6) *Lophocolea bidentata.*

B. R. is recommended to make his want known through the usual channel of advertisement.

Vinum.—Griffin's 'Chemical Testing of Wines and Spirits.' See a paper by Nessler and Barth, before, p. 43.

Southwalian.—The visitor from the country to the Annual Meeting is not confined to one evening's social intercourse, since the Conversazione is preceded by the Annual Dinner. The Annual Ball is held in the early part of each year.

G. W. Gorman and *R. H.*—To a solution of chloride or nitrate of cobalt in water add sesquicarbonate of ammonia sufficient to redissolve the precipitate at first formed.

J. R.—See a paper on the Testing of Olive Oil, by Mr. Conroy, *Pharm. Journal*, May 14, 1881, p. 933.

Communications, Letters, etc., have been received from Messrs. Clark, Baldock, Parker, Devonian, A.P.S., R.L.

* Evidently a free rendering of the theoretical requirement.

THE BITTER PRINCIPLE OF HYMENODICTYON EXCELSUM.*

BY W. A. H. NAYLOR.

The interest attaching to the two species of *Hymenodictyon*, viz., *H. excelsum* and *H. obovatum*, is derived from the circumstance that they both yield a bitter bark which is in common use among the natives of India as a tonic.

Surgeon-Major Dymock has remarked that the bark of *H. excelsum* is the more bitter of the two and is therefore probably the more valuable, although he is not aware that either of the barks has been properly tested in European practice.

As a remedy of repute it was invested with additional importance when it received a place among the non-official drugs of the Pharmacopœia of India for 1868. Referring to the species *H. excelsum* it is there stated that the "inner coat of the bark, according to Roxburgh, possesses the bitterness and astringency of cinchona. . . . The outer light spongy layer of the bark is comparatively tasteless. Considering the natural order to which the tree belongs and the sensible properties of its bark, it is not improbable that it may prove a valuable remedy. In all future inquiries into the subject of Indian antiperiodics this bark should be one of the first to which attention should be directed." The success which attended its use as a native febrifuge probably gave rise to the supposition that its medicinal properties were due to the presence of quinine. Consequently, in 1870, Mr. Broughton, who was at that time the Government Quinologist at the Ootacamund plantations, submitted to an examination the *fresh* bark of the tree. He found that the bitter taste was due to the existence of *æsculin*, and that the bark when dry was almost tasteless owing to its transformation into *æsculetin*, the decomposition having been induced by contact with decaying organic matter.

Through the kind services of Mr. E. M. Holmes, who placed at my disposal a quantity of the dried bark, an opportunity was afforded me of investigating its bitter principle. As the results obtained differ widely from these obtained by Mr. Broughton I am induced to place them on record.

The following was the mode of treatment. The bark, after being reduced to a moderately fine powder, was mixed with one fourth of its weight of lime and made into a thick paste with water. The mixture was dried and exhausted by percolation with boiling alcohol of 90 per cent. The percolate was acidified with sulphuric acid and the alcohol recovered by distillation. The residue was treated with hot water, filtered and the filtrate precipitated with caustic soda, when a gelatinous precipitate fell. The precipitate was collected, washed and dried in a water oven. Its weight was taken and found to be equivalent to 1·75 per cent. In this condition it presented the appearance of a blackish-brown gum-resinous mass, friable at the temperature of the water-bath, but readily becoming sticky through absorption of moisture as the temperature was lowered. It had a persistently bitter taste which was more quickly perceived when in solution than when in the solid state. It had an unmistakably alkaline reaction and dissolved readily in the mineral acids to all but neutralization. Its solution in dilute hydrochloric acid reacted with the following reagents:—With phosphomolybdic acid it gave a canary yellow precipitate; with iodide of bismuth and potassium, a brick red; with iodine in iodide of potassium, a brown flocculent precipitate; with iodide of mercury and potassium, a cream-coloured precipitate; with iodide of cadmium and potassium, a feebly coloured precipitate; with picric acid, a bright yellow precipitate, and with tannic acid a brownish precipitate. The several precipitates were amorphous. If to these reactions be added the fact that the body contained a quantity of nitrogen there can be no reasonable ground to doubt its alkaloidal character. In order, however, to study its properties more fully and with greater certainty it was necessary to resort to some method of purifying it. It was found that treatment of its alcoholic solution with animal charcoal was far too wasteful. The object was largely accomplished by digesting the crude alkaloid in a limited quantity of ether, dissolving the ether residue in acetic acid, and submitting the solution to partial precipitation with caustic soda or ammonia. The result was a white gelatinous precipitate, which became yellow on drying and assumed a darker colour when subjected to a temperature of 100° C. It dissolved readily in ether, alcohol and chloroform, but was little soluble in water. Its solution in alcohol of 95 per cent. had no action on a beam of polarized light. With the mineral and many organic acids it formed amorphous salts. Every attempt to crystallize the alkaloid or its salts of the mineral acids proved a complete failure. It began to fuse at about 120° C. Its solution in hydrochloric acid gave precipitates with perchloride of mercury, ferro- and ferridcyanide of potassium, iodide of potassium, phosphate of sodium, chloride of sodium and ammonium and nitrate of sodium. The precipitates resembled each other in character, and varied in colour from grey to brownish-yellow. The sulphate of the alkaloid was precipitated by nitric acid. Knowing as a matter of experiment that both beberine and quinoidine behaved in a similar manner towards these reagents, the thought was naturally suggested that the body I had isolated might be identical with one of these alkaloids, or more probably with paricine.

To decide this point a platinum compound of the alkaloid was prepared, and the percentage of carbon and hydrogen contained in the alkaloid itself was estimated. The double compound, when freshly formed, was a yellow amorphous precipitate, which became reddish yellow on drying at 110° C. On ignition it left 20·08 per cent. of platinum. The formula $(C_{16}H_{18}N_2O.HCl)_2+PtCl_4$—the platinum compound of paricine as determined by Hesse—requires 19·68 per cent., while that of beberine requires 19·50 per cent., and quinoidin from 26·28 to 26·59 per cent. of platinum respectively.

The combustion of the alkaloid was made with cupric oxide in a current of oxygen. Before it was burnt it was dried at 115° C. The mean of a series of satisfactorily accordant results gave 75·82 per cent. of carbon and 9·8 per cent. of hydrogen as against 75·59 per cent. of carbon and 7·08 per cent. of hydrogen for paricine dried at 100° C. Here it will be observed that while the carbon is within the limit of experimental error the hydrogen lies quite outside the field of computation.

A not improbable explanation of this anomaly—if anomaly it be—is to be found mainly in the high temperature at which the alkaloid was dried. This

* Read at an Evening Meeting of the Pharmaceutical Society, April 4, 1883.

was adopted as being the one at which beberine becomes anhydrous. Subsequent experiments proved that the alkaloid suffered partial decomposition, becoming converted into a resinous substance. Be this as it may, this much may be affirmed, that the bitter principle of the *dried* bark of *Hymenodictyon excelsum* is not the glucoside æsculin or its decomposition product æsculetin, but an alkaloidal substance. That as such it is allied to quinoidine, beberine and paricine. From quinoidine it differs in being optically inactive and from its double compound containing relatively less platinum. From beberine it differs in that it contains a higher percentage of carbon, while its double compound also yields a relatively larger amount of platinum. From paricine it differs alone in the percentage of hydrogen it gave, to which reference has already been made. So far the balance of evidence is clearly in favour of paricine.

In that I have been compelled, through force of circumstances, to discontinue for a time my investigations upon this subject, constitutes my apology for presenting the results while yet in so incomplete a condition. So soon as opportunity affords, I hope to resume my work on this inquiry and satisfactorily determine the identity of the alkaloid.

It may be stated that 2·5 per cent. of a waxy substance was extracted from the bark.

[*The discussion on this paper is printed at p.* 832.]

REMARKS ON SOME MEDICINAL PLANTS OF CEYLON.*

BY W. C. ONDAATJE, F.L.S.,
Colonial Surgeon of Ceylon.

It is well known that several Indian drugs have been incorporated into the British Pharmacopœia, which have added to the number of remedial agents, thus conferring no small advantage on the medical profession, and the publication of the Pharmacopœia of India has conferred an incalculable benefit on the medical practitioner in the East, but still there are many medicinal plants of the colonies and India which deserve a scientific examination.

The public revenue of the colonies is applied to many useful purposes for promoting the general welfare of the people. I believe that if a sum of money were voted annually to be expended in carrying out the chemical examination of indigenous drugs and other products by competent persons in this country, all expenditure would be well repaid by the advantages reaped in the saving of Government expenses for medicines and in the demand created for native products.

It is a matter of great importance to the millions in the East, and in fact to the whole community, that they be enabled to avail themselves of efficient substitutes for many official drugs which our colonies supply.

I may here mention that the annual cost of drugs for the use of the public service of Ceylon forms a considerable item. The natives are now more largely availing themselves of European medical practice, since the extension of Government hospitals and dispensaries, and consequently an increasing expenditure under this head cannot be avoided without detriment to the best interests of the population.

The necessity for adopting such a measure as I have suggested will be apparent to those who have studied Indian drugs.

The natives of the East have attributed imaginary properties to many plants and drugs, and much that is absurd is mixed up with much that is valuable.

While clinical observations in hospitals and medical colleges are of much importance to ascertain the therapeutic action, chemical examination will perfect the knowledge thus obtained, and will, with the aid of pharmacy, show the best mode of preparation and administration, and no institution can more efficiently carry out this work than the Pharmaceutical Society of Great Britain.

I will now proceed to make a few brief remarks on some medicinal plants which I brought with me from Ceylon.

1. *Randia dumetorum*, Lam.—The seeds of this tree are used by the natives of Ceylon and India as a reliable agent in producing emesis.

I am not aware that any chemical examination has been made to detect the active principle.

It belongs to the same family (Cinchonaceæ) as *Cephaelis Ipecacuanha*, and it would be important to determine if it contains emetine, more particularly since an allied species, *R. uliginosa*, is, according to Dr. Dymock, used in India as a remedy for dysentery. This species is also indigenous in Ceylon. The bark of *R. dumetorum* also possesses the same qualities.

I have seen the powdered seeds used with as good effect as ipecacuanha in doses of 5 to 10 grains. If analysis should prove *Randia* to possess the same active principle as ipecacuanha, a great saving might be effected by its substitution for the more expensive Brazilian drug.

Some weeks ago I had the pleasure of presenting a small quantity of the fruit to your Museum.

2. *Sethia acuminata*, Arn.—This is a remedy much used by the Cinghalese as a vermifuge. The part used is the leaves, the juice of the leaves being mixed with sugar and castor oil, or with the powder of the leaves. The leaves are easily powdered when dried.

Professor Bentley notices its vermifuge properties in his 'Manual of Botany.'

Dr. Thwaites, in his 'Enumeratio Plantarum Zeylaniæ,' also refers to it. He says, "the Cinghalese attach much value to this plant as an anthelmintic for children, giving the juice expressed from the fresh leaves." It is chiefly used for expelling round worm and possesses the advantage of not having a disagreeable taste. The powder is used in the dose of 10 to 15 grains.

I presented a small quantity of the leaves and a flowering specimen of the plant to your Museum.

3. *Coscinium fenestratum*, Colebr.—Many years ago, while using it as a tonic, I found by experiment that it possessed *antiseptic* properties, to which I beg to invite your attention.

I found that pieces of beef immersed in an infusion of the stem were preserved for several weeks. I am unable to give more details, as my notes made in Ceylon are not at hand.

I also used in Ceylon a weak infusion of the stem as a lotion for foul ulcers with great success.

I believe the plant has already been subjected to chemical analysis in this country and contains the active principle berberia.

It has been used also as a yellow dye. As this drug has recently been imported in quantity into England it could easily be obtained, and an examination of the cause of its antiseptic properties seems desirable.

4. *Vateria Indica*, L.—Some of the bark of the tree I have presented to your Museum. The natives use it daily to arrest the alcoholic fermentation of

* Read at an Evening Meeting of the Pharmaceutical Society, April 4, 1883.

the juice of the Jaggery palm, *Caryota urens,* which is a favourite beverage with them. This property of preventing fermentation might, I think, be turned to account in some of the great manufacturing industries, if not in medicine, and I trust the bark may be thought deserving of chemical investigation by some members of your Society.

5. *Semecarpus Gardneri,* Thw.—The black resin yielded by this tree, although not possessing medicinal properties, may be of some interest in the arts.

I have presented to the Museum some of the resin.

The resin is hard, breaks with a smooth fracture, burns with a bright flame, is soluble in turpentine, and adheres strongly to wood and metal. It is free from acridity.

The formula for using the resin as a varnish is as follows:—

To a saturated solution of *Vateria Indica* resin in oil of turpentine, add by degrees pieces of black resin, and put it into a bottle and shake it well until the whole is dissolved, then apply it to wood or metal, which will give a varnish of great lustre and beauty. The resin should be first melted and strained through coarse calico or a sieve, to free it from impurities.

6. *Vernonia anthelmintica,* Willd.—This plant is cultivated by the Cinghalese and is in great repute as a remedy, which is indicated by its name.

The seeds are black, of a bitter and nauseous taste, are easily procured from bazaars, and are commonly used by the village people for expelling the ascaris lumbricoides and act as a vermicide.

The dose of the powdered seed to an adult is from ½ to 1 drachm.

The native physicians prescribe it generally as a tonic in the shape of an infusion.

The Cinghalese name is *sanne nayan* and the Tamil name *kadoseragam.*

European practitioners in India, from personal observations, confirm the truth of the above statement.

7. *Alstonia scholaris,* R. Br.—In 1865 I forwarded to England, to my friend and correspondent, Mr. P. L. Simmonds, the Editor of the *Technologist,* specimens of a kind of caoutchouc, as a substitute for gutta-percha.

The following information supplied by me appeared in that periodical for August 1865:—

"Another substitute for gutta-percha, the milky juice of the *Alstonia scholaris,* a tree belonging to the natural order Apocyneæ, has been forwarded from Ceylon by Mr. Ondaatje; it is stated to possess the same properties and to be workable as gutta-percha. It readily softens when plunged in boiling water, is soluble in turpentine and chloroform, receives and retains impressions permanently, and is adapted for seals to documents."

The bark of this tree is thick and spongy. Its properties as a medicinal agent are fully described in the Pharmacopœia of India.

8. *Acorus Calamus,* Linn.—The well-known sweet flag I merely notice as an anthelmintic, which property is not included in the Indian Pharmacopœia.

An infusion of the rhizome or root-stock given to young children acts effectually, as I have seen many such cases treated among the natives.

I hope on a future occasion to be able to contribute further notes on the native materia medica of Ceylon.

[*The discussion on this paper is printed at p.* 833.]

NOTE ON ESSENCE FROM GREEN GINGER.*

BY C. SYMES, PH.D.

The increased use of ginger by manufacturers of mineral waters and others, of late years, has created a demand for a "soluble essence," *i.e.,* an essence which, when mixed with water, causes little or no opacity therein.

Dr. Thresh's scientific investigation of the constituents of this rhizome, particularly of the nature of its resinous constituents, added considerably to our knowledge of its composition. But strange to say, the process devised by him on the basis of this investigation, for the preparation of a soluble essence did not give (to my mind) very satisfactory results. Indeed, Dr. Thresh has since testified to the superiority of an essence produced by another maker.

It would seem, therefore, that the field is still open for the application either of science, or the results of experience. The contribution I have to offer this evening is a simple, short, and practical one. Many, indeed most, drugs deterioriate by age, whilst some few, such as *Rhamnus Frangula* bark, are said to improve as they grow older, at least to a certain point. Now, it occurred to me, that the nature and properties of ginger, and its behaviour towards certain solvents of its active constituents, may not be constant at all periods, and the receipt from Rio Janeiro of a supply of green ginger grown at Santa Catherina, enabled me to make an experiment in this direction. The ginger, of which I have here a sample, occurs in large pieces; it is quite soft, and is not decorticated. Two methods were tried for removing the outer portion; the one simple scraping, the other by first soaking in boiling water. The latter did not appear to possess any special advantage, and by the former it lost fully 15 per cent. of its weight. After a few hours' exposure to the air it was weighed, thoroughly dried and reweighed, when it was found to have lost 65 per cent. of moisture.

Taking a sample of the ginger from which the epidermis had been removed, and which had been surface-dried by exposure for a few hours to the air, I cut it in thin slices, and macerated it for some days with an equal weight of rectified spirit, which, when filtered, yielded an essence possessing a very fine aroma, and which when mixed with water scarcely rendered it turbid in the least degree. It is fairly strong, and could doubtless be prepared stronger were the drying of the ginger carried a little further. Probably, however, its solubility would diminish if the drying were completed, and of course the result would cease to be essence of green ginger.

[*The discussion on this paper is printed at p.* 834.]

A NOTE ON SAP.*

BY PROFESSOR ATTFIELD, F.R.S.

Beneath a white birch tree growing in my garden I noticed, yesterday evening, a very wet place on the gravel path, the water of which was obviously being fed by the cut extremity of a branch of the birch about an inch in diameter and some ten feet from the ground. I afterwards found that exactly fifteen days ago circumstances rendered necessary the removal of the portion of the branch which hung over the path, 4 or 5 feet being still left on the tree. The water or sap was dropping fast

* Read at an Evening Meeting of the Pharmaceutical Society, April 4, 1883.

from the branch, at the rate of sixteen large drops per minute, each drop twice or thrice the size of a "minim," and neither catkins nor leaves had yet expanded. I decided that some interest would attach to a determination both of the rate of flow of the fluid and of its chemical composition, especially at such a stage of the tree's life.

A bottle was at once so suspended beneath the wound as to catch the whole of the exuding sap. It caught nearly 5 fluid ounces between eight and nine o'clock. During the succeeding eleven hours of the night 44 fluid ounces were collected, an average of 4 ounces per hour. From 8.15 to 9.15 this morning, very nearly 7 ounces were obtained. From 9.15 to 10.15, with bright sunshine, 8 ounces. From 10.15 until 8.15 this evening the hourly record kept by my son Harvey shows that the amount during that time has slowly diminished from 8 to a little below 7 ounces per hour. Apparently the flow is faster in sunshine than in shade, and by day than by night.

It would seem, therefore, that this slender tree, with a stem which at the ground is only 7 inches in diameter, having a height of 39 feet, and before it has any expanded leaves from whose united surfaces large amounts of water might evaporate, is able to draw from the ground about 4 litres, or seven-eighths of a gallon of fluid every twenty-four hours. That at all events was the amount flowing from this open tap in its water system. Even the topmost branches of the tree had not become, during the fifteen days, abnormally flaccid, so that, apparently, no drainage of fluid from the upper portion of the tree had been taking place. For a fortnight the tree apparently had been drawing, pumping, sucking—I know not what word to use—nearly a gallon of fluid daily from the soil in the neighbourhood of its roots. This soil had only an ordinary degree of dampness. It was not wet, still less was there any actually fluid water to be seen. Indeed, usually all the adjacent soil is of a dry kind, for we are on the plateau of a hill 265 feet above the sea and the level of the local water reservoir into which our wells dip is about 80 feet below the surface. My gardener tells me that the tree has been "bleeding" at about the same rate for fourteen of the fifteen days, the first day the branch becoming only somewhat damp. During the earlier part of that time we had frosts at night, and sunshine, but with extremely cold winds, during the days. At one time the exuding sap gave, I am told by two different observers, icicles a foot long. A much warmer, almost summer, temperature has prevailed during the past three days and no wind. This morning the temperature of the sap as it escaped was constant at 52° F. while that of the surrounding air was varying considerably.

The collected sap was a clear, bright water-like fluid. After a pint had stood aside for twelve hours there was the merest trace of a sediment at the bottom of the vessel. The microscope showed this to consist of parenchymatous cells, with here and there a group of the wheel-like or radiating cells which botanists, I think, term sphere-crystals. The sap was slightly heavier than water, in the proportion of 1005 to 1000. It had a faintly sweet taste and a very slight aromatic odour.

Chemical analysis showed that this sap consisted of 99 parts of pure water with 1 part of dissolved solid matter. Eleven-twelfths of the latter was sugar.

That the birch readily yields its sap when the wood is wounded is well known. Phillips, quoted by Sowerby, says:—

> "Even afflictive birch,
> Cursed by unlettered youth, distils
> A limpid current from her wounded bark,
> Profuse of nursing sap."

And that birch sap contains sugar is known, the peasants of many countries, especially Russia, being well acquainted with the art of making birch wine by fermenting its saccharine juice.

But I find no hourly or daily record of the amount of sugar-bearing sap which can be drawn from the birch, or from any tree, before it has acquired its great digesting or rather developing and transpiring apparatus—its leaf system. And I do not know of any extended chemical analysis of sap either of the birch or other tree.

Besides sugar, which is present in this sap to the extent of 616 grains—nearly an ounce and a half—per gallon, there are present a mere trace of mucilage; no starch; no tannin; $3\frac{1}{2}$ grains per gallon of ammoniacal salts yielding 10 per cent. of nitrogen; 3 grains of albumenoid matter yielding 10 per cent. of nitrogen; a distinct trace of nitrites; 7·4 grains of nitrates containing 17 per cent. of nitrogen; no chlorides, or the merest trace; no sulphates; no sodium salts; a little of potassium salts; much phosphate and organic salts of calcium; and some similar magnesian compounds. These calcareous and magnesian substances yield an ash when the sap is evaporated to dryness and the sugar and other organic matter burnt away, the amount of this residual matter being exactly 50 grains per gallon. The sap contained no peroxide of hydrogen. It was faintly if at all acid. It held in solution a ferment capable of converting starch into sugar. Exposed to the air it soon swarmed with bacteria, its sugar being changed to alcohol.

A teaspoonful or two of, say, apple juice, and a tablespoonful of sugar put into a gallon of such rather hard well-water as we have in our chalky district, would very fairly represent this specimen of the sap of the silver birch. Indeed in the phraseology of a water-analyst, I may say that the sap itself has 25 degrees of total, permanent, hardness.

How long the tree would continue to yield such a flow of sap I cannot say; probably until the store of sugar it manufactured last summer to feed its young buds this spring was exhausted. Even within twenty-four hours the sugar has slightly diminished in proportion in the fluid.

Whether or not this little note throws a single ray of light on the much debated question of the cause of the rise of sap in plants I must leave to botanists to decide. I cannot hope that it does, for Julius Sachs, than whom no one appears to have more carefully considered the subject, says, at page 677 of the recently published English translation of his text-book of botany, that "although the movements of water in plants have been copiously investigated and discussed for nearly two hundred years, it is nevertheless still impossible to give a satisfactory and deductive account of the mode of operation of these movements in detail." As a chemist and physicist myself, knowing something about capillary attraction, exosmose, endosmose, atmospheric pressure and gravitation generally, and the movements caused by chemical attraction, I am afraid I must concur in the opinion that we do not yet know the real ultimate cause or causes of the rise of sap in plants.

Ashlands, Watford, Herts.

CATALOGUE OF SPECIMENS OF CINCHONA BARK, WITH ILLUSTRATIVE BOTANICAL SPECIMENS,

FORWARDED THROUGH HER MAJESTY'S SECRETARY OF STATE FOR INDIA FOR THE PHARMACEUTICAL SOCIETY FOR GREAT BRITAIN.

Number on Specimens.	Name of Specimen.	Number of Herbarium Specimens.	Kind of Bark.	Habitat.	Remarks.
				NILGIRIS.	
1/2	*C. officinalis, Uritusinga*	1	Natural .	Dodabetta .	This is the *C. Uritusinga*, type of Pavon.
2/7	*do. do.*	1	Mossed .	do. .	*C. Uritusinga*, Pavon type.
3/12	*do. Condaminea*	1	Renewed	do. .	*C. Condaminea*, How. variety.
4/15	*do. do.*	1	do.	do. .	*do.* How. type.
5/22	*do.*	1	From coppice shoots	do. .	These botanical specimens and also the bark were taken from coppice shoots.
6/27	*do.*	1	Renewed after shaving.	do. .	The bark belonging to this specimen is renewed, after the tree had been subjected to the Java shaving process. In this the outer cellular portion is shaved or pared off, the inner vascular layer being left intact.
7/28	? corky bark	1	Natural.	do. .	Bark covered externally with a thick corky layer, and very peculiar, of officinalis type but undetermined species.
8/29	*C. officinalis*	1	Renewed	do. .	
9/36	*do. Condaminea*	1	do.	Naduvattam	This is the *C. Condaminea* type of How.
10/9	*do. Uritusinga*		do.	Dodabetta .	Large leafed or *C. Uritusinga*, Pavon type.
11/16	*do. angustifolia*	1	Mossed .	do. .	This is the No. 1 form of *C. Angustifolia*, How., according to the estate nomenclature.
	do. do.	0	Renewed	do. .	
12/13	*do. do.*	2	do.	do. .	This is the No. 2 variety, in the estate nomenclature, of the variety *C. angustifolia*, How.
A/0	*do. Uritusinga*	0	Natural .	do.	
B/44	*do.*	0	do.	Naduvattam	
C/25	*do. angustifolia*	0	do.	Dodabetta	
D/0	*do. Uritusinga*	0	Mossed .	do.	
E/43	*do.*	0	do.	Naduvattam	
F/42	*do.*	0	do.	do.	
G/0	*do.*	0	Renewed	Dodabetta	
13/0	*C. Pitayensis*	1	Natural .	do.	
14/0	*do.*	1	No bark.	do.	
15/1	*C. Pahudiana*	1	Natural .	do. .	This species was discovered by Hasskarl, cultivated on a large scale in Java and found to be worthless. From Java it was introduced into India, but fortunately its culture here never went beyond the stage of an experiment.
16/23	*do.*	1	Mossed .	do.	
17/50	*do.*	2	Natural .	Naduvattam	
18/5	? corky bark	2	Renewed	Dodabetta .	This plant was said by Cross, on his recent visit to the Nilgiris, to be the *C. crispa* of which he sent seeds from the Loxa Mountains. That it came from Loxa there is no doubt, as the few specimens of it on the estate of Dodabetta are growing amongst the "crown" barks introduced from that region. It differs, however, very much from the *C. crispa* of Tafalla, which belongs to the *C. officinalis* group of Weddell. In general appearance it is more nearly allied to Weddell's section *Pahudianæ*. Its bark is also very peculiar, in fact unique.
19/14	? do.	1	Natural .	do.	
20/32	*C. micrantha*	2	do. .	Naduvattam	
21/48	*C. Calisaya*	1	do. .	do. .	This form of the *C. Calisaya* grows to a considerable size and has bright green shining leaves, some of which measure from 6 to 7 inches in length by 3½ to 4 inches in width. Flowers pink, very sweetly scented.
22/49	*do.*	2	do. .	do. .	This plant approaches the *Boliviana* form of Weddell, but the *Calisayas* are most variable.
23/47	*do. Josephiana* .	1	do. .	do.	

Number on Specimens.	Name of Specimen.	Number of Herbarium Specimens.	Kind of Bark.	Habitat.	Remarks.
24/38	*C. anglica*	1	Natural .	NILGIRIS. Naduvattam	This plant, according to Howard, is a hybrid between *C. Calisaya* and *C. succirubra*. On the other hand it is said to come perfectly true from seed, and in October last a planter sent me a fresh specimen of it from Wynaad, which had been raised from seed procured from Java, and which was identical with the Naduvattam plants. It appears to me to be only a variety of *C. Calisaya*.
25/35	*do.*	2	Renewed	do.	
H/46	*do.*	0	Mossed .	do.	
26/30	*C.* (*pubescens*)	2	Renewed Natural .	Dodabetta . do. .	This is not the *C. pubescens* of Vahl, but a plant which was considered to be a hybrid by the superintendent of the cinchona estates, the late Mr. McIvor. Mr. Cross, the explorer who was employed in collecting cinchona plants and seeds in the cinchona regions of South America for the Indian Government, regards it as the pubescent form of "Cuchicara," referred to by Dr. Spruce in the Parliamentary Blue Book of 1863, p. 116. Mr. McIvor stated that it is a hybrid between *Cinchona succirubra* and *Cinchona officinalis*.
27/10	*C.* (*pubescens*)	2	Renewed	do.	
28/37	*do.*	2	Natural .	Naduvattam	
29/39	*do.*	1	Renewed	do.	
30/6	? . . . . *do.*	1 0	Renewed Natural .	Dodabetta . do. .	This plant has been known on the Government estates as "McIvor's hybrid" and "Magnifolia," and Mr. Cross, the South American explorer, pronounced it to be the *Pata de gallinazo*, referred to by Dr. Spruce at p. 117 of the Cinchona 'Blue Book,' of 1863, as the smooth variety of the "Cuchicara." The term "Magnifolia" applied to this plant is purely a local one, as it is in no way related to the *C. magnifolia* of Ruiz and Pavon. The Kew authorities, under date the 24th January, 1882, remarked, "it may be said with some certainty that the Nilgiri "Magnifolia" is not the *Pata de gallinazo* of Chimborazo." Mr. Howard, from bark alone, identified it as *C. coccinea*, Pav., which Spruce considered identical with *C. erythrantha*, Pav. For a list of other species to which the name *Pata de gallinazo* has been applied, see Weddell's Notes, Article No. 10.
31/11	? *Pata de gallinazo* .	1	Renewed	do. .	Pata de gallinazo of Cross.
32/20	? *do.* .	1	Mossed .	do. .	Do. do.
33/34	? *do.* .	1	Natural .	Naduvattam	Do. do.
34/40	? *do.* .	2	Mossed .	do. .	Do. do.
35/31	*C. succirubra* . . . . *do.*	1 0	Renewed Mossed .	do. do.	
36/33	*do.*	2	Natural .	do.

The Pharmaceutical Journal.

SATURDAY, APRIL 7, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POSITION OF PHARMACISTS IN RELATION TO THE PHARMACOPŒIA.

THE unanimity with which the Council, at its meeting on Wednesday last, agreed to the motion of Mr. HAMPSON on the subject of the Pharmacopœia, proves that British pharmacists think the time has come when they should occupy a legally recognized position in respect to the compilation of the text-book which has towards them the force of law. The occasion is certainly opportune. A quarter of a century has now elapsed since the Council established under the Medical Act of 1858 was authorized to publish under its direction one National Pharmacopœia, which should authoritatively take the place of the three Pharmacopœias then existing in the British Islands. At that time, though there was already a promise of better things, it cannot be said that the status of pharmacists in this country was such as to entitle them as a body to expect legal recognition as coadjutors with the medical profession, even in a work for one department of which the pharmacist is so peculiarly well fitted as the preparation of a Pharmacopœia. The task of producing the national medicine book therefore fell inevitably to the medical profession alone, as represented in the Medical Council, by whom it was accomplished with a success that has called forth grateful recognition, not only from members of the medical profession, but also from pharmacists, and might well explain and excuse a certain amount of sentimental objection felt in some quarters,—though, we believe, not widely,—to any proposition which might have the appearance of disturbing a kind of vested interest which the Council had during this time acquired to a monopoly in the ordering of the Pharmacopœia. The twenty-five years during which the Medical Council, as at present constituted, has been in existence have, however, brought many changes, and, thanks to the work done by the Pharmaceutical Society, pharmacists in this country are now in a position to undertake duties which could not have been accorded to them when first the unification of the three Pharmacopœias was decided upon. Consequently, signs have not been wanting of a growing disposition to put forward claims with respect to the position of pharmacists towards the next edition of the British Pharmacopœia which the Medical Council might have found it impossible to acknowledge and embarrassing to refuse. That the claims themselves are not, however, thought to be unreasonable may be assumed from the fact that the organ of the British Medical Association has, within the last few weeks,* reiterated an opinion expressed some years ago on the occasion of the publication of the "Additions," as to the "necessity of giving greater prominence to the element of practical pharmacy in the Pharmacopœia Committee."

In this condition of affairs the introduction into the House of Lords by the Government of a Bill having for its object to substitute for the body which has so long had the control of the Pharmacopœia another one very differently constituted, furnishes a *tabula rasa* for the reconsideration of the whole subject, without the slightest suspicion of discourtesy or rivalry to anyone. But since in this Bill it is simply proposed to vest in the new body exclusively powers similar to those exercised by the old, it will be learnt with satisfaction that the Pharmaceutical Council has instructed one of its Committees to take immediate steps to secure the introduction into the Bill of a provision by which pharmacists shall be empowered, conjointly with members of the Medical Council, to revise and prepare future editions of the British Pharmacopœia.

It will be for the Committee to decide upon the arguments with which it will approach the Government upon the subject. But a strong one would appear to be available in the resolution which less than two years since was adopted by the International Pharmaceutical Congress assembled in London, to the effect that the future revision of any national Pharmacopœia should be entrusted to a permanent committee comprising among its members the largest possible number of pharmacists. Moreover, the important discussion, following the reading of a paper by the present President of the Pharmaceutical Society, which led up to the adoption of this resolution, showed that the proposition was no innovation, but that already in every country represented at that Congress pharmacists held a legally recognized position together with medical men in respect to the duty of revising the national Pharmacopœia.

As, notwithstanding the justice of the claim which the Council has determined to urge at the present juncture, some little extraneous effort may possibly be necessary in order to overcome the inertia inherent to conditions that exist, it may serve a good purpose to recall a few of the statements made at the Congress upon the subject. Looking first across the Channel towards our nearest neighbour, M. PETIT said that the French Codex Commission should, according to law, be composed solely of professors of medical schools and professors of superior schools of pharmacy; but to these have been added members of the Société de Pharmacie with only a consultative voice. In practice, however, the greater part of the work is done by the Société de Pharmacie and the other pharmacists belonging to the

* *British Medical Journal*, March 10, p. 478.

Commission, the medical members rarely attending the meetings and the decisions being generally arrived at by the pharmacists alone. Respecting Germany, Dr. Carl Schacht was able to say that the Pharmacopœia Commission, then engaged upon the work just issued, included seven practical pharmacists. In this Commission the decision as to the admission of new medicines, or the expunging of obsolete ones, lay with the medical members, but the pharmacists alone had the decision as to the manner in which the preparations were to be made. A small sub-committee, consisting of chemists and pharmacists only, was entrusted with the working out of the chemistry and pharmacy of each subject, and the results were afterwards submitted for the approval of the Commission at a general meeting. In Austria, according to Herr von Waldheim, the Pharmacopœia Commission consists of the Superior Board of Health and six chemists, who are summoned from time to time when any alteration or addition is thought to be required. In Russia, Dr. Poehl says the revision of the Pharmacopœia is carried out by the Medical Council, which includes two pharmacists among its members, the Pharmacopœia being first drafted by these pharmaceutical members acting by themselves, and then submitted to a full meeting of the Council for confirmation. In Italy, according to Signor Sinimberghi, the Commission entrusted with the preparation of the first national Pharmacopœia for the new Kingdom, as originally appointed, consisted entirely of medical men, but representations having been made to the Government, an equal number of pharmacists were added to the Commission. Dr. De Vrij described a position just the reverse of this as obtaining in Holland, where in 1864 the King appointed a Commission consisting of two professors of botany and pharmacology and one of chemistry, and four pharmacists, so that at first pharmacy was preponderant, whilst medicine was absent; at the request of the pharmacists, therefore, a medical member of the Commission was appointed. In Denmark the existing Pharmacopœia was prepared by a Commission consisting of eight physicians and two pharmacists. In Belgium, according to Professor Gille, the Commission engaged at the time of the Congress upon the revision of the Pharmacopœia was composed of three pharmacists and two medical men. Lastly, the recently issued edition of the United States Pharmacopœia is, as has been before stated, the work of a large Revision Committee, including a majority of pharmacists.

It will be seen, therefore, that whilst these Commissions present many points of difference they have all one feature in common, in the provision made that whilst medical men are present to decide as to the selection of new or the rejection of obsolete remedies the practical skill of pharmacists is utilized in working out the best methods of preparation.

THE VISIT OF THE BRITISH ASSOCIATION TO CANADA.

From a circular just issued by the Executive of the British Association it would appear that it has been decided to waive the opposition which the unexpected decision of the General Committee to accept an invitation to visit Montreal, if repeated for 1884, at first provoked, and as far as possible to secure that the meeting shall be a representative one, "creditable to the Association and gratifying to the Canadian hosts." Certainly the prospective hosts are doing all they can to remove every obstacle by means of arrangements that will ensure every visitor from this country an opportunity of making the most of his time at a minimum of expense. The inhabitants of Montreal have now repeated the invitation, as stipulated, and have already formed committees on invitation, finance, and conveyance, and opened a guarantee fund. The Dominion Government has also undertaken to ask Parliament to contribute a sum of twenty thousand dollars in aid of the money subscribed by the public.

The circular includes a letter from Sir A. T. Galt, High Commissioner for Canada, resident in this country, containing information as to the probable expenses that will be involved in attending the meeting, every line of which bears evidence of the generous hospitality the colonists are prepared to accord. In the first place, in respect to the cost of the journey to and from Montreal, the Committee offer to arrange fifty free passages for the conveyance of the officers of the Association whose attendance at the meeting is indispensable. Beyond this it is prepared to devote the balance of £3000 either to securing to a number of *bonâ fide* members passages at the single rate—about £15 10s.—for the single journey, or for a general reduction of the fares as far as the funds will admit. Arrived at Montreal, the Committee are willing to give assurance that free entertainment will be provided for at least one hundred and fifty, and probably for all others who may attend. But even those who may scruple to accept such free hospitality are told that the tariff of Montreal hotels ranges between two and a half and four dollars a day inclusive, whilst private accommodation may be obtained at much lower prices than in England. As to proposed excursions, Dr. Sterry Hunt says that the Grand Trunk, the Canada Pacific and the Intercolonial railways will furnish free transport over their lines from Nova Scotia to the North West. The Canada Pacific will also arrange an excursion to the Rocky Mountains and the Grand Trunk one to the Great Lakes (including Niagara) and Chicago, while the South Eastern Railway will do the same for the White Mountains and Portland and Boston. For an excursion of this kind, occupying three or four weeks, it is estimated that a sum of £20 would be required for hotels, carriages and other incidental expenses, though it is possible that a less sum will suffice.

The programme is a tempting one, and will give the members of the British Association an opportunity of visiting the Dominion under conditions more favourable than are likely to occur oftener than once in a lifetime.

THE ANNUAL DINNER.

We are pleased to be able to state that a large number of gentlemen, including the majority of the members of Council and all the officers of the Society, have already signified to the Honorary Secretary their desire to act as Stewards on the occasion of the Annual Dinner. But it is believed that there are many more, especially among the Local Secretaries, who will be glad of a further opportunity for sending in their names, and for this reason it has been thought advisable to postpone the closing of the List of Stewards until Wednesday next, the 11th inst.

The last Evening Meeting for the present session of the North British Branch of the Pharmaceutical Society will be held in the Society's Rooms, Edinburgh, on Wednesday evening next, when a paper on "The Preparation and Composition of Unguentum Hydrargyri Nitratis" will be read by Mr. T. Maben; after which Mr. Patrick Geddes will deliver a lecture on "The History and Present State of the Cell Theory."

* * *

The Government Medical Act Amendment Bill was read a second time in the House of Lords on Thursday evening, and committed to a Committee of the whole House, which is fixed for Thursday, the 19th inst.

* * *

An anonymous correspondent, using the suggestive initials A.B.C., asks in the *British Medical Journal* for an opinion on the following prescription which he appears to have written: "℞ Liq. ammon. acetatis ʒj; vini. ipecac. ʒjs (? ʒss); liq. morphiæ hydrochlor. ʒjs (? ʒss); syrupi acaciæ ℥j; aquæ, ad ℥j." He wished a two-ounce mixture to have been made, but his first doubt as to whether he had succeeded in expressing his intention correctly seems to have been excited when the prescription was shown to him at his patient's house, with the word "ad" marked through. A.B.C. is not particularly happy in explaining how his instructions were to have been carried out in their integrity, and as if conscious of his non-success, he adds: "If I am wrong, I pray Heaven that the examiners who allowed me to obtain my diplomas will try to find out if men know how to write a prescription accurately before giving a degree, and save them from the reproof of druggists." Probably most "druggists" will be ready to utter a devout "amen!" to this aspiration.

* * *

A correspondent, after describing in the current number of the *Medical Press and Circular* the "disreputable practice" of a qualified medical practitioner in keeping a chemist and druggist's shop, managed by an unqualified assistant, who also prescribes and signs certificates in the name of his principal, asks whether a M.R.C.P. Edin. is allowed to keep a druggist's shop, and sell penny nostrums and patent medicines. The reply is of course in the affirmative; but whilst deploring the fact the Editor informs his correspondent that "unfortunately such examples are legion in poor neighbourhoods." Both question and answer are worth pondering by those medical practitioners who are fond of blaming chemists and druggists for the propensity displayed by the public to seek medical relief in the chemist's shop.

* * *

One of the tendencies of medical dispensing is illustrated in the *British Medical Journal* of last week by a request of a correspondent for information as to the making of concentrated infusions "similar to those sent out by wholesale druggists."

* * *

The *Lancet* recommends prescribers who are in the habit of ordering pills to be coated to make the experiment of dissolving one of such pills in a bag of slightly acidulated liquid at a temperature of nearly 100° F., and prophesies that in a majority of cases it will be found, even when frequent agitation is applied, that the "mass is barely approached by the fluid after many hours and does not completely break down until a very considerable period has elapsed." The inference drawn is that "pills coated with gold, silver and even mastic—unless quite recent—are not brought into a condition in which the drugs of which they are composed could be appropriated by the stomach until long after the time of administration."

* * *

The new edition of the United States Pharmacopœia would appear to be meeting with a large sale, since a fresh issue—the third or fourth—has been announced as just ready.

* * *

After a lapse of more than six years a new edition—the fifth—of the 'Price List' compiled by the Committee appointed at a general meeting of Chemists and Druggists of Glasgow and neighbourhood has been issued. It contains a few modifications in the dispensing charges, chiefly in the direction of inserting alternative lower prices, and in the retail list, to which also a number of articles have been added. Copies may be obtained from the Convener of the Committee, Mr. J. A. Clarke, 148, Gallowgate, Glasgow.

* * *

At the next Wednesday evening meeting of the Society of Arts, on the 11th inst., a paper will be read on "The Portrush Railway and the Transmission of Electricity," by Mr. A. Siemens and Dr. Hopkinson.

* * *

In the Chemical Section of the same Society, on Thursday evening, the 12th inst., Mr. R. W. Atkinson will read a paper on "The Formation of Diastase from Grain by Moulds."

* * *

At the meeting of the Chemists' Assistants' Association, on Wednesday evening next, a paper will be read, entitled "A Few Hints on Germ Disease," by Mr. W. R. Dodd.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, April 4, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams and Young.

The minutes of the previous meeting were read and confirmed.

Nominations for Council and Auditors.

Council.

The Secretary reported that he had received *seventeen* nominations to fill the *fourteen* vacant seats on the Council, and that the following *sixteen* had declared their willingness to accept office if elected:—

Andrews, Frederick, 34, Leinster Terrace, W.
Atkins, Samuel Ralph, Market Place, Salisbury.
Baldock, John Henry, 3, High Street, South Norwood, S.E.
Borland, John, 7, King Street, Kilmarnock.
Bottle, Alexander, 37, Townwall Street, Dover.
Butt, Edward Northway, 13, Curzon Street, Mayfair, W.
Carteighe, Michael, 180, New Bond Street, W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hills, Walter, 225, Oxford Street, W.
Radley, Wm. Valentine, 42, Hampton Road, Southport.
Richardson, John G. F., Elmfield, Stoneygate, Leicester.
Robbins, John, 147, Oxford Street, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Symes, Charles, 14, Hardman Street, Liverpool.
Woolley, George Stephen, 69, Market Street, Manchester.
Young, John Rymer, 42, Sankey Street, Warrington.

The following had declined to accept office:—

Sandford, George Webb, 47, Piccadilly.

Auditors.

Hodgkinson, William, 198, Upper Whitecross Street, E.C.
Lescher, Frank Harwood, 60, Bartholomew Close, E.C.
Stacey, Samuel Lloyd, 300, High Holborn, W.C.
Thompson, Henry Ayscough, 22, Worship Street, E.C.
Watts, William Manning, 32, Lower Whitecross St., E.C.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Ball, Henry ....Southport.
Drew, Walter Clark ....London.
Marshall, Joseph Jewison ......Beverley.
Rouw, Theodore John............Eastbourne.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Austen, Charles Wilson ....Chatham.
Bolton, Frederic William ......Winchester.
Evans, Thomas Fryer ....Flint.
Francis, Charles Ernest ....Burnley.
Gray, John ....Forres.
Guy, Frederick.......................Brighton.
Hodgson, Alfred ....London.
Horrod, Thomas Samuel.........London.
Knight, Ramsey ....Pendleton.
Lindewald, Wilhelm Edvard ...Menton, France.
Newsam, William Henry ......Stoke-Ferry.
Stirling, George ....Dunoon.
Watson, John ....Newcastle-on-Tyne.
Willis, Henry James ....New Brompton.

Modified.

Bolton, Edgar Benjamin.........Winchester.
Hern, William Henry, jun. ...London.

ASSOCIATES.

The following, having passed the Minor examination and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Dadson, Horace Charles ....King's Lynn.
Davies, Llewelyn ....Newport, Mon.
Hudson, William ....Sunderland.
Ombler, William Henry ....Windsor.
Puckey, Courtenay ....Herne Hill.
Reeves, Alfred ....London.
Smith, Harry James ....Speenhamland.
Wall, Edward John................Peckham.
Walton, Frederick Miles.........Reading.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adams, Joseph ....Bristol.
Bayley, Cornelius...................Boston.
Bulmer, John ....Pocklington.
Elliott, Henry Alfred ....Derby.
Field, Ebenezer......................Cambridge.
Heath, Walter Edwin ....Coleshill.
Henshall, Harry ....Lymm.
Jones, William ....Bolton.
McDiarmid, Fraser ....Deal.
Moody, William Morton.........Salisbury.
Terry, Edwin ....Tadcaster.
Walklett, George James ....Oxford.
Watkins, William Richards ...Llanelly.
Weston, Henry.......................Devizes.
Wride, William Blake............Shirley.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restorations to the Register.

The names of the following persons who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

James Benjamin Bond, 6, Cornbrook Street, Manchester.

Edward Todd, 110, Newhampton Road, Wolverhampton.

Addition to the Register.

The Registrar reported that—

Alexander Clark, 89, Gilmore Place, Edinburgh, having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been duly supported by qualified persons, his name had been placed on the Register.

Honorary Members.

The President reminded the Council that it was usual to elect Honorary Members in May, but looking to the fact that the number was limited to fifty, and that there are already forty-eight on the list, and also that a proposal had been made to create a class of Corresponding Members, he suggested that no election should be made at present.

This suggestion was unanimously agreed to.

Reports of Committees.

FINANCE.

The report of this Committee included a recommendation that various accounts be paid; also that a certain sum be guaranteed towards the expense of laying down wood pavement in Great Russell Street, outside the Society's premises (some portion of which would probably be subscribed by other householders), in consideration of which it was stated that the District Board of Works was prepared to undertake this improvement.

The report stated that some correspondence with regard to the purchase of ground rents had been laid before the Committee.

The Committee also recommended that a sum not exceeding £10 be expended in repairs, etc., of the Society's premises in Edinburgh.

After some conversation, the report and recommendations were received and adopted.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a pharmaceutical member for twenty-nine years.

£5 to a registered chemist and druggist, aged 71, who had a grant of £10 in March, 1882.

£10 to the widow of a life member, who died in March last.

£5 to a registered chemist and druggist.

£10 towards the support of Isherwood's orphans.

Two applications the Committee had declined to entertain, and one had been deferred.

Further information with regard to the case of the widow of a life member having been given by a member of the Council, the grant of £10 recommended by the Committee was increased to £15. With this alteration the report and recommendations were received and adopted.

Further particulars were also given by the Vice-President with regard to a case which he had been requested to investigate, the applicant being the wife of a member for many years, who is now in an imbecile condition. In this case a grant of £20 was made.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
February	Day	608	40	19	25
	Evening	197	18	4	10

Circulation of books.	Town.	Country. (No. of Entries.)	Total.
February	180	134	314

Carriage paid, £2 4*s.* 3½*d.*

The undermentioned Donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Britten (J.), Dispenser's Vade-mecum, 3rd ed., 1863. From Professor Attfield.

Mathematical Questions, with Solutions, edited by W. J. C. Miller, vol. 38, 1883. From the Editor.

Putsage (J.), Le determinisme et la science rationnelle, 1883. From the Author.

The Committee recommended that the undermentioned works be purchased:—

Allen (G.), The Colours of flowers, 1882.

Brewer (The), Distiller and Wine Manufacturer, 1883.

Deutsche botanische Gesellschaft, Berichte.

Hardwich (T. F.), Manual of Photographic Chemistry, 9th ed., 1883.

M'Alpine (D.), Botanical Atlas. 2 vols.

Schützenberger (P.), On Fermentation, 1880.

Curator's Report.

The Curator had reported the attendance in the Museum during February to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	523	32	11	20
Evening	134	12	0	6

The following Donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimen of Natal Cayenne Pepper Pods. From Messrs. Hodgkinson, Stead and Treacher.

Specimen of Chilian Aniseed. From Messrs. Horner and Co.

Specimens of Chilian Aniseed. From Messrs. Jenkin and Phillips.

Specimens of Paraldehyde, Aldehyde Ammonia and Aldehyde resin, and of the root of *Dorstenia Brasiliensis.* From Messrs. Hopkin and Williams.

A letter had been received from the India Office, stating that a very complete collection of cinchona specimens had been forwarded from the Madras Government and on arrival would be sent to the Society.

The Professors had attended and reported satisfactorily as to their respective classes.

The Council went into committee to discuss in detail some of the matters mentioned in the report.

On resuming, the report was received and adopted.

GENERAL PURPOSES.

The report of this Committee was taken as usual in committee. It included the reports from Professors Bentley and Redwood as to the class examinations at the end of the first course (five months).

Professor Bentley had reported that the attendance and conduct of his students had been very satisfactory, the number being larger than last year.

Professor Redwood's report had also been of a highly satisfactory nature, stating that the attendance had been regular and punctual, and that there had been evidence at the after-lecture examinations of the existence, among a large number, of a desire to avail themselves of the means provided for their instruction. There had been fifteen competitors, eleven of whom furnished papers in which answers were given to the whole twelve questions. He did not recollect ever having had such a large number of equally good papers at a one course examination.

The Committee, having opened the motto envelopes to ascertain the names of the successful competitors, recommended that the following awards be made:—

Chemistry and Pharmacy.

Bronze Medal ....David Rees.
Certificate of Merit ...Edward Baily.
" " Charles Ranken.
" " Sidney Phillips.
" " Francis Ransom.
" " Thomas Southall Dymond.
" " William Edward Crow.
" " James Haddock.
" " David Low.
" " Edward Ernest Sewell.
" " Arthur Pumphrey.

Botany and Materia Medica.

Bronze Medal ....William Edward Crow.
Certificate of Merit ...Edward Baily.
" " David Low.
" " William Lloyd Williams.
" " Sidney Phillips.

The report also included the usual letter from the Solicitor stating the result of certain actions which he had been instructed to commence, and the progress which had been made in others. It reported that—

Edward Clayton Lewin, 7, Whimple Street, Plymouth, had paid £10 penalties and costs £8 7*s.* 10*d.*, as reported in last week's Journal, for the sale of poisons and use of title "Chemist."

Thomas Harrison, 42, Marsh Lane, Leeds, had paid £5 penalty for sale of poisons.

W. E. Pratt, Beck Street, Nottingham, had paid £5 penalty for use of the title "Chemist and Druggist."

Alexander G. Clark, 89, Gilmore Place, Edinburgh, had paid £5 penalty for carrying on the business of a chemist and druggist.

It also contained particulars of various other matters which had been brought before the Committee.

A long discussion took place in committee on some of the matters referred to in the report. On resuming, the report and recommendations were received and adopted unanimously.

The Amended Pharmacy Bill.

Mr. Churchill asked if there was any report from the Parliamentary Committee with regard to the various suggestions which had been sent up by local societies and meetings with respect to this Bill.

The President said the Committee had not yet considered these suggestions; it could not very usefully do so until it knew what were the intentions of the Government.

Mr. Symes thought some reply was desirable to the various bodies throughout the country which had been sending up recommendations, and were anxiously looking forward to know what would be the result. These people had never had any opportunity of discussing the Bill or any of its clauses before it was sent to the Privy Council, and, therefore, it was only reasonable that such communications should now be received. He had no doubt the Council would consider these suggestions and send a reply to them, because such a course would best tend to ensure unanimity when the Bill came before Parliament. If on the other hand the Council went to Parliament with all these men feeling that their views had not been duly considered, they would be very likely to oppose the Bill at a very important time.

The President said he could assure Mr. Symes and the Council that every one of these suggestions would be most carefully considered, but it would be much more convenient to deal with the whole of them together: one was coming forward that day, and there might be amendments coming from the Government. The Committee could not deal with the matter efficiently until the whole of these proposed amendments were before it.

Mr. Symes said he thought this statement would be quite satisfactory.

The Council again went into committee whilst the President answered several questions which were put by members with reference to the Bill, and the action which was being taken in respect to it.

Visitors to the Museum.

Mr. Symes said he wished to ask a question regarding the Museum. At page 232 of the Calendar there was a note saying that persons not eligible to become members of the Society who were desirous of obtaining admission to the Museum must make application to the Secretary, and he wished to know whether that rule would prevent the Secretary from granting admission to a person who was eligible to become a member. The case in point was that of a person who had passed the Preliminary examination, but not with a view of becoming a chemist and druggist; but prior to an examination he wished to pass, he asked, in his father's name, that he might be permitted to use the Museum for a few days in conjunction with his brother, who was studying at the School of Pharmacy. The two came together; the one who subscribed to the Society was, of course, admitted, but the other was refused. He came next day at his father's request, and again asked admission, but did not see the Secretary and was requested to withdraw. His father, who was a member, then came and made a similar application and was informed by the Secretary that the rules prevented his granting it. He (Mr. Symes) did not blame the Secretary in any way, for he had no doubt he had acted according to what he considered his duty, but it would be well for it to be understood by members generally whether they had any influence in introducing visitors to the Museum for proper purposes, or whether the Secretary had discretionary power in the matter. If no good reason were alleged for not joining the Society, but it appeared to be only an excuse for saving a half-guinea subscription, then no doubt it was quite proper for admission to be refused. It was not so much in the interest of any individual he asked the question as of the members generally.

The President said it was almost impossible for him to say what the Secretary might think it his duty to do. He took it they would all be disposed to give him the utmost latitude in dealing with such cases, and he could conceive that a few cases might occur in the course of the year where some discretion must be placed in the hands of their officer, and if he had not already exercised it it would be convenient for him to do so.

Mr. Symes said he did not understand that the note he had referred to dealt specially with the case of persons who were eligible to join the Society, although it might be inferred that they were meant to be excluded.

The President said the obvious intention was that the Museum should not be used to the detriment of those connected with the Society. The house was not large enough to accommodate all students, but he fancied the Secretary might manage to use a discretion by which the Museum might be placed at the service of anyone who was not likely to abuse the privilege.

The Vice-President said the gentleman referred to had written to him in his official capacity calling his attention to the matter. He had not the slightest charge to bring against the Secretary, who had, no doubt, acted fully within the law and according to the best of his light; but he thought the Council might do him a service in giving him a little more latitude, or intimating its wish that in cases where he was convinced there was no *mala fides*, he should be allowed to grant admission. The strong point seemed to be this, that the young man was not seeking to save his half-guinea by deferring his subscription until a later period, the fact being that he was going into veterinary practice. His father, who was an old member, thought he had a privilege, which it seemed he had not. It was a pity that an old member should be alienated if the law could be relaxed a little.

Mr. Richardson said this was not the first time a similar complaint had been made, for he remembered a case of the kind some two years ago. He thought, therefore, it would be well if it were referred to a committee to consider whether more power should not be given to the Secretary. Cases might occur where gentlemen from the country would be put to great inconvenience through being refused admission.

Mr. Hampson thought the Library Committee might very well consider the matter. He was sure the Secretary did not wish to exclude anyone who was really eligible, but possibly he might have been too zealous in serving the Society. The simple fact seemed to be that the present regulations were a little too rigid, and probably the Committee on consideration might be able to introduce a little more elasticity.

Mr. Greenish thought the Secretary ought to be asked to give his account of the matter. This question had been discussed several times within his recollection by the Library Committee, and the Secretary had been allowed a certain amount of discretion, which had been used on the whole very satisfactorily. If any discretion were used at all, admission must sometimes be refused, for if every one were admitted there would be no advantage to subscribers.

The President did not understand that there was any complaint made against the Secretary, it was simply a question whether the regulations in the Calendar were not a little more tightly drawn than was convenient.

The Secretary said the matter was very simple; it was a mere question of pounds, shillings and pence. If the Council said the Museum should be open to anybody who felt disposed to use it there was an end of the subject. He did not desire discretionary power, which would be unsatisfactory to all parties. Looking at the results for the last year it appeared that there were 1037 apprentices and students who subscribed to the Society, being about one-third of those who were on the Register as having passed the Preliminary examination. Were the other 2000 to be allowed the same privileges as these men who contributed to the funds? The gentleman who now complained had passed his Preliminary examination, and it was competent to him, if disposed, to acquire the right to use the Society's house as part of his own property; but he did not think that he should have been doing right in discharging his duties if he had allowed him to use the Museum the same as those who subscribed. His father came and said he was a member of the Society, and that he felt in that position he was able to delegate his privileges of using the Museum to whom he felt disposed, either his son or anybody else. In reply he had been informed that he had a right to use the Museum himself, but the privilege could not be delegated to anyone.

Mr. SYMES said there was no imputation on his part on the Secretary, who he had no doubt felt he was acting strictly according to the rules.

After a little further conversation, it was decided to leave the matter to be considered by the Library, Museum, Laboratory and House Committee.

MEDICAL ACTS AMENDMENT BILL.

Mr. HAMPSON then moved a resolution of which he had given notice, though in a somewhat different form, as follows:—

"That inasmuch as the Medical Acts Amendment Bill introduced into the House of Lords contains no provision by which pharmacists shall be empowered, conjointly with members of the Medical Council, to revise and prepare future editions of the British Pharmacopœia, the Library and Museum Committee be authorized to take immediate steps with a view to remedy this omission."

He said he considered that this motion was a very important one, inasmuch as up to the present time British pharmacists had not been recognized in the making of the Pharmacopœia to which they were compelled to comform. When the Pharmacopœia received the sanction of the Privy Council, it became, to all intents and purposes, a legal document, and pharmacists were bound to obey it, and it appeared to him that it was very strange after the Society had been engaged for many years in granting degrees to practise pharmacy according to the Act of Parliament, and in furthering education in every possible way, that pharmacists were simply to remain as heretofore servants in the matter, having no official voice in the preparation of the Pharmacopœia. In all other civilized countries where Pharmacopœias were used, scientific pharmacists took a part in their preparation on equal terms with the medical men, but in England, up to the present time, they had been entirely left out and ignored. The Government had now brought in a Bill to amend the Medical Act, the Bill being the result of a commission of inquiry held last year, and the Pharmacopœia was referred to in the Bill. Seeing the word mentioned he naturally looked to see if the Pharmaceutical Society or British pharmacists received any official recognition, but to his astonishment, he found that if this Bill became law the old conditions would prevail. He supposed the probable reason of this was that pharmacy was very slow in development in this country. On the continent of Europe, pharmacy, as a distinct branch of medical art, had received the sanction of the state for many years, and it was not to be expected that they in England should at once receive the reward which the education and improved culture of pharmacists in this country entitled them to do. It seemed to him that the Council was now bound in self-respect to make this request, for unless it did so pharmacists would probably have to wait twenty years until they could do so with any effect. Years ago, before the Society had got fairly into work, it might have been inequitable to make such a request, but it was felt now that it was entitled to fair recognition when legislation was in progress, and he could not conceive that the medical profession would object to the proposal. Anything which would advance pharmacy by giving it an improved social and scientific status must be beneficial to the medical profession. In making this request it would be clearly understood that the Society did not claim anything except to be officially consulted as to the preparation, and methods employed: they had nothing at all to say as to what should be included or excluded. Physicians must appoint the dishes and say what should be served, but educated pharmacists had some claim to speak with reference to the preparation of the dishes. It was an old joke that pharmacists were only a sort of physicians' cooks, and that was perfectly true; but cooks generally prepared cookery books. They had been singularly fortunate in having Professor Redwood on the Pharmacopœia Committee as representing pharmacy up to the present time, and that gentleman was worthy of full recognition, but what he wanted to see now was a recognition of pharmacists as a body by giving to them an official share, by legal arrangement, in the preparation of the Pharmacopœia.

Mr. SYMES, in seconding the motion, said it must commend itself to the mind of any thinking person that the preparation of a Pharmacopœia consisted essentially of two portions: first, of the medicines which it should contain; and secondly, how they should be compounded and prepared. It was quite certain that members of the medical profession were fully competent for the first of those duties; but the tendency of their education during late years had been to render them less capable of dealing with the second branch of the subject than they formerly were, and there were no persons educated for that purpose, except the pharmacists. They must all feel that this was only a matter of justice; it could not be sought under the Pharmacy Act or in any other way than under the Medical Act, and he took it that the present Bill was in so forward a state, the second reading being put down for the next day in the House of Lords, that there was no time to be lost. He hoped, therefore, there would be a unanimous vote in support of the motion.

Mr. SCHACHT said this motion, as far as it went, had his cordial support, but as the greater included the less he should have preferred if it had embodied the suggestion which he put forward some time ago, that the Council should take steps to endeavour to get itself represented on the Medical Council. Mr. Radley had already asked that this new Medical Bill should be placed in the hands of all the members of the Council for consideration, and his proposition was that it should be considered in all its aspects with regard to pharmacy. If it struck any of his colleagues that a special attempt might be made to remedy the defect with regard to pharmacy, and that it was not too much to ask for such recognition as he had named, he should be glad, and it seemed to him this would be an opportune moment to assert that pharmacy was an essential ingredient in the art of medicine, and might fairly claim to be represented in some sort on the Medical Council. He did not think that at all too ambitious a position to take up, and it would be a good opportunity now to put it forward. Why pharmacy should be systematically ignored passed his comprehension, except upon the supposition that it was generally understood that what was not worth asking for was not worth having. Even if such a request were not granted at present it might be entertained in such a way that its acceptance at some future time would be more hopeful.

Mr. WILLIAMS suggested that Mr. Hampson should explain what practical steps he thought ought to be taken.

Mr. HAMPSON said the motion itself referred to a committee which would necessarily take immediate steps to obtain the ear of the Government upon this question. That committee would have to consider what fair proposal it would have to make, and to formulate it before seeking an interview with the promoters of the Bill. He was not ready with any special proposal, but probably the experience of other countries would lead in a particular direction. He thought that was all he need say at present, the committee being left to consider details.

Mr. GREENISH cordially supported the motion. He only regretted that it had not been sent round in its amended form to members of the Council, because there were one or two expressions in the original notice of motion to which some exception might be taken. The remark had been made about pharmacists being physicians' cooks, which he wished to protest against, for at the present time a great many compounds came before the medical profession which never had any recipe for their formation in the proper cookery book, and it would be very desirable, in his opinion, if medical men would confine themselves to their recognized cookery book. He could quite understand that at the present time the medical profession was getting more than ever unable to frame a proper Pharmacopœia. Pharmacists did not wish to interfere with the remedial agents to be made use of, but simply to have a voice in laying down the methods by which those agents should be prepared. Medical education was advancing day by day, and as it did so medical men ceased to have much knowledge of pharmacy. When he was in St. Petersburg eight years ago, and an International Pharmacopœia was discussed, he had to state that in England pharmacists had no voice in their national Pharmacopœia, when the look of astonishment on the part of the different delegates at that Conference was perfectly unique. He believed this was the only civilized nation in which pharmacists did not sit upon the Committee for the formation of the Pharmacopœia. This was certainly the proper time to move in the matter, for the probability was there would be a Medical Council very differently constituted to what it had been. The Bill in question indicated the constitution of that Council, but there was no hint that any pharmacist should have a seat on the Pharmacopœia Committee.

Mr. YOUNG thought the Society would be justly blamed if it did not take this opportunity of making itself heard. It would be a very strange thing if after what the Pharmaceutical Society had done during the last twenty years no members of it were consulted in the formation of a new Pharmacopœia. He saw no objection whatever to the motion as it now stood, and hoped it would be carried.

The VICE-PRESIDENT also wished to support the motion. Reference had been made to the position that Professor Redwood occupied in the preparation of the last Pharmacopœia, and that seemed to him to be a very important point. It was at least a recognition of pharmacy, though in what way it originated he was not aware; but the fact of a well-known pharmacist being consulted by that Committee at any rate gave pharmacists a status, and was a small leverage which might be made use of again. With regard to Mr. Schacht's larger suggestion, of course, if pharmacists had a position on the Medical Council that would include the whole thing, but he thought their truer policy now would be to ask for recognition on this particular point. He believed that practical pharmacists found out soon after the last Pharmacopœia was published that there were many defects which would have been remedied had a practical man been on the Board, and if that consideration was brought forward, as well as the higher culture now possessed by the pharmaceutical body, he had no doubt the claim would be considered.

Mr. GREENISH said as a matter of fact the Pharmacopœia of 1864 was published without the assistance of any pharmacist at all, but as soon as it was published it was found to contain so many errors that it was immediately withdrawn, and Professor Redwood was called in to assist, but he had no vote.

Mr. ROBBINS said he believed pharmacists had always been called in in an indirect way, Mr. Phillips's assistance having been obtained with regard to the Pharmacopœia published in 1836.

The motion was then put and carried unanimously.

WRITTEN EXAMINATIONS IN THE PROVINCES.

The PRESIDENT then moved the following, of which he had given notice:—

"That on and after December 31, 1883, the resolution of January 7, 1874 (*Pharmaceutical Journal*, January 10, 1874, p. 563), respecting the method of conducting the Preliminary examination be rescinded, and that the following regulations be enacted, and come into force on January 1, 1884:—

"That persons be especially appointed by the Council to superintend the Preliminary examination in London and the provinces; that they be called Superintendents of examinations, and be paid fees for each examination; such Superintendents not being necessarily members of the Board of Examiners.

"That a Deputy Superintendent be also appointed by the Council in each centre.

"That a fee of one guinea for the first part and half-a-guinea for the second part of the examination be paid to the Superintendent or Deputy Superintendent on the occasion of each examination.

"That the Local Secretary be, in the first instance, offered the appointment of Superintendent.

"That the examinations be held in the months of January, April, July and October, on the second Tuesday of the month, from 11 a.m. to 4.30 p.m., with an interval of one hour from 2 to 3 p.m.

"That the examinations shall not be held in the house of the Superintendent or Deputy Superintendent, but he shall be authorized to engage some apartment suitable for the purpose, and charge a sum not exceeding 15*s*. to the Society on account thereof.

"That the examination for the Jacob Bell Memorial Scholarships be held annually on the second Tuesday in July, concurrently with the Preliminary examination.

"That notice be issued in the *Pharmaceutical Journal* two months prior to the day of holding the Preliminary examination, that such examination will take place, and giving a list of the centres at which it will be held.

"Candidates for the Preliminary examination must give notice to the Registrar not less than fourteen days prior to the day on which the examination is to be held, of their intention to present themselves for examination, and state the centre at which they desire to be examined.

"That the instructions to Superintendents and Deputy Superintendents of examinations be as follows:—

"INSTRUCTIONS TO SUPERINTENDENTS AND DEPUTY SUPERINTENDENTS OF EXAMINATIONS.

"*To be read aloud to the Candidates before commencing their writing.*

"*The Preliminary Examination.*

"The examination papers must be forwarded by the Registrar, under seal, to the Superintendents or Deputy Superintendents, so as to be received by them on the morning of the day fixed for the examination. Special sheets for the candidates to write upon will also be sent by the Registrar.

"Writing materials for each candidate must be provided, and all arrangements for the accommodation of the candidates completed before the hour fixed for opening the packets of questions from the Registrar.

"Candidates must be in their places at the time appointed, and after this time no candidate will be admitted.

"Candidates must be placed at a sufficient distance from each other to prevent copying, and they are not permitted to take either books, scribbling papers, or memoranda into the examination room.

"The examination papers must be opened by the Superintendent or Deputy Superintendent at the appointed time, in the presence of the candidates, and immediately distributed by him.

"He must see that each candidate signs his papers in the place indicated.

"The answers to the questions are to be written on one side of the paper only, the other side being intended for scribbling and calculations; no other scribbling paper is allowed to be used.

"No examination paper shall be taken from the room until the examination is complete.

"The Superintendent or Deputy Superintendent must carefully watch the whole examination, to see that the candidates do not use unfair means, either by assisting each other, or using books or notes. No person except the Superintendent or Deputy Superintendent is permitted to be present, and on no consideration shall candidates be allowed to speak to each other after the papers are distributed.

"A candidate wishing to ask any questions must hold up his hand; the Superintendent or Deputy Superintendent will come to him and satisfy any legitimate inquiry, but no explanation will be given on the subject matter of the questions.

"At the expiration of three hours from the time of the distribution of the questions on Latin and arithmetic, the written papers of the candidates, with all memoranda and scribblings thereon, shall be delivered to the Superintendent or Deputy Superintendent, who must immediately enclose all the papers in the envelope sent for that purpose by the Registrar, seal it with his seal, and forward it by first post thereafter to the Registrar enclosing the accompanying declaration duly filled in and signed.

"At the expiration of one hour and a half from the time of the distribution of the questions on English, the written papers of the candidates, with all memoranda and scribblings thereon, shall be delivered to the Superintendent or Deputy Superintendent, who must immediately enclose all the papers in the enveloped sent for that purpose by the Registrar, seal it with his seal, and forward it by the first post thereafter to the Registrar enclosing the accompanying declaration duly filled in and signed."

He said the object of this proposition was simply to alter and amend the regulations in order to meet the resolution arrived at by the Council in December last, that the Preliminary examination should be conducted at two different periods of the day, with an interval between. It was found very difficult to move any direct resolution which would carry out that change, and, therefore, it was considered desirable to rescind the original resolution and begin with a new one.

Mr. BORLAND pointed out that the first two clauses of the second section seemed to have no special reference to the candidate, but only to the Superintendent. He would also point out that in Scotland, in order to avoid casualties which might arise from examination papers not arriving on the morning appointed, it was provided in the case of the Science and Art Department examinations, that the papers should be deposited in the hands of some responsible person in the neighbourhood twenty-four or forty-eight hours previously. He thought a similar arrangement might be desirable in this case.

Mr. SAVAGE said in the University Local examinations it was laid down that the candidates should sit four feet apart.

The PRESIDENT said he should be inclined to leave the Superintendent some discretion on such matters. It was possible to be too elaborate in detail.

Mr. HILLS said there seemed to be some difference with regard to the fee for the Bell Scholarship examination when held concurrently with the Preliminary. He supposed that was intentional.

The PRESIDENT said that was so.

Mr. HILLS remarked that formerly the Superintendents of the Preliminary on the day of the Bell Scholarship examinations received two guineas. In view of the proposed alteration in the examinations, he thought that the Society could well afford to make the fee two guineas on each occasion, as it was very important to obtain the services of the very best men at each centre.

Mr. WILLIAMS thought this being a matter which included the voting of money, it ought to have come before the Council on the report of a committee.

Mr. RADLEY thought one guinea was quite sufficient. He remembered the examinations being conducted for years without any fee whatever, and he did not think there would be any complaint from their friends in the country if one guinea only were paid. He had heard complaints sometimes of the extravagance of the Council, and he thought it would scarcely be justified in giving a guinea and a half merely for superintending.

Mr. BORLAND asked if some words could not be introduced so as to allow of a member of the Council being present at one of these examinations, if it took place at a town where he resided.

The PRESIDENT said he would rather leave the draft as it was. He thought any member of the Council presenting himself would not be refused admission.

The VICE-PRESIDENT asked if Mr. Borland knew of any case in which the papers had not been delivered on the appointed day.

Mr. BORLAND said he believed that was the cause of the regulations being introduced to which he had referred.

The VICE-PRESIDENT asked if there would be any objection to the Superintendent receiving a sealed packet twenty-four hours beforehand.

The PRESIDENT thought there would.

The VICE-PRESIDENT said it would certainly be an awkward dilemma if a number of youths were assembled, having come some distance, and had to go home in consequence of the papers not being ready.

Mr. HAMPSON suggested as there were several points which the Council was not quite agreed upon it would be as well to refer the regulations to the Library Committee if the subject did not press for immediate decision.

Mr. WILLIAMS said it was not at all unusual for letters from the north to be delivered in London some hours late, and the probability was, therefore, that the same thing occurred with letters going to the north.

Mr. SYMES said although on a former occasion he had criticized the resolutions as passed by the Council, he quite accepted the decision, though that made him scrutinize these regulations more closely. He must say they seemed thoroughly in conformity with the resolution of the Council.

The PRESIDENT said there was no occasion to press the motion that day, and, therefore, in accordance with the suggestion which had been made, he would agree to refer it to the Library and Museum Committee for report.

THE HANBURY MEDAL.

Mr. GREENISH asked if the President's attention had been called to the fact that two years had passed since the Hanbury medal was presented at the International Congress, and that it should be awarded this year. He suggested that the meeting in October, when the sessional address was delivered, would be a suitable occasion on which to publish the award and present the medal.

The PRESIDENT said his attention had been called to the matter, although he had not yet taken any formal steps with regard to it. He thought the suggestion as to the time when the award should be announced was a very good one.

The Amended Pharmacy Bill.

The Secretary read a resolution which had been forwarded by the Chemists' Assistants and Apprentices' Association of Edinburgh, approving of the Pharmacy Act Amendment Bill and suggesting in the event of its becoming law that the Council should make provision by which the present Major examination should be continued after the year 1886.

The communication was referred to the Law and Parliamentary Committee.

Conversazione.

The Secretary stated that he had received a letter from the Lords of the Committee of Council on Education, stating that the South Kensington Museum would be placed at the disposal of the Society for holding its Conversazione on the evening of the 23rd of May next.

EVENING MEETING.

Wednesday, April 4, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The last Evening Meeting of the present session was held on Wednesday evening, the 4th inst. Mr. Carteighe, President, occupied the chair.

The minutes of the previous meeting having been confirmed, a paper was read on—

The Bitter Principle of Hymenodictyon Excelsum.

BY W. A. N. NAYLOR.

The paper is printed on p. 817, and gave rise to the following discussion:—

The President said he was sure it would be the desire of the meeting that Mr. Naylor might shortly find an opportunity of completing his investigations on this subject.

Professor Bentley said that this question was invested with interest now in consequence of the "cuprea" barks and other barks obtained from allied plants, which were formerly placed among the cinchonas, having yielded a certain amount of cinchona alkaloids. At the first blush a botanist would naturally expect that *Hymenodictyon excelsum* would have yielded some of the alkaloids of cinchona, since the genus *Hymenodictyon* was formerly included in the genus *Cinchona,* and this plant was the *Cinchona excelsa* of Roxburgh. One would naturally expect to find paricine or some allied alkaloid. The first plant in which paricine was discovered, as far back as 1845, was a rubiaceous plant, namely the *Buena hexandra.* The interest of paricine being found in *Hymenodictyon excelsum* was still further brought out by the fact that it had been found in red bark together with quinamine. Therefore the investigation of substances derived from plants which had been within a comparatively few years disassociated from the cinchonas became a matter of great interest, and he looked forward with interest to the confirmation or otherwise of Mr. Naylor's present results by his further investigations.

Mr. Holmes said that his name had been mentioned by the author in connection with this bark, but he should like to disclaim any thanks with regard to the matter. The bark had been sent to him by Dr. Dymock, of Bombay, a gentleman who had in a most disinterested manner contributed very largely to the museum on various occasions. Dr. Dymock had kindly promised to complete the collection of Indian drugs for the museum.

Dr. Ondaatje, referring to the virtues of *Hymenodictyon excelsum* as a febrifuge, said that he was in India many years back, when Sir William O'Shaughnessy was compiling his first book on Indian drugs, the 'Bengal Dispensatory,' and this drug was then tried in the hospitals of the Medical College and found to be most valuable. In mild cases of fever it was almost equal to the cinchona bark. There was another species almost as efficacious as the *Hymenodictyon excelsum.* He believed that it was the *H. laxiflorum.*

Mr. Luff wished to ask Mr. Naylor whether heat was employed in drying the pasty mixture of the powdered bark. He would suggest that Mr. Naylor, on resuming his investigations, should extract the alkaloid under somewhat different conditions. According to his (Mr. Luff's) experience of alkaloid work, Mr. Naylor had employed almost the very conditions which were most likely to bring about a decomposition of the alkaloid, namely, in the first place, contact with a fixed alkali, lime; in the second place, percolation with boiling or hot alcohol; in the third place, contact with a strong inorganic acid—sulphuric acid—during the distillation; and in the next place precipitation with a fixed alkali, caustic soda. In his experience those conditions were likely to produce that destruction of the alkaloid which was generally spoken of in chemical phraseology as saponification. This change consisted of a decomposition of the alkaloid into another alkaloid of a lower molecular weight and an acid. Probably the reason why Mr. Naylor obtained a resinous mass, and failed to get a crystallizable alkaloid or crystallizable salts, was that he had brought about this kind of decomposition. All the different kinds of alkaloids which Dr. Wright and he had worked upon were decomposed by contact with even warm alcohol, by contact with any of the alkalies, and by contact with any of the mineral acids. He would suggest that Mr. Naylor should percolate the bark with alcohol acidified with tartaric acid, for an organic acid produced scarcely any saponification, and avoid precipitation with a strong alkali such as caustic soda or potash. Assuming that the alkaloid present with the bark was paricine, which seemed probable, Mr. Naylor's experiments would point to an actual decomposition or saponification of the alkaloid, for the general result of saponification was that, whilst the carbon percentage of the alkaloid remained the same, the hydrogen percentage was increased; and this Mr. Naylor's figures showed.

Mr. Gerrard differed somewhat from the statement which had just been made by Mr. Luff, especially with regard to the use of lime as the means of liberating alkaloids under certain conditions. He thought that the process employed by Mr. Naylor was admirably suited for the purpose where an alkaloidal body was in combination with an acid of the tannic acid series. Lime lent itself most readily to combinations with acids of that series, and also with many of the colouring matters. Let any one take a sample of cinchona bark, and mix it with potash, soda, or ammonia, and another portion and mix it with lime, and prepare a tincture from each mixture; the difference of colouring of the two mixtures would be astonishing. Of course an operator conducting an experiment with lime and a bark would take care that he did not carry his temperature too high. It was possible to exhaust cinchona bark with lime and alcohol at a normal temperature, provided that the bark and the lime were in a proper state of division. He did not say that lime was adapted all round under all circumstances; but under certain circumstances it was the best agent. Especially was it the best thing for beberine. He had lately had a bark sent to him from the west coast of Africa, and he had experimented upon it with various alkalies, but he found lime the best of all. He should like to ask Mr. Naylor whether he prepared the hydrobromide or the phosphate of the alkaloid. Those salts usually yielded themselves very readily to crystallization, and as a rule they were insoluble in cold alcohol, but they dissolved readily in hot alcohol, from which they were generally deposited upon cooling in a crystalline form. That was, in his opinion, one of the best methods of obtaining a pure crystalline salt of an alkaloid. He should like to know what quantity of bark Mr. Naylor operated upon, as the quantity made a considerable difference in the investigation. It was not possible to carry out a thoroughly exhaustive investigation with a small quantity; from 7 to 14 pounds were needed for a full investigation.

Mr. LUFF remarked that Mr. Gerrard had not brought forward any experimental evidence that lime did not bring about the decomposition which he (Mr. Luff) had mentioned.

Mr. TANNER said he should like to ask whether Mr. Naylor had examined the liquid from which the precipitate was obtained, and whether he concluded that by the precipitation of the body which appeared to be allied to paricine he had separated all the alkaloidal constituents. If not, Mr. Naylor's results and those obtained by Mr. Broughton might be brought into accordance. It was known that when alkaloids were precipitated with caustic soda or potash, the residual liquor might contain another body, even æsculin, or the product æsculetin. With regard to the non-crystallizability of the alkaloid, he should like to ask what solvents Mr. Naylor employed, for it was known that in some cases the addition of a body having a less solvent action on the alkaloid than the one in which it was dissolved would determine crystallization.

Mr. NAYLOR, in reply, said in reference to the remarks of Mr. Luff, that he did not think that any process which could be devised would be suitable for the extraction of an alkaloid in every instance. Had he not been pretty certain from preliminary investigations that the alkaloid in question was very closely allied to beberine on the one hand, and to quinine on the other, and further, had he not found the colouring matter somewhat troublesome, he certainly should not have employed such a process as the lime process. That process was by no means original. Not only was it largely employed for the extraction of quinine from cinchona barks, but it was the process which Dr. Hesse had himself made use of for the extraction of paricine. He thoroughly agreed with what Mr. Gerrard had said as to the use of lime, and he only needed to emphasize his remarks on that point. Oxalic acid was perhaps about as serviceable an acid as could be employed for the extraction in this case. It extracted the alkaloid with probably the minimum amount of colouring matter, and it might be advisable to employ a weak solution of oxalic acid; but decomposition took place very largely in the heating of the body afterwards. In reply to Mr. Gerrard, he might state that he did not prepare the hydrobromide, but he did prepare the phosphate, though he did not succeed in getting it to crystallize. The quantity of bark that he worked upon was 300 grams. The bark was tested for æsculin, but that body was not found. The solvents employed were benzol, chloroform, ether, petroleum spirit, acetic ether, organic acids and mineral acids. As to temperature, he had employed various temperatures ranging from 60° to 120°; and with regard to time, the periods had varied from very short ones to periods of four or five days, with a temperature of 110° F. It was well known that paricine had not yet been obtained in the crystalline condition. He wished it to be distinctly understood that he did not state that the body which he had obtained was paricine; that point remained for further investigation.

A vote of thanks to Mr. Naylor was then passed.

A paper was then read, entitled—

REMARKS ON SOME MEDICINAL PLANTS OF CEYLON,

BY DR. W. C. ONDAATJE, F.L.S.

The paper is printed on p. 818, and gave rise to the following discussion:—

The PRESIDENT said that it was always a pleasure to have members of the medical profession present at the meetings of the Society, and it was particularly gratifying to have present a member of the medical profession who had come from a long distance and brought with him typical specimens of the materia medica of his island, and who further enlightened the Society by a graphic description of them. The meeting was very much obliged to the author, both in his capacity of a member of the medical profession and in that of a pharmacologist.

Mr. HOLMES said that it was perfectly true, as Dr. Ondaatje said, that the natives of a country were very apt to ascribe imaginary virtues to some of their plants; but when a medical man who had made experiments on the properties of those plants came forward and stated which were valuable and which were not, he conferred a great favour both on pharmacists and on the medical profession. One of the specimens to which Dr. Ondaatje had called attention, *Sethia acuminata*, was a plant which was interesting, partly because it belonged to the same family as the coca, and partly because as an anthelmintic it was almost free from taste. Several of the anthelmintics which were in common use were not only disagreeable in their effects but also disagreeable in flavour. Another anthelmintic which had been mentioned, *Vernonia anthelmintica*, belonged to the same order as the Persian insect powder. It had somewhat astonished him sometimes that Persian insect powder had not been tried as a remedy for worms. If it killed insects outside the body, it might have a similar effect upon internal parasites. If any gentleman was willing to undertake the investigation of one or more of these drugs, he felt sure that Dr. Ondaatje would be quite ready to send him specimens in the quantity which had been mentioned, namely, from 7 lb. to 14 lb.

Mr. GERRARD inquired if Dr. Ondaatje could tell them if the bark of *Randia dumetorum* was known as emetic bark in Ceylon.

Dr. ONDAATJE said that he believed that it was so called, but he was not quite sure. He believed that the natives used the seeds of it as an emetic.

Professor BENTLEY said that he could not allow the paper to pass without expressing his thanks to the author for coming forward and giving his experience. It was most important that medical practitioners, who were scattered all over the world, should, when they were placed in a particular district, take an opportunity of trying the virtues of the remedies of the country. There was no doubt a vast amount of useless material, and it was almost impossible to sift it in this country; but medical men like the author of the paper could try the effects of the drugs in the country in which they grew, and separate the chaff from the wheat. If native remedies were not tested by practitioners like the author of the paper there would not be any opportunity of getting new remedies brought to this country. In different parts of the world there might be many drugs which would yet be found to be of incalculable benefit. With regard to *Randia dumetorum* it was a substance which had been known and canvassed over and over again. O'Shaughnessy spoke of it many years ago as being a remedy which was not at all reliable; but at the time of the compilation of the Indian Pharmacopœia, Dr. Bidie brought it forward as a substance well worthy of more particular investigation. Dr. Bidie spoke of the ripe fruit as being the active part of the plant. He (Professor Bentley) should like to know if the author had ascertained whether the valuable part was the seed or the fruit. There was no doubt that a substance which had been so long used deserved investigation, and it was desirable to know whether it contained emetia in any quantity and whether it could be employed as a substitute for ipecacuanha. *Sethia acuminata* was a well-known vermifuge. Anything concerning *Coscinium fenestratum* must be interesting to members of the Society, for he believed that he was right in saying that one of the earliest papers, if not the very first paper, which the lamented Hanbury read in that room was upon calumba wood, the origin of which he traced to that plant. As to the antiseptic properties of *Coscinium fenestratum*, as the author would know, there was nothing remarkable in a pure tonic possessing qualities of that kind. Quassia and almost all pure tonics had the same effect in preventing the decay of animal matter. As to *Vateria Indica*, the statement concerning its power to arrest fermentation was altogether new to him, and he should take care to notice it. The plant was interesting as the source of a resin which at the time the Indian Pharmacopœia was brought out was spoken of as a substitute for the official resin. Moreover, the bruised fruit of the same plant yielded, when boiled, a fatty substance which was called "piney tallow." This substance had been used externally in different parts of India as a remedy for chronic rheumatism. As to *Semecarpus Gardneri*, the fact of its yielding resin was what one would naturally expect from any anacardiaceous plant. He was glad to have confirmatory evidence as to *Vernonia anthelmintica*. It had been well known for a long time that the seeds were used as a vermifuge. He was particularly interested in *Alstonia scholaris*, because the medical properties of the bark were well known as the author had noticed. With regard to the juice being a substitute for gutta percha, he should like to know whether the author had got any further information on that subject since his communication to Mr. Simmonds. The plant belonged to the order Apocynaceæ, which yielded substances analogous to gutta percha. In view of the difficulty of obtaining gutta percha, and in prospect of the loss of that substance, anything which would act as a substitute would be of incalculable value. If he recollected rightly he was a member of the Council of the Society of Arts in 1865, and therefore this subject had rather impressed itself upon his memory, for even at that time the Society of Arts offered a premium for a substitute for gutta percha. Gutta percha was then very largely in use, and there was a fear that in consequence of the destruction of the trees the substance would be entirely lost. The next substance mentioned in the paper, namely, *Acorus calamus*, or the sweet flag, was one which he had heard his dear old master, Dr. Pereira, speak of over and over again. He always used to say that it was an aromatic stimulant, superior almost to any other. It was a substance which was somewhat put aside in this country, but it was not so in other countries, and although it was not actually in the Pharmacopœia of India, it was at the present time in the Pharmacopœias of the United States and of Germany. This would show that there were a good many other people of the same opinion as his far-sighted and much respected old teacher as to the value of this substance. Its anthelmintic properties were new to him, and they added still more interest to the subject of sweet flag.

Mr. Martindale said that no doubt the antiseptic properties of *Coscinium fenestratum* were due very largely to berberine, as Professor Bentley would acknowledege. Berberine was used very much in America to make lotions in cases of gleet and other diseases. Its antiseptic properties had never been well worked out.

Mr. Andrews said that there was an allusion made in this paper to a black varnish which was used in the arts. It had long been a desideratum among musical instrument makers to find a varnish which should be equal in hardness to the varnish which was found on old Cremona violins. He believed that age had a great deal to do with the hardness of that varnish; but there was certainly a very great benefit to be derived by any one who could, either by means of this varnish or any other, find a material which would be very hard and imitate the varnish of the old violin makers. Speaking from some little experience of the matter, he believed that the resonance or tone of a violin was, to a great extent, due to the quality of the varnish.

Mr. Bland said that the question of "fiddleology" and the matters connected with it was one which would require many hours for its discussion; but he could tell the last speaker that he had set out on an entirely wrong datum if he thought that the Cremona varnish was a very hard substance. If he obtained a varnish which would produce a very hard surface he would not have Cremona varnish. This subject, however, was not one which could be gone into at that meeting.

Dr. Ondaatje said that he was exceedingly obliged to Professor Bentley for his most interesting remarks on the paper, and he was highly encouraged to contribute to that great Society what he knew as to the plants of his island. With regard to the juice from *Alstonia scholaris*, he regretted to say that he had no further information than that which he had supplied to Mr. Simmonds, in 1865. His attention was called to the substance whilst he was travelling, for his servant, having accidentally cut the top part of a tree, he saw a large quantity of milky juice exuding from the cut branch, some of which he collected. A sample was sent in response to the prize offered by the Society of Arts for a substitute for gutta percha. As to *Randia dumetorum*, in Ceylon the seeds were used in the state of powder, and were found to be very efficacious. The author of the 'Supplement to the Indian Pharmacopœia' stated that in India the pulp was used. The drug had been employed in the east from time immemorial, and the tree was mentioned in all the ancient Sanscrit works as possessing valuable properties. As an emetic it was equal to ipecacuanha. It was in fact the ipecacuanha of the natives. The latter when in powder very often deteriorated in quality through being kept.

The next paper read was a—

Note on Essence from Green Ginger.

by Charles Symes, Ph.D.

The paper is printed on p. 819.

Mr. Tanner asked whether this particular form of ginger was yet an article of commerce. If it was, it seemed that it was likely that it would come into very great demand. The essence was one which would seem to meet the requirements of a great many consumers.

Professor Bentley said that a great deal of it came over a few years ago. There would be no difficulty in getting it if there was a demand for it. This form of ginger had been described by Pereira.

Dr. Symes said that he did not think it was a thing of very large demand. He was informed that its commercial value was somewhat low, simply because there was not much demand for it.

A vote of thanks was then accorded to Dr. Symes.

The next paper read was a—

Note on Sap.

by Professor Attfield.

The paper is printed on p. 819, and gave rise to the following discussion:—

Mr. Ekin said that with regard to the chemical aspect of this very interesting paper, he took it that that must more or less be new. As to the botanical aspect of the paper, it was a well known fact that various forest trees bled immensely if they had their limbs lopped off, especially large ones, before the leaves were expanded. He did not remember ever having seen the rate of flow determined; that was certainly very wonderfal. He once had under his observation a row of sycamore trees of considerable growth. Limbs of nearly a foot in diameter were lopped off, and the amount of bleeding was very great. The sap in that case was sweeter than the birch sap, as might be expected in the case of one of the maples. He was not surprised at the largeness of the quantity of sap yielded by such a tree, for the wood was very soft. But he had found sap exuding from the centre of a beech tree, the heart wood of which was very hard. The other part of the tree was dry, and not a leaf had expanded. He looked at some of the books, and according to them it seemed that the beech had no business at all to allow its sap to exude in that way.

Professor Bentley said that he should not have expected that such a large amount of sugar would have been found in the sap mentioned by Dr. Attfield, although perhaps the particular nature of the birch might account for it. He had himself seen gallons of fluid come in a few hours from a wounded tree before the leaves had expanded; and the fact that the leaves had not expanded was the explanation of the matter. At this season of the year, before the leaves were expanded, the reserve materials of the tree were largely stored up in the root, and from chemical changes actively going on the fluids in that part became very dense, and the consequence was that an excessive osmotic action took place. There was far more fluid absorbed from the earth than the plant could use, and what botanists called "root pressure" took place. This was a matter which had not been clearly explained until the last few years; it had nothing to do with the leaves. The pressure which took place forced the fluid up the stem. This was clearly the explanation of what was called bleeding. The process did not take place at any other time of the year, for as soon as the leaves were fully developed, the fluid which was absorbed by the roots was naturally carried up the plant, and became transpired and thus carried off. Probably the ascending sap had greater force in summer, but the tree did not bleed, for the leaves carried off the fluid. An analysis of the sap of a tree at this time of the year by a competent chemist like Professor Attfield was exceedingly valuable and useful.

Professor Attfield said that if there had been time he should have liked to ask Professor Bentley what root pressure was.

A note by Dr. Paul on the results of the analysis of samples of the cinchona barks recently received from Jamaica for the Museum was laid before the meeting by Mr. Holmes. The note will be printed in a subsequent number.

The President said he was sure the members would vote their cordial thanks to Dr. Paul for this very complete series of analyses.

Mr. Holmes then called attention to various specimens of Indian bark which had been forwarded under the instructions of the Indian Government by Surgeon-Major Bidie, the Superintendent of the Museum at Madras. A descriptive catalogue of the barks, and of the Herbarium specimens accompanying them, is printed on pp. 821, 822. Mr. Holmes said that the barks were accompanied by excellent specimens of the plants themselves, representing the flower, the leaf, and the fruit, the Herbarium specimens being labelled with numbers corresponding to the numbers of the barks. The specimens had been prepared with the greatest care, and full details had been given in each case, both of the plant and of the bark. This was one of the most valuable collections of Indian barks which had ever been sent to this country. Great credit was due to the gentleman who had superintended the collection of these specimens. It would be possible in the future for any person who wanted to identify the bark which he was using to do so by comparing it with the Museum specimens. Two of the specimens were very interesting from a botanical point of view as showing that the cinchonas, like the elms and maples of England, sometimes produced a bark which was excessively corky. The cork in some of these barks varied from $\frac{1}{4}$ inch to $\frac{1}{2}$ inch in thickness. There was also on the table a specimen of *Manilla Elemi* presented by Messrs. Evans, Lescher and Webb. It was imported in a new kind of packing, which he had never seen before. There was also a specimen of crude and refined ozokerit and an elastic bitumen from Castleton, in Derbyshire, somewhat approaching the coorongite of Australia.

The President said that the members of the Society would better appreciate the very complete catalogue of the specimens which had been sent with the collection of barks when they were able to read it. The Council of the Society had already expressed its thanks officially to the Government of India for its courtesy in passing on to the proper authorities the request of the Society to be furnished with these specimens. They had been collected and arranged under the personal superintendence of Surgeon-Major Bidie. If it had not been for Surgeon-Major Bidie's zeal, probably the Society would not have been so successful in getting a complete collection, and certainly not so successful in getting such excellent botanical specimens. Their thanks were eminently due to him and the officials of the Government for their courtesy.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

The anniversary meeting of this Society was held at Burlington House, on Friday, March 30th. Dr. J. H. Gilbert, F.R.S., President, in the chair.

The President read his annual report. There have been occasions in the history of the Society when important questions had to be discussed, sometimes involving matters of internal working and management, at others the consideration of some new departure with a view to more extended usefulness. At present there are no such questions requiring special notice; the attainment of the objects for which the Society was founded is steadily progressing, and the President, taking advantage of the fact that he was elected a Fellow during the first session of the Society, now nearly forty-two years ago, presents the Society with a review of its progress from the commencement of its existence up to the present time. Of the twenty-five gentlemen who met on February 23, 1841, for the formation of the Society, only two now remain in the list of the Fellows, and out of the one hundred and eighteen members on the register at the first anniversary meeting, March 30, 1842, only ten could now answer the roll call,—the President, Professor Andrews, Drs. De La Rue, Longstaff, Lyon Playfair, James Young, and Messrs. Heisch, F. R. Hughes, Pearsall and Denham Smith. The number of Fellows at the last anniversary was 1175. One hundred and four have joined during the past session. Nine have died,—Mr. John Gray, Mr. Dugald Campbell, Mr. J. J. B. J. Grosjean, Mr. A. Jesseman, Dr. G. A. C. Pearce, Dr. G. W. Septimus Piesse, Mr. E. Wilcock, Professor H. J. S. Smith and Mr. Frank Hatton; twenty-three have withdrawn, etc., so that the present number of Fellows on the register is 1247. One foreign member, F. Wöhler, is deceased, whilst nine have been elected, the total number of foreign members being now thirty-seven. The objects of the Society, as stated by the founders, were the reading, discussion and subsequent publication of original communications and the formation of a chemical library and museum. The number of papers read during the five years ending 1846 was 167, giving an annual average of about 33; in 1854–55 only 17 papers were read; during the past session 70 papers were communicated to the Society, and one discourse on the "Recent Development of the Theory of Dissociation" was given by Professor Dewar. As to the Journal, 1775 copies were printed during the past year. About 1851 an attempt was made to found a museum in connection with the Society, and some specimens were sent from the great Exhibition, but were eventually again dispersed. The President suggests that as a nucleus of a future museum the authors of papers on new compounds might be requested to present specimens to the Society. A much more favourable account can be given of the library. At the time the last catalogue was issued to the Fellows in 1873, the number of volumes was 3540; since that time 3260 volumes have been added, making a total of 6800. During the same period the number of pamphlets has increased from 540 to 840. The Council have decided that a new catalogue, arranged in order of subjects, shall be prepared, printed and issued to the Fellows as soon as possible. The income of the Society has steadily increased from about £183 in 1846 to over £3000. The report then dwells upon the vast facilities for the study of chemistry which are now afforded in all parts of this country, so that while less than fifty years ago there was no systematic course of analytical training in the kingdom, now almost every public school has some arrangements for teaching practical chemistry. With this great development in the past and all that it promises in the future there is surely every reason to believe that the Society must increase both in the number of Fellows and in the number and value of the papers communicated to it. There have been two offshoots from the Society during the last few years, the Institute of Chemistry and the Society of Chemical Industry, but neither has prospered at the expense of the parent Society; the valuable papers which have been published by the Society of Chemical Industry have probably been originated altogether under the auspices of the new Society, and are, so far, a pure gain rather than a transference of energy. The President then concluded this portion of the report with a most interesting *résumé* of the arrangements for chemical education and chemical research on the American continent, founded upon the experience gained during his recent tour in that country and on information received from Sir A. Galt, High Commissioner for Canada, and from His Excellency, Mr. Lowell, the American Minister in London.

Dr. Schunk said that all must regret that Dr. Gilbert was not in a position to accept the office to which he had been nominated by the Council; the Fellows were much indebted to him for his constant attendance and courtesy. He had much pleasure in proposing a hearty vote of thanks to Dr. Gilbert, and that his report be adopted. This was seconded by Professor Ronalds and carried unanimously.

Dr. Gilbert said that he appreciated very highly the honour of having been President, and most sincerely regretted that in consequence of the pressure of his own avocation, and his distance from London, he had been compelled to relinquish the office at the end of the first year. His successor was a tried officer of the Society, and had by his researches contributed largely to the interest of the meetings and of the Journal. It seemed only fitting that a chemist who had devoted himself specially to organic chemistry should fill the chair, when that branch of the science was so constantly brought forward at the meetings of the Society.

The Treasurer then presented his report. The total income of the Society was about £3073, the expenditure about £2770, leaving a surplus of £303. This surplus was rather smaller than last year for several reasons; there had been an increase in the expenses connected with the Journal of £217, and with the library of £61. The income was also rather less than was anticipated, owing to the fact that a smaller proportion than usual of the new Fellows had compounded. Next year there would probably be no surplus, as it would be taken up by the expenses connected with the new catalogue, and the redecoration of the Society's rooms. The assets of the Society consisted of £7788 stock and a balance at the bank of £1194. As to the Research Fund, £220 had been given in grants during the year: the assets consist of £4500 stock and a balance at the bank of £166. The donations to the Fund had fallen off considerably.

Mr. Warington proposed a vote of thanks to the Treasurer, which was seconded by Mr. Makins, and carried unanimously.

Votes of thanks were also given to the Auditors, the Council and Officers, and the Editor, Sub-Editor and Abstractors.

Messrs. W. Thorp and Newlands were then nominated Scrutators, and the following Officers and Council were declared duly elected:—President, W. H. Perkin, Ph.D., F.R.S.; Vice-Presidents, F. A. Abel, Warren De La Rue, E. Frankland, J. H. Gilbert, J. H. Gladstone, A. W. Hofmann, W. Odling, Lyon Playfair, H. E. Roscoe, A. W. Williamson, A. Crum Brown, P. Griess, G. D. Liveing, J. E. Reynolds, E. Schunk, A. Voelcker; Secretaries, H. E. Armstrong, J. Millar Thomson; Foreign Secretary, Hugo Müller; Treasurer, W. J. Russell; Council, E. Atkinson, Capt. Abney, H. T. Brown, W. R. E. Hodgkinson, D. Howard, F. R. Japp, H. McLeod, G. N. Makins, R. Meldola, E. J. Mills, C. O'Sullivan, C. Schorlemmer.

Correspondence.

Acetic Ether.

Sir,—It would be unnecessary for me to notice the courteous criticisms of Professor Redwood and Mr. Abraham on my paper on "Acetic Ether," were it not evident that my postscript has not yet made clear how it was that I assumed the Pharmacopœia to mean liquids by measure. It is quite true that, following the scientific usage, I would have read such a formula as meaning parts by weight; but so far from Squire's 'Companion' bearing this out, it supports the interpretation I put on it. To quote Professor Redwood's words will at once show this: "I have never seen it (parts) used otherwise than to represent parts by weight, unless accompanied by an explicit representation of its having a different meaning, as in the case of Squire's 'Companion to the Pharmacopœia,' where the explanation is given at the head of every page, clearly indicating what would be inferred in the absence of such explanation." From this I understand, unless I suffer from mental obliquity, that as Squire distinctly says, "solids by weight —liquids by measure" at the top of the page containing the B.P. formula for acetic ether, this is an "explicit representation of its having a different meaning" from parts by weight, and "clearly indicating what would be inferred (viz., parts by weight) in the absence of such explanation."

Of course Professor Redwood's statement that parts by weight were meant at once settled this, and I am glad to find that the B.P. proportions correspond so well with my own. At the same time perhaps my remarks may not have been out of place, seeing that they have elicited an official explanation on the point. I should like to ask if the solubility (1 in 12 parts of water), is also intended to be taken by weight.

Mr. Abraham will doubtless, ere this, have noticed his mistake in referring to my proposed proportions, but for the benefit of others I will just draw attention to the error in his numbers. He gives my proportions as—

	According to Abraham.	As given in my paper.
Alcohol ·838.	50	50
Dry acetate of soda . .	62	74
Sulphuric acid, B.P. . .	92	110

How he has fallen into this error it is of no importance to discuss. The fact remains that my proportions show an excess of sulphuric acid along with the theoretical amount of sodium acetate.

I can assure Mr. Abraham that I find no difficulty in obtaining a uniform composition by following the directions given, and that the sp. gr. is always about 902 to 901, and the product (even without distillation) contains at least 97 to 98 per cent. ethyl acetate. It would be interesting if Mr. Abraham would analyse his sample "about sp. gr. 891, of pretty constant composition," and determine the percentage of ethyl acetate.

26, *S. Canongate.* Wm. Inglis Clark.

Communications, Letters, etc., have been received from Messrs. Rice, Abraham, Atkinson, Kirkby, Traub, Galen, Omega.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 758.)

OLEUM AMYGDALÆ AMARÆ, U.S.P.—The oil, either in its crude state or freed from hydrocyanic acid, is official, since the sp. gr. is given for each; the former should be 1·060 to 1·070, and the latter 1·043 to 1·049. The distillate, obtained at a temperature of 80° C. (176° F.), should not have the odour or characteristics of chloroform or alcohol. The potash test for the presence of nitrobenzol is given.

OLEUM AMYGDALÆ EXPRESSUM, U.S.P.; OLEUM AMYGDALARUM, P.G.—The sp. gr. in both Pharmacopœias is almost identical. The U.S.P. states that the oil does not congeal until cooled to near − 20° C.; the P.G. that it remains limpid at 10° C., and that when shaken with fuming nitric acid it should give, after some hours, a solid, white, not a brown or red mass, and an almost colourless liquid. This test excludes the use of peach kernel oil, which is said to be largely used in France as a substitute for almond oil. The U.S.P. states that when two drops of concentrated sulphuric acid are allowed to fall on about eight drops of almond oil on a white plate, the mixture should not assume a dark colour at the edge of the acid, and after stirring, the "mixture should not assume a dirty yellow colour, retaining its tint for several minutes."

OLEUM ANISI, U.S.P. and P.G.—Oil of *Pimpinella anisum* only is official in the P.G., but that of *Illicium anisatum* also in the U.S.P. The difference in the solubility of the two oils in proof spirit, pointed out by Mr. Bland (*Pharm. Journ.*, [3], xiii., p. 363), and the discrepancies likely to result from this cause in dispensing, render it desirable that only one oil should be official.

OLEUM AURANTII CORTICIS, U.S.P.—By a singular oversight (?) the botanical name of the orange to be used is not given, hence it is open to question whether the oil of the *Citrus Aurantium* ("essence de portugal") or the more valuable oil of *C. vulgaris* ("essence de bigarade") is intended. Under these circumstances the pharmacist who values his reputation will, of course, use the best variety. Its sp. gr. is given as about 0·860. The disagreeable terebinthinate taste which the oil acquires by keeping may be prevented by "mixing it while fresh with 5 per cent. of alcohol, and decanting the oil after it has become clear from the sediment."

OLEUM AURANTII FLORUM, U.S.P. and P.G.—The same remark as to the omission of the botanical source of the oil in the U.S.P. applies in this case, but in the P.G. it is attributed to *Citrus vulgaris*. It should be soluble in an equal quantity of alcohol, should exhibit a violet fluorescence when a little alcohol is poured on it and the fluid gently undulated (U.S.P. and P.G.), and a spirituous solution should be neutral to test paper (P.G.). The sp. gr. is given in the U.S.P. as 0·850 to 0·890. When pure the sp. gr. of *Ol. Neroli Bigarade* should be 0·899, according to Hanbury.

OLEUM CAJUPUTI, U.S.P. and P.G.—The P.G. gives *Melaleuca Leucadendron* as the botanical source of the oil, and the U.S.P. *M. Cajuputi*, Roxb. The latter gives the sp. gr. as 0·920. On shaking 5 c.c. of the oil with 5 c.c. of water and one drop of dilute hydrochloric acid, the oil should become decolourized (P.G.), nearly colourless (U.S.P.). When 1 part of iodine is mixed gradually with 5 parts of the oil and the mixture cooled, it should solidify to a crystalline mass (P.G.). This mass is easily decomposable.

OLEUM CARI, U.S.P.; OLEUM CARVI, P.G.—The U.S.P. gives the sp. gr. as 0·920. The P.G. orders the portion of oil obtainable from the fruits at a higher temperature, and, therefore, carvol. This does not appear to be in demand in Germany, but must of course be kept for dispensing. The question whether carvol or oleum carvi is to be used will therefore arise when old prescriptions containing oleum carvi have to be dispensed. It would have been better, therefore, that the name carvol should have been given to the fluid ordered in the P.G., of which the sp. gr. should be not less than 0·910. It should give a slightly violet or reddish colour with solution of perchloride of iron, and a white crystalline mass with alcoholic sulphide of ammonium.

OLEUM CARYOPHYLLI, U.S.P.; OLEUM CARYOPHYLLORUM, P.G.—The sp. gr. should be 1·050 (U.S.P.), or 1·041 to 1·060 (P.G.). According to the P.G. on adding a solution of perchloride of iron to water in which the oil has been shaken, it should not give a green or blue colour, indicating probably the presence of carbolic acid; if the oil be pure, a drop of the oil spread on the inner surface of a glass vessel, when the vapour of bromine is introduced, should become of a blue or violet colour. It should be miscible with an equal or larger quantity of spirit of wine.

OLEUM CINNAMOMI, U.S.P. and P.G.—The oil of cinnamon of the U.S.P. of course includes oil of cassia. The sp. gr. of the oil of Ceylon cinnamon is given as about 1·040, and that of Chinese cinnamon (oil of cassia) as about 1·060. The P.G. gives the sp. gr. (of Chinese cinnamon oil) as 1·055 to 1·065. The presence of carbolic acid is recognized by the test with perchloride of iron. No reference is made to the oil of cinnamon leaf, which has somewhat different odour from that of the bark.

OLEUM EUCALYPTI, U.S.P.—The oil may be derived from the fresh leaves of *E. globulus* or *E. amygdalina*, Labill., and some other species of *Eucalyptus*. The sp. gr. is given as 0·900. Muller (*Proc. Montreal Coll. Pharm.*, 1873, p. 28) gives the sp. gr. of *E. globulus* as 0·917, that of *E. amygdalina* as 0·881, and that of *E. oleosa* as 0·911, so that it would appear as if the oil from which this sp. gr. was taken was a mixed oil. Indeed, the oil of *E. globulus* until recently has generally been replaced with that of other species in commerce. For antiseptic purposes this is probably of little consequence; but if used internally, the difference in flavour of the different oils would, probably, be quickly detected by patients and lead to difficulties with the dispenser.

OLEUM FŒNICULI, U.S.P. and P.G.—The sp. gr. is given in both as 0·960. The clear spirituous solution should not be coloured by sesquichloride of iron (P.G.).

OLEUM GAULTHERIÆ, U.S.P.—The sp. gr. is given as 1·180. One of the adulterations commonly used, consisting of a mixture of chloroform and alcohol, is detected by the colourless distillate obtained at 80° C. (176° F.). The other, oil of sassafras, if present, gives a deep red colour when five drops of the adulterated oil are mixed with five drops of nitric acid, and the mixture solidifies to a dark red resinous mass. Oil of wintergreen being the heaviest of the volatile oils, the sp. gr. alone serves as a guide to the detection of any admixture of other essential oils.

OLEUM GOSSYPII SEMINIS, U.S.P.—It should be of a bright pale yellow colour, with a sp. gr. of 0·920 to 0·930. Concentrated sulphuric acid should instantly render it dark reddish-brown. The oil replaces olive oil in five of the official liniments. In the case of *Linimentum Calcis* the drying property of the oil might prove an advantage, but in the others oleum olivæ would probably be preferable so far as the comfort of the patient is concerned.

OLEUM HEDEOMÆ, U.S.P.—The sp. gr. should be about 0·940. This oil, commonly known as American oil of pennyroyal, may be recognized by its sp. gr. (that of *Mentha Pulegium* being 0·927), and by dissolving iodine with an explosive reaction. In some persons it produces unpleasant symptoms, and the English oil is therefore to be preferred in this country.

OLEUM JUNIPERI, U.S.P. and P.G.—The P.G. does not give the sp. gr. The U.S.P. states that it should be about 0·870, and that the oil should be soluble in about 12 parts of alcohol, forming a turbid liquid. The P.G. directs that a drop of the oil rubbed with sugar and shaken with 50 grams of water should not impart an acrid taste to the liquid. This test is probably intended to detect the cheaper oil prepared from the tops or wood of the plant. The P.G. remarks also that the oil is but little soluble in spirit, but forms a clear mixture with bisulphide of carbon. The solubility and specific gravity of the oil depend upon age and upon whether the oil is derived from unripe or ripe berries (*Pharm. Journ.*, [3], viii., 887), but in neither Pharmacopœia is any direction given as to the age of the fruit to be employed.

OLEUM LAVANDULÆ, U.S.P. and P.G.—It should not give evidence of alcohol, and the sp. gr. should be about 0·890 (U.S.P.), 0·885 to 0·895 (P.G.).

OLEUM LIMONIS, U.S.P.; OLEUM CITRI, P.G.—The U.S.P. states that it should be soluble in 2 parts of alcohol and have a sp. gr. of about 0·850, and should be soluble in all proportions in absolute alcohol or disulphide of carbon. The addition of 5 per cent. of alcohol to the oil when fresh and decantation after a sediment has been deposited is recommended to prevent it from acquiring a terebinthinate taste. The P.G. directs that it should not yield alcohol on distillation.

OLEUM MENTHÆ PIPERITÆ, U.S.P. and P.G.—The test given in the U.S.P. of the solubility in an equal weight of alcohol, and in the P.G. of its forming a clear mixture under these circumstances, as well as the test of not becoming heated when powdered iodine is moistened with it, would appear to be intended to exclude the American oil, which is said to explode with iodine and to form a turbid mixture with alcohol (*Pharm. Journ.*, [3], ii., 338). The American oil also has usually a sp. gr. of 0·85 to 0·86, while that ordered in the P.G. is 0·90 to 0·91, and in the U.S.P. 0·90. No test is given for the presence of castor oil (*Pharm. Journ.*, [3], ii., p. 981) or for other known occasional adulterants of oil of peppermint. Now that Japanese oil is a marketable article, a test for its detection if used as an adulterant might be useful.

(*To be continued.*)

NOTE ON DRIED ALUM.*

BY E. BAILY,

Bell Scholar in the School of Pharmacy of the Pharmaceutical Society.

[Contribution from the Research Fund of the School of Pharmacy Students' Association.]

So many different and conflicting opinions have from time to time been put forward as to the use and solubility of the alumen exsiccatum of the Pharmacopœia, that, after reading the evidence on both sides, one is left in considerable doubt as to which is most worthy of credence. For instance, in the *Pharmaceutical Journal* for November 26, 1870, Dr. Tilden states that "dried alum is nearly insoluble in water, but recovers its solubility by long boiling." Similar remarks are made in Watts's 'Dictionary of Chemistry' and other works. On the other hand, several well-known books, among which I may mention Roscoe and Schorlemmer's 'Treatise on Chemistry,' speak of it as a porous mass, slowly but entirely dissolving in water. It was with a view to investigating the truth as regards these statements, and ascertaining whether alum can be thoroughly dried without the occurrence of an insoluble residue, that the experiments were made of which the following is a brief report.

In the first place samples were obtained from a dozen different sources. These all differed considerably in appearance, degree of fineness, colour, and also, as will be seen, in solubility. A commencement was made by dissolving, as far as possible, 2 grams from each sample in 50 c.c. of cold water, filtering the solution and washing till the filtrate ceased to give a precipitate with chloride of barium. The following table shows the result of the process:—

	Percentage of residue insoluble in cold water.
No. 1	2·5.
" 2	6·5.
" 3	5·5.
" 4	·5.
" 5	1·0.
" 6	6·5.
" 7	·5.
" 8	None.
" 9	None.
" 10	3·5.
" 11	2·0.
" 12	5·5.

The insoluble residue consisted of oxysulphate of aluminium. As all the samples had absorbed more or less water, the above percentages may perhaps be placed somewhat higher than they have been given; but, even allowing for this, it is obviously a mistake to speak of the dried alum of the Pharmacopœia as being "nearly, if not quite, insoluble in water." Moreover, the effect of "continued boiling" is not to render the dried salt more soluble; but, on the contrary, to decompose it and cause the deposition of more insoluble matter than is the case when cold water is employed; thus, a sample which, with cold water, yielded 5·5 per cent. of insoluble residue, yielded, after boiling for four hours, as much as 17 per cent.

When the difference thus presented by various commercial samples is considered, we are driven to conclude either that those which were entirely

* Read before the School of Pharmacy Students' Association.

soluble had never been thoroughly dried, or that those which yielded an insoluble residue had been heated above the requisite temperature; my next object, therefore, was to prove which of these suppositions was correct.

Little or no trustworthy information on this point could be obtained by further drying, for dried alum rapidly absorbs moisture from the air; hence it was impossible to say whether the loss in weight on heating was entirely due to water absorbed after drying, or whether any of it had existed in the salt as water of crystallization. Therefore the effect of different temperatures upon ordinary commercial alum was tried, and the following results were obtained. One gram was first as far as possible dried over a water-bath; this heat was found only sufficient to expel three-fourths of the water, the residue weighing ·64 gram. At 240° F. the alum lost four-tenths of its original weight, about 7 per cent. of water being still left in combination with the salt. After drying at the maximum temperature allowed by the Pharmacopœia, viz., 400° F., the sample, upon examination, was found to have lost all its water of crystallization, and at the same time yielded a residue that was entirely soluble in water. With care I have been able to expel all water at temperatures below 400°, but since the products do not differ in composition, no advantage is gained by proceeding thus, while the time occupied is considerably longer. After several experiments, the conclusion arrived at is that when the directions of the Pharmacopœia are carefully followed, a good soluble product, answering all requirements, is always obtained.

It is, therefore, quite evident that dried alum ought always to be freely (though slowly) soluble in water, and that, when this is not the case, the insolubility of the product is caused by carelessness in the mode of preparation.

Having performed the above experiments I was still at a loss to account for the conflicting statements in chemical works alluded to at the outset; for, although the experiments proved that some of the samples must have been dried above the proper temperature, yet even these yielded only a comparatively small residue of insoluble matter, by far the greater part entering readily into solution. However, on referring to former Pharmacopœias, an explanation of the cause of the mistake was soon discovered, for I find that the methods of proceeding used to be as follows. The first quotation is from the London Pharmacopœia of 1788:—"Take alum, a pound, burn it in an earthen vessel so long as it bubbles." The compilers of the Pharmacopœia for 1836, having more regard for technical phraseology, give this direction: "Let alum melt in an earthen vessel over the fire, then let the fire be increased until the ebullition has ceased." Here, though the wording is altered, the sense is evidently the same, and in the Pharmacopœia of 1851 similar instructions are laid down. When thus prepared, dried alum is not only "nearly," but altogether insoluble in water, for, on proceeding in the above manner, the residue obtained consisted principally of oxide of aluminium.

From the results of the above experiments the following facts may, in short, be deduced. Dried alum of the Pharmacopœia should be entirely soluble in cold water. As a rule, among commercial specimens this is not the case, some insoluble matter being generally found, the occurrence of which is due to the employment of too much heat in its manufacture. This residue consists chiefly of oxysulphate of aluminium, and varies from ½ to 6½ per cent. of the whole mass.

In conclusion, I may state that only one of the above samples contained ammonium, the rest being sulphate of aluminium and potassium, and, on making inquiries I was informed that this solitary exception had been in stock for several years and was consequently no guide to the constitution of alum at the present time. To this extent, therefore, I can confirm what has been stated by others, namely, that potassium alum has quite replaced the ammonium alum ordered in the Pharmacopœia.

TURMERIC OIL—TURMEROL.*

BY C. L. JACKSON AND A. E. MENKE.

This oil, to which turmeric (and therefore curry-powder) owes its aromatic taste and smell, was extracted from Bengal turmeric with light petroleum, and after being freed from the higher-boiling portion of that solvent by heating to 150° in a flask, formed a thickish oily yellow liquid having a pleasant aromatic odour. It was purified by fractional distillation under diminished pressure, and was thereby separated into three portions, the first boiling below 193°, the second at 193–198°, and the third consisting of a viscous semi-solid residue. The middle portion consisted of nearly pure turmerol; the first, of that compound contaminated with hydrocarbons from the petroleum. The middle fraction, after further purification by distillation in a vacuum, gave, as a mean result of several analyses, 83·62 per cent. carbon and 10·42 hydrogen, agreeing nearly with the formula $C_{19}H_{28}O$, which requires 83·81 C. and 10·29 H.

Turmerol is a pale yellow oil having a pleasant, moderately strong aromatic smell, and a density of 0·9016 at 17°. It is optically dextrogyrate, $[\alpha]_D = 33·52$. Under ordinary pressure it boils at 285–290°, but decomposes at the same time, yielding a substance of lower boiling point. Under 60 mm. it boils at 193–198°, still, however, with slight decomposition. It is essentially insoluble in water, but mixes readily with all other ordinary solvents. It does not unite with acid sodium sulphite.

Turmerol is an alcohol, and is converted by heating at 150° with strong hydrochloric acid into turmeryl chloride, $C_{19}H_{27}Cl$, which is a pale brownish fragrant oil decomposed by distillation. The same compound is formed, but less definitely, by treating turmerol with phosphorus trichloride; the pentachloride appears to act partly in the same manner, but at the same time to add chlorine. By treating turmeryl chloride with boiling water, and with alcoholic solution of sodium acetate, potassium cyanide, or ammonia, substances are obtained having the characteristic odours of the classes to which they belong, but they have not yet been obtained pure. Turmerol treated with sodium yields a semi-solid mass having the composition of *sodium turmerylate*, $C_{19}H_{27}ONa$.

Isobutyl turmerylate, $C_{19}H_{27}.OC_4H_9$, prepared by boiling the sodium compound with isobutyl iodide in a reflux apparatus, is a heavy yellowish fragrant oil. The *ethylic ether* is a similar substance.

Oxidation of Turmerol.—By the action of a hot aqueous solution of potassium permanganate in excess, turmerol is oxidized to terephthalic acid. With a cold solution of the same salt, not in excess, it appears to yield some new acids, with the study of which the authors are at present occupied.

---

* From the *Amer. Chem. Journ.*, iv., 368–374. Reprinted from the *Journal of the Chemical Society*, April, 1883.

THE EXPLOSIVE POWERS OF NITRO-GLYCERINE AND DYNAMITE.

The following information as to the extent of the destructive effects following the explosion of nitro-glycerine and dynamite has been supplied by Mr. G. M. Roberts, F.C.S., the Technical Manager for Nobel's Explosives Company, Limited, in a letter that appeared in the *Times* on Wednesday last:—

"I observe that exaggerated statements as to the destructive effects of exploded nitro-glycerine and dynamite have appeared in the newspapers. As those statements are likely to produce unnecessary alarm and augment the prevailing "scare," it may be well to reassure the public somewhat by giving them, instead of the grossly exaggerated assertions that have appeared, exact figures from which they will be able to judge how very little cause there is for alarm. Nitro-glycerine and dynamite do not when exploded, exert such a force as is popularly believed. To speak precisely, the power developed by the explosion of a ton of dynamite is equal to 45,675 tons raised one foot, or 45,675 foot-tons. One ton of nitro-glycerine similarly exploded will exert a power of 64,452 foot-tons, and one ton of blasting gelatine, similarly exploded, 71,050 foot-tons. These figures although large, are not enormous, and need not excite terror. Seventy-one thousand tons of ordinary building stone, if arranged in the form of a cube, would measure only 96 feet on the side, and if it were possible to concentrate the whole force of a ton of blasting gelatine at the moment of explosion on such a mass, the only effect would be to lift it to the height of a foot. The foregoing figures are derived from experiments made at Ardeer with an instrument which gives accurate results in measuring the force of explosives. The power exerted by an explosion on surrounding objects is in the inverse ratio of the cube of the distance from the point of explosion. Thus, at 100 feet from the exact point of an explosion, the power is only the cube of $\frac{1}{100}$, or $\frac{1}{1000000}$th part of what it is at a distance of only one foot from that point; or, in other words, if the power at one foot from the spot be represented by 1,000,000, at the distance of 100 feet it will be but 1. It is thus seen that the effects are intensely local, but comparatively trifling at even short distances. If a ton of dynamite or nitro-glycerine were exploded in a London street the effects would be felt severely in the immediate neighbourhood only of the explosion, and beyond that they would be confined to the mere breakage of windows. Indeed, it would be impossible by a single explosion, however large, to do damage to any considerable extent beyond the immediate neighbourhood in which the explosion took place. On one occasion I happened to witness the explosion of over a ton of nitro-glycerine from a distance of only 60 yards. The nitro-glycerine was about 10 feet beneath the level of the ground, which was of sand and covered with water. Beyond the breakage of windows, and the bursting of a few doors in the surrounding buildings, there was no damage done. A little sand was thrown over me, but I received no personal injury. Vague statements have been from time to time promulgated to induce the belief that there are stronger explosives than nitro-glycerine and nitro-glycerine preparations, and that the wretched men who have been guilty of the late attempts on public buildings, etc., are in possession of more powerful explosives than any known to chemists. The public may rest assured that such is not the case. Nitro-glycerine and its preparations form the strongest explosives yet known. The strongest of these is the material known as blasting gelatine. It consists of nitro-glycerine combined with a certain proportion of nitrated cotton. It is much more difficult to prepare than either nitro-glycerine or dynamite, and cannot be made by unskilled persons. If the power of dynamite be represented by 1000, that of nitro-glycerine will be 1411, and of blasting gelatine 1555.

"The $1\frac{1}{2}$ cwt. of nitro-glycerine seized by the police the other day would, if exploded, exert a force of only 4833 foot-tons, and if converted into dynamite, it would represent a force of only 4567 foot-tons. The conversion of nitro-glycerine into dynamite reduces the power of the former, but renders it more easy and safe to handle and use. The power given above is comparatively insignificant, and as it is the maximum effect that could be produced under the most favourable circumstances on the very spot of explosion, it never could be obtained in practice. It is, therefore, absurd to say, as was said the other day in a London paper, that the explosion of such a quantity of nitro-glycerine would blow up the whole of London. In fact, the explosion could scarcely be heard over London, and the damage done by it would be strictly local.

"I have often, by way of experiment, exploded a pound of dynamite suspended from the end of a fishing rod by string of about 6 feet long, holding the rod in my hand the while. As there was no solid matter to project I received no injury, and the end of the fishing rod was not even scratched. About 3 feet of the string at the end of the rod was always left uninjured.

"It will be seen from the foregoing that the scoundrels who attempt to destroy public buildings are powerless to do much harm by their operations. They cannot by any means at their disposal lay a whole city in ruins—not even a street. They may injure special buildings, but that is the most they can do."

KHAT, CAFTA, OR ARABIAN TEA.*

With the Arabs *Catha edulis* is a plant of some importance, inasmuch as it furnishes them with one of the necessities of life in every country, namely, tea. What the leaves of *Camellia Thea* are to us, those of *Catha edulis* are to them. The plant is of a shrubby nature, growing about ten feet high, with smooth, elliptical, serrate leaves, two or more inches long, and about an inch wide. They are peculiar in being arranged on some branches opposite to each other, and on others alternate. The flowers are small and white. The plant is largely cultivated in the interior of Arabia, mostly in gardens along with coffee. For the purposes of commerce, the twigs, with the leaves attached, are gathered and carefully dried; they are made up into closely pressed bundles of different sizes, the quality being known by the form and size of the bundles, the best of which are about a foot or fifteen inches long, and three inches wide; about forty slender twigs compose these bundles, which are tied together with strips of bark. The bundles are sent into Aden from the place of cultivation in the interior of Arabia in very large quantities, and sell at an average price for good quality of about two annas per bundle. The use of this tea in Arabia is said to antedate that of coffee; the effects of its use are described as similar to those of strong Chinese green tea. In consequence of its stimulating effects khat was at one time classed by the people as an intoxicant; the use of intoxicating substances being forbidden by the Koran, this fell under condemnation. A synod of learned Mussulmans, however, made a decree that, as it neither injured the health nor hindered the proper observance of religious duties, but simply increased good-humour and hilarity, it was perfectly lawful to use it. Besides the use of the leaves in the preparation of a beverage, the Arabs also chew them both in the green and dried state, the effect of which is to increase the flow of hilarity or mirth, and to produce extreme wakefulness and watchfulness, so that a man may fulfil the duties of sentry all night without a feeling of drowsiness, an effect somewhat similar to that produced by cocoa. The plant is considered by the Arabs as an antidote to the plague, and they also say that infection cannot be contracted if a twig is carried about on the person. About three hundred camel-loads are brought into Aden in the course of a year.

PATENT MEDICINES.

WE have so frequently drawn attention to the various evils resulting from the popular faith in secret remedies, and from the support afforded to their use by the apparent authorization given to them under the existing system of Government stamping and licences, that it would be superfluous to say more upon the subject from this general point of view than to reiterate the opinion already expressed, both in these pages and in those of our medical contemporaries, that the conditions under which the trade in so-called patent medicines or specifics for the cure of disease is carried on constitute an anachronism inconsistent with the advanced state of the arts of medicine and pharmacy. So far as human credulity is concerned in furnishing favourable opportunity for the continuance of this trade, it is probable that little can be hoped for in the way of counteracting the specious recommendations with which secret nostrums are brought under the notice of the public; but there is another circumstance to which these articles owe much of the appreciation they possess that certainly admits of being dealt with to that end. We refer to the relation existing between the trade in "patent medicines" and the State. A certain amount of revenue is derived from the sale of patent medicines, insignificant from a fiscal point of view, but productive of a mischievous influence, inasmuch as the Government stamp which represents it lends to patent medicines the appearance of having the recognition and sanction of the State for being what they profess. That such a state of things is out of accord with modern enlightenment is, we think, a strong reason for doing away with patent medicine stamps altogether, and in support of this view we may refer to the reply sent some time ago by the German government to an application from the United States government for information as to the number of patent medicines and the extent to which they were sold in Germany. This reply was to the effect that Germany being now a civilized country, patent medicines had no existence in it.

There is, however, a particular class of "patent medicines" which claim especial consideration in regard to the facilities given for their sale and to the implied recommendation of their use, by reason of their bearing the government stamp, viz., those containing powerful poisons or potent drugs. Without raising the question whether preparations of this class do or do not come within the exemption of the Pharmacy Act in regard to the trade in "patent medicines," there can be no doubt that the sale of such preparations without proper precautionary labels is a breach of the spirit of that Act in so far as it was intended to provide for the safety of the public.

Our readers will not need to be reminded that in the draft of a Pharmacy Acts Amendment Bill, now under consideration by the Privy Council, this particular aspect of the patent medicine trade has met with attention, and that in accordance with numerous expressions of opinion on the part of medical men and others it has been proposed to enforce the use of poison labels for patent medicines containing potent drugs, and thus to reduce the risk attendant upon their use. Having regard to the forcible terms in which the necessity for such a step has been spoken of in the medical press we cannot imagine that this proposition will be disregarded. Not long since the *Lancet*, in referring to the numerous fatal results of indiscriminate sale of poisons in the form of patent medicines, did not hesitate to speak of "the revenue derived from the sale of stamps" for such articles as the "price of blood" and of the entire question of patent medicines as calling urgently for legislative revision.

In the current number of *Macmillan's Magazine*, Dr. H. W. HUBBARD again treats of this subject, and directs attention to the anomalous character of the law relating to patent medicines, its inconsistency with the provisions of the Pharmacy Act, and the disastrous effects of the system under which potent drugs can be obtained and employed without any knowledge of their deleterious characters. After instancing cases attended with fatal results that have come within his observation, Dr. HUBBARD remarks that "many of these medicines, though composed "of the most potent poisons of the Pharmacopœia, "are sold indiscriminately to the public from grocery "and provision stores. They are constantly proving "treacherous pitfalls to robust adults as well as to "tender infants. Being so easily obtainable, they "largely facilitate the development of the pernicious "practices and enslaving habits of chloral and opium "taking, now so common in the under currents "of the domestic life of these times."

This subject is capable of assuming a still more serious aspect, for as Dr. HUBBARD remarks, when deaths ensue as a consequence of overdoses of secret compounds, the potency and dangerous nature of which are known only to the proprietary compounders of them, such deaths can hardly come within the conditions of "circumspection" and "moderation" which BLACKSTONE had in view when defining "excusable homicide" or "death by misadventure."

As regards the position of the State in relation to the trade thus represented, Dr. Hubbard adds that "the one requirement is the exhibition of the stamp certifying the Government duty," and it may therefore be well to place beside his comments a statement that the revenue derived from the patent medicine trade, according to official returns for the year ending 31st March, 1881, amounted to only £144,451 8*s*. 10½*d*.

We cannot altogether agree with Dr. Hubbard's comment upon this comparison where he says that "legislation enacted for the purpose of gaining "revenue to the State at the risk of health and life "of the community can hardly be considered the "highest class of statesmanship;" for though the influence of the law to which he refers is pernicious at the present time, the statesmanship which sanctioned its enactment is not necessarily chargeable with defect. The true view to take is that the law having become effete and inapplicable to modern conditions, it presents itself as fitting material to contribute by its repeal to the domestic legislation of the present.

ELECTRIC LIGHTING.

In the fourth of the series of lectures on the applications of electricity, now in course of delivery before the members of the Institute of Civil Engineers, Dr. John Hopkinson, F.R.S., dealt with "Some Points in Electric Lighting." Dividing his subject into two parts—the methods of production of electric currents and the method of conversion of the energy of those currents into heat at such a temperature as to be given off in radiations to which the eye is sensible—the lecturer proceeded to point out that electrical phenomena are essentially mechanical in form and closely related with mechanical laws. Thus the terms "potential," "current" and "resistance" have close analogues in "head," "rate of flow" and "co-efficient of friction" in the hydraulic transmission of power. In hydraulics "head" multiplied by "velocity of flow" is power measurable in foot-pounds per second or horse-power; in a similar manner "potential" multiplied by "current" is power measurable in the same units. Again, just as water in a pipe has inertia and requires an expenditure of work to set it in motion, and is capable of producing disruptive effects if that motion be too suddenly arrested, so a current of electricity in a wire has inertia requiring the work of electromotive force for a finite time to set it in motion, and if arrested suddenly by breaking the circuit the electricity forces its way across the interval as a spark. Whilst, however, the inertia of water in a pipe is confined to the water, the inertia of the electric current resides in the surrounding medium, and this gives rise to the phenomena of induction of currents upon currents and of magnets upon moving conductors, which have no immediate analogues in hydraulics.

The laws upon which the action of dynamo-electric machines is based have been the subject of successive discoveries. Oersted first found that an electro current in a conductor exerts force upon a magnet; and Ampère, that two conductors conveying currents generally exert a mechanical force upon each other. But the most important was the discovery of Faraday, that when a closed conductor moves in a magnetic field, a current is induced in it, in one direction if the number of lines of magnetic force passing through it are increased by the movement, and in the other if they are diminished. Since the dynamo-machine consists essentially of a conductor made to move in a magnetic field, the variation in the direction of current, due to the above cause, furnishes the explanation of the action in the alternating current machine. Alternating current machines cannot be worked in series, but they can be worked in parallel circuit, and are, therefore, quite suitable for the distribution of electricity without the necessity of providing a separate circuit for each machine. In the continuous current machine a commutator revolving with the armature is so arranged as to reverse the connection between the armature and the external current just at the point where the current would reverse; but though it is possible in this way to obtain a current constant in direction, such a current is not constant in intensity. The irregularity may, however, be reduced to any extent by multiplying the wires of the armature, giving each its own connection with the outer circuit and so placing them that the electromotive force attains a maximum successively in the several coils. A practically uniform electric current was first commercially produced with the ring armature of Pacinotti as perfected by Gramme.

A dynamo-machine is not a perfect instrument for converting mechanical energy into electricity, certain losses inevitably occurring. The properties of a machine depend very much upon its dimensions, and were there no disturbing influences it would appear, judging from known data, that a large machine is capable of doing thirty-two times the work done by one half its size. But practically no such result is obtained, for many reasons, and it may be briefly stated—(1) that the capacity of similar dynamo machines is pretty nearly proportionate to their weight, that is, to the cube of their linear dimensions; (2) that the work wasted in producing the magnetic fluid is directly as the linear dimensions; and (3) that the work wasted in heating the armature consequent upon its electrical resistance is as the square of the linear dimensions.

In dealing with the second part of his subject, Dr. Hopkinson referred mainly to incandescence lamps, the Institution having been temporarily lighted with about 230 Edison lamps. The electrical properties of such a lamp were discussed, and in particular it was shown that its efficiency increases and its resistance diminishes with increase of current. One of the advantages presented by the incandescence lamp is the smaller amount of heat communicated to the atmosphere as compared with a gas flame. The light equal to sixteen candles given by each lamp used was described as being produced by 75 Watts of power developed in the lamp; to produce the same amount of light in good flat-flamed gas-burners would require between 7 and 8 cubic feet of gas per hour, contributing heat to the atmosphere at the rate of 3,400,000 ft.-lbs. per hour, equivalent to 1250 Watts, or nearly seventeen times as much heat as the incandescence lamp of equal lighting power.

At the present time, Dr. Hopkinson is of opinion, lighting by electricity in London, using incandescence lamps, must cost something more than lighting by gas. Neither is there much prospect of reduction of cost in the direction of the engine and boiler or of the dynamo-machine, except so far as the prime cost of the latter may become less. Any hope of considerably increased economy must be based upon probable improvements in the incandescence lamp itself. It has been shown that marked economy of power can be obtained by working the lamp at high pressure, but this is done at the expense of its permanence, the filament soon giving way under the strain. Ordinarily each horse-power is made to produce light equal to from 140 to 200 candles from incandescence lamps, but the same amount of power is capable of producing from them, for a short time, light equal to 1000 candles. The problem then is so to improve the lamp in its details that it may last a reasonable time when pressed to this degree of efficiency. If this improvement could be realized, the cost of electric lighting by incandescence lamps would be reduced to one-fifth of what it now is.

It might seem at first sight superfluous to say anything in these columns as to the Explosive Substances Act which Parliament, at the request of the Government, has just passed with very unusual speed. Some of the provisions of the Act are, however, so far reaching that a word of caution may be useful in helping some of our readers to avoid being unwittingly drawn into a position where they may meet with much inconvenience and annoyance. Under the fifth section of the Act any person who, by the providing of premises or the supply of materials, aids, abets, or is accessory to a crime under the Act will be guilty of felony. It is, therefore, easy to conceive of conditions, as for instance where by means of invoices or labels the source of certain "materials" may be identified or suspected, a perfectly legitimate business transaction may be productive of a considerable amount of inconvenience and annoyance to the unwitting seller.

* * *

The Pharmacy Board of New Zealand appears to have recently issued a circular setting out the qualifications at present recognised by the Board for registration under the New Zealand Pharmacy Act of 1880, the fourth clause of which circular reads as follows:—"Any person who holds a certificate or diploma of competency, as pharmaceutical chemist, from the Pharmaceutical Society of Great Britain." The editor of the journal issued under the direction of the Pharmaceutical Society of Victoria, commenting upon this clause, remarks that it would appear from it that "the Minor examination of Great Britain (chemist and druggist) is not accepted." In order, therefore, to prevent any further misconception arising through the incomplete statement in this circular it will be as well to point out at once that under the existing law the New Zealand Pharmacy Board has no power to refuse it. In the 3rd sub-section of the 19th section of the Pharmacy Act for New Zealand, 1880 (*Pharm. Journ.*, x., 402) it is definitely enacted that any person who "holds a certificate or diploma of competency as a pharmaceutical chemist, *or as a chemist and druggist*, . . . from the Pharmaceutical Society of Great Britain, . . . shall be entitled to be registered as a pharmaceutical chemist without being subjected to examination." The justice of this will be seen when the fact is recalled that in this colony there is only one examination, the passing of which qualifies for registration as "pharmaceutical chemist." On the other hand it may be remarked that only such persons as have passed the qualifying examination in this country will be in a position to present certificates or diplomas of competency from the Pharmaceutical Society of Great Britain.

* * *

The Executive Committee entrusted with carrying out the arrangements for the International Pharmaceutical Exhibition, to be held in Vienna in August next, has established in Paris, at 39, Rue Rodier, a branch office for the States of Western Europe. The accredited agent is Herr Maximilian Leucht.

* * *

At the meeting of the Chemists' Assistants' Association on Wednesday evening next, the adjourned discussion upon Mr. Giles's paper on "Pharmaceutical Politics"—a portion of which is printed in this number of the Journal—will be resumed. It is anticipated that a resolution will be proposed expressing approval of the draft Pharmacy Acts Amendment Bill.

* * *

In like manner the late hour at which Mr. Frazer concluded the delivery of his lecture on "The Proposed Changes in the Pharmacy Act of 1868 and in the Educational System of the Pharmaceutical Society" at Glasgow on Wednesday evening last—a portion of which also appears in the present number—necessitated the postponement of the discussion. It is expected that a General Meeting of Chemists and Druggists in Glasgow and the West of Scotland will be held on an early day for the purpose of affording an opportunity for an expression of opinion on the subject.

* * *

At the meeting of the Chemical Society on Thursday next there will be a ballot for the election of Fellows, and a note by Mr. L. Thorne will be read on "An Apparatus for Fractional Distillation under Reduced Pressures."

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, April 4, in the College of Physicians, Dublin, at three o'clock. The Vice-President, Dr. Aquilla Smith, presided.

The other members of the Council present were:—Messrs. Allen, Bennett, Brunker, Dr. Collins, Messrs. Grindley, Hayes, Sir George Owens, Mr. Wells and Dr. Whitaker.

Mr. Hugh Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

Mr. Fennell read a letter from Mr. Hatchell Whitby, 61, South Great Georges Street, asking what arrangements had been made for the meeting of a joint committee of four members of the Society and four of the Council, which had been appointed in pursuance of a resolution moved by him, to report to the Council on the best means of improving the prospects of the Society.

Mr. Brunker: That committee is waiting for his action in the matter.

Mr. Wells: There was a letter from him stating that he could not do anything in the matter himself.

Mr. Fennell: The committee were named at the Annual Meeting.

Mr. Brunker: And Mr. Whitby was written to, asking him to name the members of the Society not on the Council who were to confer with the members of the committee representing the Council. He declined to do so, and there the matter rests.

At the request of members, Mr. Fennell read from the minutes a record that a letter, dated November 29, had been received from Mr. Whitby, stating that he could not undertake to arrange for the meeting of the committee.

Mr. Allen: I understood that the matter was to be to a great extent left in his hands.

The Chairman: Let Mr. Fennell inform him that the Council did not take any action in the matter in consequence of his letter of November 29. The matter originated with him and it is not for the Council to help him. Let him take his own course.

Dr. Whitaker: The committee is still in existence.

Mr. Fennell was directed to write to Mr. Whitby in accordance with the suggestion of the Chairman.

A report from the Law Committee was read.

The Chairman remarked that the cost of two prosecutions carried out by the Society last year amounted to £29 3*s.* 2*d.*, and only £3 was received by the Society as a fine in one of the cases.

Mr. Wells: But you gained a very substantial advantage.

Dr. Whitaker: The money was well spent in sustaining a principle.

Dr. Collins said there was an instance in which a prosecution had cost the Apothecaries' Hall of Ireland £125, out of which they got £24 or £25.

Dr. Whitaker said it appeared to him that prosecutions could be more readily and inexpensively conducted in Dublin than in the country.

Mr. Wells: If you do not protect the members of the Society you will have no members shortly.

Mr. Brunker: The great excuse which licentiates make for not being members of the Society is, that we are not putting a stop to illegal dispensing. We reply that we cannot do it because they will not give us funds. We have 219 licentiates and 61 subscribing members.

Mr. Wells: You will get a great many more members if you show them something for their money. If it be a general complaint that you do nothing for the licentiates, they will not subscribe.

On the motion of Mr. Wells, seconded by Dr. Whitaker, the report was adopted.

A report of the Certificate Committee, containing the following passage was read:—"The declaration of Mr. John P. Middleton, brought before the Committee, having been substituted by a certificate, could not be entertained by them. The certificate is signed by Mr. G. H. Grindley, M.P.S.I., representing himself as 'late managing partner of the firm of Brooks and Co., 136, Lower Baggot Street.' The certificate goes to show that Mr. Middleton was for five years engaged with the firm. The Committee cannot undertake the responsibility of declaring that Mr. Grindley was a pharmaceutical chemist legally keeping open shop for the dispensing of prescriptions in the sense of the regulation on page 55 of the Society's Calendar for 1883, he being associated with an unqualified partner in the business."

Mr. Brunker: The position of the firm referred to is analogous to that of another in respect of which a prosecution is to be undertaken. We are not prepared to say that the member of such a firm is entitled to give the certificate required by our regulations. One member of such a firm is only half a pharmaceutical chemist.

Dr. Collins: It is for any member of the Council who thinks the young man is aggrieved to move that the certificate be accepted.

On the motion of Mr. Bennett, seconded by Sir George Owens, the report of the Certificate Committee was adopted and ordered to be entered on the minutes.

Mr. Brunker moved—

"That Mr. Middleton be informed that the certificate of practical pharmacy presented by him cannot be accepted as complying with the regulation relating to such certificate on page 55 of the Calendar of the Society for 1883, Mr. Grindley not being a pharmaceutical chemist keeping open shop in the strict sense of that regulation."

Mr. Hayes seconded the resolution, which was carried.

The Chairman moved the following resolution pursuant to notice:—

"That the subscription for the *Pharmaceutical Journal* be discontinued from and after the 30th of June next."

He had given this notice in consequence of having noticed the heavy expense the Society had incurred for the last three years in supplying the *Pharmaceutical Journal* to members of the Society. The facts had satisfied him that the experiment which had been going on since 1879 had proved an utter and costly failure. In 1879, the amount paid for the Journal was £45 2*s.* 4*d.* In 1880, it cost them £47 10*s.* 0*d.*; and in 1881, the cost was £42 9*s.* 2*d.* The cost for 1882 was still outstanding.

Mr. Allen: You have it on the paper £34 14*s.* 4*d.*

The Chairman said the fact was that they had lost a great deal of money by the matter. They had been told that it would be a great inducement to licentiates to join the Society; but so far from that having been the case the reverse had happened, as the following figures would show. In 1877 they had fifty members, and in 1878 they had seventy-nine, and there were no resignations in either of those years. In 1879 they had eighty members and there were two resignations; in 1880 there were seventy-four members and four resignations; in 1881 there were seventy-seven members and six resignations; in 1882 they had seventy-three members and eleven resignations; and in 1883 they had sixty-one members and ten had ceased to subscribe. The fact was that if they had only twenty-seven members now and were not obliged to supply the Journal they would be better off than they were under the existing arrangement.

Dr. Collins stated that the President had told him that he would not be able to be present that day, but that it was his opinion that the resolution of which the Vice-President had given notice was opposed to a resolution which the Council had passed on his motion about two months back, to the effect that when any member should become a month in arrear of his subscription to the Journal it should not be supplied to him.

Mr. Grindley: I think the motion has not been seconded yet.

Mr. Bennett seconded the motion.

The Chairman said Dr. Tichborne's resolution did not touch that which he now proposed at all.

Mr. Brunker said he was altogether with Dr. Smith in the opinion that this arrangement about the Journal was a losing game, and the sooner it was given up the better. But would it be fair towards gentlemen who had paid their subscriptions from October 1, last, on the understanding that the Journal was to be suppled to them for a year, to put an end to the arrangement in June?

The Chairman: That could be met by supplying those gentlemen with the Journal for the remainder of the year.

Mr. Grindley said the fact was being lost sight of that although financially the arrangement had not been a success, morally it had been. It had kept the members of the Society together. If they discontinued giving something for the subscriptions they would soon have no members at all except the Council, the greater part of whom did not pay anything at all towards the support of the Society. He moved that instead of hastily discontinuing the supply of the Journal, which many members considered a right, the Registrar should be instructed to send out post cards to all the members of the Society asking them whether in the event of the Journal being discontinued they would continue members of the Society.

Mr. Hayes thought that would be a very injudicious proceeding.

Mr. Brunker said the Journal was costing them a great deal, and their ability to put an end to illegal dispensing was very much interfered with by their want of funds.

Mr. Grindley: The mistake was in giving the *Pharmaceutical Journal* instead of the *Chemist and Druggist*.

Mr. Allen: Would we cease to have reports of our proceedings?

Mr. Grindley: That would follow naturally.

Mr. Brunker: No; the journals would be very glad to get them.

Mr. Wells: We should explain to the members that we want funds to carry on prosecutions. That would satisfy a great many.

Mr. Grindley: The cost of the Journal will be very much reduced in consequence of the adoption of Professor Tichborne's motion.

Mr. Brunker suggested that the Chairman should alter the date from which his resolution proposed that the subscription for the Journal should be discontinued to the 1st of October next.

The Chairman accepted the suggestion; and the resolution so altered was put and carried, Mr. Grindley dissenting.

Some financial business having been disposed of, the Council adjourned.

At the Preliminary examination, held on April 2, ten candidates presented themselves, all of whom passed.

The examination for the licence was held on April 4 and 5 (this being the first occasion on which it was held on two days under the new regulations). There were three candidates for this examination, two of whom passed. The report will be presented at next Council meeting.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting of the above society was held at the Royal Institution, on Thursday, March 15. The President, Mr. Councillor Woodcock, in the chair.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal*, from the Society; a specimen of *Cassia Fistula*, from Mr. J. Parkinson; 'The Sixth Annual Report of the Lancashire and Cheshire Entomological Society,' and 'Proceedings of the Liverpool Geological Society,' from the respective Societies; 'The Thirteenth Annual Report of the Free Public Library, Museum and Art Gallery,' from the Committee.

Dr. Symes showed some kola nuts which had been sent over in the moist state in earth. He mentioned their active principle, caffeine, and the use to which they were put by the natives of the districts where they are used, viz., as a stimulant under fatigue.

Mr. A. C. Abraham then showed a copy of Linnæus's first published 'Systema Naturæ,' and also the 'Pharmacopœia Augustana,' respecting some of the formulæ in which he made a few remarks.

The thanks of the meeting having been voted to Messrs. Symes and Abraham for these communications, the Chairman called upon Mr. Albert H. Samuel to read a paper upon "Indophenol." This paper will be printed in a future number.

Mr. E. Davies, in proposing a vote of thanks to the author, said that he had listened to him with considerable interest, and that by means of the diagrams the production of indophenol, although complicated, had been made clear even to those who had only an ordinary knowledge of chemistry. He had himself learned much that was new to him from the paper. He thought that there was a moral to be learned from it. He was not surprised to hear that so far the English dyers had not been successful with such a delicate preparation as this, nor were they likely to be so until the ignorant and self-conceited foremen so often employed at the head of their establishments were replaced by chemists of ability. The consequence of the present state of things would, he feared, be that we should have to send our calicoes to Germany to be printed.

The motion was seconded by Mr. M. Conroy, and carried unanimously.

The meeting closed after a few words from Mr. Samuel, in reply.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

A meeting of this Association was held on Wednesday evening last. The chair was occupied by the President, Mr. McAdam, who, after reading some apologies for non-attendance, called on Mr. Daniel Frazer to deliver a lecture that had been announced. At the close of the lecture, Mr. Frazer, on the motion of Mr. Kinninmont, was awarded a vote of thanks. In consequence of the lateness of the hour the discussion was adjourned. The following is a report of the lecture:—

The Proposed Changes in the Pharmacy Act of 1868, and in the Educational System of the Pharmaceutical Society, together with some Remarks on the present Position of Pharmacy.

BY DANIEL FRAZER.

Through the great kindness of our esteemed President, in convening the present meeting at my special request, I am permitted to address you on the proposed changes in the Pharmacy Act of 1868. These changes have been proposed by the Council of the Pharmaceutical Society itself. They (not we provincials) have broken the ice. Our footing as traders on the unbroken ice of the legal safeguards that to a large extent give us a practical monopoly in carrying on the more legitimate part of our business has not been an over secure or comfortable one of late years. What will it be when we have to tread upon the broken ice? That the ice will be broken when we get into Parliament seems to me so manifest that I stand amazed at what I consider the judicial blindness of the wise men of Bloomsbury Square.

In vindication of this strong language I will, with your permission, *first* discuss the proposed Pharmacy Acts Amendment Bill, as issued by the Council at their meeting in February last, along with some notice of the proposed changes in the educational system of the Pharmaceutical Society; and *second*, I will make some general remarks on the present position and future prospects of Pharmacy. I need hardly preface these remarks by saying that I by no means seek to commit a single person here to accept as his my views on the topics I now proceed to discuss.

Our esteemed friend, Mr. Kinninmont, with his usual honest impetuosity, lost no time in taking part in the discussion of the Bill that has been waged in the *Pharmaceutical Journal* since its publication there. In his letter, Mr. Kinninmont expresses satisfaction with the action of the Council for having, in his opinion, "avoided everything which had the appearance of grasping at a monopoly."

Truly, appearances are sometimes deceitful—it is not all gold that glitters. To my apprehension the weakness of the Act lies mainly in the opposite direction. It so nakedly demands additional protection for ourselves in carrying on our business that I feel sure that when it reaches Parliament this feature of it will lead to the wrecking of the Bill as a whole, and to the sweeping away of some of the protection we now enjoy. With my views on such subjects I would not object to this; but not so, I believe, with some of you.

This feature is exhibited in the preamble. Its words are:—"Whereas it is expedient for the safety of the public that sales of poisonous articles should be regulated: also, that any seller or keeper of an open shop for the retailing, dispensing, or compounding of poisons and medical prescriptions should possess a competent skilled knowledge, and also that the sale of poisons should be further regulated."

There are two quite new things embraced in this preamble—the first being the bringing within the scope of the law several articles hitherto unrestricted in their sale to the public, and the second is the demand made in it to have the sale of *non-poisonous* agents, when in the form of "medical prescriptions," confined to pharmacists and other "qualified" men. Regarding the first, I remark that as every pharmacist of any standing has hitherto labelled all the "poisonous" articles referred to in it as "poisons," little, if any, inconvenience will be caused by its enactment to us. But I would have opposed its introduction into the Bill as an unnecessary interference with trade in articles of enormous consumption, and from the sale of which no hint of any inconvenience has come from any part of the country save from the Veterinary College of Lincoln. I would also have objected to it from being persuaded that, even if it be enacted, it will prove a dead letter so far as the sale of the mineral acids by outsiders is concerned, and I think it a serious mistake to pass laws that cannot or will not be enforced.

Some years ago, along with Mr. Mackay, and other members of the Council, I strongly opposed the introduction of the first four of these "poisonous articles" into the Poison Schedule. This took place originally in 1875, when a Bill, called the "Drugging of Animals Bill," was introduced into the House of Lords. Mr. Sandford brought it under the notice of the Council, and our law agent, then present, characterized it as too absurd to have any chance of passing. The Council then was unanimous in petitioning against it. On at least three occasions since then, when white hellebore powder was included in the list, there was a considerable support given to the suggested additions to the Poison Schedules by some members, but happily the Council, by a majority, threw the suggestion overboard. But, in an evil hour, as I think it, our present Council at last yielded to the application of the men of Lincoln, and last summer it applied to the Privy Council to sanction their insertion in one of the Poison Schedules.

But, as those who interfere in other people's quarrels generally come off second best, so with our Council on that occasion. It got a direct rebuff. The Privy Council refused to add to our existing monopolies. Hence Clause 2 of the present Bill, which is so generally denounced by pharmacists who are ignorant of its history and origin, as well as by those of our number who take all the protection they can get and ask, like little Oliver, for more.

I would still more have objected to the restriction sought, for the first time in Britain, though it is embraced in the Irish Act, of confining the sale of non-poisonous agents, when in the form of "medical prescriptions," to registered pharmacists and medical licenciates. If there is one thing more than another in which pharmacists have an almost absolute practical monopoly it is the dispensing of prescriptions. So far as I know, the dispensing of prescriptions by others than pharmacists proper and medical men in their surgeries, is confined to two or three of the larger stores in London, Liverpool and Manchester. But supposing that they are dispensed in even a dozen stores scattered over the kingdom, is it worth our while risking a battle on such a subject in the House of Commons? It is in these few stores alone, so far as I know, that our practical monopoly in the dispensing of prescriptions is in any way interfered with. It cannot be doubted that the existence of this monopoly will be made plain in Parliament by the representatives of the stores. And, whatever may be said as to injuries arising to the public from the unrestricted sale of poisons or of poisonous agents, as it cannot be alleged that injury or accident has arisen from the sale of any of the non-poisonous drugs, I cannot conceive of Parliament sanctioning this addition to the monopolies already enjoyed by pharmacists.

As directly bearing upon this point, and in proof that the views I am now enunciating have not been hastily or lightly arrived at, I will here refer to a speech I delivered in the London Council on February 3, 1881, when moving the first of eleven amendments I had tabled against the Bill, then under discussion, and which, with a few exceptions, is practically the same Bill as the one now before the country (*Pharm Journ.*, [3], xi., 641).

To the views thus expressed two years ago I adhere still, if possible, with a stronger conviction as to their soundness than ever. The terms of the amendment I ventured to move against the preamble of the proposed Act, for our adoption in 1881, were these:—"Omit '*and medical prescriptions*'; or if these words are retained, insert after them the words 'containing scheduled poisons.'" To that, so long as restrictions are laid on the sale of scheduled poisons themselves, I do not object, much as I do object to the fettering of ourselves or others by any sort of legal entanglements not demanded by the laws of truth and justice.

I further ask your attention to what seems to me a remarkable change in the terms used in the preamble, and continued with a distinct emphasis throughout the Act, to describe the owner of the "open shop." In the Act of 1881 the terms were:—"Whereas, it is expedient, for the safety of the public, that all persons *selling* or keeping open shop for the retailing, dispensing or compounding of medical prescriptions, should possess a competent knowledge of their business." In the proposed Act now before us the terms are these:—"Whereas, it is expedient, for the safety of the public, that sales of poisonous articles should be regulated; also, that any *seller* or keeper of an open shop for the retailing, dispensing, or compounding of poisons and medical prescriptions, should possess a competent skilled knowledge," etc. Lawyers do not generally substitute one term for another without a distinct purpose in doing so. What I want to know is this. Is the "seller" another name for the "keeper" of an open shop; or is it a lawyer's mode of getting at the proprietors of co-operative stores? If so, if the mere salesman in a co-operative store can thus simply be made responsible for the sale of poisons or "medical prescriptions" that he may make, then, most assuredly, the same law will be measured out to our own "unqualified" assistants. That such a result was intended by the authors of this Bill need not be insisted upon. That is not the question. If it become a part of the law of the land, its interpretation and administration will fall into other hands than those of its authors and present supporters. For my own part, though I have as yet failed to get any pharmacist to agree with me, I hold that if this clause comes into court in its present form both judge and jury will interpret it in the way I have pointed out.

So much then, for the preamble. My only apology for dwelling at such great length on it is that it is the keystone of the bridge—the arch on which the whole superstructure of the Bill rests.

The next, or "Definition Clause," as it is innocently termed, is also an all-embracing one, and demands our maturest consideration. Mr. Kinninmont sees no monopoly even in it! I see in it on the other hand, nothing but monopoly!

"Words importing the singular number only shall include the plural number." If they say one thing and mean another, why use such words at all? If you mean the plural, why not use the plural? Why, in short, not say in plain and unambiguous terms "Co-operative stores shall not be permitted to sell scheduled poisons or 'medical prescriptions' unless every single person in them be on our register?" If that is what is meant by this clause, why not say so? Do the authors of it expect this clause to pass the gauntlet of a free discussion in the House of Commons without this fact being discovered by the lynx-eyed "fourth party," if by no other? And, when discovered, when it is seen that the whole purport of it is to stab the co-operative stores and to prohibit their dealing in scheduled poisons or dispensing prescriptions, I can only express my unbounded surprise at the innocency of our Council expecting to carry it. I hold now, as I have done all along, that it is a very foolish proceeding on our part, whatever it might be for other and disinterested parties to do, to attack the stores, and that, too, in the "house of their friends." I said so over and over again long before the House of Lords decided in their favour and against our claims. With this decision in their favour in the highest Court of Appeal in the country, does any sane man expect that the House of Commons will sanction a Bill depriving the stores of their existing legal rights? No, emphatically I say, no. Do not then risk such an encounter on the floor of the House of Commons as the introduction of this clause in the Bill will certainly provoke. Our Society has already, as I have said, suffered defeat in attempting to interfere with the dispensing of poisons by the stores. Why then court another and a still more disastrous one in the very face of Parliament itself—the law-making Court of the land? Does the present most sagacious and energetic President of our Society's Council expect such a clause to be passed by men — many of whom are members of the stores themselves? Will they put their hands to the rope that is intended to hang them?

Having discussed the substance of the second clause while dealing with the preamble, I now pass on to the third clause. This is to compel wholesale drug houses to keep a record of their sales of poisons. I really do not see the need of it. Practically the thing sought is already done; and even where, in some rare cases, it may not be done, I for one would be slow to entangle our wholesale friends in the meshes of the law in the conducting of their business. It is bad enough that we are so entangled that not a few of us, I believe, would give a great deal to be free of it. Why so needlessly provoke a collision on the subject with the wholesale trade?

Then comes the fourth clause—or the first of two clauses bearing on the sale of patent medicines containing scheduled poisons. This is the labelling one. What shall I say of it; or rather, what will makers of and wholesale dealers in proprietary articles containing, in however minute and innocent a form, any of the scheduled poisons say of it? That they will oppose it cannot be doubted. Mr. Davenport, Messrs. Savory and Moore, Powell, the maker of Locock's wafers; Messrs. Edwards, Newberry, Barclay, and Maw and Sons will be up and stirring; and, as their interest in this matter is ours, we are pretty safe to leave it to them to fight our battle at this corner of the field. Only this will I ask here—how is it possible to secure that this labelling be done by makers in France, in America, or anywhere out of the United Kingdom? And if we cannot do this, how can we recover the penalties from men who are beyond our jurisdiction? For myself, I do trust that this attempt to assimilate the laws of this country to those that obtain on the Continent regarding the sales of such remedies as are here aimed at will be unsuccessful. It is bad enough when Messrs. Jones, Brown, and Robinson, in their journeys on the other side of the Channel, are put to their wits' end to obtain five drops of laudanum or a teaspoonful of paregoric when a colic or a cough requires such medicaments for their alleviation or cure. Do not, for any sake, attempt to legislate for such restrictions in this free country; or, at least, do not do it so long as our rivers and canal banks are open to would-be suicides, and so long as six-chambered revolvers and nine-inch bladed knives can be obtained without let or hindrance by the would-be assassin, or even by "Number 1" himself.

I would here ask, On whom do our Councillors seek to impose these shackles? Is it on our enemies the stores or on ourselves? On ourselves in at least the first instance. It is we pharmacists, and we almost exclusively, and not the stores who are the makers of those proprietary articles, and so it is ourselves that we are asked to burden with these legal restrictions! The Government of its own accord did impose a restriction on the sale of arsenic now many years ago, but they did it for a specific reason—the poisoning of children by its means in several districts in England; and if the Government of its own accord were now to impose such a restriction on the sale of any proprietary articles that can be proved to have been employed at all extensively for wilful poisoning, or that, through their potency, have proved to be dangerous agents in the hands of the public, I would not object. But why ourselves seek to impose these restrictions upon a whole class of remedies against which no such evidence can be adduced, and very many of which are of unquestionable value, and are largely prescribed by some of our most eminent medical men? You may like them or not like them, but you cannot put them down as long as the columns of our newspapers and the pages of our magazines, of our own Journal, and of the *Chemist and Druggist*, are open to the reception of their advertisements.

Clause 5.—This is a penalty clause. It need not trouble us much. Our wholesale friends will take good care that it does not become law, and so we can quite safely leave it in their hands.

Clause 6.—Even more certain and successful will be the opposition of the makers and of the wholesale trade to this penalty-recovering machinery.

Clause 7.—This is superfluous. The common law abundantly provides for this. Just as the great railway companies are responsible for the action of their servants, so are we for that of ours, and rightly are so.

This responsibility, both at civil and criminal law, on the part of pharmacists, not only for their own actings, but for the actings of every one of their assistants and apprentices, is, I have all along held, the greatest safeguard that the public can have for the careful conducting of our most onerous business. Self-interest comes in here with immediate and immense force. If I, by any chance, take down this bottle instead of that one, and substitute a poisonous for a simple remedy, and fatal results follow, I am responsible at criminal law, and liable to be tried for culpable homicide or manslaughter; or if I escape this, as happened in well-known cases in England and in Ireland some yeare ago, and I be only made responsible at civil law, I may have, as in one of these cases, to pay £2000 of damages, in addition to immensely injuring, if not ruining, my business. With such possibilities attached to the proper conducting of our business, even apart from all the feelings of grief and mortification engendered by our being the means of death or of serious injury to another, can more stringent securities for the proper administration of our business be reasonably demanded of us? I think not; and certainly we ourselves should not, however much we may be annoyed at the stores, be instrumental in imposing still furthur penalties on the conducting of it.

Happily we have at last reached a clause to which I can give my most cordial support. I mean the one requiring the placing of a "qualified" assistant in every branch shop. But I wonder how many of the London Council agree with me in this. They have all accepted it, but how many of them love it? This I have no means of knowing; but this I know, that when I in committee two years ago proposed, as I think I did—but at least I supported—the insertion of such a clause as the present in the Bill then before us, it was most strenuously and successfully opposed by the great majority of the then existing Council—one not largely differing from the present one.

I wanted such a clause then, and I welcome this one now, because I maintain that as long as the Act of 1868 exists in its integrity I have no right to open a second or third shop, in addition to the one qualified by my own attendance, unless I put a qualified assistant in it.

Clause 9.—Though I have already referred to the substance of this clause, I wish here to draw your special attention to the exact wording of it—"Duly qualified persons to sell medical prescriptions and sell poisons." Hitherto the words "medical prescriptions" were modestly placed in the rear of "poisons." Now they are boldly put in the front, and "poisons" are made to play second fiddle to the prescriptions. There is also here a decided step taken in advance in the use made of the terms "seller" and "keeper." In the preamble it is "any seller *or* keeper of an open shop." Now it is boldly stated "unless the seller *and* keeper of any such open shop." If the seller and keeper are one, why "seller *and* keeper?" I would strongly urge, whatever may be your views as to the general purport of the Bill, that you get a clear and explicit explanation of all that is involved in the use of these words—"the seller *and* the keeper" of an open shop. Ask any lawyer how he would interpret the words, were he employed to defend you, in regard to their true meaning in a court of law.

Clause 10 is apparently aimed at the co-operative stores, or at medical men who carry on business in other names than their own. The penalty asked is a pretty heavy one, but as it does not affect aboveboard traders who do not object to their names being given, even where the firm under which they trade may not contain it, we need not greatly concern ourselves with it.

Clause 11.—A clause of penalties that need not in any way disturb us, law-abiding subjects of Her Majesty.

Not so with clause 12.

It is remarkable above all the other clauses of the Bill from the quiet way in which it seeks arbitrary powers for our Society that, if obtained in the terms of it, will, in my opinion, whatever the Council itself may have intended by it, completely override even the powers of the Privy Council itself. To the corresponding clause of the Bill of 1881 I moved that after "Britain" the words "with consent of the Privy Council" be inserted, but I was overruled by the authority of our legal adviser —he stating that that was necessarily implied. Well, it it is implied, why is it not so stated here, as it is stated in a much less important and less far-reaching clause—namely, the second, or "Poisonous Articles" clause? There the authority of the Privy Council is recognized; here it is completely ignored.

Further, I would oppose it even were this saving clause in it, on the ground of the demand it makes for powers to revolutionize the examinations and powers to alter the fees, and that means, judging by all antecedent legislation on the subject, to increase them. If it be carried, the Council shall practically, as representing the Society, have full power to institute a curriculum through which all our candidates must pass, and this, probably, without the Society, in its corporate capacity, being consulted in the matter. In the face of the large numbers of our best men who are leaving our ranks in consequence of even the existing standard of examinations in use, and their expense, and in face of the transference of large portions of our business to other traders—including the stores—are you willing to give your Council such enormous powers? Unless you are so prepared you had better take care that, whatever other part of the Bill be carried, this clause shall not. What makes me the more anxious upon this point is—(1st) that in the opinion of two members of the existing Council, as we shall see further on, the Council has already in its actings infringed the existing law; and (2nd) because of finding, in a letter to the Council to which I shall also refer later on, this sentence:—

"But little alteration of the Pharmacy Act of 1868 is needed to effect all that is above indicated in the way of Parliamentary legislation; *the rest* can be accomplished by bye-laws and by the *resolutions of the Council.* (*Note.* —By the Council: not by the Privy Council—not by the Society!)"

And all this, too, in face of the closing sentence of clause 2 of the Act of 1852:—

"Provided always, that all such original bye-laws and all altered, amended, or additional bye-laws, shall be confirmed and approved by a special general meeting of the members of the said Pharmaceutical Society and by one of Her Majesty's principal Secretaries of State."

Before parting with this part of my subject, I frankly repeat the opinion I have never ceased to hold—that I believe the examinations are already, in their stringency, and in their expense, beyond the requirements of the case. As an evidence of this you have but to read the results of the February examinations:—

11 Majors examined	. . . . .	6 failed!
84 Minors examined	. . . . .	56 failed!!*

Clause 13.—£5 of a penalty if I admit an apprentice into my premises before he has passed the Preliminary! I do not know what it may be in England, where large premiums are often given by the apprentices, but in Scotland, where we pay ours salaries ranging from £10 to £25 a year, such apprentices cannot, judging by my own experience, be obtained. Though I have some six at present in my different shops, only one of them had passed his Preliminary before entering. If it be replied, the penalty is only to apply to articled apprentices, then I reply it does not affect me, for I have ceased articling apprentices for many years. The demand for apprentices who have passed the Preliminary is as likely to be obeyed, in Scotland at least, as was the old demand of calling spirits from the mighty deep. The reason is quite simple. The families who alone, or who almost exclu-

* "Indeed, looking at the results of the examinations, I do not consider any material change at present desirable. The Minor examination, which confers all the privileges of the Pharmacy Act, as now conducted, affords a sufficient guarantee of competence to keep an open shop for retailing, dispensing and compounding medicines. It is thoroughly practical, and any increased stringency could only have the effect of adding to the already large number of candidates who are rejected."—*From Dr. Greenhow's Report on Examinations*, March 8, 1881.

sively supply us with our apprentices do not and cannot educate their children up to the point needed for passing the examinations until the candidates themselves earn the means of obtaining the needed education by their labours. Such, at all events in Glasgow, is my experience over the last forty or more years. I need not add that I oppose this clause, as I have done most of its predecessors.

Clauses 14 and 15 can pass without remark.

Clause 16 I do not object to. But why make two bites of a cherry—why not make a good bolt when swallowing so much? Why not at once abolish the Major examination and declare all the present and future Minors to be Majors? Some say this would be an injustice to the existing Majors. Well, call them Majors No. 1, or "Fellows," if they like. It will cost no money and break no bones, and if it please them it will do us no harm.

Clause 17.—I think this quite right, having on several occasions seen the beneficial working of the principle it contains. It will not keep out any proper candidate, and it may be useful in keeping out an improper one. During my ten years of experience I only recollect of two cases in which it was put to active use, and in both cases I quite agreed with the action of my colleagues in the Council.

Clause 18.—This dog is so nearly dead that I hardly think it worth while spending a clause on him—giving him the last knock on the head.

Clause 19.—No objection to it.

Clause 20.—I suppose we must have a little red tape now and then, and as there does not seem a formidable use of it here, I do not object to it.

Clause 21.—Most certainly. Punish to your heart's content everybody guilty of falsehood. No punishment can well be too severe for wilful misrepresentations.

Clause 22.—That is, that this Act is not to apply to Ireland. Most certainly not. It is, however, quite worth while, to show the hopeful progress cur Society is making in some points, if it is losing in others, to recall how matters stood in 1875, when the Irish Act was before Parliament. After one of the keenest discussions at which I ever was present, the Council, in June of that year, petitioned the House of Commons against the Bill, and petitioned for one to embrace the whole kingdom. Mr. Sandford, Mr. Schacht and myself, were the only opponents in a meeting of eighteen members, and so the petition against it was sent to the House of Commons. In the Journal (that of June 5, 1875) reporting this discussion there is a list of one hundred and sixteen petitions sent in to Pariiament against the Act—Edinburgh, Aberdeen, Dundee, Perth, Greenock, Dumfries, Montrose, Peterhead and Elgin, being the Scotch towns. Glasgow, happily, is not on the list.

Clause 23.—Commencement of the Act. Instead of fixing on a specific date, better say—"The Act shall come into operation in two years, or thereby, from the date of its receiving the signature of Her Majesty." This would give all a reasonable time to prepare for its operation.

The Schedule of Poisonous Articles.—On the merits of the proposed addition to Scheduled Articles, the only article in it that I think there is any colour for inserting here is the last one—carbolic acid. It certainly has been the cause of numerous poisonings by misadventure, and so I think there is a call for some restriction being put on its sale—much as I object to all unnecessary legislation of a restrictive character.

Having now gone over the Bill as issued by our London Council, and having frankly stated my views on what it contains, I will now, with your permission, refer to some three things it does *not* contain, but which formed parts of the Bill in 1881. Regarding the first of these, namely, Clause 5 of that Act, as published in the Journal of June 8, of that year, I remark:—This clause was intended to prevent the widows of deceased pharmacists carrying on their husbands' business by means of a qualified assistant for a longer period than three years, except with the permission of the London Council. This clause formed the subject of much earnest debate in the Council. Mr. Sandford pled with great eloquence against the insertion of this prohibitory clause. With his permission I was allowed to move its rejection; while Mr. Sandford seconded and supported the rejection with all his known ability and earnestness. Nothwithstanding this, and the fact that Messrs. Mackay, Williams, Bottle, and others took the same view of the question, we could only command six out of nineteen votes, and consequently it stood a part of the Bill sanctioned by the Council at that time.

Now, it is not once referred to in the Bill of to-day, nor in the published discussion that took place when it was carried in the Council. The Council of to-day differs but little from that of two years ago—Messrs. Young and Borland have taken the place of Mr. Mackay and myself; Messrs. Carteighe and Walter Hills the place of Messrs. Sandford and Hills; all the others are the same. Whence, then, this change of view, or, at least, of action? Is it due to influence from without or from within? This I have no means of knowing; but this I do know, and you all may know, that at a meeting of the Executive of the Chemists and Druggists' Trade Association, held in Birmingham, on the 19th of February last, Mr. Barclay, of Birmingham, moved for its insertion in the Bill of this year. Mr. Barclay's motion was carried and remitted to "officers" of the Association and a small Committee to take such steps as they may deem desirable to carry out the wishes of the Executive in amending the Pharmacy Acts Amendment Bill of 1883. One of these officers, Mr. Hampson, occupied his place as President, and there were also present Messrs. Andrews and Churchill. There is no record in the published reports of the London Council's proceedings of any of these gentlemen standing up in it for the insertion of this clause, as they all did two years ago. Neither, on the other hand, is there any record in the report of the Trade Association meeting of their opposing Mr. Barclay's motion. I have the highest respect for the personal qualities of all these three gentlemen, and I by no means intend to hint that they took one side of the question in Bloomsbury Square and another in Birmingham. Over and over again did I find myself in the position of appearing to support, or at least of not actively opposing motions in the Council against which I had protested in Committee, but being in a hopeless minority, did not renew a profitless opposition in the Council. That, I am convinced, was the case with Messrs. Hampson, Churchill and Andrews, in one or other of the meetings. I am, however, curious to know which view had the benefit of their personal support. Do they still hold the views on the subject they held in 1881, or have they come to accept the views then so eloquently pled by Mr. Sandford and Mr. Mackay? I sincerely hope they have. I also would like to know if Mr. Schacht still holds the opinion he held then, when he moved that the widow should only have *one* year to wind-up her husband's business? Have such men as Messrs. Greenish, Woolley and Symes altered the views they then held and come to accept those of Mr. Sandford that they so strongly opposed. It would indeed be quite a feather in my cap to find a band of such men as these accepting the views on this subject I so unsuccessfully advocated in their presence so long ago. I cannot too strongly express the surprise I felt at Mr. Hampson's view on this special question, knowing well his leanings to "Women's Rights" in other fields.* On the merits of the question, I maintain that to deprive, through legislative interference, the widow of the means of carrying on her husband's business for her own behoof and that of her children, when she has them, is a piece

* It is, however, only fair to add that the grounds of the opposition to widows carrying on their husbands' business was their want of that *personal* qualification that these gentlemen hold the Act of 1868 implied, and the safety of the public demanded.

of intolerable tyranny, and which, happily, no Parliament in these days, even when backed up by all the influence which Mr. Barclay undoubtedly possesses, can for a moment be supposed capable of granting.

There were two other clauses of the Bill before the Council in 1881 which have disappeared from that of this year, namely, the first and the last enacting one. Thanks to Mr. Mackay and the opposition all over Scotland, the first—that to allow of others than residents in Scotland being appointed to the Examination Board in Edinburgh —was lost by eleven to six, being the only one out of my eleven amendments that was carried.

The last clause to which I have to refer as having been in the Bill of 1881, but which has not been repeated in that of this year, is the one that proposed to exempt Minors from serving as jurymen. The Trade Association have, however, resolved to demand its insertion. So, I think, has the Scotch Council, and if so, in face of my protesting against their doing so. I have always opposed this proposed exemption, and for two reasons:—First. I feel convinced that the application to Parliament will not only be unsuccessful, but will almost certainly lead to the deprivation of the pharmaceutical chemists themselves of the right of exemption which they now enjoy. Second. I oppose it on the merits as well. Though not professional men, we are generally very fairly educated, and enjoy a social position superior to many other classes of traders. The Government will not readily deprive themselves of some twelve thousand men so qualified for the office of jurymen as are the chemists and druggists of the nation. The wise course in the matter, I believe will be "to let sleeping dogs lie."

(*To be continued.*)

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, April 5, Dr. W. H. Perkin, F.R.S., President, in the chair.

It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society (April 19).

The following certificates were read for the first time:—H. R. Mill, J. E. Richardson, A. H. Samuel, R. Williams.

Mr. L. T. Wright then read a paper—

On the Estimation of Hydrogen Sulphide and Carbonic Anhydride in Coal-gas.—In the analysis of crude coal-gas by absorbtiometric methods, as in Bunsen's, etc., it is usual to term that portion of the gas which is absorbed by manganic peroxide, ferric oxide, etc., hydrogen sulphide, whilst that portion which is absorbed by caustic potash and not by manganic peroxide is usually designated carbonic anhydride. The author first gives some results obtained by absorption with a bullet of manganese peroxide, and with KHO solution in a Frankland and Ward apparatus; higher results were always obtained when the gases were absorbed successively, than when they were absorbed simultaneously by using a solution of KHO. This difference between the results was considerably diminished by submitting the manganese bullet to a current of clean coal-gas, before using it for absorption. The author prefers the following method:—The crude coal-gas dried and freed from ammonia by passing through phosphoric acid, is passed through two weighed U tubes; the first charged with roughly powdered cupric phosphate in one leg and calcium chloride in the other, the second containing soda lime (slightly moistened by exposure to the air for about eighteen hours) and calcium chloride. The increase of weight in the first gives the sulphuretted hydrogen, in the second the carbonic anhydride. The copper phosphate is prepared thus:—2 lbs. of ordinary phosphate of soda are dissolved in 1 gallon of water and 2½ lbs. of cupric sulphate in 1½ gallons of water. The two solutions are vigorously stirred together, the precipitate washed by decantation and dried at 100° C. Phosphate thus prepared absorbs hydrogen sulphide very perfectly. Before using the absorption tubes, 3 cubic feet of clean dry coal-gas are passed through to "saturate" the reagents. The gas during the absorption should be passed at the rate of ¼ to ½ cubic foot per hour. The total quantity must vary with the impurity in the gas. The sum of the hydrogen sulphide and carbonic anhydride thus estimated is always greater than the number obtained by absorbing these gases simultaneously in one U tube charged with soda lime. A 6 inch U tube charged with cupric phosphate will absorb 20 grains of hydrogen sulphide. A similar sized U tube charged with soda lime will absorb perfectly 18 grains of carbonic anhydride.

Dr. Armstrong suggested that some acetylen might be absorbed by the cupric phosphate.

The President asked if bisulphide of carbon vapour was absorbed by soda lime.

Mr. Wright said that he did not think that the gain of weight was due to absorption of acetylen, and in answer to the President said that bisulphide of carbon was not absorbed by ordinary soda lime from gas previously freed from hydrogen sulphide.

The Secretary then read a paper entitled—

Contribution to the Chemistry of the Cerite Metals. By B. Brauner.—In the first part of the paper the author gives an account of a most careful determination of the atomic weight of didymium. The numbers obtained by chemists differ widely from each other, from 142· to 147·39. The author finds that the so-called pure didymium can be split up into heterogeneous constituents. By an elaborate process of purification a sulphate was obtained which was proved by fractional precipitation with ammonia and with sulphate of potassium to be homogeneous. From this precipitation the atomic weight of didymium was found to be 145·4. In a previous paper the author obtained the number 146·58, while Cleve gave the atomic weight as 147·2; such discrepancies seemed to indicate the presence of some metal of higher atomic weight and of a less basic nature. This metal the author eventually succeeded in isolating; its formiate is difficultly soluble, and by its absorption spectrum it was identified with samarium. The author has calculated its atomic weight to be 150. The effect of the presence of samarium on the absorption spectrum of didymium is carefully studied. The paper concludes with an investigation as to whether cerite contains earths of the yttria group as well as those of the cerium group. By taking advantage of the solubility of the formiates of the yttria group, the author separated out a fraction with atomic weight 114·5, whose spark spectrum showed the presence of yttria, whilst holmia, thullia and erbia were recognized by their absorption bands, and the presence of terbia also was determined.

A communication entitled—

Some Compounds of Antimony and Bismuth containing two Halogens, by R. W. Atkinson, was then read by the Secretary.—Amongst the so-called double salts, one of the best characterized is that produced from antimonious chloride and potassium chloride. The author has prepared the compounds obtained by combining antimonious chloride with potassium bromide and antimonious bromide with potassium chloride. On the theory of a molecular combination the first compound should be $SbCl_3 + 3KBr$, the second $SbBr_3 + 3KCl$. In both cases the author finds that the compound $Sb_2Cl_6Br_6K_6 + 3H_2O$ is formed. The identity of the two compounds was proved by identity in colour, crystalline form, formula and chemical behaviour. The action of heat upon the crystals is of considerable interest; at 100° the lemon-yellow substance darkens, and between 200° and 300° white antimonious fumes escape, leaving a white mass behind which contains chlorine and bromine in equal atomic proportions. Attempts to prepare a similar bismuth compound were unsuccessful, but a yellow crystalline salt, $Bi_2Cl_6Br_4K_4 + 3H_2O$, was obtained.

Professor McLeod said that it would be of great interest to ascertain the composition of the antimonious fumes given off when the substance was heated.

The Society then adjourned until April 19.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of this Association, held on Tuesday the 3rd inst., the following paper, on "Pharmaceutical Politics," was read by Mr. R. W. Giles.

The discussion upon the paper was postponed until Wednesday evening next.

Pharmaceutical Politics.

BY R. W. GILES.

"The word politics," said Mr. Pickwick, "comprises in itself a difficult study of no inconsiderable magnitude."

This oracular and incontrovertible proposition reproves the temerity which would presume to condense the whole subject of pharmaceutical politics into a single evening's address; especially as time must be allowed for others to express their opinions. For politics without discussion would be about as insipid as cold veal without bacon.

I am, however, unexpectedly assisted in contracting my observations by the appearance of the new Pharmacy Bill, which has flashed meteor-like across the horizon since you did me the honour to invite me to address you, when you at the same time suggested the subject for our evening's meditations.

This happy accident droppeth upon me in the quality of mercy and like the gentle rain that is twice blessed. It justifies me in concentrating attention upon the legislative aspect of pharmaceutical politics, and cannot fail to give an interest to our proceedings which I could not hope to arouse under less stimulating circumstances.

In order to open the discussion logically I must refer at some length to the history of pharmacy; though in so doing I cannot help repeating a twice-told tale, and must run the risk of wearying you by going over again a series of events with which you are all more or less familiar. It would, however, be a mere waste of time to dwell upon the condition of pharmacy previous to the formation of the Pharmaceutical Society. Pharmacy can scarcely be said to have existed in this country before that epoch. It was in a state of chaos, without organization and without order. Not but what there were, even then, some pharmacies in which business was conducted creditably and even scientifically; but these were rare exceptions to a prevailing average of incompetence.

Let me give you an illustration from a London house of considerable repute, where my father was an assistant in the early part of the present century. The proprietor was an apothecary in large practice, at the sign of the Galen's Head, in the city. There was a good laboratory, in which pharmaceutical preparations were manufactured upon a large scale. Everything was genuine and of best quality. There was a staff of assistants, qualified as times went, directed by an old apothecary who had charge of the retail shop and dispensing department. One day, shortly after the publication of the Pharmacopœia of 1809, a high functionary of the College of Physicians came in and interrogated this ancient worthy upon the preparations of mercury, which had been newly named in the recent publication. The old gentleman was at fault, and being requested to furnish 2 grains of "hydrargyri submurias," he proceeded to weigh out 2 grains of corrosive sublimate, which had been previously known as "hydrargyrus muriatus." The doctor (very probably with a pedantic assumption of superior knowledge, which is always exasperating) pointed out the serious mistake the dispenser was making, whereupon the old man's temper boiled over and he burst out with, "Confound your new-fangled names, your submuriates and your oxymuriates, your carbonates and your subcarbonates. I wish the whole College of Physicians was in H—,"—well let us say Hades, though it is a feeble substitute for the original Saxon.

If this was the state of pharmaceutical science amongst the responsible managers of London houses of first rank, it may be imagined what was the condition of obscure shops in the provinces. Happily for the lives of King George's lieges, the medical practice of that day was more simple than it has since become; the materia medica, with which the pharmacist had to deal, comprehended no deadly alkaloids and few ambiguous salts; nor was he often called upon to supply potential remedies in concentrated forms, whereby the patient gets the maximum of doses and the dispenser the minimum of remuneration; the relations of pay and responsibility being ingeniously adjusted according to the rule of three inverse. Provided he could manipulate some innocent decoctions and infusions (they used to be made "fresh" in those unsophisticated days), and could compound a saline mixture or an almond emulsion, *secundum artem*, he was esteemed capable of performing the whole duty of man in that station of life.

It is told of a French *avocat* that he thought fit to trace the sequence of events which led up to his client's wrong from the creation of the world, and that he pursued this part of his narrative with so much prolixity that the Court, losing patience, presently interrupted him with the gentle monition—"*Eh bien! passons au deluge!*"

I am much indebted, sir, to your greater forbearance that you have not yet interrupted my antediluvian reminiscences, and I will now pass on, as rapidly as I may, to that deluge which swept away the old world of pharmacy and is gradually replacing it with the better order of things inaugurated by the Pharmaceutical Society.

But in spite of my desire to escape reproof it will first be necessary to refer to those events which remotely called the Society into existence; for it is almost an axiom that no bodies (much less one so disunited as were the chemists and druggists of that period) ever reform themselves without external pressure.

The early history of pharmacy presents a view of the chemists and druggists in a chronic (if intermittent) state of persecution at the hands of the medical profession, especially of the Society of Apothecaries, who, having unmistakably "interloped" upon the practice of medicine and surgery, and to a great extent neglected their own legitimate functions, naturally looked with the greater suspicion upon the chemists and druggists, who in their turn had shown a disposition to take up the business which the apothecaries had only half thrown up; for they were still willing to retain its privileges and emoluments.

It is only necessary to remind you of the derivation of the word "apothecary," from ἀποθήκη, a store, to show that the apothecary was originally the storekeeper for drugs, or in other words, a pharmacist. The pharmacists of to-day are therefore the veritable successors of the apothecaries of former times, who then claimed the exclusive right to the name "pharmaceutical," which they have since as completely abandoned. Thus we find that in one of the many assaults made upon the chemists and druggists by the apothecaries, viz., in the year 1794, an attempt was made to put them down by a system of what we should now call "Boycotting," for which amiable purpose an association was formed "under the title of the General *Pharmaceutical* Association of Great Britain," consisting entirely of apothecaries; and curiously enough it established itself in Bloomsbury Square. The chief object of this notable combination, as stated in its articles, was that the members "should engage to deal with such druggists only as would immediately consent to relinquish the composition of all medical prescriptions—to retain to themselves their wholesale occupation alone—and to receive no apprentice and employ no assistant who had not had a classical education." It is a pity that the composers of this liberal manifesto had not had the advantage of an *English* education, that they might have made it more clear that it was the qualified apothecary, and not the unqualified druggist, who was to insist upon the classical education of his assistants and apprentices. We cannot suppose that at this early period the apothecaries were agitated by a desire to establish a "Preliminary examination" for chemists and druggists concurrently with a determination to keep them down to the level of traders.

It is sufficiently clear, from the above quotation, that at this time the business of the apothecary and that of the chemist and druggist bore the same relations to each other in this country as still exist in many Continental states between the profession of pharmacy and the trade of the Drogueries or Drogherrias; and I am much mistaken if that distribution of business is not tending to re-establish itself. I think pharmacy will again sever itself from drysaltery, which will either be carried on in a new order of shops, or, more probably, will be divided between the grocers and the oilmen, who are quite competent to perform it. "Men do not cut blocks with razors," by which I mean that you do not want a scientifically trained man to sell common drugs and chemicals required for rough domestic or technical uses. There is, to my thinking, an incompatibility between the two functions which have hitherto been united in the person of the chemist and druggist, in consequence of which both have suffered. I feel sure that a separation will prove advantageous to pharmacy, and that it will (by affording more suitable conditions) give an impetus to pharmaceutical research which the old system tended to stifle. I also believe that this new development will be hastened by the operation of the proposed Pharmacy Bill, if it should become law, as I sincerely trust it may.

So long as the attacks upon the chemists and druggists were confined to the medical profession, the former were always able to resist legislative interference with their trade. Parliament seems to have penetrated the motives by which these attacks were instigated, and would not lend itself to the efforts of the apothecaries to secure for themselves a monopoly which would have operated as a tax upon the public without equivalent advantage. From this we may learn (and it is of the utmost importance that we should learn, from whatever source the teaching may come) that it would be absolutely useless to apply to Parliament for anything savouring of monopoly in these later days of more enlightened political economy.

All the Bills affecting chemists and druggists which had been submitted to Parliament previous to 1815 were prompted by this spirit, and had one common character—they proposed to place the druggists at the mercy of a medical control, in which they themselves would have no voice. It was usually provided that the druggists should be examined by a Medical Board of Examiners, from whom they must obtain licences before they would be permitted to go into business; but no provisions were made for pharmaceutical education. It was the old story of making bricks without straw,—the cause of the first workman's strike upon record and the type of a good many that have happened since, in which obstinate journeymen have set their faces against economic improvements. The druggists were as obstinate as their neighbours, and had better reason. In fact, the incorporated medical bodies (and the Society of Apothecaries most of all) wanted to "domineer" over the unincorporated chemists and druggists; but they attempted this selfishly, without showing a corresponding desire to accomplish a public benefit, and consequently all their attempts fell through.

The Apothecaries Act, 1815, was the last of the measures of this epoch. It deserves some notice here because it is the Act upon which apothecaries, and other medical practitioners also, have relied as prohibiting what is known as "counter prescribing." It was a stringent measure, in the form in which it was presented to Parliament, and aroused the strenuous opposition of the druggists, who succeeded in obtaining the withdrawal of all the obnoxious clauses aimed at themselves, and secured the insertion of a clause which expressly exempted their trade from its operation. That clause is as follows, viz:—

"Provided always, and be it further enacted, that nothing in this Act contained shall extend, or be construed to extend, to prejudice or in any way affect the trade and business of a chemist and druggist; but all persons using or exercising the said trade, or who shall or may hereafter exercise the same, shall and may use, exercise, and carry on the same trade in such manner and as fully and amply to all intents and purposes as they might have done in case this Act had not been made."

It is difficult to believe that even a lawyer would attempt to put an Act thus limited in force against the trade of a chemist and druggist. It has been attempted nevertheless, though the attempt failed, and the capacity of the English language to express what it intended was upheld. But so marvellous is the possibility of legal ambiguity that an eminent judge lately deceased has said that if a competent lawyer were to contend before him that black was white, he should feel it necessary to suspend his judgment until he had listened to the argument.

"Counter prescribing" is a delicate and difficult question of pharmaceutical politics, and I could not therefore omit to refer to it; but do not suppose that I am an advocate for the abuse of the practice. It is a practice which every good pharmacist desires to keep within reasonable bounds—only to be defined by public convenience. None but idiots (of whom I have met many) desire or expect to suppress it altogether. I go just so far as, and no farther than, the Committee of the General Medical Council appointed in 1865 to inquire into and report upon the two Pharmacy Bills which were before Parliament in that year. Their report contains the following passage, viz.:—

"It is well known that many existing chemists and druggists, both members of the Pharmaceutical Society and others, practise medicine, although unqualified by law and not competent by education. To a limited extent this practice may be inevitable, and at all events cannot be prevented. But the existence of it gives peculiar facilities and temptations to the pharmaceutic chemist to embark largely in irregular medical practice as an unqualified practitioner."

It is thus officially admitted on the authority of the Medical Council, that counter prescribing "to a limited extent is inevitable and cannot be prevented." I may say that the person least able to prevent it is the "pharmaceutic chemist," who has to choose between obliging and offending his customer, and who would generally find his own pecuniary interests better served by referring his "inevitable" patient to the nearest doctor, if he dared to do so. The only practical question is, therefore, how can the "inevitable" be kept within such reasonable limits as not to interfere with the public convenience on the one hand and not to imperil the public safety on the other. I utterly refuse to recognize the interests of the medical profession in the matter. Neither they nor pharmacists have a vested interest in the diseases and sufferings of their fellow-creatures, who have the most unimpeachable right to cure themselves by any means accessible to them. Let there be no nonsense about that. I say confidently that improved pharmaceutical education is the only agency by which "counter prescribing" can be kept within legitimate bounds. Education teaches us to know certain things. That is its first aim, but it is not its sole effect; it also generates a logical mind, which enables us to distinguish between that which we know and that which we do *not* know. A mind thus trained will fight very shy of meddling with obscure symptoms which it *knows* that it has not the power to interpret. It will make a prudent application of the proverb "Omne ignotum pro mirabili," and will not make speculative shots at disease in the dark. On the other hand the illogical man, who sees no danger, because his eyes are shut though he knows it not, concludes there is none, like the much libelled ostrich, and proceeds with the confidence of ignorance to treat the premonitory symptoms of paralysis as a bilious headache. For still—

"Fools rush in where angels fear to tread."

Pharmaceutical education operates in yet another way. By the dignity it gives to his calling and the pride it inspires in the pursuit of that calling, it offers a worthy goal for the pharmacist's ambition, and creates a perfect horror of empiricism. Is it not well known that high pharmacy and counter prescribing are the opposite poles of the pharmaceutical microcosm?

It was not in the nature of things that the anomalous condition of pharmacy, at the period of which I am speaking, should be regarded with approval in other quarters, outside the medical profession. Its Bashi-Bazouk irregularity was too flagrant to escape the notice and censure of less interested reformers, although no overt proceedings were taken until the year 1839. It should, however, be recorded to the honour of the late Mr. John Savory, that he endeavoured to induce the chemists and druggists of London to co-operate with him in promoting a Pharmacy Bill in the interests of the trade in the year 1830. But it was too early then to enlist hearty support or to rouse a real belief in the practicability of such a novel proposition. The druggists were not yet prepared to assert that they too were men and brothers, or to look for anything better than to be left to live and die in peace. Mr. Savory met with so much apathy and incredulity that he found it hopeless to persevere, and he reluctantly abandoned his enterprise, which, however, deserves to be held in honour, not the less because it failed, as every first attempt in similarly new ground is likely to do. It was the first enunciation of the principle that chemists and druggists were entitled to be legislated for, instead of to be legislated against; and it cannot be doubted that it was one of those useful failures that lay the foundation for future success.

The Medical Reform Movement, which began in 1839 in a parliamentary inquiry, came to no immediate result, but it continued to simmer until it took shape, in 1841, in the obnoxious Medical Bill, brought in by Mr. Hawes, which literally bristled with penalties and bid fair, should it become law, to improve the chemists and druggists off the face of the earth. I can well remember the announcement of this measure and the consternation which it spread amongst the trade throughout the country. It would have compelled the druggists to obtain a licence to carry on their business from a body practically constituted by the votes of the medical profession, amongst whom their old enemies, the apothecaries, would have been dominant by reason of their numerical majority. The Bill, in fact, attempted too much and was too arbitrary. It has been wisely said that "strength is strong, but weakness is stronger," and this attempt to crush the weak proved the wisdom of the saying. Vigorous action was taken by the chemists and druggists in London, to whom the provinces have often been more indebted than they are always ready to acknowledge. A committee was formed to watch and to oppose the progress of the Bill in Parliament, consisting of the following members, whose honoured names I ask your permission to read, viz.:—William Allen, F.R.S., Robert Alsop, Jacob Bell, Richard Battley, John T. Barry, Charles Barron, Thomas Butler, Edwin Briggs, George Baxter, Charles Dinneford, Charles Davy, Samuel De Castro, John Ellis, Robert Farmer, Samuel Foulger, Joseph Gifford, Samuel Green, Thrower Herring, Thomas Herring, Edward Horner, W. B. Hudson, William Ince, Thomas Keating, William Lowe, J. S. Lescher, T. N. R. Morson, Samuel M. Mayhew, Richard Hotham Pigeon, Matthew Pound, John Savory, Peter Squire, George W. Smith, Joseph Smith, Edwin Simkin, Ralph Stamper, John Toller, George Waugh, Edward Winstanley, Thomas Walker.

This was not the first occasion by many that the disintegral atoms of which the drug interest was made up had been brought together to make common cause against hostile attacks; but this particular occasion was characterized by special features producing important consequences, without which it is probable that we should not be here to-night discussing pharmaceutical politics, for there might, in all probability, have been no such thing as pharmaceutical politics to discuss. The speciality of this defensive combination will be best told in the words of the resolutions passed by the Committee and adopted by a general meeting of the trade held on April 15, 1841, viz.:—

"That a Society be forthwith formed under the title of 'THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.'

"That the object of the Society be to benefit the public, and elevate the profession of pharmacy, by furnishing the means of proper instruction; to protect the collective and individual interests and privileges of all its members in the event of any hostile attack in Parliament or otherwise; to establish a club for the relief of decayed or distressed members."

The Report of the Committee presented upon this occasion concluded with the following memorable declaration of independence, which must have appeared little less than revolutionary to the mass of those to whom it was addressed, and evidently required no small exercise of courage on the part of those who made it, to wit:—

"Your Committee, having considered the subject, are of opinion that the chemists and druggists are capable of self-government."

I like that interpolation, "having considered the subject." What a picture it presents of the hesitation and mistrust to be overcome before the Committee could screw their courage to the sticking point and venture to call their souls their own!

At this meeting, viz.: on the 15th of April, 1841, the Pharmaceutical Society was formally constituted by the enrolment of a hundred members on the spot. Let the 15th of April be for ever marked with a white stone in the calendar of all good pharmacists.

I shall ask you to pause at this first epoch of inauguration and to consider how sagaciously comprehensive was the programme of the young Society, including the three great purposes of Education, Protection, and Benevolence, to be from thenceforth the Faith, Hope and Charity of the pharmaceutical creed; but the greatest of these is Education. It was this which gave vitality to an ephemeral association called suddenly into being by fear and self-interest, to be as quickly dissolved when the immediate crisis was past if it had not consecrated itself to public usefulness by a wise, elevated, and far-seeing policy. I shall also ask you to observe how steadfastly the Society, as it grew in years and in organization, has held to the principles thus early propounded; amplifying, perfecting and extending, but adding nothing thereto and diminishing nothing therefrom. I shall ask you to give your loyal support to the institution which has done so much on these broad lines and has deserved so well,—to resist the temptation to small criticism (the weakness of little minds), and to the still more detestable spirit of schism (which is as the sin of witchcraft), to do that which in you lies to strengthen and still further to extend its influence and the scope of its operations, and this not solely upon sentimental grounds, in grateful remembrance of how much its disinterested founders have done for you and for the vocation which I hope you love, and of whose coming estimation in the eyes of men I trust you will have reason to be proud,—how much greater reason if you yourselves contribute, as I doubt not you will, to that estimation—I say not solely upon these grounds, though I should do injustice to your generous sympathies if I doubted your willing acknowledgment of these strong claims, but also upon practical, I might almost say upon selfish, grounds, namely, that the Society is the only corporation which is empowered, or is ever likely to be empowered, to regulate the education and qualification of pharmacists, or in other words to uphold and, as we hope, to exalt the standard and dignity of pharmacy. The Society may, it is true, fall short of its obligations; it may become apathetic or even obstructive; it may become selfish and forget its high duties as the guardian of scientific pharmacy and the trustee of the public welfare in connection therewith; it may take a low view of its responsibilities and grasp vainly at some illicit advantages which are not consistent with these higher aims; and by so doing you may say that it has forfeited your allegiance. But remember, if it does these things it will be the fault of its members, or of those who should be members but are not. The Society *is* what its founders and many worthy successors *have* made it, it *will be* what you and those who follow you *shall* make it. Take heed, therefore, that you neither negligently, disloyally nor wilfully detract from the high character which has been impressed upon it by other hands than yours; for of this be sure that if the Society fails there is none other power to which English pharmacy can look for rescue. Above all things see that you do not entrust its government to unworthy hands.

The Society being now launched, the work of organization proceeded briskly. A school of pharmacy was established, comprising a laboratory for instruction in practical chemistry, which it may astonish many of you to hear was the first of the kind opened in this country; also a library and museum, with the extensive resources of which you are doubtless familiar. Lectures were instituted for which the services of eminent professors were secured—I need only mention the name of Dr. Jonathan Pereira—and finally examinations were arranged as a means of admission to the Society for all engaged in the pursuit of pharmacy who chose to submit themselves to the ordeal.

But the Society was now, and remained for many years, a merely voluntary Association, and had nothing to offer to those who satisfied the examiners beyond a bare certificate of membership, which conferred no more substantial privileges. Those who sought pharmaceutical education for its own sake accepted the opportunities offered with alacrity, and thought themselves amply rewarded; but those who hankered after more solid pudding, according to their notions of substance and shadow, flattered themselves that they were not to be caught with that hollow sort of chaff. Obviously such an organization as this was not competent to effect any marked or immediate improvement in the general aspect of pharmacy. It is not true that all mankind, or even the majority, are possessed of an insatiable thirst for knowledge. And, alas! pharmacists are but men.

It is rather to be wondered at that the Society effected so much within its narrow powers, than that it did so little. By means of evening meetings held in Bloomsbury Square for scientific papers and discussion, by the publication of the *Pharmaceutical Journal* and by some other less conspicuous agencies, the influence of the Society began to be disseminated, and a considerable awakening in practical pharmacy, to be followed in due course by signs of more scientific activity, became apparent. The example of London spread to the provinces, where local associations with similar objects sprang into existence, and attention began to be directed to the scientific aspect of the vocation which had hitherto been followed according to the good old rule of thumb.

In this way the Pharmaceutical Society made itself known and respected not only by its own members, but by members of the medical profession, whose good opinion it was and is most desirable to conciliate. They were in those days frequent attendants at the evening meetings in Bloomsbury Square, and often took part in the discussions. Of late years they have been conspicuously absent, which is to be regretted. It was a pleasing incident of the last evening meeting, and strongly suggestive of the good old times, to meet a medical gentleman there who contributed valuable remarks to the discussion of a subject which lay between pharmacy and therapeutics.

The Society became also favourably known to the Government, and slowly but surely laid the foundation for that influence which it has since exercised with good effect upon various legislative measures, which would otherwise have passed through Parliament in a form not only objectionable to chemists and druggists, but also prejudicial to the interests of the public. Even so early as 1841, that is, in the first year of the Society's existence, the Home Secretary consented to recognize it as the representative of the trade, and undertook that no legislation upon medical reform should be proceeded with without notice to the President. This was an important point gained, and contrasts strongly with the unrecognized position held by the unassociated chemists and druggists of former times. Thus within the short space of a few months had this purely voluntary, and as yet unlicensed, Association come to be a political power.

As soon as the Society felt itself fairly established and could point to good work in full operation, it made the first move towards consolidating its position by applying for a Royal Charter of Incorporation. This explosive strategic movement was appropriately executed on November 5, 1842, by petition to the Queen, which was "graciously" received, and the *ci devant* private association became a chartered corporation with perpetual succession, common seal, right of suit and such like incidents of a Royal grant, on February 18, 1843.

The Royal Charter forms the second important epoch in the progress of the Society. But the powers of a Royal Charter in these days of constitutional Government are, properly, very limited; and the Charter neither did nor could confer upon the Society any authority over persons outside its own list of members. It left it, as it found it, a purely voluntary Association; and none knew better than the leaders of the Society, who had petitioned for the Charter, that larger powers were needed, which only an Act of Parliament could give, to enable them to carry out their views for the regeneration of pharmacy. They knew this—they knew also that "everything comes to the man who waits." Accordingly they took for their text the familiar motto of the Onslows, "Festina lente," which has been happily translated into the vernacular as "Go it, ye cripples." And they waited and watched.

As the years rolled on the necessity for further powers grew more apparent and seemed to come more within the range of practical politics; but the long incubated Medical Bill stopped the way and gave time to trim the Pharmacy Bill into shape before it was eventually presented to Parliament in 1851. Let me take advantage of the lull during these eight years to introduce a personal recollection of another great Charter, which was mixed up with the School of Pharmacy in a manner deserving a place in the page of history.

In the session 1847–8 my connection with the School of Pharmacy commenced. The year 1848 was politically remarkable. A democratic wave swept over the Continent, tumbling thrones in the dust, and driving their royal occupants across the Channel in menial disguise, exposed to the perils of the sea in open boats, to seek refuge in the greater stability which England owes to her free institutions. But even here there was a faint reverberation of the convulsion that was shaking Europe to its foundations. April 10, 1848, was fixed for the great Chartist demonstration to perambulate the streets of London in force from Kennington Common to St. Stephens, there to carry the great Charter to the very doors of Parliament with throng and tumult, in flagrant defiance of the statute in that case made and provided. But the boys of Bloomsbury Square were equal to the occasion. They rose up as one man; were sworn in at St. Giles' Church, and with the staves of special constables in their hands and loyalty in their hearts mustered under the leadership of their professor, who gallantly headed them under his umbrella! for the day was drizzly, and severely tried though it could not damp the ardour of the specials. And now you know by what means London was saved and the constitution preserved from outrage. The public buildings were garrisoned with troops; the Bank was fortified with a breastwork of sand bags, loop-holed for musketry. But these precautions were needless, the perils and the honours of the day were with the "specials," to whom the School at Bloomsbury furnished its heroic contingent, as the treasured relic now lying upon the table (being the staff that I carried on that memorable day) will testify.

In the years 1848–50, the Society was busy in maturing its first Pharmacy Bill; but the Council were met at the outset with a serious obstacle. It was impossible to find a member of Parliament with sufficient knowledge of pharmacy, of its wants, its claims and its peculiar relation to the medical corporations and to the public, to whom the conduct of the Bill through Parliament could be prudently entrusted. It was obvious that an efficient advocate must possess a competent knowledge of "Pharmaceutical Politics," and where amongst the representatives of the nation was such an advocate to be found? This was a perplexing question, to which no ready answer was forthcoming.

On the other hand there was one circumstance that greatly favoured the Society's movements. The Sale of Arsenic Act had been brought before Parliament in 1850. The Pharmaceutical Society, by means of their organization, had collected valuable statistics relating to the trade in arsenic, though it was the Provincial Medical Association who had first raised the question and who now brought it under the consideration of the Government. The Government took charge of the Bill and brought it in as a Government measure, and in the course of the inquiry, the chaotic state of pharmacy came so prominently under notice of Parliament as to encourage the hope that the evils might be remedied by speedy legislation. Thus early did the sale of poisons mix itself up with the question of pharmaceutical legislation.

Finding that there was no chance of securing the assistance of a member of Parliament whom the Society could trust to pilot the Bill through the House, Mr. Jacob Bell took the bull by the horns and determined to look for a vacant seat since the full ones would not help him. Accordingly he became a candidate for the representation of St. Albans, for which town he was elected member after a severe contest. It is amusing to hear that he had decided upon offering himself as a candidate before he had made up his mind to which political party he belonged; but as it was necessary that he should espouse the principles of one or the other, he was not long in coming to the conclusion to appeal to the constituency as a Liberal, which in the best sense of the word he certainly was. Liberality went a long way in St. Albans, and Mr. Bell was returned.

And now I can no longer postpone an obligation from which I have hitherto shrunk from conscious inability to deal with it creditably. I have not, until now, mentioned the name of Jacob Bell in connection with the formation and direction of the Pharmaceutical Society. Yet it is well known that Jacob Bell was the moving spirit in it all; and his name, his work and his memory have been present to my mind with every line that I have penned. Mr. Bell had able and influential colleagues, who did good service and whose services are held in grateful remembrance, as they deserve to be. They did all and more than all that patriotism could reasonably claim from them. But Jacob Bell was more than this. He gave, without stint, his time, his talents, his means, and, alas, he finally sacrificed his life to the object with which the best years of his life had been identified. If you read the first part of the 'Progress of Pharmacy' written by his hand—and everyone who wishes to understand pharmaceutical politics should read the whole of it—you will see that no name is less prominent in the early proceedings of the Society than that of Jacob Bell. This is not solely due to the modesty of one who writes of events in which himself played the leading part, for you will find that he as studiously kept himself in the background while those events were passing. You will never read of Mr. Bell as the chairman of a meeting; it is always someone else, whose co-operation he desired to secure. I think you will never meet with his name as the mover or seconder of a resolution. He was careful that the distinction attending these little ceremonies should fall upon the shoulders of others. This was not affectation; it was downright, genuine unostentatiousness. Jacob Bell was the most unselfish man I ever knew, and I am proud to say I knew him well. Yet whenever there was real sustained hard work to be done,—no mere flash in the pan,—and from which no κύδος was to be expected, it was Jacob Bell who did it. It was he who toured the provinces, holding meetings, making himself all things to all men if only he could thereby stir up their sympathies to co-operate in the great work upon which he had set his heart, though he had no selfish benefit to reap. It was he who projected the *Pharmaceutical Journal* and edited and published it at his own risk for twenty years, finally handing it over, a valuable property, to the Society to which he bequeathed the copyright. The Journal, perhaps, did more at this time to extend the reputation and influence of the Society in the provinces than all other agencies put together, and it still continues to be its most valuable organ and auxilliary; for this we are indebted to the enterprise and generosity of Mr. Bell. I do not attempt to eulogize him. I feel how inadequate any words of mine must be to do justice to his worth, his ability, his liberality, and to his complete devotion to the cause of pharmacy. I also feel that such words, could they be spoken, are entirely unnecessary; for wherever English pharmacy is known, there the services of Jacob Bell are remembered, and his memory is revered. He has long ceased to be with us, alas! and there have been times when the want of his influence has been grievously felt. "But though dead he yet speaketh," and the echo of that silent speech may be felt by all who will put aside suggestions of self-interest and open their hearts to a broad conception of the duty that lies before them—the duty of loyalty to a worthy cause.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 29, Mr. R. H. Parker, Vice-President, in the chair.

A paper was read by Mr. J. B. Barnes, on "Vortmann's Method for the Separation of Chlorides, Bromides and Iodides," which will be published in a future number of this Journal.

In the discussion that followed the Chairman, Secretary, and Messrs. Crow, Dymond and Elworthy took part.

A vote of thanks was accorded to Mr. Barnes.

The Reporter on Botany, Mr. J. O. Braithwaite, then made a report on "Plant Movement."

A discussion followed in which the Chairman, Secretary, Messrs. Crow, Elworthy, Rankern, Ransom, Reynolds and Taylor took part.

Parliamentary and Law Proceedings.

Alleged Death through a Cough Mixture.

An inquest was opened at Brighton on Wednesday, March 28, touching the death of Arthur Long, aged eighteen months. The mother stated that on Sunday evening she obtained some cough mixture for the child from Mr. Goyne Stevens, chemist, in North Street, and the dose as stated on the label was a teaspoonful three times a day. She gave the child one dose at half-past seven and another at twelve o'clock. In the morning upon going to the child's bed she found it was dead. She used an ordinary teaspoon.

Dr. Ross, who had been called in, said he had made a *post-mortem* examination of the body and he was of opinion that the child died from an overdose of morphia.

Mr. William Goyne Stevens, chemist, 53, North Street, said the mixture had not been dispensed by him and he was much surprised to learn that it had been supplied, since he always declined to give medicine of the kind to children. It was a mixture kept for coughs in the case of adults. According to the manner in which the assistant had told him he prepared what was given to the child's mother there would be one 120th part of a grain of morphia in each measured teaspoonful. Looking at the bottle he found that there were four doses gone, instead of two. The spoon produced was not a teaspoon, but it would hold double the ordinary dose; the old silver teaspoon was the type of what the measure should have been. The mixture had been supplied against his general instructions not to give morphia or any dangerous drug to children. There would only be one-eighth of a grain of morphia in the whole bottleful.

The inquest was adjourned to allow of an analysis being made of the remainder of the medicine in the bottle.—*From the Sussex Daily News.*

Correspondence.

"Quackery Rampant."

Sir,—Under the above heading, your contemporary, the *Lancet*, in the spirit of justice and fair play it usually adopts when speaking of chemists, says in its "Annotations," March 17, at page 463, after a diatribe against quackery and quack medicines, that "The real cause of this evil is the counter practice of the druggists." The *Lancet* then goes on to demonstrate the ignorance of the druggist, and suggests that the public, especially the poorer classes, should be educated so as to be able to discover this ignorance, by which they are misled and induced month after month to squander money and waste precious time in the futile attempt to get cured of their disorders. On the face of this, one would be tempted to think that perfection, or at any rate something like it, would at least be found among the class of men represented by the *Lancet*, yet what do we find?

Turning again to the same number, on page 461, we find a leader on the "Testing of Urine," called forth by some demonstrations given by Drs. Pavey and Oliver, and following a mass of correspondence on the same subject in its own pages. In this article the writer says, "It is a platitude to insist on the importance of this branch of clinical investigation, and yet we do not exaggerate when we say that no part is more generally neglected or more perfunctorily made." It would seem, therefore, that the charge of "knowledge defective as regards disease" is not always confined to the druggist, but, diagnosis being at fault, may exist also in the medical man.

Again, one would suppose, after so severe a denunciation of "quack medicines," that the *Lancet* itself would be above reproach. But what do we find? Still in the same number, on page 458, under "Analytical Records," a list of secret preparations, with the names and addresses of the makers attached, the composition of some of which is, according to the *Lancet's* own admission, known only by advertisement, and yet that Journal does not hesitate to recommend them. If this is not advertising advertised secret—which can be only another name for quack—medicines, may I ask what is? Can there be any moral difference between a patient taking a remedy prescribed by a chemist who knows at least something about it, and the same patient taking a remedy prescribed by a medical man who knows nothing about it, except that it is advertised in the columns of the *Lancet*?

South Norwood, S.E. J. H. Baldock.

The Constituents of Cacao Oil.

Sir,—I have had under my notice a letter from Mr. Kingzett respecting an investigation of cacao oil carried out by me, which induces me to make the following reply.

Mr. Kingzett, without making himself acquainted with the contents of my original communication, notwithstanding that the necessary reference was given in the abstract in question, has cast doubt upon the correctness of the facts experimentally demonstrated by me. I therefore dispute the right of Mr. Kingzett to exercise criticism upon the basis of a report in which only the results of my investigation are given, since he is ignorant of the grounds upon which I formed my opinion that the arachic acid which he declared to be a mixture was a single body.

I maintain against Mr. Kingzett and against any other opponent the accuracy in every respect of all the results obtained by me in my investigation of the subject of cacao oil, and at the same time I here state that I would give further consideration only to criticism supported by facts.

Mr. Kingzett's offered acid I decline, since I could not be influenced by the analysis of a body, as to the origin of which I had not personally satisfied myself.

Whilst, in conclusion, I assure Mr. Kingzett that I do not require instruction from him upon the criteria of an individual body and a mixture, I would refer him in any case upon the subject he is interested in to my original communication (*Archiv der Pharmacie*, 1883, p. 19).

M. C. Traub.

Bern, Laboratory of Professor Percenoud.

W. J. W.—(1) The test is worthless. (2) Gynogardic acid is an acid first separated from chaulmoogra oil by Moss. See *Pharm. Journ.*, [3], x., 251.

Inquirer (who should have sent his name and address) is recommended to consult his legal adviser as to the possibility of evading the provisions of the Pharmacy Act.

G. S. Boutall.—We do not think any useful purpose will be served by giving to the handbill in question further publicity by reproducing it in these columns.

G. Agar.—We are unable to insert requests for assistance in imitating specified proprietary preparations.

J. W. L.—See a note by Dr. Symes in last week's Journal, p. 819; also Dr. Thresh's communication in vol x. (1879), pp. 193 and 260.
