THERMO-MICROSCOPY IN PHARMACY.

BY W. H. SYMONS, F.R.M.S., F.C.S.

The effects of heat upon a body are often some of the most important data in the examination of that body; this is especially so in the case of organic compounds. To propose a method of studying a few of these effects is the object of the present paper.

Some months ago, I exhibited at the Royal Microscopical Society "a hot or cold stage for the microscope," and was subsequently asked to bring it further under the notice of the Fellows of that Society at one of their evening meetings.

This was done on December 14, of last year; the paper, with an illustration, was given in the Journal published in February of this year. The apparatus has since received the approval of eminent scientific men, and possibly some of its applications in pharmacy may not be uninteresting to the readers of this Journal.

The stage first described was intended for comparatively low temperatures, being furnished with a special form of thermometer graduated to 150° C.; it was, moreover, somewhat expensive and liable to get out of order. The form here figured can be obtained for a nominal sum, is capable of being used with an ordinary thermometer, and is available for all temperatures within the range of that instrument.

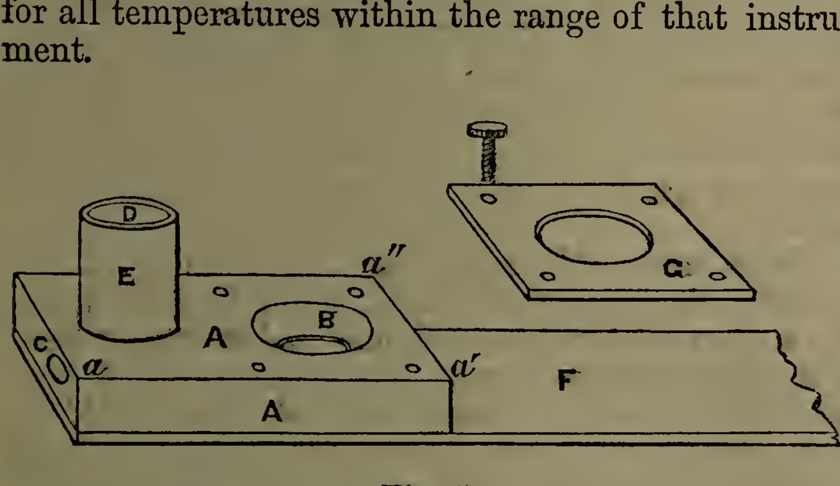

Fig. 1.

It is made principally of one piece of copper, A, and measures from a to a' 6 cm., from a' to a'' 4 cm., and is 2 cm. thick. A hole, B, 2·5 cm. in diameter, passes right through it, but is closed on both sides by thin glass or mica held between thin rings of cork by means of plates, as G, which are screwed down sufficiently tight to prevent leakage. A slightly tapering hole, C, is drilled lengthways, on one side, through the copper; it meets and extends a little beyond the hole, B, and is sufficiently large to take a cork carrying a thermomete.r The tube, E, is in one piece with the rest, and its bore, D, meets the canal, C. A piece of copper, F, some 3 mm. thick, extends about 15 cm. beyond one end, and should be brazed on to the body before the hole, B, is drilled. The whole arrangement may advantageously be plated with platinum, silver, or nickel, care being taken to insure the complete coating of the inner surfaces. The part placed on the stage of the microscope is mounted on some non-conducting body, such as a piece of well-seasoned mahogany. An aperture corresponding with B is of course left.

The thin glasses or mica having been firmly packed in their places, and the thermometer put in position, taking care that it does not come into contact with any portion of the metal, perfumed oil is carefully poured into the open aperture, D, until, when in a horizontal position, it completely fills the space B; the whole arrangement is then placed on the stage of a microscope, so that B shall correspond with its optic axis. The object to be examined is placed on the upper thin glass.

Melting Points.—For example, suppose we wish to take the melting point of wax. A small piece of that substance, about the size of a pin's head, is so placed, covered with a piece of thin glass and surrounded by a cardboard shade (a bottomless pill box answers well) to protect from currents of cold air; heat is now applied to the projecting copper plate until the wax melts; the temperature being observed, the source of heat is removed, and, when the wax has congealed, the crystals in it are focussed. Heat is again cautiously applied so that when the temperature approaches that at which the wax was observed to melt it shall rise very slowly, the crystals at the same time are carefully watched; the moment they disappear the temperature is noted and is considered "the melting point." The heat being removed, the field is watched for the reappearance of the crystals; as a rule this occurs very near the same temperature as their disappearance, cacao butter being a notable exception to this.

The following are some results by this method:—

Beeswax	61° C.
White wax, genuine	61° C.
White wax, commercial	51° to 55° C.
Paraffin wax, of low melting point	50° C.
Spermaceti	43° C.

Attention is particularly directed to the samples of white wax. Several lots were examined with fairly constant results, and, therefore, the above are not to be considered exceptional; they undoubtedly contain paraffin or spermaceti. The almost constant presence of an adulterant, of low melting point, in commercial white wax, may, to some extent, account for the difficulty experienced in obtaining spermaceti ointment of suitable consistence if made according to the official formula. The adulterators might at all events use a paraffin wax of suitable melting point, if indeed they cannot supply a pure article.

This mode of taking the melting point possesses in the case of fats no advantage over that usually followed; it is merely noticed in passing. In the case of resins and alkaloids, to be spoken of hereafter, it is, however, exceedingly useful.

Starches.—The tumefaction of granules of starch may be observed in much the same way. The starch is rubbed down with water, and a drop of the mixture placed on the stage and covered with a thin glass and shade as in the case of wax; the bursting of individual granules can then be observed, taking care that the temperature rises very slowly.

The following are some results by this process:—

Starch.	A few swollen.	Majority swollen.	All swollen.
Tous-les-mois	65° C.	68° C.	74° C.
Potato	55° C.	60° C.	65° C.
Sago	64° C.	68° C.	74° C.
Maranta, var. Bermuda .	62° C.	69° C.	73° C.
Maranta, var. Natal . .	58° C.	65° C.	70° C.
Maranta, var. St. Vincent	66° C.	73° C.	77° C.
Wheat	60° C.	65° C.	70° C.
Maize	65° C.	70° C.	77° C.
Cassava	58° C.	63° C.	68° C.
Oat	65° C.	70° C.	77° C.
Rice	70° C.	75° C.	80° C.

As a control to the above method the respective starches were mixed with ten times their weight of water and the mixtures placed in thin test tubes, of equal size, in a double water-bath, and gradually heated; the water in the inner bath was at no time allowed to exceed the temperature of the mixtures by more than 2° C., and the water in the outer bath not more than 5° C. Every few degrees the mixtures were stirred with a thermometer and (having been kept at a constant temperature for one minute) a drop removed and examined under the microscope. Approximately the same results were obtained.

From this list it will be seen that potato starch is very readily affected by heat; in point of fact, its granules are freely acted upon when action has scarcely begun in those of the others. Bakers seem to be aware of this, and hence use mashed potatoes to make their ferment, and they say wheaten flour would not answer alone. The more tumefied potato starch is more susceptible to the yeast than the less tumefied wheat starch.

The next point to be noticed is that although starches as a rule seem to vary but slightly in their behaviour to hot water, the three principal varieties of Maranta show marked differences. At first it was thought this might be accidental to the special specimens under examination, so samples from various museums, wholesale houses and private sources were treated in the same manner with almost constant results.* Subsequently, my attention was directed to a paper, by that veteran pharmaceutical microscopist, Mr. Greenish, published in the 'Year-Book of Pharmacy' for 1875, page 534, in which comparatively the same results were chronicled. The samples of starches which I examined, obtained from such various sources, were probably representative of the crops of different years, and, this added to the fact that my results were approximately the same as those obtained by Mr. Greenish seven years previously, doubtless also from many samples representing different years' growth, seems to show that this difference in the tumefying points of these varieties of Maranta arrowroot is a constant characteristic.

It is quite possible the cause may be found in the temperature under which the plants bearing them are grown. The higher that temperature, the higher the point of tumefaction. A glance at the following table will suffice to support this view:—

District.	Latitude.	Longitude.	Rain fall per annum	Temperature. Max.	Min.	Mean.	Tumefying points
Natal	30°·40′ S.	29°·55′ E.		27° C.	13° C.	20° C.	70° C.
Bermuda ..	32°·20′ N.	64°·50′ W.		30° ,,	10° ,,	22° ,,	73° ,,
St. Vincent.	13°·15′ N.	61°·15′ W.	76ins	31° ,,	21° ,,	26° ,,	77° ,,
British Guiana	4°·40′ N.	59° W.	74ins	33° ,,	24° ,,	28 ,,	78° ,,

Furthermore, potato starch, from plants grown in England, where the mean temperature is under 9° C., tumefies at 65°. Tous-les-mois (which has larger granules, and, therefore, other circumstances being equal, might be expected to be more easily tumefiable), grown at St. Kitts, lat. 17° 22′ N., long. 62° 48′ W., mean temperature about 24° C., tumefies at 74° C. Maize starch may likewise be compared with wheat in the same way. But cassava and oat starch are exceptions; these, however, occur as compound granules, whereas all those previously mentioned are simple.

It is proposed to grow potatoes, and other starch-bearing plants, under various conditions of temperature and to ascertain from their examination the results.

Following the example of Lippman and Greenish, the temperature is noted at three distinct stages of tumefaction, viz., when the first few granules swell, when the majority have swollen, and when all have done so. This latter point is synonymous with the formation of a jelly, if the granules are present in sufficient quantity, and is alone given in the above table.

To ascertain if by a prolonged exposure to a lower temperature the same results could be obtained as by a short exposure to a slightly higher temperature, a sample of potato starch was taken (this had been previously found to reach the first stage at 55° C.; the second at 60°; the third at 65°), mixed with ten times its weight of water, placed in a thin test-tube with a thermometer as a stirrer, in a double water-bath; the inner, which consisted of an earthenware vessel, being furnished with a thermometer; the outer, with a simple form of thermostat, so arranged as to keep the inner bath at 60° C.

As I am not aware that so simple an arrangement has yet been published, a description of the Thermostat may not be out of place. It is a modification of Kemp's regulator, and is thus made:—

Two test tubes are selected, one of which is capable of sliding loosely inside the other: the smaller one is heated near its centre and slightly drawn out; it is then severed at the contracted part, the upper half being thrown away, the rough edges

* Except in the case of commercial Bermuda arrowroots, some specimens of which behaved in the same way as St. Vincent arrowroot; but as the same samples showed a marked deficiency in the number of granules with processes, so comparatively abundant in genuine Bermuda, the title Bermuda arrowroot was probably a misnomer.

of the lower half are rounded in the flame. The smaller tube is then inverted in the larger one and

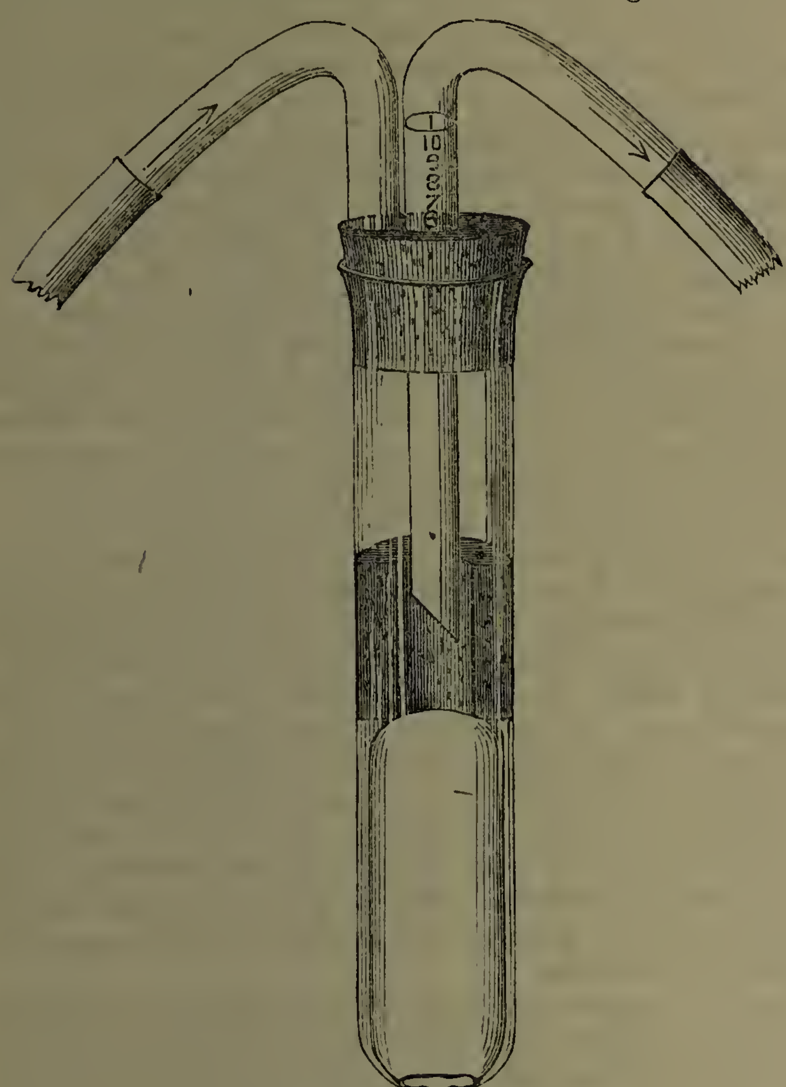

Fig. 2.—Thermostat.

kept in its place at the bottom by means of a cork, in which a fair sized groove has been made, on one side, by means of a rat's-tail file. The mouth of the larger tube is now fitted with a good cork which carries two glass tubes, as large as possible, both tubes being bent at an angle of 45° outside the cork; one terminates immediately inside, the other, which is capable of sliding through the cork, passes down to the bottom of the groove. It should terminate obliquely and have a pinhole, easily made by pressing a needle into it when red hot, about one cm. from its lower end. A mark is made on the tube outside the cork, the tube is then withdrawn until its termination is near the top of the groove, and another mark made; the space between the two marks is to be graduated into ten divisions, this can be done by a paper scale of suitable length, sliding it up the tube until it is between the two marks, where it is kept either by its own elasticity or by means of a minute quantity of sealing wax or gum.

To adjust the instrument, the cork carrying the two tubes is removed, and the test-tube heated to the highest temperature required in use; after about one minute's exposure, mercury is poured in until the groove is completely filled, the cork is again fitted to the test-tube, and the longer tube adjusted so that its mouth is just closed by the mercury; the open end is attached to a Bunsen's burner by means of a caoutchouc tube, the other tube is, in a similar manner, connected with the gas supply. The test-tube is then placed in an oil or water-bath over the Bunsen, and when the flame lowers the temperature is noted; the sliding tube is then withdrawn one division, the operation repeated, and so on, if necessary, for each division on the scale.

In using this thermostat it should be seen that the corks remain in the same position, and that the body heated is sufficiently voluminous, or at such a height above the flame as to allow of the temperature falling when the gas is supplied through the pin hole only. This simple arrangement is sufficiently delicate to keep a water, oil or air-bath within a few degrees of any required temperature, or if a double bath be used and the thermostat placed in the outer, the inner bath will remain constant within 1°.

The value of one division should be found each time of using, as alterations of the barometer may affect it slightly.

The mixture of potato starch and water by the arrangement above described was kept at a temperature within 1° of 60° C. for nine hours. Examination under the microscope during the first few minutes and after the nine hours showed that the starch had not been further altered by the prolonged exposure. The mixture was now diluted with four times its weight of water and a portion of it kept at 60° C. until it had been so heated for forty hours; still no further change. On the temperature being raised to 65° C. most of the unaltered granules tumefied, but it required a temperature of 70° C. to complete the alteration, whereas when a sample of the same starch which had not been so treated was mixed quickly with water of 65° C. the whole of the granules tumefied.

It, therefore, seems that prolonged exposure to a temperature a little below that of tumefaction, not only does not tumefy the granules but enables them to bear a slightly higher temperature than they otherwise would do.

Slow tumefaction might perhaps throw some light on the histology of starch granules; it is, however, quite possible that it may have already been thoroughly studied by some of the German writers to whom we are indebted for nearly all our knowledge on this subject. I notice that when the granules are gradually heated as described above the majority do not burst their integument, by splitting it from the nucleus in all directions, as when they are subjected to a sudden rise of temperature, but a small bladder-like process is thrown out near the nucleus, and if the temperature be kept constant, the swelling increases, although still confined to that portion of the granule, bursts, the granulose oozing out, and, if sufficient time be allowed, the integument, still retaining the original size and shape of the truncated granule, is all that is left.

At the same time other granules having thinner integuments will be acted upon to a greater extent, leaving nothing but a mere cap of cellulose, and in some cases the whole of the integument is completely acted upon, nothing eventually remaining but a mass of jelly.

The swelling of the granulose within the integument of a starch granule has the same effect as an ignited charge in a gun. Suppose a modern cannon, which increases in thickness by successive coils of metal towards its breech, were closed by a stopper of less strength than the barrel of the gun, a charge of suitable power, capable of acting with equal force on the whole surface, having been previously introduced. This being fired, the stopper would give way. If a more powerful charge were used, not only the stopper but the front part of the gun would be carried off; and so on as in the case of the starch granule in which the so-called nucleus represents the closed muzzle, the integument the cannon, and the granulose the greater or lesser charge, according as it is subjected to more or less heat.

Fig. 3.—Potato starch showing different granules at various stages of tumefaction. The upper four are supposed to be the same granule.

From the action of warm water on starches, that portion of the granule near what is called the nucleus or hilum is shown to be the softest and newest part, and possibly the granule may receive its nutriment through this point. Much opposition has been shown to both the above terms, and if what is surmised above be corroborated by others, then, the term *micropyle* (*Gr.* a little gate or orifice) would more suitably express its probable functions. It may be asked, if the granule is built up by the entrance of nutriment through this micropyle, how is it that, when the starch is used to furnish material for the growth of the plant, it does not send out the granulose through the micropyle, that being the softest part, and leave the celluloidal integuments as a skeleton of the granule? It must be remembered, however, that the protoplasm from which the starch is formed must be diffusible through the primordial integuments which are first "secreted on the inner surfaces of the cavities or vacuoles formed in the general protoplasm of the cell;" but when converted into granulose it is no longer diffusible.

How starch is utilized has not been satisfactorily explained; it was at one time thought that the immediate cause of its transformation into available substances was diastase, but it is now known that diastase exerts no influence on raw starch. Starch has been examined after having passed the alimentary canal of man and other mammals, and it has been observed that the whole surface of the granule is more or less corroded, the action being no more violent at the micropyle than at other parts. Whatever agent is employed in the plant probably acts on the integuments as much as on their contents, the action once begun being most likely very rapid, those granules first attacked disappearing before action has begun on others.

(*To be continued.*)

EXAMINATION OF POWDERED SENNA LEAVES *

BY DR. W. LENZ.

The pharmacist who is not in a position himself to prepare his vegetable powders, or who for other reasons purchases them, in proportion as he is in the habit of conscientiously examining his goods, must have often regretted the want of a suitable method for testing the powders of plants and parts of plants. For the examination of many commercial powders, but especially of condiments, masterly works by Wiesner, Vogl, Müller and others have been published, which in conjunction with characteristic figures, render the microscopic analysis and identification of the constituents of such vegetable powders possible to the expert. But many of the officinal powders most in use are not so well worked out, and some not at all, at least as regards the indispensable figures.

For the examination of a vegetable powder it is requisite to have an exact knowledge of all, or at least of the characteristic cell and tissue forms of the plant or parts of the plant from which it is derived. Such a knowledge can only be attained by a thorough previous examination of authentic entire specimens. Before proceeding to the examination of an undoubtedly pure powder, preferably prepared by the experimenter, it is therefore necessary to acquire by means of sections, a clear idea of the anatomical relations. When the student can recognize and define each cell from the powder, and refer it to the part of the unpowdered drug in which it occurs, he will have attained a general preparation for the testing of commercial powders.

The microscopic examination and discovery of special characters in powdered leaves is rendered more difficult by the fact that leaves in general present a great similarity in structure. The epidermal cells covered by the cuticle are always rounded off parallel to the surface of the leaf, single cells or entire groups being developed into papillæ, hairs, glands and scales; when fresh they contain colourless or coloured cell-juice, which in dried leaves naturally disappears, though it may colour the cell-walls. The peculiar fundamental tissue of the leaf (mesophyll), permeated by vascular bundles, which is enclosed by the epidermis, is formed, as a rule, of two layers; the upper of which consists of cylindrical cells elongated vertically to the epidermis (palisade tissue), and the lower of parenchyma tissue enclosing large intercellular air-spaces. The cells of the fundamental tissue are mostly thin-walled, presenting however, in many leaves, as for instance in tea, especially in the neighbourhood of the vascular bundles, stone cells that may be very characteristic. Moreover in the mesophyll there occur crystals, mucilage, and receptacles containing essential oil, etc. The vascular bundles, the course of which (venation) is so important in the recognition of the entire leaf, afford fewer points for the characterizing of leaf powders than the epidermis and mesophyll.

I. *Folia Sennæ Alexandrinæ.*

This drug consists of the dried pinnate leaflets of *Cassia lenitiva*, Bischoff, free from argol leaves. The leaflets are somewhat leathery, oval, oblong or oblong lanceolate, unequal at the base, broadest in the middle, shortly accuminate, pale greenish with a bluish lustre on both the upper and under surfaces, covered with fine hairs on the under side, especially in neighbourhood of the midrib. The epidermis (fig. 1) of the upper surface resembles that of the under surface in structure, except that thick-walled one-celled hairs (H), inserted in the midst of a group of four to six epidermal cells, occur more plentifully on the under than the upper surface. These hairs are straight or curved, simple, with the canal nearly as thick as the wall; they are brittle and consequently easily detached at the base, so that only the basal portion, forming a characteristic scar (R), remains in

* Abstract of a paper in the *Archiv der Pharmacie*, [3], xx., 106.

the epidermis. Along the midrib occur single thin-walled hairs, which are in some instances five times as long as those represented in the figure. The stomata,

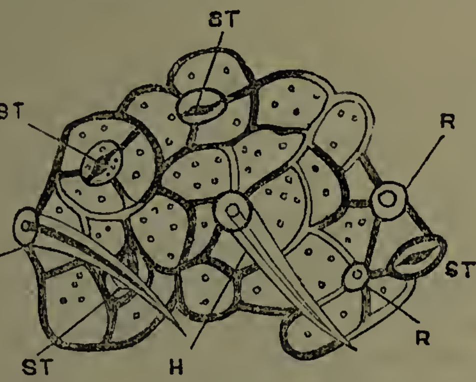

Fig. 1. *Cassia lenitiva*, Bisch.: Epidermis of leaf.—H, hairs; ST, stomata; R, point of insertion of detached hair. 144/1.

which are usually surrounded by a circle of 2 to 4 epidermis cells, occur with equal frequency on the upper and the under surfaces. The epidermis consists of a single cell layer, which, however, is developed somewhat more thickly on the upper surface of the leaf than the under, and occupies (the two layers together) one-third of the diameter of the leaf. Beneath the epidermis, and contrary to the usual rule, near both the upper and lower surfaces of the leaf, lies the palisade tissue, some cells of which, strongly magnified, are represented in fig. 2. This also consists of only one layer of cells, which, however, are notably larger in the layer near the upper surface of the leaf than in that near the under. The thickness of the two layers of palisade tissue taken together amounts to more than one-third of the diameter of the leaf. The contents (fig. 2, B) forming large cylindrical cells standing with their long diameter vertical to the surface of the leaf, are peculiarly shrivelled up, so that they themselves may be taken for thickened cells.

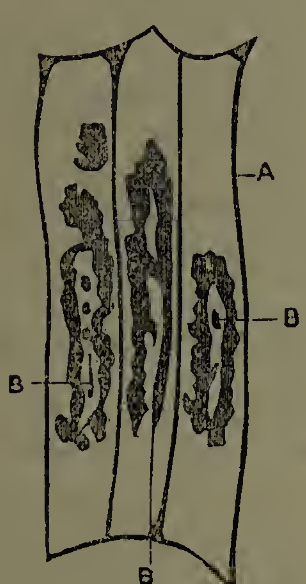

Fig. 2. *Cassia lenitiva*, Bisch.: Palisade tissue of leaf.—A, cell-wall; B, dried up cell contents. 420/1

Fig. 3. *Cassia lenitiva*, Bisch.: Palisade tissue of leaf, seen from above. 144/1

Upon a superficial view, therefore, the palisade tissue presents the appearance of a layer of stone-cells (fig. 3). The middle of the leaf is permeated by an abundant network of vessels, the elements of which, consisting of smooth fibres, spiral and scalariform vessels, as well as parenchymatous tissue, are not specially characteristic. As little characteristic are the large roundish cells of the fundamental tissue, the shrivelled h•rny contents of which catch the eye whilst the delicate cell-walls are only perceived with difficulty.

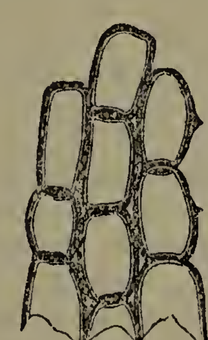
For examination, the powder is best boiled with 90 per cent. alcohol, and being thus freed from resin, is brought under the microscope in glycerine. The elements of the vascular bundles stand out prominently; the palisade tissue is characteristic, but so especially are the fragments of the epidermis.] True Alexandria senna is distinguished by the relative abundance of the hairs; the powder should contain, therefore, a corresponding number; if the hairs have been broken off, the fragments of epidermis will exhibit plentifully the unmistakable points of insertion. Frequently a strong preponderance of vascular bundles consisting of large spiral vessels points to a powder containing much leaf-stalk.

II. *Folia Sennæ Tinnevelly.*

This drug, derived from *Cassia angustifolia*, *γ Royleana*, Bischoff, differs from the preceding in the leaves being less leathery, lanceolate, and with fewer hairs. The upper surface of the leaf is yellowish green, the under surface being of a somewhat darker shade. The anatomical structure does not differ essentially from that of Alexandria senna. The epidermis, however, is far less hairy and the hairs do not break off so readily as from the Alexandria variety. In the powder of Tinnevelly senna, therefore, there occur proportionally a much smaller number of the hairs characteristic of the official leaves, and the fragments of epidermis seldom show the corresponding points of insertion of the hairs, represented in fig. 1, R. Further the elements of the vascular bundles are not so prominent in the powder of Tinnevelly as in that of Alexandria senna, and they appear to be richer in spiral vessels.

Whilst Tinnevelly leaves occur very pure in commerce, the Alexandrian leaves mostly contain more or less leaf-stalks and fruit (husks), from which only the "picked" quality (which is probably not used for powdering) is free. These admixtures naturally occur, therefore, in the powder, so that a knowledge of their peculiar elementary forms—which may be looked upon as characteristic of Alexandria leaves—is indispensable in the examination of commercial senna powder.

The epidermal cells of the stalk (fig. 4) are considerably smaller (elongated in the direction of the stalk) than those of the leaf epidermis, and have fewer hairs and stomata. The parenchyma tissue specially distinguishing the stalk shows nearly the cell-form of ordinary cork (fig. 5).



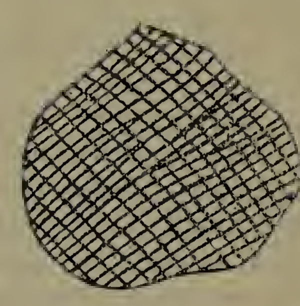


Fig. 4 *Cassia lenitiva*, Bisch. Epidermis of leaf-stalk. 144/1.

Fig. 5. *C. lenitiva*, Bisch. Parenchyma tissue of leaf-stalk. 144/1.

Fig. 6. *C. lenitiva*, Bisch. Middle layer of the fleshy portion of the husk, seen from above. 144/1.

The epidermis of the husk is remarkably similar to that of the leaf, only the epidermal cells, seen from the surface, appear somewhat more elongated than those of the leaf. Most characteristic of the husk, however, is a tissue traversing about the centre of the fleshy portion and parallel to the walls. This consists of several layers of unthickened, acuminate, tube-shaped fibres, lying one upon another, which in each layer are arranged close together in the same direction, whilst those of the different layers (of which with only a moderate enlargement two can be seen) cross one another at an angle. If the powder contains husk, this tissue (fig. 6) always occurs, and is unmistakable by the most unskilled observer. Frequency of pieces of husk tissue can be taken as indicating a powder prepared from Fol. Sennæ Alex. parv. The fleshy portion lying under the epidermis, outside the fibre layer above described, is not unlike the large-celled parenchyma tissue of the stalk, the inner portion consisting of larger cells, and therefore possessing more the type of a true fruit flesh. There is nothing characteristic in the cellular layer constituting the inner wall of the fruit. The elementary tissue of the small seeds has never been observed by the author in a powder.

At a first glance the Alexandria leaves appear to contain more woody fibre than the Tinnevelly. A chemical examination made by Dr. Popp of senna powders, prepared by himself, gave the following results:—

1. *Folia Sennæ Alex.*

1·85325 g. lost at 100°–110° C. 0·20925 = 11·29 per cent. of water.

2·1297 g. (air-dried) exhausted with absolute alcohol gave 0·3995 g. = 18·76 per cent. of resinous residue, dried at 100°.

1·1304 g. (air-dried) gave 0·1189 = 10·52 per cent. of woody fibre.

2. *Folia Sennæ Tinnev.*

1·8740 g. lost at 100°–110° C. 0·1800 = 9·6 per cent. of water.

2·2426 g. (air-dried) exhausted with absolute alcohol, gave 0·4280 g. = 19·09 per cent. of resinous residue, dried at 100° C.

1·2073 g. (air-dried) gave 0·1400 g. = 11·59 per cent. of woody fibre.

The opinion that Alexandria leaves contain more woody fibre than Tinnevelly, was consequently not confirmed; the evidence was rather that upon the basis of a determination of moisture, resin and woody fibre, the two kinds of senna leaves cannot be distinguished.

QUININE IODATE AND BROMATE, AND THE PHYSIOLOGICAL ACTIVITY OF SUPEROXIDIZED MOLECULES.*

BY CHARLES A. CAMERON, M.D.

The researches of Arthur Gamgee, Priestly, and Larmuth have shown that the three forms of phosphoric acid and of vanadic acid have very different degrees of physiological activity. The salts of orthophosphoric acid are almost inert when their bases are inactive, whilst the pyrophosphates and metaphosphates are poisonous. The orthovanadic acid is poisonous, but pyrovanadic acid and metavanadic acid are still more poisonous.

The high physiological activity of the pyro and metaphosphates has been attributed to the unsaturated condition of their nuclei. These salts are not statical, for they can take up additional basic material. For example, calcium metaphosphate can combine with two molecules of lime to produce a molecule of calcium orthophosphate—

$$Ca(PO_3)_2 + 2CaO = Ca_3(PO_4)_2.$$

Carbon dioxide and carbon monoxide are poisonous, but the latter is by far the more poisonous. According to the modern doctrine of atomicity carbon atoms have four "bonds"—that is, a carbon atom has an atom-fixing power equal to that of four atoms of hydrogen or other monad elements. In carbon dioxide the four bonds of the carbon atom are fully satisfied by the four bonds of the two oxygen atoms—

$$O=C=O$$

In carbon monoxide only two of the carbon atom bonds are in combination with oxygen, and the remaining bonds combine with each other—

$$\langle C=O.$$

Such a molecule is said to be unsaturated.

High Molecular Weights a cause of Physiological Activity.—High atomic weight and complex molecular structure are stated to be causes of high physiological activity. The poisonous elements have as a rule higher atomic weights than elements belonging to the same groups which are comparatively physiologically inert. There are, however, exceptions to these rules. Lithium with an atomic weight of 7 is more active than sodium with an atomic weight of 23. Arsenic with a lower atomic weight than antimony is more poisonous than the latter. Chlorine in the free state is more active than iodine, though on the whole the iodine compounds used in medicine have somewhat smaller doses than the corresponding chlorine compounds.

Rabuteau found that with one exception (that of methyl alcohol) the toxic power of the alcohols increased with their molecular weight. Amyl alcohol, which has a molecule composed of 18 atoms, is eight times more poisonous than ethyl alcohol, the molecule of which contains 9 atoms. On the other hand, oxalic acid has a molecular weight of 90, and is poisonous, whilst malic acid, with a molecular weight of 134, is a constituent of wholesome fruits. Albumin has a very high molecular weight.

Superoxidized Bodies.—Physiological activity seems to be more influenced by an unsaturated condition of molecules than by their molecular weight or degree of complexity. It is also, I am disposed to believe, influenced by a condition of molecules which I venture to describe as *superoxidized.* In potassium iodide we have according to the doctrine of quantivalency a saturated molecule. The salt is composed of two monad elements, and the unit of equivalence of each of its two atoms is fully satisfied. According to the graphic or pictorial method of representation the molecule is constituted as follows—

$$K—I.$$

Although potassium iodide is a saturated and stable body, three or four atoms of oxygen may be combined with it so as to form potassium iodate (KIO_3) or potassium periodate (KIO_4). In the latter salt only two of the atoms of oxygen are in union with the potassium and iodine, six oxygen bonds satisfying each other—

$$K—O—O—O—O—I.$$

In this compound there are three atoms of oxygen in excess of the number requisite to saturate the iodine and potassium; hence we may term potassium periodate a superoxidized compound.

Periodic anhydride is a more striking example of a superoxidized body. It is composed of two atoms of iodine combined with seven of oxygen—

$$I—O—O—O—O—O—O—O—I.$$

In this compound only two of the fourteen oxygen bonds are in combination with the iodine.

It may of course be said that iodine is a septivalent element, but in atom-fixing power it acts in general like other monads.

If we hold that iodine and bromine are monads, then the higher terms of their oxygen series may be regarded as in reality unsaturated molecules. They contain oxygen atoms combined only with other oxygen atoms. Such compounds are unstable. They are all decomposed by simple heat at comparatively low temperatures.

When superoxygenated compounds are introduced into the system, it might be expected that their oxygen being loosely combined would unite readily with elements of the blood. It is, however, stated that potassium chlorate passes through the body unchanged. It is open to doubt whether or not the whole of the chlorate taken appears subsequently in the urine. It has been alleged that quinine passes unchanged through the body, but it is now known that only two-thirds of the quinine taken into the stomach can be detected subsequently in the urine. Even if all the potassium chlorate taken were found afterwards in the urine, that would not be positive proof that the potassium chlorate had not been partially deoxidized and reoxidized in its passage through the system. Besides drugs produce powerful catalytic effects without undergoing themselves any chemical changes.

Potassium iodate appears to act more powerfully upon the system than potassium iodide. I know a person,

* Read before the Medical Society of the King and Queen's College of Physicians, Wednesday, May 3, 1882. Reprinted from *The Dublin Journal of Medical Science,* June, 1882.

accustomed to take ten grain doses of potassium iodide without experiencing any unpleasant symptoms, who cannot take even five grains of the iodate without being attacked by coryza.

I am disposed to believe that the chlorates, bromates, and iodates are more active physiological agents than the corresponding chlorides, bromides, and iodides. They are all composed of superoxidized molecules. It is certain that chlorate of sodium is more powerful than chloride of sodium, or common salt. We may from analogy infer that iodate of potassium is a more active physiological agent than the iodide of potassium.

Ferric Iodate.—Some years ago I suggested the use of ferric iodate ($Fe_2(IO_3)_6$) as a substitute for the unstable ferrous iodide.* It was largely prescribed in Dublin, and although a nearly insoluble salt it was found in large doses to produce iodism. It was favourably noticed by Dr. Anstie in *The Practitioner* for June, 1869, page 366.

Quinine Iodate.—Last year I gave a formula for the preparation of iodate of quinine, in combination with an effervescing preparation, to Messrs. J. J. Graham and Co., of Westmoreland Street, Dublin, and since last May they have, as they inform me, disposed of nearly 1 cwt. of the compound. It has been prescribed largely by Mr. Porter, Surgeon to her Majesty; Dr. Samuel Gordon, Professor Moore, Dr. Smyly, Professor Macnamara, and many other leading practitioners. These gentlemen inform me that they have found it a very useful remedy in the treatment of neuralgia, severe articular pains which had resisted the employment of the usual remedies, sluggish forms of pulmonary congestion, secondary syphilitic disease, and malarial enlargement of the spleen.

Iodate of quinine is a salt which appears to have been scarcely studied. Only two references to its existence are to be found in the books and journals relating to chemistry and pharmacy. Sérullas states (*Annales de Chimie et de Physique*, t. xlv., 282) that it may be prepared by dissolving quinine in a hot solution of iodic acid, and that on cooling the solution the salt crystallizes out in a form resembling sulphate of quinine. Sérullas does not appear to have analysed the salt. According to Pelletier and Caventou (*Annales de Chimie et de Physique*) both iodate and hydriodate of quinine are formed by digesting quinine and iodine by the aid of heat.

Quinine iodate may be prepared by digesting freshly precipitated and still moist quinine with a warm solution of iodic acid in the proportion of a molecule of each (the iodic acid should be dissolved in 8 or 10 parts of water). The resulting mass cannot be dried at the water-bath heat, as it causes some decomposition of the salt. Dried at a temperature of 60° F., and then placed *in vacuo* over sulphuric acid, it undergoes no further loss of weight. The salt has a white-pearly appearance, and consists of extremely minute needle-shaped crystals, which contain no water. Boiling water does not decompose it. It is very slightly affected by strong sulphuric acid. Hydrochloric acid and dilute sulphuric acid dissolve it readily; it is not quite so soluble in acetic acid. Spirit of wine effects its solution readily, but in ether and chloroform it is sparingly soluble. Seven hundred parts of cold water dissolve 1 part of the iodate; in warm water it dissolves much more readily.

The mean of several determinations of the amount of iodine in the dried iodate of quinine gave 21·8 per cent. The salt has therefore the following formula:—

$$C_{20}H_{24}O_2N_2,HIO_3.$$

The theoretical amount of iodine for such a formula is 22·92, but the small deficiency in the salt was due to the presence of a little free quinine; the iodate was found to be faintly alkaline from this cause.

The granulated effervescing iodate of quinine is composed of a mixture of the pharmacopœia compound of sodium bicarbonate and citric and tartaric acids with the iodate. Each drachm of the compound contains 2 grains, or 1 dose of the iodate.

I have not made many examinations of the urine of persons under administration of quinine iodate. In the case of a patient of Dr. Elliott, who was using the iodate for about a fortnight, the urine contained so much free hydriodic acid or iodides that it gave a yellow precipitate with nitrate of lead. In another case iodic acid and hydriodic acid were detected in the urine within half an hour after the iodate had been taken, but no trace of quinine could be found in it. In the urine of the same person, passed three hours later, quinine was found.

Bromate of Quinine ($C_{20}H_{24}N_2O_2,HBrO_3$).—I can find no account of this salt in the chemical books or journals. So far as I am aware it has not been described up to the present. It may be prepared by precipitating barium bromate by sulphate of quinine, or by neutralizing quinine with bromic acid. It occurs when air-dried in small asbestos-like masses, which, under the microscope, are seen to consist of very long needles.

Quinine bromate has the same constitution as the iodate of quinine, but it is more soluble in water—namely, 1 part in 250. Warm water dissolves it freely. The dry salt may be heated on the water-bath without discoloration, but its solution, when evaporated to dryness, leaves a residue more or less decomposed. The salt dissolves readily in hydrochloric and dilute sulphuric acids, and in spirit of wine. Acetic acid acts less readily upon it. Touched with a drop of strong sulphuric acid it detonates, emits a puff of dark smoke, and almost wholly disappears. On iodate of quinine, sulphuric acid produces only a slight yellow coloration, which vanishes on the addition of water, the salt dissolving and forming a colourless solution.

The original paper is supplemented by the medical opinions of a number of physicians who state that they have found the quinine iodate and bromate valuable remedial agents.

HYDROBROMIC ACID.*

BY G. R. TUCKER, PH.G.

The credit of having introduced hydrobromic acid as a medicine is generally given to Dr. J. Milner Fothergill, who extolled its virtues in the *British Medical Journal*, and gave a process for its preparation, viz.: by the decomposition of potassium bromide by tartaric acid.

Dr. De Witt C. Wade has also written much of value on the subject, and in the *Peninsular Journal* for February, 1875, gave an account of its action, and a formula for its preparation, correcting certain inaccuracies in that of Dr. Fothergill. This acid is now quite extensively used, and is considered of sufficient importance to merit a place in our next Pharmacopœia. It is certainly desirable to have a process that will not be too difficult of execution, and one yielding uniform results, of such purity as we expect to find in pharmacopœial products.

In regard to the formula of Dr. Wade, all that can be said in its favour is simplicity. If correctly proportioned, we can perhaps avoid either excess of bromide or of tartaric acid, but we always get a not inconsiderable amount of potassium bitartrate along with it.

Methods have been proposed to obviate this objection, the most successful being that proposed by Dr. Charles Rice, which consists in precipitating the cream of tartar by alcohol. This yields a reasonably pure product, but detracts from the simplicity for which the process has been recommended, making it tedious and expensive. Dr. Rice's formula is as follows:

* *Dublin Quarterly Journal of Medical Science*, May, 1869, vol. xlvii., p. 354.

* Abstract of a thesis presented to the Massachusetts College of Pharmacy. Reprinted from *New Remedies*, April, 1882.

Dissolve 1191 grains of potassium bromide in 15 fluid ounces of water, add 1500 grains of powdered tartaric acid, heat, and set aside in a cool place for twenty-four hours. Thirty-two ounces of alcohol is then added, and the mixture again allowed to rest for twenty-four hours, after which it is filtered, and the alcohol evaporated or recovered by distillation. The product should measure 16 fluid ounces. Sp. gr. about 1·075, containing 10 per cent. of HBr.

Dr. Wade claims that the slight amount of cream of tartar taken up is of no consequence, as it in no way interferes with its medicinal qualities. However true this may have been at the time of Dr. Wade's article, it cannot apply now, in view of the uses to which the acid may be applied, as, for example, in the preparation of hydrobromates of organic bases, which are coming somewhat into use, as hydrobromates of quinia, cinchona, morphia, strychnia, etc.

For the extemporaneous preparations of bromides, there is no process more satisfactory than the saturation of a strong aqueous hydrobromic acid with an oxide or carbonate of the base required. The pharmacist can in this way prepare bromides or hydrobromates, which he may be called upon to dispense, and for which the demand is so slight that it is not an object to purchase.

Various modes of preparation have supplied the market, up to the present time, with acid of various and commonly unknown strengths; hence, as might reasonably be expected, the experiences in regard to its utility are confused and often conflicting. Physicians prescribe such articles and pharmacists buy and dispense them, too often as if there could be but one thing supplied; for example, physicians prescribe hydrobromic acid, not knowing that it may be of any strength from one to fifty per cent., although substituting it for bromide (KBr). It is true that the dose cannot be determined by the quantity of bromine present in the acid, yet there is doubtless some relation which, when studied, forms the basis for its use. It being now generally established that it is the bromine element which is effective in all the bromides, hydrobromic acid should be adjusted in strength, so as to bear some easily remembered relation of its bromine constituent to the potassium salt, this being the one most commonly used.

Potassium bromide contains 67·22 per cent. of bromine; sodium bromide, 71·4; and ammonium bromide, 81·6; that is, 20 grains of the potassium is equal to a dose of 18·8 grains of the sodium, or 16·5 grains of the ammonium salts. Potassium bromide containing in round numbers sixty-seven per cent. of bromine, a solution of hydrobromic acid containing also sixty-seven per cent. of bromine would have the same bromine value.

The most convenient and simple relation is to have an acid of 33·5 per cent. of bromine, or 34 per cent. of hydrobromic acid, or half the strength of the potassium salt; such an acid can be made and dispensed without difficulty, while an acid of 67 per cent. would be inconvenient to dispense, being strongly corrosive, and fuming in the air even more than hydrochloric acid.

This strength is a convenient one to remember, as compared with potassium bromide, being in proportion of two to one. Hydrobromic acid is a sedative neurotic, and its principal use appears to be as a substitute for potassium, sodium and ammonium bromides. It is well known that salts of the alkalies, when given for a long time, are apt to produce undue alkalinity. To correct this, and to forestall against it when likely to occur, this acid finds its principal use. It also acts like other mineral acids in being tonic, refrigerant, solvent, alterative, etc.; combined with quinia, it is said to be very satisfactory in intermittent fever, and has been highly spoken of as a corrective and preventive remedy for headache and ringing in the ears, which often follows upon the use of salts of quinia, called "quinism." Various combinations have been recommended from to time with drugs, such as mercury, stramonium, digitalis, bismuth, pepsin, tartar emetic, etc., but the advantages claimed for these combinations have not been satisfactorily established.

Hydrobromic acid is not, like hydrochloric acid, readily formed by direct union of its elements; mixtures of bromine vapour and hydrogen do not unite by direct exposure to sunlight, nor do they explode when brought into contact with flame, but combination does take place in the immediate neighbourhood of a red-hot wire, when introduced into it, and more quickly when the mixture is passed through a red-hot tube, or by platinum wire, if kept hot by the galvanic current. It is rapidly and copiously absorbed by water, which, when saturated, has a density of 1·29, and fumes strongly in air; this saturated solution boils at a temperature below 100° C., giving off the gas and becoming weaker; a more dilute acid boils at a temperature above 100° C., and a very dilute acid becomes stronger by boiling. The gas is not decomposed by heat alone; potassium introduced into it decomposes it completely, forming potassium bromide, and leaving a volume of pure hydrogen equal to half that of the original gas. Tin produces the same effect when aided by a gentle heat. This reaction can be used to determine the composition of the gas, for the weight of one volume of the gas (the observed sp. gr.), diminished by the weight of one-half the volume of hydrogen, gives a number which is very nearly half the sp. gr. of bromine, 5·54; hence the gas is composed of equal volumes of hydrogen and bromine, united without condensation. The gas or its aqueous solution is immediately decomposed by chlorine, hydrochloric acid being formed and bromine separated, which is recognized by its red colour. Iodine, on the contrary, does not decompose it, hence the affinity of bromine for hydrogen is, under similar circumstances, less than that of chlorine, and greater than that of iodine. The acid is also decomposed by oxygen and by highly oxydized bodies.

Nitric acid separates bromine on heating the liquid, and a mixture of these acids has the power of dissolving gold. Sulphuric acid decomposes it, yielding sulphurous acid, bromine and water

$$2HBr + H_2SO_4 = SO_2 + 2H_2O + Br_2,$$

with bromic acid it yields water and free bromine.

Many formulæ have been proposed for making this acid for medicinal use, but all so inaccurate, or inconvenient, or difficult, as to be impracticable for ordinary use. The process usually noticed in the older works on chemistry is that of Balard, and as modified by Professor J. M. Maisch, and still farther by Professor G. F. H. Markoe, is on many accounts to be preferred to any that have been proposed. Goebel's process* consists in decomposing a solution of barium bromide by sulphuric acid, but this process, although a good one, is inconvenient, as it renders necessary the previous preparation of barium bromide. Loewig tells us to distil potassium bromide with sulphuric acid; a purer product can be obtained by using phosphoric acid in a concentrated form. If calcium hypophosphite be placed in a retort with water, and bromine added through a funnel-tube, hydrobromic acid will be formed immediately, without the aid of heat; the water, being decomposed, furnishes the hydrogen necessary to convert the bromine into HBr, while the oxygen changes the calcium salt to a neutral phosphate. The proportions are: water, 1 part; bromine, 5 parts; and calcium hypophosphite, 4 parts. Sodium sulphite could be substituted to good advantage, but will require a slight heat. The salt in this case becomes a sulphate, and the proportion would be: water, 1 part; bromine, 3 parts; sodium sulphite, 6 parts, yielding 10 parts of acid. In making monobromated camphor, one-half the bromine is converted into HBr, and may be readily obtained as such by passing the gas into water.

A new method has been developed from the known fact that bromine associates itself with certain organic bodies at ordinary temperatures, and is again liberated

* *New Rem.*, 1880, 262.

on heating in form of hydracids; essential oil of copaiba and lemon have been used as a medium for this purpose.

A very interesting and instructive process is that by which hydriodic acid is prepared, and with a modification noticed in *New Remedies*, 1880, page 5, answers admirably for hydrobromic acid. When hydrosulphuric acid is passed into iodine or bromine, hydriodic or hydrobromic acid is formed and sulphur precipitated; when iodine is used, the sulphur persistently envelopes it, preventing further action; but if carbon disulphide be used, this difficulty is entirely obviated, it being a solvent for iodine, bromine, and sulphur. The most suitable proportions are: carbon disulphide, 3 parts; bromine, 2 parts; distilled water, 8 parts; yielding an acid of about the sp. gr. 1·090.

Dissolve the bromine in the carbon disulphide, pour this solution into a tall glass cylinder, cover it with the water, and then by means of a delivery tube, reaching to the bottom of the cylinder, pass a stream of sulphuretted hydrogen to the liquid, till the bromine is all converted into hydrobromic acid, which will dissolve without loss in the water. The reaction is known to be finished when the liquid loses its deep red colour. Then separate the aqueous solution of HBr; boil to expel sulphuretted hydrogen and filter. The rationale is extremely simple, the reaction takes place when sulphuretted hydrogen comes in contact with bromine; one equivalent of hydrogen unites with one of bromine to form hydrobromic acid, while the sulphur with which it was combined is isolated, and remains dissolved in the carbon disulphide. In the report compiled by Dr. Charles Rice, on the Revision of the United States Pharmacopœia, a place is given to the process of Dr. Squibb, but it is yet to be decided whether that or the excellent process of Professor Markoe will be adopted. In 1875, Professor Markoe introduced his process, which has been extensively used, as it is by far the most economical and especially adapted to manufacture on a large scale. The mode of procedure is as follows: One pound of phosphorus is placed in a one-gallon jar (stoneware), covered with water, and the jar half filled with ice, a large funnel is then inserted into the throat of the jar, and a funnel tube adjusted so as to reach a short distance above the phosphorus, the funnel is filled with ice, and the apparatus placed in a vessel, that the jar may be surrounded with ice; three or four pounds of bromine may now be very slowly added through the funnel tube, waiting after each addition until the reaction has ceased; large quantities would give rise to an explosion. The two elements unite to form pentabromide of phosphorus, PBr_5, and this reacting with water, forms phosphoric and hydrobromic acids:

$$PBr_5 + 4H_2O = H_3PO_4 + 5HBr.$$

After the reaction is completed, the excess of phosphorus is removed, and the aqueous liquid distilled until hydrobromic acid ceases to come over. The syrupy residue left in the retort, when properly diluted, is utilized as phosphoric acid. It usually happens that this residue is coloured from impurities, but it can easily be rendered perfectly colourless by heating for a short time with nitric acid, being careful to expel all the excess of acid before diluting. As a practical point in the manufacture of phosphoric acid, Professor Markoe has recommended to add to the mixture of phosphoric and nitric acids small quantities of oxalic acid; on coming in contact with hot nitric acid, oxalic acid splits up into carbonic acid and carbonic oxide. By this means we can get rid of all excess of nitric acid at a comparatively low temperature and avoid the danger of converting a portion of the product into metaphosphoric acid.

To successfully manufacture hydrobromic acid by this process is a matter of the greatest ease when one is familiar with it. The most that can be said against it is that the addition of large quantities of bromine is tedious; this is obviated in a measure by using a stoppered glass globe in place of a funnel tube.

Professor Markoe has lately modified the process as here given, and is at the present time conducting a series of experiments, to adapt it to the pharmacopœia. From remarks by Professor Markoe I gather the following information: Bromine, although insoluble in water, readily dissolves in hydrobromic acid, in proportion as the acid is weaker or stronger; if we start with water, it will be necessary to first form a small quantity of hydrobromic acid by slowly dropping bromine upon phosphorus covered with a little water, after which we can convert any quantity of bromine into hydrobromic acid with great rapidity and perfect safety, no more apparatus being required than a glass flask.

There is, of course, a limit to the quantity of bromine that can be added, but only by the liquid becoming saturated with the gas. To determine this limit I placed two ounces of phosphorus and 500 c.c. of water in a glass flask, then added drop by drop two or three grams of bromine, after which it was a matter of the greatest ease to introduce the remainder of the bromine, by pouring off the acid liquid and shaking with fresh portions of bromine after each addition. The quantities dissolved by the acid liquid showing a gradual increase, until finally I could add 150 grains of bromine at each time, the reaction proceeding quietly, with an increase of temperature. It required 732 grams of bromine to saturate the liquid, resulting in a highly corrosive and fuming acid.

By heating in a flask connected with a delivery tube, the excess of gas is driven off and absorbed by distilled water. The remaining acid is then transferred to a retort and can be distilled unchanged. Specific gravity 1·4832, containing about 48 per cent. of HBr.

Dr. Squibb has overcome the difficulty of distilling hydrobromic acid made from potassium bromide by sulphuric acid, by allowing the potassium sulphate to crystallize out. This is more readily accomplished if an excess of sulphuric acid is used. However carefully the distillation may be conducted, the product always contains noticeable quantities of sulphurous and sulphuric acids. In my opinion, the process is far more difficult and tedious than that of Professor Markoe's, and certainly yields no better results.

If a large quantity of concentrated hydrobromic acid is to be distilled at one time, I have found it advantageous to use a small retort, arranging the bulk of acid in such a manner that it will flow into the retort only as fast as it distils over. In this way I have been able to distil from a quart retort two or three gallons of strong hydrobromic acid, with only the heat of a Bunsen's burner.

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from Vol. XII., page* 827.)

INFUSUM CINCHONÆ RUBRÆ (*Infusion of Red Cinchona*).

Red cinchona, containing at least 6 per cent. of alkaloids, in fine powder	15
Normal hydrochloric acid	5
Water to make 200.	

Macerate the cinchona with the acid and a little water for several hours, occasionally stirring, until the froth has disappeared. Pour the mixture into a percolator closed with a linen pellet at the bottom. As soon as the liquid begins to run clear, pour water on top until 200 parts of filtered liquid are obtained.

The infusion is clear, of a reddish-yellow colour, and should yield a copious precipitate both with solution of soda and with strong hydrochloric acid. (De Vrij.)

MAGNESII METATARTRAS (*Metatartrate of Magnesium*).

Metatartaric acid (see next)	10
Distilled water	40
Magnesium carbonate, about	7
Alcohol	q.s.

Dissolve the acid in the water, and add, under stirring,

* From *New Remedies*, April, 1882.

so much carbonate of magnesium as may be required to be in slight excess. Filter the solution immediately, and add to the filtrate double its volume of alcohol. When the precipitate has settled, pour off the alcohol, spread the magma upon a plate of glass or porcelain, and let it dry in a cool place.

Metatartrate of magnesium is an amorphous, not hygroscopic salt, which may easily be converted into a white powder and is soluble in four parts of water. When dissolved in water it soon is converted into ordinary tartrate of magnesium, and, therefore, it should not be kept in stock in solution.

ACIDUM METATARTARICUM (*Metatartaric Acid*).

Tartaric acid, in powder	q.s.

Heat it in a porcelain capsule, upon a sand-bath, to 180° C. (356° F.); pour the melted mass, by means of a warmed glass-rod, in drops, upon a glazed plate, and transfer the pieces immediately, when cold, in a well-closed bottle.

Metatartaric acid appears in form of transparent, yellowish pieces, having an agreeable acidulous taste, and being hygroscopic.

When dissolved in water, the acid is soon converted into normal tartaric acid, particularly if the solution be warmed.

MISTURA ANTICARRHALIS (Hufeland's) (*Hufeland's Catarrh Mixture*).

Extract of carduus benedictus	3
Extract of dulcamara	1
Fennel water	24
Cherry-laurel water	3

Mix them.

N.B.—Extract of carduus benedictus and extract of dulcamara are prepared thus: pour as much boiling water upon the finely-cut plants (dry or fresh) as is required to make a pulp, set aside for twenty-four hours, occasionally stirring, then express. Again pour on a somewhat smaller quantity of boiling water, let stand twelve hours and express. Evaporate the united liquids to a thick extract.

Cherry-laurel water (*Pharm. Neerlandica*) is prepared by distilling six parts of cherry-laurel leaves with enough water to obtain *at first* five parts, a portion of which is to be assayed for the amount of hydrocyanic acid present, after which the remainder is to be diluted with distilled water, so that 1000 parts of the finished preparation may contain 0·839 parts of hydrocyanic acid, or so that one part of hydrocyanic acid is contained in 1191 parts of the liquid.

MISTURA ANTICHOLERICA (Bleeker's) (*Bleeker's Mixture*).

Aromatic wine of opium	2
Oil of peppermint	1
Spirit of ether	4
Water	750

Mix then.

N.B.—Vinum opii aromaticum corresponds to the vinum opii of the U.S. Ph.

Spirit of ether is the continental modern form of Hoffmann's anodyne, prepared by mixing equal parts (by weight) of ether and alcohol (*Pharm. Neerlandica* and *Codex*) or one of ether and three of alcohol (*Pharm. Germ.*), etc.

MISTURA BALSAMICA (Choppart's) (*Choppart's Balsamic Mixture*).

Spirit of nitrous ether	1
Balsam of copaiva	8
Alcohol (stronger)	8
Spear-mint water	8
Orange-flower water	8
Syrup of orange peel	8

Mix them.

The original prescribes aqua menthæ crispæ, for which spear-mint water is the nearest substitute.

OLEUM BETULÆ RECTIFICATUM. OLEUM RUSCI. (*Rectified Oil of Birch. Oil of Birch Tar.*)

Oil of birch tar is a red-brown, volatile oil, of a specific gravity of 0·800–0·987, soluble in an equal weight of alcohol, and imparting an acid reaction to water, after being shaken with it. It has the odour of so-called Russia leather, which is, in fact, due to it.

OLEUM CADINUM (*Oil of Cade*).

Oil of cade is a brownish or dark-brown, clear, viscid oil, obtained by the dry distillation of the wood of *Juniperus Oxycedrus*, L.

The oil has a peculiar tarry odour, and an empyreumatic, bitter taste. It is readily inflammable and has an acid reaction. It is insoluble in water, but soluble in ether, chloroform, bisulphide of carbon, and amylic alcohol.

OLEUM MORRHUÆ IODOFERRATUM (*Cod Liver Oil with Iodide of Iron*).

[Oleum jecoris aselli cum iodeto ferrico.]

Iodine, in powder	5
Iron, in powder	10

Pour the cod liver oil into a dry flask, which must be completely filled thereby, close it well, and dissolve in it the iodine, frequently shaking. After the solution has stood at rest for some time, and has acquired a specific gravity of 0·932 to 0·937, add the iron, and shake the mixture, until it has assumed a purple-violet colour and no longer imparts a blue tint to a dilute solution of iodide of potassium with gelatinized starch. Agitate the mixture occasionally, during twenty-four hours, then repeat the reaction for free iodine, and, if this appears to be absent, let the oil become clear by standing and transfer it to small amber-coloured vials, which must be completely filled and well stoppered.

The product has a purple-violet colour, a specific gravity of 0·937 to 0·940, and contains about 1·23 per cent. of iodine and 0·27 per cent. of iron.

By shaking with a solution of starch containing some iodide of potassium, the oil should be readily converted into a bright-yellow liquid, free from blue tint or colour.

Twenty grams of the oil, incinerated in a porcelain or platinum crucible, should leave 0·077 gm. of ferric oxide.

If 5 gm. of the oil be saponified with an alcoholic solution of caustic potassa, the soap incinerated, and the residuary carbonaceous matter extracted with water, the aqueous solution, strongly acidulated with hydrochloric acid, should yield, with palladium chloride, a precipitate which, when washed and dried, weighs about 0·087 gm.

OLEUM MORRHUÆ FERRATUM (*Ferrated Cod Liver Oil*).

Benzoate of iron (ferric) (see next)	1
Cod liver oil	100

Dissolve the benzoate of iron, with the aid of a gentle heat, and by frequent agitation, in the oil.

The solution is reddish-brown, clear liquid.

FERRI BENZOAS (*Benzoate of Iron*).

Benzoic acid	10
Water of ammonia	14
Solution of chloride of iron (ferric) specific gravity, 1·480	11
Distilled water	q.s.

Rub the benzoic acid with three parts of distilled water, and add the water of ammonia, or so much of it as is required to produce a neutral solution. Dilute this with seven parts of warm distilled water and filter, if necessary. Precipitate the liquid by means of the solution of chloride of iron previously diluted with 200 parts of warmed distilled water. When the precipitate has subsided, pour off the supernatant liquid, collect the precipitate on a strainer, and wash it with distilled water until the washings are no longer rendered cloudy by nitrate of silver. Finally dry the salt at a temperature of about 30° C. (86° F.).

The resulting salt is a flesh-coloured powder, odourless and tasteless, insoluble in water, losing 4·5 per cent. in weight by drying at 100° C. (212° F.), and containing about 15·5 per cent. of iron.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, JULY 1, 1882.

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

The Report of the Commissioners appointed last year under Her Majesty's Royal Sign Manual to inquire into the grant of Medical Degrees has just been presented to Parliament and published. From it we learn that the Commission has held forty meetings, at which all the subjects committed to it for consideration have been inquired into. Witnesses have been examined; written communications have been obtained from various persons, and from the Universities, Medical Colleges and other bodies in the United Kingdom which grant medical degrees, memberships, fellowships, licences and other diplomas; books, documents, papers, records and Acts of Parliament have been examined, as well as the several Bills relating to medical reform which have been from time to time presented to Parliament with a view to legislation on this subject, and the evidence given before the Select Committee of the House of Commons appointed in 1879 and 1880 to consider certain of those Bills. The Report itself is signed by all the eleven members of the Commission, and it is divided into nine sections, which severally deal with the Grant of Medical Licences; The General Medical Council; Courses of Education; Courses of Examination; Grant of Medical Degrees, etc., by Universities and other bodies; Privileges of Registered Practitioners and Restrictions imposed upon Practitioners not Registered; Positions of Medical Practitioners holding Foreign and Colonial Diplomas; Conditions of Registration and Removal from the Register; and lastly, the Medical Act, 1858, and the Acts amending it.

Starting with the assumption that the Act of 1858 was passed rather in the interests of the general public than with a view to protecting the separate interests of the medical profession, the first section of the Report refers to the defects of the present licensing system resulting from the number of licensing bodies and from the differences in the character of their examinations, especially drawing attention to the circumstance that nearly all of them grant diplomas in medicine alone or surgery alone, although there is no point of medical reform on which there is such a general agreement as that the holding of a medical licence ought to imply the possession of a complete qualification for practice in all the three essential branches of medicine, surgery and midwifery. It is considered that the majority of the licensing authorities have shown a praiseworthy readiness to introduce improvements and that in most cases their examinations have been improved, but that in regard to some the possession of a diploma affords no such guarantee that its holder has a competent knowledge of medicine, surgery and midwifery as the Commission considers to be indispensable. In regard to this point it is considered that the only mode of duly ensuring such a standard of proficiency is by reducing the number of licensing authorities. It is therefore proposed that there shall be in each of the three divisions of the United Kingdom a Board, representing all the medical authorities of the division, for the purpose of conducting examinations for licence, subject to the general control of the Medical Council. It is proposed that each divisional board should contain one or more delegates of each chartered university or medical corporation, either existing or hereafter created, and the certificate of that board is to be necessary for admission to the Medical Register. Each divisional board is also to appoint members of the Medical Council and examiners; to regulate and supervise the courses of professional study and examinations; to keep a register of medical students in the division, and to report to the Medical Council, annually, on their general proceedings, as well as on the results of the examinations.

In speaking of the Medical Council the Report states that it is clearly proved to have rendered valuable services to the profession and to the public, notably in having brought about the universal adoption of a preliminary examination for intending medical students, and in the belief that there ought to be a supreme controlling authority in regard to medical licensing, the Commission proposes to entrust to the Medical Council larger powers than it has hitherto possessed. It is suggested that this Council shall be the sole licensing authority, and that it shall consist of eighteen members chosen for five years and eligible for re-election, six to be nominated by the Crown, two elected by registered members of the medical profession resident in England, one by the members in Scotland and Ireland, respectively, four by the English Divisional Board and two by the Scotch and Irish Boards respectively.

As regards the direct representation of the profession upon the Medical Council, the Commission recognizes the vital interest of the whole medical profession in the constitution of that body, while it insists that the interest of the public is the reason of its existence, and for the sake of better securing the full and complete confidence of the profession in the Council, it is deemed advisable to give the general practitioners an effective voice in it instead of only the governing bodies of the Medical Corporations, which can hardly be said to represent the great majority of practitioners. But while the Medical Council would thus be the supreme medical authority, exercising a general control over everything relating to medical licensing, it is not intended that the Council should be the executive or even the initiating body in questions relating to medical education and examination. The regulation of these matters would originate with the divisional boards, which would also be the executive bodies for administration. At the same time it would be in the power of the Council to inform the divisional board as to such conditions of educational examination as in its opinion ought to be of universal obligation throughout the United Kingdom, and when proposals of the Board are submitted for approval the Council should have power to vary them. It is not proposed to interfere with the administrative functions hitherto discharged by the Medical Council in connection with the Medical Register and the Pharmacopœia.

In regard to courses of education the Commission considers it would be a mistake to introduce absolute uniformity. Being anxious not in any way to diminish the interest which teaching bodies now take in medical education, or to lessen their responsibility in that respect, the Commission desires to leave them as much initiative as possible, and it holds the opinion that nothing should be done to weaken the individuality of the universities and corporations or to check emulation between the teaching institutions of the country.

As the details of courses of examinations are in a great measure dependent upon the adoption of the Commission's recommendations, they do not receive much notice in the Report, but it is especially mentioned that every intending medical student ought to pass an examination in general education before entering upon his medical studies, the purpose of this examination being to test the candidate as to the possession of a reasonable amount of general culture. Its subjects should not be of a technical or professional nature, and while care should be taken to prevent its standard being unduly raised or lowered by individual examiners, a sufficient variety of subjects should be included in it to allow of candidates making a selection from them according to their previous education and mental qualifications. According to the recommendations of the Medical Council, every student of medicine is now required to be registered on passing his preliminary examination. The Commission considers that this system should be continued and that the full period of medical study should be passed after the date of registration. It is proposed that this registration of medical students should be placed under the charge of the divisional boards and that it should be obtainable by forwarding a certificate of having passed a preliminary examination as required by the Medical Council. It is considered that there should be power to hold the examinations of the divisional boards at more than one place in each division if that be found desirable, and that while all candidates who pass are placed in one class, the examiners should have power to state that any individuals had passed with distinction. The fees should be such as to cover the cost of the examinations and the other expenses of the divisional boards, and also to provide the sum required to compensate such of the medical authorities as may be entitled to compensation for any pecuniary loss they may sustain by reason of the abolition of their privilege of conferring a licence to practise.

In regard to diplomas and degrees granted by medical authorities in virtue of powers conferred by Royal Charter or Act of Parliament the Commission recommends that the statutory privilege of conferring a medical licence should no longer be attached to them as was provided by the Medical Act, 1858; but it does not propose to interfere with the present powers of universities or corporations to confer these titles, and it deprecates any interference with the examinations of the medical authorities for their higher titles, to which the Commission attaches the greatest value as being the means of encouraging the acquisition of knowledge and skill in the medical profession.

On the subject of the assumption of medical titles by unregistered persons, the Commission is of opinion that the failure of the attempt to deal with the offence by clause forty of the Medical Act of 1858 was chiefly due to the difficulty of defining the offence in words, and not to any neglect of the Medical Council. The Commission also considers it undesirable to attempt preventing unregistered persons from practising, though it holds that they should be prevented from representing themselves as being registered or from assuming titles which would lead the public to believe they are regular medical men. In connection with this subject, it is held that prosecutions for offences under the Medical Act should be undertaken in England by the Public Prosecutor, in Scotland by the Procurator Fiscal, and in Ireland by the Crown Prosecutor, the moneys arising from conviction and recovery of penalties being paid to the Medical Council.

The difficulties arising from the position of registered medical practitioners in the colonies and that of the holders of colonial and foreign medical diplomas in the United Kingdom, and from the necessity of discriminating between the diplomas given by different foreign and colonial universities, are in the opinion of the Commission best dealt with by the Medical Council as proposed in the Government Bill of 1880.

As regards registration under the system proposed by the Commission, it is considered to be unnecessary to maintain more than one Registrar and one office of registration, as heretofore; but the correctness of the register being very important to the public, as well as to the medical profession, it is suggested that every registered practitioner should send annually to the Registrar his address and correct designation, in order to secure retention on the register; the power of erasure from the register for misconduct to rest, as now, with the Medical Council.

As a supplement to the Report and to a very great extent limiting its effect, if not entirely neutralizing it, there are appended a number of memoranda, in which six members of the Commission express their dissent from certain portions of the Report; but we must defer until a future occasion any futher reference to these memoranda.

We are pleased to be able to state that Mr. J. C. Thresh, Pharmaceutical Chemist, of Buxton, was a successful candidate in the recent examination for the degree of Doctor of Science in the University of London.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The ordinary monthly meeting of this Society was held in the Society's rooms, on Wednesday evening, June 14. Mr. Preston, the President, in the chair.

The minutes of the previous meeting having been read and other business transacted, the President called upon Mr. Dunnil to read a paper on "Dispensing in Sheffield."

Mr. Dunnil commenced by referring to the small amount of dispensing done by the pharmacists of Sheffield, due to the medical men doing their own dispensing. He argued that the explanation sometimes put forward, —namely, that chemists prescribed and that their charges for dispensing are too high,—was insufficient, and that dispensing should be in the hands of the class specially trained to the work and that it should be paid for in accordance with the skill and care involved. Regret was also expressed that there is not greater uniformity in chemists' charges. The author, in conclusion, said he hoped the time was not far distant when all the dispensing would be done by pharmacists, and he was of opinion if it were compulsory that medical practitioners should dispense only in cases of emergency that body would be glad.

In the discussion which followed, which was joined in by most present, the feeling prevailed that better and more uniform prices ought to be obtained, and that dispensing ought to be in the hands of the chemist entirely.

Mr. Ellinor said that the members of the Society had, on several occasions, tried to increase the prices for dispensing, and most certainly the chemist ought to be paid for his labour and his skill; it is not the cost of the articles, but the skill and care required that have to be considered. A query presented itself to his mind in connection with errors in prescriptions, Whose is the responsibility, the writer's or the chemist's? Certainly not the chemist's. The fact of there having been certain prescriptions sent out to chemists, with large doses of medicines ordered, to test if chemists used the full quantity of drugs ordered,—this being done by and with the consent of borough officials, in order to prosecute them, if necessary, under the Adulteration Act,—might be said to prove this? If so, the Adulteration Act relieved the chemist of the responsibility, and he must carry out the directions of the prescription, in order to comply with the Adulteration Act, regardless of the patient being poisoned or injured thereby.

A vote of thanks was awarded to Mr. Dunnil, on the motion of Mr. Furness, for his valuable paper.

Mr. J. P. Hewitt was elected a member of the Society.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, W.C., on Wednesday, June 21, 1882. Present:—Professor Attfield, F.R.S., President, in the chair; Messrs. H. B. Brady, F.R.S., Benger (Honorary Secretary), Carteighe (Honorary Secretary), Chipperfield, Ekin (Treasurer), Groves, Plowman, Southall, Squire, Taylor and Thresh.

The minutes of the previous meeting were read and confirmed.

Letters of apology for non-attendance were read from Messrs. O. R. Dawson (Southampton), Kinninmont (Glasgow), Payne (Belfast) and Randall (Southampton).

A grant of £10 to Mr. A. H. Jackson, of Strangeways, to purchase material for an investigation on the Oils of Cinnamon and Cassia was confirmed.

Mr. Chipperfield (Southampton), reported that the preparations of the Local Committee at Southampton were now complete. They had obtained for the meetings of the Conference the use of rooms admirably adapted to the purpose in the Watts Memorial Hall. Twenty-five beds had been secured at Radley's Hotel.

Mr. Chipperfield was thanked for his kindness in attending, and requested to secure, if possible, a larger number of beds at the same hotel.

Letters of thanks for copies of the 'Year-Book of Pharmacy for 1881' were read, from the Royal Society of London, the Pharmaceutical Society of Great Britain, the Hull Chemists' Association and the Sheffield Pharmaceutical and Chemical Society.

The Honorary Secretaries reported that papers had been already promised for the Southampton Meeting, by Messrs. Bransom, Dott, T. B. Groves, R. H. Parker, L. Siebold, Thresh and Dr. Quinlan.

The following eight gentlemen were elected members of the Conference:—Mr. H. B. Blayney, Liverpool; Mr. R. A. Fairclough, London; Mr. J. D. Hazard, Bournemouth; Mr. E. Jones, Hanley; Mr. W. A. McKeown, Belfast; Mr. H. E. Parkes, Hornsey; Mr. J. G. Sangster, London; and Mr. K. Senior, Sydney.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, June 22. Mr. R. H. Parker, Vice-President, in the chair.

Mr. R. A. Cripps read a paper on the "History of Citrine Ointment," in which he traced the entire history of this preparation up to recent times, giving a full account of the different processes and modifications which have been from time to time proposed.

A discussion followed the reading of the paper, in which the Chairman, Secretary, Messrs. Alcock, Braithwaite, and Taylor took part.

The Reporter on Botany. Mr. J. O. Braithwaite, then made a Report upon "Plant Movement." The author intends to bring the subject of "Plant Movement" before the Association in two Reports, the first dealing with the researches of Darwin, the second with those of Wiesner. The present paper dealt exclusively with the work of Darwin, of which a full and interesting account was given. The author had himself made experiments upon the circumnutation of certain parts of the plant. Diagrams showing the result of these experiments upon germinating peas, and also upon the shamrock, were exhibited, as were also the plants themselves.

A discussion followed the reading of the paper, in which the Chairman, Secretary, Messrs. Alcock, Haward, Short, Thompson and Yeatman took part.

The meeting then adjourned.

ROYAL INSTITUTION OF GREAT BRITAIN.

Some of the Dangerous Properties of Dusts.*

BY F. A. ABEL, C.B., F.R.S.

(*Continued from Vol. XII., page* 1066).

The report of Faraday and Lyell was published in the *Philosophical Magazine* for January, 1845, and was followed by a letter from Faraday in the February number of the same publication, in which he referred to the lecture just delivered at the Royal Institution, and made further suggestions with respect to the method of ventilating the mines suggested in the report. But it appears that these publications remained long unknown in France, for in 1855 M. du Souich, Chief Government Mining Engineer of the Saint Étienne arrondissement, when referring to an explosion which had occurred at Firminy, advanced, as new, the view that the deposition of crusts of a light coke upon the props was due to dust which was

* Read at the Weekly Evening Meeting, Friday, April, 28, 1882.

swept up and transported to a distance by the violent current produced by the explosion, and which, being in part inflamed, would carry on and prolong the effects of the fire-damp. The fact that men near the pit's mouth received burns and other injuries, while others who were in workings near the seat of the explosion, but out of the main air current, escaped unhurt, was ascribed by him to this ignition and carriage of flame by dust. Had the results of the explosion been entirely due to the mine being highly charged with gas, the explosion must, he considered, have extended to those portions. On the occasion of two explosions in 1861, M. du Souich again dwelt upon his views regarding the part played by coal dust in increasing the disastrous effects of fire-damp explosions. In 1864–67, M. Verpilleux instituted experiments which led him to the conclusion that coal dust plays an important part in coal mine explosions; the subject was also pursued by several other French mining engineers at about the same time, and especially by M. Vital, who made some experiments on a small scale, in 1875, in connection with an inquiry into the nature and cause of an explosion which had occurred the year before at the Campagnac Colliery, and in a part where no fire-damp had ever been detected. An examination for gas had been made by the overman with a Mueselcr lamp just before a shot was fired, and after the first shot, a second shot was prepared, and the fuse having been ignited, the men retreated, when, after a short interval, an explosion took place, and the men stated that they saw a body of reddish flame advancing upon them. After examining the nature of dust collected in the mine, and instituting some special experiments upon a very small scale for the purpose of ascertaining whether, and to what extent, the flame from a small charge of powder was lengthened, when projected, like the flame from a blown-out shot, into air containing fine coal dust in suspension, M. Vital concluded that very fine coal dust, very rich in volatile (inflammable) constituents, will take fire when raised by an explosion, and that portions of the coal are successively decomposed, yielding explosive mixtures with the air, whereby the fire is carried along; the intensity or violence of the burning being much influenced by the physical characters (fineness, etc.) of the dust. He also pointed out that an explosion of fire-damp, while taking place almost instantaneously, inflames or decomposes a small quantity of coal dust raised thereby; explosive action being thus propagated after the fire-damp explosion has ceased. Soon after M. Vital's investigation of the subject, Mr. W. Galloway commenced a series of valuable experiments upon a larger scale, with the view of investigating the influence of coal dust in colliery explosions, and the results were communicated by him to the Royal Society in two papers in 1876 and 1879. The conclusions to which Mr. Galloway was led by the experiments described in his first paper, were to the effect that a mixture of air and a particular coal dust which had been made the subject of chemical examination and practical experiment was not inflammable at the ordinary pressure and temperature, but that the presence of a very small proportion of fire-damp in the air, the existence of which could not be detected with the Davy lamp by the most experienced observer, rendered this dust inflammable, and caused it to burn freely with a red, smoky flame. From this it was inferred that an explosion, when originated in any way whatever in a dry and dusty mine, may extend itself to remote parts of the workings, where the presence of fire-damp was quite unsuspected.

In his second paper, Mr. Galloway shows that the return air of a fiery mine which, though furnishing no indication of the presence of gas when examined in the usual way (by means of a Davy safety lamp), might in his opinion contain from 2 to 2·5 per cent., may be rendered inflammable by suspending coal dust in it. He also described experiments by which it appeared to be demonstrated that the flame produced by the explosion of fire-damp in a particular part of a mine might be propagated, at any rate to some extent, by coal dust raised by the explosion and suspended in the air travelling through the mine, even in the *complete absence* of fire-damp in the air. The apparatus used by Mr. Galloway was constructed on a somewhat extensive scale. In connection with the channel or gallery through which a current of air, with or without coal dust in suspension, was passed, was a receptacle in which a mixture of pit gas (from Llwynpia Colliery) and of air was prepared and exploded. The direct communication between the gas vessel and the gallery (representing a mine way) was only interrupted by a diaphragm composed of from two to six leaves of newspaper; this separator being burst through by the explosion of a mixture of nearly two cubic feet of fire-damp with the requisite proportion of air. The coal dust was placed on the floor of the gallery and upon certain shelves fixed in it. It appeared open to question whether, with the employment of this apparatus, there was not a possibility of very small quantities of fire-damp penetrating, before the explosion, into the gallery from the explosive chamber, through the closing arrangement above alluded to, and whether the results obtained in the gallery might, consequently, be accepted as produced solely by the effect of the concussion produced and flame promoted by the gas explosion in the separate chamber.

In a paper just communicated to the Royal Society, Mr. Galloway argues that any amount of gas which may thus escape into the gallery must be altogether insignificant as regards any possible influence upon the results obtained.

The conclusion now arrived at by Mr. Galloway, as the result of continued experiments with this apparatus, of which he has just given a further account, and of his examination into the effects produced by the Penygraig explosion in December, 1880, and the Risca and Seaham explosions of that year, is confirmatory of that published by him last year, namely, that the very decided view which he first held, "that a mixture of air and coal dust is not inflammable at ordinary pressure and temperature without the presence of a small proportion of fire-damp," has not been borne out by his further experiments, as he considers that he has now shown "conclusively that fire-damp is altogether unnecessary for the propagation of flame with explosive effects by a mixture of coal dust and air," when the scale on which the experiments are made is large enough, and when the fineness and dryness of the dust are "unquestionable."

This conclusion coincides in the main with that arrived at in 1878, as the results of experiments by Professor Freire Marreco, conducted in connection with the North of England Institute of Mining and Mechanical Engineers, which Society, as well as the Chesterfield and Derbyshire Institute of Engineers, has laboured very usefully in this direction cotemporaneously with Mr. Galloway. The most recent conclusions of the latter in respect to coal dust were in fact forestalled by those which the late lamented Professor Marreco in association with Mr. P. D. Morison communicated to the first named Institute in November, 1878, and which were published in its 'Transactions' of that date.

Messrs. Marreco and Morison's experiments were carried out in galleries or long boxes, representing mine workings, though on a smaller scale than Mr. Galloway's later apparatus, and constructed somewhat differently in their details. The apparatus used by them at Harton Colliery (and with which experiments have since been continued by Messrs. Lindsay Wood and G. May) was in fact a double gallery, so arranged that the air current which passed into one gallery made its exit at the end of the second, alongside the point of its first entrance. The mode of proceeding was to fire successively two powder shots, in different positions in the gallery box, from small cannon, so as to represent blown-out shots in the effects produced; coal dust was placed upon the floor of the box, and one shot was first fired against the air current which was passing at a known velocity. The dust cloud thereby raised was carried along by the current and a second shot was fired into it, and, in a large number of experiments made with many different descriptions of dust, the flame produced by the second shot was increased by that of inflamed dust, a comparatively clear flame being sometimes produced, while in other instances it was accompanied by a shower of sparks. The view taken by Vital, Marreco, and others, regarding the action of coal dust in propagating flame in air free from fire-damp, is to the effect that the first portions of dust acted upon by the inflamed gases of the shot liberate inflammable gas which mixes with the air, and is fired, the non-volatile part of the coal being in part consumed and in part deposited as a feeble coke. Some examination of coked deposits of dust, sent to Marreco subsequently by Mr. Galloway, confirmed the observations originally made by Faraday and Lyell, that the coal dust is in part submitted to destructive distillation during the progress of the flame through the dust-laden air. Marreco considers that, although a proportion of the heat developed by the burning dust is absorbed by the gasification of the coal-constituents, the heat of combustion of these suffices to leave a margin for the carrying on of the action from one particle of dust to another, provided these be in sufficiently close proximity to each other.

In the experiments made by the Chesterfield and Derbyshire Institute of Engineers, in a very long gallery, results were obtained very similar to those of Marreco and Morison, and it was also found that a lengthening of a gas flame, which was placed in the gallery, could be obtained by causing the current of air to carry with it thick clouds of some descriptions of coal dust.

Many instances are on record in this country and others of the firing, with semi-explosive violence, of clouds of coal dust, produced either in the open air, or in localities where no fire-damp could exist, some portions of the mixture of dust and air having come into contact with a flame or fire. Thus Marreco and Morison mention a case of a considerable quantity of coal dust, which had been accidentally thrown over some screens at a pit's mouth, flashing into flame as the dust cloud came into contact with a neighbouring fire, and burning a man very severely; and another accident, which occurred in a stone-drift, where it was believed that no gas could possibly be present. A considerable body of rock was dislodged and coal dust raised by the firing of a shot, the flame of which fired the air-and-dust mixture, with very mischievous results. From 50,000 to 60,000 cubic feet of fresh air were said to be passing through the drift per minute when this accident occurred.

There appear good grounds for believing that, provided coal dust be sufficiently fine and thickly suspended in the air, and of a readily inflammable nature, fire may travel to a considerable distance in the working of a mine, through its agency, in the complete absence of fire-damp. The effects of transmission of flame in this way would be decidedly different, and much inferior in violence, to those produced by an explosion of fire-damp and air, or of a mixture of these with coal dust; the comparative suddenness of the gas explosion would produce greater destruction and less burning effects than the comparatively gradual explosion, or the rapid burning of a dust-and-air mixture. In the latter case, the coal dust will generally be considerably in excess of the air needed for its combustion, so that, however finely divided, much will escape being burned, and may be only very partially coked, and it is conceivable that, as suggested by Mr. Galloway, a second rapid burning or semi-explosion may be caused by the inrush of air, following the first explosion, into the workings which may be thick with heated and only partially burned dust, some of which may still be incandescent.

Considering that, since first Faraday and Lyell directed attention to the dangers of coal dust in mines, its behaviour has been made the subject of many series of experiments and published reports here and abroad, it is remarkable that in most instances of coal-mine explosions, until quite recently, the probable effect of coal dust in increasing their magnitude does not appear to have received the serious attention which it merits at the hands of mine owners and of those in authority connected with coal mines. When the Royal Commission on Accidents in Mines was appointed it collected evidence from H.M. inspectors of mines, from experienced colliery owners and mining engineers, and from selected pitmen, with respect to the causes of accidents, and that evidence included several statements regarding the possible influence of coal dust in aggravating explosions, but the preponderance of opinion of H.M. inspectors was against the view that explosions could originate with, or be to any great extent propagated by coal dust *in the absence* of fire-damp. The only experiment on a practical scale bearing upon the subject which appears to have been made until quite recently is that of Mr. H. Hall, Mine Inspector of the N. Wales, etc., District, who, in firing charges of 4 lbs. of powder from a cannon in an adit driven about 50 yards from the surface in a coal seam on the dip, coal dust being sprinkled upon the floor, obtained flame extending to distances of 30 to 60 yards, while without the dust the flame of the shot did not extend more than 6 or 7 yards.* Some decided opinions were expressed that the supposed influence of coal dust in aggravating explosions was over-rated, and that it would certainly not lead to explosions in the absence of gas. On the other hand, Mr. Galloway expressed a strong opinion that some of the most extensive of recent explosions, such as those at Llan and Abercarne, were at any rate largely contributed to by coal dust, and more recently, on the occasion of the inquiry into the Penygraig explosion, he gave evidence to the effect that the disastrous results of this explosion were mainly if not entirely ascribable to the action of coal dust, supporting this opinion by the results of a minute examination into the condition of the pit, of the sufferers, etc., after the accident.

When the terrible calamity which occurred at Seaham Colliery in September, 1880, was officially inquired into the suggestion was very decidedly put forward by the miners' representatives that the coal dust which existed in large quantities in some parts of the mine, and especially near the spot where it was surmised that the explosion had originated, might have had much to do with the accident. Indeed the opinion was strongly entertained by some that it was entirely due to the ignition of coal dust, in the absence of gas, by the flame from a blown-out shot. The lecturer was consequently requested by the Home Secretary to make experiments with samples of dust collected in different parts of the mine, and the results obtained with them led to an extension of experiments with dust from other collieries in different parts of the kingdom. These experiments, carried to a certain point for the immediate purpose of the Seaham inquiry, have been interrupted for some time, but the Royal Commission has now resumed them with the object of obtaining more precise data in connection with certain results which were elicited by the first part of the investigation.

The earlier experiments were carried on at the Garswood Hall Colliery, where a constant and abundant supply of pit-gas (a so-called blower) is brought to the surface, and was kindly placed at the service of the Commission by Messrs. Smethurst and Co., together with many conveniences, for the purposes of these and other important experiments upon which they have been engaged. The apparatus used at Garswood for the experiments with the Seaham and other dusts, was similar in character to those employed by Freire Marreco, Galloway, and others, great pains being taken to secure accuracy

* Mr. Hall stated that the air in this adit was "practically" free from gas, but did not maintain its *absolute* freedom.

and uniformity in the velocity of the air currents passing through the gallery, in the proportion of pit-gas, or fire-damp, used with the air, and in the intimacy of the mixture. In order to raise the air current in the gallery to a temperature similar to that of the atmosphere in colliery workings, the air supply was drawn through a system of heated pipes, so that, when passing at as high a velocity as 1000 feet per minute its temperature would be raised up to 80° or 85° F., even in the very severe weather during which some of these experiments were made.

The samples of coal dust experimented with were examined with respect to fineness, proportions of volatile matter and ash, and one or two other points, and they were all carefully dried before use.

Experiments were made in the first instance with a view of ascertaining the smallest proportion of fire-damp which, when mixed with the air passing through the apparatus, would furnish an atmosphere capable of firing at a naked flame of a particular size, placed in the gallery. It was next ascertained what quantity of gas below that proportion was needed to impart to the mixture of air with a large quantity of each particular coal dust the property of exploding throughout the gallery. By these experiments the samples were classed in the order of their sensitiveness to explosion, and it was found that those which were very rich in pure coal and which contained the highest proportion of very fine dust were the most sensitive, *i.e.* required the lowest proportions of fire-damp in air to bring them to explode readily when suspended in a dense cloud. But with the samples containing larger proportions of non-combustible matter the order of sensitiveness did not necessarily harmonize with the comparative richness of a sample in pure coal, nor with its comparative fineness, and this was strikingly illustrated by a sample of dust from one of the roads in Seaham Colliery, which contained more than half its weight of non-combustible matter, yet ranked only third in order of sensitiveness, while another sample, containing considerably more coal and a somewhat larger proportion of the finer dust, ranked fifth.

Another point clearly established, and confirming by more accurate data the observations of earlier experiments, was, that the proportion of fire-damp required in a mine to bring dust into operation as a readily exploding material when thickly suspended in the air is bordering upon and even below the smallest amount which can be detected in the atmosphere of a mine by the most practical observer with the use of the Davy lamp, the only means of searching for gas which has until quite recently been employed in mines. The highest proportion which can be thus detected by an experienced operator is stated to be about 2 per cent. Explosions were produced by dusts suspended in air travelling at a velocity of 600 feet per minute, when fire-damp was present in proportions ranging from 2 to 2·75 per cent.; in currents of low velocity the same result was produced with a sensitive dust in the presence of only 1·5 per cent. of fire-damp, and ignitions which approached explosions in their nature and extended to considerable distances were obtained with this dust in air containing still smaller proportions of gas. Mixtures of fire-damp and air bordering upon those which will ignite upon the approach of flame were found to be instantaneously fired by a lamp if they contain only a few particles of dust in suspension, and in connection with this fact the interesting observation was made that such dust particles need not be inflammable nor combustible to produce the result named. Mixtures of air and gas which passed a naked flame without any symptom of ignition were inflamed when particles of a fine light powder such as calcined magnesia were suspended in them. The action of certain of the pit dusts which contain comparatively little coal, in determining the ignition of mixtures of air and small proportions of fire-damp, is possibly of the same character as the behaviour of such a dust as calcined magnesia. The power of favouring the ignition of mixtures of fire-damp and air was not exhibited by some other powders similar in fineness to the latter, but differing in structure and density from this and one or two other non-combustible dusts which may be called active; even different samples of magnesia, differing somewhat in lightness from each other, appeared to possess the activity in different degrees. These facts seem to favour the view that a dust possessing particular physical characteristics exerts a contact- or catalytic action upon gas mixtures, similar to that known to be possessed by platinum and some other substances under particular conditions. Thus, when finely divided platinum, or even a clean recently heated surface of the compact metal, is brought into contact with mixtures of hydrogen, or of a hydrocarbon gas or vapour, with oxygen or air, oxidation of the hydrogen or hydrocarbon is at once established, accompanied by the development of heat, whereby the temperature of the metal is raised and chemical activity promoted, so that heat speedily accumulates, raising the metal to a temperature sufficiently high to bring the surrounding gas-mixture to the exploding point. If the metal presents a very large surface, or is in a specially porous condition, as in the form of sponge or very fine powder (*platinum black*), the explosion of the gas-mixture may follow very rapidly, or almost instantly, upon the first contact of some portion with it.*

In many of the experiments with calcined magnesia just referred to, it was distinctly noticed that a dark space intervened between the gas flame used as the source of heat and the flare produced by the ignition of the gas mixture through the influence of the dust cloud suspended in it, which would seem to indicate that the dust particles immediately upon passing through the flame established some amount of oxidation of the fire-damp, which proceeded with increased rapidity as the dust became more highly heated through the chemical action developed, so that within a short distance from the point where the heating commenced the dust became incandescent, and the ignition of the gas-mixture followed. Further experiments which are contemplated may elucidate the precise nature of this action of non-combustible dust in promoting the ignition of gas-mixtures which, in the absence of dust, are not inflammable; there appears little doubt, however, that it constitutes one element in the dangers arising from the presence of dust in the air of a mine which contains a small proportion of fire-damp, and in which a large body of flame is accidentally produced, either by a blown-out shot, or by a fire-damp explosion of local character.

Numerous experiments similar to those of Marreco and Morison were made by the lecturer at Wigan with mixtures of air and coal dust from Seaham and other collieries, in the complete absence of fire-damp, which were passed through the apparatus at different velocities up to 1000 feet per minute. Small cannon, specially constructed to ensure uniformity in the volume of flame produced at different times, were fired in them, either singly or in pairs in rapid succession; and exposed heaps of guncotton and of slow and quick burning gunpowder were exploded in the dust-laden air. The results occasionally confirmed to some extent those of Marreco and Morison and the Chesterfield experiments. At velocities of 400 feet per minute the dust, which was either passing at the time or was raised by the concussion of a first shot, did not appear to produce any increase in the volume of

* This action of platinum (or palladium) has recently received applications bearing special reference to the existence of explosive gas mixtures in coal mines. The one consists in an apparatus proposed by Mr. Körner for removing, by slow combustion, local accumulations of fire-damp; the other is a very simple and portable photometric apparatus devised by Mr. G. H. Liveing, by which proportions of fire-damp much lower than the smallest amount discoverable by the Davy lamp in the hands of the most expert, can be readily and quickly detected, and the amount estimated with considerable accuracy.

flame furnished by the cannon, but a decided though inconsiderable lengthening of the flame was several times observed at higher velocities and with the employment of the most inflammable dusts. Some of these, when thickly suspended in air travelling at velocities of 500 to 1000 feet per minute, and exposed to the action of a large flash of flame (as produced by the loose heaps of guncotton and *blasting* powder) exhibited a tendency not only to burn explosively in and close around the flame but also to propagate flame, or cause it to travel along some distance; but the most decisive results of these experiments were not of a nature to warrant the conclusion that flame could be carried along indefinitely, or even to a very considerable distance, by coal dust in the complete absence of fire-damp, as now maintained by Mr. Galloway. There can be no question that the scale of magnitude upon which the first ignition in the dust-laden atmosphere is produced must greatly influence the extent to which the propagation of flame in this way will extend, and Mr. Galloway's experiments at Llwynpia, therefore, were likely to develope conditions more nearly approaching those of the real state of things in a mine than experiments in galleries of smaller dimensions, and with small initiating volumes of flame. But the necessity for caution in deducing very decided conclusions from even large-scale experiments appears to be illustrated by some of Mr. Galloway's results, inasmuch as some of the great distances to which the flame extended were observed under conditions decidedly favourable to the projection of the flame by causes which would not come into play in the same way in a mine-working. The experiments made some years ago by Mr. Hall in an adit (which have already been referred to) appear to have a more direct bearing upon results likely to be actually produced underground in a dust-laden atmosphere. In those experiments the extreme distance to which flame was carried by dust first ignited by the flame from a very excessive charge of powder (4 lb.) was 180 feet. It is of course possible that the coal used was not of the most inflammable description, and that its fineness and density were not most favourable to its becoming very thickly suspended in air. On the other hand, Mr. Hall stated, in his evidence before the Royal Commission, that the atmosphere in the adit was only "practically" free from gas.

The volume of flame from a blown-out shot in a mine-working is generally considerable, but it appears that exaggerated estimates are entertained of the distance to which, *in the absence of dust*, the flame will be projected, and it is probable that the large volumes of flame, extending occasionally to many yards from the spot where the shot was fired, are in a great measure due to the ignition of dust raised by the concussion and rush of air at the instant of firing. Mr. Hall, in his experiments in the adit, found that the flame from the shot of 4 lb. of powder reached to a distance of only 18 to 21 feet when no dust was present. A few months ago that official directed the attention of the lecturer to the occurrence of two accidents in the Liverpool district, each one occasioned by a shot of 1 lb. of powder blowing out its stemming without shaking or bringing down any coal. In both instances the shot lighter and two pitmen had retired about 100 feet from the seat of the shot, that is, about 30 feet in a straight line with it, and 60 to 80 feet along both directions of a working running at right angles to the drift in the face of which the charge was fired. In the case of one accident a man was killed, and serious injuries were sustained by the other men in both instances. There were signs of charring upon the props up to, and 5 or 6 feet beyond, where the men were standing, but they did not extend farther. The drift and the level in which these accidents occurred were 5 feet high and 12 feet wide. Mr. Hall informed the lecturer that a strong impression existed among mining men on the spot that the flame of the shot, quite unaided by gas or coal dust (the latter was known to be present), would have extended so as to produce the effects described. This appeared so at variance with Mr. Hall's experiments in an underground working, and with Mr. Abel's own experience in other directions, that the latter has endeavoured to obtain some precise experimental data with regard to the distance to which any burning effect from a blown-out charge of 1 lb. or 1½ lb. of powder would extend in a mine working, in the absence of dust. With this object he availed himself of the friendly assistance of Major Durford, R.E., Instructor in Field Fortifications at the School of Military Engineering, Chatham, under whose direction Lieutenant Raban has carried out an instructive series of experiments in accordance with suggestions made by Mr. Abel as the work proceeded.

(*To be continued.*)

Parliamentary and Law Proceedings.

PROSECUTION UNDER THE 17TH SECTION OF THE PHARMACY ACT.

At the Hyde Petty Sessions, on Monday, June 19, before Messrs. John Wood (Chairman), and W. Sidebottom, Owen Stafford, of 51, Market Street, Hyde, was summoned by the Chemists and Druggists' Trade Association for selling a certain poison, to wit laudanum, the same being a preparation of opium, and not labelling the article properly.

Mr. Henry Glaisyer, Solicitor to the Association, appeared for the prosecution; Mr. T. Drinkwater appeared for the defence, and said he should plead guilty to the offence.

Mr. Glaisyer said Mr. Templeman was the Assistant-Secretary to the Chemists and Druggists' Trade Protection Association, whose head office was at Birmingham, and the prosecution was brought under the provisions of the Pharmacy Act of 1868, which required that certain formalities should accompany and precede the sale of poisons. They would be found in the 17th section of the Pharmacy Act of 1868. Defendant was not a registered chemist and druggist, and had no right to deal in poisons at all.

The Chairman supposed it was a question as to whether defendant was or was not a qualified man.

Mr. Glaisyer said it was more a question of using labels, so that there might be no mistake when the poisons came to be used. The 17th section of the Pharmacy Act provided that no person should undertake the sale of poisons by wholesale or retail unless the boxes or covers were distinctly labelled with the name of the article, and the word "poison," supplemented by the name of the particular poison sold. The poison in question was a preparation of opium, and was dealt with in the second part of the schedule. In this case, on the label in question appeared the word "poison," and the name of Mr. Stafford as the seller, but the name of the article did not appear, and the Bench would see that that was a very serious offence, because if the nature of the poison was not known, and supposing several bottles were standing together, a person would not know which to take.

The Chairman said he should think the word "poison" was sufficiently distinctive. Supposing the Latin word for the poison appeared on the label, how could that afford any security?

Mr. Glaisyer said a person might have several bottles labelled with the word "poison," and being ignorant of the specific contents of each bottle might very easily select the wrong one if laudanum was wanted. Laudanum was sufficiently well known in English, and was often used for the toothache.

The Chairman mentioned that there were vegetable poisons.

Mr. Glaisyer said if the bottles were properly labelled a person would know which of the bottles he had to take. On the 12th inst. Mr. Templeman visited Hyde, and proceeded to the shop occupied by Mr. Stafford. Amongst other things he purchased was a bottle of laudanum produced. The label on the bottle was marked "Poison, Owen Stafford, formerly with T. Standring and Son, Manchester, Medical Hall, 51, Market Street, Hyde." 9½*d.* was paid for the bottle. Mr. Templeman subsequently analysed the laudanum supplied, and had found it to be a preparation of opium, as he expected. All preparations of opium and poppies were poisons in the meaning of the Act.

The Chairman: You say it should be described as laudanum?

Mr. Glaisyer: Yes.

Mr. Sidebottom: Is Mr. Templeman one of the agents of the Association?

Mr. Glaisyer: He is the Assistant-Secretary.

The Chairman: He goes about to see that the articles sold are genuine?

Mr. Glaisyer: Yes, and for the protection of chemists and druggists generally.

Mr. Drinkwater said he was not going to dispute the facts, as the Act plainly stated that the word "laudanum" should have appeared on the paper. He wished, however, to state the circumstances under which the sale took place. Mr. Templeman went into his client's shop and asked for a 6*d.* feeding bottle, then for some linseed meal, and afterwards for 2*d.* of laudanum to mix with it, as he wanted to make a poultice for his wife. Defendant asked Mr. Templeman what quantity of ingredients should be put together, and knowing it was to be made into a poultice he did not take the same care he would have done in an ordinary individual, but to someone like Mr. Templeman, who appeared to have some faculties about him, the word poison would be sufficiently distinctive.

The Chairman said the Act was intended to apply to the general public. Mr. Templeman no doubt knew what the word poison meant, but caution must be used to protect the general public.

Mr. Drinkwater said that in the case of a gentleman like Mr. Templeman no harm could be done. Defendant was a very respectable gentleman, and held certificates from gentlemen in London that he had a good knowledge of his profession, therefore he submitted that as the word laudanum had merely been omitted from the label it was not a serious offence, and he thought the ends of justice would be met if the Bench imposed the smallest fine it was in their power to inflict. Mr. Stafford would take care that he should not again be wanting in due caution.

The Chairman said they were quite satisfied that the requirements of the Act had not been complied with. Because there might have been no fear that evil consequences would ensue in this case, yet if the public saw that the Bench were inclined to treat the present offence with laxity serious consequences might ensue from the future sale of poisons, and the Bench would be blamed. It was not a case calling for a heavy penalty, and as it seemed to have been an act of carelessness on the part of Mr. Stafford rather than with an intention to infringe the law, he would be fined 10*s.* and costs.

Mr. Glaisyer asked if any extra costs would by allowed.

The Chairman said they thought it was a prosecution which could not have been conducted without the aid of an advocate, and therefore they should allow one guinea for the advocate's fee in addition to the other costs.—*North Cheshire Herald.*

Adulterated Sweet Spirit of Nitre.

At the same court, Joseph Green, grocer, Hyde, was summoned for having sold to Sergeant Harrison, on May 24, a quantity of sweet spirit of nitre which was not of the nature, quality and substance demanded.

Defendant pleaded not guilty.

Sergeant Harrison stated that on May 24, he called at defendant's shop in Hyde Lane, Hyde. Defendant's wife was in charge of the shop, and he asked her for 2 oz. of sweet spirit of nitre. She supplied it, and witness paid her 6*d.* He afterwards told her he was buying it for the purpose of being analysed by the county analyst, Mr. Carter Bell, and offered to divide it into three parts, but she said it did not matter, she sold it the same as she got it from a firm in Ashton. Constable Ashford sealed the bottle, and witness put on a label in her presence to distinguish the bottle. The following day he delivered it to Mr. Bell. After he had paid her for the sweet nitre she drew his attention to a small label at the bottom of the bottle, which stated that the sweet nitre was not pure and would not stand the test.

Defendant produced a bottle containing sweet nitre, and asked witness if he could not see the label upon it through the shop window.

The sergeant said it was not the same bottle, but a much smaller one than that from which he was supplied, and the label was nothing near as large.

Defendant said he had no other bottle in the shop, and he was not aware that there was any other quality of sweet nitre.

Constable Ashford corroborated Sergeant Harrison.

Captain Lingard produced the analyst's certificate, which stated that the sample submitted to him was adulterated with 25 per cent. of water.

A fine of 10*s.* and costs or seven days was imposed.

James Buckley pleaded guilty to a similar offence.

Sergeant Harrison stated that on May 18, he called at defendant's shop at Micklehurst, and purchased 4 oz. of sweet spirit of nitre, for which he paid 1*s.* Defendant and his wife were present, and the defendant sold the article as they got it.

The sweet spirit of nitre, according to the analyst's certificate produced by Captain Lingard, was adulterated with the same percentage of water as in the last case.

Defendant, in reply to Captain Lingard, said he purchased the sweet nitre from Bickell's, of Ashton.

The Chairman said it was an extraordinary thing tradesmen did not protect themselves when they knew the regulations of the Act of Parliament, and defendant would be fined 10*s.* and costs.

Paregoric without Opium.

At the same court, Thomas Farrand, of Tintwistle, pleaded guilty to having sold to Sergeant Harrison a quantity of paregoric which was not of the nature, quality and substance demanded.

Sergeant Harrison stated that on May 18, he called at defendant's shop at Micklehurst, and purchased from his wife 2 oz. of paregoric, for which he paid 6*d.* He also bought 2 oz. of mustard, but that had been returned pure.

The analyst's certificate stated that the sample was adulterated with 17 per cent. of water, and it did not contain opium, which was one of the ingredients of paregoric, therefore it came under the 9th section of the Act.

Defendant said he bought it and sold it as pure paregoric.

The Chairman: Have you a written warranty from the seller?

Defendant: They will not give us a warranty.

The Chairman: Then you must take the consequences.

Defendant said he bought the paregoric from Bostock's, of Ashton.

Fined 10*s.* and costs or seven days.—*North Cheshire Herald.*

Reviews.

A Treatise on Chemistry. By H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S. Volume III. The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. Part I. London: Macmillan and Co.

This is a continuation of the treatise on chemistry upon which Professors Roscoe and Schorlemmer are engaged, which they have previously carried to the end of the metallic elements.

The volume before us commences with an historical introduction, giving an account of the gradual development of our knowledge of the carbon compounds up to 1844, when Gerhardt introduced the terms homologous and heterologous series. Then follows a description of the various methods of organic analysis, commencing with that employed by Lavoisier, in 1781, and ending with those at present in use. This section closes with a very complete account of the methods of determining vapour densities, which includes a full description of those recently introduced by Victor and Carl Meyer. These practical matters are followed by an explanation of the methods by which molecular formulæ are ascertained, and by a notice of the phenomena known as isomerism, metamerism, polymerism. The system upon which carbon compounds are classified is next entered upon, and then the authors pass to the consideration of the members of the chief groups. In this, as in the earlier part of the book, the treatment adopted is historical, systematic, and at the same time in the case of the more important substances, eminently practical, full details of the modes of production being given in these cases. The system of classification which Professors Roscoe and Schorlemmer have adopted is not unfamiliar. Commencing with the paraffins, methane and its derivatives are first studied, then ethane and its derivatives and so on. Thus methane, methyl alcohol, and the oxide, chloride, and cyanide of methyl are considered together with formic aldehyde and formic acid; an arrangement which has the advantage of impressing the relations of these bodies on the mind of the reader with great distinctness. The general nature of classes of compounds, such as the alcohols, acids, amines, etc., is to some extent discussed before the detailed study of the hydrocarbons and their derivatives is commenced.

From the foregoing sketch it will be seen that in this work the subject is treated in a somewhat different manner to that which has of late been most frequently adopted by writers on organic chemistry in this country. In the first place, there is generally more detailed information about important commercial operations, and rather a fuller account of analytical methods. In the second place, each substance is here considered in connection with a group of dissimilar bodies, all of which may be regarded as derived from the same hydrocarbon by substitution, instead of being taken with a group of similar bodies. Thus formic and acetic acids instead of being grouped together with the other fatty acids are apart, being placed with the methane and ethane groups respectively. As it is highly desirable that neither of these points of view should be lost sight of, this latter feature in Professors Roscoe and Schorlemmer's work is all the more welcome.

In the sections on organic analysis the student will find almost all that is necessary to enable him to attack work of this kind, and attention is drawn (p. 58) to the importance of certain precautions in employing the modern breechloading process for determining carbon and hydrogen. Our own experience with this process seems to show that very often the inaccurate results obtained are due to the employment of too greatly reduced pressure, which seems to result in air, highly charged with moisture and carbon dioxide from the neighbouring furnace, diffusing through the india-rubber connection between the drying tube and that employed for absorbing the carbon dioxide. This can be avoided by using a very short connection; but a more satisfactory plan is to so arrange the flow of water from the aspirator that the pressure inside the tubes is only just below that of the air. We are sorry not to see any mention of the method lately introduced by Mr. Perkin of absorbing nitrous fumes by means of a mixture of chromate of potassium and manganese dioxide heated to about 230° C. This plan requires a little care, it is true, but if properly carried out it offers considerable advantages.

The portions of the work which treat of such bodies as alcohol, ether, acetic acid, and methyl chloride, generally include a considerable body of information as to the manufacturers' modes of preparing them, and with the very complete account of the various methods which have been used for rectifying alcohol, and for determining the strength of solutions of it, would be specially valuable to our readers.

The part of organic chemistry included in so much of the work as is in our hands at present does not extend beyond the paraffins and their derivatives, and certain bodies allied to them, and it closes with an account of the chemistry of soap. This division of the subject is so comparatively well known that there is not so much room for controversy as in many others.

The numerous references to original papers which occur throughout the book and the historical details with which it abounds from beginning to end are features which add enormously to its value and to the interest with which it will be read. Here and there, however, there are blemishes due to imperfect revision, as, for instance, in the description of the preparation of zinc-methyl (p. 247), where it is stated that upon methyl chloride being added to zinc sulphate crystalline zinc-methyl iodide is formed. Nevertheless, we can strongly recommend the work to students of this branch of science who would know their subject in all its aspects, and to more than an elementary extent. Probably there never was a more thoroughly readable book on chemistry written.

On the Treatment of Cancer. By John Clay. London: J. and A. Churchill. 1882.

This pamphlet, although written principally for the medical practitioner, contains an unusually large proportion of matter that is of interest to the pharmacist. Rather more than two years have elapsed since the publication in the *Lancet* of a communication from Professor Clay upon the treatment of cancer with Chian turpentine directed considerable attention to that nearly obsolete drug. Such pharmacists or wholesale druggists as were fortunate enough to have any quantity of the drug then among their old stock were able to dispose of it profitably; those who had not were compelled to look about for a supply, and speculative calculations were even made as to whether the next year's production in the island of Scio would be equal to what would be required. No doubt the demand suddenly created for a comparatively unknown drug brought some spurious articles into the market, and Professor Clay has shown great readiness to attribute the non-success following the treatment that has been reported by different practitioners to the substitution of other substances for Chian turpentine by the dispenser. It may be useful to remark, therefore, that Professor Clay adopts the "excellent description" of the drug given in the 'Pharmacographia' as a means of diagnosing the genuine article. He also speaks of an unstrained or rough kind of Chian turpentine that he has received direct from Scio, which although "the most genuine form of the drug, as it has not been subjected to any artificial method of purification," presents external characters so different to those of the strained gum that it might be condemned by the uninitiated as impure. The passage is worth quoting:—

"The Pistacia terebinthus tree, from which the gum is procured, is a very hardy one, it lives to a great age, and in the island of Scio attains the size of an American elm—between 30 and 40 feet high. In June or July an incision is made into the bark, through which the gum flows and runs down the tree and soon solidifies on exposure to the atmosphere. The sticky nature of the gum causes various matters, such as sand, the fruit of the tree, straw, leaves, etc., to adhere to it. When the gum has ceased to ooze from the incision, it is scraped off the tree with a large dull knife, and this process necessarily brings off portions of the bark, thus constituting an additional impurity. When the rough turpentine is strained, the minute particles of the foreign substances above mentioned cannot be separated from it and form the impurities found in all strained Chian turpentine. The rough Chian turpentine after it has been exposed to the atmosphere is found on importation to be a rough dry substance, of a light brown colour, covered with a dirty white powder, and it appears to be one mass of seeds, bark, sand, etc. On taking a small piece of the mass and rubbing it for a few minutes between the thumb and finger the characteristic odour of the gum is at once strongly perceived. It is almost tasteless; the turpentine is readily dissolved out of the rough mass by ether, or it may be melted and strained. This rough turpentine is admirably suited for making an emulsion, as the whole of the properties of the gum are extracted by the ether without waste, and would probably add to its efficiency. Mr. Whinfield, the dispenser to the Queen's Hospital, informs me that from 3 pounds of the rough turpentine he obtained 1 pound and 11 ounces of the real gum, of excellent quality, the rest being impurities."

Professor Clay has also received a greyish-white variety, having an appearance similar to that of glazier's putty, which gives off the characteristic odour when rubbed between the thumb and fingers and is tasteless; it is said to be used by the natives for chewing, but he has not tried it in medicine.

Notwithstanding unfavourable opinions that have been expressed Professor Clay says there is now no doubt that Chian turpentine administered internally does prove very beneficial in most forms and situations of cancer, especially if it be used early. He still adheres to the form of pill containing 3 grains of turpentine and 2 of sulphur, with a caution against the use of magnesia as an excipient. The original form of emulsion, difficulty in dispensing which gave rise to some correspondence in this Journal, has been abandoned; the sulphur has been left out, being administered separately in a pill, and the powdered gum tragacanth is rubbed up with rectified spirit, as first suggested, we believe, by Mr. J. S. Palmer (*Pharm. Journ.*, [3], x., 1011). The following are the author's present directions:—

"It is necessary in the first place to provide an ethereal solution of Chian turpentine. This is made by dissolving ½ ounce of Chian turpentine in 1 ounce of pure ether, sp. gr. 720. Then take 1 drachm of powdered gum tragacanth and 1 drachm of rectified spirits of wine, rub together and add water gradually to make a mucilage up to 9 ounces; then add the solution of Chian turpentine to the mucilage in a bottle, and shake until the whole is properly mixed. A more elegant but more expensive essence is made by using powdered gum arabic instead of the powdered gum tragacanth. To make a 10-ounce mixture, take 1½ ounce of powdered gum arabic, and water to 9 ounces to make a mucilage. Then put this into a bottle and add the solution of Chian turpentine, and agitate until the whole is well mixed. One teaspoonful of the essence is equal to one Chian turpentine pill, the dose is therefore two or three teaspoonfuls three times a day."

It may be useful to mention that in some cases, in addition to the internal treatment, Professor Clay dusts the parts affected with a powder made in the following proportions:—Tannic acid, ½ ounce; powdered charcoal, 2 drachms; and powdered sulphate of copper, 10 grains.

Hot Water Heating on the Low Pressure System. By F. A. Fawkes, F.R.H.S. London: B. T. Batsford. 1882.

The author of this handy little book has been engaged for some years as a hot-water engineer, and for the convenience of inquirers has brought together some useful information upon the principles involved and the apparatus used in the heating of buildings by hot water. A brief but clear description, illustrated by diagrams, of the low pressure system, forms the principal portion of the book. Other systems of heating are also briefly alluded to, and there is also a list of the possible causes of failure. Advertisements are present in unusual force for so small a book, but their introduction may be excused on the ground that they will be useful to any person intending to carry the teaching of the text into practice without further consulting the author.

Notes and Queries.

[729]. I have not experienced the slightest difficulty in preparing this tincture. To the quinine in a bottle add the proof spirit, shake well, then add the liq. ammonia (either gradually or all at once, it makes no difference), and a perfect solution is instantly obtained. *No heat is required.* Quinine will dissolve in the mixed proof spirit and liq. ammonia, but this takes a little longer to prepare. The former process is the one I always adopt.

Leamington. Samuel A. Smith.

[731]. I think, with your querist "Specific Gravity," that Squire is slightly in error with the "colour description" of syr. ferri iodidi, and that "*nearly* colourless" would have been more accurate.

By using a pure sugar, exposing the solution of iodide to the air as short a time as possible, and filtering with the funnel dipping into the syrup, previously prepared, I obtain a syrup, the colour of which is scarcely perceptible in a filled 2-oz. white glass phial. After passing through the filter the solution should be of a beautiful sea-green tint.

Squire says, "it keeps colourless in well-filled bottles." It may not colour so rapidly in "well-filled bottles," but from actual experiment I find, that with a single air bell, decomposition takes place, which is indicated by the syrup nearest the contained air becoming of a decided straw colour in the course of four or five days.

Edinburgh. John.

Correspondence.

⁂ *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

E. L. Riddell.—To be able to answer your question it is necessary in the first place to know what is the composition of the ink.

A Co-Executor.—There is no exemption in the Pharmacy Act under cover of which even the executors of a deceased medical practitioner can legally carry on the business of a chemist and druggist with or without the aid of a qualified man. In the case, therefore, that you put, where the executors of the deceased widow of a medical practitioner carry on such a business, there can be no doubt that they are breaking the law.

Pilocarpine.—"Cascara sagrada" is the name under which the bark of the Californian *Rhamnus Purshiana* has been introduced to the medical profession in the United States as a remedy in cases of obstinate constipation. The plant is closely allied to *Rhamnus Frangula*, and probably resembles it in its therapeutic value.

"*Cœsariensis.*"—Johnston's 'Elements of Agricultural Chemistry and Geology' (Blackwood, 1871).

A. H. H.—Either Ganot's or Deschanel's work would answer the purpose equally well.

H. Peet.—To a great extent it is a matter of individual discretion as to what coating is put upon pills, for prescriptions seldom give any instructions upon the point.

W. T. Phillips.—A solution of one of the aniline compounds is usually used, such as Hofmann's purple dissolved in 1 part of alcohol and 7 parts of water.

J. H., A.P.S. (who should have sent his name and address) is recommended to address his question to the Registrar.

Communications, Letters, etc., have been received from Messrs. Hayden, Smith, Philos Lex, H. C. H.

THERMO-MICROSCOPY IN PHARMACY.

BY W. H. SYMONS, F.R.M.S., F.C.S.

(*Concluded from page* 4.)

The Melting Point of Resins.—Time and mass have almost as much to do with the melting of a resin as temperature, as may be seen by the ease with which Burgundy and common pitch flow at normal temperatures, and accommodate themselves to their surroundings. To render mass a constant factor, the resin to be examined is coarsely powdered, the finest particles sifted off through fine muslin and the largest separated by means of the same material of fewer meshes. The particles of intermediate size being chosen, a few are placed on the warm stage, as in the case of wax, except that it is advisable to use a shallow cell to keep the thin glass cover from the resin. The focus having been adjusted, heat is applied so that the temperature shall rise a definite number of degrees per minute, say five. By so doing time is rendered a constant factor. The resin is kept continually in view until the sharp angles suddenly round off and a drop is formed. The following are some results:—

Resin from tolu	60° C.
Guaiacum resin	75° C.
Common resin	80° C.
Scammony resin from root	110° C.
Scammony resin from gum	125° C.
Tampico jalap resin	130° C.
Vera Cruz jalap resin	150° C.

It will be noticed that according to the above list the resin of scammony prepared from the root has a lower melting point than that prepared from the gum. The two resins are commonly asserted to be identical. Several specimens were examined, some prepared by myself, others guaranteed as genuine, and although by using various methods sundry melting points could be obtained, they invariably occupied the same order on a list. In one case thin glass tubes, about the size of a quill, were partially filled with the resins and plunged into mercury, so that the resin should be about 1 cm. below the surface of the metal, and heat applied; when the resin rose to view the temperature was noted. By the hot stage process as accurate results can be obtained as by any other, and it possesses the great advantage of requiring only a few milligrams of the resin for each determination.

The Melting and Subliming Points af Alkaloids.—These are now admitted data in their examination. Various methods have been suggested for taking them, perhaps the best being that of Mr. Wynter Blyth. He takes a porcelain crucible, nearly fills it with mercury or fusible metal; places a minute speck of the substance to be examined on a thin disc of microscopic covering glass and floats it on the metal; the cell is completed by a glass ring and upper disc. The crucible is supported on a hot plate, and is protected from the unequal cooling effects of currents of air by being covered with a flask from which the bottom has been removed. The neck of the flask conveniently supports a thermometer, which passes through a cork, its bulb being immersed in the bath of liquid metal. "In the first examination of a substance the temperature is raised somewhat rapidly, taking off the upper disc with the forceps at every 10°, and exchanging it for a fresh disc, until the substance is destroyed. The second examination is conducted much more slowly, and the discs exchanged at every 4° or 5°, whilst the final determination is effected by raising the temperature with great caution, and exchanging the discs at about the points of change (already partially determined) at every ½°. All the discs are examined microscopically."* This method is exceeding simple in application, but at the same time tedious; the chief objection seems to be that the apparatus has to be disturbed at every ½°, and this may interfere with the result.

Using the hot stage, above described, the process may be watched throughout, not once disturbing the parts, unless it be thought advisable to make a permanent slide for future reference, at any point. Moreover, the alkaloid and its sublimate can, in many cases, be alternately viewed by merely adjusting the focus.

The following results merely refer to a preliminary examination, and are not put forward as carried out to the tenth or even to half of a degree. The alkaloids examined were commercial specimens, and the presence of water, as water of crystallization and otherwise, may have considerably influenced the result. The subject is an exceedingly interesting one, and I hope to be able to pursue it much further. In no instance is it likely that the temperature mentioned is too low. Like evaporation in the case of liquids, sublimation in that of some solids appears to take place incessantly at all temperatures. The resultant sublimate, however, may not appear until after the lapse of some time.

The alkaloid to be examined is placed like the resin, the glass stage and cover being alternately focussed. The formation of a nebula will, in many cases, be apparent first to the unaided eye, magnification simply dispersing and making it less visible. As soon as the nebula is capable of resolution into dots or drops a high power may be used, but a ½ or 1 inch glass is quite powerful enough to resolve any sublimate worthy of the name, and these low power objectives can be focussed down to the glass stage without removing the cover.

Theine.—This body, which is asserted by various authors to yield a sublimate at points varying from 79·5° C. to 184·7° C., gave its characteristic sublimate in fair size crystals, at 65° C. It sublimed so quickly that it underwent no further change as the temperature increased.

Quinidine.—At a temperature of 75° C. melts (in its own water?), but soon after crystallizes again and does not further alter until 150° is reached, when droplets begin to condense on the cover glass; at 170° the mass again melts. No other change appears to take place until it darkens at 240° and further decomposes at 260°. The sublimate solidifies but does not crystallize.

Quinine.—At 150° C. a slight cloud, resolved by a high power into numberless droplets, forms on the cover glass, while the mass of the alkaloid on the stage throws out long acicular crystals, some of which are very curiously branched. As the melting point (about 170°) is neared, the particles heave and throb like living monsters and rapidly assume the fluid state. If the heating be continued for a short time the cover glass will be found coated with silky crystals, which hang in graceful festoons from its surface, a temperature of 200° giving the best results. Melted quinine solidifies if left undisturbed at about 125°.

Cinchonine.—Clouds at 160° C., and very slowly

* 'Practical Chemistry.' By A. W. Blyth, M.R.C.S., Griffin and Co. 1879. Page 285.

at 180° gives acicular crystals. The residue becomes a charred mass at 260°, but is completely enveloped in efflorescent crystals.

Cinchonidine.—Clouds at 160°, gradually forming a curious network of crystals. It melts at about 205° and remains liquid until cooled down to about 160°, when it suddenly becomes a mass of crystals. The solidification of this and other melted alkaloids can, however, be brought about at much higher temperatures by the introduction of a crystal or other nucleus.

Codeine.—Begins to sublime about 140° C. The sublimate appears as small drops, but, although the temperature be rising, these suddenly become massive irregular crystals. Codeine melts about 150°.

Morphine.—Begins to sublime about 150° C., forming but a slight cloud on the cover, and it is not until about 220° is reached that sublimation proceeds freely, and crystals form. At 240° the alkaloid melts and begins to brown.

Aconitine.—Melts at about 110° C., a slight cloud forming on the cover glass and gradually accumulating into drops, some of which eventually become crystals. The liquid alkaloid browns at about 180°. It cracks on cooling.

Veratrine.—Melts at about 140° C. Browns at 210°, only yielding a slight nebula on the cover, and this needs a high power to resolve it into dots.

Strychnine.—Sublimes slowly at 180° C. in short needle-like crystals; as the temperature rises to the melting point of the alkaloid, about 225°, sublimation proceeds more rapidly.

The sublimates of most of these alkaloids answer the same tests as the alkaloids themselves, but it would be interesting to make a more complete examination to ascertain if any constitutional change had been undergone, as it is well known that some of them, *e.g.*, morphine, are very much changed by being heated in closed tubes.

Sublimation of Inorganic Bodies.—Arsenious Anhydride.—By the hot stage I found that this substance sublimes slowly at 95° C. Beasley, in his 'Chemist and Druggist's Receipt Book,' 5th ed., p. 455, gives as the subliming point of arsenic 380° F. (=193° C.). A more recent writer gives it as 280° F. (=137·7° C.). But that both of these observations deviate more than 70° F. from the truth may be proved by anyone who cares to place a few milligrams of arsenic, enclosed between two watch glasses, over a water-bath; in time a distinct sublimate will condense on the upper glass, and, in point of fact, arsenic will be found to sublime slowly at 205° F.

Calomel.—Sublimes at 110° C. The sublimate consists of well defined crystals, belonging to the right rhombic prismatic system, not unlike those of Rochelle salts.

The following slides have been placed in the Library of the Pharmaceutical Society illustrative of this paper:—

Beeswax and other bodies showing fat crystals.

Potato starch, which has been subjected for forty hours to a temperature of 60°. This slide shows various stages of tumefaction in different granules.

Scammony resin, small particles before and after melting.

Sublimates of the following alkaloids:—Theine, quinine, cinchonine, cinchonidine, codeine, morphine, aconitine and strychnine. Also sublimates of calomel and arsenic.

These sublimates of the alkaloids must not be considered as wholly characteristic, but rather as forms into which most of them could be made to pass by suitable treatment. Polarized light affects them variously, and is sometimes useful for their early detection on the cover glass. Calomel crystals not only display brilliant colours under polarized light, but are themselves analytic, so that this effect can be obtained without the use of the upper Nicols prism.

NOTE ON ALUMEN, B.P.

BY W. WATSON WILL.

Ammonio-aluminic sulphate manufacture seems to have become a thing of the past and great difficulty is now experienced by pharmacists in obtaining it, the potassic salt having entirely taken its place. No doubt the consumption of alum from a pharmaceutical point of view is small in comparison to the enormous quantities used in the arts and manufactures of this country, but I think if there had been a persistent demand, however small, for ammonia alum, its manufacture would not have become obsolete. In a communication I had from Mr. R. King, of Glasgow, some time ago, he assured me there was no demand for ammonia alum, a statement fully endorsed by Mr. P. Spence, of Pendleton, in a note I had from him regarding this subject. Various have been the processes employed in the preparation of ammonia alum, some makers preparing the aluminum sulphate from aluminous schist or shale, others using clay or kaolin. The following is a brief *résumé* of one of the processes:—Shale of coal measures, previously calcined, is placed in iron vessels lined with lead, and sulphuric acid from an adjoining receiver is poured over it; the mass then allowed to digest at a temperature of 240° F., this degree of temperature being sustained by a fire underneath the vessels and also by steam and ammonia vapour being blown into the pan. The solution, after evaporating for some time, is poured into large coolers and strongly agitated to prevent formation of large crystals. The deposit of fine crystals, commonly called "flour alum" is now washed and redissolved by steam, and the solution run off into large vessels called "roaching casks" to crystallize. After seven or ten days the staves of these "casks" are taken off and a complete shape is left of crystallized alum. A few holes are made in the side of this mass, and the mother-liquors allowed to drain off; then it is broken and packed for sale. Other makers, instead of adding ammonia in a state of vapour, more generally used the chloride or sulphate made by neutralizing ammoniacal gas liquor with hydrochloric or sulphuric acid; the former of the two solutions was mostly used on account of the amount of iron contained in the crude aluminum sulphate. Following the latter of the two processes just mentioned, I would suggest a short mode for the preparation of ammonio-aluminic sulphate, easy in manipulation, adaptable to small laboratories, and satisfactory in result. Take of aluminum sulphate (cake alum) 14 lbs., ammonium sulphate 3½ lbs., warm water 4 gallons; dissolve the ammonium sulphate in half a gallon of water and the aluminum sulphate in the remainder, filter the solution to free it from the finely divided silica, and to the filtered liquid add the ammonia solution; then apply heat until the solution boils, pour off into a suitable vessel to crystallize. After a few days draw off the mother-liquor; then drain the crystals on a loosely stopped funnel. One hundred grains of ammonia aluminic sulphate made by this process, on being incinerated, left a residue which on cooling weighed 54 grains, corresponding to the requirements of the Pharmacopœia.

THE ACTIVE PRINCIPLES OF BUXUS SEMPERVIRENS.*

BY P. E. ALESSANDRI.

Box tree bark has already been the object of chemical research by Fauré, Pavia, and more recently Barbaglia of Pisa, who thought to extract from it an alkaloid which would be an efficient substitute for quinine. Pavia claimed the discovery of two alkaloids, which he named *buxine* and *parabuxine*. The supposed alkaloids, however, which the three above-named chemists believed they had extracted were really a mixture of resinous matters of a deep yellow colour. Thinking it necessary from these failures to change the method of extraction, the author used his oxalic acid process, which has already been described in the *Pharmaceutical Journal*, vol. xii., p. 993.

Dried and fresh leaves and bruised bark were macerated for twenty-four hours in a strong solution of oxalic acid. The clear yellow supernatant liquid was poured off and filtered, and gave the following reactions:—

Tests.	Precipitates.
Liquor ammoniæ	Greyish-yellow, copious.
Caustic soda	Greyish-yellow, moderate.
Sodic carbonate	Greyish-yellow, slight.
Liquor ammoniæ and tannic acid	Dirty-yellow, copious.
Platinum chloride	Yellowish-white.
Tincture of iodine	Brick-red.
Mercuric chloride	Yellowish-white.
Sodic phosphomolybdate	Dirty-yellow.
Fehling's liquid	Reduced by heat.

The solution was then fully precipitated by a slight excess of ammonia, the precipitate washed and dissolved in dilute acetic acid, a greenish substance remaining undissolved. The acetic solution was once more precipitated with ammonia and the precipitate dissolved in sulphuric acid, again precipitated and washed with dilute ammonia and dissolved in absolute alcohol, in which it dissolves without residue. The alcoholic solution obtained was evaporated, first in the air and then *in vacuo*, and left a residue analogous to that described by Fauré and Barbaglia.

The author found that by the same treatment the leaves and bark yielded different compounds; he consequently made two oxalic solutions, one with the pounded fresh leaves, the second with the pounded bark and small twigs. The first infusion in the cold was treated with sodic carbonate, and heated, and also with liquor ammoniæ.

In the first case the precipitate formed is but small, so the second process with ammonia was adopted. The precipitate being washed and filtered, it was dissolved in acetic acid and again precipitated and dissolved in alcohol, the alcohol evaporated and the residue treated with ether, which on being also evaporated gave a distinctly crystalline substance of a canary-yellow colour. The ether left behind it a soft, gummy, sticky substance, which, being allowed to remain exposed to the air, turned of a greyish-green colour and of a crystalline structure.

The canary-yellow crystalline principle extracted from the leaves dissolves pretty easily in water and ether, and freely in alcohol. It also dissolves readily in the mineral and vegetable dilute acids, giving well-marked crystalline compounds of a light-yellow colour, very bitter, and soluble in water. The sulphuric and hydrochloric solutions gave a precipitate with platinum chloride. The principle is precipitated of a light-yellow colour by phosphomolybdic acid, white with tannic acid, as a cloud with mercuric chloride, and brick-red with iodine. With the alcoholic and ethereal solutions these reactions are not so marked. With pure sulphuric acid it turns of a dark colour. With pure nitric acid it is transformed into a rose-coloured powder.

The oxalic solution made from the bark gave different results. The colour of the ammoniacal precipitate was greyish-yellow and dissolved entirely in dilute acetic acid. Precipitated by an excess of ammonia it gave a very light crystalline precipitate of a light flesh colour which dissolved completely in alcohol. By successive evaporations and treatment with ether a white substance is obtained which crystallizes in brilliant transparent scales.

This body is but little soluble in water and benzene, a little more so in chloroform and carbon disulphide and freely in alcohol and ether. It is also soluble in dilute acids, from which it is precipitable of white colour by ammonia. Tannic acid throws down a yellow precipitate, passing to deep orange; phosphomolybdic acid, white; tincture of iodine, brimstone; chloride of platinum, canary colour; potassic dichromate, canary, turning to orange; and mercuric chloride, white. Pure sulphuric acid turns it of a yellow colour, which disappears on the addition of water. Pure nitric acid gives immediately a reddish-purple colour, which passes into amaranth and then disappears. Treated with caustic potash ammonia is developed. With sulphuric acid and potassic dichromate, it gives a yellow precipitate, which becomes emerald green on heating.

The ethereal solution leaves behind another body formed of amber crystalline scales, very bitter and differing from the last-mentioned body in many particulars. It is soluble in cold dilute alcohol, slightly soluble in water, and insoluble in ether, benzene and chloroform. It is soluble in all the dilute acids and a precipitate is thrown down by ammonia when it is in great excess. Pure nitric acid turns it to a dirty brick-red; hydrochloric acid to a greenish hue, and sulphuric acid first to a dirty-red, and then to a dark-green.

The neutralized acid solution gives a white precipitate with tannic and phosphomolybdic acids and mercuric chloride, yellow with potassic dichromate and brick-red with tincture of iodine.

It is evident that we have to deal with three distinc principles which possess particular characters. The first the author has named *buxine*, the second, *buxeine*, and the third *parabuxine*.

The acetic solution, before referred to, from which the buxine has been precipitated by ammonia, will give a copious white precipitate with tannic acid which will also give a copious greyish-white precipitate with the residue of the oxalic solution remaining after its treatment with ammonia. After an excess of ammonia or potash has been added to the oxalic solution it is still precipitable by tannic acid; but the precipitate cannot be buxine, for with tannic acid this principle is thrown down of a yellowish-red colour.

The chemical and physical characters of the three principles, are as follows:—

	Buxine.	Buxeine.	Parabuxine.
Colour.	White.	Yellowish-white.	Purplish-red.
Structure.	Crystalline.	Crystalline.	Amorphous.
Solubility.	Slightly soluble in water; more so in alcohol; freely in ether.	Soluble in alcohol and ether; slightly so in water.	Freely soluble in water and alcohol, but insoluble in ether.
With HNO_3.	Turns reddish purple.	Turns greenish-yellow, and then brick-red.	Turns greenish-yellow, with no approach to red.
With H_2SO_4.	Turns brick red.	Turns blood-red.	Turns greenish-yellow, and then darkens.

* *Annali di Chimica*, April, 1882.

	Buxine.	Buxeine.	Parabuxine.
With H_2SO_4 and $K_2Cr_2O_7$.	Turns canary yellow in the cold. Gives a green cloud when hot that at once disappears.	An orange precipitate; when heated the precipitate dissolves and gives a green solution.	Gives no precipitate, but with heat gives a grass green cloud.

In the *Buxus sempervirens*, therefore, there are three special and distinct principles, viz., buxine in the bark, buxeine in the leaves, and parabuxine in both, but in the greatest quantity in the former. There appears to be comparatively little difference between buxine and buxeine, and it is just possible that further researches will prove them to be one and the same body; parabuxine, however, is sufficiently distinct from either in both its physical and chemical characters. On the exact nature of parabuxine the author declines for the present to give any decided opinion. It appears sometimes to have an acid reaction, but other experiments tend to prove the contrary. If it could be proved beyond a doubt that it was an organic acid it would explain why it clings so tenaciously to the buxine.

The last method adopted by the author for the extraction of buxine and parabuxine is as follows:—

1. Make a cold infusion of coarsely powdered box bark with a 2 per cent. solution of oxalic acid.
2. Filter and press after twenty-four hours, and exhaust the remaining bark with a fresh portion of oxalic solution, filtering, and press again.
3. Concentrate the infusion at a gentle heat, add ammonia in excess and allow the resulting precipitate to subside.
4. Collect the precipitate on a filter and treat with dilute acetic acid. Precipitate again with ammonia and wash with weak ammonia.
5. Treat the precipitate with hot alcohol and evaporate to one-third.
6. Shake up the residue with ether repeatedly.
7. Evaporate the ether and set aside the undissolved portion.
8. Dissolve again in acetic acid and precipitate. This process gives buxine in a nearly pure condition. This product is nearly white and may be entirely decolorized by animal charcoal, but a large quantity of the alkaloid is absorbed and lost in the process.
9. The portion undissolved by the ether is treated with acetic acid and mixed with the residual liquor of the first treatment.
10. Evaporate the acetic solution slowly down to one-half and treat with ammonia. Collect the yellowish magma on a filter. Evaporate the residual liquor down to one-half, precipitate, unite the two precipitates and wash with weak ammonia water.
11. Wash the magma with ether and dissolve the residue in pure alcohol. This alcoholic solution on evaporation yields nearly pure parabuxine.

Instead of acetic acid dilute sulphuric acid may be used for dissolving the first ammoniacal precipitate and the buxine thrown down with baryta water.

Analogous treatment of the pounded leaves gives buxeine.

The author denies that the alkaloid obtained by Fauré is buxine at all, but a mixture of heterogeneous substances.

Pavia worked with the leaves and twigs and obtained a mixture of buxine, buxeine and parabuxine, but in small quantities. Pavia's second process, in which sulphuric acid was used, did not give the pure alkaloid either, for the solvent dissolved out a number of products upon which a cold solution of oxalic acid has no action; besides which he only used the leaves and twigs and treated the precipitate he obtained with nothing but alcohol, which only gave him an impure mixture, which he took for true buxine.

Barbaglia followed an analogous process, but used sodic and calcic carbonate to precipitate the sulphuric acid solutions, the precipitate being dissolved in pure alcohol. This method of proceeding could not produce pure buxine, because sodic carbonate will not throw down the alkaloidal principles of box leaves or bark. Barbaglia by this means obtained a mixture, which he sought to purify by dissolving it in alcohol and pouring the resulting solution in a thin stream into distilled water. It is true that by this means a white glutinous deposit is formed; this is not pure buxine, however, but a mixture of that substance and parabuxine. This may be proved by a simple experiment which eluded Barbaglia's vigilance. The mixture containing the white precipitate is shaken up in a test-tube with absolute ether in excess. Part of the precipitate dissolves and the liquid divides into three layers. The top layer is ethereal, the middle layer contains a number of flocks, and the lowest is aqueous. The ethereal solution when evaporated yields pure white crystalline buxine, the aqueous solution contains impure buxine, and the red flocks are parabuxine.

The author claims to be the first to have obtained pure crystalline buxine, the so-called buxine obtained by Fauré, and others being a mixture of alkaloidal and glucosidal principles in proportion varying according to the source from which the substance was extracted, whether from the bark or leaves. Fauré and his successors all admit the existence of what they took to be a resin, in the alkaloidal mixture obtained by them, which could not be separated even by nitric acid, as recommended by Mayr. This supposed resin does not exist; what was taken for a resin is really the principle which the author has called parabuxine provisionally. This body is different in its physical and chemical characters to the parabuxine of Pavia, which was a mixture of buxine and true parabuxine.

The author concludes by remarking that now we have an easy method of obtaining buxine in a reasonable state of purity, the investigations of its value as a febrifuge may be carried on with more certainty than those made with Pavia's buxine, the efficacy of which as a substitute for quinine as an antiperiodic has been so often contested. The true chemical formula of buxine can now be established, and the question of its identity with bibirine, asserted by Walz and confirmed by Flückiger, who also states that it is identical with pareirine and paricine, definitively determined.*

The author promises to give us another paper detailing his researches into the chemical properties of a number of buxine salts and substitution compounds.

HOW BEESWAX IS MADE.†

BY W. Z. HUTCHINSON.

I presume that the majority of people who are not bee-keepers suppose that bees gather wax from some source, in the same way that they gather honey, pollen, and propolis. I once heard even a bee-keeper remark: "We had a nice spring day yesterday. My bees had a splendid 'fly,' and I noticed that some of them came in loaded with pollen and wax." That bees do not gather wax is easily proved by confining them in an empty hive or box, and feeding them on honey or a syrup made of sugar, when they will immediately commence the construction of combs. During the working season wax is secreted by the bees, and forms in thin white scales, or flakes, between the rings, or segments, of the abdomen. Such renowned scientists as Professors Agassiz and Tyndall have made some very amusing blunders (blunders which showed they had never seen bees building comb) in attempting to tell how honeycomb is built. The exact manner in which these little pellets of wax are formed into beautiful

* See *Pharm. Journ.*, [2], xi., 192.

† From the *Country Gentleman*. Reprinted from the *Oil and Drug News*, May 16, 1882.

white combs is well described in the 'A B C of Bee Culture':—

"If we examine the bees closely during the season of comb building and honey gathering, we shall find many of them with the wax scales protruding between the rings that form the body, and these scales are either picked from their bodies, or from the bottom of the hive or honey boxes in which they are building. If a bee is obliged to carry one of these wax scales only a short distance, he takes it in his mandibles, and looks as business-like with it thus as a carpenter with a board on his shoulder. If he has to carry it from the bottom of the honey box, he takes it in a way that I cannot explain any better than to say he slips it under his chin. When thus equipped, you would never know he was incumbered with anything, unless it chanced to slip out, when he will very dexterously tuck it back with one of his fore feet. The little plate of wax is so warm from being kept under his chin as to be quite soft when he gets back; and as he takes it out, and gives it a pinch against the comb where the building is going on, one would think he might stop awhile and put it into place; but not he, for off he scampers and twists around so many different ways, you might think he was not one of the working kind at all. Another follows him sooner or later, and gives the wax a pinch, or a little scraping and burnishing with his polishing mandibles, then another, and so on, and the sum total of all these manœuvres is that the comb seems almost to grow out of nothing; yet no bee ever makes a cell himself, and no comb building is ever done by any bee while standing in a cell. The finished comb is the result of the moving, restless mass, and the great mystery is that anything so wonderful can result at all from such a mixed-up, skipping-about way of working."

In every apiary should be a box or barrel in which to throw all waste comb, and the cappings that are shaved off the combs when extracting. When much transferring or extracting is done, considerable wax can in this manner be saved, and it is as easy to save it as it is to throw it away. During the hot weather these refuse combs and cappings should be melted up into wax quite often; otherwise they will become infested with the bee moth's larvæ, and thereby destroyed. There are several methods of melting up combs and cappings into wax, but I have tried none that is more simple, or better, than to make a bag out of some coarse sacking, fill it with pieces of comb, tie it up, and put it into a wash boiler. Set the boiler on the stove and fill it nearly full of water. When the water is almost hot enough to boil, take a stick and punch, poke and press the bag until the wax is all melted and risen to the top. Now lay a narrow strip of board across the top of the boiler, and tie it fast to the handles; then take two or three sticks that are nearly as long as the boiler is deep, press the bag down to the bottom of the boiler with these sticks, and keep it in this position by putting the upper end of the sticks under the strip of board that is fastened across the top of the boiler. Now set the boiler off the stove, and when its contents are cold, the wax can be taken off in one solid cake. In passing through the bag the wax is cleansed from all coarse impurities, while the fine particles of dirt that do escape will be found either upon the top or bottom of the cake of wax, from whence they can easily be removed.

When the combs and cappings have all been worked up, and the cakes of wax have been scraped free from all dirt or sediment, the cakes should all be put into the boiler, melted up together, and the wax run into neat cakes.

To clean utensils from beeswax, they should first be scraped with a knife as clean as possible, and then rubbed with a cloth saturated with kerosene oil. Beeswax is sometimes adulterated with paraffin, ceresin, or tallow. To detect these frauds, a piece of wax should be chewed; if adulterated, even slightly, with either, it will chew like gum, while if pure, it will crumble and break to pieces in the mouth, and will not make gum at all.

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from page* 10.)

OLEUM LINI SULPHURATUM (*Sulphurated Linseed Oil*).

Linseed oil	1
Washed sulphur	6

Mix and heat them together, in a porcelain capsule, at a temperature between 120° and 130° C. (248° to 266° F.), under constant stirring, until the sulphur is dissolved.

A dark-brown liquid, having a yellow colour in thin layers, and completely soluble in oil of turpentine.

OLEUM TEREBINTHINÆ SULPHURATUM (*Sulphurated Oil of Turpentine*).

[Balsamum Sulphuris Terbinthinatum. Haarlem Oil.]

Sulphurated linseed oil	1
Rectified oil of turpentine	2

Mix and filter.

The product is a bright, red-brown oily liquid.

FERRUM DIALYSATUM IN LAMELLIS (*Dialysed Iron in Scales*).

Solution of dialysed iron	q.s.

Evaporate it to a syrupy consistence at a temperature of 40° to 60° C. (104 to 140° F.). Spread it upon glass and dry it by exposure to the air.

Red-brown scales, generally not entirely soluble in water, and containing 75 per cent of iron.

PASTA ESCHAROTICA (Canquoin's (*Canquoin's Caustic*)

	No. 1	2	3	4.
Chloride of zinc, parts	1	1	1	1
Wheat starch or linseed meal, parts	2	3	4	5

Mix them to a paste by means of water, roll it out, form it into suitable pieces, and deliver them in well-closed bottles.

The paste should be freshly made when wanted for use.

PEPSINUM (*Pepsin*).

Pepsin may be prepared from pigs' stomachs by washing the mucous coat, chopping it fine, and macerating it for two days with water acidulated with hydrochloric acid, or with a mixture of water and glycerin. The pepsin is precipitated from the solution either by a saturated solution of chloride of sodium or by alcohol; and precipitated pepsin is dried in a vacuum at a temperature below 40° C. (104° F.).

Pure pepsin is a brownish-yellow, amorphous, very hygroscopic mass, soluble in water and dilute acids. These solutions do not coagulate on boiling, and are scarcely precipitated by acetate of lead and chloride of platinum.

Commercial pepsin varies considerably in colour and hygroscopic property, according as it is mixed with different substances, as milk, sugar, etc. In general, good pepsin should respond to the following tests:—

Dissolve 0·1 gm. of pepsin in 100 gm. of distilled water, and 2 gm. of hydrochloric acid; then add 10 gm. of white of egg, coagulated at a temperature of 95° C. (203° F.). Let the mixture stand for forty-eight hours, occasionally shaking it, at a temperature of about 40° C. (104° F.). The white of egg should thereby be completely dissolved or the undissolved portion should not amount to more than 0·5 gm.

The more rapidly the white of egg is dissolved and the smaller a precipitate is produced in the solution by nitric acid, the better is the pepsin.

QUINIÆ CARBOLAS (*Carbolate of Quinine*).

[Quiniæ Phenylas.]

Carbolic acid	6
Quinine (alkaloid)	10
Alcohol (0·820)	30

Dissolve the carbolic acid in the alcohol, warm the

* From *New Remedies*, April, 1882.

solution, add to it the quinine, then filter, and evaporate the filtrate to dryness upon the water-bath.

The product is a white powder, soluble in 400 parts of water and in 80 parts of alcohol. It is rendered violet by solution of ferric chloride.

ZINCI PHOSPHIDUM (*Phosphide of Zinc*).

Phosphide of zinc occurs either in brittle lumps, having more or less a metallic lustre, or in form of a grey, metallic, fine powder, having an odour of phosphorus, permanent in the air, and of the specific gravity 4·7. When heated out of contact with air, it is completely volatilized; with access of air, it is converted into phosphate of zinc. Acids decompose it, setting free phosphoretted hydrogen, and forming the corresponding zinc salts. Alkalies leave it unaltered.

When examined by a lens, the salt should not show the presence of unaltered metallic zinc. *One* part of the finely-ground powder, covered with a solution of chloride of ammonium, and digested for one day, should yield a precipitate which, when collected on a filter and washed successively with water, strong alcohol, and ether, and dried in the air, should weigh at least 0·9 parts.

PHOSPHORUS PULVERATUS (*Powdered Phosphorus*).

Phosphorus, cut in pieces	q.s.

Drop the phosphorus into a flask half filled with a solution of chloride of sodium. Warm the mixture until the phosphorus melts. Then shake it until the liquid becomes cold. Pour off the solution of the salt and wash the powdered phosphorus thoroughly with water.

It should be preserved under water.

POMATUM DUPUYTREN (*Dupuytren's Pomade*).

Extract of cinchona fusca (cold prepared)	12
Lemon juice	6
Tincture of cantharides	6
Beef-tallow, fresh	96
Oil of bergamot	1

Dissolve the extract of cinchona in the lemon juice and tincture of cantharides, and add the other ingredients.

PULVIS CINCHONÆ SUCCIRUBRÆ (JAVANICÆ SEU INDICÆ). (*Powdered Red Cinchona* (*Javanese or East Indian*).)

The powder of any cultivated red cinchona bark, yielding at least 6 per cent. of total alkaloids. The quantity of the latter is to be ascertainded by the following process of assay:—

	Grams.
Bark of the stem of Javanese or East Indian red bark, in fine powder	10
Normal hydrochloric acid	10
Oxalate of potassium	0·15
Solution of soda (10 per cent.)	q.s.
Distilled water	q.s.
Acetic acid	q.s.

Macerate the powder with 30 gm. of distilled water and 10 gm. of normal hydrochloric acid during twelve hours, frequently stirring. When the froth is settled, transfer the mixture to a percolator, the lower orifice of which is closed by a linen pellet (or other contrivance), and percolate with distilled water, until a few drops of the liquid passing through are no longer rendered cloudy by solution of soda.

Mix the liquid carefully with dilute solution of soda until a slight cloudiness makes its appearance; then add just enough dilute acetic acid to cause the cloudiness to again disappear. Heat the clear liquid to near the boiling point, and add to it the oxalate of potassium dissolved in water. Filter off the resulting precipitate, wash it, and add to the filtrate an excess of soda solution.

Collect the resulting precipitate upon a double filter, wash it, first with dilute soda solution and afterwards with distilled water, until the washings are almost colourless. Dry the precipitate by exposure to air until it can be easily detached from the filter; then transfer it to a tared capsule, and dry it on the water-bath.

The weight of the precipitate multiplied by 0·041 gm. for every 100 cubic centimetres of mother-liquid and wash-water, indicates the quantity of total alkaloids in the 10 gm. of the powder.

N.B.—Normal hydrochloric acid is standardized upon normal solution of soda and this is standardized upon normal solution of oxalic acid.

Normal oxalic acid contains 63 gm. of the pure acid in 1000 c.c.

Normal soda solution contains 40 gm. of pure sodic hydrate in 1000 c.c.

Normal hydrochloric acid is made by mixing 120 gm. of hydrochloric acid (specific gravity 1·160) with about 750 cubic centimetres of distilled water, and trying how much normal soda solution is required to exactly neutralize 10 c.c. of this solution. From the figure obtained calculate the amount of distilled water which must be added so that it takes exactly 10 c.c. of the acid to neutralize 10 c.c. ol the alkaline solution.

FERRI SACCHARAS (*Saccharate of Iron*).

[Ferri Oxidum Saccharatum Solubile.]

Solution of chloride of iron (ferric) specific gravity 1·480	2
Syrup	2
Solution of soda (specific gravity 1·33), a sufficient quantity, or about	
Sugar	q.s.
Distilled water	q.s.

Mix the syrup with the solution of chloride of iron, and drop the mixture, while stirring, into so much solution of soda that the precipitate first formed is redissolved. Let the mixture stand for twenty-four hours; then pour the clear liquid into 30 parts of boiling distilled water, and let it deposit, after stirring it up.

Pour off the clear liquid from the precipitate, collect this upon a filter, and wash it with warm distilled water as long as it runs off colourless and has an alkaline reaction. Then let the precipitate drain, transfer it to a capsule, mix it with 9 parts of sugar, and dry the mixture, while stirring, on the water-bath, and finally add enough sugar to make the whole product weigh 10 parts.

Saccharate of iron is a brown-red powder, having a sweet, faintly metallic taste, and, when mixed with 5 parts of water, dissolving to faintly alkaline liquid. The reaction for iron compounds is not developed in this liquid until it has been acidulated by hydrochloric acid.

It contains 3 per cent. of iron, and should be preserved in well-closed vials.

SAL CARLSBADENSE FACTITIUM (*Artificial Carlsbad Salt*).

Sulphate of sodium, dried and powdered	46
Bicarbonate of sodium, powdered	42
Chloride of sodium, powdered	20
Sulphate of potassium, powdered	3

Mix and keep in a well-stoppered bottle.

QUINIÆ SALICYLAS (*Salicylate of Quinine*).

Hydrochlorate of quinine	15
Salicylate of sodium	6
Distilled water	q.s.

Dissolve the hydrochlorate of quinine in 600 parts of boiling distilled water, and add to it a solution of the salicylate of sodium in 20 parts of distilled water. Collect the precipitate, after cooling, on a filter, wash it until the washings are no longer rendered turbid by nitrate of silver, and dry it with a gentle heat.

The salt may be obtained in crystals by dissolving it in strong alcohol and concentrating.

When crystallized from alcohol, the salt appears in silky needles; when obtained as a precipitate, it is a white, amorphous powder, soluble in about 900 parts of cold water and in 20 parts of stro ng alcohol.

The aqueous solution has a fluorescence, which increases very much by adding dilute sulphuric acid. Addition of solution of ferric chloride renders the solution dark violet.

(*To be continued*).

The Pharmaceutical Journal.

SATURDAY, JULY 8, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

A MEDICAL VIEW OF THE LEGITIMATE RELATIONS BETWEEN MEDICINE AND PHARMACY.

Now that attention is being largely directed to the achievement of reforms in regard to the practice of medicine and of pharmacy, as well as to improvement of the systems of education by which students are trained for either career, it is with special interest that we have read a letter in a late number of the *Lancet*, in which the proper lines of distinction between the practice of medicine and the practice of pharmacy are sketched out by a writer who signs himself an M.D. of the University of Edinburgh. At the present time the improvement of the social status of medical practitioners is acknowledged to be a desideratum, and it is also acknowledged that the means by which such a result is most likely to be attained is suitable modification of the educational system. Precisely the same requirements are recognized in regard to those engaged in the practice of pharmacy, but it has not been sufficiently taken into consideration that for the success of either project it is necessary to bestow some care upon the regulation of medical and pharmaceutical practice, so as to do away with, or at least to diminish that confusion of the one with the other which is almost peculiar to this country and has been a source of much embarrassment.

It is to this point that the letter we have referred to is directed, and we are glad to take the opportunity of placing before our readers the views of a medical man upon the subject, feeling sure that they will in many respects meet with hearty concurrence from them as they do from ourselves. It is, in the opinion of our contemporary's correspondent, high time that some serious inquiry was made whether or no any laborious education and high-class degree are likely to reconcile the owners of such with their position as *confrères* of the majority of their profession who are at present engaged in the compounding and sale of drugs. According to his view of the case the time has arrived when the necessity for medical men dispensing their own drugs no longer exists, and in seeking to ascertain the causes for the maintenance of such a "miserable practice," he comes to the conclusion that the first and foremost of them is the fact that our English students look, as a rule, to the possession of a qualification to be obtained from a trading company as their highest ambition in medicine. Another reason that he assigns for the continuance of the practice of dispensing by medical men is the fact that those who carry it on are "catering for popularity by the sale of cheap physic." As regards those who cannot otherwise keep their patients, however, it is maintained that they have mistaken their vocation; they would have done better to take to trade, and they surely pay themselves but a poor compliment when they acknowledge that without their cheap physic their services would be in no request.

With this expression of opinion from a medical practitioner's point of view there will be, we are confident, a very general concurrence on the part of those engaged in the practice of pharmacy and from their point of view the separation of medical from pharmaceutical practice will be regarded as one of the most essential conditions for the advancement of pharmacy. In this respect there is a perfect harmony between pharmacists and the views enunciated by the Edinburgh physician. But it is very frequently asserted that there is some difficulty in the way of medical practitioners giving up the preparation of their medicine and on this point, therefore, it is desirable to hear what is said by the authority we have quoted. As a traveller over the greater part of the world he speaks from his own experience of the position that medical men occupy in different countries, and his conclusion is that nowhere is the social position higher than it is in Edinburgh. But in that city he adds that out of the very great number of medical men residing in it no such thing is known as a man sending out his own medicine. In regard to the alleged necessity for medical men dispensing their own drugs in some places, it is urged that this arises only from the fact that in such places there is an apothecary wishing to be considered a medical practitioner, but not too proud to cater for popularity by the sale of cheap physic; if the apothecary ceased to undersell the legitimate tradesman, a chemist and druggist would soon appear upon the scene for the supply of what was needed.

In thus tracing back some of the worst grievances of the pharmacists of modern times to the apothecaries of a past age the writer of this letter has taken the same view of the matter that we have frequently expressed in this Journal, not only in regard to medical dispensing, but also in regard to counter prescribing, and it is by the removal of those prejudicial legacies of their predecessors that the pharmacists of the present must seek to establish a more natural and mutually advantageous relation between themselves and medical men. But while expressing our satisfaction at finding an admission on the part of a medical man that dispensing is properly the business of the pharmacist, and that to him should be left everything that has to do with the preparation of medicine, we cannot but regret the evidently contemptuous feeling with which the writer of the letter referred to regards the pharmacist as compared with a member of the class to which he belongs himself. It may be that this state of mind is one of the consequences of that inharmonious relation between medical and pharmaceutical practitioners which is to a great extent prevalent in this country as well as peculiar to it. Therefore it is not surprising to find the pharmacist spoken of as a mere tradesman having no right to look for more than an ordinary trade profit any more than a grocer. But as this view of the position of the pharmacist in relation to the medical practitioner is not one common in other countries it might have been expected that the travelling experiences of the Edinburgh physician who writes in the *Lancet* would have enabled him to form a more liberal estimate of the pharmacist's claim to recognition as something different from a "petty tradesman." In this respect, however, much has to be learnt and to be established on both sides before we can congratulate ourselves upon the existence of such relations of mutual respect and intelligent recognition as are to be found in various other countries regulating the conduct of medical men and pharmacists towards each other.

THE PHARMACOPŒIA COMMITTEE OF THE MEDICAL COUNCIL.

At the late meeting of the Medical Council a Report was presented by the Pharmacopœia Committee. On a previous occasion the Council had passed a resolution to the effect that the Pharmacopœia Committee should report to the Council, year by year, as to addenda, and in the Report now presented it is stated that after due inquiry the Committee has not obtained sufficient information to enable it to report in accordance with the terms of that resolution. The Report further states that the present stock of the last edition of the Pharmacopœia amounts to 2550 copies, and that the average sale is about 1000 copies, from which data it is assumed that a fair estimate may be formed as to the period at which it will become necessary to supply a new edition. With a view to providing for the publication of such a future edition of the Pharmacopœia, the Committee recommends that the Pharmacopœia Committee be a Standing Committee until the issue of the work, and further that the Committee be authorized to appoint from amongst its own members a Sub-Committee, assigning to it such duties as may be thought fit, and to take such other steps as may be necessary for fulfilling the duties appertaining to the work; also that a sum not exceeding £100 per annum should be placed at the disposal of the Committee. The adoption of this Report was moved by Dr. Pitman and seconded by Dr. A. Smith, and agreed to. In reply to a request by Dr. Storrar for detailed information as to what the Committee proposed to do, Dr. Quain said it was proposed that the Sub-Committee should appoint editors, who would draw up a report to be submitted to the Council, pointing out what should be done with regard to the Pharmacopœia. Until such reports came before the Council no steps could be taken towards issuing the new edition of the work. Mr. Senior expressed a hope that at least one of the editors would be a person well acquainted with pharmacology abroad.

PERSONATION AT EXAMINATIONS.

At one of the sittings of the Medical Council last week, the subject of the possibility of personation at examinations was brought forward by Mr. Macnamara, who mentioned that some time ago it came to the knowledge of the Branch Council of Ireland that a sum of two hundred pounds had been offered to a practitioner by a student to pass some of the examinations for him that he might obtain registration. About the same time also information had reached the College of Surgeons that a certain student, whose name had figured at the top of the preliminary examination list, had been absent from Ireland at the time of the examination in which he had been supposed to have thus distinguished himself. Mr. Macnamara further spoke of a "successful grinder" who kept a student for the purpose of passing preliminary examinations, and adduced the deficiency in general education manifested in later examinations in support of his opinion that so long as the present plan of conducting the examinations was followed there would be no security against such personations. This view was to some extent adopted by Dr. Haughton and Mr. Teale, the latter saying that the deficiency in spelling and in Latin exhibited by many candidates was shocking. Eventually a resolution was passed to the effect that it is desirable that the Medical Council should know what provisions, if any, are taken to ensure the impossibility of personation at the examinations of the several bodies, the certificates of which are accepted by it as evidence of preliminary examination, and that the Executive Committee should be requested to inquire into and report upon the subject.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The eleventh meeting of the French Association for the Advancement of Science is to be held in La Rochelle, where it will commence on the 24th of August and terminate on the 31st. Persons wishing to read papers before the Congress should communicate either with Dr. Gariel, Secretary to the Council, 4, Rue Antoine-Dubois, Paris, or to M. Caillot, General Secretary to the Local Committee, La Rochelle.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, July 5, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Gostling, Greenish, Hampson, W. Hills, Radley, Robbins, Savage, Schacht, P. W. Squire, Symes, Williams and Young.

The minutes of the previous meeting were read and confirmed.

INAUGURAL ADDRESS.

The PRESIDENT announced that Mr. Joseph Ince had consented to deliver the inaugural address to the students in October next, in accordance with the unanimous request of the Council.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Shephard, William Arthur.
Short, Frederick William.

ELECTIONS.

MEMBER.

Pharmaceutical Chemist.

Frederick William Short, having passed the Major Examination and tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Darch, Alfred ....London.
Warburton, Walter ....Swinton.

Modified.

Nutt, Archbell James ....London.

ASSOCIATES.

The following, having passed their respective examination and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Bird, Frederick Charles John...Bath.
Coates, Udolphus Aylmer ......Walsall.
Dangerfield, William Henry ...Devizes.
Hall, John Thomas ....Manchester.
Hill, Arthur ....Leicester.
Lowther, Thomas William ......Cardigan.
Mills, Anne Emily ....Herne Hill.
Spencer, George ....Hitchin.
Wilkins, Edward ....Reading.
Wilcocks, Arthur Squire.........Portsea.

Modified.

Twiss, William ....Hunstanton.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Ayre, Harry ....Darlington.
Cullwick, Herbert Ernest ......Knighton.
Oram, Frank.........................Totnes.
Pattison, Sydney ....London.
Reynolds, Richard Freshfield...Leeds.
Surman, Thomas William ......Bristol.
Taggart, Robert ....Glasgow.
Williams, John Owen ....Anglesey.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

RESTORATION TO THE REGISTER.

The names of the following persons, who had made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

David Davies, 44, Regent Street, Liverpool.
Joshua Hughes, Abercarn, Monmouthshire.

APPOINTMENT OF PROFESSORS.

Professor Redwood was reappointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor Bentley was reappointed Professor of Botany and Materia Medica for the ensuing year.

Professor Attfield was reappointed Professor of Practical Chemistry for the ensuing year.

THE COUNCIL EXAMINATION PRIZES.

On the motion of the PRESIDENT, seconded by the VICE-PRESIDENT, Mr. Gibson (Leven) and Dr. W. Inglis Clark (Edinburgh) were appointed to conduct the examinations in the present month, for the Council examination prizes.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former associate in business.

£10 to a registered chemist and druggist, aged 63.

£5 to a registered chemist and druggist, who has had two previous grants of £10 each.

£5 towards the support of an orphan who was unsuccessful at a recent election to an orphan asylum, the Secretary not having expended the money voted for the purpose, as he did not think it would ensure the election.

One other application had been deferred for further consideration.

The report and recommendations were received and adopted.

The SECRETARY announced that Mr. Thomas Buck, of Stamford Hill, had given a further donation of five guineas to the Benevolent Fund, making a total of one hundred and five guineas (£110 5*s.*)

LIBRARY, MUSEUM, LABORATORY AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
May	Day . . .	344	22	7	13
	Evening . .	131	14	2	6

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
May	175	169	344

Carriage paid, £2 8*s.* 0½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Attfield (Professor), Pamphlet on the Relation to each other of Education and Examination, especially with regard to Pharmacy in Great Britain, 2nd ed., 1882. 2 *copies.* From the AUTHOR.

Squire's Companion to the British Pharmacopœia, 13th ed., 1882. 2 *copies.* From Mr. P. WYATT SQUIRE.

Thorowgood (J. C.), Student's Guide to Materia Medica and Therapeutics, in accordance with the British Pharmacopœia, 2nd ed., 1882. From the AUTHOR.

Pharmacopœia of the United States of America, 1820.

Pharmacopœia of the Massachusetts Medical Society, 1808.

Bigelow (J.), Treatise on the Materia Medica, 1822.

Thacher (J.), American New Dispensatory, 2nd ed., [1813]. From Dr. B. F. DAVENPORT.

Constable (H. S.), Our Medicine Men.

Constable (H. S.), Fashions of the day in Medicine and Science, 1879. From Mr. W. Young.

Méhu (C.), Nouvelle méthode d'extraction de la matière grasse des urines dites chyleuses, 1882. From the Author.

The Committee recommended the purchase of the undermentioned works:—

Babington (C. C.), Manual of British Botany, 8th ed., 1881.

Jackson (B. D.), Literature of Vegetable Technology, 1882.

Kilner (W. B.), Compendium of Modern Pharmacy and Druggists' Formulary, 2nd ed., 1881.

Linnean Society of London, Transactions.

Oldberg (O.), Unofficial Pharmacopœia, 1881.

Pharmacopœia of the London Hospital, 1882.

Whitla (W.), Elements of Pharmacy, Materia Medica and Therapeutics, 1882.

The Committee also recommended that the Library and Museum be closed in the evening during August, and entirely for repairs during September.

Curator's Report.

The Curator had reported the average attendance in the Museum to have been—

		Total.	Highest.	Lowest.	Average.
May	Morning	258	25	3	11
	Evening	76	9	0	4

The following donations to the Museum had been received and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

African "Quina" Bark. From Messrs. Evans, Lescher and Webb.

Crystals of Ammonio-Chloride of Iron. From Dr. Prosser James.

Herbarium Specimens of Balsamodendron Roxburghii, Artemisia Sieversiana, and Origanum Majorana, used by the Portuguese in India; Root of *Gloriosa superba*; Fruit of *Randia uliginosa*. From Dr. Dymock, of Bombay.

Fresh Bael Fruits. From Mr. P. W. Squire.

Leaves of the Deer Tongue (*Liatris odoratissima*); *Euphorbia pilulifera*, and tincture of the herb. From Messrs. Burgoyne, Burbidges, Cyriax and Farries.

The Curator had submitted estimates for printing the Catalogue of the Hanbury Collection in the Museum of the Society.

Application for specimens from the Museum for scientific investigations had been received from Professor Bayley Balfour and Mr. W. H. Symons, also an application for a few specimens for a local museum at Bolton, through Mr. Woolley. The requests had been acceded to.

The Professors had attended the Committee and reported satisfactorily of their respective classes.

The list of Local Secretaries had been revised.

The details of painting and cleaning to be done during the recess had been considered, and an estimate for a new Council table had been obtained.

The Council went into committee to consider the details of the proposed alterations in ventilation of the Council room, etc.

On resuming, the report and recommendations of the Committee were received and adopted.

Deputation to the Privy Council.

The Council then went into committee for the purpose of enabling the President to state in detail what had passed on the previous day between a deputation of the Council, consisting of the President, Vice-President, Messrs. Bottle, Greenish, Hampson, Schacht and Williams, and the Lords of the Privy Council on the subject of the sale of poisons.

Local Secretaries.

The following list of Local Secretaries, submitted by the Library, Museum and Laboratory Committee, which had been further revised by the President and Secretary, was submitted:—

List of Local Secretaries, 1882–83.*

Towns eligible.	Names of persons appointed.
Aberdare	Thomas, Watkin, J.
Aberdeen	Davidson, Charles.
Abergele	Hannah, John.
Aberystwith	Wynne, Edwin Price.
Abingdon	Smith, William.
Accrington	Sprake, David Lewis.
Altrincham	Hughes, Edward.
Andover	Gould, Robert George.
Ashbourne	Reckless, Arthur Henry.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Ayr	
Banbury	Ball, George Vincent.
Banff	Ellis, Bartlett.
Bangor	Baker, Henry Villars.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow-in-Furness	Steel, Thomas.
Bath	Commans, Robert Dyer.
Beaumaris	
Bedford	Anthony, John Lilley.
Belper	Calvert, James.
Berwick	Carr, Walter Paterson.
Bewdley	
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Bishop Auckland	Dobinson, Thomas.
Blackburn	Farnworth, William.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, Francis.
Boston	Fowler, Wm. Ratcliffe.
Bournemouth	Duncan, Alexander.
Bradford (Yorkshire)	Rimmington, Felix M.
Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner.
Bridlington	Jackson, Henry John.
Bridport	Beach, James.
Brighton	Gwatkin, James Ross,
Bristol	Stroud, John.
Buckingham	
Burnley	Cowgill, Bryan H.
Burslem	Blackshaw, Thomas.
Bury	Bowker, Ellis.
Bury St. Edmunds	Summers, Frank.
Buxton	Thresh, John Clough.
Calne	
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Hollway, Albert Brown.
Cardigan	Jones, John Edward.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard Morgan.
Carnarvon	Lloyd, William.
Chatham	Crofts, Holmes Cheney.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Baxter, George.
Chesterfield	Windle, John T.
Chichester	Long, William Elliott.
Chippenham	Coles, John Coles.
Christchurch	Green, John.
Cirencester	Mason, Joseph Wright.
Clitheroe	
Cockermouth	Bowerbank, Joseph.
Colchester	Cordley, William Bains.
Congleton	Goode, Charles.
Coventry	Hinds, James.
Cricklade	
Croydon	Barritt, George.
Darlington	Robinson, James.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other towns as contain not less than three Members of the Society or Associates in Business.

Towns eligible.	Names of persons appointed.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Goodall, Henry.
Devizes	Edwards, Thos. Roberts.
Devonport	Codd, Francis.
Dewsbury	Matterson, Edward H.
Diss	Gostling, Thomas Preston.
Doncaster	Howorth, James.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	Gare, Charles Hazard.
Dumfries	Allan, William.
Dundee	Hardie, James.
Dunfermline	Seath, Alexander.
Durham	Sarsfield, William.
Eastbourne	Crook, Herbert.
Edinburgh	Stephenson, John B.
Elgin	Robertson, William.
Ely	Pate, Henry Thomas.
Evesham	Dingley, Richard Loxley.
Exeter	Delves, George.
Exmouth	Laugher, William.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, Walter Francis.
Fareham	Batchelor, Charles.
Faversham	Lanfestey, William G.
Flint	Jones, Michael.
Folkestone	Goodliffe, George.
Forfar	Ranken, James A.
Frome	
Gainsborough	Spouncer, Henry Thomas.
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Ward, Joseph.
Gosport	Hunter, John.
Grantham	Cox, John.
Gravesend	Bulgin, William.
Greenock	McNaught, Archibald.
Grimsby, Great	Cook, Robert, junior.
Guernsey	Arnold, Adolphus.
Guildford	Martin, Edward W.
Haddington	Watt, James.
Halifax	Dyer, William.
Harrogate	Davis, R. Hayton.
Hartlepool	Jackson, William G.
Harwich	Bevan, Charles F.
Hastings and St. Leonards	Bell, James Alfred.
Haverfordwest	Saunders, David Price.
Hawick	Craig, John.
Helston	Wakeham, Charles.
Hereford	Williams, Walter.
Hertford	Lines, George.
Hexham	Gibson, John Pattison.
Heywood	Beckett, William.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Bains.
Huntingdon	Provost, John Pullen.
Huntly	Chalmers, George.
Hyde	Wild, Joseph.
Hythe	Lemmon, Robert Alce.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut. John, jun.
Kendal	Severs, Joseph.
Kidderminster	
Kilmarnock	Borland, John.
King's Lynn	Palmer, William Joseph.
Kingston-on-Thames	Walmsley, Samuel.
Kirkcaldy	Storrar, David.
Knaresborough	Potter, Charles.
Lancaster	Bagnall, Wm. Henry.

Towns eligible.	Names of persons appointed
Launceston	White, Thomas.
Leamington	Davis, Henry.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Clark, Walter Beales.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lichfield	Perkins, John Jaquest.
Lincoln	Maltby, Joseph.
Liskeard	Young, Richard.
Liverpool	Symes, Charles.
Llandudno	Penney, William Sealy.
Longton	Prince, Arthur G.
Loughborough	Paget, John.
Louth	Hurst, John B.
Lowestoft	Sale, Thomas J.
Ludlow	Woodhouse, George.
Lyme Regis	Thornton, Edward.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.
Maidstone	Rowcroft, A. E.
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Buckle, James.
Malvern	Metcalfe, Edmund Henry.
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Candler, Joseph Thomas.
Marlborough	
Marlow	
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Buck, Thomas.
Midhurst	Cowap, Samuel Evan.
Monmouth	Key, Hobson.
Montgomery	
Montrose	Burrell, George.
Morpeth	Marshall, George T.
Neath	Hibbert, Walter.
Newark	March, William.
Newbury	
Newcastle-under-Lyme	Cartwright, William.
Newcastle-on-Tyne	Martin, Nicholas H.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Seys, James Ancas.
New Radnor	
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Fitzhugh, Richard.
Nuneaton	Iliffe; George.
Oldham	Hargraves, H. Lister.
Oswestry	Evans, John.
Over Darwen	Shorrock, Ralph.
Oxford	Prior, George Thomas.
Paisley	Hatrick, William.
Pembroke	Treweeks, Rich. Harwood.
Penrith	Kirkbride, William.
Penzance	Cornish, Henry Robert.
Perth	
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Hearder, Henry P.
Pontefract	Bratley, William.
Poole	Penney, William.
Portsmouth, etc.	Childs, James L.
Preston	Barnes, Lawrence R.
Ramsgate	Morton, Henry.
Reading	Hayward, Wm. Griffith.
Redditch	Mousley, William.
Retford	Clater, Francis.
Richmond (Yorks)	Thompson, John Thomas.
Ripon	Judson, Thomas.

Towns eligible.	Names of persons appointed.
Rochdale	Taylor, Edward.
Rochester	Harris, Henry William.
Rugby	Chamberlain, Arthur G.
Ryde (Isle of Wight)	Pollard, Henry Hindes.
Rye	Waters, William Allen.
St. Albans	Ekins, Arthur Edward.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, Samuel Ralph.
Sandwich	Baker, Frank.
Scarborough	Whitfield, John.
Seacombe	Walker, John Henry.
Selby	Cutting, Thomas John.
Shaftesbury	Barry, Frederic.
Sheerness	Bray, John.
Sheffield	Ward, William.
Shields, South	Mays, Robert J. J.
Shoreham	Fenner, Edwin.
Shrewsbury	Cross, William Gowen.

Mr. YOUNG raised the question whether it was necessary to appoint a Local Secretary for Edinburgh.

The Council went into committee to discuss the matter. On resuming,

Mr. YOUNG said he did not wish to divide the Council upon the question, and on the assurance of the President that the matter should be further considered before the appointments were made next year, the list as submitted was unanimously approved.

LOCAL EXAMINATIONS.

The SECRETARY presented the following table showing the attendance of candidates at the various centres for the last eleven examinations:—

PRELIMINARY EXAMINATION.

List of Centres and Table of Attendances of Candidates at each Centre.

	1880. Jan., Apr., July, Oct.	1881. Jan., Apl., July, Oct.	1882. Jan.	1882. Apr.	1882. July.	Total number of attendances at each centre at 11 examinations.

It was resolved that Superintendents be appointed at the above-mentioned centres, and that the appointments be offered in the first instance to the Local Secretaries in the respective places, with the exception of London.

Reports of Committees—*continued.*

LAW AND PARLIAMENTARY.

The report of this Committee dealt with a communication from the Colonial Office, relating to an ordinance to regulate the dispensing and sale of drugs and poisons in St. Lucia, and stated that the following letter had been sent in reply:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.,
"*June* 22*nd*, 1882.

"Robert G. W. Herbert, Esq.,
"Colonial Office,
"Downing Street, S.W.

"Sir,—I have the honour to communicate, for the information of the Secretary of State for the Colonies, the following observations which the Council of this Society offers upon a copy of an Ordinance of the Legisture of St. Lucia, entitled 'An Act to Regulate the Sale of Drugs and Poisons in this Colony,' transmitted by you for that purpose under date 20th of May last.

"Section 6 appears to assume that the law relating to apothecaries and chemists and druggists in the United Kingdom of Great Britain and Ireland is uniform, whereas the contrary is the case (38 and 39 Victoria, cap. 57, relates exclusively to Ireland).

"It may prove in the course of the administration of this section that inconvenience will not arise upon the language used, but in fact verbal accuracy would be promoted by insertion of the words 'or a pharmaceutical chemist,' after 'apothecary,' and before 'or a chemist and druggist,' and of the words 'in any part of' immediately before 'the United Kingdom of Great Britain and Ireland.'

"Section 7, sub-section 1.—The exemption of homœopathic medicines is the first instance known to the Council of special exemptions in favour of such medicines. However harmless so-called 'homœopathic medicines' may for a time have been, it is now not open to doubt that potent and dangerous poisons are sold as 'homœopathic medicines,' and it is deemed probable that wherever an exemption, such as is contemplated by the sub-section, may prevail, the exemption will become used so as to practically evade and defeat the general law.

"Section 7, sub-section 1, and section 8.—And it may be added that retailers of 'homœopathic medicines' so-called, are not, as a rule persons holding qualifications.

"Section 7, sub-section 1, and section 8.—Observations made by the letters which in 1881, under dates June 9th and 20th, I had the honour to address to Mr. Wingfield, for the information of the Secretary of State for the Colonies, on the Sale of Drugs and Poisons Law (Jamaica), apply to these sections. (See heading sections 18 and 19 of the letter of 9th June.)

"Section 10.—This appears to have been framed upon provisions contained in the Apothecaries Act, of 1815, which provisions soon became and now are practically obsolete.

"The official copy of the ordinance you sent me is returned herewith.

"I have the honour to be, Sir,
"Your obedient servant,
"Richard Bremridge.
"*Assistant Secretary.*"

The report also included the following correspondence with the Privy Council respecting the proposed addition of sulphuric and other acids to the Poison Schedule:—

"Privy Council Office,
"Whitehall,
"9 *June*, 1882.

"Sir,—I am directed by the Lords of the Council to transmit to you the enclosed copy of a letter which has been received from Messrs. Dale and Plant giving reasons why sulphuric and other acids should not be added to the list of poisons under the Pharmacy Act, 1868, and I am to state that their Lordships would be glad to receive any remarks that the Pharmaceutical Society might desire to offer in reply to the objections raised by Messrs. Dale and Plant.

"I am, Sir,
"Your obedient servant,
(Signed) "C. L. Peel.

"The Secretary,
"Pharmaceutical Society,
"17, Bloomsbury Square, W.C."

"*Copy.*
"(44688).
"81, Smallbrook Street,
"Birmingham,
"31*st May*, 1882.

"Dear Sir,—In reply to your kind memorandum of the 18th inst., No. 44599, respecting the addition of sulphuric and other acids to the Pharmacy Act:—

"1. Firstly, we believe it would be injurious to freedom of trade in creating monopoly, especially in manufacturing towns, where it is largely used.

"2. Secondly, it would enhance prices considerably, as chemists do not lay themselves open, at present, for this branch of trade, therefore, would require special hands for supplying these articles.

"3. Thirdly, we believe that chemists, as a whole, would not care for this trade being added, as it is extremely cumbersome, heavy, dirty, and very liable to accident. It would, no doubt, interfere with their dispensing department, on account of the dirty bottles in which it is usually supplied to consumers.

"4. Fourthly, it would be very inconvenient to manufacturers, as a whole, to be compelled to send to certain places for a supply, instead of getting it near at hand.

"5. Fifthly, we do not see how any public good can accrue from any fresh restrictions, as it is rarely, if ever, used as a poison.

"6. Sixthly, it would very largely affect a large number of old-established drysalters, who have cultivated a manufacturing trade in these goods, and do not dispense medicines; therefore, we think they should receive an amount of consideration before destroying their trade.

"If you should deem it necessary, we shall be pleased to forward you a memorial from the trades interested in the matter.

"Thanking you for your courtesy, and hoping to receive a favourable reply.

"We are, Sir,
"Yours obediently,
(Signed) "Dale and Plant

"The President,
"Privy Council,
"London."

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.,
"*June* 22*nd*, 1882.

"C. L. Peel, Esq.,
"Privy Council Office.
"Whitehall, S.W.

"Sir,—I am directed to send for the information of the Lords of the Council the following observations on a letter received by their Lordships from Messrs. Dale and Plant, in reference to the proposed addition of sulphuric and other acids to the poison schedule of the Pharmacy Act.

"Messrs. Dale and Plant assume that if these acids be added to the schedule it would entail considerable inconvenience on manufacturers as purchasers, and dealers in heavy chemicals as sellers of these acids. They seem to be unaware that such dealings as are referred to would be of the nature of sales by *wholesale*, and as such would be exempted by Section XVI. from those provisions of the Act which require that the sale should be confined to registered persons. The only restriction imposed by the Act in the case of such wholesale dealings is that the vessel containing the scheduled poison shall be labelled with the name of the article and the word 'Poison.'

"This assumption renders it unnecessary to reply in detail to the points raised in Messrs. Dale and Plant's letter, except, perhaps, No. 5.

"As to this it is submitted that, though cases of poisoning resulting in death by these acids are not so numerous as by some other poisons, it is undeniable that many serious cases of accidental poisoning, inflicting much harm and damage to the health, do occur. Vitriol throwing, moreover, is not by any means an uncommon form of the misuse of sulphuric acid.

"I am further instructed to state that the Council of this Society, before resolving to recommend that these acids should be added to the schedule, made numerous inquiries throughout the country as to the probable effect of bringing these acids within the provisions of the Act, the result of which satisfied them that it would be conducive to the safety of the public to place some restrictions on the sale of them, and that it would be practicable to impose such restrictions without seriously interfering with trade or industrial manufactures.

"I have the honour to be, Sir,
"Yours obediently,
(Signed) "Richard Bremridge,
"*Assistant Secretary.*"

The report was received and adopted.

GENERAL PURPOSES.

The report of this Committee was, as usual, read in committee. It included letters from the Solicitor, giving particulars of cases that had been placed in his hands for prosecution; also details of several cases of alleged infringement of the Pharmacy Act, some of which were recommended for prosecution.

The report and recommendations were received and adopted unanimously.

Pharmaceutical Education.

The following letter from Professor Attfield including one from Dr. Carpenter, was read:—

"Ashlands, Watford,
July 4th, 1882.

"To the Council of the Pharmaceutical
"Society of Great Britain.

"Mr. President and Gentlemen,

"I hope I shall not incur a charge of excess of zeal, if I venture to lay before you some opinions that happen to have come before me in support of the principle you recently adopted respecting the future relationship of education and examination.

"Ever since I commenced the advocacy of a recognized compulsory curriculum in pharmacy, namely, ten years ago, in a paper read at the Conference at Brighton, I have frequently had to meet the objection that the Society's existing plan of examining all comers was also carried out at the London University, and that what was good enough for the latter was good enough for the former. The reply, of course, was that the University made an exception to the rule in the case of medical candidates, with whom pharmaceutical candidates might fairly be classed. That this contention was well founded is shown by the enclosed letter from Dr. Carpenter, than whom no one else is better acquainted with the aims and objects of the University. I have lately received equally satisfactory opinions from Sir Robert Kane, Professor Tyndall and other high authorities.

"Since the Council's adoption of the principle referred to, but prior to the last Annual Meeting, I have distributed to each of the three thousand six hundred Members and Associates in Business of the Society, copies of that Essay on the Relationship of Education and Examination which two years ago I sent to the Members of Council, Examiners, and other prominent pharmacists. Already upwards of three hundred letters, besides acknowledgments, have come to hand, *all but five* being in favour of the action taken by the Council.

"I apologize for having urged reform in this matter with a persistence which may at times have appeared obtrusive. I can only plead love for pharmacy and that the end has crowned the means.

"Yours faithfully,
"John Attfield."

"56, Regent's Park Road,
"London, N.W.
"*May* 7, 1882.

"Dear Professor Attfield,

"In my former official position as Registrar of the University of London, it was my duty to administer a great system of examination for degrees in arts, science, and laws, open to all comers, but devised, with the aid of the experience of able teachers, to defeat cram, as far as possible; and the proof of its efficiency has been given by the much greater success of really *educated* candidates, as compared with those who were merely trained for the examinations.

"It has often been urged that the medical degrees of the University should be opened, like those of the other Faculties, without any restriction as to the mode in which candidates for them should prepare themselves. But the Senate have firmly held (and I trust that they will ever continue to hold) to the principle, that as medical degrees attest the candidate's qualification to practise medicine, they stand upon a footing altogether different from degrees which simply attest the possession of certain intellectual attainments. And they consider it essential to the possession of that qualification, that the candidate should have been systematically educated for it, the use of examinations being to test the thoroughness of his education, and the degree in which he has profited by it.

"As pharmacy partakes in this respect of the character of medicine, I am entirely at one with you in the principle that candidates for a qualification to practise pharmacy should be required to go through an education suited to qualify them, rather than a training which may enable them to pass examinations; or, in other words, that the examination should be adapted to test the thoroughness of the education which the candidate has received, rather than that the education should be adapted to bring up those who receive it to a certain examination standard.

"Believe me,
"Yours very sincerely,
"Wm. B. Carpenter."

The President said it was very satisfactory that a man who had been at the helm of a great examining body like the London University should have stated so definitely that free trade in examinations was not the wisest policy to pursue where special qualifications were required. It was also remarkable that, concurrently with the writing of this letter and with Dr. Carpenter's resignation, a new university had come into existence, in which examinations were made secondary to training.

Mr. Hampson thought it was free trade in education rather than in examination which the President meant to refer to.

The President said that was so. Those who had had experience of graduates from various universities were aware that there was a vast difference in the result produced by a process which involved good training, finishing up by an examination, as compared with simply an examination which might be passed at any time without the candidate being properly trained. In pharmacy they could never hope to go in for such a kind of training as was contemplated in the London University for degrees, but it was important that this letter should be placed on record.

Mr. HAMPSON said it was rather remarkable that these letters should have been sent just at this moment when Mr. Schacht was about to move his resolution with regard to examinations.

Mr. SCHACHT said he had no knowledge of these letters until he came into the room that day. At the same time he was very glad that Dr. Carpenter had been kind enough to write this letter, as, though it would not be likely to alter the views the members of Council themselves entertained, it might have some weight outside, inasmuch as Dr. Carpenter's opinion would carry great weight with the public mind.

After some further discussion, it was resolved to print the letters above given, providing the permission of the writers were obtained.

Mr. SCHACHT then moved the following resolution, of which he had given notice:—

"That a Committee be appointed for the purpose of considering the best method of giving effect to the resolutions of the Council of April 5, upon the Report of the Special Committee appointed to inquire into the Relation to each other of Pharmaceutical Education and the Pharmaceutical Examinations, and of reporting thereon to the Council; together with any suggestions it may desire to advance as the result of its deliberations: and that the Committee consist of the President, the Vice-President, Messrs. Bottle, Greenish, Hampson, Hills, Schacht and Symes."

He said he should occupy but a very short time, seeing that it seemed to be the natural consequence of what was done on the 5th of April. Certain propositions were plainly approved and adopted, and as practical men their next step must be to see their way to carry out those conclusions. He would venture just to intimate that one of the first duties the Committee would have to do would be to inquire how far the present legislative power would enable the Council to carry out the resolutions which were adopted, and if it should appear that the Council had no power at all in the matter, of course the subject must be relegated to a future time when its power was increased. But if it should appear that existing powers would enable the Council to go a long way, if not the whole way, towards carrying out the desired results, then further steps could be taken. His own opinion was that the Council had power at present to carry out these resolutions which had been approved and adopted, and he hoped that it would be found on investigation that the Solicitor not only confirmed that view, but would amplify and enlarge his own idea of the scope of the Council's powers. That was a question entirely for consideration and inquiry. In the last sentence of the motion he had ventured to indicate that if in the course of the Committee's inquiries any further suggestions arose which it was thought ought to be presented to the Council for approval, it should have power so to do. In asking that he was simply asking for power to report to the Council; that the Committee should have within the scope of its duties to formulate any fresh ideas on this large subject which occurred to it, and present them to the Council. The motion was so simple that there was no occasion to enlarge further upon it.

Mr. SYMES seconded the motion.

Mr. ROBBINS thought it must be left to the Solicitor to decide what power the Council possessed, and he thought the first thing the Committee should do would be to consult the Solicitor.

Mr. GREENISH said the Committee would have full power to consult the Solicitor if necessary.

Mr. HAMPSON said he should ask Mr. Schacht to leave out the last part of the motion. A new Committee, appointed to give effect to the resolution of the Council, would naturally go into the details of the resolutions and the practical steps to be taken, and the latter part of the motion did not seem necessary unless Mr. Schacht was anxious to reopen the whole question and amplify his scheme. He did not want to enter into Mr. Schacht's inner consciousness, but that gentleman had made use of the expression that he wished the Committee to formulate fresh ideas, and it appeared to him that the Council having come to a decision upon this question, there ought not to be further recommendations from another committee upon it. The Committee sat a long time and inquired into the question very minutely, and after that inquiry the vote of the Council was given, when the greater part of the scheme was accepted, but one portion was rejected; and it seemed to him that after having come to a distinct decision, there was considerable danger in passing this resolution and reopening the whole question. What had been already passed was extremely simple and was all that was required, perhaps more than was required under the present conditions of pharmacy; more education was really being demanded than the pharmacists of to-day could possibly use, and he hoped this matter would not be pressed in such a way as to nauseate the chemists of this country with this grand philosophical scheme, which might not after all be a matter of practical utility.

Mr. BOTTLE also asked Mr. Schacht to withdraw the last two lines, as it seemed to him they were not necessary. The Committee would report anything it had to suggest, but he took it it would not be open to the Committee to take the comprehensive view which Mr. Hampson referred to. Its deliberations would be entirely confined to giving effect to the resolution of the Council; anything beyond that would be outside its duty.

Mr. SCHACHT said it might be remembered that there were practically four recommendations offered by the Committee, and after a considerable amount of discussion three were adopted, and the fourth was negatived by a very small majority. But between the passing of the third and the refusal to pass the fourth, there was a good deal of conversation. That fourth recommendation referred to the way in which it was suggested by the Committee that the examination should be divided. The Committee recommended that it should be divided into two portions of a certain character, and that one portion should be conducted in the provinces, and the other solely in London and Edinburgh. Between that suggestion and the process of conducting the examinations in future as they were now there were several views; amongst them was a suggestion that it should be divided, but not that any portion of it should be conducted in the provinces. Another view was that it should be divided, but that the arrangement of subjects should be different to that recommended by the Committee. There were many opinions on that point, and it seemed to him that the three recommendations which were adopted, though complete as far as they went, failed to carry out a complete scheme for the future, such as the Council could agree to, and that, therefore, it would be necessary to go a little further and do something in the way of arranging the details.

Mr. HAMPSON said he had asked Mr. Schacht a question, and Mr. Schacht was now going into the whole matter.

The PRESIDENT said he must hold that Mr. Schacht was in order. He was justifying the use of these two lines which he was asked to withdraw.

Mr. SCHACHT said he did not want to enlarge any further upon the point except to say that almost as matter of necessity the Committee, in considering recommendations 1, 2, and 3, must touch on the subject of number 4 more or less, and if it came to a conclusion unanimously that it was desirable somewhat to moderate the decision arrived at on April 5, he thought it would be a pity it should not have power to present that conclusion to the Council. It was really more or less a matter of detail.

Mr. Hampson said he gathered that Mr. Schacht declined to withdraw the last part of the motion, and he could see quite clearly why he wished to press it as he had framed it. He evidently contemplated a re-opening of the entire subject and had very frankly stated his views. He said that the Council had accepted three propositions, but that these would not be complete without the adoption of the fourth. Although Mr. Schacht was perfectly frank and fair in so stating, he (Mr. Hampson) did not think it was altogether fair to attempt to circumvent the resolution of the Council in this way and force upon it the fourth recommendation. He admired Mr. Schacht's tenacity, but that was not what the Council wished. It had after very careful consideration accepted only three propositions, and he maintained that those three could be adopted and the details settled without entering upon the fourth at all. In his opinion the Committee ought not to reopen the matter, but abide by the motion accepted by the Council and carry it out as the Council desired.

Mr. Williams very much agreed with the view expressed by Mr. Hampson. It did seem to him very strange that when the Council had, after full consideration and discussion, come to a distinct conclusion that it should be called upon under the guise of completing and carrying out that conclusion to really agree to something which would be just the contrary. The Council had arrived at that decision by a considerable majority, but that decision, if he understood it aright, Mr. Schacht wished to reverse. Under these circumstances he must vote against the motion, unless Mr. Schacht would modify it.

Mr. Hills asked what was the majority on April 5, on this resolution.

Mr. Williams said it was not a question of what the majority was; it was the decision of the Council.

Mr. Hills said he thought he was entitled to ask the question.

Mr. Schacht said there were 8 votes for the proposition and 9 against it.

Mr. Young suggested that it would be as well, since Mr. Schacht frankly stated that he intended to raise this question again, for the Council to be reminded of what the fourth proposition was.

Mr. Schacht said his object was to enable the Committee to arrive at a conclusion which the Council did not arrive at. The Council gave no verdict, except one, and that was, not to approve of the exact thing submitted. There were many things suggested, but nothing carried with reference to number 4; but it was imperatively necessary that something should be carried with reference to the subjects included in number 4, otherwise the Committee could not report intelligently on "recommendations" 1, 2 and 3. He only wished the Committee to have the power of completing that which was left incomplete.

The President said he was by no means sure that if the two lines were left out it would not be perfectly in order for the Committee to consider various points of detail in connection with recommendation number 4. The Council had decided on nothing except the broad lines. Number 4 was a recommendation that the Minor examination should be divided into two parts with an interval of not less than six months between the first and second.

Mr. Hampson said it was clearly understood that the Council had accepted the three recommendations. Was it now meant that this Committee would have power to make recommendations with regard to carrying out the fourth proposition?

The President said numbers 1, 2 and 3 could not be carried out by themselves.

Mr. Hampson asked if it were not possible for the Committee, irrespective of the fourth recommendation, which was rejected, to make regulations for carrying out the first three.

Mr. Schacht said, no, he thought not.

Mr. Williams said in that case he should vote against the motion.

The President then read the first three recommendations of the former Committee, which had been adopted by the Council. He said the Committee had been unanimous that the Minor examination should be divided, and it was only a question as to how it should be done.

Mr. Savage said time was an important consideration.

The President said it appeared to him that the Committee must consider the recommendations under number 4 in some shape.

Mr. Hampson again stated his opinion that the three recommendations were complete in themselves. It was most irregular to include the fourth in the discussion at all.

The President said if the word "fourth" were obliterated from the discussion the question would be much clearer. Mr. Schacht's opinion was that certain recommendations, previously submitted by the Committee, would have to be considered in carrying out the three recommendations adopted.

Mr. Greenish thought the portion of the motion to which Mr. Hampson objected was almost an invitation to open the whole question. It was true Mr. Schacht referred to the fourth recommendation only, but under the terms of this motion it would be competent for the Committee to open the entire question, which he thought was a dangerous proceeding whilst the resolution of the Council rejecting that fourth proposition still existed.

Mr. Williams said the motion was quite clear. The Committee was to report on the resolution of the Council, not of the former Committee. The whole sting of the thing lay in the last sentence, and the gloss Mr. Schacht had himself given of it was that it was intended to revive all that which the Council had rejected.

Mr. Schacht said he did not think that was a fair interpretation of it. His first explanation was simply this, that there was something left unconcluded by the Council, and that was included in a certain recommendation which the Council rejected; still that something had to be formulated in some shape. He did not say it was to be done in his fashion, but that the Committee should have the power of considering the subject and reporting upon it. He was perfectly willing to withdraw the two lines, but the subject of what was called number 4 must be taken up if the discussion of the details of numbers 1, 2 and 3 were to have any practical effect.

Mr. Symes said if Mr. Schacht withdrew those two lines he must ask him to withdraw his name from the Committee. He could not undertake any duty which would be of such a piecemeal character as the report would then necessarily be. The first duty of the Committee would be to ascertain the legal position, and he thought it was quite possible the Council was wasting time in discussing this matter before it knew whether it had any legal power at all. Much of what he intended to say had been already said by the President and Mr. Schacht. The Committee made a report which, as far as he could judge, was complete in itself, and had four legs to stand upon, but the Council had taken away one of the legs; now the Committee were asked to report upon this three-legged arrangement. It seemed to him the Committee must deal with the whole four points to make the thing work at all, and unless it was entitled to do so its work would be useless. There were many occasions on which the Council had come to a decision by a majority of one, and had regretted that decision subsequently. There was nothing very dreadful in reconsidering the matter.

The Vice-President said he gathered from Mr. Schacht that he was willing to withdraw those two lines, and if he did so he hoped Mr. Symes would not withdraw his name from the Committee. Mr. Schacht had told the Council frankly what his motive was in introducing those words, but he believed the whole of his object would be covered, even without them. If the Committee went into those three points and found that they formed three legs which would not stand without a fourth, it would have to report it to the Council. Without referring to the strength of the majority, he exceedingly regretted that by one vote a point which he considered of some importance was lost, and he believed when the Committee went into the details it would be found impossible not to deal in some way with the fourth recommendation. It was important that all who had worked on the original Committee should continue their labours, and therefore he hoped Mr. Symes would not withdraw.

Mr. SAVAGE could not see the logic of the Vice-President's observations. If it were to be open to the Committee to deal with this fourth recommendation, those lines ought to stand, and Mr. Schacht ought to have an opportunity of introducing anything which might be thought advantageous and necessary to consolidate the three previous resolutions. Whatever was the result arrived at, it would have to come before the Council for confirmation; therefore, he trusted Mr. Schacht would not withdraw these words.

Mr. SQUIRE agreed with Mr. Hampson. He differed from those who said that the consideration of the first three points necessitated a consideration of number 4. The first was that every candidate for the Minor should produce evidence of apprenticeship; the second that the Preliminary should be passed prior to apprenticeship; the third, that on presenting himself for the Minor the candidate should bring evidence that he had attended certain courses of lectures on practical chemistry. The fourth was that the Minor should be conducted in a certain way. Surely that had nothing to do with certificates of attendance at lectures and evidence of apprenticeship or that the Preliminary should be passed prior to apprenticeship. He could not see that the fourth had anything whatever to do with the first three. Whether it was an advantage to consider it at the same time was another point, but he thought it would simplify matters very considerably to deal with the first three first, and if necessary to deal with number 4 separately.

Mr. GOSTLING thought there was a great deal in the remarks made by Mr. Bottle, and that by cutting out the last two lines the motion would be equally effective. It was very undesirable to adopt these two lines, especially the words "together with any suggestions," because they involved a great deal more than the division of the examination. If this were omitted he should be pleased to vote for the motion.

Mr. SCHACHT remarked that it was only "any suggestion as to the result of the Committee's deliberations," and the line of its deliberations was laid down in the earlier part of the motion.

Mr. HILLS hoped Mr. Schacht would not withdraw the last two lines. If he, as one of the proposed Committee, was not permitted to say anything about the points covered by recommendation number 4, he thought a great deal of the work would be of no use, because the scheme was one which depended very much for its value on being carried as a whole.

Mr. BORLAND agreed with Mr. Hills. Without coming to some conclusion as to the mode in which the examinations were to be carried out, the Council could not come to any definite conclusion as to the first three recommendations. When the resolution was before the Council he voted against it solely on the ground that the details were not defined in such a manner as to enable him to come to a conclusion, but if the result of the Committee were such as to bring before the Council a clear and concise method for carrying out the curriculum and the examinations he should be able to come to a conclusion on the matter.

Mr. YOUNG said he was sorry to say that he must differ from his friend, Mr. Borland. He supported Mr. Schacht on the last occasion, but he thought with Mr. Bottle, who had put the matter very plainly, that with the omission of these words, the Committee would have all that was wanted, and on principle they should be omitted. But for the explanation so frankly put forward by Mr. Schacht, the Council would not have known what the sentence meant, but Mr. Hampson had admitted that if those two lines were taken away Mr. Schacht had a perfect right to make such recommendations as he desired.

Mr. SYMES said, assuming these lines withdrawn, and that the report to be drawn up included the recommendations which were related to what was known as clause number 4, would not those gentlemen, who were now taking exception to it, rise and say it was out of order, that the matter was never delegated to the Committee? With regard to the appeal made to him by the Vice-President, he was always willing to do any work on Committee if he could be of any use, and his reason for withdrawing his name was not because he felt hurt at the scope of the Committee being cut down, but he could not afford to give up time which was valuable to him in doing work which could be of no possible use.

The PRESIDENT said if such an exception were taken at the Committee, he should have ruled that it would have been perfectly competent to consider the proposition known as number 4 as supplementary to the others without the last two lines being included in the resolution, but this discussion had altered the case very materially. It indicated an intention to tie the hands of the Committee instead of leaving them open.

Mr. WILLIAMS said after the explanation which had been given he thought he could only consistently support the action of the Council by voting against this motion. He was sorry to do so, but he considered that with regard to number 4, not merely the wording but the principle involved had been rejected. He thought the best thing would be to reject the proposal *in toto*, and, perhaps, on some future occasion it might be brought forward in such a way that it might be carried.

Mr. SCHACHT asked leave to put a parallel case. Supposing the Council sent a Bill to the Privy Council for adoption, and that body declined to take it up, would the Council understand that it was never again to present a Bill to the Privy Council with any hope of its being adopted?

Mr. WILLIAMS said not the same Bill certainly.

Mr. SCHACHT said he was not asking any permission from the Committee to send up number 4 again, but anything which occurred to the Committee as a wise and sensible recommendation. He had said just previously he was willing to withdraw those lines, simply because he understood the President to hold that the subject could be gone into without those two lines, and if that were understood he would withdraw them; but if that was not the reading he could not do so, because the usefulness of the Committee would be almost entirely lost if that question were not considered.

The VICE-PRESIDENT said he considered that the ground which Mr. Schacht intended to cover would be covered by the motion, omitting the last two lines.

Mr. SAVAGE said, whilst he opposed number 4, it was only right Mr. Schacht should have an opportunity of bringing any modification of it forward again.

Mr. BORLAND thought the Council was treating the matter on too narrow a ground. It did not follow that the proposition number 4 would be recommended again; there might be an alternative suggestion. Without maturely considering the details the Council was not in a position to come to a decision.

Mr. HAMPSON then moved as an amendment:—

"That the following words be omitted from the motion proposed by Mr. Schacht:—'together with any suggestions it may desire to advance as the result of its deliberations.'"

Notwithstanding his persistent opposition, Mr. Schacht had kindly put his name on the Committee, but he must decline to serve on these grounds. It appeared to him that the ruling of the President was likely to be of such a nature as to include the consideration of one of the recommendations which the Council had excluded by passing three only. Mr. Schacht had told the Council what position he should take on the Committee. He regretted that decision. He had no objection to serve on the Committee if its duties were confined to carrying out the decisions of the Council, but it ought not to enter into extraneous matter which the Council had already decided upon.

Mr. Young asked if Mr. Hampson objected to any suggestion the members of the Committee might make.

Mr. Hampson said not in carrying out the first three recommendations.

Mr. Young said that would avoid all reference to the way in which the examinations should be carried out.

Mr. Hampson said incidentally perhaps the Committee could not avoid it, but he was told by the President that he should rule that the fourth proposal could be entertained.

The President said that was not exactly what he said. His opinion was that any proposition under number 4, if brought before the Committee, would be worthy of consideration.

Mr. Gostling seconded the amendment.

The President thought this was a matter now to be voted upon, and that no further discussion was necessary.

On a vote being taken, 7 voted in favour of the amendment, and 7 against it.

The President gave his casting vote against the amendment.

Mr. Schacht's motion was then put and carried by 8 to 7.

Report of the Board of Examiners.

June, 1882.

ENGLAND AND WALES.

Preliminary Examination.

Six certificates received in lieu of the Society's examination:—

2 College of Preceptors.
1 Incorporated Law Society.
2 University of Cambridge.
1 University of Oxford.

The Secretary read the following resolutions, which had been forwarded from a meeting of chemists and druggists at Aberdeen:—

"Resolutions carried at a meeting of the Chemists and Druggists of the N.E. of Scotland, held in Aberdeen, on 28th June, 1882:—

"I. That this meeting, while approving of recommendations 1 and 2, disapproves of the proposed compulsory curriculum.

"II. That in order to enable assistants and apprentices to obtain an education suitable for the successful carrying on of the business of a chemist and druggist, this meeting is of opinion that the Council of the Pharmaceutical Society should formulate a scheme for the subsidizing of approved classes for pharmaceutical education, or otherwise that the Council of the Pharmaceutical Society should memorialize the Science and Art Department anent the institution of classes suitable for the same.

"III. That in the opinion of this meeting the provisions of the Pharmacy Act should be applicable to patent medicines and the compound preparations of the Pharmacopœia, and that in the interests of the public the sale of such articles should be confined to chemists."

The Secretary also read the following memorial from the Stockport Chemists' Association:—

"Memorial to the Council of the Pharmaceutical Society of Great Britain, from the Stockport Chemists' Association.

"Stockport Chemists' Association,
"Stockport,
"*June* 19, 1882.

"Your memorialists having observed that the sale of drugs and pharmaceutical preparations by grocers, tailors, etc., is increasing, and also, that they sell them at cost price, as an inducement for the sale of their legitimate wares,

"We, therefore, strongly feeling the injustice of our position, are of opinion that in any future legislation, affecting pharmacy, some attempt should be made to secure to the qualified chemist the sale of all pharmaceutical preparations, and if possible the materia medica contained therein, with a few manifest exceptions.

"On behalf of the Stockport Chemists' Association,
"We are,
"Yours faithfully,
(Signed) "Hervey Lowndes, *President*,
"Wm. Billing Orton, *Secretary*."

The British Pharmaceutical Conference.

The following members of the Council were appointed delegates to attend the meeting of the Conference, in August:—The President, the Vice-President, the Treasurer; and Messrs. Andrews, Greenish, Hampson, Savage, Schacht, Squire, Symes and Williams.

Provincial Transactions.

MEETING OF CHEMISTS AND DRUGGISTS OF THE N.E. OF SCOTLAND IN ABERDEEN.

A meeting of the chemists and druggists of the N.E. of Scotland was held in the Imperial Hotel, Aberdeen, on the 28th inst. There were twenty-seven present, twenty-one sent in apologies regretting their inability to be present. Mr. James Paterson occupied the chair.

It was moved by Mr. W. M. Ferrier (Brechin), and seconded by Mr. J. M. Munro (Aberdeen):—"That this meeting, being of opinion that the chemists and druggists in the North of Scotland are inadequately represented on both the London and Edinburgh Councils of the Pharmaceutical Society, resolve to appoint a Committee for the purpose of inducing suitable candidates to allow themselves to be put in nomination at next election."

The motion was carried unanimously, and the following gentlemen were nominated as a Committee to carry the resolution into effect, viz.: Messrs. Burrell, Montrose; Ellis, Banff; Robertson, Elgin; Chalmers, Huntly; Ferrier, Brechin; Reid, Sangster and Strachan, Aberdeen. Mr. Strachan, convener.

It was moved by Mr. A. Strachan (Aberdeen), and seconded by Mr. Ritchie (Aberdeen):—"That this meeting approves of the report of the Committee appointed by the Council of the Pharmaceutical Society to inquire into the relation of pharmaceutical education to pharmaceutical examination, as adopted by the Council in April last."

An amendment to the following effect was made by Mr. John Gordon and seconded by Mr. R. D. Presslie, viz.:—"That this meeting, while approving of recommendations one and two, disapproves of the proposed compulsory curriculum."

On being put to the meeting there voted—

For the Motion:—Messrs. Giles, Broomhead, Ritchie, Munro and Strachan, Aberdeen; Henry, Macduff; and Fraser, Clatt.—7.

For the Amendment: Messrs. Sim, Presslie; John Gordon, Johnston, Cruickshank, Spence, Mortimer and Paterson, Aberdeen; Ferrier, Brechin; Stephen, Macduff; Simpson, Woodside; Simpson, Peterhead; Bertie, Auchinblae; Fewtrell, Turriff; Sievewright, Cullen; and Clark, Portsoy.—16

The amendment was declared carried.

It was moved by Mr. John Gordon (Aberdeen), and seconded by Mr. R. D. Presslie (Aberdeen):—"That, in order to enable assistants and apprentices to obtain an education suitable for the successful carrying on of the business of a chemist and druggist, this meeting is of opinion that the Council of the Pharmaceutical Society should formulate a scheme for the subsidizing of approved classes for pharmaceutical education, or otherwise that the Council of the Pharmaceutical Society should memorialize the Science and Art Department anent the institution of classes suitable for the same."

The motion was carried unanimously.

It was moved by Mr. W. Giles (Aberdeen), and seconded by Mr. G. E. Broomhead (Aberdeen):—"That in the opinion of this meeting the provisions of the Pharmacy Act should be applicable to patent medicines and the compound preparations of the Pharmacopœia, and that in the interests of the public the sale of such articles should be confined to chemists."

The motion was carried unanimously.

It was moved by Mr. J. Hay Henry (Macduff), and seconded by Mr. Clark (Portsoy):—"That this meeting approves of the formation of a Chemists and Druggists' Society for the N.E. of Scotland, and resolves to take the necessary steps for having such a society constituted, and that it be remitted to the Aberdeen Society of Chemists and Druggists to report."

The motion was carried unanimously.

After the usual vote of thanks the meeting terminated.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The annual dinner of the members of the above Society was held in the Imperial Hotel, on Wednesday.

There were present—Messrs. Broomhead, Cruickshank, Giles, A. Gordon (Sim and Co.), Gordon (J. and J. Urquhart), John Gordon, Jun., Johnston (Reid and Sons), Mortimer, Munro, Paterson, Presslie, Ritchie, Sim, Sinclair, Shepherd and Strachan, Aberdeen; Bertie, Auchinblae; Clark, Portsoy: Ferrier, Brechin; Fewtrell, Turriff; Fraser, Clatt; Henry, Macduff; Lunan, Banchory; Simpson, Peterhead; Simpson, Woodside; and Stephen, Macduff.

Mr. Broomhead, the President, occupied the chair; and Mr. Munro, Vice-President, acted as croupier.

After a substantial repast, a number of toasts were proposed, including "The Queen and Royal Family," by the Chairman; "The Aberdeen Society of Chemists and Druggists," by Mr. Fewtrell, Turriff, and replied to by Mr. J. Gordon; "The Pharmaceutical Society of Great Britain," by Mr. J. Hay Henry, Macduff, and replied to by Mr. W. Sinclair, Aberdeen; "The Town and Trade of Aberdeen," by Mr. J. W. Stephen, Macduff, and replied to by Mr. D. Ritchie; "Country Friends," by Mr. J. Sim, and replied to by Mr. J. Clark, Portsoy; "The Ladies," by Mr. W. Giles, and replied to by Mr. R. D. Presslie; "The Croupier," and "The Chairman."

In the evening a number of the members drove out to Corby, where, after enjoying an hour's stroll in the pleasant grounds, they were hospitably entertained by Mr. and Mrs. Paterson.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A pharmaceutical meeting of the members of this College was held on May 16. The first paper read was the following on—

Bay Rum.

BY A. H. RIISE.

Bay rum is made by distillation of the leaves and berries of the bayberry tree with rum. Although bay rum is so much used in the United States, very little is known there about its origin, production, and the characters by which it is distinguished from imitations. A brief sketch of it will, therefore, be of interest to the druggist and importer as well as to the public in general.

The bayberry tree (*Pimenta acris*, W. A.; *Myrcia acris*, DC.) belongs to the large family of Myrtaceæ, which abound in fragrant volatile oils. The plant is glabrous, of a considerable size, the stem is straight and rigid, the branchlets green and shapely four angled, the leaves opposite, oval or roundish, shining, coriaceous, from 3 to 5 inches long, with numerous parallel nerves, and sprinkled with many pellucid dots. The flowers are arranged in axillary panicles, and are white, with a reddish tinge. The berries are round, of the size of a pea, two-celled, and contain six to eight seeds. The leaves, and particularly the berries, are of a very aromatic odour. The tree flowers from June to August.

There exist many varieties of the bayberry tree throughout the West Indies, scarcely to be distinguished botanically, but with a quite different odour from that which the genuine tree has, and, therefore, great care must be taken in collecting the leaves which are to be used in the distilling of bay spirit, as the admixture of a small quantity of the other leaves may entirely spoil the product of distillation.

In the manufacture of distilled bay spirit only the true leaves are used, and they are not dried, but thrown fresh into the still, as experience has shown a great difference between the spirits distilled from good fresh and from dried leaves, the odour of the latter being materially altered by the necessary exposure to the sun and air in drying.

The leaves are mixed, in the still, with the ripe berries in a certain proportion. The ethereal oil of the berries having a much stronger aroma than that of the leaves alone, a bay rum distilled partly from the berries has, therefore, a much stronger odour, and keeps its flavour much longer than if distilled alone from the leaves, but the cost of the berries is also from fifteen to twenty times that of the leaves, since they can only be procured with great difficulty.

The rum used for the distillation must be selected with great care. It must be of the very best quality, perfectly pure, and without any foreign odour. Rum from different sources cannot be used indiscriminately. A good St. Croix rum serves the purpose best, but it must be considerably stronger than what is generally brought into the market from there.

After having thus obtained the proper materials for the distillation, the next care is to be bestowed upon the operation. Distillation by steam, in large copper stills, ensures, to a certain extent, a uniform good quality of distilled bay spirit; it never gets burnt; the distillation is not carried too far; nothing of the fine aroma is lost by this process, which generally is the case by distilling over an open fire. Nearly all the distilled commercial bay rums are prepared over an open fire, to the great detriment of the flavour, but most of the bay rums in the market are not the product of distillation, being simply a solution of bay oil of a more or less good quality in common rum, or even in alcohol.

A comparison of bay spirit distilled from fresh material by steam with other bay rums will at once show the difference, the former being much stronger and finer in odour, so that a small quantity of it has not merely the same strength as a larger quantity of the others, but its odour will be found to be much more lasting and agreeable.

Bay spirit is used as a wash for the face, the hands, and the whole body, refreshing and invigorating the skin, and is highly valued when diluted with water for soothing the soreness after shaving. A bath to which about a quarter of a bottle of bay spirit is added strengthens the flesh, takes away the heat and dryness of the skin, gives softness and strength to the tired limbs, destroys all smell of perspiration, and produces a feeling of invigoration. In the sick room it is invaluable, as well for the sick person as for those around him; it purifies and refreshes the air in a remarkable degree. It is inestimable to travellers, especially in hot climates or in summer in the North, quickly relieving the feelings of lassitude of voyages. In fact, its uses are numberless and, while other perfumes quickly sicken many persons with excess of fragrance and the pungency of their aroma, the consumer will never get tired of using a good bay spirit.

In the discussion on this paper this subject was said to be of importance from the little that had been published. Bay rum is hardly known on the continent of Europe, and twenty-five years ago its true origin was also unknown in the United States. In a paper published in the *American Journal of Pharmacy*, in 1861 (p. 289), it was shown that bay rum was produced from *Myrcia acris*, the material for identifying the plant being a few leaves and branchlets, without flowers and fruit. Subsequently, the late Mr. Elias Durand ascertained, through one of his West Indian correspondents, that the plant had been correctly determined, but nothing was then known of the use of the fruit in this connection. That the volatile oil of this plant contained eugenol was known for some years, but this was first published by Professor Markoe, in 1877, who had made many interesting experiments with the volatile oil distilled by himself from the leaves, which proved its close chemical relation to the volatile oils of clove and pimenta. The composition accounts for the resemblance in odour; still there is a marked difference in this respect, fully as great as, for instance, in those volatile oils which contain anisol, and the cause of this difference is as yet not known. Plants which are of near botanical relation are often of very similar chemical composition; yet in the volatile oils there is sometimes a wide difference, not merely in odour, but in their constituents. Attention was drawn to the collection of volatile oils of different species of Eucalyptus which some years ago were presented to the College cabinet by Mr. Bosisto, of Melbourne, and of which one, obtained from *Eucalyptus persicifolia*, possesses not only an odour closely analogous to, but contains also the same chemical compounds which are found in the volatile oil of bitter almonds. It was suggested by Professor Maisch that probably the volatile oils of several of the many West Indian myrtles might contain eugenol and have a more or less distinct allspice odour, but that others had most likely an entirely different composition, and that the many varieties of the bayberry tree, referred to in the paper of Mr. Riise, were really different species of the genera Pimenta, Myrcia and other Myrtaceæ.

Mr. Shinn showed four samples of commercial bay rum, of which the one made by Mr. Riise had the specific gravity ·9210, corresponding to 48½ per cent. by weight of alcohol, while the density of the others was ·9290, ·9325 and ·9380, equal to 44½, 43 and 40½ per cent. of alcohol. A specimen of St. Croix rum had the specific gravity ·930 = 44 per cent. alcohol. The fragrance of these and similar spirits may be compared by first filling a clean test-tube or small vial and then emptying it, after which the peculiar flavour and its permanence become more apparent.

(*To be continued.*)

Notes and Queries.

[729]. Tinct. Quiniæ Amm.—I think there are points in this query not cleared up by the two replies It is easy to get a clear solution if you use proof spirit, full strength, liq. ammon. (B.P. 0·959), and distilled water. The variation in the strength of liq. ammon. usually kept, no doubt, is the cause of the complaint of the quinine precipitating, and I find the use of a hard water produces the same effect, which is assisted also by the small quantity usually made and kept in stock.

A Country Chemist.

[*** Seeing that quinine is soluble in ammonia, it is questionable whether quinine is precipitated at all in this case.—Ed. Ph. J.]

---

[731]. Colour of Pil. and Syr. Ferri Iodidi, B.P.—Your correspondent, "Specific Gravity," very properly calls attention to the colour of the above preparations. This might appear trivial, but for the fact that Squire's 'Companion to the B.P.' is held in such high esteem by the medical profession; and since a case in point has occurred where a medical man refused a well-made syrup, because it had the tinge of green in the transparent liquid, the words "is a transparent liquid with a tinge of green," would be better than "a colourless liquid."

This is the colour of syrup made either with the proper quantity of solution of iodide of iron and syrup, or as ordered in the B.P.

With reference to the pil. ferri iodidi, which certainly should not be black, if "Specific Gravity" were to varnish small masses of it before placing in well corked bottles, the minimum decomposition would be ensured, and then it would have the colour of the ingredients, viz., yellowish-grey.

William Fowler.

Correspondence.

Pharmaceutical Apparatus.

Sir,—In reply to the letter of Mr. W. Watson Will, which appeared in the Journal of June 24, I regret to say that I cannot give any information respecting the use of gas as a source of steam for laboratory purposes. We may, however, look forward to the time when gas, having been driven out of the market as a source of light (or very greatly so), it will be manufactured in great measure for the sake of the ammonia, aniline, etc.

We may then expect to have the gas supplied at such a moderate price as to be available as a cheap source of heat.

A. C. Abraham.

John.—The pin hole may be too small or the Bunsen defective. In the case of the Bunsen used by Mr. Symons the supply of air is regulated by the usual ring, so that the flame shall not descend when the gas is supplied *viâ* pin hole only, and there is still sufficient air to give a smokeless flame when full on. If your Bunsen is not so manageable, the difficulty can be overcome by placing a cap of wire gauze over its mouth.

Erratum.—In the notice of Roscoe and Schorlemmer's volume on Organic Chemistry last week it is incorrectly stated (p. 19, col. ii., l. 22) that the authors speak of the addition of methyl chloride to zinc sulphate to form zinc methyl iodide; it should have been to zinc coated with copper (copper zinc couple).

E. Hayward.—An explosion might be expected to occur when such substances are triturated together. See *Pharm. Journ.*, [2], xi., 552.

Communications, Letters, etc., have been received from Messrs. Lambie, Chipperfield, Shenstone, Warden, Peet, Chemicus.

THE INTERNATIONAL ELECTRIC EXHIBITION.

(*Continued from Vol. XII., page* 1032.)

The fact of a continuous solid conductor being raised to incandescence by the passage of a current of electricity of sufficient volume through its substance has been known from the earliest days of current electricity, and the heating of metallic wires by the transmission of a current of electricity has received thorough investigation at the hands of the older experimenters. Among those who have worked at this subject may be mentioned the great names of Davy, Faraday, Joule, Becquerel, Lenz, Harris, Grove, De la Rive Fourcroy, Vauquelin and Thenard.

Joule's masterly experiments resulted in the discovery of the law of the heating effect of a current. This law has been given in a previous paper when treating of the "electric arc;" but being peculiarly apposite in the present instance it may be stated once more—

$$H = C^2 R\, t \times 0{\cdot}24.$$

Where C is the current in ampères, R the resistance in ohms, t the time in seconds, and H the amount of heat produced in gramme degrees. It can be shown from this law that* "*a current of* 1 *ampère flowing through a resistance of* 1 *ohm developes therein* 0·24 *heat units per second.*"

When *the same* current passes alternately through a thick and a thin wire of the same metal, the thin wire becomes hotter than the thick one; this follows from the greater resistance of the thin wire, and also on account of its smaller capacity for heat and lesser radiating surface. Different metals having unlike specific resistances, and the heating effect being directly proportional to the resistance, it follows that in wires of different metals having the same length and diameter, the greater resisting wires will become the most highly heated. For instance, in similar wires of copper and platinum, ten times more heat would be produced by the same current in the platinum wire than in the copper wire, as the specific resistance of platinum, according to E. Becquerel's determinations, is ten times greater than that of copper. The heat produced in a wire is of the same amount, whatever may be its length, provided its diameter be the same throughout, *and the same quantity of electricity passes through it.* Faraday has left it upon record that the same current that will heat an inch of wire to redness will heat a mile or even a thousand miles of similar wire to the same extent. This statement is strictly true. It must, however, be remembered that as the length of the wire increases, the resistance increases proportionately; and so in order that the *same current* may flow, it follows that the electromotive force must be increased proportionately. This may easily be seen as a consequence resulting from Ohm's law (*Pharm. Journ.*, xii., p. 822). As regards the influence of the diameter of the wire on the amount of heat produced, it has been deduced from Newton's law of cooling that "for the same quantity of electricity, the increase of temperature in different parts of a wire is inversely as the fourth power of the diameter."

The foregoing considerations will greatly assist in the discussion of the various methods of obtaining light by the incandescence of a solid conductor.

* Silvanus Thompson.

As far as can be ascertained it was not until the year 1845 that any attempt was made to utilize an electrically incandescing solid conductor as a source of light. It would seem that the merit of being the first experimenter in this direction rests with Mr. Edward Augustin King, of London. Mr. King's patent is dated November 4, 1845. The preamble of the specification commences by stating that "this invention has for its basis the use of metallic conductors or of continuous carbons, heated to whiteness by the passage of an electric current. The best metal for this purpose is platinum; the best carbon is retort carbon." The lamp consisted of a vertical incandescent conductor of retort carbon generally resting upon conducting blocks at each end; from these blocks proceeded metallic conductors. Parallel with the incandescent rod was a bar of porcelain attached by metallic arms to the conducting blocks. One of the metallic conductors passed into a bath of mercury; the conductor in connection with the other end of the incandescing carbon passed through the upper part of a cylindrical glass envelope, which covered the whole arrangement. The lower narrower part of the glass cylinder was continued as a barometer tube, about 30 inches long. The lamp was exhausted of air by filling the lamp and the attached barometer tube with mercury; on inverting the entire apparatus the glass cylinder containing the rod of carbon emptied itself of mercury, thus forming the torricellian vacuum. The mercury in the barometer tube was made part of the electrical circuit. No dimensions are given of the carbon rod; the patent specification merely states that the retort carbon may be made into pencils or thin plates by the aid of saw and file. If platinum were used it was to be worked into thin sheets a quarter of an inch broad and of a length proportional to the number of battery cells used. The method recommended for obtaining the platinum in thin sheets was to place a piece of platinum foil between thick plates of copper and reduce the whole to a thin sheet by rolling; by this means the sheet would be of equal thickness throughout. The patentee makes the curious and interesting statement that, by this method of rolling, the platinum may be obtained so thin that on holding it before a printed page the letters can be distinguished through it. This early attempt to produce an incandescent lamp must be pronounced an extremely creditable one. The distance between King's thin carbon rod and the modern carbon filament cannot be considered remote. King's invention was much ahead of his time, and it really does seem as though, if the period had been favourable to such an invention, the "carbon filament in a vacuum" might have been a matter of near forty years ago instead of a thing of to-day.

The next advance was made by Greener and Staite, in 1846. These inventors devoted their experimental efforts to the preparation of purified carbon and the fashioning of this manufactured carbon into rods, hollow cylinders or square prismatic shapes. This patent is another striking example of the aphorism which declares that "there is nothing new under the sun." The patent practically, with slight exceptions, describes the modern manufacture of carbon rods for arc lights.

Messrs. Greener and Staite note that when carbon, in the purest state hitherto obtainable, is ignited by an electric current in an air-tight glass vessel the glass becomes obscured by the volatilized impurities.

The process of the inventors has for its object the removal of this inconvenience. They take lamp-black, charcoal or plumbago, or preferably* Church's patent coke in fine powder. The finely powdered material is digested with dilute aqua regia, afterwards washed with a weak alkaline solution, and finally with distilled water. The purified carbon obtained in this manner is dried and pressed into solid prisms or into cylinders, either hollow or solid, by means of hydraulic or screw pressure or by a fly press, "in the same way as the well-known porcelain buttons are formed." Sometimes to ensure better dryness and homogeneity the moulded carbons are exposed to intense heat in a furnace for twenty-four hours.

The lamp in which these purified carbons are used consists of an air-tight globular glass vessel containing two platinum cones whose bases face each other. In these cones is fixed a rod of the purified carbon, which may be either plain or have projecting points formed on its surface. This latter feature is claimed as an improvement, and some little stress is laid on it. The ends of the platinum cones are attached to the terminals of the battery. The inventors do not definitely state whether the containing vessel was vacuous or not, nor do they think it necessary to say how the external connections were made. Greener and Staite's incandescent lamp is thus seen to be identical in principle with King's. In practice, however, no doubt the superior purity and homogeneity of the prepared carbon rod would be found of material advantage, both as regards economy and durability.

In 1849, Petrie obtained a patent for an incandescent lamp, in which it was proposed to use rods of metallic iridium as the incandescing material. The iridium was to be fused in the electric arc and in some way formed into an ingot, which was then to be cut into rods of suitable shape. These iridium rods were to be used in place of the carbons used in the previous lamps. This scheme cannot be regarded as an advance on the previous ones, either as regards practicability or economy; indeed, it was undoubtedly somewhat retrogressive.

According to Fontaine, several other patents have been taken out in America, France and England for obtaining light by the electrical incandescence of a conductor, but he states that none of them are more complete or practicable than the method proposed by King.

* Church's patent coke was purified by an extraordinary kind of electrical process. The following are the details given in the patent which was taken out in 1845. As soon as the flame on the ignited mass of coal in the coke oven begins to die away, the air apertures are closed and through the temporary brickwork an iron-rod is introduced into the ignited coke near the bottom of the mass, and another iron rod is laid on the surface of the coke, taking care to make as good a contact as possible. The lower iron rod is made the positive electrode of a powerful battery, and the upper rod is arranged to complete the circuit. Care is taken that no short circuiting of the current occurs. Six tons of coke are said to require two hours of this electrical treatment. Church states that by repeated analysis he has found that the electrically treated coke is freer from sulphur than the same coke untreated, in the proportion of twelve to one. This statement is made so clearly and definitely that it is perhaps worth while for interested proprietors of coke ovens who have a dynamo machine in the works to consider the advisability of ascertaining whether any such obscure reaction takes place or not.

The whole subject appears to have been forgotten and lost sight of until 1873. In that year M. Lodyguine, of St. Petersburg, brought forward a lamp which appears to have been a reinvention of the leading principle of King's lamp. The St. Petersburg Academy of Sciences, however, awarded a substantial prize to Lodyguine for his invention. In the report made to the Academy upon it, it is stated that M. Lodyguine was the first who had conceived the idea of replacing the incandescent platinum by bars of carbon (coke) analogous to graphite, retort carbon being meant probably. It is evident from the preceding matter that this statement was a mistake, and the incandescent carbon lamp may be fairly regarded as of English and not of Russian origin.

The next inventor after Lodyguine appears to have been M. Konn, also of St. Petersburg. His lamp was apparently an improvement on its predecessors, as in this lamp arrangements were made so that when a carbon rod burnt out or failed, another rod was automatically put in circuit; no extinction of light therefore occurred until the second rod failed. Konn's lamp appears to have found some little practical application in Russia. Although the lamp was vacuous, the carbons only lasted on an average two hours each.

M. Bouliguine, another Russian, designed an incandescent carbon lamp with one long carbon rod, of which only a portion was incandescent at once. As the carbon rod consumed it was raised by the joint action of a counterweight and an electromagnetic contrivance. The additional complexity of M. Bouliguine's lamp would probably be found in practice to have little advantage over Konn's arrangement.

The foregoing descriptions are representative of the most important developments of this interesting subject, with one important exception, which will be dealt with fully later on. The record now reaches down to the time when Mr. Edison began his experiments in electric lighting, which have now reached such a successful issue.

NOTE ON THE PRESENCE OF A SECOND POISONOUS PRINCIPLE IN THEVETIA NEREIFOLIA.

BY C. J. H. WARDEN,

Bengal Medical Staff, Professor of Chemistry, Calcutta Medical College.

In the annual report of the Chemical Examiners' Department for 1880–81, the poisonous nature of thevetin,—a glucoside, isolated by De Vrij, contained in the kernels and bark of the *Thevetia nereifolia* plant,—was maintained. A further examination of the kernels has resulted in the detection of a second poisonous principle, apparently of greater activity than thevetin.

This second principle was obtained by precipitating the mother-liquor left after the crystallization of thevetin by aqueous tannic acid, and decomposing the precipitate by lime. By the action of absolute alcohol a yellow extractive was obtained, which had the following properties: it was persistently bitter, non-crystalline, and readily soluble in water. On aqueous solutions reagents produced the following effects: concentrated nitric or sulphuric acid, a yellow coloration; concentrated hydrochloric acid, no change in the cold or on heating; bichromate of potash and sulphuric acid, ferric chloride, or chlorine water and ammonia, no colour reactions; tannic acid, a white precipitate. ·017 of a gram injected into a cat's stomach caused in five minutes convulsive movements of the hind legs, which lasted for some time; there was also vomiting and profuse salivation. The cat recovered.

The amount of this principle isolated was only ·067 of a gram, so that it has only been possible to make a very cursory examination of its physical and chemical properties. It appears to differ from thevetin in a marked manner. Pure thevetin is white and crystalline, and only faintly bitter, and its aqueous solution is not precipitated by tannic acid. At present, through lack of material, I am unable to continue the investigation, which, however, I trust I shall be in a position to complete before the end of the current year.

THE ANALYSIS OF WINE.*

BY J. NESSLER AND M. BARTH.

I. Determination of the Amount of Extract.

The methods at present in use for the determination of the amount of extractive in wine differ from one another not only in subordinate details, but also in principle, according as extract is understood to mean the constituents of the wine absolutely non-volatile without decomposition, or the wine deprived of its water, alcohol and volatile acids. In the former case it is especially necessary to volatilize the glycerine completely without partially decomposing the non-volatile constituents of the wine through submitting them to too high a temperature. Determinations of extract in this manner are usually made with only a small quantity of wine (5 or 10 c.c.), which is heated upon a water-bath so long as water is perceptibly driven off, and the drying is then continued in an air-bath at 110° C., or preferably *in vacuo* until the weight remains constant. The other kind of determination has for a special object the retention of the glycerine as completely as possible in the extract. This can be effected either by avoiding raising the temperature above 100°, or by making an addition to the wine which will prevent the volatilization of the glycerine at a temperature of from 110° to 115° C.

In estimating a wine extract the authors concentrate 50 c.c. of the wine to a syrupy consistence on a water-bath, and then further dry it for three hours at the temperature of boiling water. In order to maintain this temperature exactly they used a jacketed apparatus, arranged like a paraffin drying chest, the interspace being filled with boiling water, and made sufficiently large for the water to be maintained in vigorous ebullition during four hours without exhaustion.

In order to ascertain whether in this process access of air exercised an essential influence upon the weight of the extract parallel experiments were made in which 25 c.c. of wine were placed in each of two platinum boats, enclosed in test-tubes, and arranged so that whilst side by side in the above-mentioned drying chamber a current of dried coal gas could be passed over one and a current of dried air over the other. A thermometer fixed in the drying chest showed that when the water was boiling vigorously the temperature in the interior was 100° C. After heating for eight and ten hours the residue was weighed with the following results:—

	Eight hours.	Ten hours.
Current of coal gas .	1·84 per cent.	1·80 per cent.
Current of air . .	1·90 „	1·86 „

* Abstract of a paper in Fresenius's *Zeitschrift für analytische Chemie*, xxi., 43.

The difference between the results of the two estimations is probably due to the extractive matter in the one case taking up oxygen from the air; but it is not considered sufficient to constitute an essentially larger quantitative result in drying under access of air than in a current of coal gas.

If the wine be first evaporated upon a water-bath in an open platinum dish to a syrupy consistence it only requires to be heated for three hours in the drying chest before reaching a point where the difference between two weighings is dependent entirely upon the volatility of the glycerine. Experiments made to determine the extent of this volatility showed that it amounted to about 10 per cent. of the glycerine present during the evaporation on the water-bath and another 4 per cent. in the drying chest. So that a wine containing 1 per cent. of glycerine would lose about 0·14 per cent. through its volatilization during evaporation and drying; but in a low wine, which with 5 or 6 per cent. of alcohol would probably contain only 0·4 per cent. of glycerine, the loss would only amount to 0·05 per cent. If, however, the extract be dried at 110° C., experiment has shown that in this part of the operation alone, in three hours, about 10 per cent. of the glycerine present is driven off, so that at the end of the drying the total loss is considerably larger than in drying at 100° C.

Alteration in the other constituents of the extract is relatively small when the drying is effected at 100° C. Fifty c.c. of wine, containing 0·47 total acids, was evaporated to the consistence of a syrup, then heated further for half an hour upon a water-bath, after which the non-volatile acid amounted to 0·36 per cent. The extract of the same wine after drying three hours at 100° showed upon titration 0·28 per cent.; that dried at 110° C. showed 0·22 per cent.; and that dried at 120° C. 0·11 per cent. of non-volatile acid.

Grete has recommended that in order to obviate the decomposition of the non-volatile constituents of the extract during drying, and especially to entirely prevent volatilization of glycerine, the wine should be evaporated with a measured quantity of titrated baryta water. Some experiments have been made by the authors to determine (1) whether an indifferent body like glycerine actually enters into chemical combination with caustic baryta so as to be no longer volatile at 110° C.; and (2) whether, if this be the case, the quantity of extract usually present in 10 c.c. of wine is sufficient to combine chemically with the whole of the baryta in 10 to 15 c.c. of baryta water of ordinary strength, so that in the dry residue no barium hydrate shall be present, since the reckoning of a variable amount of it as BaO would affect the result. An Alsace wine of 1876 was used, and it was found that the first of these questions must be answered in the affirmative, 0·489 per cent. out of 0·5 per cent. of added glycerine being recovered. As to the second, it was found that when 10 c.c. of baryta water was used it was certainly all combined, and that this was also the case with 15 c.c., unless the wine was particularly poor in extract. The partial decomposition of the nitrogenous organic constituents, which is made evident by the odour of trimethylamine when the extract containing baryta is heated, does not appear to exercise any essential influence upon the weight of the extract, whilst the acids of the wine, in the form of barium salts, better resist decomposition at a high temperature than in the free state.

This method has, however, the disadvantage that the same wine would be made to appear considerably richer in extract by the presence of traces of acetic acid, because whilst this would have been produced from the alcohol, it would be weighed with the extract. But the purpose of the adulterator, who had added glycerine to make up for the want of extract in a wine which had been diluted before fermentation with alcohol and water or sugar and water, would be thus served, as the extract would be brought up to the normal quantity, whilst in external characters the extract containing baryta from a diluted wine that has been treated with glycerine does not differ from that of a natural wine. In practice, therefore, in many cases an estimation of the acetic acid and glycerine would also be necessary. As previously mentioned, by far the greater portion of the glycerine present in wine is retained in the extract. A wine, therefore, to which any considerable quantity of glycerine had been added would yield an extract that is soft and viscous even after three hours' drying, whilst the extract from a natural wine is hard and generally bulky and blistered, or at the most,—where the wine is strongly alcoholic through fermentation, which increases the normal quantity of glycerine,—is plastic, somewhat like hard dough.

Hager has compiled a table* by the help of which the amount of extract in a wine can be ascertained from the specific gravity of the liquid after being deprived of alcohol. In almost all the completely normal wines the quantity of extract found by the above method corresponded within two to three hundredths per cent. to that indicated by Hager's table. If the wine contains sugar still unfermented, or unfermentable constituents of potato sugar, then usually the extract calculated is somewhat higher than what is found; but if, on the contrary, it contains an abnormal quantity of glycerine the extract calculated is considerably less than what is actually found. Therefore, it is always advantageous to compare the amount of extract calculated according to Hager's tables with that found by the method described. This method does not do away with the necessity for an estimation of the glycerine itself in such wines as may be suspected to have received an addition of glycerine.

The authors have applied this method in the estimation of the extract of several hundred kinds of undoubtedly genuine wines of different years and from widely separated districts. The results of these determinations are set out in a tabular form in a separate communication.† It was found that the absolute quantity of extract in pure natural wines may vary within very wide limits. Among other conditions exercising an essential influence upon it are the nature of the soil of the district in which the wine is grown, the situation of the particular vineyard, the weather, degree of ripeness of the grapes, the course of the fermentation, and unskilful treatment of the wine, which may induce a considerable alteration in the composition of the extract without any foreign addition being made.

The amount of extract present in pure, completely fermented wine stands in definite relation to the acid present. It amounted in none of the genuine wines examined by the authors, after the deduction of the free acid of the wine, to less than 1 per cent. It may happen that a genuine wine may contain less than 1 per cent. of extract free from acid; but in such cases the *non-volatile* acid is determined, and after deducting this fixed acid from the total extract there is always a residue amounting to at least 1·1 per cent. The estimation of the fixed acid is made with sufficient exactitude by evaporating 20 c.c. of the wine to a syrupy consistence, heating it further for half an hour to an hour on a water-bath, subsequently treating it with hot water and titrating after it has cooled.

But a larger proportion of extract than 1 per cent. after deduction of total acids may be expected—

(1) In wines which contain much sugar still unfermented, but in which from any cause fermentation is stopped. The fully fermented dry wines usually still contain a small quantity of sugar, which may vary between 0·01 and 0·001 per cent. The minimum of extract free from acid to be expected in a natural wine would exceed 1 per cent. by as much as the quantity of sugar as ascertained under suitable precautions by means of Fehling's solution exceeds 0·1 per cent.

(2) In wines from certain districts which are known by experience to produce in their best years a relatively full-bodied wine.

(3) In red wines. In these the smallest amount of acid-free extract is usually 1·2 per cent.; but in "berry wines," and in such red wines as have stood only for a very short time over the husks and stalks, the minimum is exceptionally 1 per cent.

Wines rich in ash also stand higher in respect to amount of extract. If a wine yields much ash and gives relatively little extract, and if in addition the ash is easily fusible and not blackened by incineration, then the authors thinks there is reason to suspect that the wine consists partially of the product of fermentation of a solution of sugar over wine residues.

Provided that the total amount of extract, free from ash and sugar, does not sink below a certain quantity, it may vary very considerably in composition according to the quality of the wine. For instance, since glycerine is a bye-product of fermentation, and may amount to from 7 to 10 per cent. of the weight of alcohol produced, a clear natural wine, rich in alcohol, would evidently contain more glycerine than one poor in alcohol. Another portion of wine extract consists of pectin bodies, which occur, however, in less quantity in proportion to the ripeness of the grapes used in making the wine. Very ripe grapes, rich in sugar, leave after fermentation relatively much glycerine and little pectin substance, while with unripe, very acid grapes, poor in sugar, the contrary is the case.

The ash constituents amount on the average to about 10 per cent. of the entire weight of the extract, but this amount is not an indispensable characteristic of a pure wine, since it may be affected by various conditions. For instance, a wine may be rich in extract, but not in ash, when it contains a considerable quantity of unfermented sugar; or the ash may be low through separation of tartar not only when a wine contains much alcoool, but when it has been exposed for a long time to a low temperature, which causes a separation of the tartar in crystals that do not redissolve on the normal temperature being restored. The total amount of ash found by the authors in genuine wines did not fall below 0·14 per cent.

II. A Modification of Neubauer's Test for Potato Sugar in Wine, and the Optical Behaviour of Pure and Saccharated Wines.

Neubauer's method for the recognition of an addition of potato sugar to wine or must is based upon the optical behaviour of the wine in a polarimeter. Whilst pure natural wine, which contains unfermented fruit sugar, rotates the plane of polarized light to the left, and completely fermented wine is quite neutral in its behaviour or rotates the plane only a few tenths of a degree of Wild's scale to the right, a fermented potato solution has a considerable residue of strongly dextrogyre constituents, which are not sugar. According to recent experiments by the authors with various kinds of commercial potato sugar, even the best qualities, pure white and in crystalline granules, contain from 15 to 18 per cent. of unfermentable substance, each 1 per cent. of which, in 200 mm. tubes, has a dextrogyre action of 1·5° (Wild). Consequently 1° of rotation by the fermented wine due to this cause would, on the average, correspond to an addition of 4 kilos of potato sugar to the hectolitre of wine. In the presence of unfermented sugar this result would be modified: 1 per cent. of sugar rotates about 1·25° to the right, so that 1° of rotation, due to unfermented potato sugar, would correspond to about 800 grams of chemically pure grape sugar in the hectolitre. But inferior kinds of potato sugar contain from 26 to 30 per cent. of the unfermentable substances, which do not reduce Fehling's solution.

As before mentioned, wine frequently contains a small quantity of a dextrine-like constituent, capable of exercising a slight dextrogyre action amounting to 0·03° to 0·6° (Wild). But this substance is almost completely

* *Zeitschrift f. analyt. Chemie*, xvii., 502.
† *Zeitschrift f. analyt. Chemie*, xxi., 198.

insoluble in alcohol, whilst the greater portion of the dextrogyre residue from fermented potato sugar is soluble in 90° alcohol. Upon this fact Neubauer based a method of distinguishing between the slight dextrogyre action of a normal wine and that of one containing potato sugar. The method, however, has the defect of admitting the possibility of the result being affected by the presence in the test solution of free tartaric acid, which also has a dextrogyre action. It is, therefore, proposed by the authors to modify it as follows:—

210 c.c. of wine, after the addition of a few drops of concentrated solution of potassium acetate, is evaporated to a thin syrup, treated with 90° alcohol, the alcoholic solution decanted when perfectly clear or filtered, water added, and the liquid decolorized with animal charcoal, evaporated to about 15 c.c., filtered, the filter washed and the filtrate brought up to 30 c.c. (one-seventh of the original volume of the wine) and polarized. If the resulting liquid shows a rotation of more than 0·6° (Wild), the wine may be considered with certainty to contain potato sugar.

If a wine contain non-inverted and unfermented cane sugar, which would probably have been added to it after fermentation to increase the amount of extract, the dextrogyre action of such a wine would be changed into a levogyre action during the evaporation even by the influence of the natural acids, but more certainly if a few drops of hydrochloric acid be added. The presence of unfermented cane sugar would therefore be indicated when a wine first shows a dextrogyre action and then after evaporation with hydrochloric acid shows a corresponding levogyre action.

A 6·5 per cent. solution of cane sugar, which rotated 8·4° to the right, was heated in a water-bath during three-quarters of an hour with some hydrochloric acid, brought to its original volume and polarized, when it showed a left-handed rotation of 2·2°. In order to test whether the inversion was quite completed, this solution was now kept in active ebullition for half an hour, evaporated water being restored as far as possible; it had then acquired, without any perceptible charring, a wine yellow colour, and having been brought to its original volume, showed a left-handed rotation of 1·7°. A sugar determination with Fehling's solution gave 5 per cent. of invert sugar. It follows that a 1 per cent. aqueous solution of invert sugar rotates about 0·34° to the left (1 per cent. cane-sugar solution rotates about 1·3° to the right); that the inversion of a tolerably large amount of sugar is completely effected in three-quarters of an hour on the water-bath; and that by longer heating to a little over 100° C. (*i.e.*, to the boiling point of the sugar solution) a portion of the resulting invert sugar is again decomposed. When small quantities of cane sugar are present the natural acids of the wine are sufficient to effect complete inversion during heating; but with larger quantities (1 per cent. and upwards) it must be assisted by a little hydrochloric acid. As soon as cane sugar in wine has completely fermented its addition to the must can no longer be detected by optical means.

The question whether an addition of caramel to a wine exercises any influence upon its optical behaviour has been answered in the negative by the authors' experiments, caramel proving to be optically inactive.

III. Chlorine Determination and the Amount of Chlorine in Wine.

It is known that in the estimation of wine by experts an essential value is placed, among other things, upon the amount of ash found in it, and that manipulations for increasing its bulk considerably lower the proportion of incombustible substances that it yields. In order to cover this poverty of ash constituents an addition is often made of such salts as will remain completely dissolved in the wine and hence not raise suspicions, and for this purpose an addition of common salt to a sophisticated wine is not very extraordinary. But it is more common to use water from a spring rich in residual matter, by which means the lowering of the ash constituents through dilution of the wine is much lessened. Such waters, however, are often very rich in chlorine compounds, and therefore the estimation of chlorine in wines is not unfrequently of especial interest. But isinglass occasionally, though not very often, contains some added salt, so that the presence of a sophistication cannot be assumed with certainty upon the single ground of the occurrence of a somewhat too large quantity of salt.

All wines that contain abnormal quantities of common salt are distinguished by the ash not burning white so easily as that of most other wines: it pertinaciously retains carbon, and upon using a very strong heat in incinerating it probably fuses and a large portion of the alkaline constituents is volatilized. If the incineration residue be left to cool, treated with water so as to separate the salt from the carbonaceous particles, and then heated carefully so as to avoid spirting (a characteristic of common salt), a pure white ash will probably be obtained, but it will not contain all the salt. Further, if the extract be simply carbonized and then treated with water, the residue from the evaporation of the liquor cannot be looked upon as containing all the sodium chloride as such; because the organic acids of the wine, immediately upon being heated, and before they are decomposed, expel a considerable quantity of hydrochloric acid and eventually form carbonates. Consequently a chlorine determination of ash produced as carefully as possible gives the amount of chlorine compounds in a wine too low.

In the estimation of chlorine in original wines those quantitative analytical methods which depend upon the use of potassium chromate as an indicator are not available, because the red-brown silver chromate is not insoluble in the free acids of wine. The previous neutralization of the wine results in the production of colour during the reaction, which prevents the commencement of the end reaction from being distinguished with the necessary sharpness.

In using Volhard's method of determining chlorine white wine must be first decolorized with animal charcoal free from chlorine compounds, as the yellow tannin-like substances of the wine will produce with the ferric salt used as an indicator an intensely dark green or black colour, and even by this decolorization the production of colour in the wine upon the addition of ferric salts, silver solution and potassium sulphocyanide cannot be entirely avoided.

A slight modification of Volhard's method induces a sharp end reaction and gives exact results. 40 to 50 c.c. of decolorized wine is acidulated with nitric acid and treated with excess of titrated silver solution, and titrated solution of potassium sulphocyanide added gradually, until a drop of the liquid allowed to fall into a drop of dilute solution of a ferric salt (iron alum) upon white porcelain shows a distinct red colour. If the quantity of potassium sulphocyanide solution required be large, the experiment should be repeated, taking as small an excess of silver solution as possible. Twenty-five undoubtedly genuine wines from different districts (including five red wines) were examined for chlorine, and it was found that the normal amount of chlorine in wine does not exceed 0·005 per cent., whilst in most wines it is below 0·002 per cent. Five genuine "Markgräfler" wines, of the years 1822, '62, '68, '70 and '75, showed an amount of chlorine varying between 0·002 and 0·0025 per cent. Italian and similar wines, grown in the neighbourhood of the sea-coast, frequently yield an easily fusible ash that does not burn perfectly white; but none have yet been observed in which the amount of chlorine exceeded 0·006 per cent. At Carlsruhe several wines have been examined in which the chlorine amounted to 0·03 per cent., representing 0·05 per cent. of common salt, or 25 per cent. of the entire ash.

IV. Detection of Free Tartaric Acid in Wine.

If 100 c.c. of wine be evaporated to a thin syrup, and this, while kept stirred, be treated with strong alcohol until a fresh addition of spirit no longer causes precipitation, all the tartar will separate within two hours and the alcoholic solution will contain the free tartaric acid. The alcohol is evaporated, the residue taken up with water, the somewhat turbid liquid cleared by the addition of pure washed animal charcoal,* filtered, and the filtrate, which may amount in volume to one-tenth of the original wine, treated cold with 1·5 to 2 c.c. of a 20 per cent. solution of acetate of lime. A wine, which tested according to Berthelot and Fleurieu's method is found to contain no free tartaric acid, does not show the slightest turbidity when treated in the above manner. Wines containing 0·05 per cent. of free tartaric acid show after a short time a crystalline separation, and after half an hour a distinctly crystalline granular deposit on the sides and bottom of the containing vessel; in two hours the separation is considerable, after which it does not perceptibly increase. An amount equal to 0·01 per cent. gave in two hours distinct crystals of tartrate of lime. The presence, however, of so small a quantity of free tartaric acid is of little consequence in judging a wine. Wines from unripe or partially unripe grapes contain free tartaric acid; but according to the results of experiments on wines from most diverse districts it never exceeds one-sixth of the non-volatile acids present.

V. Estimation of Citric Acid in Wine.

Citric acid is sometimes used as an addition to the acid in an excessively diluted wine, either in substance, or, if it be desired to give to the beverage at the same time body and the appearance of old wine, in the form of tamarinds, in which it is present in considerable quantity. The estimation of citric acid in wine has therefore considerable interest.

For the detection of citric acid the characteristic behaviour of its lime salt can be used, it separating in a crystalline form upon prolonged boiling of the aqueous solution; but the citric acid must previously be separated as much as possible from other acids and the special extract constituents of the wine, since citrate of lime remains dissolved in the neutral saline solutions of most acids. After many unsuccessful experiments the following method was found to give useful results.

100 c.c. of wine being evaporated to about 7 c.c., it is allowed to cool and then treated with 80 per cent. alcohol; after standing about an hour the undissolved matter is removed by filtration, the alcohol evaporated off, water added to bring the residue up to 20 c.c., part of the acid neutralized with a thinnish milk of lime (red wine requires here an addition of some washed animal charcoal), and then filtered. The filtrate, which must still be distinctly acid, is brought up to the original volume of the wine with water, and 0·5 to 1 c.c. of a cold saturated solution of neutral acetate of lead added and very briskly agitated. The lead precipitate contains a portion of the malic acid (another portion remains dissolved as an acid salt in the dilute acid liquid), phosphoric acid, a trace of sulphuric acid, tartaric acid and citric acid. It is filtered off, washed with cold water, placed together with the filter in a closed retort containing water saturated with sulphuretted hydrogen and energetically shaken and thus decomposed. After standing some time the perfectly colourless, clear liquid, which contains the above-mentioned acids, is filtered off, washed with water containing sulphuretted hydrogen, the sulphuretted hydrogen driven off by evaporation, and the liquid, amounting to about 15 c.c., made faintly alkaline with thin milk of lime, so as to separate phosphoric acid, then filtered, the filtrate acidulated with the smallest possible quantity of acetic acid, and by standing from half to one hour the tartaric acid present sufficiently removed as tartrate of lime. The liquid is then evaporated to dryness to separate free acetic acid, the residue taken up with hot water and this concentrated until the separation of the crystalline citrate of lime. After being once separated it is no longer soluble in hot water; it is filtered off, washed hot, dried and weighed. The salt has the composition $(C_6H_5O_7)_2Ca_3 + 4H_2O$. In this way, in a case where 20 mg. of citric acid had been added to a wine a precipitate corresponding to 13 mg. of citric acid was obtained.

In a specimen of commercial tamarinds 13·5 per cent. of citric acid was found.

Most of the natural wines tested were found to be free from citric acid. Some of them contained traces; as, for instance, a white Alsace wine of 1878 and a white Italian wine of 1880. But the amounts of citric acid in these wines only amounted to between 0·003 and 0·002 per cent.

* The charcoal must be boiled with hydrochloric acid and washed so that whilst moist it shall have a perfectly neutral reaction, and contain scarcely any salts, especially phosphate.

EXAMINATION OF THE ROOT OF BERBERIS AQUIFOLIUM—VARIETY REPENS—OREGON GRAPE ROOT.*

BY HENRY B. PARSONS.

This plant is found in the mountainous regions of Oregon, California, Utah, Colorado, Nevada and Montana, from which latter section the sample here examined was received.

The roots, as received, were in broken pieces, about a foot in length and ½ inch in diameter; they had a brownish exterior layer, underneath which was a bright yellow layer. The powdered sample has a bright lemon-yellow colour and a decidedly bitter taste.

The root is said to be much used in form of decoction for the treatment of what is known as the "mountain fever" among the western miners. By them it is reported to be an efficient tonic and antiperiodic, capable of replacing salts of quinia in the treatment of malarial disorders.

In 1837, a French physician, Piorry,† stated that he preferred a properly made extract of the root of *Berberis vulgaris* (a closely related plant) to quinia salts in all diseases where "he found the spleen enlarged in a patient suffering from ague, intermittent, or hectic." Some years later, his former pupil, Dr. L. M. Klein, made further experiments in treatment of fevers in Algeria, and he strongly confirmed the statements of Piorry. As the root of *Berberis vulgaris* (the common "barberry" of the Eastern States) is very similar in composition to the root of *Berberis aquifolium*, variety *repens*, the therapeutic action of the two is likely to be about the same, and the statements based on trials of the one are probably applicable to the other. Be this as it may, the fact remains that recent trials in the United States seem to show that the tonic properties of *Berberis aquifolium* are unquestionable, and eclectic practitioners have long claimed that its antiperiodic virtues were equally well defined and established.

A careful chemical analysis of the powdered roots reveals the presence of two alkaloids, to which, in all probability, can be ascribed the medicinal effects of the roots. None of the other substances were of a character likely to have any decided activity.

The first alkaloid, *berberina*, is the substance to which the yellow colour of the root is due; it is freely soluble in alcohol, moderately soluble in water and in chloroform and ether. Its taste is decidedly bitter. It forms sparingly soluble lemon or orange-yellow salts with sulphuric, hydrochloric and nitric acids, and salts more freely soluble with acetic, phosphoric and hypophosphorous acids.

* Report of the United States Commissioner of Agriculture, for 1880, p. 139. From *New Remedies*, March, 1882.

† *Lancet*, 1872, December 5, p. 498.

	Properties and Reactions.	Berberina.	Hydrastina.	Oxyacanthina.
		$C_{20}H_{17}O_4$	$C_{22}H_{23}NO_6$ (?)	$C_{16}H_{23}NO_6$(?). $C_{32}H_{46}N_2O_{11}$ (?).
1	Colour	Lemon or orange	Pure white	White; yellowish, on exposure.
2	Taste	Bitter	Nearly tasteless	Bittter.
3	Water	Moderately soluble	Insoluble	Nearly insoluble.
4	Absolute alcohol	Moderately soluble	Soluble	Soluble.
5	Commercial 90 per cent. alcohol	Soluble	Soluble	30 cold; 1 boiling.
6	Ether	Nearly insoluble	Soluble	125 cold; 4 boiling.
7	Chloroform	Moderately soluble	Soluble	Freely soluble.
8	Benzole	Nearly insoluble	Soluble	Soluble.
9	Ammonia	Soluble	Insoluble	Sparingly soluble.
10	Soda	Soluble	Insoluble	Moderately soluble.
11	Sodium carbonate	Soluble	Insoluble	Nearly insoluble.
12	Tinct. iodine	Dark red precipitate	Dark red precipitate	Dark brown-red precipitate.
13	Iodine in iodide	Nearly black precipitate	Nearly black precipitate	Dark brown-red precipitate.
14	Potas. merc. iodide	Yellow precipitate	Yellow precipitate	Yellowish precipitate.
15	Phosphomolybdic acid	Yellow precipitate, soluble in ammonia.	Brownish precipitate: not soluble in ammonia	Brownish precipitate, insoluble in but turned dark-blue by NH_4OH.
16	Potas. cadmium iodide	Yellow precipitate	White precipitate	White precipitate.
17	Picric acid	Yellow precipitate, insoluble in dilute HCl.	Yellow precipitate, insoluble in acetic acid	Yellow precipitate, insoluble in acetic acid.
18	Platinum chloride	Yellow precipitate, soluble in HCl.	Yellowish precipitate, soluble in HCl	Yellowish precipitate, insoluble in HCl.
19	Gold chloride	Yellow precipitate, insoluble in HCl.	Yellow precipitate, insoluble in HCl.	Orange precipitate, insoluble in HCl.
20	Tannic acid	Yellow precipitate, insoluble in HCl or $HC_2H_3O_2$.	Brownish precipitate, soluble in $HC_2H_3O_2$, but insoluble in HCl.	Brownish precipitate, insoluble in $HC_2H_3O_2$ and dilute HCl.
21	Conc. sulphuric acid	Yellowish-red, olive-green, brown, olive-brown	Yellow, purple-brown, green	Brownish-purple, browner, more purple on standing.
22	Sulphuric and molybdic acids	Yellow-brown, olive-green; same warmed.	Deep green, brick-red, red-brown, dark chocolate-brown	Purple; fades slowly; becomes yellow, then green.
23	Conc. nitric acid	Orange-red; no effervescence	Orange-red; effervesces; brown and darker	Orange-red; effervesces; colour permanent.
24	Fused zinc chloride	Yellow; light-brown	Light yellowish-brown	Chocolate-brown.
25	Specific rotatory power		+153·5 (in excess dilute HCl).	

This alkaloid is removed from the plant by water; much more readily, if a little acetic acid is added.

The alkaloid and its salts have been used as a tonic, and as an antiperiodic, and glycerin solutions of the alkaloid are still considerably employed in treatment of ulcerated surfaces.

The second alkaloid is called "*oxyacanthina*;" it is a white, bitter, difficultly crystallizable solid, which changes to a light yellow colour if it is long exposed to the air in a moist condition. The presence of a little caustic or carbonated alkali seems to intensify this colour, and may possibly cause the change. If this alkaloid be treated with dilute nitric acid in excess, and slightly warmed, it gives off nitrous vapours, and is converted partly into a yellowish-red resin-like substance, and a soluble substance much resembling berberina in colour, and precipitated by Mayer's solution. It may be possible that this alkaloid is closely related to berberina; a similar action occurs with hydrastina.

There seem to be no statements regarding the medicinal properties of oxyacanthina. As it is easily prepared, the matter might readily be investigated. It may be separated from the mother-liquors, after berberina has been crystallized from extracts of *Berberis aquifolium* or *B. vulgaris*, by adding a very slight excess of sodium carbonate solution with constant stirring. The yellowish precipitate should be allowed to separate; it can then be washed on the filter until nearly free from berberina, dissolved in dilute hydrochloric acid, and again precipitated by careful addition of ammonia. After washing and drying the substance is moderately pure. It may be further purified by crystallization from alcohol. It cannot be crystallized from chloroform alone.

The other chemical properties of these two alkaloids are given in the above table.

The yellow alkaloid, berberina, is geographically very widely distributed, plants containing it having been found growing in Europe, Asia, Africa and America. It is also found, probably, in more natural orders, and also in more distinct plants, than any other alkaloid; possibly caffeina may prove an exception.

Of the natural orders, it has been found in *Ranunculaceæ*, *Anonaceæ*, *Menispermaceæ*, *Berberidaceæ*, *Rutaceæ*, and *Leguminosæ*. The first five of the above natural orders are closely related, and it may prove that the presence of berberina, together with certain other alkaloids, may be of service in the identification and classification of doubtful botanical specimens. Thus it is at present possible to distinguish chemically between the root of *Hydrastis canadensis* (nat. ord. *Ranunculaceæ*) and the root of *Berberis aquifolium* or *B. vulgaris* (nat. ord. *Berberidaceæ*); for while both plants contain berberina, still this yellow alkaloid is associated in hydrastis with a white alkaloid (hydrastina), which gives quite different chemical reactions from the white alkaloid of berberis (oxyacanthina). A more complete study of this question would be of scientific and practical interest.

The following is a proximate analysis of the roots:

Proximate Analysis of the roots of Berberis Aquifolium, variety repens. "Oregon Grape Root."

Moisture		6·08
Ash, soluble in water	1·63	
Ash, insoluble in water	2·08	
		3·71
Crude fibre		23·33
Albuminoids, insoluble in water and alcohol	3·15	
Albuminoids, soluble in alcohol, insoluble in water	1·68	
		4·83
Berberina*		2·35
Oxyacanthina*		2·82
Black substance with oxyacanthina		0·23
Resin, insoluble in ether, soluble in alcohol		1·91
Sugars (traces), organic acids (?), extractives, colours		4·55
Ether extract, chiefly wax		1·36
Gum and yellowish colour		5·56
Starch isomers, by titration		18·05
Substances extracted by acid and alkali, determined by difference		25·22
		100·00

In the table on the previous page are given some of the properties and characteristic reactions of these three alkaloids. It will be seen that the different solubilities of the platinum salts (18) and of the tannate (20) and the strikingly different colour reactions, especially with sulphuric and molybdic acids (Fröhde's reagent), (22), serve to make the distinction between hydrastina and oxyacanthina comparatively easy and certain. Lack of material and of time prevented further chemical investigation of oxyacanthina.

TAPIOCA CULTIVATION IN MALACCA.†

The mode of cultivating tapioca in the Straits varies but little on different estates, whether owned by Europeans or Chinese. If jungle composed of large trees is to be cleared the trees are cut down at some height from the ground, the stumps remaining in the ground, and the whole set on fire, the charred remains of the trees being generally allowed to lie where they fall until the first crop is being cleared off, when they are utilized for fuel. After the ground has been dug over and the soil put into a friable condition the cuttings of tapioca are planted in rows from 3 to 4 feet apart and about 9 inches or a foot in the rows. The cuttings are lengths about a foot long of the stem of the matured plant. These root easily, and in less than two months the ground is covered with a carpet of green almost a foot high. From this time to the time the crop is lifted, beyond weeding and slightly banking-up, nothing is done to the crop, although on some estates the tall stems are sometimes cut down to about 4 feet from the ground, which must evidently keep the plants in a growing state, and prevent the proper storage of starch. On some estates I have known the crop lifted nine months after planting, with good results; but the Chinese planters in Malacca usually keep the roots in the ground sixteen or even eighteen months. Perhaps each has its advantages, but it has struck me that tubers kept in the ground over a year develope a large amount of woody fibre without increasing the quantity of starch, which is evidently a disadvantage to the machinery.

* The figures of berberina and oxyacanthina are probably a little too low, owing to the sparing solubility of the alkaloids or compounds which were weighed. The error does not probably exceed 0·1 per cent. in either case, and is probably least for berberina, which was weighed as platinum salt. The oxyacanthina was weighed as base.

† Extract from a communication to the *Gardeners' Chronicle*, June 17, 1882.

The general mode of lifting the crop is to cut off a certain portion of the tops, and pull up the tubers, the broken pieces being dug out afterwards. Of course, on land that has previously carried a tapioca crop, manure should be used, which by some planters is applied previous to planting, and by others after the young plants have started into growth. In Malacca, however, cow-shed refuse is a scarce article, and the cost of carriage would be considerable where estates are distant from the base of supply and roads in many instances steep and bad.

On one estate in Singapore under European management a green crop is grown with the tapioca, consisting principally of *Arachis hypogœa*, various crotalarias, principally *C. striata*, etc., which is dug in with lime, etc., while green, for the next crops, but the plan does not appear to find acceptance with other planters. The root of the tapioca it is hardly necessary to describe here, but I may state that while in Malacca I saw some specimens over 2 feet long, and weighing between 6 and 7 lbs. The roots being laid in heaps are carted to the manufactory, and the sticks laid in stacks for supplying cuttings for the next crop.

The estate first visited in Malacca was Buki Bruang (literally Bear Hill), and here we found J. M. Lyon and Co's patent machinery in full working order.

Of course steam is the motive power, in fact the most primitive styles of preparation seem unable to do without this, as I will show later on. The roots, being first divested of their woody tops, are thrown into a large revolving drum, in which pipes are so arranged that constant jets of water play on them as they are turned over and over, and gradually they reach the farther end of the drum perfectly clean, and empty themselves into a rasping machine, whence they emerge in the form of a fine pulp, which is thrown direct from the rasper into another cylinder covered either with stout muslin or brass-wire gauze, through the sides of which jets of water are continually passing. By this process the starch is separated from the pulp, the starch passing through the muslin or gauze into a tank beneath, where further supplies of water send it off through gutters to vats prepared for its reception, while the pulp is discharged from the drum into baskets and thrown into heaps either for cattle feeding or manure, for either of which I imagine it is little suited.

After the starch in the vats has been allowed to subside the water is gradually drawn off, fresh water supplied, the whole stirred up and again allowed to subside, and the water again drawn off. The treatment of the starch in this stage depends on the purity of the water used—as, unless the tapioca when prepared is of the purest whiteness it can hardly be given away. Hence, one of the principal points to be attended to is the supply of clean water in abundance. After the starch has become sufficiently pure it is allowed to dry in the vats, whence it is cut out in cakes and is then ready for the last stages of preparation. If tapioca flour is required it is placed first on racks to dry, then on large, almost flat tin sheets which form the top of a brick flue where an extremely gentle fire is kept up.

If flake tapioca is requisite it is submitted to rather stronger heat in concave pans at first, whence it is removed to the previously mentioned sheets and kept turned over with wooden rakes, etc., until it assumes the flake-like form so familiar to consumers in Europe. The flakes are then sifted, to separate the various sizes, and the prepared tapioca is ready for placing in the bags for shipment.

Next morning at 6 o'clock we were *en route* to another estate, belonging to Mr. Koh Hoon Boh, at Matchap, about eighteen miles distant. The first ten miles is along the public road, along some parts of which in wet situations are large indigenous plantations of the glam (*Melaleuca leucodendron*), the bark of which is used by Malays for caulking their boats. In all directions we saw the natives busy planting the rice fields.

On leaving the public road, however, our troubles began; to drive over the road we did the day before was a delight compared with the one it now fell to our lot to drive over, and it was with no little satisfaction that I gave up the reins at Matchap to the syce, after his informing me when within fifty yards of the house that I had two miles more to drive. Here we found the primitive style at work. The roots are first half-peeled with knives, in which operation a large part of the root is cut off, then thrown into a tank of water, when they are washed by the Chinese treading on them; thence they are lifted in baskets to the rasping machine, which is worked by a traction engine, built in the brickwork, and regulated by hand. The pulp falls from the rasper into baskets, which are carried about twenty yards, and the contents emptied on muslin covers of concave wickerwork baskets, above which a wooden water gutter is placed, the supply of water being regulated by plugs over the baskets. Here the Chinamen separate the starch by arranging a constant fall of water on the muslin, and keeping the mass well stirred with their hands until they think they have extracted all the starch, when they throw the refuse pulp away, and receive a fresh supply from the rasper, the water with which they wash the pulp serving to convey the starch to vats prepared for it. Of course the starch prepared in this manner requires more washing than that prepared by the machinery I have described, and I venture to think that consumers in England would prefer tapioca, made by machinery, when it need never be handled, to that which is carried about so much amongst decaying vegetable matter and mud, as that hand-prepared usually is. Here the starch is baked by fire passing beneath a tile-covered flue on which it is placed. Pearl tapioca is manufactured here as follows:—A cloth is attached like a hammock to the beams and kept open by cross sticks. A man at each end alternately jerks the cloth to and fro, the slightly warmed starch under this treatment soon forming small, completely spherical balls, which are afterwards baked on a tile covered flue.

The number of coolies about here was surprising, and it is hardly necessary to say that only about 30 piculs of tapioca is produced per diem; in fact, Mr. Koh Hoon Boh is so thoroughly convinced of the superiority of manufacture combined with economy of the preparation by machinery, after comparing the cost at his estate, which we visited the day before, with the cost of hand preparation, as at Matchap, that he ordered a machine to be erected at once.

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from page* 26.)

SODII SALICYLAS (*Salicylate of Sodium*).

Salicylic acid, dialysed	33
Bicarbonate of sodium	20
Distilled water	q.s.

Mix the acid and bicarbonate in a porcelain capsule, with the least possible quantity of distilled water to a thick paste and heat the mixture, on the water-bath, to a temperature no exceeding 60° C. (140° F.). When no more carbonic acid gas escapes, ascertain if the solution has still a slight acid reaction, and, if this is the case, evaporate it to dryness, under constant stirring.

A white powder, crystalline or amorphous, soluble in 0·8 part of water and in 5 parts of strong alcohol.

SANGUIS BOVINUS SICCUS (*Dried Ox-blood*).

Fresh ox-blood	q.s.

Free it, while still fresh, by beating, from the fibrin, strain and evaporate it, under continuous stirring, on the water-bath to dryness, at a temperature not exceeding 60° C. (140 F°.).

Preserve the powder in a well-stoppered bottle.

SAPO GUAIACINUS (*Guaiac Soap*).

Guaiac	2
Potassa	1
Water	q.s.

Rub them together and add enough water, in drops, to produce a mass of a pilular consistence.

It should not be kept in stock.

SAPO PICIS LIQUIDÆ (*Tar Soap*).

Medicinal soap (Castile soap)	24
Carbonate of sodium, dried and powdered	2
Borate of sodium, powdered	1
Tar	8
Water	q.s.

Mix them together to a mass of a pilular consistence and divide it into pieces of suitable size.

SAPO TEREBINTHINÆ LIQUIDUS (*Liquid Turpentine Soap*). [Balsamum vitæ citrinum.]

Carbonate of sodium	3
Medicinal (Castile) soap	4
Oil of turpentine	6
Compound spirit of mastic	6
Compound spirit of juniper	6
Water	60

Heat the carbonate of sodium, soap, oil of turpentine and water for several hours on the water-bath, filter and add the spirits.

COMPOUND SPIRIT OF MASTIC (*Pharm. Neerl.*) is prepared thus:—

Mastic	1
Olibanum	1
Myrrh	1
Amber	1
Stronger alcohol	10
Water	12

Distil them together until the distillate has a specific gravity of 0·873 to 0·878.

COMPOUND SPIRIT OF JUNIPER (*Pharm. Neerl.*):—

Juniper berries	3
Caraway	1
Fennel	1
Stronger alcohol	14
Water	30

Distil them together until the distillate has a specific gravity of 0·929 to 0·935.

LIQUOR ACIDI ARSENICI (*Solution of Arsenic Acid*).

Arsenious acid, powdered	4
Hydrochloric acid	1
Nitric acid	9
Distilled water	q.s.

Boil the acids together in a glass flask, until a portion of the liquid, after being neutralized with soda solution, is no longer rendered green by solution of bichromate of potassium.

Evaporate, on the water-bath, in a porcelain capsule, until acid vapours are no longer given off, and the liquid has a syrupy consistence.

Finally, add enough distilled water to obtain 80 parts of product.

The solution contains 5·75 per cent. of arsenic anhydride (As_2O_5).

LIQUOR FERRI ALBUMINATIS (*Solution of Albuminate of Iron*). [Solutio Albuminatis Ferrici.]

Albuminate of iron	1
Hydrochloric acid	0·1
Distilled water, warm	100

Dissolve the albuminate of iron by aid of the acid in the water, and filter the solution, if necessary.

The product contains 0·033 per cent. of iron, and should be freshly prepared when wanted for use.

(Fer formula of Ferri albuminas, see vol. xii., p. 662).

* From *New Remedies*, April, 1882.

Liquor Hydrargyri Albuminatis (*Solution of Albuminate of Mercury.*

[Solutio Albuminatis Hydrargyrici.]

White of egg	32
Bichloride of mercury	1
Chloride of sodium	4
Distilled water	q.s.

Mix the white of egg thoroughly with 45 parts of distilled water; filter the mixture, and precipitate it by enough of a solution of the bichloride of mercury in 19 parts of distilled water, until a few drops of the liquid, when mixed with solution of carbonate of sodium, begins to assume a red colour.

Then add a solution of the chloride of sodium in 16 parts of distilled water, or as much thereof as may be required to redissolve the precipitate.

Dilute the mixture with distilled water to 100 parts.

Let it stand a few days, filter it, and preserve it in small, completely closed vials.

Sapo Stibiatus (*Antimony Soap*).

Sulphide of antimony (Schlippe's salt)	1
Medicinal (Castile) soap	3
Water	3

Dissolve the sulphide of antimony in the water, add the soap and reduce the mass to a pilular consistence, by a gentle heat.

Whenever the mass assumes a red colour, on the water-bath, add a little solution of soda.

The soap should have an ash-grey colour, and be soluble in water. It should be kept in a well-stoppered bottle.

N.B.—Schlippe's salt is prepared as follows:—75 parts of carbonate of sodium (cryst.) are dissolved in 300 parts of water, heated to boiling and mixed with a milk of 26 parts of lime and 100 parts of water. After half an hour's boiling, 9 parts of sublimed sulphur and 36 parts of levigated sulphide of antimony are added, and the whole boiled until the grey colour has disappeared, when the liquid is filtered and crystallized. The salt has the composition: $Na_6Sb_2S_8.18H_2O$. It is a sulphantimoniate of sodium.

Liquor (Bromo-) Arsenicalis Clementis (*Clement's Solution of Arsenic and Bromine*).

[Solutio Arsenicalis Clementis.]

Arsenious acid	1
Carbonate of potassium	1
Bromine	2
Distilled water	q.s.

Heat the arsenious acid with the carbonate of potassium and 10 parts of distilled water in a flask, until the acid is completely dissolved. When cold, add to it the bromine and enough distilled water to make the product weigh 100 parts.

Liquor Arsenicalis Isnardi (*Isnard's Solution of Arsenic*).

[Isnard's Water.]

Arsenious acid	1
Distilled water	q.s.

Dissolve the acid in 100 parts of distilled water, and dilute the solution with distilled water to 10,000 (ten thousand) parts.

Liquor Chloroformi cum Morphia (*Solution of Chloroform with Morphine*).

[Solutio Chloroformi cum Morphino.]

Morphine (alkaloid)	1
Acetic acid	q.s.
Stronger alcohol	20
Chloroform	80

Dissolve the morphine in just enough acetic acid at a gentle heat. Then add the alcohol and chloroform, and preserve the mixture in a well-stoppered bottle.

Liquor Ammonii Citratis (*Solution of Citrate of Ammonium*).

Citric acid	16
Water of ammonia	q.s.
Distilled water	q.s.

Dissolve the citric acid in 40 parts of distilled water; add enough water of ammonia to neutralize the solution (about 40 parts). Filter and dilute with enough distilled water to make the product weigh 100 parts.

The solution contains 20 per cent. of citrate of ammonium, and should be freshly prepared when wanted for use.

Tinctura Ferri Iodidi (*Tincture of Iodide of Iron*).

[Solutio Iodeti Ferrosi Spirituosa.]

Iron, in powder	3
Iodine	8
Distilled water	q.s.
Stronger alcohol	q.s.

Mix the iron and iodine in a glass flask, with 20 parts of distilled water. When the mixture has acquired a bright green colour, filter it, wash the filter with a little strong alcohol, and add enough alcohol to the filtrate to make it weigh 100 parts.

The tincture contains 9·7 per cent. of ferrous iodide, and should be freshly prepared when wanted for use.

Tinctura Iodinii Decolorata (*Decolorized Tincture of Iodine*).

[Solutio Iodii Decolorata.]

Iodine	10
Hyposulphite of sodium	10
Spirit of ammonia	16
Distilled water	q.s.
Alcohol (stronger)	75

Digest the iodine with the hyposulphite and 10 parts of distilled water in a glass flask until all is dissolved. When cold, add the spirit of ammonia, shake a few minutes, and then add the alcohol. Let the mixture stand in a cool place until it has become colourless; then filter.

A clear, colourless liquid, of a peculiar ammoniacal odour, and a specific gravity of 0·940 to 0·945.

Liquor Ferri Dialysati (*Solution of Dialysed Iron*).

[Dialysed Iron.]

Solution of chloride of iron (ferric chloride), specific gravity 1·480–1·484	35
Water of ammonia (0·960)	20
Distilled water.	

Place the solution of chloride of iron in ice for fifteen minutes; then mix it gradually with the water of ammonia, previously cooled by ice. Stir the mixture, and when it has become clear again, pour it into a hog's bladder, previously cleansed by treatment with dilute solution of potassa and washing with water. Tie the bladder as close to the liquid contents as possible, and suspend it in a cylindrical glass containing five times the volume (of the bladder) of distilled water, so that the surface of the water is about 1 cm. above the top of the bladder.

Change the water, first every twelve, afterwards every twenty-four hours, and continue to do this until the water, when acidulated with nitric acid, is no longer rendered turbid by nitrate of silver. Then dilute the liquid in the bladder with distilled water until it has a specific gravity of 1·046.

The solution contains 5 per cent. of iron, is clear, has a dark brown colour, no odour, and scarcely any taste. It is miscible with strong alcohol, but on addition of an acid or an alkali, it separates a red-brown precipitate.

It should give no reaction either with ferricyanide of potassium or with nitrate of silver.

Liquor Sodii Carbolatis (*Solution of Carbolate of Sodium*).

[Solutio Phenylatis Natrici.]

Carbolic acid	5
Solution of soda (specific gravity 1·330)	1
Distilled water	4

Mix them.

A clear liquid of an alkaline reaction, a specific gravity of 1·060 to 1·065, and miscible with water and alcohol in all proportions.

It should be freshly prepared when wanted for use.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, JULY 15, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PROPOSED AMENDMENT OF THE WEIGHTS AND MEASURES ACT.

CONSIDERABLE inconvenience has been experienced in the working of the Weights and Measures Act, 1878, from the permissive character of the provisions in regard to the fees charged for verification and stamping, and the opportunity thus afforded for inequality in the charges made for this work. It is from the manufacturer's point of view highly desirable that, whatever charges are made for verification and stamping of weights and measures, there should be one uniform rate for the whole Kingdom. Probably it is from considerations of this kind that a Bill has been brought into Parliament by Major Ross and Dr. CAMERON to amend the Weights and Measures Act, 1878. According to the official report of the votes and proceedings the Bill was read a second time on Wednesday evening and committed for Monday next, and as it deals with apothecaries' weights and measures, as well as those of other denominations, it will be well to recapitulate the amendments which it proposes to effect.

According to the forty-seventh section of the Act an inspector may take for verification and stamping any fees fixed for the time being by the local authorities appointing him, provided only that they do not exceed in amount those specified in a schedule appended to the Act. By the Bill now before the House of Commons it is proposed to repeal so much of the forty-seventh section as relates to the amount of the fees, also to replace the schedule in the Act by another scale of fees, and to enact that an inspector under the Act shall take in respect of the verification and stamping of weights and measures such fees and no other as shall be according to the scale contained in the new schedule.

The chief point of interest in this Bill for pharmacists is the introduction of a scale of fees for the verification and stamping of what are termed apothecaries' weights and measures. For each weight from ten ounces to one ounce inclusive the fee is to be twopence, and for each weight from four drachms to half a grain inclusive the fee is to be one penny. The fees for graduated measures are to be one shilling for each measure containing more than one hundred subdivisions; sixpence for each measure containing more than fifty and not more than one hundred subdivisions; fourpence for a measure containing between one and fifty subdivisions; threepence for each measure of forty fluid ounces to one fluid ounce respectively, and twopence for each separate measure of four fluid drachms to one minim. These fees will obviously add to the cost of the weights and measures referred to; but in view of the purposes to which they are applied, and the importance of accuracy for those purposes, it does not appear that the proposed fees would unreasonably augment the cost of the weights and measures used by pharmacists. In any case, however, it is desirable that a Bill of this nature should not pass unnoticed through it various stages and become law without due consideration.

THE BRITISH PHARMACEUTICAL CONFERENCE.

WITHIN six weeks from the present date, the period fixed for the meeting of the British Pharmaceutical Conference will have arrived, and it is not too soon to remind our readers that this year the Conference will hold its sittings at Southampton, under the presidency of Professor ATTFIELD. The course hitherto followed of associating this meeting with that of the British Association will again be adhered to, the Tuesday and Wednesday of the fourth week in August being the days fixed for conducting the ordinary business of the Conference. A circular is now in course of being issued by the Honorary General Secretaries to the members of the Conference, informing them of the arrangements that have been made, and requesting those who intend to be present to communicate with Mr. O. R. DAWSON, the Secretary of the Southampton Committee, to that effect, and for the purpose of making inquiries as to the local arrangements for lodgings, hotel accommodation and railway routes, etc. We understand that a room has been engaged at RADLEY'S Hotel for the general use of the members of the Conference, and that a limited number of beds have been secured in the same house for those who desire to be at the headquarters of the Conference. The business meetings will take place at the WATTS Memorial Hall.

One of the first points to be remembered is that intending contributors of papers are expected to send in their manuscripts to the General Secretaries ten days before the meeting takes place, accompanied with a short abstract for insertion in newspapers, and that the titles of their papers are to be forwarded two or three weeks before the meeting, addressed to the Secretary of the Conference, 17, Bloomsbury Square. It is important that this requirement should be attended to in order to admit of the subjects for discussion being brought under the notice of pharmacists beforehand, and thus to secure for them full interest.

The attractions presented by Southampton as a place of meeting are not equal to those of towns situated in the manufacturing districts of the

Midland counties and the North; but there are in the neighbourhood many objects of interest, both ancient and modern, which, together with the well-known natural beauties of Hampshire and the Isle of Wight, may be expected to excite a very general desire to take part in this year's Conference. The town itself possesses some remarkable antiquarian remains, notably the Bargate and portions of the wall which probably existed in the time of CANUTE, while the modern extension of the town beyond the old boundaries has the advantage of comprising a large area of public parks and finely wooded common land. Within a few miles of the town are the picturesque ruins of Netley Abbey, and close by is the Royal Victoria Military Hospital. At somewhat greater, but still easily accessible distances, are the New Forest, the Isle of Wight, the naval port and dockyard of Portsmouth, and the cathedral cities of Salisbury and Winchester, all presenting features of interest that are worthy of observation.

The works connected with Her Majesty's Ordnance Survey Office, where operations are carried on for the production of the ordnance maps, are situated at Southampton, and it is expected that the Local Committee will be able to obtain permission for the visitors to the Conference to inspect these works during their stay in Southampton.

The excursion which is a usual feature of the Conference gatherings will this year be by steamer to the Isle of Wight, on Thursday, the 24th August. On this occasion the visitors will have an opportunity of seeing Ryde and Ventnor and the remains of a Roman villa at Brading. If the weather should by that time have assumed a character more consistent with the summer season there is much reason for anticipating that this excursion will not form the least agreeable part of the proceedings at this year's Pharmaceutical Conference.

AMERICAN PHARMACEUTICAL ASSOCIATION.

A CIRCULAR has been issued notifying that the thirtieth annual meeting of the American Pharmaceutical Association will commence on Tuesday, September 12, at Niagara Falls, New York, and it is anticipated that the conditions under which the meeting is to be held will tend to make it one of the largest the Association has yet had. It is incidentally mentioned in the circular that the Association now numbers thirteen hundred members.

PROPRIETARY REMEDIES.

THE Connecticut Medical Society appears to have listened approvingly last month to a vigorous denunciation, by Professor LINDSLEY, of the patronage of proprietary remedies by the medical profession, which was described as destroying scientific nomenclature, rendering useless scientific pharmacy, and unfitting the physician to combine remedies. There was a disposition to make an exception in favour of preparations that could be best made on a large scale and elegant pharmaceutical preparations, even though protected by a trade mark. But there was an unsparing condemnation of the use of proprietary preparations having complicated and unknown formulæ, or representing such articles as a pharmacist with a moderately well equipped laboratory could make, as well as a "host that are advertised to the profession exclusively and used with the same blind faith and for precisely the same reason that the people use hop bitters and St. Jacob's oil." It was pointed out that the practice encouraged indiscriminate dosing amongst the people, since each circular contained a list of diseases and their symptoms for which the compound is alleged to be a certain cure, and presented a temptation to an invalid to fit his symptoms and disease to a remedy and buy his bottles without the intervention of the physician, especially if his disease were of a chronic nature and had once been named.

THE RESPONSIBILITY OF PHARMACISTS.

AN important case has recently been tried in the State of New York, which involved a decision as to how far the pharmacist is bound to act under the physician's orders. It appears that in October, 1880, a prescription was presented by a woman to an assistant in a drug store in the Broadway, New York, ordering a considerable quantity of laudanum, and bearing the instruction, "Please give to bearer sixty drops in the store." The assistant sought the advice of his employer, who objected that twenty-five drops of laudanum was a full dose, and refused to administer sixty drops in the store unless the physician were present to take the responsibility. Eventually, upon the woman's plea that she was ill and needed the laudanum, the pharmacist poured out ten drops, which she swallowed in his presence. A year afterwards, two suits for damages were entered against the pharmacist, one by the woman for ten thousand dollars and one by her husband for five thousand dollars, on the ground that had the pharmacist complied strictly with the physician's orders the woman would have been spared a miscarriage and its consequences. For the defence it was urged that whilst a pharmacist is bound to make up a physician's prescription it is no part of his duty to administer the medicine. The judge adopted this reasonable view, and further remarked that if a physician, intentionally or by mistake, wrote a prescription for a dangerous quantity of poison, and a pharmacist administered the poison with a knowledge that it was dangerous, he would be personally responsible for the consequences if the patient died. It was further urged that the quantity of laudanum administered was not only insufficient to do good, but had acted injuriously. But this argument also failed and the jury returned a verdict for the defendant.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

THE annual meeting of this Association will be held on Thursday, July 20, at 8.30 p.m. precisely. The President, Professor ATTFIELD, F.R.S., will occupy the chair.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

On Wednesday the 5th instant, the usual monthly meeting of the Council of this Society was held in the College of Physicians, Kildare Street, Dublin, at three o'clock.

The President, Professor Tichborne, in the chair.

The other members of the Council present were:—Dr. Montgomery, Messrs. Allen, Bennett, Brunker, Grindley, Hayes, Pring, and Simpson.

Mr. Hugh J. Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

A letter was received from Dr. R. W. Harley, stating his wish to resign the Examinership in Pharmacy.

The President suggested that Dr. Harley, who was at that moment conducting an examination in an adjacent room, should be asked whether he could conveniently assist at the next following examination, so that the election for his successor could afterwards be held cotemporaneously with the other elections.

Dr. Montgomery was deputed to ask that question and, having done so, brought back word that Dr. Harley wished to be relieved at once from the duties of examination, as from the extent of his private practice he felt that he should be unable to devote to them the necessary time and attention.

On the motion of Mr. Brunker, seconded by Mr. Grindley, it was resolved that the resignation of Dr. Harley be accepted with regret, and that the Registrar be directed to advertise for another Examiner to be appointed at the August meeting of the Council.

A letter was received from Mr. Adam Speers, B.Sc., of London University, and Head Master of the Sullivan Schools Laboratory, Holywood, county of Down, dated June 28, requesting that the Chemical Laboratory of that institution should be recognized by the Pharmaceutical Society. The writer stated that the laboratory was licensed for advanced chemical work by the Science and Art Department, and was large enough to accommodate twelve students, analysing at the same time. It was constructed on the South Kensington plan, and contained all the appliances necessary for qualitative and quantitative analyses of both organic and inorganic substances. Amongst the students there were always some who were studying for the examinations of the Pharmaceutical Society. An inspection of the laboratory was invited. He (Mr. Speers) had had seventeen years' experience as a teacher.

The President: Does Mr. Pring know anything about the school?

Mr. Pring: I know Mr. Speers. He is a very superior man; but I never inspected the school.

The President suggested that the matter should be referred to Mr. Pring for investigation. At the same time it might be laid down as an axiom that unless an establishment of the kind was exactly suited to what the Society required it should not be recognized. What they wanted was practical working for a given period, quite independent of any theoretical teaching. The theoretical course was a separate matter.

Mr. Brunker said he did not like the idea of adding any schools to the list of institutions already recognized by the Society. The English Society was making strides in the direction of a fixed curriculum, which was quite inconsistent with maintaining a connection with small schools that they knew nothing about. The Society had already recognized two schools in Belfast, which was quite sufficient for the North.

On the motion of Mr. Brunker, seconded by Dr. Montgomery, it was resolved:—

"That the Council are not disposed to extend their list of schools of practical chemistry at present."

A letter was received from Mr. William Savage, B.A., of Rathfarnham, in reply to a letter which had been addressed to him by the Registrar relative to the Medical Hall, No. 4, Mall, Waterford. The writer stated that he was the only brother of the late Mr. Savage, proprietor of the concern, and was appointed his executor by the Court of Probate on March 22, 1881. The deceased, who left no issue, had named as his successor a son of the writer, Mr. James Savage, who was studying for a qualifying examination and had a pharmaceutical chemist engaged in conducting the establishment. The writer was merely managing the establishment as executor until certain liabilities were paid off, and so far from having even received his administration expenses he was already a loser.

The Registrar was directed to acknowledge the receipt of the letter of Mr. Savage.

A letter was read from Mr. G. A. Webb, of 141, York Street, Belfast, who stated that he had seen a statement which was erroneous in the report of the proceedings of the last meeting of the Council in reference to the case of Mr. Carse.

The consideration of the letter was postponed until next meeting.

The Registrar was directed to send a copy of the letter to Mr. Payne.

A letter was read from the Secretary of the British Pharmaceutical Conference, requesting the Society to appoint delegates to the approaching meeting of the Conference at Southampton.

The Registrar was directed to reply that the President and Mr. Bennett would attend the Conference as delegates.

A communication was made to the Council in reference to Messrs. Boyd and Goodwin, and after some discussion,

On the motion of Mr. Pring, seconded by Mr. Grindley, the Registrar was directed to inform that firm that the Council had proof that they were still engaged in compounding, and to call their attention to the penalties which they incurred by so doing.

On the motion of Mr. Brunker, seconded by Mr. Simpson, the Registrar was requested to communicate with the Registrar of the King and Queen's College of Physicians, thanking him for his letter with reference to the proposed additions to the Schedule of the Poisons Act, and informing him that the Council approves of the recommendations made by the College.

Mr. Brunker submitted a report of the Pharmacy Act Amendment Committee. It gave a *résumé* of the amendments which the Committee had from time to time proposed to be made in the Pharmacy Act (Ireland), 38 and 39 Vict., cap. 57. These were in print and had been circulated. The Committee now recommended for the consideration of the Council the following additional amendments:—1. That no pharmaceutical chemist or apothecary shall legally hold a branch establishment for the retail of poisons or compounding of prescriptions, except under the responsible management of a duly qualified pharmacist. 2. That all assistants engaged in dispensing must give sufficient proof of their competence by examination, or by having passed a sufficient time as apprentices. 3. That all candidates for the licence shall be required to produce evidence of having passed three years in a *bonâ fide* apprenticeship to an apothecary or pharmaceutical chemist keeping open shop.

The President said he did not think the Council ought to go back on apprenticeships, involving fees. These had been discarded in every branch of the medical profession. If the Council wished to increase the time to be spent in the practical learning of pharmacy to three years, that was another question and it should equally apply to apprentices and assistants engaged in compounding.

Mr. Pring said he never took a fee with an apprentice.

Mr. Grindley remarked that there had not been time to consider the new recommendations.

The President suggested that they should be printed and sent round.

On the motion of Mr. Hayes, seconded by Mr. Bennett, it was resolved—

"That the additions proposed by the Pharmacy Act Amendment Committee be printed and circulated amongst the members of the Council at an early date."

The report of the Committee appointed to examine the certificates of candidates for the licence was submitted. It appeared that the certificate for practical pharmacy of one gentleman had been rejected.

Exception was taken to the action of the Committee in that respect, but as it only put back the candidate for three months the report was unanimously adopted.

Some formal business having been transacted, the Council adjourned.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The last ordinary meeting of this Association for the present session was held on Thursday, July 6, 1882. Mr. H. G. Greenish, Vice-President, in the chair.

Mr. A. T. Job read the second part of his paper upon the "Artificial Production of Benzoic Acid and of Oil of Bitter Almonds." This portion of the paper dealt mainly with the practical details of the process. The two papers will be published as a whole in a future number of this Journal.

A discussion followed the reading of the paper, in which the Chairman, Secretary, Messrs. Alcock, Cripps, Evans, Haward, Parker and Yeatman took part. A vote of thanks was passed to Mr. Job.

Mr. E. Marsh then read some "Notes upon some Reactions of Glycerine," in which the tests that have been proposed from time to time for the recognition of this substance were described. The principal tests, experimentally shown, were: the permanganate of potassium test, which substance glycerine reduces only slowly; Reichl's test, depending upon the formation of glycereïn when glycerine is heated with sulphuric acid and carbolic acid, the glycereïn being recognized by its reaction with ammonia, resulting in the production of a red coloration; Senier and Lowe's test, which depends upon the property which glycerine possesses of liberating boracic acid from borax, which is recognized by the green colour imparted to the flame, and also Donath and Mayrhofer's test, founded upon the same fact as the preceding.

A discussion then took place, in which the Chairman, Secretary, Messrs. Alcock, Braithwaite and Evans took part. A vote of thanks was passed to Mr. Marsh.

After the transaction of a considerable amount of miscellaneous business the meeting adjourned.

ROYAL INSTITUTION OF GREAT BRITAIN.

Some of the Dangerous Properties of Dusts.*

BY F. A. ABEL, C.B., F.R.S.

(*Concluded from page* 17.)

The locality selected for the first experiments formed a portion of some obsolete fortifications at Chatham, and consisted of a masonry gallery or *Caponier*, 8 feet 8 inches high to the spring of the arch, and 8 feet wide below the arch, to a distance of 28 feet from the closed end; from that point it tapered on one side to 6 feet along a length of 2 feet 6 inches, and was 6 feet wide for a length of 3 feet 6 inches, up to a pier or square column 4 feet by 3 feet 6 inches; round which the gallery curved, being at this part 4 feet 2 inches wide. The straight part of the gallery, from the dead wall at one end to the projecting pier at the other, was 34 feet long. In the wall to the left of the blocked end there were six narrow loop-holes up to the curve, commencing at 18 feet from the end, and 2 feet 6 inches apart; in the opposite wall there were four, commencing at the same distance and 5 feet apart; over the wall at the blocked end of the gallery there was an opening into the outer air, and a considerable current of air passed through it along the gallery to the curved end, which led into a large narrow gallery at right angles to this wide one, and having large chambers opening into it.

In some preliminary experiments, an iron tube was let into the face of the wall at the blocked end of the gallery so as to represent a strong blast hole, and this was charged with 1½ lb. of powder, untamped in some experiments and tamped in others. Some pieces of guncotton were suspended from the roof of the gallery at a distance of 28 feet and farther along, and observers were stationed outside the gallery opposite the several loop holes. But, while the pieces of guncotton were not inflamed, there were conflicting opinions concerning the distances at which flame was seen, probably caused by the general illumination of the gallery by the flash of the explosion It was moreover, found that the iron tubes containing the charges were more or less considerably torn, so that portions of the exploding charge escaped laterally. The following method of experimenting was eventually adopted. Charges of 1½ lb. and 2 lb. of powder, untamped and tamped, were fired from a small roughly bored out gun block, the bore of which was 1 foot 9 inches long and 2⅝ inches in diameter; the gun was raised so as to project the flame right along the gallery at about its centre. A light woodwork frame, 5 feet square, was fitted with thirty-six cross wires 1 foot apart, so as to furnish thirty-six points of intersection; to each of these points a small tuft of guncotton was attached, and the target thus fitted was fixed vertically so as to face the charge, in the centre of which was fixed an electric fuse. In this way small charges of guncotton were distributed uniformly over all parts of the target, which filled a great part of the section of the gallery. The distance of the target from the charge being gradually increased in successive experiments to 20 feet, it was found that with the employment of 1½ lb. and 2 lb. charges, untamped, in three instances out of ten experiments only one, or at most two of the tufts of guncotton were inflamed, this being apparently the extreme distance to which flame, or matter sufficiently hot to inflame guncotton, was projected. At a distance of 19 feet, with 1½ lb. charges, two out three shots did not inflame any of the guncotton tufts. With 1½ lb. charges firmly tamped, one tuft only of the thirty-six was fired, in two experiments, at a distance of 20 feet, while in three others no guncotton was inflamed.

It appears from these results that in a gallery or mine working of an area not very dissimilar to that in which the accidents just referred to occurred, the flame or heated gases from 1½ lb. and 2 lb. charges, fired under conditions favourable to the production of the maximum flame, and its complete projection in the direction of the discharge, only reaches occasionally, and to a very limited extent, to a distance of 20 feet. No doubt a powerful air current in a mine, passing in the direction in which the shot is fired, must have a tendency to aid the spread of the flame to a greater distance, but the difference between 20 feet and 100 feet, the flame having in the latter instance extended to a distance of 75 feet along a gallery at right angles to the point of ignition, is far too great to be only ascribable to the effect of an air current in elongating the flame. As the first of the loopholes above referred to existing in the walls of the gallery was 18 feet from the shot, they could hardly affect the distance to which the flame was found to reach.* It will be observed that these results correspond with those which Mr. Hall obtained with 4 lb. charges of powder in an adit, the dimensions of which are not specified.

No gallery of large dimensions and free from the small lateral openings was available for the continuance of these

* Read at the Weekly Evening Meeting, Friday, April 28, 1882.

* The closing up of these was not found to affect the results.

experiments, but it was thought that some experiments in subterraneous passages of much smaller dimensions (military countermines) might give instructive results. A so-called envelope gallery was therefore first selected for the purpose. This gallery was 5 feet 9 inches high to the crown of the arch, and 4 feet 9 inches to the springing of the arch, and only 2 feet wide. The part selected for the position of the gun and the target was straight, but the portion immediately beyond was curved. In rear of the gun, the gallery was quite open to a considerable distance. One and a half pound charges, untamped, were fired, and a frame target the width of the gallery and 4 feet 6 inches high, constructed so as to give 15 points for the attachment of guncotton tufts, was placed at gradually decreasing distances from the gun, commencing at 20 feet. Even at a distance of only 14 feet from the charge, none of the guncotton tufts were inflamed; but the target was blown forward about 12 feet and partly broken. It was evident that the fact of the gallery being open at the *rear* of the charge greatly reduced the tendency to the projection of flame to a distance in the direction of the explosion. The resistance opposed to the movement of the air by the curvature of this very narrow gallery, a short distance in front of the seat of the experiments, may have also contributed to diminish the distance to which the flame or highly heated gases would extend. When the experiments were continued in another gallery, of the same dimensions, but straight and terminating in a head, like a drift in a mine, the cannon being placed close up to the face of the drift, several of the tufts of guncotton were inflamed at a distance of 27 feet; one was inflamed when the target was 30 feet off, and one also at a distance of 32 feet, but none were ignited at a distance of 35 feet from the charges. Here then, in a long gallery, narrow in proportion to its height, but in all respects representing a drift way in a mine, the distance to which the flame of a blown-out shot of $1\frac{1}{2}$ lb. of powder extended was less than 35 feet, and therefore considerably less than one-half the distance from the seat of the blown-out shot of 1 lb. of powder where the men were burned, in both directions in the cross workings, in the accident above cited. The influence of coal dust in increasing the distance to which the flame from a blown-out shot will extend in mine workings is therefore conclusively demonstrated by a comparison of the effects of those accidents with the foregoing experimental data. On the other hand, the important circumstance noticed by Mr. Hall, that no signs of burning on the props in the mine were visible at greater distances than a yard or two beyond the spots where the men were waiting, although there were open workings in both directions for some considerable distance, and although the flame was sufficiently extensive at those spots to injure the men severely, proved conclusively that coal dust had not the power, in these two instances, to carry on the flame to a great distance from the source of fire. Had there been any gas in the air of the mine the flame would doubtless have extended much farther, and perhaps throughout the adjacent workings. The amount of dust raised by the blown-out shots may, however, have been less considerable than in other similar occurrences, and the dust itself may not have been so highly inflammable, or otherwise of so suitable a character for carrying on flame, as that existing in other mines where undoubtedly dust has played an important part in enhancing the magnitude of explosions. At any rate these results demonstrate the necessity for the exercise of caution in drawing conclusions of too sweeping a nature with regard to the causes and the extent of such coal mine explosions as cannot be quite clearly ascribed to fire-damp. A few experiments have been made, in the largest gallery (Caponier) at Chatham, to test the power of coal dust to carry on the flame from a blown-out shot. A large quantity of very fine and inflammable coal dust, from Seaham collieries, was suspended in the air by employment of sufficient mechanical contrivances, and clouds of the same dust were also blown into the gallery in the direction of the shot, and immediately in front of it, just when it was fired. One of the frame screens was placed across the gallery where the pier jutted out (at a distance of 34 feet from the shot), and pieces of guncotton were attached to nails driven in the wall along the short narrow part of the straight gallery and to some distance round the curve. In every one of the experiments tried (three) with $1\frac{1}{2}$ lb. of powder, fired when dust was thickly suspended and carried along in the air, the flame burned a number of pieces of guncotton on the screen; in two experiments guncotton was burned at a further distance of 1 foot 6 inches, but not beyond; in the third, some flame travelled to the end of the straight gallery, and to a distance of 4 feet 8 inches beyond the curve, but guncotton was not inflamed beyond that point. In this case, therefore, flame reached rather more than, and in the others not quite, double the distance with dust thickly suspended in the air, to what it did in the absence of dust. Experiments will be continued in the long narrow galleries which have been spoken of.

It must now be accepted as beyond question that very few, if any explosions have occurred of which the destructive effects, so far as burning and production of the fatal after-damp are concerned, have not been more or less considerably increased through the agency of the coal dust raised by the explosion, and that the latter has been in very many cases instrumental in causing the burning effects of the explosion to spread over great areas, and to reach to workings which, in the absence of dust, would have escaped the visitation. Even of late years, long since the observations of Faraday and Lyell have been confirmed and extended, mining engineers and others immediately connected with the working of coal mines have been very prone to ascribe explosions, which did not admit of satisfactory explanation by an accidental failure of ventilation or other evident causes, to the sudden disengagement or outbursts of fire-damp, such as are, in fiery coal seams, of no uncommon occurrence, and sometimes very serious in their magnitude and long continuance, and to charge such sudden escapes of gas into some part of the mine workings with the whole extent of the disaster, rather than to credit coal dust with any important share in the origination or even in the extension of the explosion. In many instances the occurrence of such outbursts, following upon falls of roofs or the firing of shots, or the rapid disengagement of fire-damp from coal or goaves, consequent upon sudden changes in atmospheric pressure, have been clearly proved to have preceded disastrous explosions; in others, however, the conclusion that an explosion has been connected with the occurrence of a sudden disengagement of gas in considerable volume, has been based upon assumptions or conjectures, more or less admissible, or upon evidence of doubtful nature collected after the explosion (as in the case of the recent explosion at Seaham Collieries). Under any such circumstance, however, it is, to say the least, extremely difficult to realize how sufficient gas to produce an explosive atmosphere can be conveyed, even by the most powerful ventilating currents which can circulate in mines, from the seat of such a sudden outburst to far distant portions of the mine to which the actual explosion is proved to have extended, within the period which is known or believed, to have intervened between the first disengagement of the gas and the firing of the explosive atmosphere produced thereby *in the vicinity* of the outburst, by the firing of a shot, by a defective lamp, or by other means of ignition. On the other hand, the character of the effects which in many instances have been produced by the explosion; the evidences of severe burning such as could not be produced by the rapid explosion of a gas mixture only, and the deposition of partially burned or coked dust in very distant and distinct parts of the mine workings, leave no room for doubt that coal dust has played a more or less important part in almost all the explosions which have been of late submitted to investigation. Further, it must be conceded that in some instances, coal dust would indeed appear to have been the chief instrument of destruction.

To sum up; it has not been difficult, as will have been seen from the foregoing, to demonstrate experimentally that the existence of a very small proportion of fire-damp in the air of a mine may determine the propagation of flame by coal dust, ignited by the explosion of some local accumulation of a gas mixture, or by the inflammation of gas suddenly disengaged, or even by the flash from a blown-out shot. It has also been clearly established that in so called fiery mines the air is never likely to be actually free from fire-damp, and that as much as 2 per cent. may exist in the return air of a very efficiently ventilated mine of that class. It must therefore be regarded as a thoroughly well grounded conclusion that, in many disastrous explosions, coal dust is the chief agent of destruction, and it is indisputable that but few explosions occur of which the effects have not been more or less considerably extended and aggravated by the coal dust which is raised by the fire-damp explosion. It may also be admitted as not improbable that in some instances, the influence of dust may, apart from its combustibility (as described), determine the ignition of a mixture of air and dust with a small proportion of fire-damp, by the flame which a blown-out shot, or the accidental ignition of some local accumulation of explosive gas mixture has produced. Lastly, it is conceivable, as contended by Friere Marreco, Galloway, and some continental observers, that a mixture of an inflammable coal dust and air, may even, in the complete absence of fire-damp, both originate and carry on to some distance, explosions which, though much inferior in violence to those developed through the agency of gas mixtures, will be at least equal to them in regard to the disastrous effects on the lives of those exposed to them. That mixtures of coal dust and air alone may have the power to carry on the explosion originally caused and disseminated by a gas, air, and dust mixture, into regions where no gas whatever exists, will now be generally admitted. The great disturbance of the air which must proceed in immediate advance of the rush of flame produced by the ignition of a mixture of gas and air charged with coal dust, will, in many mine workings, raise a dense cloud immediately in front of the flame, and the latter will thus be fed as it advances. Mr. Galloway concludes, as the final result of his experiments with coal dust, that the presence of fire-damp is altogether unnecessary to *bring about* a coal mine explosion, but, admitting that the result of certain experiments may seem to favour this conclusion, its realization necessitates the fulfilment of conditions which cannot but be very exceptional, and its acceptance is certainly unnecessary to add to the formidable character of coal dust as a source of danger and an agent of destruction in mines.

Whether an explosion originates with, or is chiefly caused by, the production of a mixture of fire-damp with air in such proportions as to be more or less rapidly and violently explosive; whether the originating cause be the reciprocal influence of a small proportion of fire-damp and of coal dust (or dust of other descriptions of minerals occurring in coal mines) co-existing in the air of a mine; whether, possibly, it simply originates with a mixture of very inflammable coal dust and air in the complete absence of fire-damp, or whether, lastly, only the very limited concession be made that coal dust will add to the extent, and increase the burning effect, of a fire-damp explosion; in any case, the existence of dust in abundance, and in a dry state, in coal mine workings, must be recognixed as a source of danger not greatly inferior to that caused by local accumulations, or the accidental liberation, of fire-damp. The possibility of dealing with this source of danger should therefore be as much an object of earnest work as has been the improvement of ventilatlng arangements for mines.

It being generally impracticable effectually to deal, by actual removal, with the continual accumulation of dust in mine workings, the only available method of diminishing the dangers arising from its constant production appears to be that of maintaining the floor in the roads, etc., in a damp condition by efficient watering arrangemenst, almost continally applied. The high temperature of the mine, in many instances, must often render this a difficult and costly process, on account of the rapidity with which the water will evaporate; hence attempts have been made to apply hygroscopic substances (such as calcium chloride, sea-salt, or rock-salt) in conjunction with water, or to use brine, with a view to retard its evaporation, and some successful results appear to have recently attended their application in several districts. In some instances with improved appliances for the uniform and periodical distribution of sufficient water, the maintenance of mine roads in a sufficiently damp condition to prevent dust from being raised in any considerable quantity appears to have been accomplished with fair success; there are, however, localities where it is almost impracticable to maintain the floor of the roads in a damp condition, in consequence of the great increase thereby of the tendency to their being gradually raised by the pressure to which they are subject.

Apart from the effects of dust in augmenting the disastrous results of such fire-damp explosions as may arise from the existence of a defective, or an open safety lamp in the vicinity of an accumulation of gas, or of a locality where a sudden outburst of gas occurs, the *blasting* of coal or of rock, in those parts of a mine where fire-damp may exist, if even only in very small quantities, constitutes the chief source of accidents in which coal dust may have played an important share. There is no doubt, therefore, that the elaboration of really safe methods of getting coal in places where blasting by powder is now resorted to, and of removing the harder rock in the working of drifts where fire-damp may exist, will most importantly contribute towards the diminution of danger arising from the accumulation of dust in mines. The substitution of efficient coal cutting machines for blasting may to some extent supplant the use of powder, and the employment of compressed air as an agent for bringing down coal or rock has been made the subject of ingenious contrivances, which appear, however, as yet, to labour under some disadvantages in regard to cost, facility of use and general efficiency. Attempts have been made to render the employment of powder in the presence of fire-damp safe, by using it in conjunction with water. In the first instance it was proposed by Dr. Macnab to bring the latter into direct operation as the cleaving or blasting agent by inserting a cylinder containing water into the blast hole, and connecting it with a very strong external vessel, in which the powder charge was fired, much as the powder charge is fired in the powder chamber of a gun, the generating gas being brought to bear upon the confined column of water, and causing the latter to exert a rending force upon the coal by which it was surrounded. As the results furnished by this method of operation were not promising, the comparatively very simple expedient was resorted to by Dr. Macnab of employing water simply as tamping in a charge hole, a cylinder containing the liquid and of suitable length to fill the hole being inserted over the charge of powder. In the event of a charge blowing out, the dispersion of the water in a very finely divided condition was relied upon to effect the extinction of the volume of flame which, under these conditions, would be projected into the air of the mine. Some carefully conducted experiments, with blast holes charged by this method and surrounded by an explosive gas mixture, showed that occasionally no ignition of the gas resulted from the blowing out of the shot, but that in most instances, the conditions of the experiments being the same, the gas mixture in front of the blast hole was exploded, when the shot blew out. It is possible that a careful regulation of the charge and length of tamping may render this mode of operation a comparatively safe one, though it may be doubtful whether absolute reliance could be placed upon the invariable extinction of flame in the case of blown-out charges. When the attention of the Royal Commission was directed to the subject of the dangers attending the employment of explosives in coal mines, it occurred to Mr. Abel to attempt the application to the getting of coal of the principle which he developed some years ago, in the course of his researches on explosive agents, namely, the sudden transmission in all directions of the force exerted instantaneously by a *detonation*, by surrounding the detonating charge with water. It was found in a large number of experiments that when comparatively small charges of guncotton or dynamite (the latter being preferable) were enclosed in cylinders of light metal or paper filled with water, and occupying the entire available space (or nearly so) in a blast hole, the detonation of the charge in holes of excessive strength, when employed in proper proportion to the amount of water by which it was surrounded, was always accomplished without ignition of the explosive gas mixture with which the opening of the blast hole was surrounded. The interesting fact was moreover established, by operations carried out in hard coal in Lancashire, that the action of the detonating charge is modified to great advantage, by enclosing the envelope in a long column of water. Instead of exerting a powerfully crushing or disintegrating action, confined within comparatively narrow limits, whereby a charge of guncotton or dynamite is rendered of little value as a means of getting coal when used in the ordinary way, the distribution of the explosive force in all directions by the column of water causes it to exert a cleaving or splitting action even superior to that exercised by ordinary blasting powder. The farther development of this method of applying detonating agents to blasting purposes in coal-mine workings appears therefore well worthy of attention.

Another method of getting coal, which, though not new in itself, has been applied in a novel manner and with most promising results by Messrs. Smith and Moore, has the great advantage of dispensing entirely with the use of explosive agents, and of any but the most simple mechanical appliances.

It consists in applying the force which quicklime will develope if confined, and made to combine under that condition with water, whereby it undergoes very considerable expansion, a large amount of heat being at the same time developed. Messrs. Smith and Moore convert the freshly burned and crushed quicklime into very compact cylindrical masses, or cartridges, having a small groove on one side so that when the requisite number of cylinders are inserted symmetrically into the mechanically drilled hole in the coal, which they fit accurately, a narrow pipe, with perforations along its entire length, enclosed in a tight-fitting stocking of open webbing and provided with a stopcock, may be inserted into the side of the charge, which is afterwards tamped in the usual manner. The proportion of water necessary to slake the lime, *plus* an excess of about one-sixth, is then forced into the hole through the pipe by means of a simple hand syringe, and the stopcock of the pipe being closed the operation is complete. In a brief space of time sounds indicative of the cracking of the mass of coal which contains the cartridge show that the expansion of the lime by its union with the water, and the very considerable development of steam within the cartridges, are performing their work, and after an interval of time varying with the strength of the part of the seam operated upon, the coal is detached in large blocks. The holes can be charged so rapidly that a considerable number may be put into operation in quick succession by one or two men.* As the action of the charge occupies some little time (fifteen or twenty minutes), they really come into operation together, and in this way large faces of hard coal in longwall workings are brought down with ease and certainty. Whether these compressed lime cartridges can be applied with any success in stone still remains to be determined, but in point of cost, simplicity, and above all, safety, this method of detaching coal appears to rank before any other yet tried. Besides entirely avoiding the use and production of flame or fire in the blasting of the coal, the operation is conducted gradually and almost noiselessly, and the raising of dust by the more or less violent concussions which attend the employment of explosives in any form or manner is avoided.

It is insisted upon by a great majority of those most competent to judge that the employment of explosives cannot be dispensed with in the profitable working of coal mines. That the use of gunpowder in the ordinary way, even with strict attention to all practical precautions, is a most prolific source of accident has long been recognized. The development of safe methods of applying explosive agents or of simple and effective substitutes for them is therefore of such paramount importance in securing protection to the miner against the dangers of fire-damp and of coal dust, that those who are entrusted with the management of coal mines should spare no exertions to test rigorously but fairly the merits of any proposals which afford promise of success in this direction.

* In one of several operations of this kind recently witnessed by the lecturer at Shipley Collieries, Derby, in the "deep hard seam," which is nearly 3 feet thick, ten shots were fired together, bringing down a block of coal 39 feet long by 3 feet thick and 2 feet 10 inches high, weighing about ten tons. The average time occupied in boring a hole (by mechanical drill), charging and tamping it, and watering the charge was twenty minutes. The usual operation of bringing down this very hard coal by wedging is exceedingly slow and laborious.

PHILADELPHIA COLLEGE OF PHARMACY.

The following paper was then read on—

Chlorinated Oil.

BY DR. L. WOLFF.

The use of chlorine gas, in the form of chlorine water, in chronic affections of the skin, is by no means of recent origin, and already Thenard and Cluzel recommended the frequent immersion in chlorine wster of the hands of those afflicted with itch, by which they claimed to have obtained most excellent and rapid results.

About fifteen years ago I had cause to try it, and had a most excellent success with it; though to make its effect more lasting and emollient, I experimented with a liniment composed of equal parts of olive oil and chlorine water. The efficacy of this was not less potent, but the absence of any of the characteristic odour of the gas in this liniment struck me as very peculiar, and I attributed it to a chemical change taking place. As a part of this latter would naturally have to result in the formation of hydrochloric acid, the question arises, if it is the latter or the chlorine gas which had combined with the oil that gave the beneficial results. As the free chlorine in the water, however, had proved effective, the inference is that the chlorine in combination with the oil had given the curative effect.

To test this matter, I was urged by my friend, Dr. J. V. Shoemaker, to make a chlorine compound with oil free from hydrochloric acid, which in the course of therapeutic experiments proved equally effective.

To prepare it I induced a stream of dry chlorine gas, generated in the usual way, into a quantity of oil equal to that of the water in making the chlorine water of the Pharmacopœia, but, to my surprise, found that I was unable to supersaturate the oil, as I had done with the water, no free chlorine becoming at any time evident, until after many days of experiment I ultimately succeeded in my purpose.

The oil so treated showed at first but little change, save that of turbidity, which could not have been due to water being present, as the gas had been well dried. It soon warmed and heated, and vapours of hydrochloric acid were then evolved. It had changed its colour but little, grew viscid and of the specific gravity of 1·059. It was insoluble in alcohol, disproving the presence of free oleic acid; when washed with an equal bulk of water, to free from adherent hydrochloric acid, it showed an emulsifiant tendency. Dissolved therefrom with benzin, and the latter evaporated after previously filtering the solution, it left a product such as I here exhibit. Neutral to test paper at first, it grew acid at standing for some time, with well marked turbidity, thus proving the loosely molecular combination of the chlorine, which, being again substituted by hydroxyl, forms more hydrochloric acid. It possessed no marked odour, and certainly not that of chlorine, and varied in taste but little from that of ordinary oils, no irritant action being manifest when applied to the tissues.

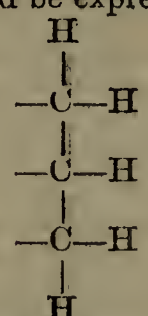
An inquiry on this subject at our former meetings led me to investigate this matter more thoroughly, and I arrived at results which, from a chemical point of view, turned out very interesting.

In order to understand the chemistry of this process it is necessary, however, to enter somewhat into the molecular position of the vegetable and animal oils and fats to show exactly where and how a chlorine substitution can take place.

Vegetable and animal oils consist in the main of two principles: one of them, forming on saponification, either with or without great heat or alkalies, is an alcohol named glycerin; the other, forming acids, are termed relatively stearic, palmitic and oleic acids, etc. The radicals of these two constituents are for the former termed propenyl or glyceryl, while for the latter they are known as stearyl, palmityl, and for what that which forms the greatest part of the liquid and semi-liquid fats, oleyl.

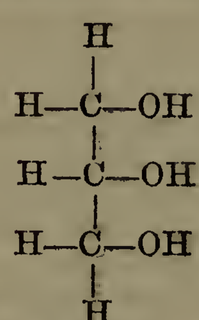
While the propenyl would be expressed as follows:—

C_3H_5 =



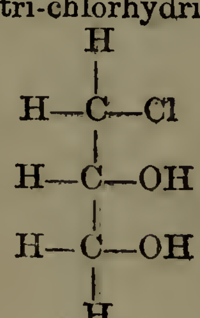
the glycerin or its triatomic alcohol would be constituted thus:—

$C_3H_5 + 3OH$ =

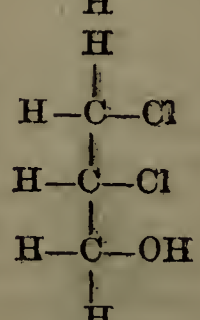


The three molecules of hydroxyl in the glycerin are easily substituted by several elements or compounds, such as acetic, benzoic, hydrochloric, hydrobromic and other acids; to illustrate this I give below the molecular position of mono-, di- and tri-chlorhydrins:—

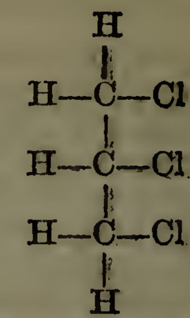
Chlorhydrin, $C_3H_5 + 2OH + Cl$ } =



Dichlorhydrin, $C_3H_5 + OH + 2Cl$ } =



Trichlorhydrin, $C_3H_5 + Cl_3$ } =



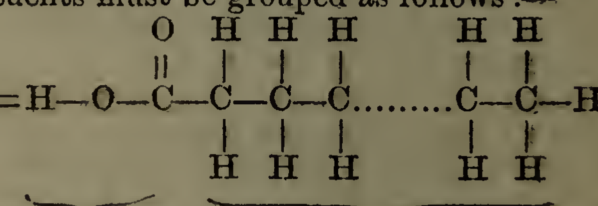
In the fats and oils, however, the molecules of hydroxyl of the glycerin are substituted by the radicals of the fatty acids, such as stearyl, palmityl and oleyl, producing ethers, as which fats and oils must be viewed, as for instance:—

Stearins or propenyl tristearyls = $C_3H_5.3(C_{18}H_{35}O_3)$

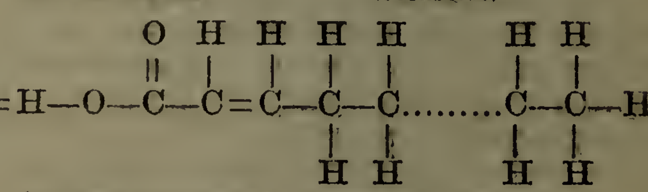
Oleins or propenyl trioleyls = $C_3H_5.3(C_{18}H_{33}O_2)$.

Again, as stearic, palmitic, and oleic acids are acids derived from stearyl, palmityl and oleyl, and have an analogous constitution, the former belonging to the series of formic and the latter to that of acrylic acids, their relative constituents must be grouped as follows:—

Stearic acid =

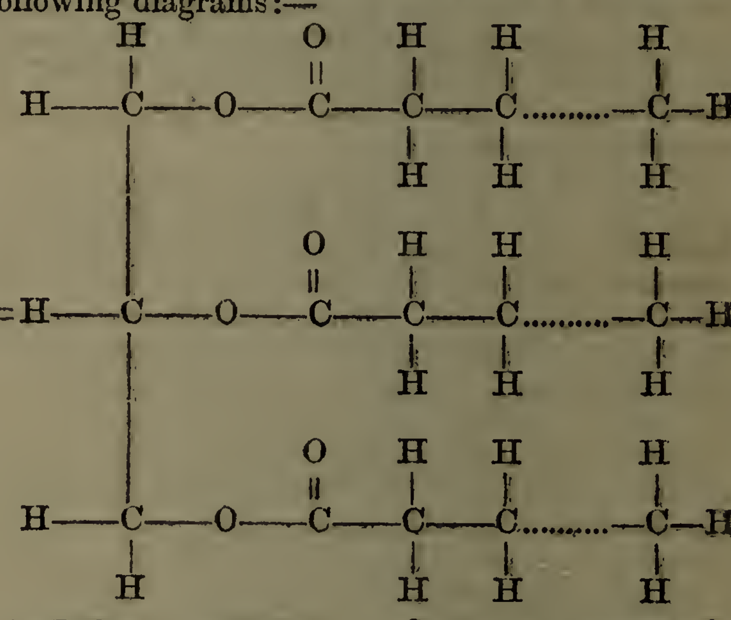


Oleic acid =

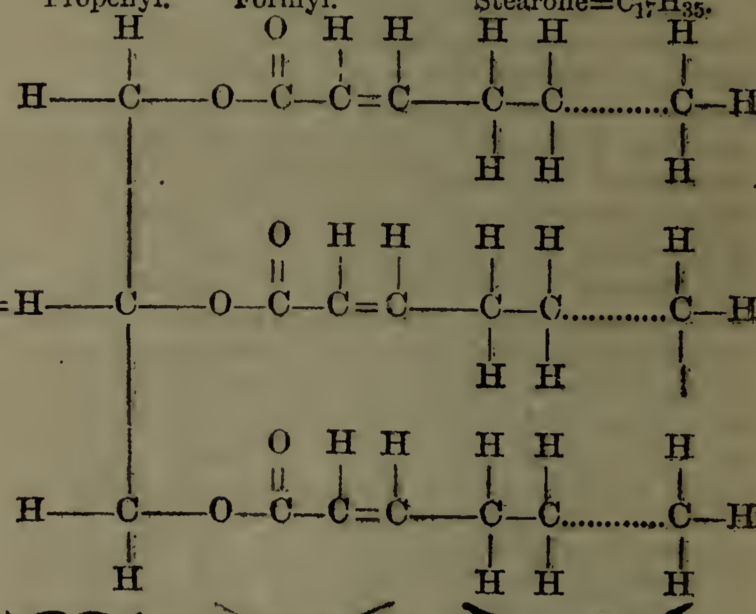


Thus the constitution of fats and oils will be represented by the following diagrams:—

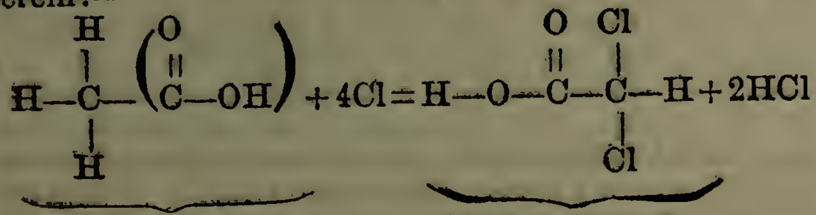
Stearin =



Olein =

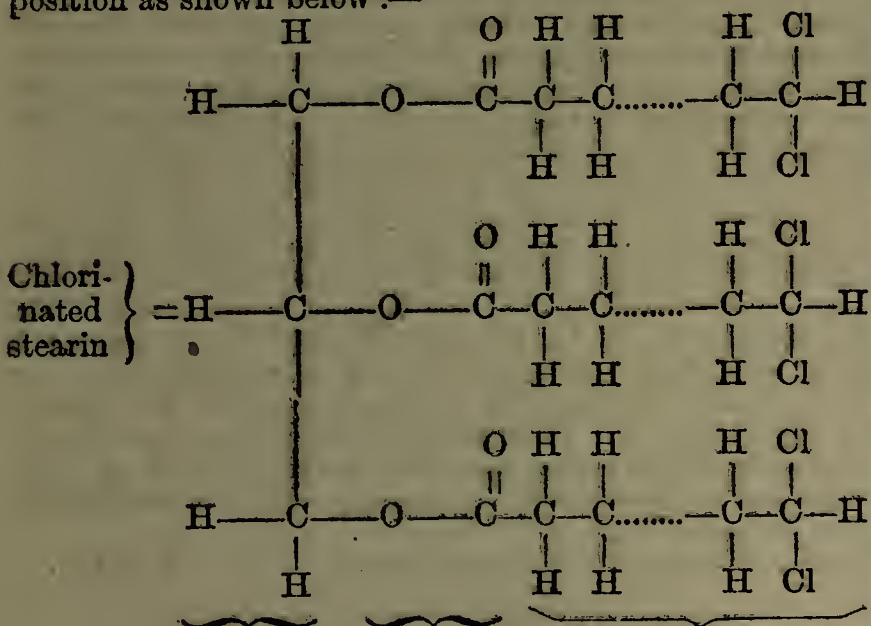


Therefore, if free chlorine gas comes in contact with these molecules, it cannot attack the propenyl, as this is really substituted by the stearyl and oleyl. Again, the stearyl and oleyl cannot be acted on by the chlorine in their acid nuclei, according to the analogy established by the formation of dichloracetic acid, as will be seen herein:—

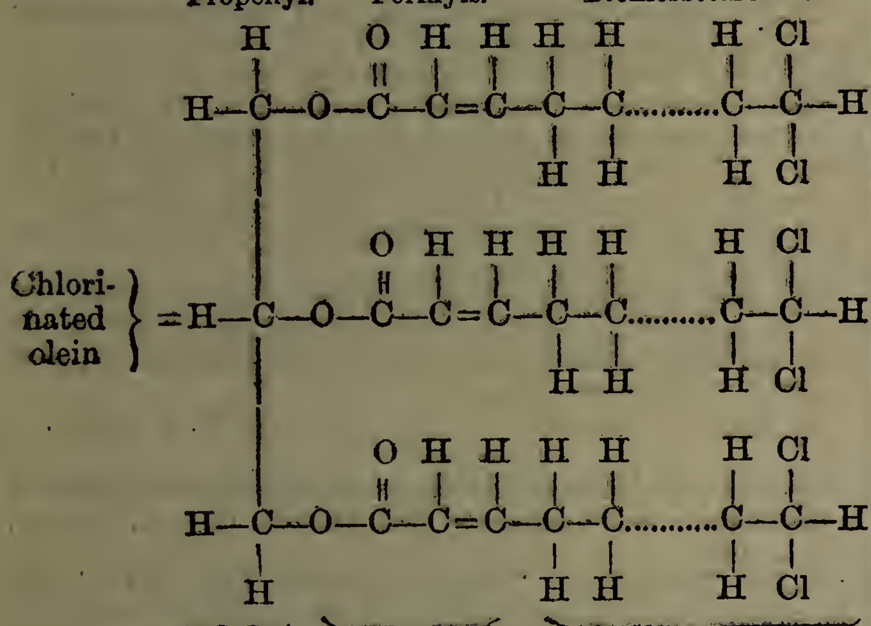


Acetic acid. Dichloracetic acid.

The chlorine must act, therefore, on the hydrocarbon appendices, $C_{17}H_{35}$ and $C_{15}H_{31}$, substituting therein the relative hydrogens by chlorine, resulting in a molecular position as shown below:—



Propenyl. Formyls. Dichlorstearones.

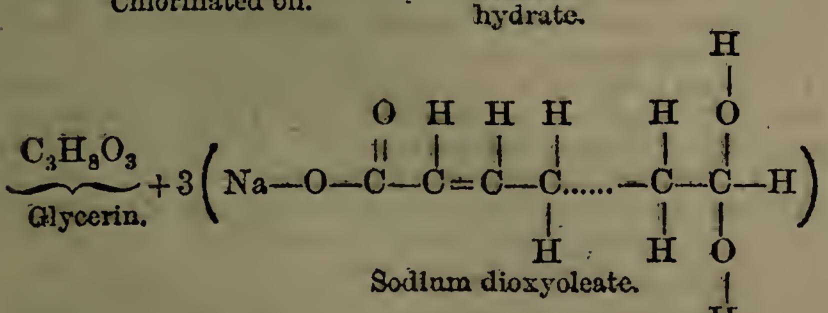


Propenyl. Acrylyls. Dichloroleones.

As palmitin and stearin are much alike in their constitution, a reproduction of the structural formula of the former is necessary.

As this chlorinated oil is saponifiable with boiling solutions of the hydrates of alkalies, yielding soap, glycerin and chlorides, I would give below a diagram illustrating its saponification with sodium hydrate:—

$$\underbrace{C_3H_5 3(C_3O_2H_2\text{—}C_{15}H_{29}Cl_2)}_{\text{Chlorinated oil.}} + \underbrace{9(NaOH)}_{\text{Sodium hydrate.}} =$$



$+ \ 6NaCl$

The soap so produced manifests no material difference from ordinary soaps, only that in the course of its preparation it separates as it is formed, owing to the great amount of sodium chloride formed in the process.

The chlorinated oil, by computation of its atomic weight, shows 100 parts by weight to contain about 17·9 parts by weight of chlorine, or, in other words, it would take 48 parts by weight of chlorine gas to convert 100 parts of oil into the chlorinated product of which 24 parts by weight enter into the 100 parts of oil, and 24 parts form hydrochloric acid.

It would appear, hence, that in chlorinated oil we have not alone a very interesting chemical body, but one that is very rich in chlorine as well; and as the latter exists therein in a loosely molecular condition, it will readily substitute itself again for hydroxyl, forming chlorine compounds with bodies of stronger affinity, and as such will prove probably of great therapeutic value wherever the use of chlorine, both as disinfectant and parasiticide, is indicated, and possibly presenting a proper antagonistic for bacteriæ, which are daily more shown to form the causation of many diseases.

During the discussion on this paper it was stated that commercial olive oil was frequently adulterated with cotton seed oil, and it was said that the latter was also mixed with lard oil, and that a reliable test for its presence was very desirable.

Dr. A. W. Miller spoke of a new and clumsy adulteration of *sassafras oil* with kerosene, detected by its odour and its insolubility in alcohol; a sample of the adulterated oil was exhibited.

Also a new *vermilion substitute*, free from mercury and of handsome appearance; it is said to be made from a fine specimen of "orange mineral" tinted with eosine.

Parliamentary and Law Proceedings.

Poisoning by Sulphuric Acid.

On Saturday, July 8, Mr. Poole (coroner for North Warwickshire) held an inquest at Aston, on the body of David Nixon, 43, grocer and postmaster, who died on the 5th inst.

The evidence of Dr. Hoare was to the effect that on May 8 deceased took a quantity of sulphuric acid. Witness was called in, and on ascertaining what had occurred he asked deceased what he had done it for. Nixon replied, "I wish I had done it completely." Deceased did not at any time express regret at having taken poison.

A juror said the deceased frequently came to his house, and had on several occasions threatened to commit suicide.

The jury returned a verdict of "Suicide whilst temporarily insane."—*Birmingham Daily Post.*

Poisoning by Ammonia.

On Saturday, July 8, a boy named George Ashworth, aged 11 years, was poisoned by mistake at Halifax. He took hold of a bottle which he thought contained ginger beer, but which contained ammonia, and had a good drink. Milk was given to him afterwards, and medical assistance sent for. By the use of emetics all danger was soon overcome, and the boy recovered.—*Yorkshire Post.*

Alleged Poisoning by Camphor.

A singular case of poisoning was investigated on Tuesday at an inquest held at Oldham. Mary Ogden had been in delicate health for some time, and her husband obtained a prescription from a Spaniard named Maurize Picano. This prescription consisted of laudanum, peppermint, and essence of camphor. Deceased partook of some, and shortly afterwards she began to be sleepy, and died.

The medical opinion was that deceased had died from an overdose of camphor.

The jury censured the seller, Mrs. Wild, who gave the mixture for the prescription, for not intimating how the medicine was to be taken.—*Morning News.*

Obituary.

Notice has been received of the death of the following:—

On the 25th of April, Mr. Frederick Farrer, Chemist and Druggist, Kessingland, late of Wrentham, Suffolk. Aged 71 years.

On the 27th of May, Mr. Thomas Day Easton, Chemist and Druggist, Danby End, Yorkshire. Aged 50 years.

On the 9th of June, Mr. Charles Christopher Spink, Chemist and Druggist, Market Place, Pontefract. Aged 44 years.

On the 12th of June, Mr. Edward Parker, Pharmaceutical Chemist, Carlisle. Aged 64 years. Mr. Parker had been a Member of the Pharmaceutical Society since 1842.

On the 18th of June, Mrs. Ruth Mabbott, Chemist and Druggist, Manchester. Aged 58 years.

On the 23rd of June, Mr. Richard Eustace Williams, Chemist and Druggist, Mumbles, Swansea. Aged 69 years.

On the 29th of June, Mr. George Alfred Webster, Chemist and Druggist, Green Road, Leeds. Aged 39 years.

On the 29th of June, Mr. Thomas Williams, Chemist and Druggist, Welshpool. Aged 28 years.

On the 8th of July, Mr. Thomas Hill, Chemist and Druggist, Bath. Aged 67 years.

On the 10th of July, Mr. Alfred Fox, Chemist and Druggist, Porter Street, Hull. Aged 27 years. Mr. Fox had been an Associate in Business of the Pharmaceutical Society since 1875.

The Future of Pharmacy.

Sir,—Our Stockport brethren evidently believe that if they have not virtue they ought to assume it. Their petition reads very well and displays a very laudable anxiety for the future state of pharmacy. I have no doubt these worthy representatives of a worthy craft will point with pride to the memorial, and lay this flattering unction to their souls that at all events their town is free from the reproach of having done nothing to improve the trade. After this commendable display of virtue, you, sir, will no doubt be surprised to hear that by far the larger number of chemists in Stockport "do a large trade" in supplying not only grocers, etc., but little hucksters' shops with (not patents that require no skill in manipulation, but) "drugs, pharmaceutical preparations, etc.;" and these men are not, as you would suppose, small chemists with large families who do not live but simply exist, they are the men of "light and leading" (save the mark), the principal chemists in the town, one, at least, of whom employs a traveller to cultivate this particular trade. One of these worthy gentlemen, when remonstrated with upon the seeming inconsistency between his words and his deeds, indignantly replied, "I am not going to give up so good a portion of my living for all the societies that ever were." Surely the height, or rather the depth, of absurdity has been reached in this. They supply a class of tradesmen with goods, take the cash for them, and then beseech the powers that be to stop these customers of theirs selling the very things they have importuned them to take; these, too, are the men who are loudest in their complaints of the Society doing nothing to help them, whilst they themselves will not so much as lift one little finger to help themselves. The immortal bard says, "To thine own self be true, and it follows," etc. Then let each individual member of our craft be true to the better interests of his chosen trade; let each man of us resolve to leave the trade better than he found it. Then, I venture to predict, we shall have very little of the jealousy and want of confidence of the medical profession, and the question of 9*d.* or 1s. 1½*d*, for "Cockle's" will become a very secondary matter, whilst at the same time the Council will be compelled to keep abreast of the opinion of the trade. But so long as every individual has no aim and no ambition higher than his own selfish ends, so long must our and every other community formed of such selfish men continue to grovel in the dust.

131, *Embden Street, Manchester.* J. Hart.

Fresh Bael Fruit (Ægle Marmelos).

Sir,—I notice that some fresh bael fruit has recently been sent to the Museum by Mr. P. W. Squire, and I am glad to find that it is coming somewhat into use.

Three years ago I presented a specimen to the Society, and drew attention to it at an Evening Meeting (April 2, 1879). This was brought to me from Calcutta, by Dr. James M. Laing, of the Indian Service, who told me that the fruit itself was most frequently ordered to be gathered and eaten as occasion required.

The best preparation of it, however, that I have been able to discover, is that made according to the directions given in the Indian Pharmacopœia for 1868, p. 47, and known as extractum belæ.

35, *Baker Street, W.* A. W. Postans.

Senex.—No doubt an iodide of bismuth is formed, which is insoluble. See a paper by Mr. Thresh, *Pharm. Journ.*, [3], x., 641.

C. S.—There is no "Tinct. Valerian. Co., B.P.," and the difference in the appearance of the mixtures was probably due to the preparation used to represent this ingredient of the prescription.

J. Currie and T. Cragg.—Your communications have been handed to the Secretary, to whom all instructions from members, etc., as to the posting of the Journal should be sent.

P. Boa.—*Hypericum pulchrum.*

"*Infantilis.*"—If you will first turn your attention to the rule respecting anonymous communications, we shall be happy to assist you in your study of the point in question.

NOTES ON THE PRODUCTION OF BENZOIC ACID AND BITTER ALMOND OIL FROM TOLUENE.*

BY A. T. JOB,

Student in the Laboratories of the Pharmaceutical Society.

The following notes are the results of a series of experiments conducted in the laboratories of the Pharmaceutical Society upon a process, recently patented by Dr. Emil Jacobsen, for the artificial production of benzoic acid and benzaldehyde from toluene.

A commercial sample of toluene was purified by successive redistillations at 111° C., rejecting all that came over below that temperature, and any that remained in the retort above that temperature.

The distillate thus obtained possessed the appearance of a clear mobile liquid, with a marked odour and powerful refractive properties. Its sp. gr. at 0° C. was 0·88.

In chemical composition toluene may be regarded as benzene, in which one of the hydrogen atoms is replaced by CH_3.

When toluene is treated with dry chlorine gas, two different series of products are obtained, depending upon the temperature. These differ both in their chemical and physical properties. Both series are represented by the same empirical formulæ, C_7H_7Cl, $C_7H_6Cl_2$, $C_7H_5Cl_3$, depending upon the amount of chlorine introduced. They are, in fact, isomeric bodies. As an explanation of this isomerism it is supposed that when chlorine is passed into cold toluene,—or even into hot toluene, if either iodine, molybdic chloride or antimonic chloride be present,—the chlorine is substituted in the benzene nucleus of toluene; but when chlorine is passed into heated toluene, the substitution takes place in the methyl or CH_3 group.

Toluene, $C_6H_5CH_3$.

Action of chlorine on toluene in the cold, substitution taking place in the benzene nucleus.	Action of chlorine on boiling toluene, substitution taking place in the methyl group.
$C_6H_4ClCH_3$	$C_6H_5CH_2Cl$
$C_6H_3Cl_2CH_3$	$C_6H_5CHCl_2$
$C_6H_2Cl_3CH_3$	$C_6H_5CCl_3$

This hypothesis is supported by the fact that when substitution products obtained by the action of chlorine upon cold toluene are treated with water, no benzaldehyde is formed; on the other hand, if the product formed by the action of chlorine upon boiling toluene be similarly treated, benzaldehyde is set free.

Such being the case a rational formula is required that shall indicate this. And inasmuch as all the bodies are chloro-substitution compounds of toluene, all are called chlorotoluenes. Beilstein and Kuhlberg have suggested a simple and graphic numerical method of indicating this, which is now generally adopted. It consists of figures indicating the number of atoms displaced in either group. Those displaced in the benzene group being represented by a numeral placed to the left of a horizontal line, and those in the methyl group by one to the left, thus

$C_6H_3Cl_2CH_3$	$C_6H_5CHCl_2$
Dichlorotoluene (2—0)	Dichlorotoluene (0—2)
(Methyldichlorobenzene)	(Dichloromethylbenzene)

Or, to express this in ordinary chemical terms, toluene being regarded as methylbenzene, the (2—0) dichlorotoluene would be called methyldichlorobenzene, whilst the (0—2) dichlorotoluene would be spoken of as dichloromethylbenzene.

The first step in the practical process is the formation of the required chlorotoluenes. Working experimentally after many trials, I found the following apparatus to give the most satisfactory results, small quantities of toluene being worked upon. A Bohemian flask of a capacity of about half a litre, and having a short wide neck, is fitted with a thermometer ranging above 215° C., a glass distillatory tube in connection with a Liebig's condenser, together with a straight tube for the introduction of the chlorine gas, which tube when fitted with a small thistle funnel also serves as a means of replacing the distillate back into the flask without in any way disturbing the cork or luting.

The chlorine before entering the flask is dried by passing through a wash bottle containing sulphuric acid.

The toluene is placed in the flask and heated over a shallow sand-bath; when it boils the chlorine is passed through it in a continuous stream, the action of the chlorine being accompanied by a rise in the temperature of the liquid.

When the thermometer indicates a constant temperature of 176° C. the distillate will be found to consist of monochloromethylbenzene, $C_6H_5CH_2Cl$, a colourless liquid with a very irritating odour.

Upon continuing the chlorination, the next body formed is the dichloromethylbenzene, $C_6H_5CHCl_2$, a colourless liquid with faint odour, boiling point 206° C.

By carrying on chlorination until no increase in weight on the part of the liquid in the flask takes place trichloromethylbenzene, $C_6H_5CCl_3$, is obtained; this is the third product of the action of chlorine upon heated toluene. It is a colourless liquid boiling at 215°–216° C.

From the two latter chlorotoluenes the benzaldehyde (bitter almond oil) and benzoic acid are respectively formed. For example, when heated in sealed tubes with water at 150° C. the following decompositions take place:—

$$C_6H_5CHCl_2 + H_2O = C_6H_5COH + 2HCl$$
$$C_6H_5CCl_3 + H_2O = C_6H_5COCl + 2HCl$$
$$C_6H_5COCl + H_2O = C_6H_5COOH + HCl$$

Benzoic acid and aldehyde may also be obtained from these substances by other reactions, thus by the action of alcoholic potash. These methods, however, as manufacturing processes, are of little value.

Jacobsen states in his patent that when benzodichloride (dichloromethylbenzene) is acted upon by glacial acetic acid in the presence of chloride of zinc the following reaction takes place, resulting in the formation of benzaldehyde, acetic chloride, and hydrochloric acid:—

$$C_6H_5CHCl_2 + CH_3COOH = C_6H_5COH + CH_3COCl + HCl.$$

He also states that the chloride of zinc in the above reaction may be replaced by oxide of zinc.

I found that upon placing together in a retort, molecular weights of dichloromethylbenzene and glacial acetic acid with oxide of zinc energetic action ensued. A liquid of a deep red colour distilled over which possessed a peculiar pungent odour, very different from that of bitter almond oil. On standing, crystals were deposited, and these were afterwards kindly analysed by Mr. Wyndham R. Dunstan, Demonstrator of Chemistry in these laboratories, and were found to be the acetyl derivative of benzaldehyde, their formulæ being $C_6H_5CH(C_2H_3O_2)_2$.

* The substance of two papers read before the School of Pharmacy Students' Association, June 15 and July 6, 1882.

Mr. Dunstan has suggested the following reactions to account for the formation of this substance.

In the first process anhydrous acetate of zinc being present it probably acts directly upon the dichloromethylbenzene, forming the acetyl derivative of benzaldehyde, thus—

$$Zn(C_2H_3O_2)_2 + C_6H_5CHCl_2 = C_6H_5CH(C_2H_3O_2)_2 + ZnCl_2.$$

In the second process, where chloride of zinc is present, this compound is most probably produced by a secondary reaction. The acetic chloride produced in the primary reaction decomposes the acetic acid with formation of acetic anhydride, thus—

$$CH_3COCl + CH_3COOH = (C_2H_3O)_2O + HCl.$$

The acetic anhydride then reacts upon the benzaldehyde—

$$(C_2H_3O)_2O + C_6H_5COH = C_6H_5CH(C_2H_3O_2)_2.$$

This acetyl derivative is decomposed by water, yielding benzaldehyde and acetic acid—

$$C_6H_5CH(C_2H_3O_2)_2 + H_2O = C_6H_5COH + 2HC_2H_3O_2.$$

It is therefore better after placing the substances together, and after heating for a short time, to add a little water at intervals. The benzaldehyde then distils over together with acetic acid. The distillate, now strongly acid, is neutralized by sodium carbonate, and allowed to stand, then redistilled; or the benzaldehyde may be separated from the solution of sodium carbonate by decantation and repeatedly washed with water until pure. Another method is to treat the neutralized distillate with solution of acid sodium sulphite, the aldehyde compound thus formed

$$C_6H_5CH{\cdot}OH{\cdot}SO_3Na$$

being decomposed by solution of sodium carbonate and freed from water by decantation.

In the preparation of benzoic acid a similar method is employed. The benzotrichloride (trichloromethylbenzene) is first heated over a water-bath with two molecular weights of glacial acetic acid in the presence of zinc chloride. The reaction takes place in two stages. Firstly, the acetic acid acts upon the trichloromethylbenzene, forming benzoic chloride, thus—

$$C_6H_5CCl_3 + CH_3COOH = C_6H_5COCl + CH_3COCl + HCl.$$

Then, secondly, the benzoic chloride acts upon more acetic acid, forming benzoic acid and acetic chloride, thus—

$$C_6H_5COCl + CH_3COOH = C_6H_5COOH + CH_3COCl.$$

After heating the retort for some time over the water-bath it is removed and any undecomposed acetic acid driven off by increasing the heat. The dark coloured residue in the retort is now treated with warm soda solution until alkaline, care being taken to avoid large excess of alkali. The precipitated zinc hydrate being removed by filtration and the filtrate evaporated to a low bulk, the benzoic acid is liberated from the benzoate of soda contained in the filtrate by acidulating with hydrochloric acid. Zinc oxide may be substituted for zinc in the above process.

This process is very satisfactory when once the trichloromethylbenzene has been obtained. This, however, is somewhat troublesome and tedious to prepare, a small quantity of toluene taking several days to chlorinate. It must also be practically free from the dichloromethylbenzene, otherwise the product will be contaminated with benzaldehyde and secondary reactions will also occur by which the yield of benzoic acid is considerably diminished. This difficulty overcome, the process bids fair to rival successfully all other methods for the artificial preparation of benzoic acid.

BLACK HELLEBORE ROOT.*

BY A. HERLANDT.

The rhizomes of *Helleborus niger* and *H. viridis* present in their external appearance a great similarity to those of other Ranunculaceæ, such as *Actæa spicata* and *Adonis vernalis*, and also, when in fragments or fine powder, in respect to odour and in a certain degree to taste, to the root of *Polygala Senega*. As the microscopic examination of rhizoma hellebori nigri reveals no characteristic peculiarities,—neither starch granules of a definite form, nor stone cells,—chemical reactions must be utilized for its recognition. The peculiar constituents of the two above-mentioned hellebore roots are two glucosides, helleborein and helleborin, which upon treatment with acids split up into helleboretin or helleboresin and sugar respectively. The blue-violet helleboretin can be used both pharmaceutically and forensically for the recognition of the rhizome.

If the comminuted rhizome of *Helleborus niger* be exhausted with boiling water, and the filtered decoction, after the addition of one-third of its volume of hydrochloric acid, be boiled, the clear liquid at first becomes quickly turbid and takes a peculiar violet colour. After cooling, a separation of blackish flocks takes place, and these, when washed upon a filter with ether, to remove yellow fatty and resinous matters, are of an intense and permanent violet colour.

The same result is obtained with the water in which the rhizome of black hellebore has been macerated. In both cases if the residue left on the filter be washed with alcohol, the alcohol acquires a violet colour, and leaves upon evaporation an amorphous greenish-violet substance, which is impure helleboretin. In the case of the rhizome of *Helleborus viridis*, the colour, after the action of the hydrochloric acid, comes out at first more greenish, probably because a larger quantity of fatty and resinous substances are present in it.

The rhizome of *Actæa* and the roots of *Polygala Senega* give, when treated in the same manner, no similar reaction, which would probably be the case with all drugs that do not contain helleboretin.

This reaction is obtained even with the use of five centigrams of rhizoma hellebori nigri. If it be cut into thin pieces, boiled with 10 c.c. of water, the decoction filtered and again boiled with one-third its volume of hydrochloric acid, the almost colourless liquid becomes after a few minutes turbid and bluish. If after cooling it be shaken with about half its volume of ether, a definite and permanent layer of blue-violet flocks forms between the two liquids. If the mixture be allowed to stand, the helleboretin dissolves gradually in the water, imparting to it an amethyst colour, whilst the ether remains colourless. Upon rendering the mixture alkaline by the addition of ammonia, the violet flocks become dirty yellow, but resume their original colour upon acidulating the liquid with hydrochloric acid. If sulphuric acid be used instead of hydrochloric acid in this reaction, the results do not appear so distinctly.

If instead of the rhizome an equal quantity of the rootlets be used, scarcely any traces of helleboretin can be distinguished, a point of some importance if, as the author appears to think, helleboretin is the active principle of the drug.

According to Chevallier there have been several cases of poisoning by black hellebore, and amongst others, one where two grams caused the death of an adult in eight hours; the evidence of the two following experiments that the helleboretin reaction can be used for chemical purposes will therefore be of interest.

In the first experiment 2 grams of finely chopped black hellebore rhizome was mixed with 100 grams of calves' liver, the mixture boiled with 200 c.c. of water, the decoction filtered, again boiled with hydrochloric acid, allowed to cool and filtered. The residue in the filter gave the helleboretin reaction most distinctly.

In a second experiment the decoction from 2 grams

* *Pharmaceutische Zeitung*, xxvii. 99.

of rhizome was mixed with 200 c.c. of beer. A portion of the mixture boiled with one-third of its volume of hydrochloric acid, allowed to cool and shaken with ether, gave, not violet, but dark brown flocks, showing that the foreign colouring matters in the mixture hindered the purity of the helleboretin reaction. The decoction, containing beer, was therefore precipitated with a solution of lead acetate and filtered, excess of lead separated by means of sodium phosphate, the liquid filtered and evaporated to one-half and precipitated with excess of tannic acid. The precipitate was decomposed with lead oxide in excess, the mixture then evaporated to dryness, and again taken up in boiling alcohol. The aqueous solution boiled with hydrochloric acid, cooled, and shaken with ether gave the helleboretin blue-violet flocks at the line of separation between the two liquids. The alcoholic solution left upon evaporation a yellowish-white residue formed of microscopic crystalline cauliflower-like aggregations, which were immediately coloured dark brown by concentrated sulphuric acid and were not altered by potassium bichromate. The alcoholic solution when diluted and shaken with ether gave a slight white precipitation at the line of separation between the two liquids.

THE ASSAY OF SPIRITUS ÆTHERIS NITROSI.*

BY PROFESSOR J. F. EYKMAN, OF TOKIO.

The so-called spiritus nitri dulcis is one of those remedies the normal constituents of which are not definitely ascertained, and for the assay of which no accurate method is known. Although the spirit is described in many chemical works as a simple solution of ethyl nitrite in alcohol, still none of the Pharmacopœias has a process according to which the resulting preparation would consist solely of ethyl nitrite and alcohol. Even when following the directions of the British and United States Pharmacopœias, where the use of copper prevents as much as possible the production of by-products, the product will never be entirely free from the latter. These by-products, mostly produced by oxidation of the alcohol, and among which are, primarily, aldehyde and acetic ether, and secondarily, common ether, ethyl formate and oxalate, cyanogen compounds, etc., occur in larger quantities when following the process of the Netherlands and German Pharmacopœias, where the alcohol itself serves as a means of reducing the nitric acid. Even when prepared according to the Codex Medicamentarius (Pharm. Gall.), the spirit contains a series of these by-products, among which are also found some less volatile ones, as glyoxal, glyoxylic acid, oxalic, malic, saccharic acids, etc. A difference in mode of preparation, however, not only alters the kind and quantity of by-products, but also the percentage of ethyl nitrite. Even when following one and the same process, a slight alteration in the *modus operandi* may essentially alter the qualitative composition and the percentage of ether. From this cause, as well as from the readiness with which ethyl nitrite changes by age, particularly in consequence of the considerable percentage of water in the spirit, or of exposure to light in only partly filled or not securely stoppered vessels, it will be understood how different samples of the spirit can show such different properties, particularly in the percentage of the ether, which is occasionally only present in traces, and sometimes even entirely absent.

It is to be regretted that not every Pharmacopœia demands the spirit to have a definite composition and a constant percentage of ethyl nitrite.

The Netherlands and German Pharmacopœias mention no such requirements. It is true both of them mention a definite specific gravity; but this is of little account so far as the percentage of ether is concerned, since both water and ethyl nitrite alter the specific gravity of alcohol in the same direction, namely, by increasing it. Even a greater or lesser amount of oxidation products, as aldehyde, is ignored by both Pharmacopœias, nor do they mention any method by which the presence of ethyl nitrite could be detected.

More detailed and exact in the description and properties are the British and United States Pharmacopœias. The latter requires that the spirit should contain 5 per cent. "of its peculiar ether," but gives no method for assaying it. On the other hand, the British Pharmacopœia says: "If it be agitated with twice its volume of saturated solution of chloride of calcium in a closed tube, 2 per cent. of its original volume will separate in the form of an ethereal liquid,* and rise to the surface of the mixture.

It is clear that this test can only be applied to a spirit prepared according to the British Pharmacopœia, and cannot be used as a method of testing such as are prepared according to other processes, for instance, those of the Netherlands or German Pharmacopœias. In no case can the percentage of absolute ethyl nitrite be determined from the amount of the ether separated by calcium chloride, because the latter separates aldehyde, acetic ether, ether, etc., likewise. Besides, a preparation spoiled by age may be so manipulated by the addition of acetic or ordinary ether that it may respond to the above test without containing the required percentage of the true ether.

The different samples of spirit of nitrous ether, which have been examined in great number here, generally separate *nothing* when shaken with 2 volumes of a concentrated solution of calcium chloride. A few times from 2 to 5 per cent. was separated, and once 12 per cent., which latter should correspond to 20 per cent. of ethyl nitrite. These differences induced me to examine whether the layer separated by calcium chloride should always be regarded as ethyl nitrite. But the methods which, so far as I know, exist for the assay of ethyl nitrite in spiritus ætheris nitrosi all depend upon its decomposition (saponification) with potassa, and the assay of the resulting potassium nitrite,† and seem to me to yield unsatisfactory results, particularly when much of the above-mentioned by-products are present. I endeavoured, therefore, to find a process in which these by-products would not seriously interfere, and I believe that I have succeeded in finding one, as will be seen from the following description and analytical data.

In general, my method agrees with those proposed by Schloesing, Schulze, Wulfers, Reichardt, Tiemann, and others for the assay of nitric acid in well-water, etc. It depends on the determination of the volume of nitric oxide gas (NO), which is produced by decomposing ethyl nitrite by a ferrous salt, and is driven over and collected by distillation in an atmosphere free of oxygen.

The accompanying figure shows the apparatus used by me for my analysis. A is a flask of about 150 cubic

---

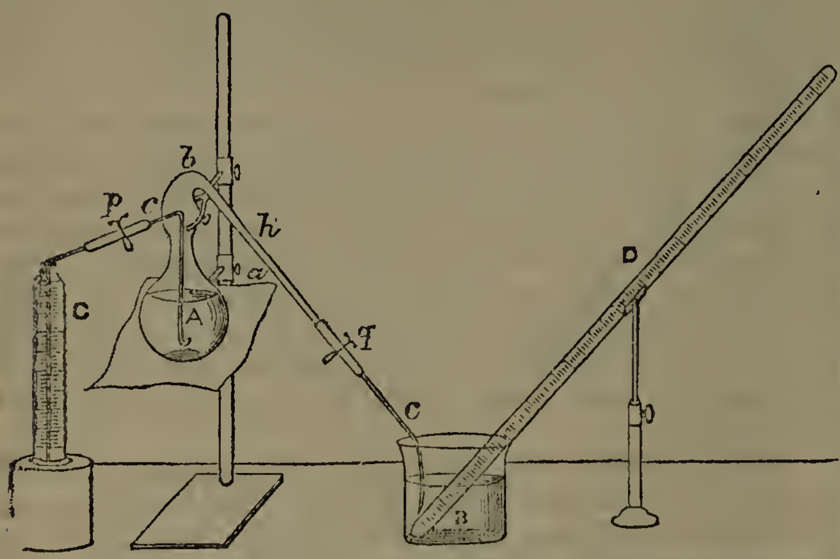
* Abstract of a pamphlet, entitled 'On Spiritus Ætheris Nitrosi.' Reprinted from *New Remedies*, May, 1882.

* A portion of it remains in the chloride of calcium solution. In Parrish's 'Treatise of Pharmacy' (1874), I found 4 per cent.; Tanner (*Jahresber. f. Pharmacog.*, 1871), Smith ('Commentary on the British Pharmacopœia') and others have 8 per cent., from which it appears that the preparation as officinal in England should contain 10 per cent. of the ether.

† In Hoffmann's 'Manual of Chemical Analysis,' a method is described, which consists in decomposing with potassa, diluting with water, and titrating the potassium nitrite, after acidulating with sulphuric acid, by means of solution of potassium permanganate of known strength, until this is no longer rendered colourless.

Rosenbladt recently published (*Zeitschr. f. anal. Chem.*, xvii., Heft 3) a method in which the spirit is saponified by alcoholic potassa in a closed tube, the alcohol driven off afterwards by evaporation, and the residue heated with a concentrated solution of chloride of ammonium in an apparatus filled with carbonic acid gas. From the volume of nitrogen given off, the quantity of ethyl nitrite is determined.

centimetres capacity. Through its neck passes a narrow (1 to 1·5 millimetres in bore) but thick-walled glass tube,



of which the leg inside the flask reaches nearly to the bottom of the latter, and is there curved over in nearly a right angle.*

The leg *c* is about 3 centimetres long, is joined by means of a short rubber tube, tied with cord, with a thin tube reaching to the bottom of the measuring cylinder C. Also the tube *c* is connected in a similar way with *h*, by means of a stout rubber tube, likewise tied with cord, of narrow diameter, and is curved at its lower end.

The other parts of the apparatus need no description. The beaker B and the measuring tube D are filled with soda solution of about 1·1 to 1·15 specific gravity. Instead of freeing the soda solution from oxygen by boiling, as is directed by Tiemann, I mixed it with a little solution of ferrous sulphate, in a closed flask, and poured the solution off after the ferric hydrate had settled.

Finally, there is required for the analysis a solution of a ferrous salt, acidulated with a little sulphuric acid, containing from 250 to 300 gm. of crystallized ferrous sulphate or 350 gm. of Mohr's salt. For shortness' sake, this solution will be indicated, in the following, by the letters *F. S.* Ferrous chloride and hydrochloric acid, which are preferable in the analysis of nitrates, are unsuited here, among other reasons, to prevent the formation of ethyl chloride, which would be produced by them when sweet spirit of nitre is distilled in their presence.

Before the tube *c* is dipped into the soda, the clamps *p* and *q* are to be opened and some of the F. S. (ferrous solution) contained in a beaker, which is put in place of the measuring cylinder shown in the cut, is made to enter the flask A. This may be easily effected by suction at the tube *e*, or the clamp *p* may be opened, and that at *q* be closed, and the flask be warmed until enough air has been expelled, when the F. S. will be sucked up into the flask on withdrawing the flame. After the flask has been about half filled with the F. S., *p* is closed, while the tube *c d* is still filled with liquid, and *q* is opened. The flask is now heated until the contents are at a brisk boil, when the end of the tube *c* is dipped into the soda solution and the boiling continued until no more bubbles of gas escape. As soon as this is the case, *p* is opened, and *q* is closed. This causes the soda solution to rise in the tube *c* up to the pinchcock, and, at the same time, the liquid still contained in *c d* is driven back into the beaker. During this last-named proceeding, the heat is moderated and regulated by the occasional withdrawal of the flame, so that the liquid recedes evenly and completely. About 5 to 10 cubic centimetres always remain in the flask, because the end of the tube does not reach completely to the bottom.

* As I had no flask of sufficiently fusible glass, I did not succeed in fusing the upper part *a b* to the flask, although the cut shows the latter to be one piece. I joined both portions with a thick rubber ring tied with twine.

Finally steam is given off; the lamp is then to be withdrawn, and the clamp *p* closed, whereupon the liquid is drawn up, from the beaker, into the tube *d* up to the clamp. The apparatus is now ready for a series of analyses. These are executed as follows:—

While the apparatus is deprived of air, 15 c.c. of F. S. are transferred to a narrow measuring cylinder (C) holding about 25·5 c.c. and graduated to 25 c.c. Next, 5 c.c. of dilute sulphuric acid are added, and, finally, 5 c.c. of the sweet spirit of nitre to be assayed.*

The cylinder, which is now almost full, is well closed, shaken a few times, and then allowed to stand for about five minutes. About 10 to 15 c.c. of F. S. is now allowed to pass into the flask, by opening the clamp *p*, and afterwards the mixture in the measuring cylinder, taking care to stop the flow when the level of the liquid approaches the bottom to prevent air from entering the flask. To the remnant a little F. S. is added, and nearly the whole of it again allowed to pass into the flask. This manipulation is repeated, finally substituting water for F. S., until the contents of the tube *c d* are filled with colourless water. The flask then contains about 70 c.c. of liquid.

After the measuring tube, filled with soda solution, has been immersed in the beaker B, the flask is heated, and, as soon as the rubber tube above the clamp *q* begins to bulge a little, *q* is slightly opened, taking care to immediately close it again if the soda solution should show inclination to ascend the tube further. This is to be repeated until the liquid is completely depressed, when the clamp *q* may be entirely opened. The developed nitric oxide (NO) gas is collected in the measuring cylinder, and the boiling is continued as long as gas-bubbles are given off; about five minutes' boiling is sufficient. After the evolution of gas ceases, *p* is opened and *q* closed. The contents of the flask then pass back into a beaker, and the apparatus is again ready for a fresh assay. Every analysis consumes about ten to fifteen minutes.

The collected gas is now to be treated as follows: By means of a capsule placed under the orifice, the measuring cylinder is transferred to a tall cylinder filled with cold water. The tube should be somewhat inclined so that the soda solution may easily run out of the tube and be displaced by water, without mixing with it. The tube is now to be closed with the finger, and by inclining it, the inner wall will be wetted by the water, so as to wash down any adhering soda solution. The tube is then entirely immersed in water. After the lapse of an hour, it is carefully lifted up until the water outside and inside of the tube occupies the same level, and the volume of gas then read off. The temperature of the water and the barometric pressure having been taken, the quantity of ethyl nitrite is calculated by aid of the following formula:—

$$\frac{V}{S \times a} \cdot \frac{H-e}{273+t} \cdot 0{\cdot}1207 = \text{per cent. of ethyl nitrite.}$$

(V represents the number of cubic centimetres of gas read off, H the barometric pressure in millimetres, e the tension of aqueous vapour at the observed temperature, S the specific gravity of the sweet spirit of nitre, a the number of cubic centimetres of the spirit used for assay, and t the observed temperature.)

For the purpose of controlling the correctness of this method, the following tests were made: The suitableness of the apparatus was first ascertained by distilling a weighed quantity of pure potassium nitrate, dissolved in a little water, with a saturated solution of ferrous chloride and hydrochloric acid. After the mixture of potassium nitrate and ferrous chloride had been sucked up, hydrochloric acid was used, in place of water, to wash the last remnants up. The following are the results:—

* If the spirit contains very much ether, take 17 c.c. of F. S. and 3 c.c. of the spirit; if it contains very little, take 10 c.c. of F. S. and 10 c.c. of the ether. The quantity of NO gas which is given off should be so adjusted that 20 to 30 c.c. of the measuring tube are still filled with soda solution.

Potassium nitrate used.	Yielded nitric oxide.	At temperature.	Barom. pressure.	Potassium nitrate found.
0·060	13·3 c.c.	7° C.	768 mm.	0·0588
0·120	26·4 „	9° C.	768 „	0·1159
0·120	26·55 „	9° C.	768 „	0·1166
0·1483	34·0 „	11·5° C.	761 „	0·1459

On comparing these results with those obtained by Eder,* who used Tiemann's apparatus,† it wlll be found that they entirely agree with them. The apparatus employed by me, however, has two advantages over that of Tiemann, namely:—1. By avoiding the use of a doubly-perforated rubber-stopper, there is greater assurance of the complete closure of the apparatus, and, therefore, a greater certainty of the correctness of every analysis. 2. A much smaller amount of time is required, since the apparatus is immediately again ready for a fresh analysis. It is, therefore, also much to be recommended for the execution of a series of *nitric acid* determinations.‡

To ascertain the influence exercised by the above-mentioned substances, *i.e.*, alcohol and its oxidation products, upon sweet spirit of nitre, nitric oxide gas, developed by heating potassium nitrite with ferrous sulphate, was passed into a solution of ferrous sulphate. Three separate portions of 10 c.c. of this solution, always freshly prepared, were distilled—the first by itself, the second with alcohol, and the third with a mixture of alcohol and aldehyde. The latter was obtained by distilling alcohol with potassium bichromate and sulphuric acid. The distillate, after being neutralized, is rectified and mixed with a little alcohol. The resulting liquid contained, besides other oxidation products, so much aldehyde that, after diluting with twenty times the volume of alcohol, a stronger reaction for aldehyde was obtained by heating with potassa than is found in strongly decomposed spirit of nitrous ether. The following figures were obtained:—

Without alcohol or aldehyde mixture.	With 10 c.c. of alcohol of 90 per cent.
I. 24·4 c.c. at 6° C. and 767 mm.	24·7 c.c. at 6° C. and 767 mm.
24·6 c.c. at 6° C. and 767 mm.	24·2 c.c. at 6° C. and 767 mm.
II. 18·6 c.c. at 6° C. and 767 mm.	18·8 c.c. at 7·5° C. and 767 mm.

Without alcohol or aldehyde mixture.	With 10 c.c. of alcohol and ½ c.c. of aldehyde mixture.
III. 22·6 c.c. at 7° C. and 766 mm.	22·0 c.c. at 7° C. and 766 mm.
22·0 c.c. at 7° C. and 766 mm.	22·2 c.c. at 7° C. and 766 mm.
IV. 31·2 c.c. at 8° C. and 768 mm.	30·7 c.c. at 8° C. and 769 mm.

These figures show that alcohol and aldehyde have but little influence upon the eliminated nitric oxide. I now prepared a small quantity of ethyl nitrite in order to ascertain whether the reaction took place quantitatively according to the following scheme:—

$$2C_2H_5.NO_2 + 2FeSO_4 + H_2SO_4 =$$
ethyl nitrite + ferrous sulphate + sulphuric acid

$$= Fe_2(SO_4)_3 + 2C_2H_5.OH + 2NO.$$
ferric sulphate + alcohol + nitric oxide

The ethyl nitrite was obtained by distilling a mixture of alcohol, sulphuric and nitric acids with copper. The mixture was heated to 71° to 75° C.; the vapours passed first through an empty flask, were next washed with a solution of calcium chloride, and afterwards condensed in a Liebig's condenser. The distillate was caught in a receiver cooled with ice, and afterwards three times shaken with about five times its volume of water. The separated ether having been allowed to stand a few days in contact with unslaked lime, it was then distilled in a fractional distillation apparatus with Linnemann's tube. The portion passing over at 19° C. was again shaken with ten volumes of water, the separated ether again dried over lime, and once more fractionated. This gave a product boiling at 18° C. and 768 mm., which was used for the following assays.

I. 2·4695 gm. were dissolved in 90 per cent. alcohol, to measure 100 c.c. Five c.c. of this solution, corresponding to 0·12347 gm. of the pure ether ($C_2H_5.NO_2$), yielded—

a. 37·75 c.c. NO, at 15° C. and 762 mm.
b. 37·68 „ „ „ „

corresponding to 0·11843 gm. of the ether, thus showing a loss of 0·00504 gm. At one time the gas was collected over mercury. After allowing ferrous chloride to pass up through it, there remained unabsorbed, at 10° C. and 762 mm., 0·45 c.c.

II. 1·2365 gm. were dissolved in 90 per cent. alcohol, to measure 100 c.c. Five c.c. of this solution, corresponding to 0·061575 gm. of the pure ether, yielded—

a. 19·2 c.c. NO, at 13° C. and 759 mm.
b. 18·95 c.c. „ „ „ „
c. Mixed with 1 c.c. of aldehyde mixture, 19 c.c. NO, at 13° C. and 759 mm.
= 0·05993 gm. of the ether, showing loss of only 0·0017 gm.

III. 5·993 gm. were diluted with 90 per cent. alcohol to 250 c.c. portions of 10 c.c. each, of this solution, were analysed according to Hoffmann's and Rosenbladt's method, and one portion of 3 c.c. was analysed according to my own method (the results are calculated for 10 c.c. to permit ready comparison with the others). Here are the figures:—

Method.		Amount of ether taken.	Temperature C°.	Pressure mm.	Consumed permanganate *	Yielded gas in c.c.	Amount of ether found.	Loss.
Hoffmann's	1	0·23971	—	—	25·4c.c.	—	0·204	0·0357
	2	0·23971	—	—	21·7c.c.	—	0·175	0·0647
Rosenbladt's	3	0·23971	8°	752	—	58·3 N_2	0·1888	0·0509
	4	0·23971	8°	752	—	57·8 N_2	0·187	0·0527
	5	0·23971	9°	752	—	49·8 N_2	0·161	0·0787
	6	0·23971	10°	761	—	68·8 N_2	0·211	0·0287
Eykman's	7	0·23971	6°	764	—	21·55 NO	0·2372	0·0025
	8	0·23971	6°	764	—	21·9 NO		

The last series of assays was repeated, with the addition of 25 per cent. of aldehyde mixture when using my own method, and only 10 per cent. with the others. The results were:—

a. Hoffmann's Method.

Ten c.c. of the alcoholic solution and 1 c.c. of the aldehyde mixture consumed 55 c.c. of the permanganate, and still the latter lost its colour.

* *Zeitschr. f. anal. Chem.*, xvi., 300.

† W. Kubel, *Anleitung zur Untersuchung von Wasser.* Zweite Aufl. v. Tiemann.

‡ To assay the nitric acid in cuprum aluminatum, 0·25 gm. are dissolved in a few c.c. of water, and distilled with a concentrated solution of ferrous chloride or of Mohr's salt (ammonio-ferrous sulphate) in hydrochloric acid.

* 1 c.c. of permanganate solution corresponds to 0·008052 gm. of pure ethyl nitrite.

b Rosenbladt's Method.

The same mixture yielded, at 10° C. and 763 mm. pressure, the following quantities of nitrogen gas:—

	Pure ether.	Loss.
a. 40·8 c.c. correspond to	0·1312	0·1085
b. 39·3 „ „	0·1260	0·1137
c. 21·8 „ „	0·0700	0·1697
d. 24·2 „ „	0·0778	0·1619

c. Eykman's Method.

A mixture in the same proportion at 8° C. and 765 mm., yielded—

	Pure ether.	Loss.
a. 21·4 c.c. correspond to	0·2331	0·0066
b. 21·7 „ „	0·2331	

Calculated per 100 c.c. of the solution, or 2·3971 gm. of the pure ether, the loss incurred by the three methods is, therefore, as follows:—

	Without aldehyde.	With aldehyde.
Hoffmann . . .	15–27 per cent.	? ?
Rosenbladt . . .	12–32 „	45–70 per cent.
Eykman	1·5–4 „	2·5 „

From these results I am justified in believing that neither Hoffmann's nor Rosenbladt's methods are useful processes on account of the interference of the oxidation products of alcohol.

I append a selection of analyses of spirit of nitrous ether, taken from a number executed by my process.

Prepared according to Pharmacopœia.	Sp. gr.	When shaken with 2 vols. sol. of $CaCl_2$, there is separated.	Result of analysis upon 5 c.c.	Per cent. of pure ether.
1. Netherl. (fresh).	0·845	nothing.	20·2 c.c. NO at 8° and 769 mm.	1·56
2. Netherl. (fresh).	0·844	nothing.	26·4 c.c. NO at 9° and 769 mm.	2·04
3. Netherl. (fresh).	0·851	nothing.	32·0 c.c. NO at 10° and 769 mm.	2·44
4. Netherl. (old)	0·856	nothing.	4·9 c.c. NO at 8° and 769 mm.	0·37
5. U. S. (fresh).	0·837	—	41·2 c.c. NO at 8° and 769 mm.	3·22
6. U. S. (fresh).	0·838	nothing.	24·4 c.c. NO at 6·5° and 769 mm. 24·6 c.c. NO at 6·5° and 769 mm.	1·92
7. U. S. (old)	0·842	nothing.	17·6 c.c. NO at 8° and 769 mm.	1·37
8. Brit. (fresh).	0·845	p.c.p.c. 2=10 ether.	38·1 c.c. NO at 6° and 769 mm.	2·94
9. ?	0·855	4=12 „	44·9 c.c. NO at 9° and 765 mm.	3·4
10.	0·856	12=20 „	48·2 c.c. NO at 6° and 771 mm.	6·2

It also appears that the ether which is separated from the spirit by shaking with two volumes of a saturated solution of chloride of calcium consists only *in part* of ethyl nitrite. From about 50 c.c. of the latter separated by calcium chloride, I succeeded in extracting a few c.c. of pure acetic ether and a little ether. The liquid had not entirely distilled over when it had reached the boiling point of alcohol; the largest part distilled at above 25° C., and only a few c.c. could be collected at a temperature of 18° C.

THE CONSTITUTION OF ALBUMENOIDS.*

The following passages are taken from an interesting report upon albumenoid matters which has recently been presented by M. Dumas to the Academy of Sciences, based upon a communication from M. Béchamp.

Among the most interesting and least known of organic substances are those which are designated under the common name of albumenoid or gelatinigenous matters, which are either liquid and coagulable, as white of egg, blood serum, and the fibrous principle of the flesh of animals, or tissues that may be converted into gelatine, as well as gelatine itself. Not being volatile or crystallizable they are most difficult to define, and just as it might be believed that we had to do with a well characterized species the substance proves to be a mixture of two or more different bodies.

* *Journal de Pharmacie*, [5], vi., 8.

The distinctive specific properties of these bodies are therefore not yet well known; there are obscure points in respect to their elementary composition; the products resulting from the action of energetic reagents upon them are complex, whilst all the formulæ by which it has been attempted to represent their composition have proved so complicated that it is difficult to lay hold of the bond connecting them with the ordinary equations of organic chemistry which have been studied with success in recent years. Such considerable efforts have, however, been made, and science has been for some time past enriched with results so worthy of attention, that the not very distant discovery of the true constitution of these substances,—which appear to be direct instruments of life,—may be considered possible and even probable, as well as the precise definition of their specific constituents.

Although these matters do not crystallize or volatilize or form well-defined combinations with bases or acids, they possess one character which is constant and distinctive, and that is the action that bodies of this nature exercise upon the plane of polarized light. In studying various albumenoid matters under this aspect M. Béchamp has succeeded in separating them into species which, if not absolutely defined and comparable to those represented by volatile or crystallizable substances, at least present the results of the first serious attempt towards a regular classification of these interesting products.

In order to appreciate the importance of this inquiry it is sufficient to recall the fact that the organs of all animals and the liquids bathing them are formed of or contain such matters, and that if they do not constitute the preponderating materials in the tissues and juices of plants, their presence in them does not seem to be less general or less essential, especially at the commencement of cell formation. If it be added that analyses of these substances and their interpretation have led chemists to admit that their molecule contains not less than from five to six hundred atoms of carbon, hydrogen, oxygen or nitrogen, it will be understood what a distance separates these bodies from those much less complex ones, the study of which has served as a foundation for the doctrines upon which systematic organic chemistry rests.

The first question to resolve in connection with this group of bodies consists in breaking up the mixtures in which they occur in nature and isolating those individuals possessing fixed and sufficiently fundamental properties to warrant their being considered specific and essential.

White of egg contains at least three bodies: one precipitable by subacetate of lead; a second by ammoniacal subacetate of lead; and a third which is not coagulable by heat, and is soluble in water and insoluble in alcohol, by which means it is separable from an aqueous solution. The first two of these substances present the general characters of albuminoid matters; the third belongs to the class of ferments and liquefies starch.

The ferment discovered in the white of egg by M. Béchamp explains some of the phenomena which occur during incubation. Its presence there caused him to look for it in other albuminoid products, and a general idea of his work may be given by saying that he has succeeded in breaking these up into two or three distinct substances, possessing the properties of albumenous products, and a well defined ferment. The question arises, for what purpose are all these albuminous liquids accompanied by these ferments? What relation exists between the abundance of coagulable animal matter, destined apparently to furnish materials for the building up of organs, and the small quantity of these ferments the presence of which appears to indicate the approaching destruction of the unstable compounds with which they are associated? Whence do these ferments come, what becomes of them, and what part do they play? Such questions are certainly of considerable interest; for these ferments are observed in the serum of the blood of all animals, in the white and the yelk of eggs, and in milk; that is in all liquids destined for the formation or reparation of the organs of animals.

Long ago, Thenard, recognizing the singularly destructive action exercised upon peroxide of hydrogen by certain bodies, such as divided silver, was led to compare their manner of action in this case with that of ferments. In fact the analogy is striking between beer yeast, which in the presence of sugar destroys it and converts it into alcohol and carbonic acid, and fibrin, which converts peroxide of hydrogen into oxygen and water. Neither beer yeast nor fibrin appears to operate in virtue of a chemical action or it would have a part to play. But yeast operates in virtue of a vital phenomenon: would this be the case with fibrin? Of this we are ignorant, and although our ideas upon the subject of ferments have been much modified since the investigation of peroxide of hydrogen by Thenard, we are not yet in a position to explain how fibrin decomposes peroxide of hydrogen apparently without borrowing anything from it or yielding anything to it.

This question, the interest of which has not escaped physiologists, has been advanced a step by M. Béchamp. The fibrin of the blood and the oxygen condensed in the globules may possibly have a part to play in the complex phenomena of respiration allied to this singular action upon peroxide of hydrogen which no other animal matter exhibits. M. Dumas states that he himself formerly sought unsuccessfully to ascertain whether arterial blood contained peroxide of hydrogen, but he would not be surprised if some more able experimenter were to detect its presence.

When fibrin is treated with dilute hydrochloric acid it swells and the greater portion of it dissolves; but as recognized by M. Bouchardat there is always an insoluble residue. M. Béchamp has demonstrated that it is in this residue that the decomposing action in respect to peroxide of hydrogen is found and not in the soluble portion that is removed by hydrochloric acid.

The granular substance insoluble in hydrochloric acid is still an albumenoid matter, possessing the general properties of albumenoids. When heated to boiling in water it loses its decomposing power upon peroxide of hydrogen. If dried in a vacuum in the cold it, on the contrary, retains the power. The same happens when it is treated with alcohol and ether; a little fatty matter is removed without modifying its decomposing power. When this singular substance has been well prepared its action upon peroxide of hydrogen is as rapid as that of the metallic oxides.

It may be mentioned that in a subsequent communication to the Academy* Messrs. Bert and Regnard confirm M. Béchamp's statement that the power of decomposing peroxide of hydrogen resides in the portion of fibrin not dissolved in dilute hydrochloric acid. They further state that if fibrin be converted into peptone by artificial digestion it is no longer capable of decomposing peroxide of hydrogen, but that this property is not affected by putrefaction. Another observation of these experimenters, that in every case an organized ferment, such as beer yeast, is immediately destroyed by contact with peroxide of hydrogen, whilst soluble ferments, such as diastase and the gastric and pancreatic juices, are not affected by it, may give a clue to the nature of the ferment associated with fibrin.

The memoir of M. Béchamp contains the results of his attempts to separate definite substances from various albumenoid matters, and enumerates the various ferments that he has found associated with them as well as their properties.

* *Comptes Rendus*, xciv., 1382.

SULPHOPHENATE OF QUININE.*

BY S. ZINNO.

The author first discusses the question as to whether "sulphophenate" or "phenosulphate" is the better name for this salt, and decides in favour of the former, for the more stable and important of the atomic groups forming the double acid is the sulphuric molecule. The acid from which this salt is formed is a substitution product of sulphuric acid in which one of the hydrogen atoms is replaced by a molecule of phenyl, thus $\left.\begin{matrix}H\\C_6H_5\end{matrix}\right\} SO_4$.

This salt appears to have been first prepared by Prota-Giurleo and analysed by Signor Zinno in 1870, although Rademaker is generally stated to have been the discoverer. It is a true chemical compound and possesses all the chemical and physical characteristics of a definite body. It contains 52 per cent. of quinine, 20 per cent. of sulphophenic acid, and 28 per cent of water of crystallization.

Sulphophenic acid is made by treating phenol with excess of strong sulphuric acid, allowing the mixture to remain for twenty-six hours. It is then diluted with water and saturated with barium carbonate, filtered and evaporated, the resulting barium salt being purified by recrystallization from alcohol; it is then decomposed by sulphuric acid, and the liberated sulphophenic acid added to an equivalent proportion of the alkaloid. Or the crude acid may be saturated with carbonate of lead, filtered, and the resulting solution of sulphophenate of lead decomposed with quinine. The salt is very difficult to crystallize and should be dispensed in the form of an accurately titrated solution.

The salt is being much used in Italy in medical practice, and its efficacy is highly spoken of by the author.

THE PREPARATION OF SYRUPS FOR AERATED BEVERAGES.†

In the preparation of syrups, which are solutions of sugar, more or less strong according to the object for which they are used, care should be taken to employ only the best refined sugar, and either distilled or filtered rain water, as they will be rendered much less liable to spontaneous decomposition, and become perfectly transparent without the trouble of clarifying. When, however, impure sugar is employed, clarification is always necessary. This is best done by dissolving the sugar in the water or fruit juices cold, and then beating up a little of the cold syrup with some white of egg and one or two ounces of cold water, until the mixture froths well; this must be added to the syrup in the boiler, and when the whole is frisked up to a good froth, heat should be applied, and the scum which forms removed from time to time with a clean skimmer. As soon as the syrup begins to simmer it must be removed from the fire and allowed to stand until it has cooled a little, when it should again be skimmed, if necessary, and then passed through a clean flannel. By using refined sugar, however, all this trouble of clarification can be avoided.

When vegetable infusions or solutions enter into the compositions of syrups, they should be rendered perfectly transparent by filtration or clarification, before being added to the sugar.

The proper quantity of sugar for syrups will, in general, be found to be two pounds avoirdupois to every pint of water or thin aqueous fluid. These proportions allow for the water that is lost by evaporation during the process, and are those best calculated to produce syrup of proper consistence and possessing good keeping qualities. They closely correspond to those recommended by Guibourt for the production of a perfect syrup, which, he says, consists of 30 parts of sugar to 16 parts of water.

In the preparation of syrup it is of great importance to employ as little heat as possible, as a solution of sugar

* From the *Annali di Chimica*, lxxiv., 282.
† From the *Chicago Confectioner*.

even when kept at a temperature of boiling water, undergoes slow decomposition. The best plan is to pour the water (cold) over the sugar, and to allow the two to lie together for a few hours, in a covered vessel, occasionally stirring, and to apply a gentle heat, preferably that of steam or of a water-bath, to finish the solution. Syrups are sufficiently boiled when some taken up in a spoon pours out like oil, or a drop cooled on the thumb nail gives a proper thread when touched. When a thin skin appears on blowing the syrup, it is judged to be completely saturated. These rude tests, however, often lead to errors, which might be easily prevented by employing the proper proportions, or determining the specific gravity by immersing in the syrup one of Baumé's saccharometers or syrup gauges, as indicated in the following table:—

Sugar in 100 parts.	Sp. Gr.	Deg. Baume.
0	1·000	0
5	1·020	3
10	1·040	6
15	1·062	8
20	1·081	11
25	1·104	13·5
30	1·128	16·3
35	1·152	19
40	1·177	21·6
45	1·204	24·5
50	1·230	27
55	1·257	29·5
60	1·284	32
67	1·321	35

A fluid ounce of saturated syrup weighs 577½ grains; a gallon weighs 13½ pounds; its specific gravity is 1·319 to 1·321 or 35° Baumé; its boiling point is 221° F., and its density at the temperature of 212° is 1·260 to 1·261, or 30° Baumé. The syrups prepared with the juices of fruits mark about two or three degrees more on Baumé's scale than the other syrups. According to Ure, the decimal part of the number denoting the specific gravity of a syrup multiplied by twenty-six gives very nearly the number of pounds of sugar it contains per gallon.

The preservation of syrups, as well as of all saccharine solutions, is best promoted by keeping them in a moderately cool, but not a very cold place. Let syrups be kept in vessels well closed, and in a situation where the temperature never rises above 55° F. They are kept better in small than in large vessels, as the longer a bottle lasts the more frequently will it be opened, and the syrup consequently exposed to the air. By bottling syrups while boiling hot, and immediately corking down and tying the bottles over with a bladder, perfectly air-tight, they may be preserved even at a summer heat for years, without fermenting or losing their transparency.

The candying of syrups may be prevented (unless the syrup be over-saturated with sugar) by the addition of acetic or citric acid, two or three drachms per gallon. Confectioners add a little cream of tartar to the syrup to prevent granulation. Syrups may be effectually prevented from fermenting by the addition of a little sulphite of potassa or lime; also by the use of salicylic acid in small quantities. Fermenting syrups may be immediately restored by exposing the vessel containing them to the temperature of boiling water. The addition of a little spirit is also good, say about ten per cent.

A solution of sugar prepared by dissolving two parts of double refined sugar in one of water, and boiling this a little, affords a syrup which neither ferments nor crystallizes.

The basis of most mineral water syrups is simple syrup, which is prepared by adding sixteen pounds finest white sugar and the whites of four eggs to one gallon of water; stir until all the sugar is dissolved; simmer over a gentle heat for two or three minutes; skim well and strain through a fine flannel bag.

The best way to keep fruit syrups from fermenting is by bottling while hot, into suitable bottles or larger vessels, and to prevent access of air. This is the principle, and it may be carried out in various ways. For instance, fill the syrup while hot in quart bottles, previously warmed, and fill them almost full. Cover or cork the bottles temporarily until the syrup cools a little and contracts in volume; then, having heated a small quantity of the syrup, refill the bottles, cork them securely and wax them.

A great variety of syrups are made by the addition of proper flavouring ingredients to simple syrup; but in other cases, especially when the juices of fruits are employed, the syrup is not first prepared and then flavoured, but the processes go hand-in-hand. In such instances specific instructions will be given. It is always advisable, when fresh fruit can be obtained, to use it in preference to the essence. One general recipe, which answers for nearly all fresh fruit, is as follows: Use nothing but the very best fresh fruit, which must be freed from stocks, etc., and crushed with a wooden instrument (not metal); when well mashed, let it stand in a room of even temperature (about 68° F.) for four days, which will give sufficient time for fermentation to take place; press out the juice from the fruit and let it settle in a cool cellar for two days, after which five pounds of the clear juice is to be simmered with nine pounds of loaf sugar; while warm, strain through flannel. The colour may be improved by a solution of some colouring agent.

It is advisable to add to the fresh fruit before setting it for fermentation, about 2 pounds of powdered loaf sugar for every 100 pounds of fruit. When cold it is ready for bottling. Cleanliness should be strictly observed in all the utensils used. When bottling for storing, skim the top off any floating matter from the syrups in the large pan, and see that no residue at the bottom goes into the bottles. Most of the syrups not made of fruit, may have a little mucilage of gum arabic added, in order to produce a rich froth. The following recipes comprise syrups made from the fruit, and also from essences. These may be varied to suit taste and requirements. A variety of syrups have been brought into use by adding the various wines, such as claret, hock, sherry, etc., to simple syrup; others, by the addition of spirits, as milk punch, by adding to vanilla cream Jamaica rum and nutmeg. Almost any syrup may be made by the addition of a sufficient quantity of flavouring essence to simple syrup; but these artificially prepared syrups are inferior to those made from fresh fruits.

Red Colouring for Soda Water Syrups.—The most convenient is probably tincture of cudbear, as it affords a good, substantial, and natural-looking colour miscible with syrups without cloudiness. It may be made as follows:—Two to 4 ounces powdered cudbear, 1 pint diluted alcohol. Exhaust by maceration or displacement. Used alone, the tincture gives a shade of red closely imitating the colour of raspberries or currants. For deeper red, like blackberries, the addition of some caramel is all that is necessary. The strawberry colour is best imitated with tincture of cochineal. *Aniline red,* owing to its cheapness, is often used for colouring syrups, but it produces a glaring, artificial-looking bluish-red, and is liable to the objection that it sometimes contains arsenic.

Ambrosia Syrup.—A mixture of equal parts of vanilla and strawberry syrups.

Apple Syrup.—Proceed with apples as for pine-apple syrups.

Banana Syrup.—Proceed with bananas as for pine-apple syrups.

Blackberry Syrup.—Prepared from ripe fruit the same as raspberry syrups. Blackberry syrup is improved by adding 1 ounce best French brandy to each quart.

Capillaire Syrup.—Nine pounds loaf sugar, 5 pounds orange-flower water. Boil till the sugar is dissolved and the syrup is clear; while hot, strain through flannel add to the cool syrup 2 drachms of tartaric acid, previously dissolved in 8 ounces of the strongest orange-flower water; lastly add 4 ounces of the best Rhine wine.

Cream Syrup (2).—One pint condensed milk. One pint water. One and one-quarter pound sugar. Heat to boiling and strain. This will keep for over a week in a cool place.

Cream Syrup—Imitation.—Make an emulsion with 3 ounces fresh oil of sweet almonds, 2 ounces powdered gum arabic and 2 ounces water; then dissolve 1 pound white sugar by gentle heat, strain, and when cool, add the whites of two eggs. It should be put up in small bottles, well corked, in a cool place. This is not only an excellent imitation and substitute for cream syrup, but will keep for a considerable time.

Currant Syrup (1).—Six pints simple syrup. Two pints water. Two ounces tartaric acid. Three drachms fruit essence. Mix; colour with liquid carmine for red currants, and with burnt sugar, for black.

Currant Syrup (2).—One pint red currant juice. One gallon simple syrup.

Grape Syrup.—One half pint brandy. One ounce tincture of lemon. One gallon simple syrup. Tincture red saunders, 1 quart.

Ginger Syrup.—Six pints simple syrup. Two pints water. One ounce tartaric acid. Two ounces ginger. Burnt sugar to colour.

Ginger Syrup (2).—Four ounces extract Jamaica ginger. One gallon syrup. Shake well. A few drops of tincture curcuma to colour.

Ginger Syrup (3).—Nine pounds loaf sugar. Five pounds water. Twelve ounces essence ginger. Four ounces Rhine wine. Boil sugar and water until dissolved and clear; when cool, add ginger and wine. Mix well and let settle.

Imperial Syrup.—Equal parts of raspberry and orange syrups.

Lemon Syrup.—Grate off the yellow rinds of lemons, and beat it up with a sufficient quantity of granulated sugar; express the lemon juice; add to each pint of juice 1 pint of water, 3½ pounds granulated sugar, including that rubbed up with the rind; warm until the sugar is dissolved and strain. Under no circumstances must the syrup be allowed to boil, and the less heat that can be used to effect the complete solution of the sugar the better will be the syrup.

Lemon Syrup (2).—Add to 1 gallon simple syrup when cold, 20 drops fresh oil lemon and ½ ounce citric acid, previously dissolved in 3 ounces water; mix by shaking well in a bottle; add 4 ounces gum solution, made by dissolving 2 ounces of fine white gum arabic in 2 ounces warm water.

Lemon Syrup (3).—Six pints simple syrup. Two pints distilled water. Two ounces essence lemon. Two ounces citric acid, dissolved in boiling water. Mix, and, if required, colour with saffron.

Maple Syrup.—Three and one-half pounds maple sugar. One quart water. Dissolve, and, if desired, add a small proportion of gum solution to produce a rich froth.

Milk Punch Syrup.—To 1 pint heavy syrup add one-half pint each of brandy and Jamaica rum; flavour with two teapoonfuls of an extract prepared by macerating 2 ounces of ground nutmegs in 8 ounces of alcohol. The syrup is first to be poured into the glass in the proper quantity, and ordinary cream syrup added before drawing the soda water.

Mulberry Syrup.—Made from the fruit, the same as strawberry, and acidulated slightly with a solution of citric acid. It may also be made from the fruit essence in the same manner as for strawberry, using about half the quantity of tartaric acid.

Nectar Syrup (1).—One ounce extract vanilla. One ounce extract rose. One ounce extract lemon. One ounce extract bitter almonds. Mix and add 1 gallon simple syrup; colour pink with cochineal.

Nectar Syrup (2).—Mix 3 parts vanilla syrup with 1 each of pineapple and lemon syrups.

Orange Syrups.—These may be made from the fresh fruit or from the essence in a similar manner as for lemon syrups. Orange syrups may be coloured slightly with tincture of saffron or of turmeric.

Orgeat Syrup (1).—One half pint of cream syrup. One half pint simple syrup. One pint vanilla syrup. Five drops oil bitter almonds.

Orgeat Syrup (2).—Beat to an emulsion in a mortar 8 ounces blanched sweet almonds and 4 ounces bitter ones, adding a little water; when smooth add 3 pints water; mix and strain; dissolve in this without heat 6 pounds sifted white sugar, and 4 ounces fresh orange-flower water.

An excellent imitation of orgeat syrup is made by flavouring cream syrup, made with eggs and milk, with a few drops of oil of bitter almonds.

Pear Syrup.—Proceed with pears as for pineapple syrups.

Pineapple Syrup (1).—Take a convenient number of the fruit; pare and mash them in a marble or porcelain mortar, with a small quantity of sugar; express the juice; for each quart of juice take 1½ pint of water, and 6 pounds of sugar; boil the sugar and water, and add the juice; remove from the fire; skim and strain.

Pineapple Syrup (2).—Six pints simple syrup. Two pints distilled water. One ounce tartaric acid. One drachm essence pineapple. Saffron to colour.

Pineapple Syrup (3).—Proceed as for raspberry (4); but the hard nature of this fruit requires pounding with a heavy chump of wood (not metal) in a tub with a strong bottom; when well mashed it will require great pressure to extract all the juice from this fruit; a cider press will answer the purpose; add 14 pounds of sugar to a gallon of juice and a little pure acetic acid; put it on a slow fire, and stir until the sugar dissolves; when cold, bottle and tie down.

Raspberry Syrup (1).—Take fresh berries and inclose them in a coarse bag; press out the juice, and to each quart add 6 pounds white sugar and 1 pint of water; dissolve, raising it to the boiling point; strain; bottle and cork hot, and keep in a cool place. Raspberry syrup is improved by adding 1 part of currants to 4 parts of raspberries.

Raspberry Syrup (2).—Five quarts raspberries. Twelve pounds white sugar. One pint water. Sprinkle some of the sugar over the fruit in layers, allowing the whole to stand for several hours; express the juice and strain, washing out the pulp with the water, add the remainder of the sugar and water; bring the fluid to the boiling pint, and then strain. This will keep for a long time.

Raspberry Syrup (3).—Six pints simple syrup, 2 pints water, 2 ounces tartaric acid, 2 ounces essence raspberry. Colouring sufficient. Colouring for raspberry, blackberry, etc., syrups may be made by boiling 1 ounce cochineal with half a teaspoonful cream of tartar; filter.

Raspberry Syrup (4).—Take any quantity of fully ripe fruit; free them from stalks; place them in a tub and crush them with a wooden spatula; after they have been mashed, let them remain for three or four honrs, and strain the crushed berries through a strong flannel bag or strainer into a suitable vessel. Dissolve ½ ounce citric acid in 3 ounces water, and add this quantity to each gallon of juice; mix 14 pounds of broken sugar to every gallon of juice; put on a slow fire and stir until all the sugar is dissolved (not boil); take off the fire, and when cold, bottle and cork for future use. If too thick when cold, it may be brought to a proper consistency by the addition of water.

Raspberry Syrup—Imitation.—Three ounces bruised orris root. Two ounces acetic acid. One ounce acetic ether. One pint of alcohol. Cochineal to colour. Mix and allow to stand a few days; filter, and use to flavour simple syrup.

Rose Syrup.—One gallon simple syrup, 1 ounce essence rose. Colour pink with prepared cochineal, and acidulate lightly with a solution of citric acid.

Sarsaparilla Syrup (1).—One gallon simple syrup. Two ounces essence sarsaparilla. Colour with caramel.

Sarsaparilla Syrup (2).—One gallon simple syrup. Essence sarsaparilla q. s. One ounce powdered extract licorice. Fifteen drops oil of sassafras. Fifteen drops oil of wintergreen. Ten drops oil of aniseed. Stir the oils with the powdered licorice; add a portion of the syrup; stir smoothly, and mix the whole together by agitation.

Sherbet Syrup.—Mix equal parts of orange, pineapple, and vanilla syrups.

Sherry Cobbler Syrup.—To 1 pint good sherry add an equal measure of heavy simple syrup, and one lemon cut in very thin slices. Allow the syrup to stand a few hours; strain through a sieve, and bottle for use.

Strawberry Syrup (2).—Proceed as for raspberry syrup (4); but the fruit being more stubborn will require a good beating with the spatula to mash them; when they have stood three or four hours strain and press the juice out by squeezing the strainer between the hands; add to the juice the same quantity of citric acid; dissolve in each gallon 14 pounds of loaf sugar; simply warm the juice sufficiently to dissolve the sugar; take from the fire, and when cold bottle and cork till required.

Vanilla Syrup (1).—One gallon simple syrup. One ounce extract vanilla. One-half ounce citric acid. Stir the acid with a portion of the syrup; add the extract of vanilla; mix.

Vanilla Syrup (2).—Four pints simple syrup. Two ounces extract of vanilla.

SATURDAY, JULY 22, 1882.

REPORT ON AN EXPLOSION IN A DRYSALTER'S WAREHOUSE.

In the early part of last year an explosion occurred on the premises of Mr. Riley, a drysalter and manufacturer of albumen, at Castleton, near Manchester, by which two persons lost their lives and another was seriously injured. According to the accounts given at the time in the newspapers and by Mr. Riley himself, it was represented that chlorate of potash had exploded in consequence of sparks—produced by an iron-hooped cask striking a wall—falling upon some of that salt scattered on the floor. This explanation of the accident was obviously improbable, since chlorate of potash is in itself perfectly harmless and free from any liability to explode even when exposed to considerable heat; but nevertheless the idea that the chlorate had exploded so far gained credence in the locality that after the accident some of the carriers hesitated to carry chlorate of potash on account of the supposed danger attending it.

The somewhat mysterious nature of this accident was considered to demand investigation, and consequently Captain Cundill, R.A., one of the inspectors of explosives, was instructed by the Home Office to inquire into the circumstances attending it. His report has recently been presented and some account of it will, we think, be interesting to our readers, besides being useful in affording an illustration of the way in which accidents may take place in such a warehouse as that of Mr. Riley. From Captain Cundill's examination of the premises, and of the stock contained in them, he came at once to the conclusion that the accident could not have occurred through the agency of any of the ordinary explosives, as the effects and visible remains of the explosion were totally different in character from those which gunpowder, gun cotton, nitroglycerine compounds, fulminates, etc., would infallibly show. Thus the idea that explosives, in the ordinary sense of the word, were illegally manufactured or stored by Mr. Riley, or introduced into his store by some one, with the design of injuring him, was entirely disposed of. Some of the results were partly consistent with the theory that an escape of gas, accidentally fired, had caused the explosion. But no importance could be attached to this view for several reasons. Search was made for picric acid or some of its salts among the stock, as they are articles used in dyeing and known to be dangerously explosive; but no trace of these materials could be found, and all the substances constituting the stock were found to be such as were in themselves perfectly harmless and free from explosive properties when pure and unmixed. However, two of these substances, viz., chlorate of potash and the yellow prussiate of potash, when mixed together, do form an explosive material of a somewhat energetic character, and they are constituents of what is known as white gunpowder. A very rough mixture of these two substances in approximately equal proportions, when ignited with a match, burns with considerable rapidity, much resembling ordinary firework composition, evolving a large amount of whitish smoke and leaving a considerable residue of a slaggy nature.

In the explosion at Castleton it was proved that there was no loud or sharp sound accompanying it, such as would be caused by gunpowder or ordinary explosives, but only a loud hissing like letting off steam, a low rumble and a noise like the "unloading of a cart of coals." There was a very large quantity of thick smoke evolved, described as grey or yellowish, and by one witness as very choking; but there was no violent local disruptive action, as evidenced by the absence of any shattering effects on the structure of the warehouse or on the persons within it, and by the fact that none of the packages of stock in the neighbourhood of the seat of the explosion were at all broken. These contained albumen, chlorate of potash, yellow prussiate of potash, and a little bone black; all separate and unmixed. On the walls, however, there were large quantities of slag or *débris* of the explosion and the floor was covered with a similar mass round the spot where the explosion took place. Some of this slag was submitted to analysis by Dr. Dupré, who found it to consist of yellow prussiate, chloride of potassium, chlorate of potash, carburet of iron and carbonate of potash. Hence, Captain Cundill infers that the cause of the accident was the ignition of a crude mixture of chlorate and yellow prussiate of potash, and he considers that this view furnishes a key to the otherwise puzzling statement of Mr. Riley that it was the chlorate of potash that exploded.

Two other questions then arise, how was the mixture made and how was it ignited? According to the evidence of Mr. Riley and his son, a spark was seen to fly from the cask hoop when it struck the wall, and there was some white powder on the floor, and on the day of the accident two kegs of "potash" had been brought into the store. An invoice for "one cask ground yellow prussiate and one cask pulv. chlorate potash" was also found among Mr. Riley's papers, bearing the date of the previous day. From the facts above mentioned, there can be little or no doubt that the explosive mixture was in considerable quantity on the floor, and not in any package, for the most careful search failed to disclose any fragments of a burst barrel or box. Moreover, the most severe burns on young Riley were on the lower part of his legs, as might be expected from the sudden outburst of a body of flame on the floor, and while the mass of slag was found on the very spot where the various brands of albumen were usually mixed in the ordinary course of business, there were found standing close by two open kegs of the prussiate and chlorate, from both of which a considerable part of their contents had been taken. From these circumstances it is inferred that either Mr. Riley was mixing the two salts experimentally, or in obedience to an order for the delivery of such a mixture, or that he mixed them purely by accident, thinking all the while he was dealing with chlorate of potash or with prussiate of potash alone. Both salts are largely used in dyeing, but there is abundant evidence to show that they are, as a rule, never mixed together in the dry state. Whatever may be conjectured as to the possibility of Mr. Riley having been mixing the salts experimentally, it is very improbable that he was doing so as a regular part of his business, and Captain Cundill inclines to the opinion that the mixing was in some way quite accidental. It is *à priori* very unlikely that this was done by the wholesale chemists who supplied the ground salts, and in addition there is the fact that no exploded package was traced. As regards accidental mixture, it must be remembered that though the ground salts are sufficiently different in appearance to be easily distinguishable in a good light they might be mistaken in a dim light such as there would be in the warehouse where the explosion took place.

However the mixture came on the floor there is little doubt that it was there, and its ignition by the spark from the iron-hooped barrel which Mr. Riley and his son were moving out of the way is readily intelligible. But since the mixture of chlorate and prussiate can be exploded by percussion and friction it is, moreover, not improbable that the mere rolling or perhaps dragging of the cask, or the movement of the feet over some portion of the mixture, exploded it so that the fire was communicated to the main body of the mixture.

This view of the case is in conformity with the verdict of the coroner's jury of "accidental death;" but Captain Cundill does not omit to point out in his report how the Explosives Act, 1875, would bear upon accidents resulting from explosion of a mixture of chlorate and prussiate. In cases where the mixture was made purposely for use as an explosive in the ordinary sense, it would come within the provisions of the third section of the Act, and the mixture would be classed under division 2 of class 4, so that if Mr. Riley's case had been of this kind he would have been guilty of illegal manufacture or storage of an explosive. If, however, the mixture were made purposely with a view to its use in dyeing or other manufacturing operations, this would not have been the case; but Captain Cundill thinks it would become a question whether provision should not be made, in the interests of public safety, for bringing the practice within the scope of the Act under the powers conferred by section 104, providing for the extension of the Act to any substance or process liable to dangerous explosion.

PHARMACY ACT PROSECUTION.

A case of prosecution for the illegal sale of a preparation of opium, reported at page 78, has been decided upon in a manner which a correspondent regards as "creditable," though we cannot quite agree with him. Of course we cannot vouch for the accuracy of the report in the local paper from which our extract is taken; but accepting that as it stands, there is, we think, equal grounds for satisfaction and regret. It would seem that we may congratulate ourselves on the fact that the police authorities who acted as prosecutors and the magistrates who heard the case were impressed with the idea that the trade in drugs and medicinal preparations should not be carried on by any persons but those qualified to do so by registration. That this is very sound as an abstract principle we readily admit; but unfortunately it is not quite in accordance with the law as it exists, and until that becomes the case it is desirable that prosecutions for infringement of the Pharmacy Act should be conducted in strict conformity with the provisions of that statute. There is the greater reason to regret any deviation from such a course since it happens that in regard to the majority of cases of infringement of that Act we must chiefly look to the application of the seventeenth section for a remedy and rely upon the properly directed action of the police and other local authorities for the stoppage of practices which are in every way objectionable. Surely in cases of this kind recourse might usefully be had to the local secretaries of the Pharmaceutical Society for instruction and advice as to the proper mode of instituting prosecutions.

RECIPROCITY IN PHARMACEUTICAL QUALIFICATION.

The May number of the Australian Supplement of the *Chemist and Druggist*, published under the direction of the Pharmaceutical Society of Victoria, contains an article in reference to the reply of the Registrar of the British Society to the request that the Council should take into consideration the conditions under which the Victorian certificate of competency as a pharmaceutical chemist might become interchangeable with that of the British Society. Our readers will probably remember that this reply was to the effect that there are no statutory provisions in the Pharmacy Act of Great Britain empowering the Registrar to place any name on the register except in the ordinary way on production of certificates of skill and competency, signed by the respective boards of examiners appointed by the Council of the Society and approved by the Privy Council. It is admitted to be only right that the leaders and authorized guardians of pharmaceutical education in England should carefully guard their diplomas against deterioration, but at the same time some degree of disappointment appears to be felt that the proposal to establish an interchange of certificates was not entertained. On reflection, however, we trust that it will be seen how difficult would be the maintenance of a proper standard of competency if the suggested acceptance of certificates were to be acceded to, while there was no corresponding interchange of control over the education and examinations. Moreover, the recognition of certificates from one colony would be a ground for admitting it with others, and thus greater harm than good might be done.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held on Thursday, July 20, 1882, the report of the College of Preceptors on the examination held on July 4 was received.

Three hundred and seventy candidates had presented themselves for examination, of whom *one hundred and eighty-one* had failed. The following *one hundred and eighty-nine* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically.)

Airey, George Richard ....Birkdale.
Allan, Alexander ....Aberdeen.
Allen, John Sutcliffe ....Biggleswade.
Askew, John Robert ....Carnforth.
Baker, Joseph Aloysius ....Manchester.
Banyard, John Albert.............Anerley.
Barker, Frederick William......London.
Bayes, William Thomas ....Leamington.
Beanland, John Milner ....Keighley.
Beck, John Wilson ....Morecambe.
Bennett, Albert ....Leeds.
Bishop, George Henry............Southampton.
Bisset, James ....Burntisland.
Bolton, Richard Lee ....Leith.
Bond, Alfred.......................Camborne.

The questions for examination were as follows:—

Time allowed: Three Hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Mons autem altissimus impendebat, ut facile perpauci *prohibere* possent. (ii.) Helvetii legatos de deditione ad eum *miserunt*. (iii.) Petit atque *hortatur*, ut sine ejus offensione animi vel ipse de eo, causa cognita, statuat, vel civitatem statuere jubeat. (iv.) Nihilo secius Cæsar, ut ante constituerat, duas acies hostem propulsare, tertiam opus *perficere jussit*. (v.) De tertia vigilia, T. Labienum, legatum pro prætore, cum duabus legionibus et his ducibus, qui iter cognoverant, summum jugum montis ascendere jubet; quid sui consilii sit, *ostendit*. Ipse de quarta vigilia eodem itinere, quo hostes *ierant*, ad eos contendit, equitatumque omnem ante se mittit.

2. Decline, in full, *opus, duabus legionibus, eodem itinere.*

3. Parse the verbs in italics, and give their principal parts.

4. Translate into Latin:—(i.) He will send an ambassador to Cæsar. (ii.) Three legions were conquered. (iii.) Let us fight bravely, that we be not destroyed. (iv.) They said they would never give up their arms. (v.) He was informed that many tribes had surrendered to the Roman people.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. Express, in words, the difference between the quotient of 9313702853 by 1987, and the product of 46481 and 936.

2. Reduce to a simple fraction $2\frac{1}{2} \times \dfrac{1}{3\frac{1}{3} + \dfrac{1}{4\frac{1}{4}}}$.

3. Reduce £16·73125 + ·$\dot{3}$ of 7*s.* 6*d.* + 3·785 of 4*d.* to the decimal of £20.

4. Into how many farms, each containing 24 hectars 2 ares 9 centiars, can an estate of 1825 hectars 58 ares 84 centiars be divided?

5. If the rent of a farm of 53 acres 1 rood 6 poles be £100 17*s.* 6*d.*, what would be the rent of another farm containing 17 acres 3 roods 2 poles, if six acres of the latter be worth seven of the former?

III. ENGLISH.

1. Define a Conjunction. How does it differ from a Preposition and Relative Pronoun?

2. Illustrate, by examples, the adjectival and adverbial use of *wide, fast, right.*

3. Give words formed by means of the following suffixes:—*ly, ling, age, dom, ship.* Explain the force of each suffix.

4. Parse fully the following sentence:—

"He that fights and runs away,
May live to fight another day."

5. Write a short composition on *one* of the following subjects:—Self-reliance, The Telephone, "Whatever is, is right;" *or*, give an outline of some Play of Shakspere.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	17	11	6	Inverness	1	0	1
Birmingham	15	9	6	Lancaster	8	3	5

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The ordinary monthly meeting was held in the Society's Rooms on Wednesday evening, July 12, Mr. Preston, President, in the chair.

The minutes of the previous meeting having been read and passed, and other business transacted—

Mr. Preston moved that as there was such a small attendance the meeting be adjourned until the second Wednesday in October, and that Mr. Furness be requested to read his paper, of which notice had been given, on that date.

Mr. Furness having agreed to do so, the motion was seconded by Mr. Ellinor and carried unanimously.

Mr. J. Preston, President, and Mr. G. T. W. Newsholme, Honorary Secretary, were appointed delegates to attend the forthcoming Pharmaceutical Conference at Southampton.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

The Chemical Technology of the Jute Fibre.*

BY CHARLES F. CROSS.

The introduction of the jute fibre into this country dates back only some twenty-five years, and during the quarter of a century of its application by Europeans it has occupied an increasingly important position in textile manufactures; and having emerged from the sphere of application, viz., that of textile drudgery, to which it was at first limited, and evinced capabilities of a high order, for the more elegant uses of woven fabrics, it is full time that it should be made the subject of accurate technical study. It was my privilege to be entrusted with an investigation of this fibre, and the results of four years' scientific work, together with the practical experience of their application, are my credentials for engaging the attention of the Society upon this important question.

The first applications of jute in Europe were, as I have said, confined to the production of the coarsest materials, such as sacking. In India, on the other hand, this fibre has been from the earliest antiquity manufactured into fabrics second only to cottons in point of fineness; and its relative importance to cotton in India is that of flax and hemp in Europe. In accounting for this fact, we have to take into consideration the conditions under which it is produced in India. Jute, as is well known, is the bast of certain species of *Corchorus*—a family of tiliaceous annuals, isolated from the matured plants (which, during their five months' growth, attain a height of 10 to 12 feet) by a process of retting. The cultivation of the plant, which has hitherto been practically confined to India, chiefly Bengal, is for the most part in the hands of the native tenant-farmers, or ryots. Now, in all bast fibres, which tend to what is known as lignification, the changes by which this is brought about set in at a definite period of growth; in the case of jute they appear to commence at a comparatively early stage of development, but are most pronounced at the period of flowering. In its practical aspect the lignification of jute is the change from the state of elastic thin-walled tubes, which is the structure of the ultimate fibrils, to that of thick-walled cylinders of much diminished pliability, the gain in substance, that is to say, being brought about at the expense of the textile quality of the fibre. The ryots know this but too well. For their own use they harvest the plants early, before the flowering season, and consequently are able to spin and weave the isolated bast into the finest fabrics; for the European market, on the other hand, they allow maturation to proceed much further, and hence the inferior quality of our commercial jute. Whether it would be expedient to secure a supply of the fibre in its finer condition, and to take steps to overcome the difficulties of organizing the native growers to such a production, is a question that should not be left unanswered; but at this opportunity we have rather to confine ourselves to jute as we find it in European commerce. The finer applications which it has received have been the outcome of periods of scarcity of the fibres with which it has had to compete. The Crimean war shortened our supply of hemp, and the American war that of cotton, and in both cases jute was called into requisition as a substitute. The applications of the fibre, however, to which our attention is about to be directed, are those which rather involve its *chemical* technology, and the more recent developments to which its study has led.

The raw fibre, as we obtain it, is composed of the upper five-sixths of the isolated bast, the root end or lower sixth being cut off, generally before shipment, and constituting the commercial article known as jute "cuttings" or "butt," which are a valuable material to the paper-maker. The former occurs in lengths of about 7ft. Its colour varies from brown to silver-grey, the average shade of yarns spun from the higher qualities being yellowish-grey. A certain depreciation in colour occurs in the process of spinning, partly resulting from the admixture of oils (generally a mixture of whale oil and petroleum), added for the purpose of loosening certain resinous constituents by which the fibres are matted together, and partly to oxidation and adventitious dirt. The jute fibre substance has the following properties: The finest fibres into which it is resolved by ordinary mechanical means consist of bundles of microscopic fibrils, each of which is a cylinder with irregularly thickened walls, the thickening often amounting to partial interruption of the central lumen. These bundles offer a smooth cylindrical surface, and to this fact we may refer the high lustre of the fibre, which, I may add, is much increased by bleaching, probably also by reason of increased smoothness resulting from the removal of substances more or less adventitous. Its chemical composition—and on this point I must be very brief—has been the subject of research by myself, in conjunction with Mr. Bevan, and our results, which have been fully published in the *Journal of the Chemical Society*, may be summed up as follows: The fibre cannot be proved to contain cellulose as such, but is made up of a derivative or derivatives of cellulose, to which we have given the general term of bastose, the disposition of these (*i.e.*, if there be several), being such as to give a homogeneous whole, which may, therefore, at least for practical purposes, be considered as a single substance. Cellulose being a member of the carbohydrate series of compounds, bastose represents a transition to what is known as the aromatic group. By the action of chlorine—and the practical importance of this will be at once evident—bastose is converted into a *chlorinated compound*, which has two very striking properties. By the action of sodium sulphite it is converted into a brilliant colouring matter of a magenta shade; and by the action of alkalies it is resolved into insoluble cellulose on the one hand and soluble bodies allied to the astringents or tannins on the other. A somewhat crude illustration may be used here with advantage to convey a clearer practical conception of these points. Cellulose in all its forms has the power of taking up tannin from its aqueous solutions to form insoluble compounds. Upon this property the ordinary process of mordanting cotton is based. When such a compound is treated with chlorine a chlorinated compound is formed in the fibre, which will give the reaction with sodium sulphite before alluded to. Further, such a compound has the power of taking up the aniline and

* Read at a meeting of the London Section of the Society, March 13.—From the *Journal*, April, 1882.

other soluble colours from their solutions, and thus of becoming dyed with fast shades. This property is possessed by the jute substance itself. By the dyer, therefore, jute may be regarded as a cellulose fibre, a portion of which has become intrinsically modified—in and by its growth in the plant—into a tannin-like substance; and this modification, moreover, having taken place homogeneously, it may be regarded as evenly mordanted. This fact is one of great technical importance; for the process of spinning jute is relatively crude, the fibre being only very imperfectly averaged, so that but for this property of dyeing evenly throughout its substance, jute would be an additional trial to the already much tried dyer. There are two other resolutions of the jute substance which must be alluded to as of great practical importance. (1) When large masses of jute are allowed to lie in the damp state, especially in contact with sea water, the fibre substance is split up into two bodies, or groups of bodies, viz.: (*a*) tannin-like substances, and (*b*) acids of the pectic class, this resolution of the fibre being attended by greater or less disintegration, often amounting to its reduction to a friable powder. Not to dwell upon the more purely scientific bearings of this decomposition, which will be found fully discussed elsewhere, its practical importance will be at once recognized; for the susceptibility of a fibre to this radical change suggests its far more general occurrence than would be indicated by extreme manifestations, and hence the possibility that our whole jute supply is more or less deteriorated by the conditions of its preparation and transit to this country. In support of this we have the testimony of practical men as to the superiority in colour and strength of the goods manufactured in the jute mills in India, although the raw material is drawn from the same source which supplies the European markets. I have made experiments in which jute, specially treated with the object of maintaining its chemical integrity, has been exposed for eight months to damp, in darkness—the conditions which it has to encounter in the hold of a ship—and the results were quite satisfactory. It seems to me, therefore, a matter of essential importance that the native industry should be inquired into by a competent individual or commission, with the view to improve as far as possible our raw material by removing the defects of the present system of production and shipment; and further that such a subject were well worthy the practical consideration of the Society of Chemical Industry. (2) Another decomposition of the jute fibre substance, which has special bearings upon its treatment in dyeing and bleaching, is that which is caused by acids, and notably the mineral acids. Again we must pass over theoretical matter, and limit ourselves to a practical sketch. The jute substance is, then, very easily degraded into soluble modifications, under the influence of acids at comparatively low temperatures; and these soluble modifications are resolved at somewhat higher temperatures into bodies of a dark-brown colour, allied to the so-called humus group, on the one hand, and volatile strongly-smelling bodies, furfurol and its allies, on the other. Hence the "tenderness," strong smell, and tendency to discoloration of jute goods in the preparation of which acids have been used without a scientific or empirical recognition of this their destructive tendency. For instance, I know of a case where a manufacturer introduced a cheap serge blue (aniline) for the dyeing of his sack stripes. The dyer found that, to dye a blue shade with this colour, in order to eliminate the red, he had to employ a large quantity of sulphuric acid. Being limited by the necessity of a fixed output, he did not alter his subsequent washing process to meet the new requirements of the case, and the result was that some tons of yarn were totally destroyed, the destruction becoming apparent only when the yarn was wound. It is only necessary to add that the use in his wash-water of 1 pound of sodium acetate to every 56 pounds of yarn was introduced with the result of allowing the colouring matter in question to be used, with no further change of process. This use of sodium acetate to antagonize the influence of acids, which is so commonly practised by calico printers, is especially to be recommended to the jute dyer, as it will be found to prevent the changes alluded to above.

We come now to the most important part of the subject of the treatment of jute which can engage our attention as chemical technologists. As a preliminary to our discussion of the processes by which jute is fitted to discharge its now more elegant offices, I must mention one or two points in connection with the action of bleaching agents upon jute. The raw fibre can be bleached with the greatest ease by means of permanganates, with subsequent removal, by treatment with sulphurous acid, of the manganic oxide deposited in the fibre, and expressing the oxidation which it has undergone. In this process the loss of weight experienced by the fibre is a minimum, generally amounting to from 2 to 3 per cent. Jute yarn is bleached somewhat less readily by these reagents, and the bleaching must be preceded by alkaline treatment for the removal of adventitious matters. The process, although leaving nothing to be desired in point of simplicity and result, is too costly for adoption on the large scale, it being necessary to employ from 2 pounds to 3 pounds of the potassium salt per 56 pounds of yarn, which alone brings the cost over 1*d.* per pound.

For commercial purposes the only agents available are the hypochlorites. Reference to what has been previously stated as to the action of chlorine upon jute will make it evident that its employment in any form upon the fibre must be watched with the greatest care. Any one ignorant of its distinction in chemical composition from the true cellulose fibres would probably treat it with bleaching powder in the usual way, and in such a way as to cause actual combination with chlorine. I myself have seen this more than once, especially in the case of jute cloth, the presence of the chlorine compound being demonstrated by the development of a magenta stain, more or less deep, when the cloth is treated with a solution of sodium sulphite. It is easy to predict the fate of such a cloth in the steam-chest of the printer—the liberation of hydrochloric acid by the decomposition of the compound in question, the development of dark brown-coloured products of decomposition, accompanied by the total disintegration of the fabric. This, too, has occurred on the large scale—often in such a way that the mischief was not detected till the fabrics came to be used; and the result has been to confirm popular prejudice against jute. Another point remains to be noticed, viz., that the jute substance is oxidized by hypochlorite solutions to form compounds which precipitate the soluble calcium salts, and when ordinary bleaching powder is used, therefore, in the bleaching of jute goods, insoluble calcium compounds of these derivatives are often formed in the fabrics. It is easy to see, therefore, how the bleaching of jute by the ordinary empirical method has yielded an inferior product, harsh to the touch, brittle, and strongly smelling; and it should not be more difficult to suggest the rational method of overcoming its defects.

The following brief sketch of a process founded upon the results of the investigation of the chemical composition and properties of the fibre substance will bring into prominence the chief points which have to be observed in the bleaching of jute, so as to conserve its integrity. The process is specially adapted to cloth. Essential details only are given: (1) The goods are scoured in a weak alkaline solution (sodium silicate, or carbonate, or borax, at 70° to 80° C.) (2) From the scouring solution they are transferred to the bleaching liquor—a solution of sodium hypochlorite prepared in the usual way by decomposing bleaching powder with the equivalent quantity of sodium carbonate. The chlorine strength of this solution should not exceed 1 per cent., and the most convenient working strength I have found to be 0·7 per cent., which therefore will require for its preparation a quantity of bleaching powder equal to about 2 per cent. of the weight of the water used for solution. The presence of the soda entirely prevents the formation of chlorinated compounds of the fibre substance. The mechanical details of the bleaching must be left to the judgment of the operator. (3) The goods, after thorough washing, are transferred to cold dilute hydrochloric acid (1 to 2 per cent.), containing a small quantity of sulphurous acid. The object of this treatment is to remove basic substances, the presence of which causes discoloration of the fibre when brought into oxidizing conditions—notably in the printer's steam-chest—and also to eliminate iron compounds, which previously to this treatment would be found to be evenly distributed in small quantity throughout the cloth, and if left would interfere with any subsequent dyeing operations. The cloth thus treated is of a pale cream colour, and is beautifully soft and lustrous. If the cloth is required to be dyed, it may be taken, of course after thorough washing, to the dye beck. If, on the other hand, for printing, it is subjected to an additional process (4), which consists in running it through a solution of sodium bisulphide of 1 to 2 per cent. SO_2 strength, the excess of the solution being removed by mangling, and returned to the bath. The mechanical arrangements of this treatment should be continuous and automatic. The cloth thus treated is allowed to lie some time (two to three hours), and then dried on steam cylinders. During this process sulphurous acid escapes, and the dry cloth will be found evenly impregnated with neutral sodium sulphite. The presence of this salt antagonizes the oxidizing and disintegrating action of the steaming by which the colour mixtures printed on the fabric require to be developed, without, however, interfering with this latter process. This treatment, moreover, causes a marked improvement in the colour of the bleached cloth, and restores the fibre substance to the normal state in which it is not susceptible to change under ordinary atmospheric conditions. The process has been patented and worked with uniform success. It only remains to be stated that the loss of weight experienced by the fabric need not exceed 7 to 8 per cent., with a diminution of tensile strength of about 10 per cent. of the original; these numbers representing the average of long experience; and the entire cost of bleaching, of course under properly regulated conditions, should not and does not exceed 1*d.* per pound.

In conclusion, I would say a few words on the subject of the position of jute in the textile market and the popular prejudices which have to be overcome before it attains the position which belongs to it by right.

The value of the fibre in its stable applications is, of course, sufficiently recognized. What we have to consider are its relations in the more elegant uses of textile fabrics. Woven mixtures, especially of cotton and jute, in which the latter is employed as weft, have of late won for themselves an extensive demand; and the lustrous and woolly character of the jute yarns, together with the bright fast colours which are so easily communicated to them, insure their permanent application to this purpose. Nevertheless, it will be found that the retailers observe a diplomatic reticence, in deference to the prejudices in question, as to the true nature of these goods; and it is the gratuitous character of this which I wish to expose. It has been commonly supposed that inferior silks are inferior by virtue of adulteration with jute; on the other hand, I have never been able to verify this supposition. It is true that in silk dye-houses in this country spun yarns and inferior silks are commonly termed by the men "jute," and this may account for its having become a general byeword in textile industry; but I have been quite unable to account for its origin in this connection, and I have certainly never met a silk dyer who was at all acquainted with the actual jute. Further, the inferiority of silks is so completely accounted for by the well-known practice of "weighting"—the scientific character of which appears to be so complete an answer to the question of its morality—that, in the absence of positive proof, jute may be left out of the question altogether. It is, however, a fact that printed goods, consisting of jute, both of home and foreign production, have been put upon the market in a form attractive enough to the eye, but so greatly "tendered" by the processes to which they have been subjected, and moreover so unpleasantly odorous, as to have earned a very emphatic and proper condemnation; and it is this fact which has done so much to confirm the existing prejudices against jute.

We are now, however, in a position to see that such a result must follow from the ignorant application of processes to this fibre, which had been erected by long experience into the position of the standard method of treating vegetable fibres; that, on the other hand, the distinctive character of the jute fibre substance postulates a very distinctive treatment, such, for instance, as I have endeavoured to set forth in this paper. It is with the view of securing the general recognition of this by practical men, and thus to aid in establishing the jute fibre in its rightful place in textile industry, that I have ventured to direct the attention of the Society to the chemistry of this interesting fibre.

In answer to questions propounded by those who took part in the discussion which followed the paper, Mr. Cross supplied the following additional information:

The chemistry of the fibre and its technological applications were independent of the changes alluded to as occurring during its shipment and transit, *i.e.*, they truly belonged to the normal fibre. In regard to these changes, their *immediate* cause had not yet been ascertained, but they were essentially due to the peculiar chemical constitution of the fibre substance. The brilliant colour reaction described was obtained, though less effectively, by treatment with sulphite after oxidation by chromic acid, as well as after chlorination.

The fibre could be perfectly bleached by confining it over phosphorus in a moist atmosphere, and also by hydrogen peroxide, but these actions are difficult to control. The normal fibre was totally disintegrated and largely converted into soluble products of decomposition of the fibre substance by both water and steam at high temperatures (120° to 130° C.)—even when heated with sodium acetate solution, in an ordinary retort, acetic acid distils—showing that it is decomposed under these conditions, and with formation of acids. The presence of sodium sulphite, in small quantity, has been found to prevent this decomposition, the explanation of its action being probably its well-known relationship to aldehydes, certain of which tend to be formed from jute when under oxidizing conditions.

Jute appears to be the first case of the employment, on the large scale, of a fibre of what may be termed a *non-cellulose* character, in such a way as to involve chemical manipulation; hence the negative experience which resulted from an uninquiring application of methods suitable only for cellulose fibres. Jute is by no means singular in chemical composition; indeed its characteristic constituent seems to be almost as widely diffused throughout the plant world as cellulose itself. Other similar bast fibres may be expected to find their way into the textile industries, and these also will require special investigation and treatment.

Parliamentary and Law Proceedings.

Alleged Poisonous Effects of a Domestic Remedy.

An inquest was held on Saturday, July 15, before Mr. Wightman, coroner, at Sheffield, on the body of Annis Bell, aged nine month.

Elizabeth Bell, the mother of the child, was called, and stated that when seven weeks old the child was ill, and was attended by Dr. Gill for a fortnight. He said she was suffering from bronchitis and inflammation on the brain; since then the child had gradually pined away. On Monday night witness gave her a teaspoonful of a mixture of "oil of almonds and violets," and again on Tuesday morning and at night—three spoonfuls altogether. She purchased a pennyworth of the mixture at the shop of Mr. Stanfield. It seemed to give the child relief, and that was why she repeated the dose. As the child was worse on Wednesday morning, and continued to "screech and whine," she sent for Dr. Gill, and he said he could not account for the condition of the child, and asked what had been given to it. She told him about the mixture, and he replied that it was poison, and she had no right to have given it to the child. He did not believe in such mixtures. The child died on Thursday, and Dr. Gill refused to give a certificate because of the poison that had been given to it. The child was not in a club, and the parents would get no money by its death.

A Juryman asked if the bottle was labelled "poison."

The Coroner said it was not, and his experience of oil of almonds was that there was no need to so label the bottle. The Coroner added that they had now got as far as they could without a *post-mortem* examination, and he put it to the jury whether he should order one or whether they were satisfied with the evidence that had been given. The reason for holding the inquiry was because Dr. Gill had refused to give a certificate, the child having had oil of almonds given to it. His (the coroner's) opinion was that it was an innocent, harmless mixture, and if the mother had given the child the whole of the pennyworth it would not have killed it.

The jury thought there was no necessity for a *post-mortem*, and they expressed themselves very strongly about the doctor, and wished to censure him for refusing the certificate.

The Coroner said he should not like them to do that, as it was a serious thing to censure a doctor.

The jury, however, had their say about it, and then came to a verdict of "Death from natural causes, probably convulsions."—*Sheffield and Rotherham Independent.*

The Sale of Paregoric.

At the Denbigh Borough Magistrates' Court, on Friday, July 6, Elizabeth Roberts, Henllan, was charged by Superintendent Vaughan with having on May 27 sold a quantity of paregoric elixir, being a preparation of opium, without being duly licensed as a dealer in drugs.

Defendant pleaded ignorance of the requirements of the law.

Superintendent Vaughan called a boy whom he sent purposely to the defendant's shop to purchase drugs. The lad stated that Mrs. Roberts had told him to be careful with the elixir, as it was a strong poison. The bottle in which he brought the drug away was not labelled.

Defendant said her late husband was registered to sell drugs.

Superintendent Vaughan had entirely failed to find his name on the register for the last nine years; but he was positive that defendant was not registered.

The Bench explained that the late Mr. Roberts being duly registered his widow would under some circumstances be allowed to sell drugs for some time after his death.

Captain Lloyd Williams (the Mayor not sitting in the case), said the bench considered the case proved, and would deal as leniently as possible with her. She had pleaded ignorance, but ignorance where drugs were concerned was a serious thing. She would be fined 10*s.* and the costs—£1 18*s.* in all.—*Carnarvon and Denbigh Herald.*

Poisoning by Sulphuric Acid.

The Manchester City Coroner held an inquest on Monday, on the body of Clarissa Tomlinson, a widow, 80 years of age. On Sunday night the deceased felt unwell, and expressed a desire to have a glass of port wine. Her son went upstairs for the bottle, and in his absence the old woman took from a cupboard a bottle which she fancied contained wine, and drank a portion of its contents. She was immediately seized with symptoms of poisoning, and an emetic was given her, but she died in a short time. The surgeon who was called in found that the bottle contained sulphuric acid. A verdict of accidental death was returned.—*Manchester Guardian.*

Review.

The Tea Industry in India. A Review of Finance and Labour, and a Guide for Capitalists and Assistants. By Samuel Baildon, author of 'Tea in Assam.' W. H. Allen and Co, Waterloo Place, S.W. 1882.

The author has written a very readable account of the Tea Industry in India, entering largely into the financial aspect of production and disposal, the labour question, and planter's life; and at the same time giving useful information both to speculators and intending cultivators. This latter portion of the subject is evidently the work of one intimately acquainted with practical matters and social details, and no one should venture upon this special industry in the hope of making it remunerative until he has carefully studied Mr. Baildon s observations.

Some idea may be formed of the importance of this branch of commerce by reading the very recent statement by Mr. J. R. Royle, who has an hereditary claim to be accepted as an authority. "It is only forty-four years ago, viz., in 1838, that the first consignment of Indian tea, consisting of the trifling amount of 456 lbs., reached the London market. This consignment sold remarkably well, realizing fancy prices, and thus gave great encouragement to the spread of tea cultivation in India. Since that time, the amount exported from India has gone on almost constantly increasing, until the exports for the official year 1880–81 are returned as amounting to 46,000,000 pounds, having a value of more than £3,000,000 sterling." The time is passed, however, for people to stand beneath the Silver tree in the moonlight, and whistle for the rupees to come down. The princely fortunes of a century ago have become rare things, and money in India, as elsewhere, must be made by steady work and a sufficiency of capital for the start. More particularly is the young adventurer warned not to leave a comfortable home "on spec.," or he will find himself among a crowd of unfortunates who have committed the same error, and generally with disastrous consequences.

The Indian introduction of the tea plant is veiled in fabulous history. Primarily there was but one kind of plant, and it is still almost an open question as to what is the difference between *Thea viridis* and *Thea bohea.*

In India, making either green or black tea depends upon the will of the planter.

All writers on Indian tea allow that there are three classes of the plant, the indigenous, the China, and the hybrid. The China is supposed to be a deteriorated specimen of the pure Indian plant, though centuries of varied cultivation, and even of neglect, have converted it into a distinct variety. Continuous changes have, moreover, assisted in the production of an entirely new plant, the hybrid. Indian tea is now almost entirely of the hybrid class of various degrees, and what little remains of the originally propagated China tea is a scrubby bush.

A good tea climate must be humid, and according to the author Indian tea was in perfection when it luxuriated in the dampness of the jungle, before a more extensive demand dragged it from its retreat and caused it to be grown in localities which were drier because more accessible to light and heat. Mr. Baildon throughout reiterates a statement which will not be palatable to many of his readers, that while Indian tea is intrinsically superior to Chinese, it is too strong to form an unmixed beverage. With certain exceptions, Mr. Baildon contends that this unwelcome opinion must be accepted.

The planters themselves, the author says, do not drink it, and it can never in an unmixed state become an article of general consumption.

Mr. Royle, discussing the same subject, considers the rage for cheap teas, the method of packing and weighing the Indian varieties, and the customs duty, as the hindrances which affect its introduction; and he points hopefully to the opening of new markets in Australia, America and Canada.

Mr. Baildon bases his expectations rather on the score that Indian tea is admirable for the purpose of blending with other, and weaker varieties; and that it is now used universally to fortify Chinese tea. He argues that from the nature of its cultivation, the whole production being under European supervision, and from its comparative scarceness, its prices must rule higher; but should it ever come into general use, that is be consumed in an unmixed condition, the low price at which then it must be offered would not prove remunerative to the planter.

This Indian tea enjoys a wonderful immunity from adulteration, and in that respect is superior to the Chinese, which is tampered with to a sensational extent.

"At a recent exhibition in Sydney, the Chinese teas subjected to a Government analysis were pronounced in many instances to be adulterated with injurious, and in some cases even poisonous matter; while in the Indian exhibits, placed under the same test, not one case of adulteration was recorded" (p. 30). Mr. Baildon may be expected to be enthusiastic about the merits of the special tea which he has set himself to describe; he considers the Indian superior to the Chinese as a growing plant; that as a manufactured article it is infinitely purer, no artificial doctoring having been required to make it presentable; and that a large proportion of the present China imports would be unsaleable without its aid.

Much light is thrown by the writer upon the private working of the tea industry; nothing more promotes success than a good understanding between the planter and the executive of an estate.

Land is not always equally productive; even in India the seasons vary; and hail-storms, blight and cholera are disturbing elements. Mutual forbearance becomes not only a virtue but a necessity; owners must not be too exacting, and planters must make allowance for irritation on account of deficient crops. At all events, owners, agents and speculative companies are advised not to make sudden alterations in their staff, but to adopt President Lincoln's motto, "Do not change horses while crossing the stream."

The chief difficulty for the planter, specially for the inexperienced young Englishman, is not so much want of knowledge of the theoretical cultivation of tea, as want of understanding the management of coolies.

Mortifying as this may seem, book information will avail but little in comparison with skill in directing labour.

Coolies are fond of change, and with great difficulty can be persuaded to remain beyond their stipulated time. They are a willing prey to intriguing speculators on the look out for old hands; and moreover, they are known occasionally to bolt. By no means the least interesting portions of the book are devoted to these causes of perplexity, and they should be well considered before any decided step is taken to exchange orderly English business habits for the supposed higher attractions of life in India.

The author ends his treatise with an elaborate statement as to the better condition of the plantation cooly (*sic*), compared with that of the ryot, or labourer who pays rent to the Government in Bengal and other localities.

"There is absolutely no parallel in the tea districts to that which is officially reported to be the state of affairs in many parts of India" (p. 209). Again. "There are no famine times in tea. The cooly has only to do his work, to receive his pay, grow fat and save money." He has no rent to raise—his house is kept in good repair; and when ill, he has the services of the doctor. The ryot, on the other hand, is ground down by perpetual exactions, legal and otherwise; and as a culminating point of misery, the rent being demanded *before* his crops have ripened, he is held in bondage by the money-lender. It would add greatly to the prosperity of the country, and benefit the planter, if coolies were recruited from the overpopulated districts of Bengal.

It is further proposed by the author that analytical chemists should be appointed to examine and report upon the soils best adapted to the tea industry; and that gardens which are at present unremunerative should be abandoned.

Mr. Baildon has issued a genuine book, which contains much valuable information; while the social aspects of the question are most graphically described.

BOOKS, PAMPHLETS, ETC., RECEIVED.

THE MEDICAL DIGEST, OR BUSY PRACTITIONER'S VADE-MECUM. By RICHARD NEALE, M.D. Second Edition. London: Ledger, Smith and Co. 1882.

THE MEDICAL MAN'S HANDY BOOK. Edited by WILLIAM SHEPPERSON. London: J. and A. Churchill. 1882.

Notes and Queries.

[729]. TINCT. QUINIÆ AMMONIATA.—As "A Country Chemist" confesses that when he prepares this tincture strictly according to the instructions of the Pharmacopœia, he does not fail to obtain a clear and presentable solution, I must admit my inability to grasp his meaning when he states that there are still some points which have not been cleared up by my communication, published in this column some weeks ago, supplemented as it was in a later issue by some practical remarks from Mr. Smith, of Leamington. Of course, if, as he states, he has made use of "hard water," the reason of the precipitation becomes at once very evident, and, as the Editor very properly suggests, is not due to the presence of quinine at all. Your correspondent is no doubt aware that ordinary "hardened" water contains, amongst other substances, a notable proportion of calcic carbonate, which is held in solution by an excess of carbonic anhydride present in the water. On the addition of the solution of ammonia to this water the dissolved gas is neutralized by the alkali and a minute quantity of soluble ammonic carbonate formed. There being now present no body capable of exerting solvent action on the salt, the calcic carbonate goes out of solution and has, no doubt, been mistaken for precipitated quinine.

J. E. SAUL.

[732]. SPONGES.—What is the method generally used for restoring "flabby" sponges? A. E. R.

Correspondence.

The Future of Pharmacy.

Sir,—You have published a letter from Mr. Hart, of Manchester, reflecting strongly upon the good faith of the Stockport chemists.

He states that by far the larger number of chemists in Stockport do a large trade in supplying not only grocers, etc., but little hucksters' shops, with drugs, pharmaceutical preparations, etc., and upon this statement he draws a series of libellous conclusions.

Now of the twenty-two chemists on the Register in Stockport, there are not more than three who do a wholesale trade; these three are not only chemists and druggists but drysalters and oil and colourmen, one of whom sends out no traveller; another sends one half a day per week, who calls only upon surgeons and manufacturers, not on shopkeepers, whilst the third very properly keeps together a connection which has been established amongst surgeons, manufacturers and shopkeepers for more than a century.

Mr. Hart having thus far drawn on his imagination for facts, not hesitating at a deliberate untruth, next invents an imaginary conversation, or distorts one for the purposes of satire.

Sir, you have in this published an unfounded and unwarranted attack upon a body of your members, who value their independence and respectability as highly or more so than Mr. Hart evidently does, and the chemists of Stockport request me to ask you to publish this letter, and to obtain for them the amends they feel themselves entitled to. Our Association has met this morning and taken into consideration the said letter, and has instructed me to take such steps in reference thereto as may be deemed advisable.

Stockport Chemists' Association, Stockport. Wm. Billing Orton, *Secretary.*

Sir,—Will you kindly find room for the accompanying correspondence in your next issue?

J. Hart.

Copy.

"Stockport Chemists' Association,
"Stockport, *July* 15, 1882.

"Dear Sir,—Having read your letter to the *Pharmaceutical Journal* of to-day, will you kindly give me the name of the one who 'employs a traveller to cultivate this particular trade,' and the name of the one 'who indignantly replied, "I am not," etc.' By so doing you will much oblige

"Yours truly,
"Wm. Billing Orton,
"*Secretary.*

"J. Hart, Esq."

Copy of Reply.

"131, Embden Street, Manchester,
"*17th July*, 1882.

"Dear Sir,—I trust you will not think me wanting in courtesy if I decline to give you the information you require; in fact, the reasons why I should not do so are so very obvious that I can scarcely credit you were serious in making your request; besides which my letter was a public one on a public matter, not attacking individual persons, but pointing out and striking at the greatest curse of our trade, that, whilst we so loudly deplore our lot we never strive to better it by our own individual effort. I do not suppose, nay, I am quite sure the Stockport chemists are not sinners above their brethren, but the fact of their presenting the memorial was the reason of my using them 'to point a moral and adorn a tale.' My strictures will, I am sorry to say, apply to a large number of towns, and if you have any remarks to make upon them, I shall be most happy to discuss them in the columns of the Journal (to which I send this correspondence), with this sole proviso that the 'Future of Pharmacy' and not individuality is to be the text.

"I am, dear Sir,
"Yours faithfully,
"J. Hart.

"W. Billing Orton, Esq."

Fresh Bael Fruit (Ægle Marmelos).

Sir,—Seeing a letter in last week's Journal under the above heading, I was induced to read it through; but up to the present moment I have not been able to decide what Mr. Postans's intention could have been when he penned that letter. It occurs very forcibly to me that his chief objects must have been to remind the pharmaceutical world that some three years since he presented the Society with a specimen, and that he also drew attention to it (the specimen, of course, not the act of presentation, or was it a little bit of both?) at an Evening Meeting.

But be that as it may, Mr. Postans may rest assured that we all know where or how we may obtain the "best preparation" of the fruit when we have occasion to use it. We have had a preparation of it in our Pharmacopœias for a number of years equal, if not even greater, than the number that Mr. Postans has spent in the business. The preparation has, therefore, had ample time to have been thoroughly tried, in point of fact it has been tried, and I fancy most chemists will differ with Mr. Postans when he says that "it is coming somewhat into use." The fact of an occasional specimen being sent to the Square does not justify such an assertion. Indeed, had he but said that its use had long since been given up and was not likely to be re-established he would undoubtedly have been nearer the mark.

Ebbw Vale. Arthur B. C. Orchard.

A correspondent writes,—"It is not often that the sober retail of a chemist's counter compasses a joke, but a very little grain of joke did occur among the 'straw' of daily business the other morning. A boy came in for 'Three pennyworth of powdered rhubarb, to give to young turkeys.' The retailer, with a grim appreciation of the 'litel geste,' smole to himself while he wrote on the packet the very appropriate label of 'Turkey Rhubarb.'"

W. R. Kermath.—Unless the nature of your objection to the practice were stated we do not think the publication of your letter would be desirable.

A. E. R.—Any convenient method of powdering will do, and the finer the powder is the better suited it will be for the purpose mentioned.

Ignoramus.—Spoonfuls.

E. F. Salmon.—We are obliged to you for your communication.

U. S. P.—Phosphate of potash has been recommended as useful in scrofulous and tubercular disease. According to Stillé and Maisch the dose is from 10 to 30 grains, which may be given dissolved in water.

A. J. H.—The prescription distinctly orders a preparation under a name that is to be found in the Pharmacopœia. The substitution of a non-official concentrated preparation, without communicating with the prescriber, is not justifiable.

Junius.—If the recipes already communicated have been found to be unsatisfactory, you are recommended to make some experiments towards their improvement and let us know the result.

Kino.—Kater's "compensation pendulum" had for its object the prevention of error arising from the effect of variations of temperature upon the length of a pendulum. The original description of it, with figures, will be found in *Nicholson's Journal*, vol. xx. (1808), p. 214, which is in the Society's library.

S. H.—(1) See the British Pharmacopœia, Appendix, "Weights and Measures of the British Pharmacopœia." (2) No decomposition appears probable beyond perhaps separation of colouring matter from the extract of belladonna by the acetate of lead.

J. J. Hall.—The appearance is due to a fungus (*Epichloe typhina*).

J. John.—*Cotyledon Umbilicus.*

B. Walker.—*Sedum Telephium* (*Crassulaceæ*).

Naphtha.—Wood spirit or crude methylic alcohol.

Non-Abstainer.—The ferrous salt is soluble in water, but is very readily converted by oxidation into the more sparingly soluble ferric salt.

Communications, Letters, etc., have been received from Messrs. Jones, Barbet, Hutchwen, Bentley, Inquirer.

"THE MONTH."

One of the most important fields of research in chemistry, and the one most likely to throw light upon the constitution of chemical compounds, is the connection, if connection there be, between the physical constants of a substance and the molecular weight corresponding to the formula supposed to represent its constitution. The connection traced by Professor Kopp between the chemical constitution of organic substances and their boiling points has already led to important results. More recently the researches of Prof. Hartley (*Pharm. Journ.*, [3], xi., 54) upon the relation between the chemical constitution of certain organic compounds and their action upon the ultra violet rays have revealed interesting and important connections. In the *Philosophical Magazine* for this month Dr. E. J. Mills has recorded the results of a series of careful experiments, made with the view of finding if any connection obtains between the chemical constitution of a number of typical organic compounds and their melting points. Many difficulties have previously stood in the way of the accurate determination of melting points, the foremost being the want of thermometers which not only should be sensitive to heat but also capable of indicating changes in temperature corresponding to minute fractions of degrees. Dr. Mills himself has considerably aided in this direction, and has devised a very accurate method of determining melting points (*Proc. Roy. Soc.*, xxxiii., 203). In short, it consists in observing the indications given by a very delicate mercurial thermometer, and then comparing these with those of the air thermometer, the actual melting point being expressed by the indications of the air thermometer. Of course a very great number of accurate determinations of melting points must be effected before an induction can be made of the connection with the chemical constitution. Yet making but a comparatively small number of experiments upon specially prepared substances, Dr. Mills has arrived at conclusions which are as interesting as they are important, and at least indicate the existence of a relation between the chemical and physical constants. The following table indicates an interesting connection between the molecular weight and the melting point:—

	Molecular weight.	Melting point.	$\phi = \frac{\text{M.P.}}{\text{M.W.}}$
Dichlorobenzene	$C_6H_4Cl_2 = 147$	52·821	0·35933
Bromaniline	$C_6H_6BrN = 172$	61·742	0·35971
Trinitrotoluene	$C_7H_5(NO_2)_3 = 227$	80·532	0·35477

Thus the melting point of the above compounds being unknown, it could be found by multiplying the molecular weight by the constant ϕ, which in the above cases has been obtained by dividing the melting point by the molecular weight. In the case of nitro-compounds the amount of the (NO_2) group introduced seems to be correlative with a constant difference in melting point. Isomeric compounds, as might be expected, differ in their melting points, but Dr. Mills has further shown by the accuracy of his method that isomerism probably exists in certain cases where it was not previously suspected.

Mr. F. D. Brown (*Phil. Mag.*, July, 1882) has made some experiments with the view of facilitating not only the construction of an accurate thermometer but also the methods of making the corrections which are necessary even with the most delicate instruments. In the researches of Dr. Mills, the readings the mercurial thermometer were not themselves taken as the ultimate indications of temperature, but were referred to the readings of an air thermometer, this being taken as the standard. Mr. Brown has experimented in order to determine whether an accurate method can be devised which shall not incur the large expenditure of time and trouble involved by this method. Two mercurial thermometers were constructed, the details being described fully in the paper, and it was found that these gave almost identical readings. Hence an accurately constructed mercurial thermometer is capable of being used as a standard, and, further, is capable of replacement by another if broken or otherwise destroyed, without the indications of the second being appreciably different from those of the first. Experiments were then made to discover the most accurate method of determining the zero point. It was found that a mixture of distilled water and ice yielded more accurate results than were obtained by the use of melting ice alone, as ordinarily recommended.

An experiment performed by Mr. Fletcher, of Warrington, at the *soirée* of the Society of Chemical Industry, has given rise to some rather wild comments in the newspapers concerning a new theory of combustion. On the occasion referred to, Mr. Fletcher heated a large mass of iron wire red hot in a gas flame, into which he directed a blast of air that was gradually increased until the flame was no longer visible. As the flame became smaller the temperature increased, until at length the iron melted and ran into drops, though no flame could be seen. The *Chemical News* quotes an account of this experiment which describes the results as being so totally unexpected that many persons present were under the impression some deception was being practised; but such a view of the matter would seem to be more suited for the gratification of admirers of the marvellous than for acceptance by minds accustomed to observation and inquiry. That the flameless, or as it might more correctly be termed non-luminous, combustion of hydrocarbon gas should be attended with a greater heating effect than the luminous combustion of the same gas is a self-evident result rather than otherwise. Such non-luminous combustion of the gas means the existence of conditions under which the elementary constituents combine with oxygen simultaneously, and not one after the other to any extent sufficient for the elimination of carbon particles in the solid state, as in the luminous flame. Under such conditions, the degree of heat produced would naturally be the highest attainable with the material burnt, and the local temperature would be proportionate to the rate of combustion, because there would be less opportunity for loss by radiation and conduction than when the oxidation of the burning materials was more progressive.

The various technical journals have recently described two electrical inventions based on the principles of Professor Hughes's induction balance, which promise to be of great importance in the immediate future if present anticipations of their value are realized in actual practice. These are the "torpedo detector" of Captain M'Evoy, and the "divining rod" of Mr. C. F. Varley. It is thought that Captain M'Evoy's invention will also be found of utility in detecting the whereabouts of lost anchors, etc. The apparatus consists of a small mahogany box containing a pair of coils or bobbins and a vibrator, similar to that of electric bells, and a telephone. To this box is attached a given length of flexible cable containing four conducting wires. To the other end of this cable is attached a flat wooden case, in which there are two coils. This case is weighted so as to readily sink in the water. There are terminals on the box for attaching battery wires, and a suitable switch arrangement for turning the current on and off is provided. One complete primary and one complete secondary circuit pass through the box, cable and wooden case. The battery, the vibrator, one coil in the box and one coil in the wooden case form the primary circuit, while the telephone and the two remaining coils form the secondary circuit. The coils are so adjusted that little or no noise from the vibrator is heard in the telephone. Thus adjusted the instrument is ready for work; if the flat wooden case is now brought near a metallic body a loud noise is heard in the telephone, thus indicating the proximity and locality of such a body.

Mr. Varley's divining rod, which makes use of the underlying principles of the preceding invention, is for the purpose of ascertaining the presence or absence of an underground mineral lode. The comparative complexity of the instrument renders it difficult to make a useful abstract description of it. Good detailed descriptions of this instrument and also of Captain M'Evoy's torpedo detector will be found in the *English Mechanic*, xxxv., p. 441.

A few weeks ago Messrs. Jamin and Maneuvrier described to the Academy of Sciences some remarkably interesting and novel effects produced in the well-known "electric egg" by Gramme alternating currents. The experiments appear to have had for their object the investigation of the alternating electric arc *in vacuo*. The authors say that the phenomenon to which the two currents contribute equally is that of Geissler tubes, but of far greater brilliancy owing to the considerable currents of electricity passing. The carbon rods get heated, redden, and reach a pale white heat, not merely at their extremities but throughout their entire length; they are then rapidly volatilized through the combined effects of heating and disintegration. Whatever be the cause of this volatilization the authors state that it is certain that a carbonaceous matter spreads in the state of vapour. In the earlier experiments the globe became filled with a blue gas, like the vapour of iodine, deepening in hue to indigo, and this vapour is abundantly condensed on the glass, rendering it opaque. This termination was avoided by using two cone-shaped bundles of carbons instead of the two single rods used previously, which obviated the volatilization. Still brighter effects were obtained by using copper rods instead of the carbons. The authors have followed up this line of inquiry and in a more recent paper have described the effects produced in the vacuous globe when sulphide of carbon vapour is present. The carbons in these experiments were parallel, fixed at the base and separable at the top by a simple mechanism; in fact, forming an electric candle similar to the one devised by one of the authors (Jamin). With a vacuum as complete as possible in the receiver, the arc, of course, does not form, and the Geissler tube phenomenon is present instead; but when a few drops of sulphide of carbon are introduced, increasing the pressure about 0·05 m. or 0.06 m., the arc appears between the points, and it persists as they are separated. At this moment there is, as it were, an explosion of light, unbearably bright and incomparably superior to the usual brilliancy of the arc. Through coloured glass the arc appears to be of horseshoe form, or like a large omega, resting with its two ends on the carbon points, and about 0·05 m. in height. A long flame rises vertically from this arc. The points of the carbons seem red and very brilliant, but the arc is pale green, and as this colour dominates, the whole room appears as if illuminated by a Bengal flame with copper in it. The brilliancy increases with increase of tension of the vapour; but, the resistance also increasing, the arc may go out and have to be started again and again. The spectrum of the light is formed of four channelled spaces in the red, the yellow, the green, and the violet, very similar in appearance, though the green is the most luminous. They are believed by the authors to obey the same harmonic law, which remains to be discovered. If air remains in the receiver the sulphide of carbon burns incompletely; a cloud of sulphur fills the space and is deposited on the glass, the carbon alone burns. If the exhaustion is nearly complete these clouds are not formed, but a brown deposit forms instead, which turns black. This deposit is volatile; its odour resembles that of sulphur. The authors regard it as a compound of sulphur and carbon. In summarizing, the authors conclude that these experiments are remarkable for the extraordinary amount of light produced, for the size of the arc, for its colour, for the constitution of its spectrum, and for the chemical actions which take place. They think it is not probable that it could ever be turned to account for illumination on account of its colour, unless for lighthouses and signalling at a distance.

Some interesting experiments are recorded in *Nature* (July 13, p. 246), by Mr. J. W. Swan, on the effect of strong sunlight in altering the perception of colour. He finds that by looking at a sheet of white paper while strong sunlight fell on it for two or three minutes the eye became red-blind to colours seen in the shade, but that the reverse effect was produced with respect to flowers seen in a strong light. This effect, however, passed off in a few minutes. These observations may perhaps throw some light on cases of colour blindness which have not a congenital origin.

A suggestive paper in *Nature* (June 22), by Dr. W. Ramsay, is devoted to the enunciation of a theory to account for the sense of smell. Assuming that the sense of smell is excited by gases only, including under this term the vapours of liquids and solids which have a low vapour tension and consequently give off vapour at the ordinary temperature, he points out that all gases which have no smell, or produce simple irritation of the nostrils, have low molecular weight, and that increase of molecular weight (*i.e.*, in gases increase of specific gravity) in compounds of the same class is correlative with increase in the intensity of their smell. Thus methyl alcohol, in a state of purity, is odourless; ethyl alcohol, when freed from ethers and as much as possible from water, has a faint smell, and the odour rapidly becomes more marked with each rise in the series till the limit of volatility is reached and solids are arrived at with such a low vapour tension that they give off no appreciable amount of vapour at the ordinary temperature. Dr. Ramsay gives many other similar illustrations and lays down the proposition that to produce the sensation of smell a substance must have a molecular weight at least fifteen times that of hydrogen. This he thinks can be sufficiently explained by the hypothesis of vibration, the period of vibration of the lighter molecules being too rapid to affect the sense, though the point at which the vibrations begin to be perceptible varies in different individuals. On the other hand it is thought doubtful whether there exists a lower limit to the sense of smell, the vapours of osmic acid, carbon tetrabromide, selenium, tellurium, and arsenious and antimonious oxides, which are among the heaviest known, having a most distinct smell. The intense perfume of flowers is ascribed to terpenes or their products of oxidation, which have a specific gravity with which is associated a rate of vibration that appears to excite the olfactory nerve most powerfully. The paper also contains some ingenious speculations as to the rate of the vibrations and the extent to which smell may resemble sound in having its quality affected by harmonics.

The effects produced by various chemical compounds upon unstriated muscle have been the subject of some recent experiments by Herr Nothnagel, the results being of considerable interest (*Lancet*, July 8, p. 25). The experiments were made upon etherized rabbits, the open abdomen being placed in a warm neutral solution and the chemical substance placed gently, in a solid form, upon the external surface of the bowel. It was found that the result produced was characteristic of the basic rather than of the acid constituent of a salt. A fundamental difference was observed in the action of potash and soda salts; a potash salt producing instantaneously a strong muscular contraction, limited to the part touched or extending round the intestine in an annular direction, whilst a soda salt produced a contraction that was not limited to the part touched, but extended for several centimetres, though always in an upward direction towards the pylorus. So characteristic is this action of a soda salt that in a case where it was desired to ascertain which was the upper and which the lower portion of a piece of exposed bowel, it would only be necessary to place upon it a fragment of common salt, which would produce a contraction that would invariably pass upwards. Several other chemical compounds were tried, but the most striking results appear to have been obtained with the potash and soda salts.

Some interesting speculations have been put forward by M. Corne (*Journ. Pharm. et de Chimie*, [5], vi., 17) as to the phenomena of the phosphorescence and oxidation of phosphorus. He has found that if fragments of phosphorus be allowed to lie in boiled distilled water, which is in contact with pure oxygen under diminished pressure, a time arrives when if a stick of phosphorus be plunged into the oxygen, although this is still in an uncombined state, there is no longer a production of phosphorescence or fumes. It is conjectured that the vapour emitted by the phosphorus under the conditions of the experiment passes from the distilled water upwards into the oxygen, but arrives there in a state in which oxygen is no longer capable of acting upon it, and that eventually the oxygen becomes saturated with this vapour, and is then incapacitated from acting upon phosphorus brought directly into contact with it. M. Corne infers, therefore, that the vaporization of phosphorus, and not oxygen, is the principal cause of phosphorescence and fumes, but that for their production it is necessary that the vaporization should take place in the presence of that gas. Further, he believes that phosphorus is not attacked directly by ordinary oxygen, but that in the vaporization electricity is generated, which, acting upon the oxygen, throws it into the form of ozone, and that this ozone attacks the phosphorus vapour with evolution of heat and light (phosphorescence), whilst the vapour passing instantaneously from the gaseous into the solid state forms fumes. Of course these conjectures will be entirely upset if it turns out, as might be expected, that the oxygen does not remain free, but enters into combination with the phosphorus vapour.

If the inferences drawn from some experiments by M. Combe, which have been brought under the notice of the Academy of Sciences by M. Wurtz (*Comptes Rendus*, xciv., 1717), prove to be correct, it is probable that any disturbance of the quinine market through the synthesis of that alkaloid by M. Maumené will be postponed for the present. It will be remembered that M. Maumené claimed that the preparation of a new compound, NH_2, had enabled him to complete the synthesis of quinine, and pending therapeutic experiments with the product he deposited a sealed packet with the Academy. M. Combe has been tempted to repeat the experiments, but he fails to find any particular novelty in the carbonate obtained in the way indicated by the action of potassium permanganate upon ammonium oxalate, since it appears to be nothing more than a compound of ammonia and carbonic acid, which is not exactly the missing link that was supposed to be hidden in the sealed packet.

In the *American Journal of Pharmacy* Dr. T. G. Wormley answers in the negative the question, "Is gelsemic acid identical with æsculin?" and states that the two differ chiefly in the following particulars:—Gelsemic acid crystallizes very readily (even the $\frac{1}{1000}$ of a grain separating in needles from 1 grain of solution), requires 29·12 parts of water for solution, is soluble in 330 parts of ether, freely soluble in chloroform, and gives a copious yellow precipitate with corrosive sublimate. Æsculin, on the other hand, does not crystallize except from strong solutions, is soluble in from 300 to 576 parts of water and in 36,000 parts of ether, nearly insoluble in chloroform, and gives no precipitate with corrosive sublimate.

In a recent communication to the Academy of Sciences (*Comptes Rendus*, xciv., 1722) M. Chapoteaut described a pulverulent white body that had been obtained by precipitating with 95° alcohol an aqueous solution of gastric juice that had been first dried and washed with ether. Finding that alcohol appeared to modify the precipitate, the aqueous solution was acidulated with sulphuric acid, which even in excess does not redissolve the precipitate, whilst hydrochloric acid dissolves it readily (*Comptes Rendus*, xcv., 140). In this way he obtained a white precipitate, closely resembling an albuminoid in composition, which appeared to constitute the active portion of the gastric juice, and which he considers is entitled to the name "pepsine." It dissolves in water at the ordinary temperature to the extent of 2 grams to the litre. It is soluble in alkalies, being precipitated from such solutions by acids whilst gradually losing its properties. This "pepsine" occurs in the gastric juice as a salt of potash, together with another albuminoid without solvent action on blood fibrin, and a fat acid without solvent action and incapable of displacing the pepsine from its potassic combination.

A lengthy and very interesting communication by Dr. Julius Wortmann throws some fresh light upon the capabilities of bacteria (*Zeit. f. Phys. Chemie*, vi., 287). The rapidity with which these organisms multiply in a solution containing albumenoid matters is now well known. According to the views held by Dr. Wortmann the change which takes place in the albuminoid is first excited by a peptonizing ferment, which under these conditions is abundantly secreted by the bacteria. The product of the action of this ferment upon the albumenoid matter is considered to constitute the food of the bacteria; in proportion, therefore, to the activity of the ferment the necessary nourishment is provided in quantity favourable to the multiplication of the bacteria, and these again yield an increased secretion of ferment. The present experiments of Dr. Wortmann were intended to ascertain what takes place in the absence of albumen, and when starch is the only source available to the bacteria for the carbohydrates necessary for their growth. In this case Dr. Wortmann says the bacteria secrete another special ferment, which is not peptonizing, but acts upon starch in every respect similarly to diastase, and like diastase is soluble in water and precipitated by alcohol. It will be observed that in both these cases it is assumed that the ferment is derived from the bacteria, and that therefore these organisms are capable of secreting different ferments, according to the necessities imposed by surrounding conditions. But, bearing in mind the recent statement of M. Béchamp (see before, p. 66) that "albumenoids" contain a ferment within themselves, which is confirmed by the research of M. Chapoteaut referred to in the previous paragraph, as well as other known facts, it does not seem impossible that the first action of bacteria may be to release from the particular substance which they attack the ferment by which it is eventually to be digested or saccharized, as the case may be. This would be quite consistent with the conclusions published by Messrs. Gautier and Étard in recent communications to the Academy of Sciences upon the chemical mechanism of putrefaction (*Comptes Rendus*, xciv., 1357, 1598). They are of opinion that the molecule of albumen is split up under the influence of bacteria into a number of less complex bodies that previously existed within it as nuclei, and it is worthy of notice that they state that in the case of beef muscle, at the very commencement of the process, there is an oozing of a clear syrupy liquid which appears to be the result of digestion of the flesh by a ferment belonging to it.

Two "new antiseptics" are described by M. Le Bon (*Comptes Rendus*, xcv., 145), a glyceroborate of calcium and a glyceroborate of sodium. They are prepared by heating together, with constant stirring, equal parts of borate of lime, or soda, and glycerine, until a drop removed and placed on a glass plate forms a brittle transparent pearl. Upon being poured out to cool the product forms a transparent glassy mass, soluble in alcohol and water, which, being very hygroscopic, is broken into fragments and kept in stoppered bottles. The glyceroborate of sodium is soluble in water in all proportions, and even in dilute solution is said to be a powerful antiseptic, though so non-irritating that a concentrated solution may be applied to the eye and other delicate organs without inconvenience. A simple coating of meat with a varnish of glyceroborate is said to be sufficient for its preservation. The similarity of these bodies to another recently referred to in these columns is obvious.

At a meeting of the Royal Society of Edinburgh, on June 19 (*Nature*, p. 264), Dr. Dobbie and Mr. G. Henderson communicated the results of analysis of the dragon's blood of Socotra obtained by Professor J. B. Balfour during the expedition to that island. The resin which is obtained from *Dracæna Cinnabari* differs considerably from the other kinds met with in commerce. The authors came to the conclusion also that different species of the same genus yield the same resin, but that the dragon's blood of commerce is derived from plants of different genera.

A material for a varnish, possessing properties that may perhaps be turned to account in pharmacy, has been discovered in aluminium palmitate (*Amer. Journ. Phar.*, p. 371). This substance melts at a higher temperature than dammar and copal, is readily soluble in oil of turpentine and benzol, and the varnish so made dries readily, remains permanently pliable, has a silky lustre, is insoluble in water and does not penetrate through paper.

In the course of some experiments undertaken with a view to investigate the nature of lignin, Herr Singer made the observation (*Monatshefte*, iii., 395) that an extract obtained by boiling pine wood in water, which presented all the characteristic reactions of woody tissue, had, when filtered and evaporated, a distinct odour of vanillin. This led him to try the behaviour of the same reagents (phloroglucin and hydrochloric acid, aniline sulphate, indol, etc.) with pure vanillin, upon which it was found they produced practically the same effect. The experiments were then extended to extracts from other woods, as well as from lignite and decomposing woods, and in every case with the same results as to colour reaction and odour. It was also found that the liquids that held the body presenting these characters in solution,—water, alcohol and soda ley,—were those in which vanillin is soluble, and that both bodies were decomposed at the same temperature. Herr Singer is therefore inclined to believe that the colour reaction and odour always observed in an aqueous extract from woody tissue are due to the presence of vanillin, in which case that body would be one of the most widely diffused in nature. Moreover, from the fact that in successive decoctions of the same woody tissue the same results were always obtained, it would appear that either lignin is a complex body from which by heating in water vanillin is continuously split off, or that the substance known under the name of "lignin" is a mixture of chemical individuals, among which vanillin is a constant constituent. Other bodies found constantly associated with woody tissue were a substance corresponding to coniferin, from which vanillin was first prepared artificially, and a kind of gum.

The astringent bark of the West Indian sapotilla tree (*Sapota Achras*) has been recommended for use as a tonic and febrifuge. It has been recently examined by M. Bernou, who reports (*L'Union Pharm.*, xxiii., 291) that he has obtained from it a crystalline alkaloid, soluble in ether, chloroform and alcohol, and insoluble in water, which he has named "sapotine." It forms a crystallizable hydrochlorate. From acid solutions the alkaloid is precipitated by ammonia, and it can also be removed by shaking with ether. The bark also yielded a large quantity (11·8 per cent.) of "sapotannic" acid, as well as two resins, one soluble and the other insoluble in ether.

At a recent meeting of a Medical Society, in Berlin, Dr. Schiffer called attention to a preparation that he thought might prove useful in the treatment of spasms, tetanus and similar affections of the nervous system (*Zeit. d. allg. öst. Apot.-Ver.*, xx., 253). It consisted of an aqueous extract of the "guachamacha," a South American member of the oleander genus, which has a considerable reputation among the natives. Its active constituent is an alkaloid soluble in water, slightly soluble in absolute alcohol, and almost insoluble in ether and chloroform. In this it resembles curare, as well as in the fact that the active constituent is almost completely precipitated by tannin. It further resembles curare in its paralysing action, with the difference that the respiration is not affected.

An action similar to that of digitalis, but without its inconveniences, is, according to Messrs. Sée and Bochefontaine (*Comptes Rendus*, xcv., 51), exerted by the lily of the valley (*Convallaria majalis*), together with diuretic properties beyond those possessed by any other agent known. In the account of their physiological experiments given to the Academy of Sciences, Messrs. Sée and Bochefontaine spoke of having used an extract of the entire plant and one of the flowers, the latter having been found the most powerful. In mentioning the subject subsequently, however, at a meeting of the Academy of Medicine (*Lancet*, July 15, p. 83), Professor Sée attributed similar properties to a new alkaloid that had been isolated from the lily of the valley by M. Hardy, to which the name "convallarine" has been given.

The leaves of *Globularia Alypum*, or wild senna, used in the south of France as a substitute for senna, have been recently investigated botanically, chemically and therapeutically by Messrs. Heckel, Mourson and Schlagdenhauffen. They find that the active principle, globularin, does not yield two products of decomposition when treated with acid, as stated by Walz, but only one, which they have named "globularetin." It is oily and resinous looking and becomes a transparent uncrystallizable mass, which under the action of caustic alkalies is transformed into cinnamic acid by taking up the elements of water. *Globularia* also contains a small quantity of a volatile aromatic substance which appears to be cinnamate of benzyl.

In the *Practitioner*, for July (p. 32), several pages are devoted by Dr. L. Shapter to *Herba Pulsatilla*, under which he includes *Anemone pratensis*, D.C., and *A. Pulsatilla*, L. It is the former of these that was recommended by Baron Störck under the name of *Pulsatilla nigricans* and which is still used extensively by homœopaths. It differs from *A. Pulsatilla* in having smaller pendulous flowers of a dark purple, with sepals connivent at the base and acute and reflexed at the tips. This plant has not as yet been recorded as occurring in this country. Dr. Phillips attributes the activity of the plant to anemonin, a crystalline principle obtained by distilling the herb with water, concentrating the distillate and purifying the resulting crystals from the inert anemonic acid by solution in alcohol, in which the anemonin is soluble. As this principle is found in several other plants of the same order, *e.g.*, *Anemone nemorosa*, *Ranunculus Flammula*, *R. sceleratus* and *R. bulbosus*, it would decide the question whether the *Anemone Pulsatilla* or *A. pratensis* is the more valuable of the two, if anemonin were experimented with instead of the crude herb. As is the case with several of the Ranunculaceæ the dried herb is much less active than the recent one, but Dr. Shapter does not state which he has used. The strength of tincture he recommends is 2½ ounces of the herb to one pound of spirit, the dose being from ♏v. or x. to ʒss. Hitherto, pulsatilla has been used chiefly as a remedy for mucopurulent discharges, especially in patients of a lymphatic temperament; but Dr. Shapter, led by the statements of Clarus and Orfila, that the plant has a stupefying or paralysing action on the nervous system, to investigate further, has arrived at the conclusion that pulsatilla is a sedative to the sympathetic nervous system. As anemonin is but little soluble in cold alcohol or cold water, it seems doubtful whether the properties that Dr. Shapter attributes to pulsatilla are due to the anemonin or to some other principle not yet detected in the plant. It is noteworthy, however, that he states that he believes the addition of tinct. chloroformi to a ♏xx. dose (anemonin is readily soluble in chloroform) assists the action of pulsatilla.

The New Zealand remedy for diarrhœa, called "koromiko" (*Veronica salicifolia* and *V. parviflora*), seems to be more valued in China than in this country. Dr. J. Jardine, writing from Kiukiang, in the 'Chinese Imperial Maritime Customs Medical Reports,' says that he was induced to try koromiko in dysentery and diarrhœa. Some of the results obtained exceeded his most sanguine expectations, cases of dysentery which had varied in duration from six weeks to four years being cured by four or five doses of the drug. He adds, "Judging from the few cases I have been able to follow, I augur a brilliant future for this remedy in the chronic forms of the disease."

It has long been known that opium has a beneficial influence in diabetes, diminishing thirst and the excretion of urine, while the proportion of sugar in the urine becomes less. Dr. R. S. Smith, in the *British Medical Journal* (p. 933), states his opinion that this action is due to codeia, which he has given with beneficial effect in this disease. The doses he gives are from 1 to 6 grains three times a day.

In *El Sentido católico en las Ciencias Méd.*, in an article by Dr. F. Guermonprez, attention is directed to the variable action of santonin, and its occasionally poisonous action. It would be interesting to determine how far this may be dependent upon the active principle being prepared from different samples of the crude drug, two or three varieties obtained from different plants being met with in commerce.

Preparations of box in one form or another have been frequently used as remedies for fevers, intermittent and otherwise, in France, Italy and Germany. The remarkable results obtained in the treatment of fever in Italy, in 1838, with Pavia's so-called buxine, by Tibaldi, Buzzoni and others, show that even in the impure form the box alkaloids have a powerful therapeutical action. Dr. Alessandri has therefore done good service in investigating the best method of extracting the alkaloidal and other principles of box leaves and bark (see before, p. 23). There seems to be little doubt that he has succeeded in isolating one at least of the alkaloids of the *Buxus*, thus giving experimental therapeutists the opportunity of working with a definite chemical compound and obtaining some trustworthy information on the subject. The most complete treatise on the medicinal properties of box is to be found in a thesis read by M. G. Bazoche before the Faculty of Medicine of Strassburg, in 1859. The remarkable experiments of Drs. Ringer and Murrell with extract of box as an exciter of tetanus in frogs, prove that whether or not the box tree deserves the name of the "poor man's cinchona" bestowed on it by Dr. Alessandri, it possesses most extraordinary physiological properties, and hence ought in all probability to be a powerful therapeutical weapon.

One of the characters formerly given for distinguishing belladonna root was the invariable presence in it of starch. Herr Brandes has, however, pointed out that belladonna root sometimes occurs perfectly free from starch, and he has expressed an opinion that in any case the quantity present is dependent upon the period of vegetation. He states that he has found that the young roots always contain starch, but less in the spring than in the autumn, whilst the older roots are rich in starch in the spring and autumn and contain less in the summer. Some experiments made by Herr Buddel (*Archiv*, xx., 414) appear to indicate that there is some correspondence between the variations in the amount of starch and the amount of atropine, and that roots that are richest in starch contain most alkaloid. They failed, however, to confirm Herr Brandes' conjecture as to the amount of starch in the root being affected by the period of vegetation, for of two specimens, collected at the same period in spring and in the same locality, one, which yielded alkaloid equal to 0·625 per cent. of the dried root, gave no reaction with iodine or perchloride of iron, showing absence of starch and tannin compounds, whilst the other, which yielded 1 per cent. of alkaloid, contained starch. Herr Buddel infers that the roots devoid of starch are derived from young plants, since it is probable that the proportion of alkaloid in a root will increase year by year up to a certain point. It must be remembered, however, that M. Lefort (*Pharm. Journ.* [3], ii., 1031) came to the conclusion that the older the root the smaller is the proportion of atropine it contains, he having obtained about as much again from roots two to three years old as from those seven or eight years old.

At a meeting of the Linnean Society last month, Mr. C. B. Clarke exhibited a large bundle of plants gathered that morning by him in Hampshire, among which the *O. incarnata*, Linn., *O. incarnata*, Syme, and *O. maculata*, Linn., were readily distinguishable at a glance. The first-mentioned has been described by Mr. C. B. Clarke (*Journ. Lin. Soc.*, vol. xix., p. 206), as a species long overlooked in this country. It resembles *O. latifolia*, but is a shorter plant, has leaves of a pale green colour, and never spotted. The flowers are of a pale flesh colour, with a yellow lip, fading to a sallow yellow. The margin of the lip has a line, sometimes bright rose when young, but the flowers never have any purple about them. The plant has been found in Hampshire and Cornwall.

In the *Bull. de la Soc. Linnéene de Paris* (p. 317), Professor Baillon describes a new *Cinnamodendron* from Porto Rico, under the name of *C. macranthum*. It has shorter, broader, and more obtuse and rigid leaves than those of the false winter's bark tree, *C. corticosum*; they are also a little oblique at the base; the secondary veins are more numerous, parallel, and forming a sharper angle; the flowers are much larger, being two centimetres every way. An interesting feature in the plant is the fact that the intermediate petals between the exterior and the interior ones, which in *C. axillare* and *C. corticosum* are considered as scales, are so placed (forming false whorls of three pieces) that he believes it ought to modify the present opinions upon the interpretation to be given to the different floral appendages in this genus, which in this particular recall those of the Magnoliaceæ, and he regards the genus *Cinnamodendron* as bearing the same relation to other Magnoliaceæ as *Monodora* to *Anona*.

The cause of the direction of growth of pollen tubes has been investigated by Dr. L. Kny, who has endeavoured to find out, by experiment, whether Sachs' theory that the direction is caused by the arrest of growth on the side in contact with the solid substance of the stigma, or that of Darwin's, that it is due to the effort to avoid the light, be correct. He immersed pollen grains in a mixture of gelatine (first warmed) and a solution of sugar with a very small quantity of extract of meat, in which nutrient fluid they readily put forth their tubes. He found that neither the spot to which the pollen tube attaches itself, nor the direction which it afterwards takes, nor the rapidity of its growth, is in any way affected by gravitation, by light, or by contact with a solid substance (*Journ. Micr. Soc.*, June, p. 372–3).

In the *Mém. de la Soc. des Sc. Nat. de Cherbourg* (vol. xxiii., p. 209, pl. iv., 11), Dr. E. Janczewski gives an account of the development of sieve tubes from the cambium cells in certain dicotyledons, monocotyledons and acotyledons. In the first-mentioned class the tubes are, after once becoming passive, rapidly replaced by the activity of the cambium; but in monocotyledons the activity of the tubes lasts much longer, in fact, as long as the organ in which they are found. In vascular cryptogams the dots in the tubes always remain closed, not giving place to perforations as in mono- and dicotyledons.

The foxglove seems to have grown very luxuriantly this year. A writer in the *Garden* (p. 6), describes a plant which he saw in a garden at Hastings as 9 feet high and not then fully grown; the flowering portion of the spike being two-thirds of that length, the central spike branching out below this point into several minor ones. A Cornish correspondent at Penzance sends a local newspaper cutting to the effect that in the beautiful Trelowarren Woods, so well-known to all visitors to the Lizard, a foxglove was found which measured 10 feet in height.

At the Botanical Gardens in Regent's Park a plant of *Pilocarpus pennatifolius* flowered for the first time in the early part of this month, its pendent spike of purplish flowers measuring about $1\frac{1}{2}$ foot in length. The blossoms opened almost simultaneously and lasted only about three days, the petals soon falling off. The carpels in the young state appear to be erect and close together as in the star anise.

At Kew the sumbul plant has flowered again this year and is now forming fruit, all the stem-leaves having died down. The berries of the mezereon are now beginning to assume their beautiful scarlet hue. Even if gathered green and dried this colour is developed, showing that it is not dependent on light so much as on chemical change.

In the London drug market this month some of the false arnica, described last month, was offered for sale. Among other unusual drugs were aricine bark (*Cinchona pubescens*), in fine pieces, the flowers of *Artemisia judaica*, and the root of a species of *Camphorosma*, probably *C. acuta*, L., from the Persian Gulf. The *Artemisia* was examined a few months since by Merck, of Darmstadt, who obtained from it a fragrant volatile oil, and a bitter principle (glucoside). The *Camphorosma* is used as an excitant, diaphoretic and diuretic in asthma, rheumatism, and chronic skin diseases. Under the name of coto bark, a pale, aromatic, bitter, but not pungent, bark has been offered. It is probably the bark of a species of *Croton*, the flavour having a family likeness to that of cascarilla. Spurious saffron, of the kind described by Hanbury as being adulterated with carbonate of lime, is still extant in English commerce, two samples having recently been obtained in London.

CONTRIBUTION TO THE KNOWLEDGE OF THE ALKALOIDS OF PAPAVERACEÆ.*

BY PROFESSOR J. F. EYKMAN, OF TOKIO.

Concerning the alkaloids of the Papaveraceæ we have, at present, more or less extended researches on *Papaver somniferum* and *Rhœas*, *Chelidonium majus*, *Glaucium luteum*, *Sanguinaria canadensis* and *Eschscholtzia californica*. Probably the most study has been bestowed upon the alkaloids of opium (from *Papaver somniferum*) and we owe particularly to the grand labours of Hesse a knowledge of different series of homologues existing in opium, among which are at least fifteen well-defined alkaloids. The interesting labours of Wright, Beckett, etc., have considerably increased the number of these homologous series by the preparation of many derivatives, and have furnished many clues to a knowledge of the constitution of these bases.

Much less attention has been paid to the other papaveraceous plants, and the number of alkaloids which they contain is much smaller. Besides the poisonous sanguinarine (=chelerythrine), which is characterized by the orange-red colour of its salts, a second alkaloid yielding colourless salts has been met with in all these plants. Chelidonine was discovered by Godefroy in the root of *Chelidonium*; glaucopicrine in the root and glaucine in the leaves of *Glaucium luteum* by Probst; Riedel discovered in the root of *Sanguinaria* the alkaloid named by Gibb "porphyroxine," and Walz found in the *Eschscholtzia* a bitter and an acrid alkaloid. Wayne claims to have found a third alkaloid in sanguinaria root, which Gibb called puccine.

Of all these bases, only sanguinarine and chelidonine have been somewhat carefully studied; while the data respecting the others are insufficient to properly characterize them.

Since the number of alkaloids known to exist in opium has risen to at least fifteen, it may be suspected that it merely requires a further research to find, in the other papaveraceous plants, a still greater number of alkaloids belonging to homologous series. The great difficulty of separating the latter and obtaining them pure, and the fact that many supposed-opium alkaloids formerly accepted have in late years turned out to be mixtures of several others, lend great probability to this suspicion.

A more detailed study of these plants is desirable and very interesting also for another reason. Namely, it is a remarkable fact that, while one and the same alkaloid (sanguinarine) has been shown to exist in all the other papaveraceous plants, it does not appear to occur in *Papaver*, and none of the substances found in opium seems to be identical with any of those extracted from other members of the family.

Hence, while sanguinarine constitutes a chemical link between most of the Papaveraceæ, no such link seems to exist between these and *Papaver*. The name porphyroxine, which has been applied to two different substances, one prepared from sanguinaria and the other from opium, does not imply that these two bodies are identical; besides one of these has since been shown to be a mixture.

The analogies which may be traced between sanguinarine and some of the alkaloids of opium,* though not at present to be depended on, at least justify the supposition that a more exact study of the Papaveraceæ will show the alkaloids existing in them to be either identical or isomeric with those of opium, or to form new members of the homologous (or isologous) series.

The discovery of such alkaloids, identical or homologous with those of opium, would not only form an additional proof of the chemical relationship of *Papaver* with the other Papaveraceæ, but would also perhaps permit the employment of some of the latter for the preparation of alkaloids at present only obtainable from opium.

Following will be found the results of an investigation of *Macleya cordata*, a papaveraceous plant previously unstudied.

Macleya cordata, R. Br. (*Bocconia cordata*, Wild.), is a native of Japan and belongs to the same sub-tribe as *Sanguinaria*, namely, Bocconieæ. It is known in Japan as a poisonous plant and grows almost everywhere upon hills and mountains, in uncultivated spots.

The hollow stem of the (perennial) herb grows to a height of more than 1 metre, the leaves are up to 30 cm. (11¾ inches) long. On puncturing the stem, veins of leaves or fruit, an orange-yellow milky juice exudes. The small flowers are arranged in a large panicle and consist of two white sepals, many hypogynous stamens and an ovary which grows to a lancet-shaped fruit of 2 cm. in length and 1½ cm. in thickness. The seeds are small and have a red colour. The root is about 5 cm. thick and on cross-section is seen to have a red colour near the periphery. It flowers in July.

The Japanese names of the plant are numerous, varying in the different provinces. The most common are: *takenikusa*,† *tsiampangiku* and *tachiobaku*.

An assay of the root and leaves with Mayer's solution showed that they contained about the same quantity of alkaloid (0·5–0·1 per cent.) as *Chelidonium majus*. Calculated for dry substance, the fruit appeared to contain the largest quantity of sanguinarine, the root much less and the leaves the least quantity. The other alkaloid (forming a double iodide soluble in alcohol) exists in root and leaves about in equal proportion, and is less in the fruit.

The root, of which larger quantities could be obtained, was further examined. Sanguinarine was extracted in the usual manner. The root having been exhausted with dilute sulphuric acid and alcohol, the percolate was deprived of alcohol by distillation, then supersaturated with ammonia, the precipitate—which had a dirty violet-red colour, the same as the liquid portion—filtered off after a few days, and, after drying, extracted with ether until the latter no longer acquired a yellow colour.

Gaseous hydrochloric acid was conducted through the clear ethereal solution, whereby a scarlet precipitate was produced which was washed with ether and was freed, by treatment with a little water, from an almost white sub-

* Condensed from the pamphlet: 'Beitrag zur Kenntniss der Papaveraceen-Alkaloide.' Von J. F. Eykman, Tokio. 8vo. Yokohama, 1881. Reprinted from *New Remedies*, June, 1882.

* These analyses are stated in detail by the author; but cannot be reproduced here for want of space.

† The plant is used in Japan for dyeing; *take*=bamboo; hence the name *take-ni-kusa*="bamboo-boiling-herb."

stance which remained undissolved. The orange-red solution was again mixed with ammonia, the grey-violet precipitate extracted with ether, and gaseous HCl again conducted through the liquid. These operations were repeated several times more, and finally the ethereal solutions were decolorized by animal chaacoal. In this manner a dark scarlet powder was obtained, easily soluble in water, and generally exhibiting the reactions of hydrochlorate of sanguinarinc.

Mixed with a little water it melted, on the water-bath, to a dark-red syrupy liquid, which, after cooling, congealed to a crystalline mass. The dark orange-red aqueous solution yielded more or less yellow to orange coloured precipitates with most metallic salts. Ferric chloride, cupric sulphate and lead acetate, however, produced no precipitate. Tannic acid, with agitation, produced a precipitate which gradually increased, particularly on addition of hydrochloric acid.

The ethereal solutions, from which the hydrochlorate of sanguinarine had been separated by hydrochloric acid gas, were freed from ether by distillation and the residue was treated with water. This left behind a brown resin (sanguinarin-resinoid?). From the filtrate the alkaloid was precipitated with ammonia, and, after drying, extracted with ether. The portion insoluble in ether was rubbed with hydrochloric acid, and the portion still remaining insoluble, together with the residue left in previous purifications of the hydrochlorate of sanguinarine, further purified by recrystallization from water. It could not, however, be obtained in a pure state, by this method, since the solutions always assumed an intense orange colour on evaporation. The aqueous solution of this substance, which turned out to be the hydrochlorate of an alkaloid, was therefore treated with ammonia, the precipitate (in order to remove any still adhering sanguinarine) first extracted with ether and the insoluble portion afterwards boiled for some time with absolute alcohol. This removed a large proportion of the colouring matter and left most of the alkaloid behind. The latter was then again converted into the hydrochlorate by trituration with hydrochloric acid, and recrystallized from alcohol. The purest portion of the separated crystals was dissolved in boiling water, the alkaloid precipitated by ammonia, dissolved in boiling alcohol, and precipitated by addition of ether. This treatment was continued until colourless, though small, crystals were obtained. They melted at 201° C. (uncorrected) and had the properties below mentioned.

The original greyish-black powder produced by precipitating the extracts from the root with ammonia, and which had been exhausted with ether until the latter no longer acquired a yellow tint, was percolated with alcohol. The dark-brown percolate was freed from alcohol by distillation, the residue treated with acetic acid to faintly acid reaction, and then mixed with water until nothing further was separated. The filtrate was mixed with excess of solution of iodide of potassium, the voluminous precipitate (which soon shrivelled up) filtered off and washed with water. This washing produced a white precipitate in the filtrate which was separated by a new filtration. Each of these substances, viz.: the last precipitate (*A*), the brown-coloured filtrate (*B*) and the hydriodate remaining on the original filter, was separately examined. The latter was first recrystallized from water, whereby a still purer hydriodate (*D*) and a fresh mother-liquor (*C*) were obtained.

A. The white precipitate produced in the filtrate by the washings was dissolved in boiling water, the solution treated with ammonia and then shaken with ether. The separated ethereal solution, on evaporation, left an almost white residue, from which ether readily separated a soluble body. The portion remaining insoluble in ether became partially soft and assumed a red colour at 180° C. and was melted completely at 198° C.

B. The filtrate after removal of *A* was treated with ammonia, the precipitate separated from the liquid, dissolved to neutralization in acetic acid, and separated from a substance thereby remaining insoluble. The alkaloid was further purified by recrystallizing its oxalate from water and, after having again separated the alkaloid, recrystallizing it from chloroform. In this way large crystals were obtained, melting at 200·5° C. (uncorr.).

C. The mother-liquor of the recrystallized hydriodate. The base having been separated from it by excess of soda, it was filtered off, dissolved in boiling alcohol and crystallized by spontaneous evaporation. After purification and recrystallization from chloroform, the alkaloid had the melting point 201° C. (uncorr.).

D. The once recrystallized hydrochlorate was covered with solution of soda, set aside for one day, then the crystalline alkaloid (*P*) filtered off and washed. After complete purification, this was chiefly used in the further investigation of the properties, etc., of the alkaloid.

The alkaloid (*P*) separated from the hydriodate was boiled with strong alcohol to separate it from the accompanying brown substance; but the attempt was only partially successful. The alcohol was then poured off and chloroform added to the still moist crystalline mass.

As soon as the alkaloid had dissolved in the chloroform, two layers were formed, the upper (alcoholic) being quite dark and black, the lower (chloroformic) having only a light-brown tint and containing the alkaloid in solution. The lower layer was separated, and, after the chloroform had been distilled off, the residuary alkaloid converted into the acid oxalate which is readily soluble in hot water. From the solution the base was precipitated by soda and then boiled with absolute alcohol. The white portion remaining insoluble therein was dissolved in a little chloroform, precipitated by addition of ether and finally again recrystallized from chloroform.

In this way about 5 gm. of quite large, colourless, well-developed and transparent crystals were obtained. At every fractional crystallization the melting point was 200·5° to 201° C., which appears to be a satisfactory proof that the alkaloid (*macleyine*) is a pure and simple body.

Properties of the Alkaloid: *Macleyine* is almost insoluble in water and alkalies. On adding ammonia to an aqueous solution of the salt, and filtering, the filtrate separates, after a while, wart-like crystals. It is scarcely soluble in cold, a little more soluble in boiling alcohol; also very little soluble in ether, except when freshly precipitated: very little in cold benzol, more so in boiling. Chloroform, especially when warm, dissolves it tolerably well. Macleyine has no pronounced taste, but its salts have a bitter, afterwards sharp and cooling taste.

When crystallized from chloroform or ether, or precipitated by alkalies and dried by exposure to air between blotting paper, the alkaloid is obtained anhydrous. Analysis led to the formula $C_{20}H_{19}NO_5$. Macleyine exhibits a number of interesting reactions, which are detailed at length in the author's paper, but which we will have to omit for the present, for want of space. It was owing to these very reactions, however, and to the general properties of the alkaloid that the author was led to suspect its identity with one of the opium alkaloids, namely, *protopine*, the rarest of the series. Concerning protopine the author had to follow Hesse, who alone had prepared and described the substance. The agreement of the observed properties of macleyine with those described by Hesse for protopine covered the characteristic globular or warty form of the substances when separating from ether, their solubility in different menstrua, their ultimate composition, the composition of their platinum salts, and other properties of the salts. In other respects the agreement is nearly as close as in the former, though the slight differences may be owing to accidental circumstances. The author does not claim that the identity is proven, but thinks it has been rendered highly probable.

PHARMACEUTICAL NOTES.*

BY R. F. FAIRTHORNE, PH.G.

Manna as an Excipient for Pills.—Certain substances are with difficulty made into pills that will retain the spherical form. Amongst others may be named reduced iron, subnitrate and subcarbonate of bismuth, oxalate of cerium, calomel, bicarbonate of sodium, tannin, extract of logwood, Dover's powder, acetate of lead, sulphate of zinc, chlorate of potassium, phosphate of iron, ammonio-ferric alum, lactate of iron, citrate of iron and ammonium, aloes, and sulphite of sodium. After these have been made up into pills with any of the ordinary excipients of a soluble character, they almost always flatten and often unite together in a mass that is both unsightly and the cause of much inconvenience. This difficulty can be overcome by using manna and syrup in variable proportions, according to the substance operated on. The quantity of manna required is from 25 to 33 per cent. of weight of the article to be made into pills. Thus, if 100 grains of reduced iron are to be made into fifty pills, 25 grains of manna will be required, together with sufficient syrup to make a mass. The quantity of the syrup must be carefully adjusted, so as not to have more than enough to produce a mass of the proper piluiar consistence. When this precaution is taken, no difficulty will be experienced in making pills which will retain their proper form. Manna possesses certain advantages over other excipients that render it of value in the instances named; one is its hardness and another its solubility. It is certainly preferable to powdered tragacanth or rice flour, which are frequently used to give consistence to the pilular mass. I would suggest the use of manna in making Vallet's mass, substituting it for both sugar and honey. The mass would be more easily handled and firmer than that as usually met with.

When manna is used in making pills with the substances named it is best to place it in the mortar first and soften it with a few drops of syrup, and add the medicinal ingredients to it.

Elixir of Blackberry.—As summer approaches, preparations of an astringent character are frequently called for, and as many of them are unpleasant to take, I offer the following receipt as one that possesses the former quality without the disadvantage of the latter:—

Take of

Fluid extract of blackberry		f℥ivss.
Syrup of blackberry fruit		f℥xv.
Jamaica spirit		f℥xij.
Curaçoa cordial,		
Cinnamon water	each	f℥iv.
Syrup of orange peel		f℥iij.
Oil of cloves,		
Oil of allspice	each	12 drops.

Mix the essential oils with the fluid extract of blackberry, add the Jamaica rum, and afterwards the other ingredients.

Elixir of Logwood is another preparation of a similar character:—

Take of

Extract of logwood		10 dr., 2 scr.
Brandy		12 fluid ounces
Curaçoa		6 fluid ounces
Syrup		6 fluid ounces
Oil of nutmeg,		
Oil of cinnamon	each	4 drops.

Warm water sufficient to make 2 pints.

Dissolve the extract in the water, add the other ingredients, and, when cool, filter.

Glycerol of Myrrh and Borax.—This preparation commends itself for many purposes, and will be found especially serviceable as an addition to gargles and tooth-washes and as an application to sore nipples. It is made by the annexed formula:

Take of

Myrrh (in coarse powder)		1 ounce.
Powdered borax		1½ ounce.
Glycerin,		
Water	each	3 fluid ounces.

Mix the borax and myrrh together, add the other ingredients, and boil in a flask for ten minutes; strain through muslin, and add enough water to make the mixture 6 fluid ounces; when cold, filter through cotton or paper.

Solution of a considerable amount of the myrrh is effected by the borax, and the addition of glycerin enables a larger quantity of the borate of sodium to be dissolved than in water alone, producing a solution that is miscible with water without precipitation taking place.

This makes an elegant *lotion* for application to the gums, or as a *mouth-wash* when diluted with decoction of quillaia bark and flavoured with oil of rose or other essential oil.

The following is a very satisfactory formula:—

Take of

Glycerol of myrrh and borax	f℥ij.
Decoction of quillaia (2 ozs. to Oj)	f℥iv.
Oil of rose	4 drops.
Oil of cloves	6 drops.
Oil of orange peel	6 drops.

Mix and filter.

A Good Black Ink can be made with the following ingredients:—

℞ Galls (in moderately fine powder)	2 pounds avd.
Copperas	10½ ounces.
Gum arabic	10 ounces.
Sugar	½ ounce.

Water sufficient to make 18 pints.

Place the galls in an enamelled vessel, pour on it 6 pints boiling water, and allow it to macerate two days; transfer to a glass percolator, in the neck of which is a piece of absorbent cotton, through which allow the liquid portion to drain. When this is accomplished, pack the galls firmly and displace with sufficient water to produce two gallons with that portion of the infusion which first passed. Then dissolve the gum and sugar in 2 pints of water; add this and the copperas to the infusion of galls. This, after standing about twelve days, will produce a very superior ink. About 8 drops of wood creasote should be added to prevent moulding

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from page* 70.)

POTASSII SULPHOVINAS (*Sulphovinate of Potassium*). [Æthylsulphate of potassium. Kali sulphovinicum. Sulphas æthylico-kalicus.]

Sulphuric acid	1
Absolute alcohol	1
Distilled water	4
Carbonate of barium	q.s.
Carbonate of potassium	q.s.

Mix the sulphuric acid and absolute alcohol gradually, and taking care that the temperature does not rise above 50° C. (122° F.). Let the mixture stand for four days at a temperature of 20°–25° C. (68°–77° F.), then dilute it with the distilled water, and add to it a sufficient quantity of carbonate of barium to render the mixture neutral. Filter the liquid, and add to it, under the application of a very gentle heat, enough carbonate of potassium to render the reaction faintly alkaline. Filter the liquid from the precipitated carbonate of barium, and evaporate the filtrate, at a temperature not exceeding 80° C. (176° F.) to the point of crystallization.

* From *New Remedies*, April, 1882.

Clear crystals, easily soluble in water, deliquescent on exposure to air, decomposing at 120° C. into alcohol and acid sulphate of potassium, and yielding acetic ether when heated with anhydrous acetate of potassium.

The aqueous solution of the salt should not be rendered turbid by sulphuric acid, and should be rendered not more than faintly opalescent by solution of barium chloride.

CUPRI SULPHAS IN BACILLIS (*Sulphate of Copper in Sticks*).

Heat crystallized sulphate of copper until it has become completely anhydrous, and rub the dry salt to a fine powder. Press or ram the powder into small cylindrical moulds made of filtering paper, about 8 cm. (3¼ inches) long, and 7 mm. (about ¼ inch) in diameter, and after having closed them, put them for one or two days in a damp place. Finally remove the casing of filtering paper.

FERRI TERSULPHAS (*Tersulphate of Iron*) (*dry*).
[Ferric Sulphate.]

Sulphate of iron (ferrous)	256
Distilled water	256
Sulphuric acid	47
Nitric acid . . . . sufficient, or about	67

Dissolve the sulphate of iron in the distilled water, heat the solution, and add to it the sulphuric acid. Then gradually drop into it nitric acid as long as nitrous vapours are given off [or until a drop of the liquid, diluted with water, ceases to give a blue precipitate with ferricyanide of potassium].

Evaporate the clear solution on a water-bath to dryness.

The product is a white powder difficultly soluble in water.

SYRUPUS FERRI BROMIDI (*Syrup of Bromide of Iron*).

Iron, in powder	1
Bromine	2
Sugar	15
Distilled water	q.s.

Put the iron into a flask, pour upon it 10 parts of distilled water, and add to it the bromine in small quantities at a time, and under constant agitation. Filter the light-green liquid into a flask containing the sugar, and wash the filter with sufficient distilled water to make the contents of the flask weigh 27 parts. Finally dissolve the sugar by agitation, and preserve it in small well-closed vials.

The syrup has a light-green colour, and contains 10 per cent. of ferrous bromide.

SYRUPUS CODEINÆ (*Syrup of Codeine*).

Codeine	1
Alcohol	5
Syrup	494
	500

Dissolve the codeine in the alcohol and add the syrup.

SYRUPUS DEPURATIVUS (Larrey) (*Larrey's "Purifying Syrup"*).

Sarsaparilla, cut and bruised	200
Guaiac wood, rasped	50
China root (*Smilax China*), in coarse powder	5
Sassafras, rasped	5
Senna	6
Borage (*Borago officinalis*)	6
Elder juice (inspissated)	40
Molasses	500
Sugar	500
Water	q. s.

Boil the sarsaparilla, guaiac wood, and China root for half an hour with enough water so that 720 parts of liquid may be separated from the dregs. Add to this liquid the sassafras, senna, and borage; let it macerate for half an hour, and strain. Then mix the strained liquid, which should amount to 700 parts, with the other ingredients.

SYRUPUS EUCALYPTI (*Syrup of Eucalyptus*).

Eucalyptus leaves	5
Sugar	20
Water	q.s.

Pour 50 parts of boiling water upon the eucalyptus, let it macerate for one hour, then strain and express.

For every 12 parts of liquid so obtained, add 20 parts of sugar, and dissolve.

SYRUPUS FUCI VESICULOSI (*Syrup of Seawrack*).

Extract of seawrack	1
Water	1
Syrup	7

Dissolve the extract in the water and add the syrup.

The extract is prepared as follows:—

EXTRACTUM FUCI VESICULOSI (*Extract of Seawrack*).

Seawrack, dried and in coarse powder	1
Alcohol (stronger)	3
Water	q.s.

Macerate the seawrack with 2 parts of alcohol and 3 parts of water during three days, occasionally agitating. Express and treat the residue again, during one day, in the same manner, with 1 part of alcohol and 2 parts of water. Again express, unite and filter the liquids and evaporate them, on a water-bath, to a dry extract.

Preserve it in a well-stopped bottle.

EXTRACTUM FULIGINIS (*Extract of Soot*).

Soot, obtained by the burning of wood or peat	1
Boiling water	2
Alcohol	2

Mix the soot with the boiling water, let it stand for one day, occasionally stirring, express, and filter the liquid. Treat the residue in the same manner with the alcohol. Unite the liquids and evaporate them, on the water-bath, to a dry extract.

SYRUPUS CHLORAL[I] (*Syrup of Chloral*).

Chloral hydrate	16
Distilled water	24
Syrup	200
Oil of curled mint	0·1

Dissolve the chloral in the distilled water, add the solution to the syrup, and finally add the oil.

[If the parts are taken in *grams*, 1 *drop* of the oil is sufficient. Oil of peppermint will answer equally well.]

SYRUPUS FERRI HYPOPHOSPHITIS (*Syrup of Hypophosphite of Iron*).
(Syrup of Ferrous Hypophosphite.]

Hypophosphite of calcium	30
Sulphate of iron (ferrous)	47
Sugar	600
Distilled water	q.s.

Dissolve the hypophosphite in 300 parts of distilled water and the sulphate of iron in 100 parts of distilled water. Mix the two solutions, let the mixture stand for one hour, occasionally stirring, then filter.

To every 370 parts of the filtrate add 600 parts of sugar and dissolve.

Keep the syrup in a cool place.

SYRUPUS CALCII IODIDI (*Syrup of Iodide of Calcium*).

Lime	5
Iodine	2
Sugar	200
Water	q.s.

Triturate the lime to a fine powder with the sugar and gradually add 100 parts of water. Let the mixture stand for several hours, occasionally stirring, then filter.

To the filtered liquid add the iodine, and when this is dissolved, 170 parts of sugar. Dissolve the latter without heat.

The syrup is clear and colourless and should be preserved in a well-stoppered bottle.

SYRUPUS JUGLANDIS (*Syrup of Butternut Leaves*).

Extract of butternut leaves	1
Syrup	60

Dissolve the extract in the syrup.

(To be continued.)

CHEMISTRY IN RELATION TO THE INDUSTRIAL ARTS.

IN almost every department of science the work that has been done by natives of Great Britain will bear comparison with that which has been done elsewhere, and though science itself is of no particular country, it is from a national point of view satisfactory to reflect that the names of some of our countrymen rank among the foremost of those who are historically celebrated for discoveries and for researches by which our knowledge of nature has been extended. But while there is on this score reason for congratulation, there is also a very important circumstance of difference between this country and many others in regard to science wherein we compare very unfavourably with them. It has been too much the habit to look upon science as having to do with something that is, if not unreal, at least outside the range of ordinary practical experience; science has been cultivated too much from an abstract point of view and without sufficient general recognition of the fact that it is of direct practical concern in every-day operations, inasmuch as its subject matter is the same as that with which all such operations have to do. Especially has this been the case with chemistry, which has been commonly looked upon as a species of parlour magic, suited for the entertainment of *dilettanti* rather than as the light by which industrial art is to be guided in order to ensure success and improvement. With that love of a formula which characterizes the Britisher as much as his love of a lord, it has been customary to act upon the assumption that science has little or nothing to do with the practical operations by which various materials are made to yield products necessary for our daily wants, or with the conduct of industrial processes by which some of those materials are adapted for useful purposes. This erroneous belief in the absence of any useful relation between science and practice is, however, dying out, and though we have not yet advanced so far as our continental neighbours in making science of advantage by combining it with practice, it is at least satisfactory to observe that some progress is being made in this direction.

One of the most recent illustrations of this progress is afforded by the formation of a Society of Chemical Industry, the main object of which is to promote that attention to chemical science which is indispensable for the successful conduct of the various branches of industry that are dependent upon the utilization of chemical action. For this purpose it is proposed to associate together persons interested in such industries or possessing a knowledge of the chemical principles concerned with them, so as to afford opportunity for the interchange of ideas and information by which important branches of national industry might be improved. This Society has now been in existence but little more than a year, and the number of its members has been increased to 1250, including representatives of manufacturing firms all over the country. Its first annual meeting has just been held at Manchester and the President, Professor ROSCOE, opened the proceedings by delivering an address in which he referred to the rapid increase in the number of members as furnishing a proof that the establishment of such a society was necessary. On the support thus afforded it has been possible to undertake the publication of a journal, of which several numbers have appeared already. It is intended to make this journal a complete epitome of the progress of chemical industries throughout the world by giving accounts of the newest discoveries and patented inventions in various branches of applied chemistry and to uphold the principle that in manufacturing operations a healthy practice can only exist when based on a sound knowledge of theory.

It is with much pleasure that we refer to this bold and uncompromising attack upon the position of the "practical men" who have been in the habit of repudiating any dependence upon theory, and we trust that it may prove the first step towards the recognition of the principle that manufacturers must be educated up to the level of the science of the day—able to understand and apply the discoveries of the purely scientific chemist, which constitute the foundation of their trade. The illustration given by Professor ROSCOE of the beneficial effects resulting from the adoption of the principle in the case of the German and Swiss colour makers is a very striking one, for it shows that even local advantages and the possession of abundant sources of raw material fail to be of practical account when industrial operations are managed, as they unfortunately have been to great extent hitherto in this country, by persons ignorant of the scientific principles involved in them. It is in consequence of this difference between our relation to science as an industrial agent and that obtaining on the Continent that we lose the profit of an industry producing annually upwards of three millions sterling, which, on account of our production of greater part of the raw material required should properly be ours. Unless this difference be done away with by timely attention to the necessities of the case, and by the establishment of schools suitable for the highest and most complete scientific training of intending manufacturers, the consequences of the deficiency on our part will infallibly make itself felt in other branches of industry to our disadvantage.

THE REGULATION OF PHARMACY IN NEW ZEALAND.

A meeting of the Pharmacy Board of New Zealand was held last month at Christchurch, at which the President, Mr. Barraud, of Wellington, stated that up to the present time there had been 234 chemists and druggists registered under the Pharmacy Act of New Zealand, a draft of which was published in the Journal for 13th November, 1880. It was also mentioned that the Board proposed to hold examinations simultaneously at Auckland, Wellington, Christchurch and Dunedin, the first of which were to take place in the first week of this month. As soon as these examinations were established it was intended to institute proceedings against all unregistered chemists carrying on business. According to a resolution of the Board it was determined that the Modified examination of the British Pharmaceutical Society should be adopted for the present standard, but that a higher standard, the syllabus of which was arranged, should come into operation wholly or in part in January, 1884. It was agreed to communicate with the Pharmacy Board of Victoria, New South Wales, Queensland and Tasmania, with a view to ascertain the standard of efficiency necessary to ensure mutual recognition of certificates. A series of text books for the use of students in pharmacy was approved, and it was ordered that the conspectus of education required by the Board should be printed and circulated through the local Registrars and that every facility should be given for placing pharmaceutical education on an efficient and permanent footing.

A copy of the regulations for the examination of candidates for registration as pharmaceutical chemists has been forwarded to us by Mr. J. A. Allan, the Secretary and Registrar, according to which the Modified examination is to include Prescriptions, Practical Dispensing, Materia Medica, Quality of Specimens, Pharmacy, and Chemistry of the Pharmacopœia.

Division I.—Prescriptions.—The candidate must be able to read autograph prescriptions, translate them into English, render a correct translation of the directions for use, and detect unusual doses.

Practical Dispensing.—The candidate must be able to weigh, measure, compound medicines, write the directions neatly in suitable language, and to finish and direct each package properly.

Division II.—Materia Medica.—The candidate must be able to recognize the Pharmacopœia chemicals in frequent demand, and specimens of roots, barks, leaves, fruits, resins, and gums in ordinary use; the following plants, either in a fresh or dried state, or from plates:—Belladonna, stramonium, hyoscyamus, conium, aconitum, digitalis, and sabina; also, to correctly estimate the quality of each specimen submitted.

Division III.—Pharmacy.—Every candidate must be able to recognize the preparations of the Pharmacopœia which are not of a definite chemical nature, such as extracts, tinctures, and powders, and give the proportion of the more active ingredients.

The proposed syllabus of study for examination before examiners appointed by the Pharmacy Board coming into existence in January, 1884, comprises, in addition to what is above specified as to prescriptions and practical dispensing, under the head of pharmacy, a practical knowledge of the processes, and the principles of the processes, by which the preparations of the Pharmacopœia are made, and of the best excipients and methods of manipulation for forming emulsions, pills, etc.; under materia medica the recognition of specimens of roots, barks, leaves, fruits, resins, gums, animal substances, etc., used in medicine, the botanical and zoological names of the plants, etc., yielding them, and the natural families to which they belong, the countries and sources from which they are obtained, and the official preparations into which they enter, judging the quality and freedom from adulteration or otherwise of the specimens, and describing the methods of obtaining their active proximate constituents in a separate state.

Botany is to comprise an acquaintance with the parts of the flower, fruit and seed. The candidate must be able to distinguish practically between each of the following natural orders:—Ranunculaceæ, papaveraceæ, malvaceæ, leguminosæ, rosaceæ, cucurbitaceæ, umbelliferæ, compositæ, gentianaceæ, convolvulaceæ, solanaceæ, atropaceæ, polygonaceæ, orchidaceæ, iridaceæ, liliaceæ, graminaceæ, and refer to their respective orders such specimens as may be shown to him.

Chemistry is to comprehend a practical knowledge of the nature and properties of the elements and their compounds, especially those used in medicine or the arts. The different combinations and decompositions must be explained by equations; also the qualitative analysis of the more important chemicals, *e.g.*, nitrates, chlorides, carbonates, sulphates, phosphates, oxalates, tartrates, etc., and the detection of impurities in them, and the volumetric estimation of the strength of all Pharmacopœia preparations in which standard solutions are ordered to be used.

We may therefore infer that the provisions of the New Zealand Pharmacy Act are being carried out, so far as circumstances admit, and the resolutions adopted by the Board afford some guarantee that the future pharmacist of that colony shall possess at all events a good education and be thoroughly efficient in his business.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July 12, 13, 14, 19, 20 and 21, 1882.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

Dr. Greenhow attended on the 13th, 14th and 19th, on behalf of the Privy Council.

July 12.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The undermentioned *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Caldecott, Clement Guest .. ...Whitchurch.
Dowdeswell, Jonathan............Tiverton.
Holmes, Francis ....Lutterworth.

MINOR EXAMINATION.

Twenty candidates were examined. *Fifteen* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Allen, Samuel ....Worcester.
Bowering, John ....Taunton.
Cave, Herbert William ....Wisbeach.
Evans, John Robert...............Carnarvon.
Nichol, Anthony ....Carlisle.

MODIFIED EXAMINATION.

One candidate was examined, but failed to pass.

July 13.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The undermentioned *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists :—

Bain, John...........................Bridge of Allan.
Drew, Walter Clark...............London.
Yeatman, Frederick James......London.

MINOR EXAMINATION.

Twenty candidates were examined. *Fourteen* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Comer, Ernest Edward ....East Dereham.
Cullwick, Herbert Ernest ......Knighton.
Daniel, George ....Holsworthy.
Dillon, Charles Linder............Hereford.
Eley, Herbert ....Derby.
Foggitt, John Blackett ....Thirsk.

July 14.

MINOR EXAMINATION.

Twenty-six candidates were examined. *Thirteen* failed. The undermentioned *thirteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Evans, William.....................Cardigan.
Frost, John Henry ....London.
Gaskin, John Henry...............Wolverhampton.
Greenall, Thomas Holdsworth...Ashton.
Hall, Amos ....Stafford.
Hankinson, George Robert......Grange-over-Sands.
Hanson, Christopher ....Buckhurst Hill.
Harston, Charles Edward ......Lincoln.
Hewlett, Thomas Charles ......Bedford.
Hickson, Robert William ......Hull.
Hodgson, Thomas Samuel ......Manchester.
Hornby, William Thomas ......Stockport.
Innes, David..........................Stalybridge.

July 19.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Murray, George ....Coldstream.
Wheatley, Joseph..................Huddersfield.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Thirteen* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Loam, James Gilbert ....Liverpool.
Longtoft, William ....Bedale.
Mann, Joseph ....Peterborough.
Meadows, John Martin ....Swindon.
Miller, Wm. Philip Faulkner...Folkestone.
Mitten, Flora ....Hurstpierpoint.
Noble, Henry Edward............Peterborough.
Thomas, Joseph Arden .... Cambridge.

July 20.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Eleven* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Norburn, Albert Edward ......London.
Northen, Charles ....Thorpe-by-Water.
Parker, Thomas Herbert ......Bedford.
Pearson, William ....Sinderland Green.
Pellew, Albert ....Woodbridge.
Pickering, Wade ....Crowle.
Pinder, Robert.......................Bourne.
Ransom, Francis ....Hitchin.
Rodmell, John Gale................Rochester.
Rowland, Thomas William......Epping.
Sergent, William Thomas ......Croydon.

July 21.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Eleven* failed. The undermentioned *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Shapcott, William Henry Pyne..London.
Thisleton, Hugh ....Preston.
Thomas, William Hendy ......Penryn.
Townsend, Henry Holden ......London.
Tyson, Thomas Balmforth ......London.
Warburton, Edward ....Farnworth.
Waymouth, Thomas Staddon...Exeter.
Weddle, William ....Gateshead.
Wellburn, John Samuel ....Scarborough.
Wells, William George ....Maidstone.
Wheeley, John Thomas Martin.London.
Williams, William Jesse ....Crickhowell.
Wood, John Ridal ....Rotherham.
Worts, Harry Augustine.........Harwich.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Dennis, Frederick Woodrow ...Louth.
Gratton, George Edwin ....Conway.

Certificate of the University of Aberdeen.

Kettle, George James ....Aberdeen.

Certificate of the University of Cambridge.

Atterbury, Clive ....Burton-on-Trent.

EXAMINATIONS IN EDINBURGH.

July 20 *and* 21, 1882.

Present—Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kinninmont, Nesbit and Stephenson.

Professor Maclagan attended on the 20th on behalf of the Privy Council.

July 20.

MAJOR EXAMINATION.

Two candidates were examined. *One* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Kinross, William Malloch ......Edinburgh.

MINOR EXAMINATION.

Thirteen candidates were examined. *One* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Adamson, William Stewart ...Edinburgh.
Bell, Charles Russel..............London.
Bell, John Henry....................Epworth.
Berry, Andrew Wales.............Aberdeen.
Bostock, Samuel Pass ....Hyde.
Dugan, Alexander Ferrier ....Aberdeen.
Gatward, Oswald ....Hitchin.
Haddon, John ....Birmingham.
Hogg, Henry Scott ....Glasgow.
Jackson, William Moses..........Ayr.
Jamieson, Simpson ....St. Andrews.
Jones, John Wesley.................Llanelly.

July 21.

MINOR EXAMINATION.

Fourteen candidates were examined. *Seven* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Mackay, William...................Edinburgh.
McRither, Alexander Buchan...Dundee.
Miller, George ....Arbroath.
Schofield, John William ....Morpeth.
Skirving, Alexander................Glasgow.
Sutherland, Adam Gordon ....Edinburgh.
Sutherland, John William ....Edinburgh.

MODIFIED EXAMINATION.

The undermentioned was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Gill, Richard Turton ....Pocklington.

Pharmaceutical Society of Ireland.

SPECIAL MEETING OF THE COUNCIL.

Thursday, July 20, 1882.

Present.—Professor Tichborne, President; Dr. Aquilla Smith, Vice-President; Sir George B. Owens, M.D., Drs. Collins, Montgomery, and Whitaker (Belfast); Messrs. Allen, Brunker, Grindley, Hayes, Payne (Belfast), Pring (Belfast), Simpson.

A letter was read from William Whitla, M.D., of Belfast, resigning his seat on the Council.

The President stated that Dr. Whitla was a candidate for the Examinership in Pharmacy, which was his reason for ceasing to be a member of the Council.

Dr. Whitla's resignation was accepted, on the motion of Dr. Collins, seconded by Mr. Payne.

Mr. William F. Wells, jun., of 20, Upper Baggott Street, Dublin, was proposed by Mr. Pring, and seconded by Mr. Hayes, to fill the vacancy.

Mr. William Harrington, of Cork, was proposed by Sir George Owens, and seconded by Dr. Collins.

A division resulted in the election of Mr. Wells.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

The first annual meeting of the Society of Chemical Industry was opened on Wednesday, July 5, at Owens College. The members assembled in the Chemical Theatre, and the chair was taken by Professor Roscoe, President of the Society.

There was a large attendance of members

The President's Address.

The President, after welcoming the members to Manchester, said: "On June 28 of last year, at the first meeting, in London, the number of members on the Society's books was 297; I am now able to announce that the number on the rolls is 1250, consisting of gentlemen connected with the most widely different departments of industrial chemistry resident throughout the United Kingdom, and including many distinguished names of English and continental scientific chemists. I have to congratulate the Society on the unprecedentedly rapid and most satisfactory progress it has made, sufficiently proving—if any proof were required—the truth of the opinion which I expressed last year of the necessity for the establishment of a society of the kind, which should include all those interested or possessing knowledge concerning the utilization of chemical action on a large scale, and having charge of, or connected with, those branches of industry dependent on chemical principles. During last autumn two sections of the Society have been founded—one a metropolitan section, under the chairmanship of Professor Abel, C.B., F.R.S., and the other established under the direction of Mr. Edmund K. Muspratt. A variety of papers on subjects interesting both from a manufacturing and theoretical point of view were read at those sectional meetings by various members of the Society, and discussions which have proved of practical utility have taken place. The Council of the Society also appointed last year a Committee on the Patent Laws. This Committee has held several meetings, and has taken active steps in view of the approaching legislation on this important question. The Committee wil lay a separate report of its action before the Society. The feature, however, of the greatest importance in connection with the Society is the adoption of the suggestion made by the Council at the first general meeting respecting the publication of a journal. The first number of it appeared in January of the present year. The Publication Committee appointed by the Council to superintend the issue of the journal was fortunate in securing the services of Mr. Watson Smith, of Owens College, to act as editor, and were able to arrange for printing and publishing by Mr. Emmott, of Manchester. The results have proved highly satisfactory, the journal supplying a want which has long been felt in English chemical industries. The Publication Committee have endeavoured to secure not only satisfactory reports of the papers which have been read and the discussions which have taken place at the sectional meetings, but have striven to make the journal a complete epitome of the progress of chemical industries throughout the world. For this purpose they have engaged a number of qualified abstractors, to whom they are indebted for the able accounts of the newest discoveries and patented inventions in the various branches of applied chemistry. It is the intention of the Publication Committee to spare no pains to make the journal of the Society the most complete and reliable one of its kind in existence. Above all the Committee has determined to uphold and retain the scientific status of the journal, convinced that a healthy practice can only exist when based on a sound knowledge of theory. In this respect the *Journal of the Society of Chemical Industry* will differ from many so-called technical journals, inasmuch as we shall have frequently to treat of the highest and most complicated problems of chemical science, just because it is these which serve as the starting point for some of the most important industrial applications. Thus conducted, I think our journal cannot fail to exert a beneficial influence on many branches of English chemical industry which have unfortunately hitherto been managed to a great extent by persons ignorant of the scientific principles involved in the processes which they carry on. In my address last year I drew attention to the fact that although the greater part of the raw material used in the manufacture of the coal-tar colours is produced in this country, we imported from Germany and Switzerland by far the largest quantity of the manufactured colours, and thus we lose the profit of an industry of the value of above three millions sterling, which should properly be ours. Many reasons no doubt have contributed to this result. Patent laws may act injuriously upon our inventors, and other grounds may be assigned, but in my opinion the chief superiority which the German and Swiss undoubtedly possess over the English colour makers is to be sought in the thorough appreciation on the part of the foreigners of the value of, and necessity for, scientific training and knowledge of the highest type in the conduct of their business. The German and Swiss colour maker is not content to manufacture a series of well-known products; he must constantly bring out novelties, and for this purpose he and his chemist must be educated up to the level of the science of the day. He must be able to understand and apply the discoveries of the purely scientific chemist, for these form the foundation of their trade. The necessity for this was long ago proclaimed by Liebig, who said, 'It has taken a long time to convince technical men of the fact that they are bound to acquire for themselves the highest possible scientific education if they wish properly to understand their processes, and if they desire to start new manufactures and to meet the ever-increasing demand for novelties.' I have recently had an opportunity of visiting some of the continental coal-tar colour works, and I think I cannot better enforce this argument than by giving a sketch of one of these, with the kind permission of the proprietors. The one I choose as an example is neither the chief nor the most famous of these works. It is a new and comparatively small one, erected on the banks of the Rhine at Basle, by Messrs. Binscheidler and Busch. These works, though far less extensive than those of Messrs. Meister, Lucius and Co. at Hoechst, or the Badische Aniline and Soda Works at Ludwigshafen, are carried on in a no less scientific spirit. As I have already stated, the first principle that governs continental colour works is the absolute necessity of having highly-trained scientific chemists, not only at the head of the works, but at the head of every department of the works where a special manufacture is being carried on. In this respect this method of working stands in absolute contrast to that too often adopted in chemical works in our own country, where the control of the processes is left in the hands of men whose only rule is that of the thumb, and whose only knowledge is that bequeathed them by their fathers. On entering the works of Messrs. Binscheidler and Busch—and I have to thank the former gentleman for his kindness in affording me information and for giving me leave to make it public—one is struck in the first place with the adaptation of means to ends, with the spacious, well-lighted, well-ventillated workshops, and above all with the all-pervading cleanliness and neatness. But it is not of these things I now desire to speak, but rather of the method in which their business is conducted. In the first place, then, the scientific director is a thoroughly educated chemist, cognizant of and able to make use of the discoveries emanating from the various scientific laboratories of the world, and under him are three scientific chemists, to each of whom is intrusted one of the three departments into which the works are divided. Each of these head chemists, who has in this instance enjoyed a thorough training at the Zurich Polytechnicon, has several assistant masters placed under him, and all these are gentlemen who have had a theoretical education in a German university, or in a polytechnic school. An important part of the system is now to be noticed, namely, that directly under these scientific assistants come the common workmen, who have of course no knowledge whatever of scientific principles, and who are in fact simply machines acting under the will of a superior intelligence. The many and great advantages of this arrangement are patent to all, and the fact of having men of education and refinement in positions of the kind renders the foreign manufacturer who adopts this system less liable to annoyance and loss than his English competitor who works on a different plan. So much then for the *personnel* of the works. Now for the means with which they carry on their work. To begin at the beginning, we find no less than ten well-equipped airy experimental laboratories, perfectly distinct from the workshops where the manufacturing processes are carried on. In these ten laboratories the chief departmental chemists and their assistants carry on their investigations respecting the production of new colouring matters or the more economical manufacture of old ones. To assist them in this work a complete scientific library is at hand, consisting of the newest researches, for these, as I have said, form the material out of which the colour chemist builds up his manufacture; and no sooner, perhaps, do the results of a purely scientific research appear which may possibly yield practical issues than the works' chemist seizes upon them, repeats them with modifications and alterations, so as at last to bring them within the charmed circle of financial success. Thanks to Dr. Binscheidler, I am able to quote a specially representative case, and a clear description of one such case is worth a host of generalities. Through the original investigations of the Messrs. Fischer the attention of the manufacturer was drawn to a colourless base obtained by the action of benzaldehyde on dimethylaniline, inasmuch as they stated that the salts of these colourless bases became green on exposure to air. Founded on these observations, an endeavour was made to effect the practical manufacture of a green colouring matter by oxidization of these colourless bodies. In order to attain the desired end the following investigations had to be made by the chemist and his assistants who were to conduct the operations. First, a cheap method had to be found for manufacturing benzaldehyde (commonly known as the oil of bitter almonds). Secondly, a profitable mode of making the colourless bases had to be worked out. Thirdly, the proper oxidizing agents and their best method of application had to be determined. Fourthly, the best method of purifying and crystallizing the green colouring matter had to be discovered. The laboratory experiments on the above points having proved so far successful as to give prospect of good results, operations on a somewhat larger scale were started, and these yielding a satisfactory issue, the manufacture of the colouring matter, now so well known as malachite green, was commenced on the technical scale, the operations still being watched and constantly under the control of the chemist. But even now their scientific work was by no means ended. Continual laboratory experiments go on for the purpose of finding improvements in the mode of manufacture. Thus, for example, the improved yield, both as to quality and quantity, of the benzaldehyde is a matter of investigation. Again, the synthetic production of pure colourless bases by a more direct process is sought for, so as to get rid of loss in working, and to obtain a yield as close as possible to that pointed out by theory. In the same way improvements in the materials used for oxidation and in their application are made, so as to effect the oxidation quantitatively without the forms of by-products. Lastly the action of various solvents is examined so as to obtain the best form of the crystallized colouring matter. As indicating the value of these improvements, made after the colour became a marketable article, it is only necessary to state that the price of crystallized oxalate has been reduced from £2 to £1 4*s*. per kilo. The foregoing may serve to give a picture of a really scientifically constructed work, where each step in advance is made systematically as the result of a well-devised plan of operations. This is indeed the only means of progress, and this fact is so well recognized in Germany that each of the larger colour works at Hoechst and Ludwigshafen possesses a staff of from thirty to forty well paid, thoroughly trained chemists to conduct its operations. But I am, of course, far from believing that because the methods adopted in these foreign colour works are scientific and productive of good, those made use of in all English works must therefore be unscientific and bad. Taking the whole applications of chemical science I think we may with truth say that the English industrial chemists have been at least as successful commercially, and certainly as productive, in new and important discoveries as their continental rivals. The Germans and Swiss, however, have been and still are distinctly before us, not only in the means of obtaining the highest technical training in their numerous universities aud polytechnic schools, but, what is more to the point, before us in the general recognition of the value and importance of such training for the successful prosecution of any branch of applied science. However, though England is apt to be late in taking up such views, she is, as Mr. Forster has well said, generally not too late, and the recent establishment of colleges and technical schools, as well as the appointment of the Royal Commission on technical instruction, on which I have the honour to serve, show that the country is now alive to the necessities of the case; and my object in the foregoing remarks has been to show that in certain branches at least of chemical industry it is only the highest and most complete scientific training that can ensure commercial success. Such a training, I may perhaps be allowed to add, can now be obtained in our own country."

Mr. Ludwig Mond, foreign secretary, read a report of the Patent Laws Committee. After full discussion the majority of the Committee had come to an agreement in the main with the bill elaborated by the Society of Arts, and brought in by Sir John Lubbock. They differed from the bill, however, on a few points, which the Committee considered of sufficient importance to lay before Mr. Chamberlain, who had undertaken to bring in a bill on the part of the Government. Mr. Chamberlain replied that it was quite uncertain when the Government bill for amending the patent laws would be introduced. He would be glad, however, if the Society would communicate with him as soon as the bill was introduced.—The Committee was re-appointed.

Mr. A. K. Huntington, Professor of Metallurgy, King's College, London, read a paper on "The Mexican Amalgamation Process." He gave the results of about forty experiments in which was shown the action of mercury on sulphide of silver, and on proustile in water in a solution of common salt, and in a solution containing sulphate of copper and common salt. The commonly accepted explanation of the action of cupric chloride on sulphide of silver in the Mexican amalgamation process was shown to be only to a limited extent correct. Other points in this process were also elucidated. Professor Huntington also read a paper on "The Metallurgy of Cobalt and Nickel." He sketched the present state of our knowledge of the metallurgy of these metals, with special reference to rendering them malleable. A fine collection of specimens was exhibited.

Mr. Watson Smith read a paper prepared by Dr. Otto N. Witt (who was unable to be present) on "The Application of Indophenol Blue to Calico Printing and Dyeing."

Mr. Charles O'Neill read a paper on "The part of Chemistry in Calico Printing." He sketched the past relations of chemistry with printing and dyeing, pointing out that in 1409, there were print works in London using colours composed of nearly the same ingredients as were in general use within the last ten years. Although calico printing and dyeing might be considered a chemical business, many houses of the second class managed to get on without any skilled chemist or even a laboratory in which experiments could be made or materials tested. This want of chemical knowledge was a source of considerable loss. It was impossible in such circumstances to determine whether or not materials supplied were genuine, and goods were often damaged in consequence. The impossibility of controlling the supply of drugs and other materials from lack of acquaintance with them often left employers in the hands of dishonest servants. He had much hope for the future of our calico printing. Employers and managers were becoming more educated in chemical matters, and better able to appreciate the services chemistry can render.

The President agreed with Mr. O'Neill as to the importance and necessity of scientific chemical training in the carrying out of the work of the calico printer. He had no doubt the fact of the Society meeting in Manchester, and this expression of opinion, would not be without influence. As to the work the Royal Commission on technical education had to do, his lips were of course to some extent sealed. But the attention of the Commission had been drawn to this subject—and no one had done more in this way than Mr. O'Neill—and it was the intention of the Commission to give full weight to what had been laid before them. Professor Roscoe, in concluding, asked Mr. O'Neill for his opinion in regard to some calico prints sent in for exhibition by Manchester firms, and some manufactured by M. Thierry-Mieg, of Alsace.

Mr. O'Neill said the examples of printing from Alsace were certainly very fine, and while he would wish to hold up the printing of this country if he could, it must be admitted that the foreign goods were something better than any of the others in the room. It was, of course, to be taken into account that the British prints were sold at cheaper rates, but home manufacturers had something to learn yet before they could produce the quality shown in the prints from Alsace.

In the evening the members of the Society dined together in one of the large rooms at Belle Vue Gardens. Professor Roscoe presided, and there were about one hundred and twenty gentlemen present.

On Thursday, the annual meeting was resumed at Owens College, the President, Prof. Roscoe, in the chair.

Mr. M. A. Chance (Birmingham), read a paper on Shaffner and Helbig's sulphur recovery process,* as to which he said the interest had extended far and wide since public attention was attracted to it in January last. The process would necessarily affect very materially importers and consumers of sulphur, and several of the leading alkali makers in England were already so convinced of its value as to be taking steps to adopt it. The pressing question of the hour was to determine the best form of plant and the best mode of manipulation to turn the reactions to the best account. Mr. Chance proceeded to describe the plant he is erecting to work the process on a scale of dealing with 300 tons of salt cake per week. This year, he concluded, would be memorable in the alkali trade as having witnessed the introduction of this beautiful process into England, a process replete with problems full of interest to chemist and engineer alike.

* See *Pharm. Journ.* [3], xii., 969.

Some discussion followed, in the course of which much admiration was expressed of the process and hope as to its ultimate success. Only Mr. Ludwig Mond was of opinion that the value of the process had yet to be shown.

On the motion of Mr. John Williams, seconded by Mr. Newlands, the office-bearers of the Society were reappointed, the only change being the substitution, in the president's chair, of Professor Abel for Professor Roscoe.

Professor Abel, in accepting office, said he was sorry the Council had not been able to persuade Dr. Roscoe to continue President for another year. To him the success of the Society was largely due, and for his indefatigable labours he moved that Dr. Roscoe be awarded a hearty vote of thanks.

The motion, which was seconded by Mr. Muspratt, Liverpool, was heartily passed.

It was resolved that the meetings of the Society next year be held in London.

In the afternoon the members visited a number of works in the city and the neighbourhood.

A Conversazione was held in the evening at the College, and largely attended by members of the Society and ladies and gentlemen invited by the Council. The guests were received by Professor Roscoe, the President of the Society. The whole of the College was thrown open, and there were a number of interesting exhibitions and entertainments of various kinds.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, July 19, at 4.0 p.m.

Present—Professor Attfield, President, in the chair; Messrs. Benger, Brady, F.R.S., Ekin, Plowman, Southall, Squire, Taylor, Dr. Thresh, and Messrs. Benger and Carteighe (Honorary Secretaries).

The minutes of the previous meeting were read and confirmed.

Letters of apology for non-attendance were read from Mr. Chipperfield, Mr. Payne, Professor Tichborne and Mr. Young.

It was reported that in addition to the papers previously announced, the following gentlemen had offered contributions:—Messrs. Bothamley, Brownen, Dunstan, Fletcher, Gerrard, Giles, Greenish, Holmes, Hooper, Jackson, Naylor, Proctor, Shenstone, Symes, Woodland and Professor Tichborne.

A letter was read from Mr. Gerrard stating that he would be unable to complete the investigation he had undertaken on *Atropa Belladonna* in time for the Southampton meeting. It was decided that he should be invited to report the result of his work up to the present time.

A letter from Mr. Carteighe stating that it was necessary for him to resign his office as one of the Honorary Secretaries was read. In accepting Mr. Carteighe's resignation, regret was expressed at the loss of his valuable services, and the thanks of the Committee were accorded to him for his services in the past. Mr. Sidney Plowman was then unanimously invited to act provisionally as an Honorary Secretary until an appointment could be made by the members at the approaching annual meeting.

The following gentlemen were elected members of the Conference:—Mr. D. Hooper, Birmingham; Mr. F. R. Squire, San Remo; Mr. M. R. Whitla, Monaghan.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The annual meeting of this Association was held on Thursday, July 20. The President, Professor Attfield, F.R.S., in the chair.

The Honorary Secretary (Mr. Wyndham R. Dunstan) read the annual report of the Executive Committee, which showed an increase, not only in the number of papers read before the Association, but also in the number of attendances at the meetings. During the session sixteen papers and seven reports have been read before the Association. The following is the list of papers:—

"The Meaning of Science," by the Secretary; "Foods and their Values as Sources of Force," by Mr. A. J. Evans; "The Rise and Development of Pharmacy in Russia," by Mr. H. G. Greenish; "The Relation of Microscopic Organisms to certain Industries and Diseases," by Mr. C. H. Hutchinson; "The Chemistry of Cerium," by Mr. H. S. Elworthy; "Animal Parasites," by Mr. E. Haward; "Vapour Densities," by Mr. F. J. Yeatman; "Note on the Preparation of Calcium Hypophosphite," by Mr. F. W. Short; "Alkaloids," by Mr. F. W. Short; "Coal Tar Distillation and some of its Products," by Mr. R. A. Cripps; "Gas Analysis," by Mr. C. Thompson; "The Production of Benzoic Acid and Oil of Bitter Almonds from Toluene, Part I.," by Mr. A. T. Job; "Note on a New Variety of Euphorbia Amygdaloides," by Messrs. F. J. Yeatman and F. W. Short; "The History of Citrine Ointment," by Mr. R. A. Cripps; "The Preparation of Benzoic Acid and Oil of Bitter Almonds from Toluene, Part II.," by Mr. A. T. Job; "Note on some Reactions of Glycerine," by Mr. E. Marsh.

The following reports have been made by the members of the Committee of Reporters, which is appointed annually by the Executive Committee:—

Two Reports on Materia Medica ("Notes on American Drugs," "New Remedies"), by Mr. W. Elborne; Report on Inorganic Chemistry ("Electrolytic Quantitative Analysis"), by Mr. C. H. Hutchinson; Two Reports on Botany ("Chlorophyll," "Darwin's Researches on Plant Movement"), by Mr. J. O. Braithwaite; Report on Pharmacy ("Thorey's Researches on Hyoscyamine"), by Mr. H. G. Greenish; Report on Organic Chemistry ("The Investigation of a so-called Catalytic Phenomenon"), by Mr. Wyndham R. Dunstan.

The President, at the commencement of the discussion, congratulated the Association upon the completion of so satisfactory a session of work.

The adoption of the report was then moved by Mr. J. O. Braithwaite, seconded by Mr. H. S. Elworthy, and carried unanimously.

Mr. C. Thompson then proposed that the balance in the hands of the Association be devoted to the constitution of a Research Fund, to defray the expenses of materials used by members in the investigation of subjects forming the basis of communications to the Association.

This proposition received support from all the members who took part in the discussion, and finally the meeting resolved, "That the proposition be adopted, and that the matter be referred to the Executive Committee for the consideration and settlement of details."

Mr. R. H. Parker then proposed that in future the meetings of the Association be held at eight, instead of half-past eight, as heretofore, on the ground that eight o'clock was more convenient for the majority of the members.

This was seconded by Mr. J. O. Braithwaite, and after a discussion, was carried unanimously.

Messrs. F. J. Yeatman and W. H. Ince were then appointed as auditors to examine the Treasurer's accounts, which they reported to be correct.

After a hearty vote of thanks had been passed to the President, Secretary, and other officers of the Association, the meeting adjourned over the summer vacation.

Parliamentary and Law Proceedings.

A Small Fatal Dose of Laudanum.

A fatal case of poisoning of an infant is reported from Keyworth, and is remarkable for the alleged smallness of the dose. A "drop" of laudanum was administered one afternoon with castor oil, to an infant, three weeks old, for the cure of diarrhœa, to which the child had been subject from its birth. Shortly after, the child became suddenly very ill. At half-past five on the same afternoon it was seen by Mr. Percy Blumer, when the child was lying with contracted pupils, livid lips, skin covered with perspiration, small pulse, and slow respiration. It could be roused with difficulty, and speedily relapsed into its former state. Notwithstanding the administration of emetics, and the use of cold effusions, the child died thirteen hours after it was first seen by Mr. Blumer. Death from 1 drop of laudanum has occurred before, but the repetition of an ascertained case of death after such a dose is worthy of record, if only to impress on the public and the profession the danger attending the administration of opium in any form to young children.—*British Medical Journal.*

Poisoning by Arsenic.

A sad case of accidental poisoning, having a fatal termination, has occurred at Ingoldmills, near Alford, Lincolnshire.

Amos Deans, waggoner, in the employ of Mr. Davison, farmer, purchased some arsenic four or five years ago, for the purpose of destroying rats. What was not used on that occasion was placed inside an American clock case, in a small spice box. Last week a nurse was engaged for Mrs. Dean, named Ellen Blades, a widow, and she, under the impression that the poison was baking powder, used some of it in making a fruit pudding. The pudding was partaken of by the nurse, Mr. Dean, and two children. Mr. Dean, remarking that it tasted "funny," asked what it had been made of, and on being told immediately replied that they were poisoned. Remedies were at once applied, and on Monday the patients appeared to have recovered, but later in the day, Mrs. Blades, who had taken the occurrence much to heart, became unwell, and rapidly got worse. Every attention was paid to her, but she died on Tuesday.—*Leeds Mercury.*

Poisoning by Vermin Killer.

Mr. J. C. Malcolm, the Leeds coroner, held an inquest at the Leeds Town Hall on Friday, July 21, touching the death of Eliza Motherby, domestic servant. The deceased retired to bed on Tuesday evening, evidently in good spirits. The following morning Dr. Creser, finding that she had not risen, called her, and knocked at her bedroom door a great many times, but as she did not respond he entered the room, and found her lying dead on the bed. Mr. Wright, surgeon, afterwards made a *post-mortem* examination of the body, the appearances of which led him to the opinion that death had resulted from some irritant poison. It was stated that on Monday last the deceased went to the shop of Mr. W. B. Ferguson, chemist, Great George Street, and asked for something to destroy mice. Mr. Ferguson supplied her, at her own request, with a sixpenny packet of "vermin killer." In answer to questions she said her name was Eliza Elwiss, and that she was employed by a Mrs. Marshall, residing in Lyddon Terrace. On receiving the packet she signed for it in Mr. Ferguson's book. On Wednesday morning a portion of the powder was found on the dressing table in the girl's room, and there were also some potted meat sandwiches, upon which was spread a quantity of the vermin killer. A razor was likewise found in the room. The girl's mother, who resides at Hensall, near Snaith, said she could not account for her daughter's act. The deceased received a sunstroke about four years ago. The other day she received a letter from her daughter, who said she was very poorly, and she hoped she would soon be sleeping in Hensall Churchyard.

The jury returned a verdict of "Suicide whilst in a state of temporary insanity."—*Yorkshire Post.*

Poisoning by Morphia in a Hospital.

A death under very distressing circumstances took place last week in Westminster Hospital. A man named Ebden was an inmate in one of the wards, suffering from severe heart disease, but sufficiently well to be able to sit up in the ward during the latter part of the day. In the same ward was another man, who was receiving hypodermic injections of morphia, which appear to have been given by the nurse in charge. One day, when about to give the customary injection, she placed the bottle containing the morphia solution on the table in the middle of the ward by which the man Ebden was sitting. He then seized the bottle and drank off about a tablespoonful of the fluid. Every effort was made to remove the fluid from the stomach, and to counteract its poisonous effects, but they proved fruitless, and the man died from the effects of the morphia. Such an event is extremely distressing, more particularly as it tends to lessen the confidence of the public in hospitals. The coroner's jury returned a verdict of "Death by misadventure," but added a rider that in their opinion the nurse was to blame for leaving poisons within reach of patients able to leave their beds. Those familiar with the working of a hospital will hardly concur in this opinion, but they will rather ask how it is that the nurse was in possession of the bottle of morphia. The coroner's jury would have done better service if, instead of trying to affix blame upon a nurse who was not shown to have been careless, they had elicited whether it was the custom in the hospital for the administration of hypodermic injections of morphia to be relegated to nurses. We have no hesitation in saying that such a practice is to be deprecated in the strongest possible terms. It is no part of a nurse's duty to determine on the necessity for such an administration, still less on the amount required, and, least of all, is a nurse qualified to inject the fluid. Had the administration of hypodermic injections of morphia been kept in the hands of the resident staff we presume a bottle of a strong solution of morphia would not have been in the ward, and could not have been left on the table. The case clearly points to a danger connected with the other plan, and we hope it will prove a warning to the authorities of all hospitals, and that precautions will be taken to prevent the repetition of such an unfortunate accident.—*Lancet.*

Poisoning by Sulphuric Acid.

The Bolton coroner on Monday investigated a case of poisoning by sulphuric acid. A number of houses in Derby Street were being whitewashed, and the occupants meanwhile placed a quantity of loose articles in a back street to be out of the way. Amongst these was a bottle of vitriol. A child named Alice Makin, aged five, took this for "Spanish juice" and drank a teaspoonful. She immediately became ill, and with difficulty reached home after falling three times, and died in four hours. A verdict of "Death from misadventure" was returned.—*Manchester Evening News.*

Reviews.

The New Hand-Book of Dosimetric Therapeutics. By Dr. Ad. Burggraeve. Translated from the French and Edited by H. A. Allbutt, M.R.C.P., L.S.A. London: David Bogue.

This book is an exposition of the dosimetric system of therapeutics, which was instituted by Professor Burggraeve, of the University of Ghent. Why the name dosimetric should be given specially to this method of treatment has never been obvious, neither is it made more so by a perusal of this book. Dosimetry, we are told by the translator in a somewhat rambling preface, "looks upon the two rival systems of medicine, allopathy and homœopathy as being both equally at variance with truth. Allopathy weakens the patient's system by bleedings, purgings, sweatings and fasting. Its massive doses also thoroughly nauseate and disorder him. Homœopathy, as taught by its founder Hahnemann, is merely another kind of expectation, for its remedies consist of infinitesimal dilutions which have no materiality."

In theory no one will object to the main principles of the dosimetric system; in fact, they are so many truisms. Thus, Mr. Allbutt tells us that "the dosimetric method takes everything, however trifling, into consideration, such as the medical constitution, the individual constitution, the hereditary condition, the age and sex, and the mode of life; the treatment being modified according to the varying conditions of each case." Again Professor Burggraeve states that "dosimetric medicine is the art of appropriating remedies to the nature and progress of diseases, to their symptoms, and to individual idiosyncrasies." The translator, in his preface, makes a statement which is so remarkable that we quote it at length. "The great object in all treatment is that the medicaments should act by physiological catalysis, that is, they should excite certain movements of nutrition, etc., without themselves participating in those movements, either chemically or physically. Hence may be seen the danger of giving too large doses of any medicament, for if such is done the economy is disordered, irritated and depressed. Every medicinal agent, when administered according to the dosimetric method, has an elective action, that is, each goes naturally to its proper address, but not otherwise." We are not discussing or criticizing the book from a literary standpoint, so let pass with mere comment the verbal contradiction and misuse which characterizes the above paragraph. Catalysis has recently been the subject of special comment in this Journal and its worthlessness as an explanation pointed out; the subject need not, therefore, detain us here. The opinion expressed in the sentences above quoted indicates, at least, an absence of knowledge concerning the fundamental facts of physiology and pathology.

Turning now to the remedies employed by dosimetry. It is stated that "dosimetry prescribes powerful remedies in a pleasant form, accurate in composition, reliable in action, and which are measured to the urgency of the case." What system of medicine, properly so called, it may be asked, does not also aim at this? This is in reality not the question, the real point is whether the means employed by any given system are capable of effecting these obviously desirable ends. Dosimetry proposes that the use of drugs in the crude form, and this includes all galenical preparations, should be abandoned, and the active principles of these drugs only employed. The fact that in a great number of cases the same therapeutical effect is not obtained from a separate active principle as from the drug itself is a sufficient objection to this proposal. And further, in many cases the active principle has never been isolated. Are we on this account to abandon the use of a powerful remedy? The case of ergot is a notable example of this. Recent work has thrown much light upon the matter, but we are not yet in possession of the active constituent or constituents in a pure state. It is an interesting and significant fact that among the "powerful remedies, accurate in composition," employed by this system occurs "ergotine," which name has been used to designate at least two preparations of ergot, both of which may be regarded as little more than fluid extracts of the drug.

The pharmacy of dosimetry is barely touched upon. It is evident, however, that as all the proposed remedies are merely definite quantities of metallic salts, alkaloids, etc., made up into pilules with sugar, even if the system was generally adopted two or three manufacturers would suffice to supply the whole of this country or indeed of the civilized world. Thus the pharmacist, as we now know him, would, if he existed at all, be reduced to the position of a mere vendor of these pilules. The translator, however, thinks, or rather says, otherwise. "Chemists need not fear that the new pharmacy will work them harm, rather will it elevate them into scientists, making them not mere vendors of quack medicines, but skilled preparers of drugs, giving them a new position equal to that of their medical *confrères*." It is almost needless to say that there is not the slightest indication given as to how this wonderful transformation is to be effected. The only passage having the least bearing upon the question is the following one, which is of paramount interest as it admirably confirms and gives authority to what we have stated would be the inevitable effect that the adoption of the dosimetric system would have upon pharmacists. "Let me caution those physicians who adopt the dosimetric method, and who desire to obtain uniform results in the treatment of cases, to be on their guard against all coarse and cheap imitations of the Chanteaud granules. No granules are genuine or reliable but those which are manufactured by M. Charles Chanteaud, the eminent Parisian pharmacist. To these only has Dr. Burggraeve attached his signature as proof of their reliability."

The whole book is written in a style which will not recommend itself to English readers. In many parts one feels that it is more of a "talk" about the subject than an exposition in a serious and systematic manner.

Examination Questions on the Medical Sciences. Selected and Arranged by James Greig Leask, M.B. Abdn. London: Baillière, Tindall and Cox. 1882.

A question suggested not unnaturally by the title of this book is, Do examiners also cram? This fear, however, may be allayed by a perusal of the brief preface, in which it is stated that the author aims at providing, in a convenient form, such a concise collection of questions as will prove useful to the medical student. To attain this end "university calendars, army medical reports and medical periodicals have been consulted;" but with result before us we are constrained to ask, *Cui bono?* We confess we cannot find an answer, although it may be assumed that at least the author and publisher would be ready with one. Even if the careful consideration of examiners' questions were the most satisfactory method of studying a science, this book is not sufficiently complete to be of much value. It is true that examiners are credited with asking wide questions; but we do not think, for instance, a medical student would be safe in expecting that he would be more likely to be asked to describe the genus *Carex*, or the geographical distribution of the Magnoliaceæ, than for particulars about such orders as Euphorbiaceæ, Scrophulariaceæ, Solanaceæ, or Polygonaceæ. Yet the former questions are quoted, but we do not see anything more nearly representing the latter than the following rather elastic question, "Describe the natural orders of plants and their essential distinctive characters." At a first glance it seemed that an important subject of a medical student's examination was omitted, there being no special section devoted to materia medica. But some of the sections are very inclusive, as may be seen from the fact that a question as to the external characters by which the substitution of dulcamara leaves for belladonna leaves may be discovered is found under "Medical Chemistry." The book is neatly printed and bound.

Notes and Queries.

[733]. Coloured Carboys.—Could any reader give me information as to the origin of the custom of chemists placing carboys containing coloured liquids in their shop windows?

I have been unable to find any information on the subject in books.

John R. Hill.

---

[734]. Decoct. Sarsæ Co. Conc. c. Quiniæ.—"Lex" would be obliged for formula for a miscible compound of dec. sarsæ co. conc. and quinine.

[735]. TINCT. OF EUONYMIN. — Could any reader oblige me with a reliable formula for tinct. euonymin, which I have frequently had occasion to make?

THETA.

[736]. TINCT. DATURÆ TATULÆ.—Can anyone give me a form for tinct. daturæ tatulæ in next impression of *Pharmaceutical Journal*?

THE FUTURE OF PHARMACY.

Sir,—I was very much pleased to see a letter from Mr. Hart appearing in the issue of the 15th inst., as I think it points to a very serious drawback to our trade; viz., the grasping propensities and love of filthy lucre which lead men in the trade to supply hucksters and other general dealers with drugs and pharmaceutical preparations, to the detriment of their more consistent brethren. When I was an assistant, in one situation which I filled the master himself used to go out soliciting orders from hucksters for drugs, pills, etc., and would not scruple to supply them even with laudanum, if he thought they would be sure to pay him for it; and yet I see his name appearing as a member of the Chemists' Defence Association. Since I have been in business, I have experienced much competition from hucksters in the retail drug line, aided and abetted by such as I have referred to. Only yesterday, a girl came into my shop, with a packet of rhubarb in her hand, for a pennyworth of white precipitate, because she could not get that where she was in the habit of buying the rhubarb and other drugs. There, I think the huckster had the best of it, as the law will not allow him to sell dangerous preparations; that unenviable business is reserved for the pharmacist. If, as Mr. Hart says, every member of the trade would be true to the interests of the trade, it would be much better for all of us. What with competition from hucksters, general supply stores, etc., and low prices by members of our own craft, our trade is not up to much. The would-be pharmacist of the future will probably, before he goes through a compulsory curriculum, come to the conclusion that the "game is not worth the candle." A great deal of this competition from outsiders is encouraged and supported by men like my example, who will do anything for the sake of gain, and yet belong to an association for defending the interests of pharmacists. But perhaps that is their peculiar way of defending and promoting the interests of their brethren. In regard to patents, I find that by breaking the government stamp, we can then retail the medicine out in any quantities. I question whether it would not pay to buy the largest size of the most extensively used patents and then retail the remedy out in any quantity the customers desired. This would save many the nuisance of being obliged to part with 9½*d*. every time they want a dose of So-and-so's pills, powders, cough stuff or lozenges, and although the turnover would be small, it would no doubt take much of the trade from tailors, hucksters, stores, etc., and put a little more in our own pockets. Many of the outsiders would not care to spend the time in measuring and labelling medicines, the druggist would be on more level terms with them then, besides the advantage of always recommending our own remedies in preference. Now that a fair profit is so seldom obtainable on what was once the paying part of a chemist's business it is time to do something. It is the outsiders dealing in such large quantities and having such enormous turnovers, that has beaten the ordinary chemist; but when it comes to small quantities, then we are more in our element.

I hope my letter may draw forth some opinions on the subject that will lead to practical good.

PILL MAKER.

FRESH BAEL FRUIT (ÆGLE MARMELOS).

Sir,—A quarter of a century since I used to procure for a customer of mine, residing at Boulogne-sur-Mer, a not inconsiderable quantity of the "Confection of Bael," which was supplied under the more homely name of "Bael Preserve or Jelly." I invariably procured it from Mr. Pound, who then occupied the old established pharmacy in Oxford Street, at the corner of Orchard Street, as I understood it was a specialty of that house. If anyone will take the trouble to refer to vol. x. of the *Pharmaceutical Journal*, for 1850, he will find on page 165 an interesting account and an illustration of the bael plant. I do not recollect whether Mr. Pound's preparation was made from the ripe fruit or from the unripe fruit or half-ripe fruit, or whether it was made in London or at Malabar, but anyone reading the paper will see that certainly it gives Mr. Pound the credit of first importing the fruit, and looking again over the paper I find that the "preserve" appears to have been made from the fruit in various conditions.

Pharmaceutical history, like other histories, "repeats itself," and different people are frequently making the same discoveries. I might mention the instances of phosphorized cod liver oil and the tincture of quinine made with the hydrochlorate instead of the sulphate of quinia.

It would be hypercritical as well as irreverent to class the discovery of the so-called new remedies with the finding of a "mare's nest." *Per contra*, is it not somewhat euphemistic to attach any great amount of novelty to them?

13, *Baker Street. W.* JOHN TAYLOR.

Theta.—The deposit should be examined; probably it is thrown down from the infusion of cinchona by the potassium iodide.

N. J. Lewis.—You are recommended to communicate with the Registrar upon the subject.

J. Miller.—*Sedum reflexum.*

D. S. Barbet.—Acetate of morphia is not a stable salt, being completely soluble in water only when freshly prepared. If kept there is a gradual elimination of acetic acid, with the formation of a basic compound. See a paper by Merck in *Pharm. Journ.*, [3], vii., 229.

J. T. Lloyd.—We are much obliged to you for taking the trouble to translate the report. See, however, p. 78 in the number for last week.

W. Ashton.—Your letter has been forwarded to Mr. Will.

M.P.S.—*Liquid Dentifrice.*—The following recipe has already been quoted from an American source :—Soap bark, 4 ounces; glycerine, 3 ounces; diluted alcohol, sufficient to make 2 pints; oil of gaultheria and oil of peppermint, of each 20 drops. Macerate the soap bark in the mixture of glycerine and alcohol for three or four days, and filter through a little magnesia previously saturated with the essential oils. See also p. 89 of the present number.

Toxicologist.—Taylor, "On Poisons" (Churchill).

T. D. Sneath.—Carbolic acid is soluble in 15 parts of water. We cannot assist with information as to the composition of the proprietary preparations mentioned.

T. O. Sandell.—For an account of salep, see 'Pharmacographia.' "*Salib misri*" is a kind of salep met with in the Indian bazaars, derived from species of *Eulophia.* Possibly a supply could be obtained through Messrs. Christy, Fenchurch Street.

W. Miller.—*Filago germanica.*

John Brown.—The specimens are apparently both referable to the same species, *Chiococca racemosa.*

J. Hutchinson.—*Impatiens parviflora.*

A. P. S.—Pereira's 'Materia Medica.'

Beautifier.—We do not think it desirable to publish your letter, but would suggest that if you are acquainted with any person in the business you might bring your views under his notice.

Anthony.—All communications respecting advertisements should be addressed to Messrs. J. and A. Churchill, 11, New Burlington Street, W.

X. Y. Z. is referred to the rule respecting anonymous communications.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mee, Lewis, Hart, C. E. L., C. S., S. L.

THE INTERNATIONAL ELECTRIC EXHIBITION.

(*Continued from page* 42.)

Mr. Edison appears to have first begun his experiments in incandescent lighting in the summer of 1878. His earliest efforts were made in the direction of utilizing incandescent platinum wire as a source of light. "He adopted for a lamp a coil of platinum wire, and endeavoured to perfect a regulator of the current which would allow the coil to become luminous without becoming so hot as to melt." The length of platinum wire used in this coil amounted to as much as 17 feet. Great difficulties were met with, owing to the constant tendency to the formation of electric arcs between adjacent portions of the convolutions of the wire, and every time an arc formed the wire disappeared in a shower of sparks. Attempts were therefore made to insulate the wire with some substance that would become luminous when the current was passing. Numerous experiments were also made with wires of other metals, including iridium, and various minerals, but all apparently without the conductor being enclosed in a vacuum. As might have been anticipated, a saving of the electric energy was found to result, depending on the ascertained fact, that radiation of heat is less across a vacuum than through air. In spite, however, of all precautions and devices, these experiments were a non-success, and after more than a year's laborious and costly experimenting the persevering investigator was unwillingly obliged to admit that he was entirely on a wrong track. The ultimate failure in this direction had been predicted from the outset by electrical experts in this country and in America. To attain economical results an incandescent conductor must have an exceedingly small section and be capable of sustaining an extremely high temperature without volatilizing or fusing, and in this latter respect all known metallic conductors fall far short of the mark. In point of fact, as far as is known at present, some form of amorphous carbon is the only substance that realizes the necessary conditions.

A comparatively small circumstance drew Edison's attention to the possibility of forming a carbon wire or filament. Having occasion to make some carbon buttons for the form of telephone invented by him, he was using a mixture of tar and lampblack for this purpose, when he noticed the facility with which the mixture could be drawn out into strings; this led to experiments which showed that it was possible to form a "carbon wire" from a mixture of this kind. After several weeks' experimenting Edison found that a wire or filament thus formed was capable of lasting for a short time in a vacuum. The key note of ultimate success had been struck and it appeared evident that what was mostly required was increased durability. Attempts were next made to use coils formed from carbonized cotton, thread, twine, etc. The texture of these materials as prepared by Edison was found to be much too loose and tender. Much more satisfactory results were found to accrue from the use of strips of carbonized paper. This material was cut into thin horseshoe shapes, carbonized, and the carbonized slips mounted in glass globes that were afterwards exhausted of air by the Crookes-Sprengel pump. The carbon horseshoes were connected by platinum wire connections with the electrical source. These lamps were found to require about one-eighth of a horse-power each when producing a light of sixteen candles or a little more. In order to see if any injurious effect resulted to the carbon filament by suddenly turning the current on and off, one of Edison's workmen was deputed to turn the current on and off to one lamp. After doing this no less than five thousand times, the lamp was found to have withstood this test without the slightest injury. The durability of the lamp appeared thus certain. A number of lamps thus constructed (something more than forty-five) were apparently found to last when lighted every night nearly a fortnight without showing any signs of breaking down. Patents were taken out for this incandescent paper horseshoe lamp in several countries. Eventually Mr. Edison relinquished the use of paper for the incandescent bridge and settled on the use of carbonized bamboo as the most advantageous incandescing substance.

Students wishing to pursue the manufacture of the Edison lamp further will find a completely illustrated article in *The Electrician* (vol. viii., p. 338); the woodcuts accompanying that article show the original bamboo and all the successive stages of the fabrication of the carbon bridge, also the successive steps by which the enclosing glass globe is prepared for the reception of the carbon bridge. For the purposes of this article it will suffice to give the description by the Incandescent Lamp Committee of the Paris Electrical Exhibition. The jurors' report commences by stating that the lamps in the exhibition, purely incandescent in character, were those of Edison and Maxim in the United States section, and those of Swan and Lane-Fox in that of Great Britain.

"They all consist of a glass envelope more or less spherical in form, in which is enclosed a carbon loop, made of carbonized organic material, and supported upon wires of platinum sealed into the glass. The space in the interior of the lamp is very perfectly exhausted.

"The Edison lamp is pear-shaped in form. The carbon filament is long and fine, and is bent into the shape of a U. It is made from Japanese bamboo, cut to the requisite size in a gauge. In section it is nearly square, being about 0·3 millimetre on a side, the ends being left considerably wider. The fibre is carbonized in moulds of nickel, and is attached to the conducting wires by copper electrolytically deposited upon them."

The committee found the resistance of Edison's lamp, cold, to range from 233 ohms to 268. Ten different lamps were taken, the mean resistance of the ten being 241 ohms. The resistance of the lamps when hot and giving a light of sixteen candles was found to be 137·4 ohms (mean); when giving thirty-two candles, 130·03 ohms. The resistance of carbon decreases with rise of temperature, carbon not following the same law as metals. Hence this decrease of resistance when heated is common to all incandescent carbon lamps.

From the committee's report it would appear that Edison's incandescent lamp is more economical than its rivals, both in point of electrical energy and in candles yielded per horse-power. This economy holds good both when yielding sixteen and thirty-two candles luminous intensity. A current of 0·651 ampères, with an electromotive force of 89·11 volts, was found to be passing when yielding a light of sixteen candles; these numbers representing 196·4 candles per horse-power of energy, or 12·28 lamps of sixteen candles per horse-power. At thirty-two candles a current of 0·7585 ampères and an electromotive force of 98·39 volts was recorded, giving three hundred and seven candles per horse-power or 9·6 thirty-two candle lamps for each horse-power expended.

The Edison exhibit at the Crystal Palace was one of the great sights of the show, the salient feature being an immense pyramidal electrolier of hammered brass, 15 feet high, representing a basket of flowers. This costly piece of work was designed and executed by Messrs. Verity and Sons, of Covent Garden. The electrolier contained some three hundred and fifty represented flowers, ninety-nine of which carried incandescent lamps on three circuits, either of which could be turned off or on without disturbing the rest. This magnificent example of the art of the brass-smith was greatly admired by the crowds of visitors to the exhibition, and was commented on in glowing terms in the columns of the daily press.

The next incandescent lamp to be referred to is the invention of an Englishman and a pharmacist, Mr. J. W. Swan, of Newcastle-upon-Tyne. Though Mr. Swan's patent for an incandescent lamp using a carbon filament in a vacuum is scarcely two years old, it appears that he nearly anticipated the present lamp some twenty years ago. The story had better be given in his own words. It forms the important exception alluded to on p. 42:—

"As a matter of history, I will briefly describe an experiment which I tried about twenty years ago.

"I had a number of pieces of paper and card of various forms and sizes buried in charcoal in a crucible. This crucible I sent to be heated white hot in one of the pottery kilns belonging to Mr. Wallace, of Forth Banks. From the pieces of carbonized card which I thus obtained I selected a long spiral; the ends of this I clipped between small blocks of carbon carried by uprights and connected with conducting wires. A small glass shade was cemented over this mounted carbon spiral, and the air was exhausted by means of a very good air-pump, lent to me for the purpose of this experiment by the Rev. Robert Green, of Longhorsley. A good vacuum (according to the ideas that then prevailed) having been produced, I applied the wires of my battery (consisting of ten cells of Callan's modification of Grove's battery) with great expectation of a brilliant result; instead of this, there was the most absolute negative presented to me, not a vestige of heat or light appeared in my long ringlet of carbonized paper. It was evident, and I immediately recognized the fact, that an electric current of the strength I was using would not go in sufficient quantity through so long a piece of carbon as I had taken. I therefore repeated the experiment with shorter carbon and a greater number of cells, and I obtained, under these altered circumstances, an extremely interesting result.

"My carbon was in the form of an arch, about 1 inch high and ¼ of an inch wide. The ends of the arch were held in small clamps with small blocks of carbon.

"The air-pump having been worked, I had the pleasure of seeing that when contact with the battery of forty or fifty cells was completed my carbonized paper arch became red hot, and it was evident that nothing more was wanted than a still stronger current to make it give out a brilliant light; but I had used up all the battery power at my disposal, and having reached this limit, I contented myself with watching the behaviour of the arch, the engrossing question being, How long will it endure?

"I noticed that the inner part of the arch was hotter than the outer part, and that, perhaps in consequence of this, the arch became bent on one side. This bending gradually increased, until at last the arch had so far curled down that the top was on a level with the clamps, and on coming into contact with the sole of the lamp it broke in two, and the experiment collapsed.

"That, I confidently believe, was the very first instance in which carbonized paper was ever used in the construction of an incandescent electric lamp."

Mr. Swan's experiments had been mentioned by Mr. Barnard Proctor nine months previously, in a letter to this Journal, which will be found in vol. x., page 600. It will be seen, therefore, from these statements that Mr. Swan must be accredited with a large share of priority in this important matter. The Paris committee thus describe the present form of the lamp:—"The Swan lamp is globular in form, the neck being quite long. The carbon filament is made from cotton thread, parchmentized before carbonization by treatment with strong sulphuric acid. The ends of this filament are very much thickened, and the loop has a double turn at the top. Its ends are clamped in a pair of metal holders, supported laterally by a stem of glass, which rises through the neck to the base of the globe. Below, these holders are fastened to wires of platinum, which pass through the glass." It may be added that Mr. Swan has patented a method of depositing carbon from hydrocarbon vapour on the junction of the metal holder and the filament. The parts of the bridge or filament on which the deposit is not to take place are electrotyped with copper. The resistance of the lamp (cold) was found by the committee to range from 74 to 39 ohms, the mean of ten lamps being 59 ohms. The hot resistance at sixteen candles was 32·78 ohms mean; at thirty-two candles, 31·75 ohms mean. The current required per lamp at sixteen candles was 1·471 ampères; at thirty-two candles, 1·758 ampères; the electromotive force in the first case was 47·3 volts, in the latter, 54·21 volts. These figures give 10·71 sixteen candle lamps, and 7·9 thirty-two candle lamps per horse-power, or 177·92 candles in the first case, and 252·4 candles per horse-power in the latter. The Swan lamp has found great favour wherever seen; the light is extremely mellow and pleasant to the eye and the lamp is now produced comparatively cheaply. Swan lamps have been introduced into the saloons of a number of ocean-going steamships, where they have very successfully replaced the paraffin lamps previously used.

Perhaps the most important and useful application that has ever been made of any incandescent lamp is the installation of Swan lamps in the Risca Colliery, a fiery mine in the South Wales district. The seam of coal worked at this colliery has an exceedingly evil reputation as regards the danger involved in getting it. It is hoped that the strongly protected Swan lamps, and the thoughtful and ingenious manner in which the necessary contacts and conductors have been arranged, will go a long way towards the prevention of the dangerous explosions that have occurred at this colliery. The experiment is one which will be watched with great interest by scientific men and by all who are interested in protecting the lives of our colliers,—and who is not?—while they are following their perilous labours in the depths of the earth.

The Swan lamp was well represented at the Crystal Palace, but no attempt was made by the Swan Company to imitate the grand surroundings of other exhibitors.

(*To be continued.*)

SOLUBLE SALTS OF CAFFEINE.*

BY C. TANRET.

Hitherto, in consequence of its slight solubility, caffeine has been administered hypodermically only in very small doses; in fact, at the ordinary temperature, it requires 93 parts of water to dissolve it, so that a cubic centimetre would contain scarcely more than a centigram. Most of the salts of caffeine mentioned in therapeutical works do not exist, and those that do cannot be employed, because upon being dissolved they are decomposed into acid and caffeine, the latter being precipitated if the water is not in the proportion required for the solution of the free alkaloid.

The alkaloidal properties of caffeine are extremely weak; it is perfectly neutral in its behaviour towards litmus, while the ordinary reagents for alkaloids do not precipitate it unless its solutions are relatively very strong. Not being alkaline, caffeine is incapable of saturating the smallest quantity of acid, and although it forms salts with certain acids these salts are far from being as stable as those of most of the other alkaloids, as will be seen upon considering its behaviour with the acids most frequently employed.

Acetic acid dissolves caffeine freely. If this solution be allowed to evaporate spontaneously the acid volatilizes entirely and there remains, not a salt of caffeine, but pure caffeine. An acetate of caffeine, therefore, does not exist.

Neither does valerianic acid form with it a valerianate of caffeine. If caffeine be saturated hot with a very strong solution of this acid, upon cooling it will deposit, not valerianate of caffeine, but simply caffeine, entirely soluble in chloroform and only retaining mechanically traces of the acid, sufficient to impart the odour. The acid titrate of the solution remains the same as before the addition of the caffeine, which proves clearly that the caffeine has not carried down with it a sensible quantity of the acid in its precipitation. Also when caffeine and valerianic acid are placed together under a bell glass, as in the preparation of valerianate of ammonia, the caffeine only becomes impregnated with the odour of the acid. I have verified this fact upon commercial "valerianate of caffeine" occurring in fine crystalline needles resembling those of caffeine, a character that was very natural, since it was only caffeine with a valerianic odour. Exposure to the air and simply washing removed this odour.

Lactic acid does not combine with caffeine to form a lactate. Syrupy lactic acid, saturated in the cold with caffeine, remains syrupy indefinitely; and as in the case of valerianic acid, pure caffeine crystallizes out upon the cooling of a lactic acid solution that has been saturated while hot.

It is the same with citric acid, which does not give a citrate. The product which is decorated with this name is only a mixture of caffeine and acid.

Another circumstance, goes to prove further the non-existence of these pretended salts of caffeine and organic acids. Whilst, for example, citric acid, which is tribasic, requires for the formation of citrates three equivalents of base, one or two of which can be replaced by one or two equivalents of water, there is required to effect the solution of one equivalent of caffeine in water a quantity of acid represented in weight by about three equivalents of acid. The relations are, therefore, precisely the inverse of those which should obtain in the formation of a citrate. To sum up, organic acids do not form definite salts with caffeine. They augment, it is true, its solubility in water, but without combining with it, and since the acidity of the acids is in no way modified by caffeine, it will be evident that with solutions of caffeine in organic acids there would be injected a quantity of free acid several times the weight of the dissolved caffeine.

With mineral acids the conditions are different. Sulphuric acid forms with caffeine a sulphate that crystallizes with difficulty. Hydrochloric and hydrobromic acids on the contrary form salts that are easily obtainable in very fine crystals. These salts are perfectly definite and have been described; but they are not stable, and water decomposes them into free acid and caffeine, which precipitates or not according to the quantity of water employed. They are also altered by the air, and the crystals of the hydrochlorate when exposed effloresce rapidly, losing their acid. After a time, more or less long, according to the temperature, nothing remains but caffeine. Therefore, from this point of view, the salts of caffeine formed with mineral acids do not present any advantage over pure caffeine.

In presence of these negative results, I had the idea of employing the natural salt which holds the caffeine in combination in coffee, the chlorogenate of potash and caffeine of Payen. But that salt is very difficult to obtain in any considerable quantity, and this presents an obstacle to its employment in the ordinary way, besides which when in solution the salt is very alterable in the air. Moreover it contains only 29 per cent. of caffeine, and in the cold requires to dissolve it several times its weight of water, which gives solutions still less charged with caffeine.

It occurred to me then, in view of the apparent similarity that exists between chlorogenic or caffetannic acid and benzoic, cinnamic and salicylic acids, that double salts analogous to Payen's salt could be formed with the three last-named acids, and my conjecture proved correct.

In presence of benzoate, cinnamate or salicylate of soda caffeine dissolves in a very small quantity of water and forms thus very soluble double salts that are very rich in quinine. That there is in this case more than a simple solution is proved by the fact that for a definite weight of caffeine there is required a definite weight of the alkaline salt; in other words, combination takes place according to the equivalents of these various bodies. But this combination is rather weak, since if the salts be treated with chloroform they give up to it all their caffeine. In my opinion these double salts may be best compared with hydrated salts, which lose their water of crystallization when treated with a neutral liquid in which water is soluble. In this way blue sulphate of copper loses its water of crystallization and becomes white when immersed in absolute alcohol.

Cinnamate of soda dissolves caffeine in water equivalent for equivalent, 170 parts of cinnamate for 244 of caffeine. The double salt thus obtained contains 58·9 per cent. of caffeine.

Benzoate of soda and caffeine contains for two equivalents of benzoate of soda (288), one equivalent of caffeine (244), or 48·5 per cent. of caffeine.

The double salt richest in caffeine can be obtained with salicylic acid. An equivalent of salicylate of soda (160) allows of the solution of an equivalent of caffeine (244), which gives 61 per cent. of caffeine in this double salt.

The solubility of these double salts is such that solutions can be easily obtained with the benzoate and cinnamate of soda containing 20 centigrams per cubic centimetre, and with salicylate of soda as much as 30 centigrams.

Benzoic, cinnamic and salicylic acids having supplied me with what I was in search of, I have not thought it necessary to ascertain to what extent analogous results might be obtained by employing these acids in combination with other bases than soda. I may mention, however, that I have been able to obtain double salts with acetic, lactic, citric, sulphuric and hydrochloric acids.

With these new salts, therefore, it will be possible in future to administer caffeine hypodermically. It is true that the alkaline salts associated with it have their own peculiar action; but this action is known, and consequently it will, according to the case and the dose, sometimes be ignored and sometimes taken account of; that will be a matter of therapeutics.

* *Journal de Pharmacie,* [5], v., 591.

In conclusion, these salts may always be prepared extemporaneously by simple solution in water in the proportions given above. But since the commercial benzoate of soda has sometimes an alkaline reaction, it will be as well, in preparing hypodermic injections, to first neutralize the soda salts with the corresponding acids.

EFFECT OF VARIOUS ANTISEPTICS UPON MORBIFIC GERMS.*

Actual experiment with morbific germs is the only way of acquiring definite knowledge on the value of disinfectants. Moreover, there is reason to believe that there are vast differences in the power of resistance possessed by germs of different kinds, so that it cannot be assumed that the results obtained with one are true of another. More facts are still needed, and we note therefore, with interest, a series of experiments which have been made at Lyons by Arloing, Cornevin and Thomas, on the influence of various disinfecting agents on the virus of symptomatic anthrax. The results have been published in the *Lyons Médicale.* If pulp from the tumours in this disease is allowed to dry slowly at a temperature of 35° C., a residue is obtained in which the organisms of anthrax retain their full activity. A few cubic centimetres of water, through which a little of the residue is diffused, has a virulence not inferior to that possessed by the fresh virus, and which continues for at least two years. The experiments on the influence of disinfectants were carried out with this dried virus, and also with perfectly fresh virus. It was found that the resisting power of the former is much greater than is that of the latter. Whatever destroys the dried is capable of destroying also the fresh virus, while the converse is not true. The different substances tested were left in contact with the virus for forty-eight hours, and the test of virulence was the hypodermic injection of five drops. The following substances were found to have no action even upon the fresh virus: alcohol saturated with camphor or with carbolic acid, glycerine, ammonia, acetate and sulphate of ammonia and sulphate of ammonium, benzine, a saturated solution of chloride of sodium, quicklime and lime water, polysulphide of calcium, a one-in-five solution of chloride of manganese, a one-in-five solution of sulphate of iron, a one-in-five solution of borate of soda, a one-in-five solution of tannic acid, a one-in-ten solution of sulphate of quinine, a one-half solution of hyposulphite of soda, essence of turpentine, and monobromide of camphor; of gases, ammonia, sulphurous acid, and chloroform. A saturated solution of oxalic acid, a one-in-twenty solution of permanganate of potash, a one-in-five solution of soda, vapour of chlorine, and of sulphide of carbon destroyed the activity of the fresh virus, but had no effect on that which had been dried, while the activity of the latter was destroyed only by solutions of carbolic acid (2 per cent.), salicylic acid (1 in 1000), nitrate of silver (1 in 1000), sulphate of copper (1 in 5), boric acid (1 in 5), saturated salicylic alcohol, corrosive sublimate (1 in 5000), and bromine vapour.

Thus many substances unanimously regarded as antiseptics were without effect upon the virus, even in the fresh state. Pure or camphorated alcohol is largely used by surgeons in France to wash their instruments, but is evidently capable of giving only an illusory safety against morbid germs. Quicklime, in which it is often recommended that the bodies of animals dying of anthrax should be buried, and with which the walls of infected places are washed, is no better. At the moment of its hydration some organisms are probably destroyed by the heat which is disengaged, but those which are not in immediate contact with the lime seem to have preserved all their activity. Very thin layers of the tissue of the tumours of anthrax were taken and rolled up and plunged into the quicklime, and left in it for forty-eight hours. At the end of that time they were rubbed up with water, and the liquid was found to possess full virulence. The inutility of tannic acid suggests the question whether tanning is really adequate to destroy the poison in the hides of the affected animals, and it is clear that salting has no influence on the virus contained in the flesh, etc. Quinine, so powerful in the paludal diseases, which are now believed to be due to organisms, was found to have no influence over the bacteria of anthrax. Ammonia and its compounds were also powerless. Ammoniacal fermentation, therefore, which is said to destroy some bacteria, does not influence those of anthrax. Sulphate of iron and chloride of manganese, substances which have been strongly recommended as disinfectants, were equally powerless. Further, the sulphurous acid, which is so potent in action upon some parasites of high organization, and on many forms of virus, has no influence on the bacteria of symptomatic anthrax. Chlorine and sulphide of carbon, which destroy the fresh virus, are powerless against that which has been dried. Of all the vapours bromine is the only one which seems to offer complete security. Another important result, from a surgical point of view, is the action of carbolic acid. A 2 per cent. aqueous solution destroys the activity of the dry virus, but all the power is lost if the carbolic acid is mixed with alcohol. This fact has already been noted by Koch with regard to other kinds of spores. On the other hand, salicylic acid mixed with alcohol preserves its power. Turpentine, recommended by Pasteur, for the purpose of destroying the bacillus of true anthrax, has no influence on that of symptomatic anthrax. At the head of the efficient agents stands corrosive sublimate, of which a solution of 1 in 5000 is sufficient; next come in order nitrate of silver, salicylic acid, and carbolic acid. A 2 per cent. solution of the latter was found, however, only to destroy the organisms when it had been in contact with them for eight hours in the case of the fresh virus, and for twenty hours in the case of that which had been dried.

The practical deductions from these experiments are obvious, and are of the highest importance. So far as their use against symptomatic anthrax is concerned, the choice of agents to destroy the fresh virus in stables, etc., is a wide one. That for the dried virus, however, is more limited; only the bromine vapour can be regarded as affording complete security. For washing down places the most efficient agent, corrosive sublimate, is rather dangerous. Solutions of sulphate of copper, carbolic acid (2 per cent.), or salicylic acid (0·1 per cent.) are recommended. For the effectual disinfection of carcases, however, no agent should be trusted but combustion; but if this is impossible it should be cut deeply and treated with corrosive sublimate, sulphate of copper, or carbolic acid.

Practitioners of veterinary medicine have the great advantage of being able to bring these questions to the test of experiment much more perfectly than is possible with regard to many of the diseases of man. It would be extremely important, for instance, to have a similar series of experiments as to the influence of the various disinfectants on the virus of scarlet fever and other maladies which are not transmissible to the lower animals. Too little regard has certainly been paid to the differences possessed by different germs in their capacity of resistance, and the results obtained in the case of one have been applied too freely to all.

* From the *Lancet.*

OCCURRENCE OF BASSORA GUM IN CYCADEÆ.*

BY C. R. BLACKETT.

Baron von Müeller, the Government botanist, in the course of his scientific researches upon some hitherto undefined species of cycadaceous plants, being anxious

* From the Australian Supplement to the *Chemist and Druggist*, May, 1882.

to examine the gum exuded by *Macrozamia Fraseri*, collected by Mr. John Forrest, the Australian explorer, and *Macrozamia Miguelli*, procured by the Rev. Dr. Wools, requested me to make an examination as to the character of this gum.

It would seem that hitherto it has not been recorded that a kind of gum is exuded by cycadaceous plants, although the abundance of a peculiar starch in the stems of the Australian Macrozamias has been noticed in various publications, and also in the pages of the *Chemist and Druggist* by Baron von Müeller. This gum is similar to Bassora and cherry gum, is secreted both from the stem and fruit-cones of the Macrozamias; in general appearance it is not unlike gum acaciæ, it is very tough and of a brownish colour. In the experiments upon these gums from *M. Fraseri* and *M. Miguelli*, it was found that they were with difficulty fractured, and swell up and soften on being macerated in cold water, becoming transparent gelatinous masses, and not rapidly dissolving; by long-continued digestion in boiling water, the less soluble matter is gradually brought into solution; the clear solution dried at 100° C. forms a clear and hard gum, adhesive to the touch of the slightly moistened finger. The addition of potassic hydrate renders the gum readily soluble, but darkens the colour considerably. In water, acidulated with H_2SO_4 it is soon dissolved, and a flocculent precipitate is formed, and after boiling for a short time the presence of sugar was detected on the addition of Fehling's copper test; absolute alcohol produced only a slight turbidity in the watery solution. The latter will keep undecomposed for several days, and dries up very slowly; therefore, this gum, even if more adhesive, could not be used as a substitute for gum arabic. Ferric chloride produces no action upon the solution whatever. The ash yielded was found to be equal to 1·75 per cent., and composed of lime, iron, sodium, potassium, carbonic acid, sulphuric acid and chlorine.

This gum is therefore analogous to Bassora gum, or tragacanth, and similar gummous exudations of plants; whether it can be used instead of gum tragacanth has yet to be tried. This gum was not found to possess any of the deleterious acridity which pervades the sap of the cycads generally, and which renders their fruit, in a raw state, poisonous. Since writing the above, I find that Dr. Pereira, in his 'Materia Medica,' p. 288, vol. iii., under Cycas, says—"A clear mucilage, which converts into a gum-like tragacanth, exudes from fresh wounded plants of several species of cycas."

Gum of Bassora, which appears to be the produce of a cactus, is white and honey-coloured, mealy, and silvery on its surface, and in the form of somewhat flattened and elongated masses. It is insipid, and crackles between the teeth. In water it swells up to a transparent jelly, but only a small portion dissolves. The soluble portion contains arabin, amounting to about 1 per cent. of the gum; the insoluble portion contains bassorin. It dissolves with the aid of heat in potash and weak acid.—'Watts's Dictionary,' p. 955.

Baron von Müeller informs me that he has "just obtained a specimen of gum from *Brachychiton ramiflorum*, which behaves like the bassorin gum of the Cycadeæ." He also says:—"In my travels I have noticed gummous exudations from all the brachychitons and sterculias in Australia, including the famous 'bottle-trees,' and I have no doubt that the gum of the various sterculia trees of the tropics of Asia, Africa and America consists of bassorin, one species from Western Africa being described by Professor Lindley as *Sterculia tragacantha*, on account of the tragacanth-like gum exuding from its stem and branches. Whether by chemical action this bassorin gum can be turned to important practical uses has yet to be seen."

THE PURIFICATION OF COMMERCIAL ALCOHOL.*

BY A. RICHE.

It is known that in fermentation sugar does not split up exclusively into alcohol and carbonic anhydride, according to the equation of Gay-Lussac, and Pasteur has shown that glycerine and succinic acid are constantly formed during the alcoholic fermentation. Many others besides these four products make their appearance at the same time, several of which are not yet defined, but mention may be made of most of the alcohols and acids of the fatty series; the aldehydes, their isomers and various derivatives; and isopropylic acid.

Alcohol is now manufactured from the most varied materials: fresh and dried grapes; beetroot and beetroot molasses; various grains, such as barley, rye, maize and rice; saccharine fruits, as figs, dates, plums, and mulberries; and several starches. Some of the bodies contaminating commercial alcohol are derived from the material used as the source of the alcohol, and are only met with if the alcohol is derived from a particular material.

The temperature to which the fermented liquor is subjected in the distillatory columns also determines the formation of contaminating products, and notably of substances possessing a disagreeable odour and taste; so that the number of compounds affecting the purity of alcohol is very large and very diverse in nature. In weight they only represent a very small portion of the alcohol, but this quantity is nevertheless sufficient not only to give the alcohol a special flavour, but also to render it more injurious for consumption than pure vinic alcohol.

It is therefore very important to free the alcohol from these impurities. At first it was hoped that this could be done by several rectifications, and M. Pierre effected it by frequently repeated operations conducted at the lowest possible temperature. But on a manufacturing scale this is impracticable, because the distillatory columns are heated strongly and for a long time, so as not to leave any alcohol in the residues: at most one third of the product would be alcohol of good flavour, and that would be still far from pure.

At the commencement of the distillation the first runnings consist of alcohol having a bad flavour (*mauvais goût du tête*), due especially to aldehydes and alcohols; then the runnings become less impure (*moyen goût de tête*). Alcohol of good flavour is collected towards the middle of the operation, and the remainder constitutes the last runnings (*moyen goût de queue* and *mauvais goût de queue*), which contain the higher alcohols and empyreumatic oils.

Attempts have been made to purify the alcohol by means of wood and animal charcoal, but with very imperfect results. Oxidation both by treatment with various oxidizing bodies, and by the action of a current of air has also been tried, but with indifferent success, in consequence of the loss of alcohol. Considering the fact that the most active and odorous of the contaminating compounds are aldehydes,—vinic, butylic, amylic, etc.,—M. Naudin conceived the idea of getting rid of them by a process of hydrogenation, and this he has carried out practically by means of the copper-zinc couple.

If a plate of zinc be immersed in a solution of a salt of copper it becomes covered with a metallic deposit, and eventually constitutes a true copper-zinc couple, in which the copper exists in a finely divided state. Thus prepared the couple is capable of decomposing pure water, with evolution of hydrogen and formation of hydrate of zinc. It can consequently act freely in neutral liquids and constitutes a powerful agent of hydrogenation. If an alcoholic distillate indicating 40 to 65 alcohometric degrees be brought into contact with such a couple in action it is found that the hydrogen evolved is absorbed

* Abstract of a paper in the *Journal de Pharmacie*, [5], v., 480.

and that the odour and taste of the distillate disappear rather rapidly. The distillates of maize and beet molasses thus hydrogenated, when rectified in the ordinary apparatus, show an augmentation of 25 to 30 per cent. of good flavoured alcohol over the old yields.

In the apparatus of M. Naudin zinc cuttings are placed in successive beds of 15 to 20 centimetres in thickness, supported on wooden diaphragms pierced with holes in a vat made of wood, copper, or iron. At the commencement of the operation a sufficient quantity of 5 per cent. solution of sulphate of copper is run into the vat. The decoloration of the cupric solution marks the completion of the precipitation of the copper in a pulverulent state upon the zinc cuttings, and the couple is then ready for work. The resulting solution of sulphate of zinc is run off, and the vat is filled with the distillate to be purified.

By a special arrangement, the alcohol is kept circulating in the vat, but the time required for it to remain in contact with the couple is not always the same. This necessarily depends upon the degree of contamination in the product to be purified, the temperature at which the hydrogenation takes place, and the condition of the couple. Temperature, especially, has a considerable influence upon the rapidity of the reaction; for instance, a sheet of zinc covered with precipitated copper gave in one hour at 2·2° C. 1·2 c.c. of hydrogen, and at 98° C. in the same time 528 c.c. The temperature of the liquor in the vat is controlled by a worm through which hot water or steam can be passed. When the hydrogenation is completed, the distillate is passed on to the rectifying column.

The hydrogenating action of metallic couples is generally sufficient for the entire purification of the distillate, and in the case of distillates from grain and beet molasses, the increase in the yield of good flavoured alcohol in the first runnings is 25 to 30 per cent.

But this treatment, although sufficient for many distillates, does not sufficiently improve those obtained directly from beet, and in these cases M. Naudin completes the action by electrolysis by means of electric machines. The distillate from the beet is first left in contact with the copper-zinc couple a sufficient time (two days or more) to ensure its complete hydrogenation and then, nearly purified but having still a slight flavour of its origin, it is acidulated by means of sulphuric acid and sent into a special arrangement of voltameters. The number of voltameters coupled varies with the intensity of the action required, and the quantity of distillate to be purified. In practice, in a factory running 6000 or 7000 gallons daily, twelve voltameters are in couple, and the electrolytic action is regulated by disconnecting or placing in circuit the required number. It is evident that in this operation there must be some oxidizing action, and to this extent it would appear to be open to the same objection as the processes based upon oxidation.

M. Pictet has recently announced that he effects the purification of alcohol by rectification carried on at a low temperature, and that this operation is carried on in a large scale in Paris. The distillates, or even the musts, are placed in a large boiler surmounted by a rectification column, above which rises a condenser surrounded with cold water, which condenses the less volatile products so that they run back into the boiler. The vapour not condensed here, passes into a refrigerator, surrounded with cold water, where they are completely condensed. The first runnings (*goûts de tête*) are collected in a receiver; next comes the good flavoured alcohol, which is then run into a second boiler.

The first still is connected with an air pump, by which a more or less complete vacuum can be produced, and the temperature thus regulated. In the second still a nearly complete vacuum is produced, so that the temperature falls quickly. The vapour which issues from it consists of nearly pure alcohol, because the few foreign bodies which pass into the first distillation do not give off vapour at the temperatures, varying between − 10° and 5°, which obtain in this part of the apparatus.

The vapour of alcohol thus purified rises into a second rectification column, terminated by a refrigerator cooled by liquid sulphurous anhydride, in which is maintained a temperature between − 25° and − 50°. The first portion is collected in a special vessel and withdrawn; the remainder is pure alcohol.

IS GELSEMIC ACID IDENTICAL WITH ÆSCULIN? WITH OBSERVATIONS ON THE PREPARATION, PROPERTIES AND RECOVERY, WHEN ABSORBED, OF THE IMPORTANT CONSTITUENTS OF GELSEMIUM SEMPERVIRENS, AND GELSEMIUM POISONING.*

BY THEODORE G. WORMLEY, M.D.,

Professor of Chemistry in the Medical Department of the University of Pennsylvania.

In the *American Journal of Pharmacy* (Jan., 1870) the writer announced that *Gelsemium Sempervirens* contained a non-nitrogenized principle, of an acid reaction, which was named *gelseminic*, or *gelsemic* acid; and also a strongly basic principle, which was named *gelsemia*, or *gelsemine*.

From a subsequent examination of the constituents of the plant, M. Sonnenschein and Charles Robbins concluded that the so-called *gelsemic acid* was identical in properties and composition with the glucoside *æsculin*, found in the bark of the horse-chestnut, and certain other barks (*Ber. der Deut. Ges.*, Sept. 1876, 1182).

Before examining this question of claimed identity, the method, of several employed, which we have more recently found the most satisfactory for the extraction of the two important constituents of the plant, will briefly be given.

Preparation.—100 grams of the powdered dry root are macerated for two days in 400 c.c. of a mixture of equal parts of water and alcohol of ·815, the mixture being slightly acidulated with acetic acid and occasionally warmed and agitated. The liquid is strained through muslin, and the solids well washed with water containing a little alcohol, the washings being collected with the first liquid. The whole is evaporated to about 200 c.c., and allowed to stand until the resinous matter has deposited. The liquid is then filtered, concentrated to about 80 c.c., and, if necessary, again filtered.

1. *The non-nitrogenized principle.*—This is extracted from the concentrated liquid, while it still has an acid reaction, by ether, in the usual manner, using three or four volumes of the liquid in two or three portions.

The crystals obtained on evaporation of the ether are washed with a little absolute alcohol, which readily dissolves the adhering colouring matter. The residue may be further purified by a second extraction by ether.

A very good method of purifying the substance, especially from the last traces of the alkaloid, is to dissolve it in about 250 parts of water, by the aid of a few drops of ammonia, and then treat the clear solution with diluted hydrochloric acid, added drop by drop until the point of neutralization is almost, but not fully, reached, taking care that the first cloudiness or precipitate produced has fully crystallized before adding another drop of the acid. The crystals are collected on a small filter and washed with a little cold water.

2. *Gelsemine.*—The liquid from which the former principle is extracted was gently warmed until the dissolved ether has been expelled. It is then rendered slightly alkaline by sodium hydrate or carbonate, and the liberated base extracted by ether, which is allowed to evaporate spontaneously.

The impure alkaloid thus obtained is dissolved by the aid of a few drops of hydrochloric acid in about 12 c.c. water, the solution filtered, and the filtrate treated with a very slight excess of sodium hydrate, when a large portion of the alkaloid will separate as a pure white

* From *The American Journal of Pharmacy*, July, 1882.

precipitate. This is quickly collected on a filter and washed with pure water. The remaining portion of the alkaloid is extracted from the filtrate by ether or chloroform.

From the dried root of the plant we obtained, after this manner, ·25 per cent. of gelsemine and ·50 per cent. of the acid principle.

Is Gelsemic Acid Identical with Æsculin?

For the purpose of answering this question various samples of the gelsemium principle were examined comparatively with a sample of *æsculin* prepared by E. Merck, of Darmstadt. It consisted of a spongy, sparkling white mass of minute (microscopic) needles and prisms. On comparing it with a somewhat coloured preparation obtained from horse-chestnut bark, the substances presented essentially the same properties in the several respects examined.

This comparative examination showed:

A. These principles agree more or less in the following respects:

1. Both substances are readily soluble in the *caustic alkalies*, forming solutions which have a yellow colour by transmitted, and appear blue by reflected light, the fluorescence appearing in both instances, even in very highly dilute solutions, being distinctly marked in a 100,000th solution.

The fluorescence of the gelsemium principle, however, is *greenish blue*, whilst that of æsculin is deep *sky blue*. The fluorescence in both instances is destroyed by free acids.

2. *Nitric acid* dissolves both substances with a yellow colour, and the solutions, when treated with excess of ammonia, assume a deep red colour. This red coloration may be obtained from even the $\frac{1}{50000}$ of a grain of either substance.

The nitric acid solution of the gelsemium principle, when present in sufficient quantity, has an orange-red colour, whereas that of æsculin is yellow.

B. They differ more or less in the following properties:—

1. *Crystallization.*—The gelsemium compound very readily assumes the crystalline form, even in the presence of comparatively large proportions of resinous matter, whereas *æsculin* crystallizes with some difficulty, even from pure solutions. Thus the $\frac{1}{10000}$ grain of the former substance, when separated from 1 grain of solution, is left in the form of needles, whilst crystals can only be obtained from rather strong solutions of æsculin, and then usually appear as transparent spherical masses, with some dense tufts of short prisms.

2. *Solubility.*—*a. Water.* The gelsemium substance, when pure, requires 2912 parts of water for solution, even when excess of the powder is kept in contact with the liquid at a temperature ranging from 18° to 24° C. (65° to 75° F.), for twenty-four hours.

Under like conditions, Merck's æsculin dissolved in 401 parts of water. According to Trommsdorff, æsculin requires 576 parts of water for solution, but according to Minor it dissolves in 300 parts (Gmelin's 'Hand-Book,' xvi., 22).

b. Ether. One part of the gelsemium principle was readily taken up by 330 parts of *ether* of specific gravity ·728, whereas *æsculin* required at least 36,000 parts of the same fluid for solution.

So also, the former principle is rather freely soluble in *chloroform*, whilst the latter is nearly or wholly insoluble in this liquid.

3. *Sulphuric acid* dissolves the gelsemium substance to a more or less yellowish solution, which when warmed in a water oven (if the substance is pure) undergoes little or no change. Æsculin readily dissolves in the acid, but on warming the solution it quickly acquires a brownish or chocolate colour and becomes charred.

If a drop of aqueous ammonia be allowed to flow into a drop of the sulphuric acid solution of the gelsemium compound, a dirty white deposit or cloud of very minute crystalline needles separates at the margin of contact of the liquids.

If only a minute drop of the acid be employed and excess of ammonia be avoided, even the $\frac{1}{10000}$ grain of the substance will in this manner yield a very satisfactory deposit of needles. If the drop of liquid be allowed to evaporate, these crystals may be re-examined, even several times, by moistening the residue with a minute drop of water, which will quickly dissolve the ammonium salt, whilst the needles will remain, they being apparently insoluble under these conditions.

This reaction is highly characteristic of the gelsemium principle.

A sulphuric acid solution of *æsculin* under like conditions fails to yield any crystals, unless a comparatively large quantity is present and the mixture be evaporated to about dryness, when transparent nodular masses with some groups of prisms may appear.

4. *Hydrochloric acid* fails to dissolve or act upon the gelsemium compound, even under the heat of a water-bath. Æsculin is readily soluble in this acid.

In the following liquid reactions the results refer to the behaviour of a few drops of $\frac{1}{100}$ solutions of both principles.

5. *Nitrate of silver* produces in a solution of the gelsemium principles a copious brownish-yellow precipitate, which soon darkens in colour, and finally the mixture becomes deep blue-black, due to the reduction of the silver salt. This reaction will manifest itself, after a time, even in a $\frac{1}{50000}$ solution.

Æsculin yields from a $\frac{1}{100}$ solution, a slight dirty yellow precipitate, which remains unchanged for several minutes; it then slowly darkens.

6. *Corrosive sublimate* throws down a copious yellowish precipitate, from which the organic acid quickly separates as large tufts of needles.

Æsculin fails to yield a precipitate or crystals.

7. *Bromine* in *bromohydric acid* produces a copious green deposit, which quickly acquires a bluish and finally a brownish colour.

Æsculin yields a slight yellow precipitate, which becomes yellowish-grey.

8. *Sulphate of copper* causes in a solution of the acid a dirty brown precipitate, which soon assumes a dull red colour, and crystalline needles separate.

Æsculin yields a bluish-white deposit, which undergoes little or no change.

9. *Acetate of lead* (neutral) produces a copious yellow precipitate, which after a time is partly changed into very minute star-like groups of crystals. These are insoluble in ammonia, but readily soluble in acetic acid, being quickly replaced by slender needles of the free acid.

Æsculin yields a somewhat similar precipitate, but no crystals were obtained.

10. *Physiological action.*—*a.* 0·010 gram (about $\frac{1}{6}$ grain) of the gelsemium principle was administered hypodermically to a frog. After a few minutes the eyes were fluorescent, and the animal seemed sluggish; after half an hour it was somewhat excited and apparently weak. No other marked symptoms were noticed during the several hours the animal was observed

A similar quantity of *æsculin* produced fluorescence of the eyes, but no other apparent effect.

b. 0·033 gram ($\frac{1}{2}$ grain) of the gelsemium substance, prepared by precipitation with hydrochloric acid, being injected into the peritoneum of a frog, was quickly followed by violent agitation; the animal became rigid, and reflex action was markedly diminished. In *five minutes* the animal was apparently lifeless; there was rigidity of the abdominal muscles, which slowly relaxed. After forty minutes, the heart had ceased to beat, was relaxed and not irritable.

c. A similar quantity, injected into the posterior lymph sack, was quickly followed by great agitation and general prostration. In fifteen minutes active voluntary movements appeared, and there was marked fluorescence of the entire eye-ball. After forty minutes the heart was found still beating, but ceased fifteen minutes later.

In another experiment, a like quantity caused a complete cataleptic condition and death within ten minutes.

d. 0·033 gram of *æsculin* injected into the peritoneum of a similar frog produced *no apparent effect*, other than a marked fluorescence of the eyes, which continued some fifteen hours.

For these physiological experiments, I am much indebted to Dr. Edward T. Reichert. These results, in regard to the gelsemium principle, confirm in a measure those previously obtained by Dr. Isaac Ott (*American Practitioner*, 1877).

Conclusions.—It is needless to add that the only conclusion from the foregoing comparative results is that the principles examined *are very different substances.* Hence the name *gelsemic acid* will be retained provisionally for the gelsemium principle.

Gelsemine.—As supplementary to our former paper on the subject, some of the more important properties and reactions of gelsemine may be mentioned.

In its pure state gelsemine is a colourless, odourless solid, having a persistent bitter taste. It has not yet been obtained in the crystalline state. At something below 100° C. it fuses to a colourless liquid. Gelsemine completely neutralizes acids, forming salts, most of which are freely soluble in water and alcohol.

The pure alkaloid is soluble, under ordinary conditions, in 644 parts of water. It is freely soluble in ether and in chloroform.

The most characteristic reactions of the solid alkaloid are the following:

1. *Sulphuric acid* dissolves gelsemine with a reddish or brownish colour to a solution which after a time assumes a pinkish hue. If the solution be warmed on a water-bath, it acquires a more or less purple or chocolate colour.

If a small crystal of *potassium bichromate* be slowly stirred in the sulphuric acid solution, reddish-purple streaks are produced along the path of the crystal. If the potassium salt be used in the form of *powder*, or, as advised by Sonnenschein and Robbins, be replaced by *ceric oxide* (CeO_2 formerly Ce_3O_4), the purplish or reddish-purple coloration manifests itself more promptly and strongly, and may be obtained from even the one ten-thousandth grain or less of the pure alkaloid. For the detection of these minute quantities, however, it is essential that only very minute quantities of the acid and powder be employed.

This reaction of gelsemine—as remarked by Sonnenschein and Robbins, who first observed it with the cerium compound—resembles somewhat that of strychnine; but these alkaloids could not thus be confounded.

2. *Nitric acid* causes gelsemine to assume a brownish-green, quickly changing to a deep *green* colour, which slowly diffuses itself through the liquid. Almost the least visible quantity of the alkaloid, if touched with only a very minute drop of the acid, will yield this green coloration in a marked degree.

This reaction readily distinguishes gelsemine from strychnine and the other alkaloids.

Solutions of the *salts* of gelsemine are colourless, and have the strongly bitter taste of the alkaloid. These solutions yield precipitates with a number of different liquid reagents, even in some instances when highly dilute; but in no instance is the reaction peculiar to this alkaloid.

Physiological action.—0·008 gram ($\frac{1}{8}$ grain) of gelsemine, administered hypodermically to a cat, caused very marked symptoms in fifteen minutes, and death in one hour and a half.

0·010 gram, given to a frog, produced, after half an hour, great prostration, followed by tetanic convulsions and death in about four hours.

0·033 gram of the alkaloid, in the form of chloride, was injected into the peritoneum of a frog. The animal soon opened its mouth convulsively, the jaws fell at intervals, and there was quickly great muscular prostration. In twenty minutes the body was completely relaxed; the muscles not irritable under pricking; reflex action was greatly dimished, and life seemed to be extinct. On opening the thoracic cavity it was found that the heart had been arrested in diastole and was not irritable.

Gelsemium Poisoning.—The cases of gelsemium poisoning thus far reported have been, with two or three exceptions, the result of accident or ignorance. The preparation of the drug most frequently employed is the *fluid extract*, each fluid ounce of which represents 480 grains of the dried root. This preparation, as found in the shops, as we have heretofore shown (*Am. Journ. Pharm.*, 1877, 151), usually contains ·2 per cent. of gelsemine and ·4 per cent. of gelsemic acid.

Of *twenty-five* cases of gelsemium poisoning that we have collected (some private), *thirteen* proved fatal. The *fatal period* varied from *one hour* to about *eight* hours. Very small quantities of the drug may cause death. A case is reported in which a quantity of a tincture equivalent to about 12 *minims* of the fluid extract proved fatal to a child aged three years. In another instance, four doses of 15 *minims* each of the fluid extract, repeated at short intervals, caused the death of a healthy man in less than four hours after the last dose was taken. So, also, a teaspoonful of the same preparation proved fatal to a woman.

There is no chemical *antidote* known for this kind of poisoning. The application of *electricity* has in several instances proved very beneficial. In others, the use of *morphine* hypodermically has been attended with good results.

Chemical analysis.—In gelsemium poisoning the gelsemic acid and the alkaloid are both absorbed, and enter the blood apparently in the proportion in which they are found in the plant. Hence, in poisoning by the drug, it becomes necessary to direct the examination for the absorbed poison to the recovery of both these principles. This is the more important, since the acid is apparently not much less poisonous than the alkaloid, and so readily reveals its presence by its fluorescent properties.

The general method for the recovery of strychnine and like substances from the blood and tissues is about equally applicable for the recovery of the gelsemium principles. As these substances are readily soluble both in ether and chloroform, either of these liquids may be employed for the extraction. The gelsemic acid would, of course, be found in the ether extract from the prepared solution, while it still had an acid reaction; whilst the alkaloid would be extracted from the solution after it had been rendered alkaline.

In applying the tests for gelsemic acid to the ether residue from the acid solution it should be remembered that although the reaction of the nitric acid and ammonia test is common to gelsemic acid and æsculin, yet when obtained from an *ether* extract, it is characteristic of the former substance, since æsculin is not extracted by ether.

The blood and liver of a cat which had been killed, after several hours, by the drug, were examined, in the main, after this general method. The first ether extract, in both instances, was distinctly fluorescent, and on evaporation left the gelsemic acid, in part at least, in its crystalline state. The true nature of these crystals was readily established by the appropriate tests. So, also, about equally satisfactory evidence of the presence of gelsemine was obtained from the ether residues from the alkaline solutions.

As a conclusion from these and other similar results, it would appear that in gelsemium poisoning evidence of the presence of the poison in the blood may be more readily and fully obtained than in the case of any of the other vegetable poisons.

MANUFACTURE OF LACTIC ACID.*

BY CHARLES E. AVERY.

When milk turns sour spontaneously, the sugar of milk which it contains is converted into lactic acid, and Scheele, in 1780, first extracted lactic acid from sour milk.

Braconnet found the same acid in rice left under water to ferment, also in the juice of beet-root, which, after having undergone viscous fermentation, became sour and yielded lactic acid. He also found the acid in products of fermentation of many other vegetable infusions.

The same acid has been found in the sour water of starch factories, and in the well-known fermented cabbage of sauerkraut.

By lactic fermentation is understood the transformation of certain sugars, such as sugar of milk and glucose, into a syrupy acid, soluble in water, under the influence of a living being classed by the eminent French chemist and microscopist, Pasteur, among the bacteria.

Messrs Frémy and Boutron, Pelouze and Gelis, ascertained the best conditions for the production of lactic acid, and found it, they say, to require the aid of nitrogenous albuminoid matter in a state of decomposition, and for its continuance that the acidity should be kept down by neutralization. For this purpose they used oxide of zinc, carbonate of soda, or, as I prefer, the carbonate of lime, that is to say, whitening or marble dust.

Pasteur brought out the idea that the albuminoid matter was non-essential, that it could be substituted by inorganic salts, and that the real cause of the change was not decomposing albuminoids but a living ferment—establishing this latter fact, which before was a conjecture.

It is substantially here that I depart from the beaten track. I find albuminoid matter, though not, scientifically speaking, essential, is essential in a technical point of view. Moreover, it is not essential nor desirable that they should be decomposing albuminoids. I prefer them as fresh and free from putrefaction as possible. As I have no putrefaction in my solutions, the manufacture is no longer a nuisance; the odour with a pure ferment is even fragrant.

To obtain this fresh albuminoid matter at no further expense, and in large quantity, I leave in the glucose solution made from the corn meal the albuminoid residue. And from this substitution I obtain the advantage of cheapness, the advantage of healthfulness, a crude product free from the products of putrefaction, and hence more easily purified; and, lastly, the fermentation takes place in three or four days, instead of requiring ten days to a month, as by other processes.

Bensch purifies his lactate of lime by extraction with water, filtration, and recrystallization, the details at present being non-essential. The only thing worth mention is that he was able to purify his crude material. It will be seen that cane sugar is the source of his lactic acid, costing to start with eight to ten cents per pound, for any article not too dark and impure. To this sour milk and cheese are added, further increasing the expense, and the time required is a fortnight.

Considering the variability of the process, its unsavory nature and products, and the expense, it is not surprising lactic acid and the lactates have received little attention.

I find it is still a common impression among chemists that in the change of starch into glucose by the acid treatment, the transformation is very incomplete; that much of the starch remains as dextrine. This is not the case. By suitable precautions nearly all the starch should turn to glucose, and that this can be accomplished is shown by testing the solutions and residues with odine. Neither starch nor soluble starch is shown. Then by testing the solutions with six times their volume of alcohol, the substantial absence of dextrine may be shown.

Since we have some 70 per cent. of starch sugar in corn, and this converted into glucose will, by assimilation of water, increase in weight some ten per cent., we have as the theoretical yield of acid 77 per cent. Now, Bensch found 9 kilos of cane sugar to yield $10\frac{3}{4}$ kilos of neutral lactate of lime, and it is not surprising that a yield of 82 to 85 per cent. of neutral lactate has been found from 70 per cent. of starch, working by my process.

The process I adopt resolves itself into three portions: 1st, manufacture of solution for fermentation; 2nd, the fermentation; 3rd, the purification; and, lastly, there is the use of the product itself as a separate consideration.

I mix 80 to 160 pounds of oil of vitriol with 2000 pounds cold water, and stir in 2000 pounds ground maize; this corn meal may be from inferior corn, from corn more or less heated, soured, or otherwise changed. The average price of corn of good quality here is about one cent per pound, and much less in the West. Inferior qualities are of less cost. The vitriol can be bought at $1\frac{3}{4}$ cent per pound by single carboy, and would cost much less if chamber acid were used and made on the spot.

I let the meal mixture stand over night, and next morning add in portions 2000 pounds of boiling water. After boiling until the tests are satisfactory, I run the hot mixture into the fermentation tank, and neutralize with 1000 pounds carbonate of lime, stirring well. The carbonate of lime is of course in large excess. I then add 4000 pounds cold water, and a variable amount of lactic ferment; 1 or 2 per cent. seems to answer well, although a larger quantity induces fermentation more speedily, saving perhaps half a day, but less will suffice.

In a day's time the most vigorous action ensues, the carbonic acid released from the carbonate of lime escaping in large bubbles, giving the impression that the liquor is boiling. In three or four days' time, with good lactic yeast, the mass sets into crystals of lactate of lime, resembling thick mortar. I then dissolve the lactate in hot water, filter it, crystallize, press, and purify, much as in other processes, with two alterations, however. I use animal charcoal to remove odour and colour, and after acidulation, distil off the butyric acid that has been formed. By more vigorous precautions in the fermentation, I expect soon to be rid altogether of the butyric ferment, and had, indeed, already greatly reduced it, when a series of mishaps stopped for a time further progress.

From experimental results already obtained on the small scale, I have reason to believe that I can reduce the waste and cost of purification, especially in the direction of animal charcoal, and experiments will speedily be resumed in this direction. I am much assisted in this search by the comparatively clean, pure, crude material with which I start, unlike the foul mass obtained by other processes of practical value. As regards the healthfulness of lactic acid there can be no doubt. Articles containing it have been sought out as food by the human race all over the world. Sour milk, butter milk, and sauerkraut are well known to be wholesome. Their reputation the world over is good, and they are used by labourers and peasantry as regular articles of diet. If there were any doubts, these would be dispelled when I state that lactic acid is present in the flesh itself, and in the mother's milk; that lactic acid is an active agent in the digestion of food in the stomach, and a constituent of the gastric juice. For this reason it is given medicinally for the cure of dyspepsia, as in the well-known preparation of lactopepsine.

As to the value of lactic acid and acid lactates in raising bread, as substitutes for cream of tartar, there can be no question, for sour milk always has raised bread, and made good bread, and cream of tartar is a

* From the *Proc. Soc. Arts*, Boston. Reprinted from the *Weekly Drug News*, July 21, 1882.

substitute for lactic acid rather than lactic acid a substitute for it. At present prices of milk the cost is greatly reduced. The corn is not fed to the cow partly to be wasted in maintaining heat and life, and partly to be returned as fat and decomposed sugar; but by a simple change turns almost completely to lactic acid. In one respect, however, I think an advantage may be fairly claimed for the acid lactate of lime over cream of tartar, namely, it will be hard for any cook, no matter how careless, to make either sour bread or alkaline bread, and every cook has such failures with cream of tartar. In cream of tartar, or acid tartrate of potash, the acid molecule reacts on the saleratus to free the gas; unless the exact proportions be hit and the mixture be complete, the bread is alkaline wholly or in spots if the saleratus be in excess, and sour if the acid tartrate be in excess.

The acid lactate is a permanent salt, not readily changed to butyrate; not diliquescent; not too gum-like to resist powdering.

In Miller and other works of good standing it is stated the raw corn meal under like conditions had but partly changed to lactic acid in forty days. Technically speaking, corn meal cannot furnish lactic acid unless the starch be first transformed. Nor will it then give lactic acid in quantity unless the albuminoid matter be either added or left in the presence of the nitrogenous phosphatic salts, if the neutralizer of the ferment is not a fulfilment of all the conditions for large and varied yield; we must at present have albuminoid matter present. It has been fully shown that it is not essential that this albuminoid should be rank or putrid, but that better and quicker results were obtained with fresh vegetable albuminoids than with stale animal albuminoids. I have improved the purification by introduction of animal charcoal and distillation, and have made the operations inoffensive. With regard to cheapness, little needs to be said. With a yield of lactic acid equalling 50 per cent. of the weight of corn employed, with meal at 1 cent per pound, chalk or whiting at $\frac{1}{8}$ of a cent, and sulphuric acid at $1\frac{1}{4}$ cent, coal being assumed at 6 dollars per ton, the cost of materials for 1 pound of lactic acid is about $4\frac{1}{2}$ cents.

By shrewd location of the factory, and good buying in large quantities, these expenses may be largely reduced.

The operations of manufacture are not unlike those of the sugar refinery, and those are known not to be excessive.

CHINESE RHUBARB.*

Curiously enough the Chinese attach but small importance to that most valuable of roots, rhubarb. In so far as they themselves are concerned, other drugs take its place, although it seems beyond dispute that at one time they were of opinion that if supplies were cut off the detested foreigners of the north would all die of constipation. This anecdote is well vouched for; indeed, prior to the outbreak of war in 1839–40, the *terrible* threat was actually held out, Lin, or Keshan (the same Ki-chan subsequently met with by the Abbé Huc at Lla-Ssa, Thibet. This statesman was not executed as commonly supposed, for ceding Hong Kong), we forget which, was so firmly persuaded of the fact as to memorialize the Emperor regarding the advisibility of forbidding the export of rhubarb, and thus starve the foreigners into submission. But dropping anecdote, rhubarb grows wild in all the northern and western provinces, yet nowhere does it seem to be brought under cultivation, invariably being found in a wild state. Several varieties of rheum plant are indigenous to China, some being inestimably valuable, and others almost worthless. Shênsi roots are by far the most esteemed—those coming from the Kanchow district being perhaps the more prized of all. This rhubarb, the best in the market, can be readily distinguished from other kinds. The roots are large, smooth, and extremely fragrant; whereas those obtained in the province of Szechwan are smaller, rough on the exterior, deficient in flavour, and when cut give out little scent. Best Szechwan rhubarb commands only about one half the price asked for Shênsi rhubarb, while inferior qualities fetch from one-tenth upwards. In this connection it is interesting to note how strongly many Chinese hold by the belief in the utter inefficacy of roots grown in the southern provinces, which, according to their theory, are only good to sell to the English barbarians. As a fact, Russian merchants look at no rhubarb that does not bear on its face evidence of a northern derivation. In this, unfortunately, they are not imitated by their English rivals, who buy anything that is offered so long as the price is sufficiently tempting or holds out a prospect of additional profit. This points to the necessity of medical men and retail druggists exercising extreme care in the selection of their rhubarb, and perhaps, more important still, to buy only of persons in whose judgment and honesty they can place entire dependence.

Another good sample arrives at Tientsin from Hsining in Kansuh, after which town it takes its name. Chungch'i rhubarb is also greatly prized, while Chihuang, Taihuang, and Shanhuang, are about as worthless as well can be. Doubtless, however, as Mr. Detring remarks, a considerable percentage of inferior rhubarb is nothing more than dock plant root, sold under the fashionable name. Upon the properties of this sham we cannot speak authoritatively, but quite likely it possesses properties similar to those of the yellow dock and other European species of this order. It is not exactly pleasant to contemplate that the greater part of this rubbish is bought for the English market, but such nevertheless appears to be the case. The other producing districts besides those mentioned above are Chihli, Honan, and different parts of Thibet, from whence several very fine varieties, formerly sent overland, *viâ* Kiakhta through Russia, are obtained.

* From a paper on the Chinese Materia Medica, by F. Newcome, in the *Medical Press and Circular*, August 2.

AMERICAN MUSK.*

BY R. S. CHRISTIANI.

One of the most important substances for the perfuming of toilet soaps is musk; it is also the most expensive, and owing to the large amount of adulteration it is the most unsatisfactory article the manufacturer has to use.

Much of this trouble and expense can be avoided by the use of what I term "American musk," obtained from the musk rat (*Fiber zebithicus*), the well-known rodent, native of the United States and found in nearly all parts of it, frequenting the streams and marshes, and having habits similar to the beaver.

The musky secretion is found in two sacks, situated between the anus and the genital organs, and is emitted by the animal when excited. These animals are easily trapped and killed for their skins, which are shipped in large quantities to Europe at this season of the year. The fur though looking coarse, from the longer hairs, is very soft and fine beneath, and is dressed and coloured and largely used for the cheaper furs.

To the manufacturer of toilet soaps the American musk is almost invaluable, being nearly as good and as strong as the real. The reaction of the alkali, necessary to all soap, having a softening and modifying property upon the strong odour, which is also improved by the addition of the spice oils and other perfuming substances.

I have for many years used this substance in soaps, sachet powders, etc., but do not recommend it for essences, though much is used in the cheaper kinds. In using it in soaps I have found that time is required to improve the odour, and when a cake of soap so perfumed has been kept for a few months, it would require a very skilful perfumer indeed to distinguish the odour from that of the best tonquin musk.

The Pharmaceutical Journal.

SATURDAY, AUGUST 5, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DECISION OF THE PRIVY COUNCIL AS TO THE PROPOSED ADDITIONS TO THE POISON SCHEDULE.

THE decision at which the Privy Council has arrived after consideration of the resolution submitted to it by the Council of the Pharmaceutical Society will doubtless be disappointing to those who were mainly instrumental in bringing about the action of the Society's Council. Of course it was not unknown that one of the chief reasons for recommending that spirits of salts, oil of vitriol, hellebore, etc., should be made poisons within the meaning of the Act was the systematic misuse of these materials by waggoners and other persons entrusted with the care of farmers' horses. The evil is no imaginary one; but if we may judge from the decision of the Privy Council, it is one that farmers and owners of horses will have to find some other remedy for besides the restriction of trade which was recommended to be enforced under the provisions of the Pharmacy Act.

From the pharmacist's point of view also a lesson may be learnt from the refusal of the Privy Council to give effect to the recommendation of the Council. It shows how little reason there is to hope for any protection of pharmaceutical interests by legislative enactments and how much more necessary it is that any such protection as those interests require should be provided by the united voluntary action of those most concerned. That the sellers of drugs should have a technical acquaintance with the articles they deal in is a proposition that will be readily assented to from the point of view of public interest alone, and from similar considerations it will be even more readily admitted that those entitled to prepare medicines for use by the sick should have a special qualification; but beyond this point it does not appear to be in harmony with the spirit of the age to push the demands for class protection. The recognition of the need for qualification being, therefore, all that seems to be obtainable from the legislature on the ground of regard of the public interest, it does not require much acumen to perceive that, if pharmaceutical interests require protection, the means of providing it is in the hands of those whose business it is to regulate and supervise the grant of that qualification. It is by such a mode of procedure as Mr. SCHACHT has devised in regard to educational training and the conditions under which examinations are conducted with a view to registration, that the protection of pharmaceutical interests is to be most thoroughly secured. That is a means which is already within the power of the Council and it is one which the Council should be supported in the application of to the very utmost. In this free trade age, when popular opinion, blinded by the glare of co-operative fallacies, has lost the faculty of judgment as to sound views of political economy, it seems almost hopeless to seek for a rational recognition of the value of pharmaceutical services on the basis of abstract principles, and nothing remains, meanwhile, but to make the best use we can of such powers as we have command of.

It is, in short, by enforcing to the utmost possible degree the stringency of the test by which qualification to carry on the business of the pharmacist is obtained that we may best hope to effect an improvement of the condition and status of those engaged in that business. It is highly improbable that we shall ever go back to the conditions of restriction which are still in force in some other countries. These conditions belong to a past epoch of society, and though they may for a while remain in countries where they have long been in existence, there is little prospect of their introduction in other countries where they have not before been operative. Even in Germany, where the restrictive system of regulation is most in force as regards pharmaceutical affairs, we have abundant evidence that it is maintained only by great effort, and that the growth of antagonistic influences is so rapid as to portend its overthrow at no very distant period. With such a tendency everywhere evident, what have pharmaceutical interests to look to for protection but the maintenance of individual qualification, and the joint efforts of all belonging to the business to secure that condition in the highest degree?

THE REGULATION OF PHARMACY IN WISCONSIN.

THE Wisconsin Pharmacy Act, which has furnished the opportunity for a pleasant courtesy, referred to at the meeting of the Council on Wednesday, is a very recent addition to the pharmaceutical legislation of the United States, having been passed in March last. In form it very closely resembles the Illinois Act of last year, and as it fairly represents one phase of American opinion as to the best way of regulating the supply of medicines and poisons, some space may be devoted to an analysis of it.

The Act commences by making it unlawful for any other person than a registered pharmacist to "retail, compound, or dispense drugs, medicines or "poisons, or to institute or conduct any pharmacy, "store or shop for retailing, compounding or dis-"pensing drugs, medicines or poisons," but it permits any unregistered person to own a business if he places the store or shop in charge of a registered pharmacist. The wide scope of the original prohibition is further modified by a later section, which exempts from its operation the supply by a physician to his patient of "such articles as may seem to him proper," the vending of patent or proprietary medicines, or of medicines in sealed packages, labelled with the name of the particular article and of the pharmacist or physician preparing it, as well as the sale of the "usual domestic remedies" by dealers.

The persons entitled to registration under the Act are such as were engaged in the business of dispensing pharmacists on their own account at the time of the passing of the Act, "Graduates in Pharmacy" and "Licentiates in Pharmacy." A "Graduate" is defined as a person who has had four years' practical experience in drug stores where the prescriptions of medical practitioners are made up and holds a satisfactory diploma or other credential from a regularly incorporated college or school of pharmacy. A "Licentiate" is a person who after two years' similar practical experience passes a satisfactory examination before the board constituted under the Act. Every assistant who has had two years' practical experience at the time of the passing of the Act, but does not possess a qualification for registration as a "registered pharmacist," if not less than eighteen years of age, is entitled to a certificate of registration as a "registered assistant," which certificate gives him the right to continue in his duties as clerk or assistant, but not to carry on business on his own account before he has had five years' experience.

The Board of Pharmacy consists of five examiners, chosen by the Governor of the State from "ten competent pharmacists," whose names are to be submitted for the purpose by the Wisconsin Pharmaceutical Society. Each successive year one member of the Board is to vacate his seat, by rotation after the first five years, and the vacancy is to be filled by the Governor nominating one of three persons selected by the Society; eventually, therefore, the appointments will be for five years. The Board is to meet at least once in three months and its business is to examine candidates, grant certificates of registration, cause the prosecution of persons violating the provisions of the Act, and to report annually to the Governor and the Pharmaceutical Association on the condition of pharmacy in the State.

The fees for registration are fixed very low, that for registration by examination being only five dollars, with the proviso that if the candidate fails the whole fee shall be returned to him. If the proportion of unsuccessful candidates be nearly as large as obtains sometimes in the examinations in Great Britain, this shifting of the penalty of failure might prove a Nemesis to too exacting examiners, since the payment of these functionaries is to come out of the proceeds of their operations, and it is expressly stipulated that none of the expenses shall come out of the coffers of the State. On the other hand, every registered person desiring to retain his position will have to transmit annually to the Board an intimation to that effect, together with a fee not exceeding two dollars.

Any person not being himself a registered pharmacist, nor employing one, who carries on business in contravention of the Act, will be liable to a penalty of fifty dollars; and any registered pharmacist who permits the dispensing of prescriptions, or the vending of drugs, medicines or poisons in his place of business, except under the supervision of a registered pharmacist or by a registered assistant, will be liable to a similar penalty. All suits for the recovery of penalties are to be prosecuted in the name of "the people of the State of Wisconsin" by the county attorney, and the penalties are to go one-half to the Board and the remainder to the school fund of the county in which the suit is prosecuted and judgment obtained.

The section of the Act relating to poisons provides that no person shall sell by retail "any poisons commonly recognized as such,"—and especially some that are mentioned by name,—without affixing a label bearing the name of the article, the word "poison," and the name and address of the seller. It is also made illegal to sell such poisons to a person under fifteen years of age, or to any one without first ascertaining that the poison is to be used for a legitimate purpose. The penalty for each offence under this section is five dollars.

Lastly, there is an adulteration clause with a penalty of not less than fifty or more than a hundred dollars for a first offence, and for each subsequent offence a penalty of not less than seventy-five or more than one hundred and fifty dollars, the offender paying the costs in all cases. Not only does the actual sophisticator come under this penalty, but every proprietor or conductor of a drug store is to be held responsible for the quality of the articles sold by him, except when they are sold in original packages, or consist of patent or proprietary preparations. An offender under this action is also liable to have his name struck off from the Register.

THE MANCHESTER PRICE LIST.

ALTHOUGH the most sanguine can hardly expect to see the time when the charges for dispensing and drugs shall become uniform, even amongst chemists living in the same towns or districts, there is much room for improvement in this respect. We are therefore pleased to notice the issue of a fourth edition of the List of Retail Prices recommended by the Council of the Manchester Chemists and Druggists' Association. Only two years have elapsed since the third edition was published, during a part of which interval it has been out of print, and in the appreciation of their work thus evidenced the Council of the Manchester Association will doubtless find a sufficient reward. The book bears the imprint of Mr. SILVERLOCK, and we presume it could also be obtained from the Secretary to the Association.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 2, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

The President said he had received a letter from Mr. Hampson signifying his desire to withdraw from the Education Committee.

Diplomas.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bain, John.
Caldecott, Clement Guest.
Dowdeswell, Jonathan.
Drew, Walter Clark.
Holmes, Francis.
Kinross, William Malloch.
Murray, George.
Wheatley, Joseph.
Yeatman, Frederick James.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Bain, John.........Bridge of Allan.
Dowdeswell, Jonathan.........Beaminster.
Kinross, William Malloch.........Newcastle-on-Tyne.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Ellard, James.........London.
Emmerson, George John.........Leyton.
Stephens, Jonathan.........Devonport.
Surfleet, Walter.........London.

ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Allen, Samuel.........Worcester.
Arthur, Charles.........Edinburgh.
Bowering, John.........Taunton.
Comer, Ernest Edward.........East Dereham.
Cullwick, Herbert Ernest.........Knighton.
Deeks, William Thomas.........Shanklin.
Dillon, Charles Linder.........Hereford.
Evans, William.........Cardigan.
Fentiman, Charles Henry.........London.
Field, Henry.........Yeovil.
Foggitt, John Blackett.........Thirsk.
Frost, John Henry.........London.
Greenall, Thomas Holdsworth...Ashton.
Hall, Amos.........Stafford.
Hankinson, George Robert.........Grange-over-Sands.
Hanson, Christopher.........Buckhurst Hill.
Innes, David.........Stalybridge.
Loam, James Gilbert.........Liverpool.
Mann, Joseph.........Peterborough.
Meadows, John Martin.........Swindon.
Nichol, Anthony.........Carlisle.
Noble, Henry Edward.........Peterborough.
Norburn, Albert Edward.........London.
Northen, Charles.........Thorpe-by-Water.
Parker, Thomas Herbert.........Bedford.
Pearson, William.........Sinderland Green
Pickering, Wade.........Crowle.
Rodmell, John Gale.........Rochester.
Rowland, Thomas William.........Epping.
Sergent, William Thomas.........Croydon.
Shapcott, William Henry Pyne..London.
Thomas, John Henry.........Chester.
Thomas, Joseph Arden.........Cambridge.
Thomas, William Hendy.........Penryn.
Townsend, Henry Holden.........London.
Tyson, Thomas Balmforth.........London.
Warburton, Edward.........Farnworth.
Waymouth, Thomas Staddon...Exeter.
Wells, William George.........Maidstone.
Williams, William Jesse.........Crickhowell.
Wood, John Ridal.........Rotherham.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students of the Society":—

Beanland, John Milner.........Keighley.
Bennett, Albert.........Leeds.
Bolton, Richard Lee.........Leith.
Brown, Joseph.........Walker-on-Tyne.
Cain, James Harold.........Douglas.
Clark, George Alexander.........Portsoy.
Clarkson, Joseph.........Skipton-in-Craven.
Cooper, Albert.........Huntingdon.
Cope, William James.........Longton.
Coutts, William Alexander.........Pathhead.
Cumming, John.........Portsoy.
Dowswell, Charles Wesley.........Tewkesbury.
Evans, Daniel Ashton.........Llanbrynmair.
Fox, Albert.........Atherstone.
Fox, William Arthur.........Cleckheaton.
Franklin, Alfred James.........Brighton.
Grant, Alexander.........Blairgowrie.
Grant, Arthur Thomas, jun., ...Helston.
Hampson, William.........Leigh.
Hawkins, Lewis Walter.........London.
Head, George.........Bridgnorth.
Honiatt, Albert Thomas.........Hereford.
Johnson, Henry.........London.
Kemplay, Arthur.........Leeds.
King, Frederick Herbert.........Market Drayton.
Lowe, Osmond Henry.........Maidenhead.
Naylor, James Louis.........Brownedge.
Pelham, Sydney.........Basingstoke.
Pettigrew, James.........Glasgow.
Rees, Colin Atkins.........Dartmouth.
Shepard, William.........Newport (I. of W.).
Smith, Charles B.........Potton.
Theckston, James.........Ulverston.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The name of the following person who had made the required declaration and paid a fine of one guinea was restored to the Register of Chemists and Druggists:—

Henry Ballinger Ryley, 38, Skinnergate, Darlington.

Reports of Committees.

FINANCE.

The report and recommendations of this Committee were received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a life member; applicant has received four previous grants.

£10 to a pharmaceutical chemist, member from 1853 to 1877, who has had two previous grants.

£5 to the widow of a former annuitant.

£10 to the widow of an associate, who has had four previous grants.

Other cases had been before the Committee, concerning which no recommendations were made.

The Secretary had reported the receipt of a letter from the Local Secretary at Worcester, stating that in company with another member he had made a canvass of the chemists in that city and obtained subscriptions to the amount of £6 15*s.* 6*d.*

The Council went into committee whilst the President explained the circumstances of one of the applicants for relief. On resuming, the report and recommendations of the Committee were received and adopted, the President drawing special attention to what had been done at Worcester.

LIBRARY, MUSEUM, LABORATORY AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
June	Day . . .	422	27	5	16
	Evening . .	131	11	3	6

Circulation of books.	No. of Entries. Town.	Country.	Total.
June	178	115	293

Carriage paid, £2 11*s.* 2½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Chemical Society of London, Journal. Sundry vols.
Royal Society of London, Proceedings. Sundry vols.
Deutsche Chemische Gesellschaft, Berichte. Sundry vols. From Mr. Walter Hills.
Gräbner (F.), Beiträge zur Kenntniss der Ptomaïne in gerichtlich-chemischer Beziehung, 1882.
Schwarz (E.), Der forensisch-chemische Nachweis des Gelsemins in thierischen Flüssigkeiten und Geweben mit Berücksichtigung seiner Unterscheidung von Strychnin und diesem verwandten Alkaloiden, 1882. From Professor Dragendorff.
Hellin-Criquelion (C.), L'exercice de la pharmacie au point de vue constitutionnel et légal, 1882. From the Author.
Massachusetts College of Pharmacy, [Sixteenth annual] Catalogue, 1882-3. From Dr. B. F. Davenport.

The Committee recommended the purchase of the undermentioned works:—

Brodie (Sir B.), Ideal Chemistry.
Napheys (G. H.), Modern Medical Therapeutics, 7th edition.
Neale (R.), Medical Digest, 2nd ed., 1882.

The Librarian had reported the need of better ventilation in the Library. The Committee had agreed that the matter should be left in the hands of the President, and that he should report and recommend to the Council.

The Librarian had informed the Committee that the annual meeting of the Library Association would be held at Cambridge on September 5, 6, 7 and 8. The Committee recommended that the Librarian should attend the meeting.

Curator's Report.

The Curator had reported the average attendance in the Museum to have been—

		Total.	Highest.	Lowest.	Average.
June . .	Morning	333	21	4	13
	Evening	120	11	0	4

The Curator had also reported that he had received an application from M. Eugène Collin, of Verdun, France, for the loan of a specimen of Canton stick rhubarb from the Pereira collection of Materia Medica. The request had been acceded to.

The Professors had attended and reported satisfactorily on their respective classes; Professor Attfield had also presented a statistical report as to the Practical Chemistry class.

The various alterations in the ventilating and cleaning of the premises had been further considered.

The Council went into committee to discuss certain matters arising on the report of the Committee. On resuming, the report and recommendations were unanimously adopted.

GENERAL PURPOSES.

The report of this Committee included the reports of the Professors as to the School of Pharmacy prizes, the report of the examiners appointed to conduct the competition for the Pereira Medal, etc., and Professor Bentley's report on the Herbarium Prize. The purport of these reports was as follows:—

Chemistry and Pharmacy.

Professor Redwood reported that at the examination at the termination of the second course of five months there were only two competitors, who, although they acquitted themselves fairly well as junior students, failed to gain the required number of marks to entitle them to any award. For the sessional examination for the silver medal there were seven competitors, of whom five furnished papers of considerable merit, and were entitled to recognition.

Materia Medica and Botany.

Professor Bentley reported that at the examination at the termination of the second course of five months there was only one candidate, there being very few eligible to compete. The answers of the candidate were, however, so good that he did not hesitate to recommend that he be awarded a bronze medal.

For the sessional examination for the silver medal and certificates the number of candidates had been over the average, and the marks obtained by the majority of candidates were unusually high. Altogether the examination was the best which had taken place for some years. He also reported most satisfactorily of the good conduct, punctuality, and regularity of attendance of the students generally.

Herbarium.

For the Herbarium Prize there had been five collections submitted, the best of which contained over six hundred specimens, and was excellent in every respect. The next two were about equal in order of merit, for the one contained the greater number of specimens, whilst the other was better prepared, and the Professor recommended that a bronze medal be awarded to each. The fourth and fifth collections each deserved a certificate of merit, the latter containing over five hundred specimens, but was not so well prepared as to entitle the competitor to a higher award.

Practical Chemistry.

Professor Attfield reported that fourteen students had competed for the prizes in his class, of whom five obtained sufficient marks to entitle them to medals or certificates. He also reported favourably of the general good conduct and diligence of the students.

Council Examination Prizes.

The examiners appointed to conduct these examinations reported that there were six competitors, five in London and one in Edinburgh. Three competitors were entitled to recognition.

The report included the usual letter from the Solicitor, stating the progress of matters which had been placed in his hands.

Several cases of alleged infringement of the Pharmacy Act had been brought before the Committee and in each case it was recommended that proceedings be taken.

This part of the report was as usual considered in committee.

On resuming, the report and recommendations of the Committee were received and adopted.

PRIZE AWARDS.

The following awards were made on the recommendation of the General Purposes Committee:—

Chemistry and Pharmacy.

[Ten months' course.]

Silver Medal	Frederick Wm. Short.
Certificates of Honour	Walter Clark Drew. Edward Marsh.
Certificates of Merit	Richd. Augustus Cripps. Thos. Goddard Nicholson.

Botany and Materia Medica.

[Five months' course.]

Bronze Medal	Henry Hamilton.

[Ten months' course.]

Silver Medal	Frederick Wm. Short.
Certificates of Honour	Equal: George F. Callaway. Thos. G. Nicholson. Walter Clark Drew. Equal: Rd. Augustus Cripps. Frdk. Jas. Yeatman.
Certificates of Merit	Edward Marsh. T. Staddon Waymouth. Edgar Haward.

Practical Chemistry.

Silver Medal	Frederick Wm. Short.
Bronze Medals	Frdk. James Yeatman. Richd. Augustus Cripps.
Certificates of Merit	Edgar Haward. Walter Clark Drew.

Herbarium Prize.

Silver Medal	Henry Hamilton.
Bronze Medals	Equal: Frdk. V. Butterfield. T. Goddard Nicholson.
Certificates of Merit	Henry Edward Skyrme. Edward Henry Farr.

Council Examination Prizes.

Pereira Medal (silver); and Books value £5, presented by Mr. T. H. Hills.

Frederick William Short.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

William Kirkby.

Pharmaceutical Society's Medal (bronze); and Books value £2, presented by Mr. T. H. Hills.

Frederick James Yeatman.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Committee appointed to make the award of the Jacob Bell Memorial Scholarships for the ensuing session, subject to the approval of the Council, reported that twenty candidates had presented themselves at the following centres:—Cambridge, 1; Canterbury, 2; Cardiff, 1; Carnarvon, 1; Darlington, 2; Lincoln, 2; Liverpool, 1; London, 8; Norwich, 1; York, 1. Of these, five had obtained more than the maximum number of marks requisite to entitle them to the award.

The envelopes bearing the mottoes of the successful candidates having been opened, their names were found to be

William Edward Crow
and
Edward Baily.

The report was received and adopted.

Upon the motion of the President, seconded by the Vice-President, votes of thanks were passed to Messrs. Clark and Gibson, who had examined the papers for the Council prizes, and to Messrs. Benger and Ekin, who had performed the same duties with regard to the Jacob Bell Memorial Scholarships.

A vote of thanks was also given to Professor Bentley for his report on the Herbarium competition.

SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

The following gentlemen were appointed Superintendents and Deputy-Superintendents of written examinations for the ensuing year:—

Superintendents.

Aberdeen	Davidson, Charles.
Birmingham	Southall, William.
Brighton	Gwatkin, James Ross.
Bristol	Stroud, John.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Hollway, Albert Brown.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard Morgan.
Carnarvon	Lloyd, William.
Cheltenham	Smith, Nathaniel.
Darlington	Robinson, James.
Douglas, Isle of Man	Breary, William A.
Dundee	Hardie, James.
Edinburgh	Stephenson, John B.
Exeter	Delves, George.
Glasgow	Kinninmont, Alexander.
Guernsey	Arnold, Adolphus.
Hull	Bell, Charles Bains.
Inverness	Galloway, George Ross.
Jersey	Ereaut, John, jun.
Lancaster	Bagnall, William Henry.
Leeds	Reynolds, Richard.
Lincoln	Maltby, Joseph.
Liverpool	Symes, Charles.
London	Taylor, George Spratt.
Manchester	Wilkinson, William.
Newcastle-on-Tyne	Martin, Nicholas Henry.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	FitzHugh, Richard.
Oxford	Prior, George Thomas.
Peterborough	Heanley, Marshall.
Sheffield	Ward, William.
Shrewsbury	Cross, William Gowen.
Southampton	Dawson, Oliver Robert.
Truro	Percy, Thomas Bickle.
Worcester	Virgo, Charles.
York	Davison, Ralph.

Deputy-Superintendents.

Aberdeen	Kay, James Petrie.
Birmingham	Churchill, Walter John.

Brighton	Savage, William Wallace.
Bristol	Pitman, John.
Cambridge	Hoare, William P.
Canterbury	Amos, Daniel.
Cardiff	
Carlisle	Hallaway, John.
Carmarthen	Davies, R. Morgan., jun.
Carnarvon	Francis, James.
Cheltenham	Barron, William.
Darlington	Hutchinson, Rev. E.
Douglas, Isle of Man	Brearey, Arthur W.
Dundee	Kerr, Charles.
Edinburgh	Ainslie, William.
Exeter	Lake, John Hinton.
Glasgow	Davison, Thomas.
Guernsey	Collenette, Adolphus.
Hull	Baynes, James.
Inverness	Galloway, George.
Jersey	Ereaut, John.
Lancaster	Hall, William.
Leeds	Smeeton, William.
Lincoln	Battle, John Scoley.
Liverpool	Sumner, Robert.
London	Bremridge, Richard. Holmes, Edward M. Knapman, John W.
Manchester	Wilkinson, George.
Newcastle-on-Tyne	Stuart, Charles Edward
Northampton	Mayger, William D.
Norwich	Corder, Octavius.
Nottingham	Parker, William H.
Oxford	Thurland, Thomas Henry
Peterborough	Saunders, James Edwin.
Sheffield	Maleham, Henry.
Shrewsbury	Blunt, Thomas P.
Southampton	Spearing, James.
Truro	Anstey, John U.
Worcester	Lunn, Thomas.
York	Sowray, Joseph.

Pharmacy in Wisconsin.

The President said he had recently had the pleasure of meeting in that house Mr. Dadd, President of the Wisconsin Pharmaceutical Association, and had to thank him for presenting the Society with a copy of an Act of Parliament recently passed by the State of Wisconsin, placing pharmacy on something like a proper legislative basis. Mr. Dadd had obtained a copy of the original document, officially certified by the Secretary of the State, which he had presented to the Society.

Mr. Williams asked what was the nature of the Wisconsin Act.

The President said it was a sort of compromise between liberty and restriction; the English and Americans were in favour of liberty, but the German element in Wisconsin was in favour of restriction.

The Vice-President said he was present when Mr. Dadd visited the premises to inspect the mode of examinations, and was very glad to hear him express the great pleasure he had experienced in witnessing those examinations. Mr. Dadd said that in America at present they had no pharmaceutical legislation except in the separate States; there was no Congressional action, which they desired to obtain. They had in America the same difficulties which had been experienced in England. He had been glad to hear Mr. Dadd's testimony to the high character of the Society's examinations, and he said it would be his endeavour on his return to get something of the same character established in his own State.

It was resolved that Mr. Dadd be thanked for the copy of the Act, and that a copy of the Journal and Transactions of the Society be sent regularly to the Wisconsin Pharmaceutical Association.

Pharmacy in Guernsey.

The President said it would be seen by the Journal of June 17, p. 1046, that there was now a Pharmacy Act in the Island of Guernsey, which provided that no person should, after a given date, dispense *aucune médicament*, unless he were either registered by the Pharmaceutical Society of Great Britain or by the École de Pharmacie of Paris. He was glad to inform the Council that much of the credit in connection with the obtaining of this enactment was due to Mr. Crossley, who had passed the Society's examination and was on the Register.

The Poison Schedule.

The following communication had been received from the Privy Council Office:—

"Privy Council Office,
"Whitehall, *July* 29, 1882.

"Sir,—I am directed by the Lords of the Council to transmit to you to be laid before the Pharmaceutical Society, the accompanying order of their lordships approving the resolution of that Society of the 1st February, 1882, so far as regards nux vomica, viz., 'that nux vomica and its preparations should be deemed a poison within the meaning of the Pharmacy Act, 1868, and also a poison in the second part of schedule A of that Act.'

"Their lordships after giving their careful consideration to the proposals contained in the resolution were of opinion that pending the consideration of the expediency of further legislation with reference to the sale of poisons it is not desirable to add to the restrictions on the sale of the acids and other articles referred to in the resolution.

"I am, Sir,
"Your obedient servant.
(Signed) "C. L. Peel.

"The Secretary and Registrar
"of the Pharmaceutical Society."

"At the Council Chamber, Whitehall.
"The 28th day of July, 1882.

"By a Committee of the Lords of Her Majesty's Most Honourable Privy Council.

"Present:
"Lord Privy Seal
"Lord Richard Grosvenor
"Mr. Mundella.

"Whereas by 'The Pharmacy Act, 1868, Section 2,' it is enacted that the Council of the Pharmaceutical Society of Great Britain, may from time to time, by resolution declare that any article in such resolution named ought to be deemed a poison within the meaning of that Act, and thereupon, the said Society shall submit the same for the approval of the Privy Council, and that, if such approval shall be given, then such resolution and approval shall be advertised in the *London Gazette*, and on the expiration of one month from such advertisement the article named in such resolution shall be deemed to be a poison within the meaning of that Act.

"And whereas the Council of the Pharmaceutical Society of Great Britain did, on the 1st day of February, 1882, resolve and declare, by virtue and in exercise of the powers vested in the Council of the Pharmaceutical Society of Great Britain, that, amongst other articles, 'Nux vomica and its preparations' 'ought to be deemed a poison within the meaning of the Pharmacy Act, 1868, and ought to be deemed a poison in the second part of the Schedule A of the said Pharmacy Act, 1868.'

"And whereas the said Society have submitted the said resolution for the approval of the Privy Council, and the lords of the Privy Council are of opinion that the said resolution, so far as regards nux vomica and its preparations, should be approved,

"Now, therefore, their lordships are hereby pleased to signify their approval of the said resolution, in so far as regards nux vomica and its preparations.

"C. L. Peel."

PHARMACY IN VICTORIA.

The following letter from the Pharmacy Board of Victoria was read:—

"Pharmacy Board, Victoria,
"Melbourne, *June* 5, 1882.

"To the President and Council,
"Pharmaceutical Society,
"Bloomsbury Square, London.

"Gentlemen,—Referring to your letter of the 10th November, 1881, in reply to a communication addressed to you on the 8th July, 1881, in reference to the certificate of the Pharmacy Board of Victoria receiving some recognition by the Pharmaceutical Society of Great Britain—

"The Board are of opinion that the nature of their request has been misunderstood, and would therefore again respectfully draw the attention of the Council to the subject.

"The concessions asked for by the Board are as follows:—

"1st. That those persons only who have passed the Major examination under the Pharmacy Act of Victoria, 1876, as directed by the 18th section, may be enabled to carry on the business of a chemist and druggist in England without further examination.

"2nd. That should any candidates holding the Victorian Major Examination Certificate elect to present themselves for the examination of the Pharmaceutical Chemists of Great Britain, some privilege should be given in recognition of their Colonial studies.

"The Board would respectfully point out that the course of study required by the Victorian Pharmacy Act for the Major Certificate is nearly identical with that required at Bloomsbury Square, and in asking for some recognition for those who have passed the Major examination the Board only seek an equitable adjustment between the Victorian Certificate and that of the Pharmaceutical Society of Great Britain.

"The exemption of holders of the English Certificate was specially made by the Pharmaceutical Society of Victoria when framing the Pharmacy Act.

"It is probable that but few of the students from Victoria will avail themselves of the privilege asked for; whereas numbers of gentlemen holding the Certificate of the Pharmaceutical Society of Great Britain are constantly arriving in Victoria, who qualify on the production of their certificate, a privilege the Board are desirous should still be retained in the Victorian Pharmacy Act.

"We have the honour to be, Gentlemen,
"Your obedient servants,
"JOSEPH BOSISTO, *President*,
"HARRY SHILLINGLOW, *Registrar*."

The PRESIDENT said it would be remembered that a similar communication had been received last year, and was referred to a Committee to report upon, the report being that at present the Council had no power to do what was asked. Of course it would be a question whether the Council would be disposed to ask for powers to accept the certificates of examining bodies outside of Great Britain. He believed the view of the Committee at that time was that, at all events for the present, and probably for some years to come, it was not expedient that such certificates should be received. A letter to that effect was sent last year, and this was a reply asking the Council to reconsider the subject.

Mr. CHURCHILL remarked that these gentlemen only asked that their Major examination should be considered equivalent to the Minor in England.

The PRESIDENT said he understood that in Victoria there were no "chemists and druggists," but all registered men had the title of "pharmaceutical chemist." Substantially it was asking that the Victoria qualifying examination should be recognized as a qualification for practice in Great Britain. The simple answer was that the Society had no power at present to do so.

Mr. RADLEY thought it would be desirable to have some such arrangement, if it could be managed satisfactorily.

The PRESIDENT remarked that at present the British Act did not even permit the recognition of certificates from Ireland.

Mr. WILLIAMS: Nor from any body in which the examinations were not controlled by the Society.

Mr. RADLEY said the Council had no power at present, but he did not see why it should not obtain power if the opportunity offered.

Mr. SAVAGE thought it desirable that as far as possible there should be reciprocity. The only thing necessary was to be sure that the examinations were of equal value.

The PRESIDENT said all depended on the value of the certificate. The Victoria Board had only lately been created, and though a syllabus of the examinations had been sent, the Council did not know anything about the way in which they were carried out. He had no doubt that in time it would be necessary for all English-speaking countries to have reciprocity in such matters; but the gentlemen in Victoria surely would not wish those who had a thoroughly high standard to lower it in any way. He did not say that the Victoria standard was lower, but that Board was a much younger body, and until it had gained some experience in the process of examination and education, it would probably be wise to hesitate before accepting its certificates. It was only of late years that men possessing the highest qualifications obtained on the continent had been accepted on the Medical Register of this country.

Mr. YOUNG sympathized with the remarks of Mr. Savage, and he thought that when a young country had grown into something like prominence, and its examinations were shown to be equivalent to those in this country, it would be well to accept its certificates, provided the Council had the power to do so.

The PRESIDENT said a reply should be sent to much the same effect as before, stating that the Council had no power at present to accede to the request, but that when it went to Parliament for fresh powers the general policy of reciprocity might be considered.

This was unanimously agreed to.

The VICE-PRESIDENT said it would be a great responsibility to ascertain what was the character of the examinations in question.

PRELIMINARY EXAMINATION.

The PRESIDENT said a communication had been received from the Hon. Secretaries to the Oxford and Cambridge Schools Examination Board describing the nature of the examinations which it was intended to institute in connection with schools throughout the country, and asking if certificates granted by that body would be accepted in lieu of the Preliminary examination. In the last paragraph inquiry was made if it would be considered satisfactory to allow the head master of a school in certain cases to supervise the examinations. He had gone carefully through the scheme with the Vice-President, Secretary and two members of the Board of Examiners, and they all agreed that certificates in class 1 might be accepted in lieu of the Preliminary examination, but they did not think it desirable that the head master of a school should be the sole supervisor of an examination conducted in his own school.

Mr. WILLIAMS said he could give no opinion on the scheme as a whole, but if it included all the subjects required in the Preliminary examination he did not see why the certificate should not be accepted.

The PRESIDENT said this appeared to be an attempt to bring the examination of schools under the ægis of the universities and as such was a movement which he thought ought to be encouraged. He then read a draft letter which he had prepared in reply.

The Council went into committee to consider this draft.

On resuming, it was unanimously approved, and the letter ordered to be sent.

Report of Examinations.

July, 1882.

ENGLAND AND WALES.

Examinations in Scotland.

It was resolved that the examinations in Scotland in 1883 should take place in January, April, July and October.

The Council Meeting in September.

The President announced that although summonses would be issued for a Council meeting in September it was not intended to form a quorum.

Erratum.—In the list of persons who passed the Minor examination on the 20th of July, page 93, column 2, after line 36, insert,

Thomas, John Henry ....Chester.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

Felspar as a Source of Potash Alum.*

BY JOHN SPILLER.

The aim and objects of this Society, as I understand them, will be not only to record the steps of progress made in actual chemical manufacture but to take account of "wasted ingredients," with a view to their possible economization in the future. It is under this latter head that I beg leave to offer a few suggestions bearing on the manufacture of alum, which have been sufficiently confirmed by laboratory work to prove my case, although I do not pretend to have turned them as yet to practical account.

Starting from felspar and the large class of rocks in which it is contained, such as granite, gneiss, porphyry, syenite, greenstone, mica-slate, and the basaltic rocks which together constitute a large proportion of the earth's surface, we find a mineral occurring which contains *more potash and alumina* than is present in common alum. If, then, in this native double silicate we could replace the SiO_2 by SO_3, we pass at once from insoluble felspar to alum. Every chemist knows of the method of decomposing silicates in mineral analysis by attacking them with hydrofluoric acid; but as it was my object to prepare a *sulphate*, and to work as cheaply as possible, I employed a mixture of fluorspar, felspar, and sulphuric acid. Alum is formed together with calcium sulphate and the gaseous fluoride of silicon. The last-named gas, passed into water, gives a finely-divided silica—most useful as a polishing powder—and hydrofluosilicic acid, for which there is already occasional use in the arts. Comparing now the percentage composition of felspar and alum, and taking for the former the mean of three analyses published by Watts ('Dictionary of Chemistry,' vol. ii., pp. 620–621) we get for common felspar, "orthoclase":—

	Alumina.	Potash.
Stolberg (Rammelsberg) . .	16·98 . .	14·42
Lomnitz (Valentine Rose) .	17·50 . .	12·00
Chamounix (Delesse) . . .	19·06 . .	10·52
Mean	17·85 . .	12·31

Or, together, say over 30 per cent. of ingredients useful in the manufacture of alum, which salt, when crystallized, contains only 10·83 per cent. of alumina, and 9·91 of potash; or 20·74 per cent of total bases. This looks hopeful from a manufacturer's point of view; for, taking the potash as regulating the yield, 100 parts of felspar should give nearly 124 parts of crystallized alum; and if the relative deficiency of alkali were supplied, then the yield (calculated from alumina) should be as high as 165 per cent.

In my own experiments I have not succeeded in getting more than an *equal weight*, but I have been working under disadvantage with samples of coloured felspar containing a considerable quantity of iron. From a piece of white granite I have obtained a fair quantity of alum, with very much less iron in solution; and to this point I had arrived when my attention was directed to a previous publication of the fundamental fact in the *Bulletin de la Société Chimique de Paris* for June 7, 1872. The particulars are as follows: At the Paris meeting M. Lecoq de Boisbaudran was describing a process for the extraction of cæsium and rubidium from lepidolite. He attacks the mineral with hydrofluoric acid, and separates the caesium and rubidium by taking advantage of the difference of solubility of the bitartrates. Then M. Guignet, in the discussion, says he "thought it might be possible for this extraction to utilize the action of *sulphuric* acid, and separate the alkalies in the state of alums, this proceeding having been used by him to extract the potash from felspars." The brief terms of this report (three lines only) do not afford much information, or make it clear that M. Guignet ever worked with a mixture of felspar and fluorspar, but he evidently aimed at economizing the potash in felspar, and may have succeeded in so doing.

Much more pertinent to this part of the subject are the experiments of Mr. F. O. Ward and Captain Wynants, who, in December, 1857, took out a patent for what they called the "Calcifluoric Attack." A full account of this process appeared in the "Reports" by the Juries of the International Exhibition, 1862, class ii., pages 50 to 54; and later, a company was formed to put it in operation at Connah's Quay, near Flint. The object seems to have been to extract potash from the primitive rocks rather than to make alum; but I am bound to say that the inquiries I have made (with the kind assistance of Mr. Eustace Carey) seem to show that the production of potash from the felspathic rock

* Read at a Meeting of the London Section, March 13, 1882.

was anything but a commercial success. Had it been worked continuously on a large scale, who knows but that we might have had by this time vast stores of lithium, cæsium, rubidium, and perhaps other yet unknown alkali-metals, concentrated from the by-products of such a manufacture?

Reverting now to my own experimental results, two or three points of practical interest may be mentioned.

1. I find it necessary to get rid of the excess of sulphuric acid by thoroughly heating the decomposed mass in a current of air before dissolving, on account of the extraordinary increase of solubility of the alum in acid liquors.

2. When granite is attacked by the nascent HF, the felspar and mica disappear long before the admixed quartz, most of the latter remaining in the residue.

3. The employment of sheet-lead vessels is not to be recommended, for the cost is great and the low fusion point of the metal restricts too much the degree of temperature which it is needful to apply in order to expedite the decomposition.

When the treatment is successfully accomplished there is the large amount of calcium sulphate to be dealt with, left as a bulky residue on treating with water. It struck me, therefore, that it would be more advantageous to use the mineral cryolite ($3NaF, Al_2F_3$), which is so plentiful in Greenland, in place of fluorspar as previously described. This would augment the amount of aluminic sulphate formed at the same time that it supplied the needful fluorine. Here, again, Persoz, Sauerwein, Thomson, and others have described the manufacture of crude alumina salts from cryolite *per se*, but none of these processes include the idea of making the hydrofluoric acid available for decomposing the native double silicates of potassium and aluminium mixed therewith. The relative proportions in which the felspar rock and cryolite have to be employed, as also the amount of sulphuric acid required, must be dependent upon the nature of the rock operated upon, the amount of admixed quartz, etc., and could be easily determined by making a few preliminary experiments upon a fair average sample of the rock about to be treated. A warm hearth, made slightly hollow, and lined with fire-bricks, or slabs of the rock itself, gently heated by reverberatory action, will probably be the best construction for conducting the operation on a manufacturing scale.

Next, as to the varieties of granite and porphyry which are likely to yield the highest percentages of potash, there are displayed in the Museum of Practical Geology about a hundred polished samples, which I have lately been to inspect. Amongst these I find that the granite from the Duke of Argyll's quarries in Mull appears to consist almost entirely of rose-coloured felspar. The blocks from the Mourne Mountains, County Down, are mostly white felspar; and large crystals of the same are seen in the white granites from Lanlivery (Cornwall), St. Barule (Isle of Man), and in the specimens from Castlean (near Penzance), and Lundy Island. Rubislaw and Cove (Aberdeen) produce almost pure felspar, containing 13 per cent. of potash. Peterhead granite is rich in felspar, but it is highly coloured with ferric oxide.

I am indebted to Professor J. S. Brazier, of the University of Aberdeen, for much valuable information respecting the granite quarried in his neighbourhood, and he has kindly sent me some of the waste chippings and *débris* from Messrs. Macdonald and Field's huge turning-lathes, such material as is used for mending the roads, but the small sample sent was a variety of grey granite which did not happen to contain much potash. More interesting information is contained in a letter which I am permitted to append.

Letter from Dr. Alexander Cruickshank to Professor Brazier.

"I have much pleasure in answering, as far as I can, your inquiries of February 4. In a note at bottom of page 265, vol. xxviii. of the *Transactions of the Royal Society of Edinburgh*," published 1877, in an elaborate paper on the "Felspars of Scotland," Professor Heddle, of St. Andrew's University, says: 'I find the grey granite of Aberdeen to consist of a great deal of oligoclase, little orthoclase, little quartz, very small quantities of muscovite (potash mica), and a good deal of Haughtonite (a new variety of mica).'

"In this paper Professor Heddle gives new analyses of oligoclase and orthoclase, and in vol. iii. of the *Mineralogical Magazine*, page 81, he gives an analysis of Haughtonite, while an analysis of muscovite is given in Professor Nicol's 'Mineralogy.'

"From these analyses I extract the percentages of potash in the minerals composing our granite.

	Contains. Per cent. K_2O.
Oligoclase, from Rubislaw Quarries . . .	3·77
Oligoclase, from Scolty Quarries	4·73
Oligoclase, from Dyce Quarries	1·34
Orthoclase, from Rubislaw Quarries . . .	13·05
Muscovite	11·80
Haughtonite, from Cove, near Aberdeen .	8·81

Mean, 7·15 per cent. of potash (K_2O).

"There is a rock called compact felspar or felstein (a mixture of orthoclase and quartz, says Professor Nicol, in his 'Mineralogy'), forming beds in the gneiss rocks, about half way between the Bay of Nigg and the Cove. It also occurs in a large mass on the Muchall's coast, where it is used for 'metalling' the Stonehaven Road. Again, it occurs near the top of Cairn William Hill, near Monymusk. I remember Dr. Shier telling us in the natural history class at Marischal College, forty years ago, that the compact felspar from some of these localities had been tried in the English potteries. It was found, however, to contain too great a percentage of silica for the purposes intended.

"I have long understood that the scrapings from the roads about Aberdeen (which are metalled with broken granite mixed with sand) are valued as a potato manure, from the large quantity of potash they contain.—Yours, etc.,

(Signed) "ALEXANDER CRUICKSHANK."

The whole subject appears, therefore, well worthy of extended investigation; and, like as the American potashes have been displaced to a great extent by the Stassfurt salts (native forms of KCl, sylvine, and carnallite), so, in time, it may chance that British sources of potash will take the place of the German supplies. On the commercial policy I beg to refer the members of this Society to the interesting column on page 25 of our new journal, wherein Dr. Grüneberg asks and argues the question: "How far would a Reduction of the Price of the Crude Potassium Salts give Impetus to the Consumption of the same in the Chemical Industries?"

Parliamentary and Law Proceedings.

DEATH FROM CHLOROFORM.

On Saturday, Mr. Carttar, West Kent Coroner, held an inquest on the body of Grace Harriet Butcher, aged 20, wife of Herbert Butcher, a medical student, of Turret House, Avenue Road, Bexley Heath. On Thursday night the deceased retired to bed, suffering from toothache, and to relieve the pain her husband rubbed some chloroform on her gums with his finger. He returned the phial containing the chloroform to the dressing-case, which he locked, placing the key in a different place to that from which he had taken it. He then retired to rest himself, and was not disturbed during the night by his wife, but on being called at seven o'clock the next morning he found Mrs. Butcher lying dead by his side, with her face on the pillow, his silk handkerchief in one hand, and the empty chloroform phial, which was two-thirds full overnight, in the other hand. She had been dead four or five hours.

The husband said he was a very heavy sleeper, but a candle was left burning in the bed-room all night.

Dr. N. A. Barrington said that he had made a *post-mortem* examination, in conjunction with a medical man who attended on behalf of deceased friends, and found the body well nourished, and the organs generally healthy, but the heart was flabby, showing deceased was not a good subject for receiving chloroform. The appearances were quite consistent with the history of the case as given in evidence. The death was due to excessive inhalation of chloroform. The bottles on the mantelpiece contained nothing that would account for the death of the deceased.

The jury returned a verdict, "That deceased died from misadventure through inhaling an overdose of chloroform, in attempting to gain relief from toothache."—*Morning Post.*

Poisoning by Laudanum.

An inquest has been held at Malton on the body of John Collier, until lately a master printer and stationer in the borough. The evidence showed that deceased had committed suicide by taking a large dose of laudanum. The jury returned a verdict of "Suicide whilst in a state of unsound mind."

The Future of Pharmacy.

Sir,—Your correspondent, "Pillmaker," has evidently been exercised with the problem which perplexes many minds, as to how a chemist is to get his living. Emerson has condensed the philosophy of it into a sentence—"Make yourself necessary to the world and mankind will give you bread."

"Pillmaker" seems to think that what the world wants is somebody to break the government stamp and retail Parr's pills in small quantities. That process would convert us from "pill makers" into pill vendors, and herein we should be at least a quarter of a century behind the hucksters, who have done this very thing for many years. Some of them have been aided and abetted by the supply of locally manufactured Parr's pills (I do not refer to any special neighbourhood), which never had a government stamp to be broken. In these cases the purveying chemists were pill makers—with a qualification.

But, sir, are we not fast becoming, if we are not already become, mere brokers of nostrums and openers of packages? The art of dispensing threatens to be simply the knowledge of the size of bottles, the ability to read the English label of an extract that must be procured in a particular town, and the capacity to count twelve small beans, supplied only, say from Kentucky. It will soon be time for some of the faculty to hold themselves forth to the public as merely advisers as to what quackery their patients should adopt, and instead of giving up their "dispensing" to chemists, they might well dress up their page boys and set them to hand over to their clients the packages as imported. The sham would at least stand acknowledged, and there would be a gain of truth to the world. It would be quixotic to attempt the subversion of such established remedies as Battley's solution or Brown's chlorodyne; but if in some town of adequate importance a bond of union could be formed sufficiently strong, and if there were courage bold enough for all the chemists in the town to refuse to dispense chemical and pharmaceutical preparations of definite composition, under cover of any person's label, and to maintain their sole and individual responsibility for all the medicines they prepare, an example would be set, and an illustration given, which would go some way to prove to the public, that not the nostrum, but the chemist is "necessary to the world"—*quod est demonstrandum.*

Ryde. Henry H. Pollard.

Sir,—I doubt very much if "Pillmaker's" scheme of buying the largest size of the most extensively used patents, and retailing them in small quantities, will ever be generally adopted. He proposes that chemists should measure and label patents, and thinks that outsiders would not care to spend so much time. Would any respectable chemist have the name of some new and much puffed patent on the same label with his own name and address? Of course there may be exceptions, but as the President of our North British Branch once said, "I find them in bad company."

I have no sympathy with chemists "cutting" patents. The huckster may charge 10*d*., but the chemist's price ought to be 13½*d*; by "cutting" he puts himself on "level terms" with such indifferent traders.

Regarding the general sale of the commoner drugs, I think the chemist who is "true to the interests of the trade" has little to fear. The other week, a lady customer came into my shop, to ask the price of chemical food; she said she got it at so-and-so's for so much. I assured her that the genuine article could not be bought wholesale at such a low figure, succeeded in getting her order, and have supplied her since. Keep drugs of standard purity only and there is no fear of our customers going elsewhere for salts or cream of tartar.

Edinburgh. John.

Leeches.

Sir,—For the past four years I have been trying experiments as to the preservation of leeches. Many means have been devised from time to time in the Journal, but few have been very successful. My plan is as follows:—I have one of Maw's bell-shaped aquariums half filled with water, also a few rough stones, about half a dozen in number and about the size of an orange. The water is changed twice only in twelve months. My object in doing this is because the temperature is varied but very little, and that very gradually, whereas when the water is changed once or twice a week, especially in winter, it is like transferring them from a warm to a very cold climate, and frequently I hear the complaint of chemists losing so many just after changing the water. I keep my aquarium in the shop, and although the water is only changed twice in a year, it is never foul but only has a slight fishy smell. Anyone adopting this plan will find it much to their advantage. When the stock of leeches is reduced to six in number, and before putting a fresh stock in the aquarium, I take out those six, as I find that they are just similar to bees, that is, when a stranger enters the hive they immemediately pounce upon it and destroy its life; so it is almost the same with leeches.

I have lost three leeches only in four years.

Devonport. J. A. Lamble.

J. Hickisson.—We are unable to comply with your request.

A. P. B.—You do not say what difficulty you experience in dispensing the prescription.

W. Wilkinson.—The question could only be determined after an examination of the precipitate.

Messrs. Wills and Wootton.—Your letter has been handed to the Secretary. A correction will be found in the official report on p. 118.

Cariad Raddy.—According to the recent researches of Mallet (*Phil. Trans.*, 1880), in which special care was taken to eliminate the influence of occluded oxygen, the atomic weight of aluminum is 27·019, taking oxygen at 15·961.

T. W.—Aqua menthæ viridis. See Disp. Mem., No. 101, *Pharm. Journ.*, [3], viii., 850.

Lux.—The formula has already been asked for more than once in this Journal unsuccessfully.

A. F. Sainsbury.—(1) Proctor's 'Lectures on Pharmacy;' (2) Gray's 'Supplement to the Pharmacopœia,' or Cooley's 'Cyclopædia of Practical Recipes.'

Communications, Letters, etc., have been received from Messrs. Davis, Proctor, Ronchetti, Macdermott, A £2 Victim, Wulfruna, Magister, J. E. J.

MADAGASCAR DRUGS.

BY E. M. HOLMES, F.L.S.

Although a list of the remedies used in Madagascar has already appeared in this Journal ([3], vol. xi., p. 853), and some remarks have been published concerning their uses (vol. xii., p. 669), no description has hitherto been given by which the various roots, barks, etc., might be identified should they hereafter enter into commerce. A considerable number, probably, do not possess active properties, and others are already well known. The remainder probably possess properties which may enable them to be turned to account in Madagascar as substitutes for European drugs, and on this account appear to merit such a brief description as will enable them to be distinguished from other drugs.

ROOTS.

FAMAMO OR FANAMAMO.—The root is woody, about ¾ inch in diameter in the upper portion, branched and tapering to ¼ inch or less, of a pale bright brown colour externally, and yellowish white within; the surface is rough with small paler warts of about the size of a pin's head.

The plant has been identified at Kew as *Mundulia Telfairii*, Boj., and belongs to a genus closely allied to *Tephrosia*, a genus which yields several fish poisons. It is for this purpose that Famamo is chiefly used, more especially in ponds or still waters. It is mentioned here because it may be presumed that it contains an active principle whose therapeutic properties might be worth investigation.

FISAVA.—A small woody root, undulated and about the size of a goose quill, with a thin smooth bark, pale brown externally, but dark brown in transverse section. The taste is aromatic and bitter, somewhat resembling that of cardamoms. The meditullium is hard and woody, and minutely porous. The Malagasy name signifies "disperser of mist." It is used for headache.

HAZOMAFÀNA.—This drug consists of woody stems varying from ¼ to ½ inch in diameter, with a reddish grey, minutely wrinkled bark, speckled all over with white dots. The bark is thin, very tough and composed of fine silky fibre, and in aspect, acridity of taste and herbaceous flavour so closely corresponds with ordinary mezereon bark that there can be little doubt that it is the produce of a species of *Daphne* (possibly *D. viridiflora*, Wall.). The pounded bark is given in doses of 1 drachm, mixed with salt and ginger, as a purgative. It probably possesses similar properties to *Daphne Mezereum*, and would be worthy of a trial as a substitute for it in the native materia medica.

HAZOMANGA.—The specimen of this drug in my possession consists of a piece of whitish exogenous wood, the details of the structure of which cannot well be seen from having been mined in all directions by insects, a fact somewhat remarkable, since the wood has a strongly camphoraceous taste and odour and considerable pungency. It is used for indigestion.

MAHATATIDY.—This drug consists of woody stem, about as thick as the little finger, with a thin whitish bark marked longitudinally with small ridges, the summit of the ridges being cracked so as to look like narrow elongated warts. A transverse section shows a very thin bark, in which minute crystals can be seen under a lens, and a white woody meditullium of ordinary exogenous structure. The taste resembles slightly that of pyrethrum, and has the same sialogogue effect. The name means "making to remember," an infusion of the plant being used to refresh the memory.

It probably belongs to the Rutaceæ, and might, perhaps, form a substitute for jaborandi in native materia medica.

MATSÀTSORANA.—Consists of pieces of stem about ¾ to 1 inch in diameter, with a hard, brittle, yellowish-brown bark, about two lines in thickness, smooth or marked with a few transverse rings and small oblong transverse warts and scars. The bark has a granular, and the meditullium a fibrous fracture, but owing to the cells being filled with starch, the structure is not easily seen, except that the white transverse surface under a lens is perceived to have scattered pores and numerous horny looking lines, transversely placed so as to form irregular zones, a feature by which it is easily recognized. The starch is peculiar, being oblong, spindle-shaped or irregularly angular, with a well marked longitudinal hilum, somewhat similar to the starch found in the Leguminosæ. The root has a faint aromatic odour and no perceptible taste, but is remarkable for its similarity in colour and general appearance to canella bark. It is used for dyspepsia.

MAINÀKIMÀFY.—A woody plant about the size of the fore finger, with a pale brown wrinkled bark and an astringent taste. A transverse section shows a bark about two lines thick, having the reddish marbled appearance peculiar to rhubarb and other polygonaceous plants. When the bark is scraped with the nail it reveals a thin yellowish-brown layer immediately below the epidermis. The whitish woody meditullium exhibits the ordinary radiate and porous structure of exogenous roots. The root probably possesses astringent and alterative properties similar to those of the common dock.

RAÌNGERAÌNGY.—Is a tapering greyish-brown root, about 1 inch in diameter and 3 or 4 inches long, with a spongy pith and a radiated woody ring between it and the thin bark, the latter being of a brown colour and having a rough scurfy surface. It has no odour, but a taste between that of aconite and pellitory in character, which developes slowly. The plant grows in a valley south of Andrangoloaka. The leaves are stalked and imparipinnate, with three or four pairs of oblong crenate-serrate leaflets, cordate and unequal at the base. The leaflets are smooth above, but underneath the veins have scattered yellowish hairs, which occur also on the petioles and rachis. The flowers I have not seen, but the plant evidently belongs to the Umbelliferæ.

RAISÀONJO.—This is a hard woody exogenous stem 1–2 inches in diameter, with a pale bright brown bark about one line in thickness. The wood, which is very hard, is seen under a lens to have numerous slender medullary rays. The bark is externally marked with transverse rows of oval or oblong warts, which, as the bark becomes older, run together into warty ridges. Internally it is pale and of a horny appearance. The taste, at first sweetish, soon becomes exceedingly acrid. It is given with "Ambilaza" in urinary diseases. It is called by the Malagasy, according to Dr. Parker, "Odinhèry," or the strongest "Ody" (charm or fetish). The plant has not yet been identified, but the character of the bark seems to point either to *Sapindaceæ* or *Euphorbiaceæ*.

ROVY.—This root is about the thickness of the forefinger, brownish-grey externally, slightly furrowed longitudinally, with a few transverse constrictions, each of which is marked by a crack on one side. The bark is whitish and spongy, and the yellowish woody meditullium is divided into numerous linear wedges by white medullary rays, easily discernible by the naked eye. The odour is somewhat earthy and the taste very bitter. In appearance and structure the root resembles that of some of the species of *Aristolochia* used under the name of guaco in South America. Possibly it may be the root of *Aristolochia acuminata*, Lam., the only species at present described as a native of Madagascar. (See Baker, 'Fl. Mauritius,' p. 322.) The root is used for indigestion, and is said to act as a purge.

Sanàtry consists of pieces of slender stems, of the size of a goose-quill and about 6 inches long, externally greyish-brown, striated and cracked longitudinally, with scattered warts of the size of a pin's head. The thin bark, pale inside, easily splits off from the tough woody portion of the stem; the latter in transverse section is seen to be pale yellow or nearly white and porous. The taste is bitter and slightly smoky. It is used as a remedy for bronchitis and catarrh, half or a whole piece being scraped and given in water. It is used more particularly for children.

Tangèn (*Tanghinia venenifera*, Poir.). — This celebrated seed, the ordeal poison of Madagascar, resembles an almond in the shell, except that it is rather broader in proportion, and has an open fissure on one side; the colour of the endocarp is also of a dull dirty brown. The kernel or seed is seen to be oily when pressed with the nail. (See Tangen Hakalava root.)

Tsìankoditra drevo.—This drug consists of a contorted rhizome, giving rise to numerous erect branches, which are attached to the rhizome by a kind of articulation, leaving a well-marked circular cicatrix or scar where they have fallen off, the base of the stem being slightly enlarged near the joint. Both the rhizome and stems have a pale brown papery epidermis. A transverse section of the meditullium under a lens shows a single row of wedge-shaped vascular bundles surrounding the pith, and then a series of transversely oblong bundles radially arranged. The bark is as thick as the meditullium, and contains a few rather brittle vascular bundles immersed in a friable parenchyma, the cells of which, under the microscope, show in a remarkable manner sclerogenous deposits and canals leading to the centre of the cell, and form an excellent object for illustrating this structure. The taste is bitter and slightly acrid. It is said to be used mixed with "Manavo-drevo."

Tsìhitrafòtotra (*Cassytha filiformis*, L., Lauraceæ).—The name means "roots not found," and indicates its parasitic nature. The drug consists of the slender thread-like stems of the plant. It has a mucilaginous taste, but no odour. It is employed in Mauritius in the form of decoction for intestinal derangement and as a tonic for scrofulous and rachitic infants. This is another eastern remedy whose use extends to Madagascar. In India the powdered plant mixed with sesamum oil is used to strengthen the hair, and by the Brahmins for cleansing inveterate ulcers, for which purpose it is mixed with butter and ginger. The juice mixed with sugar is considered a specific in inflamed eyes ('Treas. Bot.,' p. 234). Its properties are probably due to mucilage.

Tsilanky.—This drug consists of slender woody stems, about ¼ inch in diameter, with a thin yellowish longitudinally shrivelled bark, the circle of wood being formed of pale horny tissue, divided into radial wedges by the medullary rays. The pith consists of polygonal cells with well-marked pores. The effects of this drug are said to resemble those following the bite of the tarantula.

Tsilèondroàhy.—This is the root of an umbelliferous plant. Externally it is marked with small transverse ridges. The transverse section shows a central white spongy meditullium surrounded by a thick bark, the liber of which consists of vascular bundles arranged in radiating lines with parenchyma tissue between them, a dark resinous circle separating this portion from the meditullium. Another similar circle occurs between the latter and the thin brown epiphlœum. The taste is pungent and the odour like that of wild angelica (*A. sylvestris*, L.), to which plant the serrate leaflets also bear some resemblance.

Ramy.—This oleoresin has the odour of elemi and is probably the produce of *Canarium Colophania*, Baker ('Fl. Mauritius,' p. 44), from which an oleo-resin is obtained in Mauritius and employed in the form of plaster as a detersive. It corresponds in appearance with the Mauritius elemi in the Hanbury collection of materia medica, both in giving no coloration with bromine water and in leaving crystals after solution in cold alcohol.

BARKS AND WOODS.

Hafotra Fotsy.—This occurs in the form of strips of white fibrous bark, very tough and difficult to break and consisting of liber only. It has a slightly pungent odour; when chewed it has at first no taste, but a pungent acridity is slowly developed, which lasts for several hours and recalls the taste of mezereon so strongly that it seems probable that the bark is derived from a thymelaceous plant, notwithstanding the fact that the plant received under the same name at Kew proves to be *Abutilon angustatum*, Mart.

Havozo.—A dull brown bark, of which the inner surface is finely striated longitudinally and the outer minutely cracked and having small warts sparingly scattered over it. A transverse section shows a thin epidermis, beneath which lie several strata of stony cells; these give to the middle of the bark a granular texture, and at right angles to them thin medullary rays give a radiate appearance to the innermost portion of the bark. The odour of the cut or bruised bark is very powerful and exactly resembles sassafras, for which it might probably form an efficient substitute in native materia medica. It probably belongs to the Lauraceæ and may possibly be the *Hernandia peltata*, or *Sassafras mauritiana*, Boj. ('Hort. Maur.' p. 273). See Baker's 'Flora Maur. and Seychelles,' p. 294.

Mandravasorotra (*Betsileo*).—This is a pale fawn-coloured or dirty-white bark, closely resembling canella bark in appearance and structure. It occurs in the form of unrolled quills about ⅝ inch in diameter. The bark varies from ⅛-¼ inch in thickness; the outer surface has the thin periderm removed and is marked with numerous small circular depressions and a few scattered warts with a smooth depressed apex. The transverse section shows under a lens a dense white parenchyma with minute circular cavities or depressions in which glistens an oleoresinous fluid (?) which apparently, when exposed to the air, yields minute crystals. The taste and odour both strongly resemble those of

Cinnamodendron corticosum, the taste being more pungent than that of canella bark.

It is used medicinally for stricture and dysuria and as a stimulant in chronic diseases.

No species of either canella or cinnamodendron is mentioned by Baker in the 'Flora of Mauritius and the Seychelles,' nor by Bouton in his 'Plantes Médicinales de Maurice.' In Madagascar the bark is used in stricture and dysuria or as a stimulant in chronic diseases.

A bark under the same name, from Betsileo province, possesses the following characters:—Bark, dull brown, externally nearly smooth, with a few faint transverse furrows, minutely striated longitudinally on its inner surface; a transverse section shows a thin dark outer line of minute cells, beneath which lies a layer of stony cells which radiate into the yellowish woody tissue of the liber in the form of pale lines distant about $\frac{1}{6}$ inch from each other. The taste and odour strongly resemble mace, with a faint resemblance to the odour of bruised carrot leaves. The layer of stony cells gives a granular fracture to the outer portion of the bark. Although probably a lauraceous bark, it evidently is the produce of a different tree from the ordinary mandrava sarotra bark; it is not identical with the Havozo bark.

Nato.—A thin bark, from which the periderm has been removed. Externally it is of a sienna brown tint and of a bright red brown on its inner surface. A transverse section is of a much paler colour. It readily splits up longitudinally into laminæ which consist of hard agglutinated fibres. The taste is astringent and slightly bitter. It is used in Madagascar to dye cloth of a red colour, but if not poisonous might form a useful astringent.

(*To be continued.*)

THE MELTING POINTS OF PETROLEUM OINTMENTS, AND A TRIP INTO THE OIL COUNTRY.*

BY SAMUEL A. D. SHEPPARD.

There has been a desire, for some time past, especially among physicians, for a petroleum ointment that shall have a higher melting point than most of those now in the market.

It has already been intimated that petroleum ointment will have a place in the coming United States Pharmacopœia, and the only question which still appeared to be open was the melting point. Statements had been made to the effect that an ointment of high melting point could not be made without the admixture of foreign substances, and, in general, the knowledge of the preparation and properties of these products was so fragmentary that it was deemed advantageous to determine, by personal observation, the following points:—

1st. Can petrolatum be made by filtration of any desired melting point between 95° F. and 120° F.?

2nd. If such be the case, is the process so practical and the supply of crude material from which it may be made so abundant that, if the article should be directed to have a melting point not exceeding 120° F., pharmacists can readily obtain it?

With this interest in view, the writer left Boston at 3 p.m., March 14, and arrived in Corry, Pennsylvania, the next day at noon.

An invitation had been received some months before from Messrs. Clark and Warren, oil refiners, of Corry, to visit the oil country, and have carried on by them any experiments on this subject, in any way desired, at their works, where all the facilities for such experiments were ready at hand or could be easily furnished at short notice.

Mr. R. C. Clark, the senior partner of the firm, met me at the depôt, and during the seven days spent in Corry and vicinity he devoted his entire time to me, himself performing nearly all the experiments, and giving his constant personal attention to all of them, sometimes till late into the night, in order that I might see the work done in the most satisfactory manner.

He gave me in every possible way all the facilities needed in the investigation, and materially assisted me, a stranger in the oil region, to obtain information on any and all points that happened to arise, and I embrace this public opportunity to thank him, especially, for his courtesy, and also to thank his partner, as well as Mr. William H. Abbotts, of Titusville; Mr. W. R. Weaver, of the Emery Oil Company, Bradford; Mr. E. B. Frew, and Mr. Babcock, both connected with the United Pipe Lines at Warren; Mr. Edward E. Kattell, of Binghamton, N. Y.; Mr. S. C. Lewis, of the Chesebrough Manufacturing Company, New York, and many other gentlemen whom I met, all of whom, without exception, cheerfully and courteously gave me information with regard to various points connected with the subject.

Wednesday afternoon was occupied in thoroughly discussing the subject with Mr. Clark and others, and in making a careful inspection of the Oil Refinery Works of Messrs Clark and Warren, in order to familiarize myself with the proposed materials, implements, and processes.

Having had previous knowledge of the nature of what is known as B. S. oil, my plan as laid out on Wednesday evening was about as follows:—

To distil and filter such B. S. oil as I could dip out of the bottom of Clark and Warren's crude oil six-thousand-barrel tank.

To go over to Warren, some 25 miles distant, to get a supply of B. S. oil from the United Pipe Lines that had been standing several years, and to distil and filter this sample. To go over to Bradford, the great centre of the present oil-producing district, and examine personally the oil wells, and talk with oil men at the wells and in Bradford, and to obtain specimens of the heavy, crude, amorphous paraffin that sticks to the sucker-rods and clogs the pipes at the wells. Lastly, to experiment in any way that seemed best on my return to Corry.

This plan was carried out nearly as stated.

The agents of the United Pipe Lines in Warren were very courteous, and readily granted the request to take a half barrel of B. S. oil from their large wooden tank, saying that there was some 4 feet of the "stuff" in the tank, and if any plan could be devised to create a demand for it, all the oil men in this section would be pleased, as it is a nuisance everywhere, and the bulk of it is increasing every year in every tank. All the persons with whom I talked told the same story. The article is a nuisance; the bane of the oil men.

This half-barrel sample was expressed to Corry, and time being limited, we went direct from Warren to Bradford. Here as much time as was necessary was occupied in going around to the oil wells, in getting samples, and in consultation with oil men as to the quantity and quality of the B. S. oil and the sucker-rod production, or "rod wax," which articles seem to me to be both simply crude amorphous paraffin, differing in density and in the admixture of lighter products.

The "rod wax," which the oil producers simply designate as "paraffin," seems to be found in both "pumping wells" and "flowing wells;" but it is not often found at a depth much lower than 250 feet below the surface.

To clear the pipes of the "pumping wells," it is necessary to draw the "sucker rod" and use a jet of steam. In the "flowing wells," when the "rod wax" has accumulated sufficiently to stop the flow, the pressure of the gas below will, after a time, force the accumulation out into the flowing tank—in other words, the well "cleans itself."

* From *New Remedies*, May, 1882.

This happens every few days or weeks or as often as may be.

The "rod wax" from the "flowing wells" is hence found at the bottoms of the "flowing tanks;" that from the "pumping wells" on or under the derrick floors, or wherever it may have been thrown to get it out of the way.

There are in the Bradford district nearly twelve thousand wells; at each of these wells there is usually one or more tanks. The Pipe Lines refuse to receive into their pipes some twenty barrels, more or less, from the bottoms of each of these tanks. This sediment in known as B. S. oil; a portion of it is water, but the greater part of it is a mixture of crude, amorphous paraffin, with a greater or less quantity of the lighter products. Its density is according to the character of the crude oil and the length of time the tank has been used.

In addition to the "producer's tank," there are scattered all through the district immense iron tanks, each holding from twenty to thirty thousand barrels of crude petroleum. From the hill overlooking Bradford, we could count nearly one hundred of these large iron tanks, and as we rode from Bradford to Carrolton, many more. In each of these tanks is a sediment of B. S. oil.

The amount of this sediment, B. S. oil, not known to be on hand is probably not less than three hundred thousand barrels. An estimate made by reliable parties of the amount of "rod wax" that could be obtained at a fair price was from five to ten thousand barrels a year, the most of which is now thrown away.

Having obtained material with which to work, experiments were commenced at the refinery in Corry. Mr. Clark had had made a small sand pump, holding about 2 gallons, with a long rope attached. This could be used to get oil from the bottoms of the tanks.

The sand pump here mentioned may be described as follows:—It was an upright galvanized iron cylinder some 6 or 8 inches in diameter and 20 inches long, open at the top, its bottom closed by a valve so arranged that as the cylinder sank down into the oil the valve remained open, and the cylinder sank through the various strata of oil as it would were it bottomless; but immediately on an attempt being made to draw the cylinder upward, the valve closed, and the cylinder could be drawn up to the surface, filled with oil from any stratum desired. Small iron legs, 3 inches long, prevented the lower edge of the cylinder from reaching the bottom of the tank, the object being to thus prevent the taking up of water, a stratum of which is at the bottom of each tank.

He had also arranged a small still of about 15 gallons' capacity, a cheese-box still, some 20 inches in diameter and about 15 inches high, with iron piping $\frac{7}{8}$ of an inch in diameter, to serve as inlet and outlet tubes, the vapour of the lighter products being carried through the wall to the outside of the building through a similar iron tubing, and thence through some 30 or more feet of iron tubing as a condenser. The temperature of the atmosphere being somewhat below freezing, this made a pretty fair condenser, cold water being poured on occasionally.

A small pipe was arranged to conduct a jet of steam to the bottom of the inside of the still.

The still was incased in brickwork; the heat applied was that obtained from an ordinary wood fire, great care being used not to allow the heat to get too strong.

With the sand pump some 7 gallons of the sediment were drawn from the bottom of Clark and Warren's crude-oil tank with which to charge the still. This oil was not a good specimen of B. S. oil, because it had been standing only about one month, and was not so thick as could have been desired.

Very shortly after the heat was applied to the still, benzin commenced to run. As the distillate came over, its gravity was tested every few minutes. The first run stood at about 70° Baumé; it very soon came down to 65° and to 60° Baumé.

I was told that I could not judge fairly of the quantity and gravity of the light products, owing to the smallness of the quantity and the character of the stock used; but I was not so much interested in the distillate as in the residuum.

When the distillate stood at about 50° B., a small jet of steam was turned on, the force being afterwards increased somewhat. The use of steam serves to help drive off the lighter products more completely and at a lower temperature.

At 40° B., wax was struck, and the distillation was stopped by removing the heat from the still. To "strike wax" is a term used to denote that point in the process of distillation at which the distillate shows the presence of paraffin wax, by the latter congealing on the cool edges of the condensing tubes or otherwise.

The still was allowed to stand undisturbed until it was presumed that its contents were sufficiently cooled not to take fire on exposure to the air, yet not long enough to get cold. Mr. Clark stated that there would have been great danger of fire, had the residuum been drawn off at once, when the heat was removed, as the temperature was probably from 500° to 600° F., or higher. The residuum was then drawn off slowly into an open pan. Its temperature was 320° F.; quantity about 2½ gallons.

An ordinary heavy tin cone-bottom percolator, with a stop-cock, had been arranged in a box closed on three sides, one of the three sides being arranged as a door.

The percolator was 11 inches in diameter, and its perpendicular sides were 22 inches in height.

A perforated metal diaphragm, 3 inches in diameter, was placed over the outlet tube; this diaphragm was covered with a piece of unbleached cotton, over which was placed some ordinary cotton batting. Thus prepared, the percolator was ready to receive the animal charcoal and the residuum.

Coarse animal charcoal had been heated to a red-heat for about one half-hour to free it from bone odour. This charcoal was now only quite warm, so cool that it could be easily handled with the bare hands. The warm charcoal was packed firmly in the percolator to the depth of 6 inches, and the hot residuum, having stood now in the air about a half-hour, was poured on. The open side of the box, in which the percolator was arranged, was so placed as to receive a current of hot air, and thus the temperature of the air in the box was kept constantly at from 180° to 200° F.

The first run from the percolator was quite light-coloured. It soon commenced to grow darker in colour, and by the time a half-gallon had passed, it was evident that a second filtration would be necessary.

The product was very sweet and free from odour, but was not so heavy as desired (having a melting point of 100° F.), and it was decided not to spend any more time on it, but to get another lot of 10 gallons of oil from the bottom of the tank, and distil and proceed with the distillation until the distillate should have a gravity of but 37° B.

This was at once done; the temperature of the residuum when running from the still was 380° F., and, when cooled, it had a melting point of 102° F., and the melting point of the filtered product was the same.

Experiments were made to test the melting points at various stages in the process of filtration, but, in the quantity that we were handling, there was comparatively little difference, though the general rule of oil men, that "repeated filtrations lessen the cold test," proved true. In other words, the more filtering, the higher the melting point.

Two lots of 10 gallons each of the B. S. oil, from Warren, were distilled and filtered. The gravity of this oil was 36° Baumé.

The distillation of the first lot was carried on until the distillate had a gravity of 40° B. The temperature of the residuum, when running from the still, was 360° F., and the filtered product had a melting point of 100° F.

The distillation of the second lot was carried on until the distillate had a gravity of 34° B. The temperature of the residuum, when running from the still was 380° F., and the melting point of the filtered product was 110° F.

One lot of 3 gallons of crude paraffin that causes the clogging of the wells, "rod wax," was distilled and filtered.

The residuum from it was about 80 per cent. of the amount used. The temperature, when running from the still, was 400° F., and the melting point of the filtered product was 138° F.

A lot, consisting of a mixture of 2 gallons of the sediment from Clark and Warren's tank and 1 gallon of rod wax was distilled and filtered. The temperature of the residuum, when running from the still, was 405° F., and the melting point of the finished product was 130° F.

One lot, consisting of a mixture of 2 gallons of the sediment from Clark and Warren's tank and ½ pound of commercial paraffin wax was distilled and filtered. The temperature of the residuum, when running from the still, was 380° F., and the melting point of the filtered product was 110° F.

The object of this experiment was to have a sample known to contain crystalline paraffin wax, and, by future examination, to judge of the homogeneous character of a preparation when the admixture was made previous to distillation. There is so much cracking or splitting up in these paraffins that it is not always easy to say what may occur till an experiment has been made.

A quantity of *very dirty* rod wax had been brought from one of the wells in Bradford. It was the worst specimen that we could find. This was placed in an open pan in a very warm place, allowed to stand thirty-six hours, strained through cotton, and filtered through animal charcoal. The melting point of the finished product was 140° F.; colour and odour very good, and, by repeated filtrations, it was made nearly white.

An experiment was made by filtering a small lot of very nice inodorous petrolatum through ordinary animal charcoal. The filtrate was quite offensive in odour, especially when warmed.

A similar experiment was tried with ground, unburned bones, and gave a product that, when hot, was simply disgusting in its odour, as, of course, I expected it would be.

Complaints have frequently been made by dermatologists that the petroleum ointments of the markets are sometimes irritant in their action. This can probably be explained by the fact that sufficient care is not always used to have the animal charcoal, which is used for filters, properly purified. It can be purified by heating it to 500° to 700° F., for, say, half an hour, the heating being done a comparatively short time before using the charcoal. If the charcoal be not freed from impurities, the petroleum product, when filtering through it, will be likely to absorb the condensed noxious gases, and thus may become, not only an offensive, but an irritant instead of an emollient application.

A specimen of what is known as "tar" was obtained from the oil works of Messrs. Downer and Co., at Corry. It is the residuum left in the petroleum still when the distillation had been carried to 23° to 18° Baumé. From this "tar," by destructive distillation, paraffin oils and wax are obtained, coke being left in the still. By congelation and pressure, the paraffin wax is separated from the oils. No experiments were made with this "tar," as it did not seem to have a bearing on the subject in hand.

The writer has now on hand specimens of all the crude materials used in the foregoing experiments, and also of the products obtained therefrom.

Of one fact the writer was thoroughly convinced, as he watched the slow, tedious processes of filtration through animal charcoal. It was that, in the future, pharmacists will probably use, for some purposes, a petroleum ointment that is not so thoroughly decolorized as the nice articles now found in our markets.

The process of filtration is the expensive part of the manufacture of this article. A general estimate that would be fair, would probably be that from 300 parts of residuum, but 100 parts of the nice light straw-coloured goods can be obtained; it being necessary to use so much charcoal that the 200 parts are absorbed by it, for the charcoal absorbs about one-half its weight of the residuum. If an article not quite so nearly decolorized could be used, it could be furnished by the manufacturers at a much lower price than they are now obliged to ask for it, and the question now arises, Is the very light-coloured product really any better than one slightly coloured, yet equally free from odour?

The writer does not feel competent to answer, but he thinks that it is a question worthy of consideration, for it seems probable that if a somewhat darker-coloured product, equally free from odour, should be found equally good as a base for ointments, it could be furnished at a low price, say 8 to 10 cents a pound less than is now paid for good lard. The residuum can be deodorized without the use of animal charcoal, and the opinion was freely expressed by intelligent persons, familiar with the subject, that the residuum deodorized, not filtered, is a good dressing for wounds.

Leaving Corry at noon, March 22, I went to Binghamton, N. Y., and the next morning had a very pleasant and instructive visit of a couple of hours at the Binghamton oil refinery. Mr. Edward E. Kattell, one of the proprietors, courteously showed me the whole process of the manufacture of petrolina, the petroleum ointment put on the market by them. They do not use the residuum from the still in making petrolina, preferring to make it by deodorizing a mixture of "rod wax" and some lighter product in proper proportions, and filtering the deodorized mixture through animal charcoal. The lighter product used is either crude petroleum oil or some one of the paraffin series of oils that may be somewhat unsalable.

Mr. Kattell thinks that the supply of rod wax is limited, but that should it become scarce, they would make the goods from heavy B. S. oil, by distilling it and then deodorizing and filtering the residuum, whereby they can get an ointment that shall have a melting point of 115° F.

Mr. Kattell does not think that an ointment of a higher melting point than 115° F. can be made without the use of rod wax, but a comparatively small quantity of rod wax would be sufficient to stiffen the 115° F. goods made from "tank bottoms" B. S. oil, so that they would have a melting point of 120° to 125° F., and there is no probability that the supply of rod wax will entirely cease.

Passing through New York on my way home, I called at the office of the Chesebrough Manufacturing Company to gather information on the subject of the melting points of petroleum ointments. Mr. Chesebrough was not in, but I had the pleasure of a very pleasant interview with Mr. S. C. Lewis, the vice-president of the company. He discussed the matter at some length, and gave in detail the position of the company in regard to the melting point to be adopted in the coming pharmacopœia. It was, that, from information gathered by them from many reliable sources, the consumers of the article will be best satisfied if they can have two preparations, the one having a melting point of 100° F., and the other 115° F. He also stated that the company is ready to furnish an article that should have any melting point desired below 125° F., and at the same time be entirely homogeneous, with no admixture of paraffin wax. He courteously invited me to visit their manufactory at some future time, though he could not of course reveal the trade secrets of the company. He stated that his opinion, as a manufacturer, was that if a melting point higher than 115° F. should be adopted, it would probably cause the market to be flooded with preparations that would not be homogeneous, but would have an undesirable granular character, as he thought manufacturers would resort to other ingredients as admixtures, that would deteriorate the quality.

The writer would have liked to have visited Philadelphia in order to see the process for the manufacture of cosmoline, but was not able to do so.

The conclusions arrived at may be summed up as follows:—

Although the term paraffin may be and is properly applied chemically to any one of the long series of hydrocarbons, commencing with marsh gas and running up through the benzins, the illuminating oils, and the lubricating oils to paraffin wax, the usage of trade really confines the term paraffin to those of the series that are solid or semi-solid at ordinary temperature. It is in the latter sense that the term will be used in the following remarks.

Petroleum, as it comes from the earth, may be said to be capable of division into three parts by distillation, viz., into what may be practically termed two series of oils: the benzin oils and the paraffin oils and paraffin wax.

The division between the two series of oils may be said to occur in the process of distillation when very carefully conducted, when the gravity of the distillate has been reduced to about 42° to 41° Baumé.

The benzin oils are colourless or white oils, and have a peculiar benzin odour. They are also said to have a definite boiling point.

The paraffin oils are yellow or straw-coloured oils, and have a greasy or waxy odour.

The oils in the paraffin series are very easily split up into other and lighter products of the same series by the skilful application of heat.

The article desired as a base for ointments by physicians and pharmacists is really amorphous paraffin mixed with a certain amount of one or more of the above-mentioned series of paraffin oils, but entirely free from admixture with any of the benzin series or the *crystalline* paraffin wax.

The benzin oils, if present, give an objectionable odour, and the crystalline paraffin wax, if present, will, in time, especially if the article be exposed to a low temperature, render it granular and cause it to separate, thus losing that homogeneous character so desirable in an ointment.

The question now is how to obtain this desired article. From all crude petroleum oils paraffin settles to a greater or less degree, so that if a tank containing two hundred and fifty barrels has been used at a well for three or four years, it may be expected to contain at the bottom of the tank a deposit, ranging in depth from 4 to 8 inches, of a mixture containing a large proportion of paraffin. This paraffin is always in an amorphous condition, the crystalline character being found only in those products that have been subjected to the process of distillation.

Observations show that this amorphous paraffin and the harder varieties that clog the pipes may be easily obtained in quantities sufficient for all the demands of medicine and pharmacy. We have, therefore, ready formed for us in Nature's laboratory the article we desire, but it is contaminated by oils of the benzin series, with odorous and colouring matter; the oils are gotten rid of by careful distillation, and the other by filtration through animal charcoal.

The harder variety, "rod wax," is the article that may be used to advantage to increase the melting point of petroleum ointment. Its melting point being about 140° F., and it being an amorphous and not a crystalline paraffin, it can be mixed, when purified, with goods of a lower melting point, to make a homogeneous article, as is shown by samples of such mixture that have stood more than a year. It is better, however, that the admixture be made previous to distillation. It is necessary that the animal charcoal, used as a filtering medium, be freed *by recent burning* from condensed noxious gases or other impurities.

To obtain petroleum ointment of a desired melting point it is necessary to *start* right, that is, to select such crude material as will, by distillation or purification in some way, give a residuum having the wished-for melting point. It is the opinion of the writer that to obtain an article having a melting point anywhere from 100° to 120° F., such crude material can be obtained easily, abundantly, and at a fair price, and that if a demand should be created for such an article, the demand will be quickly supplied.

The above conclusions are given as the opinions of the writer, derived from careful thought and experiment in the past, and now confirmed by observations and experiments under circumstances where it would seem that just conclusions might be formed.

While the writer does not presume that he has developed any hitherto unknown facts, and certainly will not object to any just criticisms, he hopes to add a little interest to the study of this subject, and to stimulate research in a direction to which pharmacists in the past have given too little thought and attention.

STUDIES ON THE ALKALOIDS.

BY DR. W. KOENIGS.*

ANNOTATED BY M. DE BECHI.

(*Continued from Vol. XII., page 745.*)

4. *Relations between Alkaloids and the Pyridic Bases.*

Recent works upon the acids obtained by oxidation of different alkaloids and belonging to the pyridic series, seem of great importance in respect to the constitution of these interesting bodies.

In 1867, Huber,† by treating nicotine with bichromate of potash and sulphuric acid, obtained an amide acid, $C_6H_5NO_2$, which he found subsequently‡ to be pyridinocarbonic acid, $C_5H_4N.CO_2H$, and which distilled with lime gave an oily base, C_5H_5N; soluble in water. Weidel§ obtained the same acid by oxidation of nicotine with fuming nitric acid; he found that it gave pyridine by distillation with quicklime, but he attributed to it the formula of $C_{10}H_5N_2O_3$, instead of $C_6H_5NO_2$. Luiblin|| showed the formation of a pyridino-carbonic acid by the oxidation of nicotine with potassium permanganate. By treating quinine, cinchonine, quinidine, and cinchonidine with the permanganate, Hoogewerff and van Dorp,¶ and Ramsey and Dobbie** obtained pyridino-tricarbonic acid. An isomeric acid has been obtained by Weidel†† by treating berberine with concentrated nitric acid.

Piperidine, $C_5H_{11}N$, yields pyridine, C_5H_5N, by oxidation (Kœnigs).‡‡ Lastly, Gerichten§§ obtained a pyridino-carbonic acid by means of an alkaloid of opium, narcotine. Monobasic apophyllic acid, $C_8H_7N_4$, obtained by Woehler and Anderson by oxidation of cotarnine, $C_{12}H_{13}NO_3$, is decomposed, when heated, into an oil having an alkaline reaction and chinoline odour (Woehler).|||| When heated to 240°-250° C. with concentrated hydrochloric acid, chloride of methyl separates, and a bicarbonated acid of pyridine is formed, identical with the cinchomeronic acid

* 'Studien über die Alkaloide.' By Dr. W. Koenigs. Munich: F. Straub, 1880. With annotations and additions referring to recent researches by M. de Bechi. Translated from the *Moniteur Scientifique*. The additions are included within brackets.

obtained by Weidel* by oxidizing the cinchona bases with nitric acid. Gerichten, therefore, considers apophyllic acid to be a methylic acid ether of cinchomeronic acid:—

$$C_5H_3N\left\langle\begin{matrix} CO_2H \\ CO_2.CH_3 \end{matrix}\right.$$

and he admits that cotarnine includes the group $(CO_2.CH_3)$. Up to this time then, pyridine or its carboxylic derivatives have been obtained from nicotine, the cinchona bases, berberine, narcotine and piperine.

[Gerichten† has studied cotarnine and its derivatives and arrived at the following results. Apophyllenic acid, already obtained by Wöhler, is prepared by oxidizing cotarnine by means of nitric acid. The yield is bad, only 10 to 15 per cent. of the cotarnine employed. It crystallizes in rhomboctahedra, is rather soluble in hot water, slightly soluble in cold water, and insoluble in alcohol and ether. It melts at 241° to 242° C., with evolution of carbonic acid. It is monobasic. Heated with hydrochloric acid to 240° to 250° C., it loses methyl, giving cinchomeronic or pyridinocarbonic acid.

$$\underset{\text{Apophyllenic acid.}}{C_5H_3N\left\langle\begin{matrix} COOH \\ COOCH_3 \end{matrix}\right.} + HCl = CH_3Cl + \underset{\text{Cinchomeronic acid.}}{C_5H_3N\left\langle\begin{matrix} COOH \\ COOH \end{matrix}\right.}$$

Cinchomeronic acid becomes yellow at 250° C., and melts at 266° to 268° C. Its most characteristic property is its behaviour with acetate of copper, which does not give a precipitate in the cold. Upon heating the solution it becomes turbid, and clears again upon cooling. Prolonged boiling, however, produces a permanent azure blue crystalline precipitate.]

It is customary to consider the alkaloids to be a large class of bases more or less related, and also to distinguish them by placing them in groups formed of the bases met with in the same plants, and which present common physiological and chemical properties.

The same thing is done in respect to many other (non-nitrogenated) bodies of the vegetable kingdom, which can be changed from one into another (for example, many carbohydrates into dextrine, the camphors and terpenes into cymol, etc.). The same relations have been found between alkaloids derived from the same plants, as, between caffeine and theobromine; morphine and codeine; conhydrine and coniine; hydrocotarnine and cotarnine; harmaline and harmine; strychnine and brucine; cinchonine and quinine; cinchonidine and quinidine; these last alkaloids have all given the same pyridino-tricarbonic acid by oxidation. It can therefore be admitted that the other bases of opium and the alkaloids in general would give pyridic derivatives by proper treatment. A proof that atropine and coniine will behave similarly seems to be supplied by a recent work of Harnack and Meyer.‡ These authors have found in the leaves of jaborandi, besides pilocarpine, $C_{11}H_{16}N_2O_2$, analogous to nicotine in its physiological action, a new alkaloid, jaborine, which acts like atropine; they have besides verified the researches of Poehl,§ who has found that by distilling pilocarpine with potash, a base volatile at 160° C. is obtained, very probably identical with coniine, and which perhaps accrues from the jaborine contained in the crude product, besides pyridic bases (which are also found in the mother-waters of the preparation of pilocarpine).

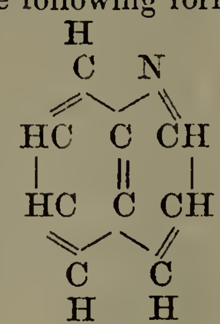
From all this, it seems that pyridine may be the nucleus around which all the alkaloids ought to be grouped, like the aromatic bodies around benzine. Some vegetable bases are known, it is true, which are not derived from pyridine, as, for example, betaine, sinapine and muscarine, which have a close relation to the oxyethylenic bases, and caffeine and theobromine, which, from the great quantity of nitrogen they possess, approach nearer to the animal than the vegetable bases. The first are not generally ranked in the class of alkaloids, which includes especially vegetable bases of which the constitution is too little known to permit them to be reckoned amongst the classified bodies. If it were desired to reckon only this kind of bodies amongst the alkaloids, the best definition would be the following:—

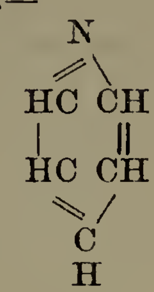
Under the name alkaloid is understood organic vegetable bases which are pyridic derivatives.

The pyridic nucleus would then be analogous to the benzoic nucleus, and the fruitful theory of Kekulé could be applied, probably with all its consequences. Twelve years ago, Koerner put forward the hypothesis that pyridine might be a benzine, in which a CH group is replaced by N, and that chinoline has a similar resemblance to naphthaline. This supposition has been shown to be true by the transformation of hydrocarbostyril or orthoamidophenylpropionic acid:—

$$C_6H_4\left\{\begin{matrix} NH_2 & (1) \\ CH_2.CH_2CO_2.H & (2) \end{matrix}\right.$$

into chinoline, and this by oxidation can be converted into pyridine-dicarbonic acid. These relations are expressed by the following formula:—

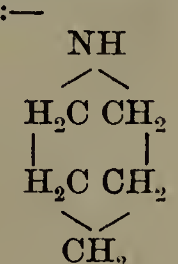


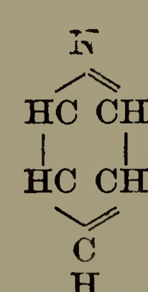


Chinoline. Pyridine.

I have been induced to study the oxidation of piperidine, nicotine and coniine and to prepare some non-oxygenated bases by means of cinchonine and quinine, and I will here state the ideas which I have conceived concerning the relations between alkaloids and pyridic bases.

Piperidine, a secondary base, can be converted by oxidation into pyridine, a tertiary base, and it seems to me that the best way to explain the great stability of piperidine in the presence of hydrochloric acid at a high temperature is to admit that piperidine is a hydrogenated addition product of pyridine, having consequently for its formula:—





Piperidine. Pyridine.

According to Cahours and Etard,* nicotine, $C_{10}H_{14}N_2$, treated with potassium ferrocyanide, gives a base containing 4 H less, which they named isodipyridine,

$$C_{10}H_{10}N_2.$$

By treating tropine, $C_8H_{15}NO$, one of the decomposition products of atropine, with hydrochloric and acetic acids to 180° C., Ladenburg† obtained a base with a coniine odour, tropidine, $C_8H_{13}N$, which is formed with elimination of water. This reaction is analogous to that produced by Wertheim, who obtained coniine with conhydrine and phosphoric anhydride:—

$$\underset{\text{Conhydrine.}}{C_8H_{17}NO} - H_2O = \underset{\text{Coniine.}}{C_8H_{15}N}$$

It seems to me probable that tropidine is a collidine, two atoms richer in hydrogen. The composition of these bases shows the great analogies which exist between them: collidine, $C_8H_{11}N$; tropidine, $C_8H_{13}N$; coniine, $C_8H_{15}N$; the first two are secondary bases, and the third a tertiary base. Now, according to Ador and

* *Annalen*, vol. clxxiii., p. 76.
† *Berichte*, 1880, p. 1635; 1881, p. 310.
‡ *Annalen*, vol. cciv., p. 67.
§ *Berichte*, 1879, p. 2185.

* *Comptes Rendus*, vol. xc., p. 275.
† *Berichte*, 1879, p. 941.

Beayer,* collidine is obtained by distillation of ammonia-aldehyde and, according to Wischnegradsky,† it ought to be considered as trimethylpyridine. The researches of Harnack and Meyer, upon the relations existing between these three bases, increase the probabilities.

It can be therefore admitted that the non-oxygenated alkaloids, or the bases obtained by their decomposition, are to the pyridic bases what the terpenes are to cymene. According to this alkaloids would contain reduced pyridic nuclei, which seems demonstrated by the fact that in plants bases are often found which only differ among themselves by a small number of atoms of hydrogen, as, for example, harmaline and harmine, hydrocotarnine and cotarnine, cinchotine and cinchonine. It might also be admitted that the bases richer in hydrogen have either been formed by a more advanced reduction, or from alkaloids produced originally or their mother-substances.

It is known that the camphors are closely allied to the terpenes and cymene, and I think that, in many cases, some similar relations exist between oxygenated and non-oxygenated alkaloids, as well as between the pyridic and chinolic bases and their polymers. For example, the conversion of conhydrine into coniine, and tropine into tropidine, is analogous to the formation of terpenes with borneol and phosphoric anhydride. By treating cinchonine with oxychloride and pentachloride of phosphorus, I have obtained a chloride, $C_{19}H_{21}N_2Cl$, which, treated with alcoholic potash furnishes a base, $C_{19}H_{20}N_2$, the relations of which with chinoline have not been yet settled. The formation of these products is analogous to that of borneol camphene, $C_{10}H_{16}$, and of chloride of borneol, $C_{10}H_{17}Cl$, by means of borneol, $C_{10}H_{18}O$.

The manner in which the oxygen is united in the oxygenated alkaloids is not known. Morphine, which is a tertiary base, contains, according to Polstorff and Broockmann,‡ three hydroxyls, for it gives, with chloride of benzoyl, a tribenzoylic compound. According to Wright and Rennie,§ only dibenzoylic-morphine can be obtained; in codeine, one of the groups OH of morphine is replaced by methyoxyl, OCH_3, and the very great oxidizability of morphine in an alkaline solution recalls certain properties of pyrogallol; in an ammoniacal solution, for example, morphine is oxidized by atmospheric oxygen into the condition of oxydimorphine, $C_{34}H_{36}N_2O_6$ (Polstorff and Broockmann).

Cotarnine, $C_{12}H_{13}NO_3$, very probably contains a CO_2CH_3 group, and the third atom of oxygen in the condition of methyoxyl. From these examples, it will be seen that oxygen is not always found in the alkaloids as in the camphors, in the condition of carboxyl $(CO)''$, or hydroxyl $(OH)'$ although this is probably generally the case. Camphors are derived from cymene, and alkaloids from pyridic bases and their polymers, by addition of hydrogen or water. At present we have no idea of the mother-substances by means of which those two great categories of bodies (camphors and alkaloids), so widely distributed in the vegetable kingdom, are formed, but it seems that an annular skeleton of atoms must be necessary for the formation of these bodies; in the case of alkaloids, it is a pyridic nucleus; for camphors a reduced benzene ring. Several facts, however, which seem to contradict this opinion, cannot be passed over in silence, such as that pyridic derivatives have not been obtained by the oxidation of certain alkaloids, such as morphine or coniine. This finds an analogy in certain products of oxidation of oil of turpentine, terebic and terpenylic acids, which do not contain the benzene nucleus. Generally, the difficulties of converting an alkaloid, or its basic products of decomposition, into reduced pyridic derivatives, augments with the number of free hydroxyls and atoms of added hydrogen.

§ *Idem*, 1880, p. 1996.

I readily admit that these general opinions concerning the constitution of alkaloids require to be rectified by numerous researches, which, I hope, will be of great utility to medicine and pharmacy, especially if the difficulties which have hitherto prevented the accomplishment of the synthesis of these interesting bodies can be surmounted, a synthesis which can only be accomplished when our knowledge of the formation of these products shall be more advanced. The examples of salicylic acid, and homatropine illustrate the utility of researches which, generally undertaken for theoretic ends, have led to some very important industrial applications.

Wallach* has recently obtained some interesting bases by the action of pentachloride of phosphorus upon substituted acid amides. These bases are non-oxygenated tertiary diamines, which present, from a physiological and chemical point of view, great analogies to the natural alkaloids.

(*To be continued.*)

THE BARK OF FRAXINUS AMERICANA.†

The white or American ash grows from Nova Scotia and New Brunswick to the western shores of Lake Superior, southward to Florida and Louisiana, and westward to Eastern Nebraska and Kansas. It attains a height of 60 to 80 feet, the trunk being from 4 to 6 feet in diameter. The wood is light, tough, very strong and elastic, and is extensively used in the manufacture of agricultural implements, carriages, oars, cabinet-work, etc. The bark is collected from the trunk and root, the latter being preferred. As seen in commerce it is usually in pieces varying from 3 to 6 millimetres (⅛ to ¼ inch) in thickness, from 25 to 75 millimetres (1 to 3 inches) in width, and sometimes 15 centimetres (6 inches) in length. The suberous tissue being generally removed from the old bark, this is externally whitish or greyish-yellow, sometimes reddish or brown-red, frequently with irregular longitudinal ridges and warts from adhering cork; internally it is yellow and smooth. Its transverse fracture is very fibrous, its odour is slightly aromatic, and its taste bitter and slightly acrid.

John M. Bradford, Ph.G., determined the amount of extract obtainable by different menstrua. The experiments appear to have been made with air-dry bark, and the amount of moisture left in the extracts does not appear to have been ascertained. In each case 1000 grains of the powdered bark were exhausted by percolation, and the resulting liquor evaporated in a water-bath; the yield was as follows:—

1. Menstruum: strong alcohol, yield: 22·4 per cent. extract.
2. Menstruum: alcohol 4 parts, water 1 part, yield: 26·2 per cent. extract.
3. Menstruum: alcohol 4 parts, water 2 parts, yield: 28·2 per cent. extract.
4. Menstruum: alcohol 4 parts, water 3 parts, yield: 29·0 per cent. extract.
5. Menstruum: alcohol 4 parts, water 4 parts, yield: 31·6 per cent. extract.
6. Menstruum: alcohol 3 parts, water 4 parts, yield: 31·6 per cent. extract.
7. Menstruum: alcohol 2 parts, water 4 parts, yield: 31·6 per cent. extract.
8. Menstruum: alcohol 1 part, water 4 parts, yield: 31·8 per cent. extract.
9. Menstruum: water (percolate turbid), yield: 28·8 per cent. extract.

All the extracts had a bitter taste, and the bitter principle is therefore soluble both in alcohol and water. The alcoholic extracts were soluble in water, leaving no per-

* *Annalen*, vol. clxxxiv., p. 1.
† Abstract from two Theses presented to Philadelphia College of Pharmacy. Reprinted from *American Journal of Pharmacy*, June, 1882.

ceptible residue, but yielding a slightly cloudy solution from suspended resin.

The bark exhausted with ether, and the ether evaporated spontaneously, yielded a fatty matter lighter than water, and having a green tint, which changed to a yellow-red colour on heating to the boiling point.

On distilling the bark with water a minute quantity of volatile oil and a white substance was obtained, the latter subsiding in the distillate. The bark was also found to contain starch, gum, tannin and a bitter principle.

Howard M. Edwards, Ph.G., examined a sediment from the wine of white ash bark, and found in it an acid and a neutral resin, sugar, gum and other matters.

In analysing the bark, the powder was exhausted with a weak alcohol of 15 per cent., the liquid was evaporated to a syrupy consistence and mixed with alcohol, which produced a light-red precipitate of gummy matter having a sweetish and slightly pungent taste, the pungency being probably due to a little resin. The filtrate was concentrated and precipitated by water, a pungent resin, having an acid reaction, separating, while the filtrate gave decided indications of the presence of an alkaloid both by Mayer's test and by solution of iodine. This last filtrate was precipitated by subacetate of lead, a thick yellow precipitate being obtained, and the filtrate, after having been freed from lead by sulphuretted hydrogen, yielded precipitates with tannin, picric acid and ammonia. After adding ammonia, the liquid was shaken with ether, which dissolved the precipitate, leaving the ammoniacal solution slightly red. The ethereal liquid, on being evaporated spontaneously, left no crystals, the alkaloid being contaminated with other substances. The amount of alkaloid being so small, I was not able to carry the investigation further. The alkaloid showed an alkaline reaction with litmus and had a bitter taste; it is doubtless the active principle of the drug.

A decoction of the bark was found to contain sugar and starch; but neither tannin nor gallic acid was found; the reactions, which were at first thought to be those of gallic acid, were afterwards shown to be due to colouring matter and acid resin. Ferric chloride gave a bluish-black colour; but gelatin and tartar emetic gave no precipitates. (J. M. Bradford obtained a precipitate with gelatin.)

The decoction was precipitated by acetate of lead, the precipitate washed, suspended in water, decomposed by H_2S, filtered, heated and then tested: ferric chloride gave a blue colour; gelatin solution, tartar emetic, lime solution and ferrous salts gave no reaction; but sodic hydrate gave a brown colour.

The volatile oil, obtained by distillation with water, was aromatic and had a bland taste.

The following pharmaceutical preparations were made:—

The *tincture*, made with 20 per cent. alcohol, four troy ounces to the pint, was bright red, slightly aromatic, of a bitter taste, and exposed to the cold became slightly turbid.

The *fluid extract*, made with a menstruum composed of water 11 parts, glycerin 1 part and alcohol 4 parts, was deep red or blackish red, very bitter and slightly pungent.

The *extract* was made with 20 per cent. alcohol; yield, 7 parts from 24 parts of the drug; it is of a blackish-red colour and has an extremely bitter and burning taste.

THE ACTIVE PRINCIPLE OF ADONIS VERNALIS.*

BY DR. V. CERVELLO.

The use of the Ranunculaceous plant, *Adonis vernalis*, L., in some forms of heart disease has led to some physiological experiments from which it would appear that it is capable of exercising an action similar to that of digitalis, with the advantage that it is not cumulative, its administration during a considerable time being without danger. But hitherto nothing definite has been known with respect to the constituent or constituents of the plant to which the action is due. The author, as the result of a chemical investigation of the plant, states that it contains only one active constituent, a glucoside, which he has named "adonidin."

In the preparation of adonidin the plant is cut into small pieces, which are macerated during two day in dilute (50 per cent.) alcohol; the liquid is filtered, the filtrate treated with basic acetate of lead, separated from the resulting precipitate by decantation and evaporated on a water-bath to a syrupy consistence. The residue, which is very bitter and has an acid reaction, is carefully made slightly alkaline by the addition of ammonia solution, and then heated with a strong solution of tannic acid, which is added as long as any precipitate is formed. The precipitate is a compound of the active constituent and tannic acid, difficultly soluble in water. This is collected on a filter, washed with a small quantity of water and dried between paper. To decompose this tannic acid compound zinc oxide and some alcohol are added and the whole is heated in a water-bath until the liquid is evaporated, when the mass is treated with strong alcohol, filtered and the residue on the filter washed with much alcohol. The filtrate is yellow and contains the adonidin not quite pure. To purify it the solution is evaporated by a gentle heat to a small volume and ether added, when inactive coloured matter is precipitated together with a trace of adonidin. Upon evaporation of the mixture of alcohol and ether by a moderate heat a residue is obtained, which represents pure adonidin and is finished by drying in a vacuum over sulphuric acid.

The quantity of adonidin obtained in this way, from two kilograms of *Adonis vernalis* was small; this the author does not consider due to any defect in the method of preparation, but to the fact that the compound, which is extremely energetic, is contained in the plant in relatively small proportion.

Adonidin is non-nitrogenous, colourless, odourless, amorphous, and extremely bitter. It is soluble in alcohol, but only slightly so in ether and in water. It is precipitated by tannic acid, the precipitate redissolving in much water. It is insoluble in dilute hydrochloric acid in the cold, but on being heated with the dilute acid it splits up into sugar and a substance insoluble in ether.

The author is not in a position to say whether the decomposition product has any action upon the organism, analogous to the case of digitaliretin, obtained under similar conditions from digitalin by Schmiedeberg.

With respect to the physiological action of adonidin the author sums up the results of his experiments by stating that it may be described as identical with that of digitalin, with the single exception that it is far more powerful. He also confirms the statement that it is not cumulative.

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Concluded from page* 90.)

SYRUPUS IPECACUANHÆ STIBIATUS (*Antimonial Wine of Ipecac*).

Tartrate of antimony and potassium . .	3
Tincture of ipecac (1 : 10)	100
Syrup	2000
Water	q.s.

Dissolve the tartrate of antimony and potassium in a little water; add the solution to the tincture and syrup

* From *New Remedies*, April, 1882.

contained in an evaporating dish, and evaporate, on a water-bath, until the product weighs 2000 parts.

SYRUPUS JUGLANDIS COMPOSITUS (*Compound Syrup of Butternut Leaves*).

[Vanier's Antirhachitic Syrup.]

Extract of butternut leaves	4
Extract of brown (grey) cinchona	2
Alcohol	4
Port wine	6
Syrup	180
Iodide of potassium	1
Oil-sugar of anise (1 part of oil and 50 parts of sugar)	3

Mix the extracts with the alcohol, port wine and 10 parts of syrup. Dissolve the iodide of potassium and the oil-sugar of anise in 170 parts of syrup and mix the two liquids.

SYRUPUS JUGLANDIS COMPOSITUS CUM OLEO MORRHUÆ (*Compound Syrup of Butternut Leaves with Cod-Liver Oil*).

Compound syrup of butternut leaves	19
Cod liver oil	1

Mix them.

SYRUPUS LACTUCARII (*Syrup of Lactucarium*).

Lactucarium	1
Sugar	q.s.
Water	q.s.

Rub the lactucarium with a little sugar, and 180 parts of water; then heat to boiling and filter the liquid.

In 10 parts of the liquid dissolve 19 parts of sugar.

SYRUPUS LENITIVUS (*Lenitive Syrup*).

Hydrochlorate of morphine	1
Cherry-laurel water	100
Syrup	3839
Tincture of cochineal (1 : 8)	60
	4000

Dissolve the hydrochlorate of morphine in the cherry-laurel water and mix the solution with the other ingredients.

SYRUPUS MANNÆ (*Syrup of Manna*).

Manna	3
Sugar	16
Water	12

Dissolve the manna and sugar in the water and strain.

SYRUPUS MANNÆ COMPOSITUS (*Compound Syrup of Manna*).

[Syrupus Sennæ Compositus. Syrup of Senna and Manna].

Senna	24
Fennel	3
Manna	50
Sugar	200
Water	q.s.

Pour 100 parts of boiling water upon the senna and fennel, allow to macerate half an hour, then strain and pass enough water through the strainer to obtain 108 parts of liquid. In this dissolve the manna and sugar. Finally strain.

SYRUPUS FERRI OXIDI (*Syrup of Oxide of Iron*).

Solution of chloride of iron (ferric), specific gravity 1·480-1·484	12
Water of ammonia	14
Sugar	85
Distilled water	q.s.

Mix the solution of chloride of iron with 120 parts of distilled water. Add to it slowly, under constant stirring, the water of ammonia previously diluted with 140 parts of distilled water. Collect the precipitate, wash it with distilled water until it ceases to produce a cloudiness in test-solution of nitrate of silver, and mix it with the sugar in a porcelain capsule. Warm the mixture for a few hours on the water-bath, occasionally stirring, then boil it gently, with occasional addition of distilled water, until one drop diluted with distilled water yields a clear, light-brown solution. Then dilute the syrup with warm distilled water until it weighs 136 parts.

Preserve the syrup in well-stopped bottles in a dark place.

One part of the syrup diluted with 5 parts of water should not produce a precipitate.

Fifty parts of the syrup contain 1 part of ferric oxide.

SYRUPUS CALCII PHOSPHATIS (*Syrup of Phosphate of Calcium*).

Phosphate of calcium	1
Phosphoric acid	3
Syrup	q.s.

Digest the phosphate of calcium with 6 parts of syrup and the phosphoric acid on the water-bath, occasionally stirring until the salt is dissolved; then add 400 parts of syrup.

SYRUPUS RHAMNI CATHARTICI (*Syrup of Buckthorn*).

Juice of buckthorn berries, fermented and clarified	8
Sugar	15

Dissolve the sugar in the juice.

QUINIÆ TANNAS NEUTER (*Neutral Tannate of Quinine*).

Sulphate of quinine	1
Diluted sulphuric acid, about	1
Tannic acid	4
Solution of acetate of ammonium	3
Distilled water	q.s.

Dissolve the sulphate of quinine in 70 parts of distilled water, with the aid of diluted sulphuric acid, avoiding an excess. Add to the solution the tannic acid, previously dissolved in 100 parts of distilled water, and afterwards the solution of acetate of ammonium, previously diluted with 8 parts of distilled water.

[The solution of acetate of ammonium is prepared by saturating water of ammonia (specific gravity 0·956–0·960) with acetic acid (specific gravity 1·051–1·055), about 9 parts of the latter being required for 10 parts of the former.]

Let the mixture stand for five hours, occasionally stirring. Collect the precipitate upon a filter, and wash it with small quantities of distilled water successively poured on, until a little of the precipitate removed from the filter, and dried, seems to have a bitter taste. Then dry it by exposure to air, and rub it to powder.

The resulting tannate of quinine is a yellowish-white, odourless, and almost tasteless powder, containing 8 to 10 per cent. of water, and which should yield 19 to 21 per cent. of anhydrous quinine, when it is assayed by the following process:—

Mix 1 part of tannate of quinine, in a test-tube, with 10 parts of solution of soda (of 6 per cent.), and warm the mixture on the water-bath for fifteen minutes. Add to it, when cold, 30 parts of chloroform, shake well, and transfer the whole to a separating funnel. As soon as the chloroform has become clear, let 15 parts of it run out and evaporate this portion upon the water-bath to dryness. Then weigh the residue.

This residue, corresponding to a quantity of anhydrous quinine contained in one-half part of the tannate, when dissolved in a little water acidulated with sulphuric acid, then treated with 2 parts of ether and an excess of ammonia, should yield a clear liquid separating into two layers.

PAPERS TO BE READ AT THE MEETING OF THE BRITISH PHARMACEUTICAL CONFERENCE.

THE following is a list of the titles of papers to be read at the approaching Pharmaceutical Conference at Southampton. It has reached us only at the moment of going to press and consequently it is only by inserting it here that we are able to publish the list this week. We regret to notice that the papers expected from Mr. J. E. HOWARD and from Mr. GREENISH have been withdrawn; but notwithstanding their loss it may, we think, be fairly assumed, on the basis of the list now presented, that the character of the communications brought before the British Pharmaceutical Conference will be fairly maintained. All the papers here mentioned may be looked upon as dealing with purely pharmaceutical subjects, and we are especially glad to notice that the somewhat trying experience of Mr. PROCTOR last year has not prevented him from coming to the front again in a less troubled arena than that of pharmaceutical politics.

1. A New Styptic of Indigenous Growth. By Professor QUINLAN, M.D., etc.

2. The Solubility of Morphia Salts. By Mr. D. B. DOTT.

3. Terpin Hydrate: its Preparation and Crystallography. By Mr. R. H. PARKER.

4. Variations in Strength of Commercial Samples of Tinctura Opii, B.P., and Extractum Opii Liquidum, B.P. By Mr. J. WOODLAND, F.L.S., F.C.S.

5. The Purity of the Salts of Silver as met with in Commerce. By Mr. J. WOODLAND, F.L.S., F.C.S.

6. The Purity of Commercial Chloride of Gold. By Mr. F. W. BRANSON.

7. Note on a Commercial Sample of Liquor of Iodide of Iron containing some Impurities probably added with a view of retarding or hiding its Oxidation. By Mr. B. S. PROCTOR.

8. Note on Methyl Orange as an Indicator of the Neutrality of Salts having an Acid Reaction with ordinary Test-papers. By Mr. B. S. PROCTOR.

9. Some Experiments on English Oil of Lavender. By Mr. W. A. SHENSTONE, F.I.C., F.C.S.

10. Vegetable Organisms in Solutions of certain Inorganic Salts. By Mr. A. H. BOTHAMLEY.

11. The Solubility of Boric Acid in Glycerine. By Mr. D. HOOPER.

12. The Iodides of Bismuth. By Mr. F. W. FLETCHER, F.C.S.

13. On some Reactions of Arsenic. By Mr. W. A. H. NAYLOR, F.C.S., and Mr. J. O. BRAITHWAITE.

14. Notes on Brazilian Drugs. By Dr. C. SYMES, F.C.S.

15. Some Results of the Action of the Digestive Ferments on Drugs. By Mr. G. BROWNEN, F.C.S.

16. First Report on the Difference between the Essential Oils of Cinnamon and Cassia. By Mr. A. H. JACKSON, B.Sc.

17. Remarks on Aconitum Napellus and Allied Species. By Mr. E. M. HOLMES, F.L.S.

18. On a New Method of Making the Volumetric Solution for Estimating Hardness of Water. By Professor C. R. C. TICHBORNE, Ph.D., etc.

19. On Ammoniated Extract of Ergot. By Mr. A. W. GERRARD, F.C.S.

20. On the Alkaloidal Value of Belladonna Plants at Various Periods of Growth. By Mr. A. W. GERRARD, F.C.S.

21. Contribution to the Pharmacy of the Pomegranate. By Mr. L. SIEBOLD, F.I.C., F.C.S.

A PROPOSED NEW MODE OF CONDUCTING THE PRELIMINARY EXAMINATION.

A SCHEME for the granting of junior certificates on the basis of examination conducted under the control of the Oxford and Cambridge Schools Examination Board has lately been drawn up in a tentative form by that body with a view of establishing a general system of examination to serve in lieu of the ordinary entrance examinations to the various professions. It appears that the Board, having been asked to institute such a system of examination, has passed a resolution in favour of doing so, provided satisfactory evidence is furnished that such a proceeding is desired by the masters of schools, further that the certificates granted under the system will be accepted by the public bodies interested, and lastly that adequate supervision of the candidates can be provided.

As regards the first point the Board has ascertained that such an examination is very generally desired by schools, and the Board has received many suggestions from schoolmasters respecting the details of the contemplated scheme. Most of those suggestions have been adopted and embodied in the provisional regulations which have been drawn up by the Board, and the question now to be determined is, how far the various bodies which demand the passing of a preliminary examination as the first step towards admission to the practice of the particular pursuits with which they have to do, will be willing to grant exemption from their own preliminary examinations in favour of candidates holding a certificate which has been gained at an examination conducted according to the regulations of the Oxford and Cambridge Examination Board and provided that each certificate shows that the applicant has passed in such subjects as are equivalent to those required for the preliminary examination. In order to ascertain what is the disposition of the various bodies in this respect the Secretaries of the Board have been instructed to communicate with those bodies, submitting a draft of the provisional regulations proposed and a statement of the subjects which the Board considers to be equivalent to those required in the preliminary examinations of the several bodies.

The Pharmaceutical Society, being one of those bodies which require the passing of a preliminary examination as a step towards the qualification they grant, it has been applied to in this manner by the Board, with a request that the subject should be brought before the Council, and a reply given as soon as possible, stating the opinion of the Council in regard to the project.

The Preliminary examination of the Pharmaceutical Society is so important a feature of the ordeal through which a candidate for pharmaceutical qualification has to pass and that examination is capable of being made to exercise such a beneficial influence upon the educational system, as well as upon the future of pharmacy in this country, that it becomes highly desirable to consider this scheme for carrying out the examination in a different, and may be better, manner than heretofore.

According to the draft which has been submitted for general consideration, it is proposed that the examination shall commence on the 23rd day of July, 1883, and that it shall extend over six days, according to a time table specifying the days allotted to particular subjects. The examination is to be conducted entirely by means of printed papers to be set at Oxford, Cambridge, or such other centres as the Board may appoint, and at every school the authorities of which desire that these papers shall form part of a school examination. In regard to this latter case the very important proviso is made that the papers must be worked under the superintendence of a supervisor appointed by the Board. In the letter addressed to the Pharmaceutical Society in common with other bodies, it is suggested that with the view of reducing the expense of the examination it might be desired in certain cases to make the head masters of the schools responsible for the supervision of the candidates, and it is asked whether such an arrangement would be considered satisfactory. On the face of the matter we can scarcely conceive what cases would render such a course either desirable or satisfactory and the responsibility thus thrown upon the head masters of schools would be one of a very serious and difficult nature.

In carrying out the scheme it is proposed that any of the boys under education at a school shall be admitted to the examination on the application of the head master of the school, made not less than two months before the time fixed for its commencement. The examination to include Latin, Greek, French and German as the first group of subjects; Arithmetic and additional Mathematics as the second group; Scripture Knowledge, English, English History and Geography as the third group; Physics and Chemistry as the fourth group. In order to obtain a certificate a boy will be required to satisfy the examiners in five subjects taken from not less than three groups, of which the groups 1 and 2 must be two, and the boys will be required to answer the questions so as to satisfy the examiners that they have an adequate knowledge of English grammar and orthography. In each subject there are to be two classes, and the certificates will specify the age of the boy, the subjects in which he has passed, and the class he has obtained in each. A fee of one guinea is to be paid for every boy examined when the examination is held at a school, and if a boy is examined away from his own school an additional fee of ten shillings is to be paid.

These are the general features of the scheme, and as regards the Preliminary examination of the Pharmaceutical Society, the subjects considered to be equivalent to those which it requires are Latin, Arithmetic and English, class one or two. It will be seen from the report of the Council proceedings last week that the Council is considering the scheme, and has entered into communication with the Board upon the subject.

WHO IS RESPONSIBLE FOR POISONING BY IMPURE WATER?

A CASE of very great interest has recently been before the Assizes at Leeds, in which the corporation of Huddersfield was proceeded against for negligence and failure in the performance of a statutory duty to supply pure and wholesome water. The complaint against the water was that as supplied for use in the plaintiff's house it contained lead to such an extent that he had been made dangerously ill and had suffered serious physical injury. Upon that ground he claimed damages from the corporation, and in the hearing of the case it became clear not only that the injuries of the plaintiff were real, but that they had resulted from the presence of lead in the water supplied by the defendant corporation. The only point of issue between the plaintiff and defendants was the question whether the impurity arose in the mains or in the service pipe, and if in the latter whether the corporation was responsible. It was agreed to reserve this point for further consideration and on the evidence the jury found a verdict for the plaintiff with two thousand pounds damages.

So far as the report of the evidence can be relied upon it appears that the water supplied to Huddersfield is soft water and that some portion of it is drawn from a source that is subject to contamination with sulphuric acid; but whether the presence of lead in the water is attributed to this circumstance or not is scarcely clear. One of the witnesses stated that he had pointed out certain objectionable features in some part of the water supply which the corporation had not paid attention to; but the particulars are not stated and we must therefore defer any further account of the case until fuller information is obtained.

ROYAL INSTITUTION OF GREAT BRITAIN.

Electric Railways.

BY PROFESSOR W. E. AYRTON, F.R.S.

We have grown so accustomed to the regular announcement—"serious accident on such and such a railway, several passengers injured"—that we have almost come to regard railway accidents as inevitable, just as parents mistakenly think the measles and whooping cough necessary accompaniments of childhood. But speed no more means disaster than a densely crowded city means disease. The first effect of overcrowding is undoubtedly to produce fever and other complaints. If, however, the knowledge and practice of the laws of hygiene increase more rapidly than the population of a town, the death rate, as we have seen, diminishes, instead of augmenting. And so it is with locomotion; the stage-coach journeys of our ancestors were slow enough for the most staunch conservative, and yet the percentage of the passengers injured on their journeys was far greater than even now with our harum-scarum railway travelling. The number of passengers has increased enormously, but the safety has increased in an even greater rate. If then we can devise methods introducing still greater security, a far larger number of passengers may travel at a far greater speed and with less fear of danger than at present.

Accidents constitute one charge against railway conveyance, but there is another, and that is the cost. Cheap as railway travelling now is, compared with the departed stage-coach locomotion, the price of the tickets is still far too high for railways to fulfil, even in a small degree, one of their most important functions, and that is transporting labourers from parts of the country where labour is scarce, to others where it is abundant and labourers in demand.

But how is a happier state of things to be realized? We cannot expect the railway companies to lower their fares merely to benefit humanity. If, however, we can prove to them that the present system of railways is neither the most remunerative to themselves nor the most beneficial to the community at large, we may hope to win the attention of railway directors, whose stock question is, and quite rightly, "Will it pay?"

Those of you who have read the life of Stephenson know what a protracted fight he had to carry one of his most cherished ideas, and that was the employment of a locomotive engine to draw the train instead of a stationary engine to pull it with ropes or chains. His adversaries saw the disadvantage of adding the weight of the locomotive to the weight of the train, whereas Stephenson was especially struck with the enormous waste of power in the friction of ropes or chains passing over pulleys. [Experiments were then shown proving, *first*, that the mass of the locomotive necessitated the engine having a greater horse-power to get up the speed of the train quickly as well as a greater horse-power to keep up the speed; *secondly*, that the friction and wear and tear of ropes, such as were employed on the London and Blackwall Railway, would have been an insuperable hindrance to the development of railways.] From this was deduced that, since in Stephenson's day the only feasible mode of communicating the power of a stationary engine to a moving train was by means of ropes, his decision to adopt the locomotive was perfectly correct at the time it was made.

Attempts have been made to propel trains by blowing them through tubes, or by blowing a piston attached to the train through a tube, but such attempts at pneumatic railways have nearly all been abandoned. The employment of air compressed into a receiver on the train by fixed pumping engines stationed at various points along the line, and employed to work compressed air-engines on the carriages has been effected with considerable success by Colonel Beaumont, especially for tram-lines. The weight of the compressed air engine is, however, still very considerable. Any system of pumping water through a pipe and employing the water to work a hydraulic engine on the train is hardly worth considering, seeing that the mechanical difficulties of keeping up a continuous connection between the moving train and the main through which the water is pumped seem insuperable. Gas engines worked with ordinary coal gas, stored perhaps under pressure, might be employed on the moving train, but the advantage arising from the absence of boiler and coal would be more than compensated for by the fact, that the weight of a gas-engine per horse-power developed is so much greater than that of a steam-engine. None of these systems, then, of dispensing with a locomotive is by any means perfect, and the success of the recent experiments on the electric transmission of power has turned the attention of engineers to the consideration, whether electricity could not successfully supplant steam for the propulsion of trains and tram-cars; whether it could not, in fact, supply an efficient means of transmitting power, the absence of which caused Stephenson to abandon ropes in favour of a heavy locomotive engine.

The whole question, like every similar one, is mainly a question of expense; and what we have to consider is, whether electric transmission on the whole leads to greater economy than can possibly be obtained by the employment of any kind of locomotive. The average weight of a locomotive is about that of six carriages full of people; ten carriages compose an ordinary train, hence the presence of the mass of the locomotive adds at least 50 per cent. to the horse-power absolutely necessary to propel the carriages alone, and therefore at least 50 per cent. to the amount of coal burned. But there is another most serious objection to the engines, perhaps even more important than the preceding. The heavy engine passing over every part of the line necessitates the whole line and all the bridges being made many times as strong, and therefore many times as costly, and the expense of maintenance consequently also far greater, than if there were no locomotive. And it is not possible to make the engine much lighter; for it would not have then sufficient adhesion with the rails to be able to draw the train; in fact, you cannot diminish the weight as long as the train is propelled with only one or two pair of driving wheels as at present. The employment of electricity, however, will enable a train to be driven with every pair of wheels, just as the employment of compressed air enables every pair of wheels to brake the train.

To propel a train we must either utilize the energy of coal by burning it, or use the energy possessed by a mountain stream, or the energy stored up in chemicals, and which is given out when the chemicals are allowed to combine, or we must employ the energy of the wind. Practically we employ at present only the first store for propelling railway trains—the potential energy of coal; and that is to a great extent the store on which we shall still draw, even when we employ electric railways. For experience shows that with the modern steam-engine and dynamo at least one-twentieth of the energy in coal can be converted into electric energy; and that this is at least twenty times as economical as the direct conversion of the energy of zinc into electric energy by burning it in a galvanic battery.

But it may be asked, did not Faraday's discovery in 1831 that a current could be produced by the relative motion of a magnet and a coil of wire settle this point half a century ago? Theoretically—yes; practically, however, the problem was very far from being solved, because the dynamo machine was very unsatisfactory, and it was not until Pacinotti, in 1860, suggested the solution of the problem of obtaining a practically continuous current from a number of intermittent currents, and until Gramme, about 1870, carried out Pacinotti's

* Abstract of a Lecture delivered on Friday, March 24, 1882, at the Royal Institution, and before the Royal Dublin Society, March 31.

suggestion in the actual construction of large working machines, that the mechanical production of currents became commercially possible. [Experiments were then shown illustrating the complete electric transmission of power, a gas-engine on the platform giving rapid motion to a magneto-electric machine, and the current thereby produced sent through an electro-motor at the other end of the room, which worked an ordinary lathe.]

In electric transmission of power there is not only waste of power from mechanical friction, but also from electric friction arising from the electric current heating the wire, through which it passed.

It was then explained and demonstrated experimentally that this latter waste could be made extremely small by placing so light a load on the electro-motor that it ran nearly as fast as the generator or dynamo which converted the mechanical energy into electric energy; actual experiments leading to the result that for every foot-pound of work done by the steam-engine on the generator quite $\frac{7}{10}$ of a foot-pound of work can be done by the distant motor.

One reason why electric transmission of power can be effected with so little waste is because electricity has apparently no mass, and consequently no inertia; there is, therefore, no waste of power in making it go round a corner, as there is with water or with any kind of material fluid. Another reason why electro-motors are so valuable for travelling machinery is on account of the light weight of the motor. Experiment shows that one horse-power can be developed per 50 lbs. of dead weight of electro-motor; a result immensely more favourable than can be obtained with steam, gas, or compressed-air engines.

In addition to the loss of power arising from the heating of the wires by the passage of the current there is another kind of loss that may be most serious in the case of a long electric railway, viz. that arising from actual leakage of the electricity due to defective insulation. To send an electric current through a distant motor, two wires, a "going" and "return" wire must be employed, insulated from one another by silk, gutta-percha, or some insulating substance; and if the motor be on a moving train there must be some means of keeping up continuous connection between the two ends of the moving electro-motor and the going and return wire. The simplest plan is to use the two rails as the two wires, and make connection with the motor through the wheels of the train; those on one side being well insulated from those of the other, otherwise the current would pass through the axles of the wheels instead of through the motor. It is this simple plan that is employed in Siemens' Lichterfelde Electric Railway, now running at Berlin; the insulation arising from the rails being merely laid on wooden sleepers having been found sufficient for the short length, $1\frac{1}{2}$ mile. The car is similar to an ordinary tram-car, and holds twenty passengers. [Photographs were then projected on the screen of this and of the original electric railway laid by Siemens in the grounds of the Berlin Exhibition of 1879, and exhibited in 1881 at the Crystal Palace, Sydenham.] It was explained that on this latter railway, which was 900 yards long, both the ordinary rails were used as the return wire, and that the going wire was a third insulated rail rubbed by the passing train. [Photographs were then projected on the screen of Siemens' electric tram-car at Paris, used to carry fifty passengers backwards and forwards last year to the Electrical Exhibition.] In this the going and return wires were overhead and insulated, connection being maintained between them and the moving car by two light wires attached to the car, and which pulled along two little carriages running on the overhead insulated wires, and making electric contact with them. [Experiments followed, proving that although two bare wires lying on the ground could be quite efficiently employed as the going and return wire, if the wires were short and the ground dry, the leakage that occurred if the wires were long and the ground moist was so great, as to more than compensate for the absence of the locomotive.] Consequently Professor Perry and myself have for some time past been working out practical means for overcoming these difficulties, and we have arrived at what we hope is an extremely satisfactory solution. Instead of supplying electricity to one very long, not very well insulated rail, we lay by the side of our railway line a well insulated cable, which conveys the main current. The rail, which is rubbed by the moving train, and which supplies it with electric energy, we subdivide into a number of sections, each fairly well insulated from its neighbour and from the ground; and we arrange that at any moment only that section or sections, which is in the immediate neighbourhood of the train, is connected with the main cable; the connection being of course made automatically with the moving train. As then leakage to the earth of the strong propelling electric current can only take place from that section or sections of the rail which is in the immediate neighbourhood of the train, the loss of power by leakage is very much less than in the case of a single imperfectly insulated rail, such as has been hitherto employed, and which being of great length, with its correspondingly large number of points of support, would offer endless points of escape to the motive current.

Dr. Siemens has experimentally demonstrated that an electric railway can be used for a mile or two; Professor Perry and myself, by keeping in mind the two essentials of success, viz. attention to both the mechanical and electrical details, have, we venture to think, devised means for reducing the leakage on the longest railway to less than what it would be on the shortest.

For the purpose of automatically making connection between the main well-insulated cable and the rubbed rail in the neighbourhood of the moving train, we have devised various means, one of which is the following:—

A copper or other metallic rod forming an auxiliary rail, rests on the top of and is fastened to a corrugated tempered steel disc (of the nature of, but of course immensely stronger than the corrugated top of the vacuum box of an aneroid barometer), and which is carried by and fastened to a thick ring made of ebonite or other insulating material. The ebonite ring is itself screwed to the circular cast-iron box, which latter is fastened to the ordinary railway sleepers. The auxiliary rail and the corrugated steel discs have sufficient flexibility that two or more of the latter are simultaneously depressed by an insulated collecting brush or roller carried by one or by all of the carriages. Depressing any of the corrugated steel discs brings a stud, which is electrically connected with the metallic rod or auxiliary rail, into contact with another stud electrically connected with the well-insulated cable.

As only a short piece of the auxiliary rail is at any moment in connection with the main cable, the insulation of the ebonite ring will be sufficient even in wet weather, and the cast-iron box is sufficiently high that the flooding of the line or the deposit of snow does not affect the insulation. The insulation, however, of the stud, which is permanently in connection with the main cable, must be far better. For this purpose we lead the guttapercha, or indiarubber, covered wire coming from the main cable through the centre of a specially formed telegraph insulator, and cause it to adhere to the inside of the earthenware tube forming the stalk. And as, in addition, the inside of each contact box is dry, a very perfect insulation is maintained for the lead coming from the main cable. Consequently as all leakage is eliminated except in the immediate neighbourhood of the train, this system can be employed for the very longest electric railways. In a modification of the contact box, the insulated rail instead of extending all along the line is quite short and is carried by the train, and by its motion presses forwards and downwards a metallic fork on the contact box, thus making contact between the two studs. [Other diagrams were explained, illustrating modifications of the contact boxes, in one case the well-insulated cable is carried inside the flexible rail, which then takes the form of a tube. In another case the cable is insulated with paraffin oil instead of with guttapercha or indiarubber.]

The existence of these contact boxes at every 20 to 50 feet also enables the train to graphically record its position at any moment on a map hanging up at the terminus, or in a signal box or elsewhere, by a shadow which creeps along the map of the line as the train advances; stops when the train stops; and backs when the train backs. This is effected thus:—as the train passes along, not only is the main contact between the two studs automatically made, as already described, but an auxiliary contact is also completed by the depression of the lid of the contact box, and which has the effect of putting, at each contact box in succession, an earth fault on an insulated thin auxiliary wire running by the side of the line. And just as the position of an earth fault can be accurately determined by electrical testing at the end of the line, so we arrange that the moving position of the earth fault, that is the position of the train itself, is automatically recorded by the pointer of a galvanometer moving behind a screen or map, in which is cut out a slit representing by its shape and length the section of the line on which the train is. In addition, then, to the small sections of 20 feet or more into which our auxiliary rubbed rail is electrically divided, there would be certain long blocked sections, 1 mile or several miles in length, for each of which on the map a separate galvanometer and pointer would be provided. [Experiments were shown of the system of graphically automatically recording the progress of a train.]

In the preceding systems there are several contact boxes in each section of the insulated rubbed rail, and several sections of the insulated rail in each section of the line blocked, but in the next system the rubbed rail is simply divided electrically into long sections each of as great a length as the particular system employed to insulate the rubbed rail will allow. In this case we arrange that the electric connection between the main cable and the rubbed conductor shall be automatically made by the train as it enters a section, and automatically broken as the train leaves a section. The model before you, shown in the accompanying figure, is divided into four sections, each about 11 feet in length, and you see from the current detectors that as the train runs either way it puts current into the section just entered, and takes off current from the section just left.

[Experiments were then shown of the ease with which an electric train could be made to back instead of going forwards, by reversing the connections between the revolving armatures and the fixed electro-magnets of the motor; also that the accidental reversal of the field magnets of the main stationary generator, although it had the effect of reversing the main current, produced no change in the direction of motion of an electric engine, the direction of motion being solely under the control of the driver.]

But more than this, not only does the train take off current from the section 1 when it is just leaving it, and entering section 2, but no following train entering section 1 can receive current or motive power until the preceding train has entered section 3. [Experiments were then shown proving that with this system a following train could not possibly run into a preceding train even if the preceding train stopped or backed.] Now why does the following train when it runs on to a blocked section pull up so quickly? The reason is because it is not only deprived of all motive power, but is powerfully braked, since when electricity is cut off from a section the insulated and non-insulated rail of that section are automatically connected together, so that when the train runs on to a blocked section the electro-motor becomes a generator short circuited on itself, producing, therefore, a powerful current which rapidly pulls up the engine. [Experiments were then shown of the speed with which an electro-moter, which had been set in rapid rotation and then deprived of its motive current, pulled up when its two terminals were short circuited.]

Whenever, then, a train, it may be even a runaway engine, enters on a blocked section, not only is all motive power withdrawn from it, but it is automatically powerfully braked, quite independently of the action of the engine-driver, guard, or signalman. No fog, nor colour-blindness, nor different codes of signals on different lines, nor mistakes arising from the exhausted nervous condition of overworked signalmen, can with this system produce a collision. The English system of blocking is merely giving an order to stop a train; but whether this is understood or intelligently carried out is only settled by the happening or non-happening of a subsequent collision. Our Absolute Automatic Block acts as if the steam were automatically shut off and the brake put on whenever the train is running into danger; nay, it does more than this—it acts as if the fires were put out, and all the coal taken away, since it is quite out of the power of the engine driver to re-start his train until the one in front is at a safe distance ahead.

But all trains will undoubtedly be lighted with electricity; must, then, the train be plunged into darkness when it runs on to a blocked section to which no electric energy is being supplied? No! If some of the electric energy supplied to the train when it is on an unblocked section be stored up in Faure's accumulators, such as are at present used on the Brighton Pullman train, the lamps will continue burning even when the train has ceased to receive electric energy from the rubbed rail.

When, then, we commit the carrying of our power to that fleet messenger to which we have been accustomed to entrust the carrying of our thoughts, then shall we have railways that will combine speed, economy and safety; and last, but not least to us Londoners, we shall have the entire absence of smoke, the presence of which nearly causes the convenience of the Underground Railway to be balanced by the pernicious character of its atmosphere.

PENNSYLVANIA PHARMACEUTICAL ASSOCIATION.

Notes on the Useful American Myrtles.*

BY JOHN M. MAISCH.

After referring to the statement in Mr. Riise's paper on bay rum (see before, p. 39), relating to the varieties of the bayberry tree, scarcely to be distinguished botanically, the author continues:—

There being a large number of myrtles indigenous to the West Indies and many also to South America, it may not appear inappropriate to give a brief account of those American species which yield useful and more or less medicinal products. Since by far the largest number of these plants possess aromatic properties, and many of them are also astringent, it may be presumed that the majority of them could be employed medicinally; but in this sketch I shall confine my remarks to those only which have, at various times, attracted some attention in Europe or in this country.

The order Myrtaceæ has affinities, more or less intimate, with a number of other orders, and its limits are variously defined by different botanists, so as to embrace a larger or smaller number of tribes or sub-orders. Between seventeen hundred and eighteen hundred species belong to it, all of which, with but few exceptions, inhabit tropical countries.

The *Barringtonieæ*, comprising tropical trees with opposite undotted leaves, are at present generally separated from the myrtles. They are often emetic and

* Read at a Meeting of the Association at Altoona, June 14, 1882.

stupefying, or bitter and astringent, and in some species an unpleasant odorous principle is prevalent.

The sub-order *Granateæ* or *Puniceæ* contains only a single species, the well-known pomegranate, which is indigenous to Western Asia, from Northern India to the Mediterranean, and is now cultivated everywhere in sub-tropical countries and the warm temperate zone. It is destitute of aromatic properties, the bark of the root and trunk as well as the rind of the fruit being anthelminthic and containing considerable tannin. Some botanists place this tree into a separate natural order, while others have united it with the order of Lythraceæ.

The sub-order *Lecythideæ* is likewise free from aromatic properties and is remarkable for the large woody fruits, which in some species open by a kind of lid, on which account they have been called *monkey-pots.* The seeds contain a considerable quantity of fixed oil, sometimes over 50 per cent., and are often edible, being of an almond-like flavour, though those of a few species are reputed to be more or less deleterious in their raw state. The well-known *Brazil nuts* or *Para nuts,* known as *touka* in Cayenne, as *juvia* on the Orinoco, and as *castanha do Pará* in Brazil, are the seeds of *Bertholletia excelsa,* Kunth. The so-called *Sapucaya nuts* are produced by *Lecythis Zabucajo,* Aublet, and of nearly the same flavour are the seeds of *Lecythis Ollaria,* Lin. The fruit of *Couroupita guianensis,* Aublet, is globular, attains a diameter of 6 or 8 inches and is known as *cannon ball, boulet de canon*; it contains in its nearly ripe condition a sweet acidulous pulp, furnishing a refreshing beverage, useful in febrile diseases. These trees are indigenous to South America.

The sub-order *Chamælaucieæ* has, like the following sub-orders, evergreen and mostly glandular-punctate leaves. The plants known as *fringe-myrtles* are shrubby, of a heath-like aspect, with small leaves, are indigenous to Australia and are not used medicinally.

The sub-order *Leptospermeæ* comprises, with very few exceptions, Australian trees and shrubs, with opposite or alternate leaves. The volatile oil of one species, *Melaleuca minor,* Smith, is the well-known *oil of cajaput.* The volatile oil distilled from the leaves of *Mel. ericæfolia,* Sm., *Mel. linariæfolia,* Sm., *Mel. Leucadendron,* Lin., and perhaps of other species, are very similar. The last-named species is known in Australia as *tea tree,* because the leaves are employed like tea; the *white tea tree* is *Mel. genistæfolia,* Sm. The leaves of different species of *Leptospermum,* like *L. scoparium,* Sm., *L. Thea,* Willdenow, and others are similarly used.

But the sub-order has attracted universal attention through the *Eucalyptus globulus,* Labillardière, which through its rapid growth, and perhaps also through the exhalation of its volatile oil, has been found useful in sub-tropical marshy countries for destroying malaria. The leaves of all species of this genus yield volatile oils, which sometimes differ widely in odour and composition. Several species yield astringent exudations, drying into a kino-like substance; the exudation of others contains more gummy matter, and of one or two species it is of a saccharine nature; the bast fibres of certain species have been found serviceable in the manufacture of paper.

Of the sub-order *Myrteæ,* there are not less than fifty-three species described by Grisebach, growing in the British West Indian Islands, all of which are more or less aromatic. The number growing in all the West Indian islands and in South America is much larger. The species best known throughout the civilized world is doubtless the clove, *Caryophyllus aromaticus,* Linné (s. *Eugenia caryophyllata,* Thunberg; *Myrtus caryophyllus,* Sprengel) which, though originally indigenous to the Molucca Islands, is now perfectly naturalized in the West Indies and South America. The unexpanded flower-buds, which constitute the cloves of commerce, contain, besides a considerable amount of tannin, an aromatic volatile oil, of which the eugenol or eugenic acid constitutes the most important part, and very similar constituents are met with in the less aromatic pedicels, known in commerce as *clove stalks,* and in the fruit known as *mother cloves* and *anthophylli.* That the allspice, the fruit of *Pimenta vulgaris,* Wight et Arnott, s. *Eugenia* (*Myrtus,* Lin.) *Pimenta,* De Cand., likewise contains a volatile oil, chemically identical with the oil of cloves, is well known; besides the fruit, the leaves are employed in the West Indies as a spice and in medicines, and the young straight shoots of the plant are largely exported to be used for walking canes. The same volatile oil seems to be present in the closely allied *Pimenta* (*Amomis,* Berg) *Pimento,* Grisebach, which differs from the preceding chiefly by its five-lobed calyx and by its longer ovate-oblong (instead of globular) fruit. The bayberry tree of the West Indies, *Pimenta acris,* W. et A., has, likewise, pentaphyllous flowers and a more ovoid fruit; however the coriaceous leaves are distinctly reticulate on the upper surface, and less distinctly so beneath, while the preceding species does not show any projecting veins above. The typical form of the bayberry tree has the young branchlets somewhat four-angled, while the variety pimentoides, which was formerly regarded as a distinct species, *Myrcia* (*Amomis,* Berg) *pimentoides,* DeC., s. *Myrtus* (*Eugenia*) *citrifolia,* Poir., has acute branchlets decurring from the petioles, and usually broader and more obovate leaves. The oil of bay, distilled from the leaves of the species mentioned, has been in the American market for about twenty years; that it contains eugenol was proven by Mr. R. Rother in 1876 (*Chic. Pharmacist,* p. 130), and this was corroborated by Professor Markoe in 1877 ('Proc. Am. Phar. Assoc.,' p. 435). The fruit contains the same volatile oil, and not unlikely also the flower-buds; at least the tree is known as *clove* in some of the West Indian Islands (Grisebach). These species and varieties possess almost identical stimulating properties, and may be substituted for one another in their applications as medicine or as spice, almost indiscriminately, or at least as far as the difference in flavour will permit.

The clove-like odour is not confined to the species mentioned before, but is met with in other plants, and doubtless depends upon the presence of eugenol. *Eugenia* (*Myrtus,* Gomez) *pseudo-caryophyllus,* DeC., and *Calyptranthes aromatica,* St. Hilaire, both indigenous to Brazil, and known there as *craveiro da terra,* possess this flavour, and the young flower-buds, particularly those of the latter, have been recommended as a good substitute for cloves; a clove-like flavour is observed in all its parts, and the ovate fruit is extensively employed both for culinary purposes and also in medicine.

While it is undoubtedly true that botanical relationship is often indicative of similar properties and composition, yet the odorous compounds met with in the volatile oils of nearly related species are often very dissimilar, if not in relation to their chemical nature, at least in their sensible properties, more particularly in their odour. Thus, for instance, *Myrcia* (*Myrtus,* Vahl) *coriacea,* De Cand., which grows in many of the West Indian Islands, so closely resembles the bayberry tree that it has been confounded with it by as thorough a botanist as Swartz, but the leaves have a lemon-like odour, entirely distinct from the allspice-like flavour of the former, and it is very obvious that the volatile oil or the spirit distilled from them must have very different properties from those of good oil of bay or of bay rum. The leaves, like those of other myrtles, vary considerably in shape, and are either oval, roundish-elliptic, or obovate, obtuse or emarginate, and usually opaque, though marked with impressed dots, some of which become finally pellucid; the veins are not conspicuous. and are usually joined near the revolute margin. There are several varieties, differing in the pubescence of the branchlets and petioles, in the length of the peduncles, and the number of flowers borne by them. The leaves possess antiseptic and astringent properties, the bark is employed for tanning, and the wood is used for dyeing yellow, green and brown.

Eugenia (*Myrtus*, Swartz) *glabrata*, De Cand., is acidulous aromatic in all its parts, more particularly the black oblong berries.

Eugenia (*Myrtus*, Swartz) *procera*, Poir., which is found in Jamaica and adjacent islands, and also in Southern Florida, has pellucid-punctate leaves, which finally become leathery and opaque and then have but a slight odour, while the flowers are very fragrant.

Eugenia (*Myrtus*, Sprengel) *fœtida*, Persoon, of Guiana, has leaves possessing a disagreeable odour, a property rarely met with among the myrtles.

Anamomis (*Myrtus*, Swartz; *Eugenia*, Willdenow), *fragrans*, Grisebach, grows in mountainous regions from Jamaica southward to Guiana; its rigid variable leaves are of a strong balsamic flavour, and are employed both externally and internally. The variety *cuneata*, s. *Eug. emarginata*, Macfillan, is known as *zebra wood.*

The odour of the flowers of *Eugenia* (*Myrtus*, Swartz) *virgultosa*, De Cand., indigenous to Cuba and Jamaica, resembles that of rhubarb.

Eugenia (*Myrtus*, Swartz) *disticha*, De Cand., is known in Jamaica as *wild coffee*, because the red ovoid berries, which are about ½ inch long, resemble the fruit of coffee and the fresh seeds have a similar taste.

Eugenia (*Myrtus*, Swartz) *Gregii*, De Cand., has oblong or roundish-ovate berries of a leathery texture and a strongly acrid-aromatic flavour. Acrid-aromatic properties are likewise found in the root and seeds of *Eugenia* (*Myrtus*, Sprengel) *angustifolia*, Lam., which grows in San Domingo.

The yellow depressed-globose berries of the Brazilian *Eugenia* (*Myrtus*, Martius) *dysenterica*, De Cand., are of an agreeable acidulous taste, but are apt to produce diarrhœa. The red or yellow berries of the West Indian *Eugenia floribunda*, West, are sweet and acidulous, are eaten raw and cooked, and on fermentation yield a pleasant vinous beverage. Eatable berries are also produced by several other West Indian species of *Eugenia*, the most important of which appear to be *Eugenia* (*Myrtus*, Swartz) *ligustrina*, Wild., s. *Myrtus cerasina*, Vahl., with a black two-seeded fruit called *pitangueira do mato* in Brazil; *Eugenia* (*Myrtus*, Swartz) *lineata*, De Cand., with a scarlet-red cherry-like but several-seeded fruit; and *Eugenia uniflora*, Lin., s. *Eugenia Michelii*, with a red-furrow one-seeded fruit, which is known in some parts as *Cayenne cherry*, and in Brazil as *pitangueira*; the last-named species is also distributed over a considerable portion of tropical South America, and has been naturalized in the East Indies. In like manner are also used the violet-purplish plum-sized berries of the Brazilian *Eugenia* (*Myrtus*, Martius) *cauliflora*, De Cand., known as *jabuticaba*.

One of the myrtles of tropical America has been introduced into and naturalized in most other tropical countries, where it is highly valued on account of its fruit, which resembles a medium-sized pear, with a downy, veined, brittle and thin rind, and containing a whitish, yellowish or reddish pulp, of a very agreeable sweet, acidulous and aromatic flavour. The fruit is known as *bay plum*, *guava* or *guayava*, and in Brazil as *aracá mirim* and *aracá goiaba*. It comes from a small tree, the *Psidium Guava*, Raddi, under which name two or three nominal species are comprised, chiefly distinguished by the shape of the fruit; this is either pyriform or globular, the latter apple-shaped or red guava being regarded as rather inferior to the former, or white guava. The unripe fruit is astringent, and is employed like other astringents; the young leaves and buds have similar properties, also the root and the bark, and are used both internally and externally. The white guava is most esteemed for eating in the raw state; but the pulp of both varieties is used in the West Indies in the preparation of two kinds of preserve, which are known as guava jelly and guava cheese, and furnish a not unimportant article of commerce.

The dark red spherical, well-flavoured fruit of *Psidium Cattleyanum*, Sabine, has the size of a large plum, and on account of its purplish pulp is known as purple guava, and in Brazil as *arácaseiro do campo*; it is indigenous to Brazil and naturalized in China.

Psidium guineense, Swartz, is cultivated in the West Indies for its somewhat smaller, dark yellow and internally red berry, and the fruit of *Eugenia* (*Myrtus*, Sprengel) *pseudo-psidium*, Jacquin, is esteemed there under the name of *bastard guava.*

Psidium montanum, Swartz, the *mountain guava* of Jamaica, has a globular fruit, scarcely ½ inch in diameter, which, like the flowers, has a bitter almond odour. A species of St. Vincent, *Psidium Guildingianum*, Grisebach, with small berries, only ¼ inch thick, has in its habit considerable resemblance to *Myrcia coriacea* and *Pimenta acris*, but the rigid leaves are devoid of pellucid dots.

Campomanesia (*Psidium*, Aublet) *aromatica*, Grisebach, has yellow globular eatable berries, and a foliage of a balm-like odour. The similar fruit of *Campomanesia lineatifolia*, Ruiz et Pavon, is known in Peru as *palillo*, and that of *Camp. cornifolia*, Kunth, in New Grenada, as *guyavo de Anselmo.*

In this connection should also be mentioned the *rose apple* and *Malay* or *Otaheïte apple*, which have been naturalized in the West Indian Islands, and there, as in tropical Asia, their native country, are highly valued on account of their agreeable taste and rose-like odour. The former, *Jambosa vulgaris*, De Cand., s. *Eugenia* (*Myrtus*, Kunth) *Jambos*, Lin., is a globular or oval yellowish or reddish berry, about 1½ inch in diameter; the latter *Jambosa* (*Eugenia*, Lin.; *Myrtus*, Sprengel) *malaccensis*, De Cand., is pear-shaped or top-shaped, 3 or 4 inches long, of a crimson or blackish-red colour externally, and with a white, juicy pulp.

The bark and leaves of both species possess strongly astringent properties, and the seeds are aromatic and acrid. The fruit of several other species indigenous to tropical Asia is employed there like those mentioned.

The jambolana, *Syzygium* (*Eugenia*, Lam., *Calyptranthes*, Wild.) *Jambolanum*, De Cand., is also naturalized in Jamaica and other West Indian islands. The dark red oval and somewhat curved fruit is of the size of a large cherry, has an astringent, acidulous taste, and is employed in gargles; the bark, notably that of the root, is astringent and aromatic. Several other species of this genus, mostly indigenous to tropical Asia, bear eatable berries.

The plants of the genus *Myrtus*, to which the frequently cultivated common myrtle of Southern Europe, *Myrtus communis*, Lin., belongs, have, likewise, aromatic and astringent properties, and their berries are in some cases eatable, like *Myrtus Luma*, Mill., whose fruit is very palatable; *Myrtus microphylla*, Humb. et Bonpl., the red berries of which are of the size of a pea and very sweet, and *Myrtus Ugni*, Molina, which has thicker brown-red berries, of a faint rosemary odour; these species are indigenous to Chili and Peru, and the leaves of the *ugni* are used as a substitute for tea. The *guayavo arayan* of the Orinoco valley is *Myrtus salutaris*, Kunth, the root of which is highly valued as an astringent.

Somewhat similar properties are possessed by a Chilian plant called *cheken* or *chekan*, which enjoys a local reputation, and the use of which in Europe and in North America has been recently revived. *Eugenia Cheken*, Molina, is a small shrub, about 4 feet high, with a rough, brown, strongly astringent bark; the leaves are sessile, about an inch long, elliptic or roundish, somewhat narrowed at both ends, delicately feather-veined, light green and smooth; the peduncles are axillary and terminal, five or six-flowered; the berries are globular, about ¼ inch thick, externally black, and contain two somewhat heart-shaped seeds. The barks and the leaves have been employed internally in indigestion, diarrhœa and various other affections of the bowels and kidneys, and externally, in the form of fomentations, in ophthalmic inflammations, rheumatic and other pains, and more recently, as inhalations of the vapours from the aqueous infusion, in bronchitis, laryngitis and diphtheria.

Very few myrtles are indigenous, but none peculiar to the United States. The five species, enumerated in Chapman's 'Flora,' are small trees, confined to Southern Florida. They are *Eugenia dichotoma*, De Cand.; *Eug. procera*, Poir.; *Eug. monticola*, De Cand.; *Eug. buxifolia*, Willd., and *Calyptranthes* (*Myrtus*, Lin.) *Chytraculia*, Swartz. Not a single myrtle has been found indigenous to California, though the climate is well suited for the growth of different species of *Eucalyptus*, and doubtless of other genera of this interesting and useful natural order. The States bordering the Mexican Gulf may likewise be adapted for the acclimatization of some of the numerous myrtles.

NEW YORK ACADEMY OF SCIENCES.

Sulphur Deposits in Utah and Nevada.*

BY ISRAEL C. RUSSELL.

Sulphur deposits, of sufficient extent to attract attention from their economic importance, have been visited by the writer at three localities in the Great Basin. These are located at Cove Creek, Millard county, Utah; near Humboldt House, Humboldt county, Nevada; and at Rabbit Hole on the eastern edge of the Black Rock desert in north-western Nevada.

Of these deposits the most interesting to the geologist are those occurring at Cove Creek, in Southern Utah, This locality is on the eastern border of the Great Basin, and at the western edge of the region of the high plateaus, recently described by Captain Dutton. Eastward of it is a high range of trachytic mountains that sweep around to the north-west and north-east, forming a crescent-shaped alcove in the western face of the range, the points of which are about ten miles apart. Between the horns of this crescent and three or four miles southwest of the Ranch Fort at Cove Creek, is a conical mountain of basalt, having the ruin of a cinder cove at the summit; for convenience, we shall call this old volcano the Cove Creek crater. From the perfection of its outlines this crater seems so be of a very recent date, but is clothed with a scattered growth of cedars, and judging from its general appearance and the amount of weathering it has sustained, it is probably older than the post-Bonneville craters near Fillmore, Utah. The Cove Creek crater is now in the condition of a nearly extinct fumerole, as hot air and gases are said to escape from cracks and fissures near the summit of the mountain. The area between the base of the crater and the mountains to the eastward of Cove Creek, is occupied by subaerial gravels, excepting along the immediate base of the eastern range, where volcanic tuffs appear at a number of localities. Along the line where the alluvian slopes upwards to meet the tuffs and volcanic rocks, is where the majority of sulphur mines have been opened.

Prospecting for sulphur was begun at Cove Creek about ten years since by Mr. C. A. Semler, and has been carried forward by him with much energy ever since. At the present time fifteen mines have been located, a few of which have been developed to a slight extent, and a large number of prospects opened. The mines, however, have not yet been worked sufficiently to make the sulphur from this locality an article of commerce.

From the hasty examination that I was enabled to make, I find that the sulphur deposits at Cove Creek arrange themselves in three convenient groups, the divisions depending, however, more on the nature of the cavities that have received the sulphur, than on any difference in the manner in which it has been introduced. In one instance the sulphur occupies a nearly extinct solfatara; again we find it impregnating and cementing beds of volcanic tuff; and at other times, the sides of fissures are sheathed with a brilliant drusy lining of sulphur crystals. In all of these instances it is evident that the sulphur has been derived from deeply seated sources, having been expelled in a gaseous form, and condensed and crystallized in the cavities and fissures in the cooler rocks above.

In the mine named the Cleveland by Mr. Semler, situated about two miles southward of the fort at Cove Creek, the sulphur occurs in quantity, filling the crater of a solfatara. The bottom of the little valley in which the Cleveland is situated, is nearly circular, with a diameter of about 1200 feet, and is totally destitute of vegetation. Over the level surface of this strange little desert the sulphur outcrops in many places, forming ledges of sulphur, and a number of prospects show an abundance of quite pure material. A shaft was sunk in the centre of this deposit, to the depth of 25 feet, all in pure sulphur, as I am informed by Mr. Semler. The material taken from this shaft has been returned to it, in order to guard against the burning of the mine, and the broken fragments are now cemented into a solid mass by the sulphur that has been deposited in the interstices between the broken masses. The deposition of sulphur is still in progress, the prospecting holes becoming lined in a few days with most beautiful plumb-like crystals of pure sulphur. The temperature in all the openings in this sulphur bed is high. At the surface of one of the prospecting holes which had been refilled with broken fragments, the thermometer read 104° F., and through all the openings vapour and heated gases are constantly escaping. In cold weather the clouds of vapour forming above this mine may be observed from a distance of a mile or two. The drops of moisture that condense on any cold object held for a moment in the excavations, are intensely acid, and from their taste seem to contain a large proportion of sulphuric acid. No chemical examinations of these acid drops, or of the gases that are constantly escaping from the openings, could be made. It is noticeable, however, that no odour of sulphuretted hydrogen can be detected about the mines, but from a few simple tests, and from the presence of dead animals in a large number of the openings, it seems evident that carbonic acid is exhaled in large quantities.

The sulphur at this locality covers a circular area of about 1000 feet in diameter, and from the prospects that have been reported cannot be less than 25 feet thick. This is not pure sulphur, however, but certainly carries a large percentage of earthy matter. The conclusion arrived at from a hurried inspection of this interesting locality is that the sulphur fills a nearly extinct solfatara, into which it has been conducted from below, seemingly by direct sublimation, or what is perhaps more probable, by the decomposition of sulphurous gases and the deposition of the liberated sulphur. A careful examination of the fumes that are exhaled from these openings would certainly be of much value in determining the chemical history of sulphur deposits.

Of the second class of mines—those in which the sulphur impregnates beds of volcanic tuff—we have examples in the Mariposa and Prince Albert, situated at the base of the mountains, two miles east of the fort at Cove Creek. At these localities the tuff is stratified, and contains scattered pebbles of quartzite and limestone, and is impregnated over a large area with sulphur, which fills all the interstices of the rock. Judging by the eye alone, much of the tuff contains from 10 to 40 per cent. of sulphur, while in localities the work is far richer than this. Overplacing the tuff are alluvial cones of gravel that are in some places cemented by sulphur in the same manner as the strata of tuff beneath, thus showing that the beds now carrying the sulphur have acted simply as condensers for the sulphur, which in every case has been derived from a deeper source.

The third class of sulphur deposits—those in which the

* Reprinted from the *Oil and Drug News*, May 30, 1882.

sulphur forms a lining of crystals on the sides of fissures —are illustrated by the Philadelphia and Mammoth mines. At the first of these, situated one mile north of Cove Creek, the sulphur occurs in drusy crystals, covering the sides of small intersecting fissures in trachyte. The work has here been much broken along a line of faulting, which may be traced northward to the top of the Cove Creek crater. The Mammoth mine is of a similar character, but formed in a dark carboniferous limestone. This mine is located on the top of the divide, between Cove Creek and Dog Valley to the northward. While standing on this pass the line of faulting on which the Mammoth mine is situated may easily be traced southward to the valley of Cove Creek, and across the valley it is again seen as a bold fault scarp, with a throw to the westward ascending the side of the volcanic crater that we have already mentioned several times. The fault crosses this cove just to the east of the summit, and has given the eastern slope of the mountain a steeper inclination than is shown by the western side. Northward from the Mammoth mine the same line of faulting is continued for many miles, and shows a recent scarp all along the eastern border of Dog Valley. The fault scarp that ascends the side of the volcanic cove, and also the recent scarp in Dog Valley are the results of slight and very recent movements along an ancient line of profound displacement. The volcanic mountain south-west of Cove Creek has been built over this old line of fracture. The sulphur in the Mammoth mine has been deposited in the fissures made by the faulting of the strata, and in the seams and openings between the layers of limestone. The rock on the borders of these fissures, beneath the thin lining of sulphur, has been altered to a brown earthy mass to the depth of about half an inch. The mines like the Philadelphia and Mammoth, that have been opened on lines of fracture in solid work, show but little sulphur, and on the whole cannot be considered as giving promise of any large deposit below the surface. In these mines also the temperature is high, but not so great as at the Cleveland.

The beds of volcanic tuff, in which the sulphur has been deposited, probably rest on harder rock that has been fissured, thus allowing the sulphur-bearing vapours to escape upwards, as in the case of the Philadelphia mine, but no section showing the tuff beds above such fissures has been exposed. As these beds of tuff occur for many miles along the base of the mountains, we may hope that the conditions for charging them with sulphur have been many times repeated. Next to the Cleveland mine, we should certainly look to the beds of tuff along the base of the mountains eastward of Cove Creek, for the principal supply of sulphur for economic purposes from this region.

Owing to the exhalation of various gases in nearly all the prospects that have been opened, we find in the bottoms of the excavations large numbers of dead insects, together with the remains of mice, bats, rabbits, etc., that have been smothered by the escaping gases. In many of the openings a choking sensation is felt, and the amount of gas, which seems to be largely carbonic acid, is so great that a person can remain in them but a few seconds; even in shallow prospects the workmen have to fan each other, in order to remain in the openings long enough to do their work. These mines can only be opened from the surface, and even by this method they cannot be worked to any considerable depth, owing to the high temperature of some of the prospects, and the constant escape of noxious gases.

Associated with the deposits of sulphur are beds of gypsum, and also irregular deposits of "alum." Just what the nature of the "alum" may be has not been determined by analysis. These beds usually overlie the sulphur deposits, the alum being sometimes 2 feet thick and the gypsum as much as 8 feet. Hot springs occur in the same field, which, together with the fumerole, at the top of the old crater, bear evidence to the expiring volcanic energy of the region.

Sulphur deposit at Humboldt Station, Nev.—The sulphur at this locality fills nearly vertical fissures, that are directly associated with a very recent basaltic butte that rises in the centre of the Humboldt Valley, near Humboldt Station, on the Central Pacific Railroad. The filling of these fissures with sulphur seems due to the same kind of solfataric action as is still in progress at Cove Creek, but at this locality the fissures are cold and the volcanic action extinct. These deposits of sulphur are of small extent, but a few years since they were opened and worked in a small way. At present they are abandoned, as the discovery of much richer deposits about thirty miles to the northward, on the border of the Black Rock Desert, has rendered their working unprofitable.

The Rabbit Hole Sulphur Mines.—These mines derive their name from the Rabbit Hole Springs, situated a few miles southward of the sulphur deposits, on the eastern border of the Black Rock Desert, in northern Nevada. The hills that rise to the eastward of the principal mines are of stryolite, bordered along their western base by beds of nearly white volcanic tuff or breccia, which is represented on the maps of the Fortieth Parallel Survey as being of Miocene age. These breccias have been greatly altered, and cemented by opal and other silicious infiltrations since their deposition, so that they now form brittle silicious rock with pebbles and fragments of older rocks scattered through the mass. In many places these porous tuffs and breccias are richly charged with sulphur, which fills all the interstices of the rock and sometimes lines large cavities with layers of crystals 5 or 6 feet in thickness. In the Rabbit Hole district sulphur has been found in paying quantities for a distance of several miles along the border of the desert, but the distribution is rregular and uncertain and is always superficial, so far as can be judged by the present openings. As in the Cove Creek mines, the sulphur at Rabbit Hole has been derived from a deeply seated source, and deposited from a vaporous condition in the cooler and higher rocks in which it is now found. Judging from the silicious material that cements the tuffs, it is evident that the porous rocks, in which the sulphur is now found, were penetrated by heated waters bearing silica in solution previous to the deposition of the sulphur. These mines occur in a narrow north and south belt along a line of ancient faulting, which is one of the great structural features of the region. The association of faults with sulphur bearing strata of tuff is here essentially the same as at the Cove Creek mines. At the Rabbit Hole mines, however, no very recent movement of the ancient fault could be determined. This absence of a recent fault scarp, together with the fact that the mines are now cold and do not give off exhalations of gas or vapour, shows that the solfataric action at this locality has long been extinct.

At all the localities visited the sulphur has been derived from sources far beneath the surface from which it has been expelled by heat, and escaped upwards through fissures that were formed along lines of faulting, and has been condensed on the sides of fissures, and in the interspaces of the cooler rocks near the surface. Whether the deposition of the sulphur took place by direct sublimation or by the decomposition of sulphuretted hydrogen, has not been determined. The date at which the sulphur was introduced into the rocks where we now find it, is in all cases very recent, and at the Cove Creek mines is still in progress.

Work at the Rabbit Hole mines is now being carried forward by a day shift of seventeen men, the production of sulphur being about 6 tons per day. The value of the sulphur produced is about forty-five dollars per ton in San Francisco. The sulphur, after being mined and assorted, is placed in upright cast-iron retorts, having a general resemblance to the common form of blast furnace, with a capacity of about 2½ tons. When the retorts are charged the openings at the top, through which the sulphur-bearing rock is introduced, are closed, and superheated steam admitted at the side. The steam pressure is at first about 70 pounds to the square inch, but as the sulphur begins to melt, the pressure is allowed to subside to 60 or perhaps 50 pounds. When the sulphur melts it passes through a grate, and is collected in a kettle beneath the retort, from which it is allowed to flow in a very liquid brown stream, into a receiving pan, with a capacity of about 12,000 pounds, where impurities that were previously held in suspension are allowed to settle to the bottom. From the receiving pan the sulphur is run into molds, shaped like the frustrum of a cone, each of which has a capacity of from 200 to 250 pounds. When allowed to stand a few days after cooling, those cylindrical masses break into irregular lumps, in which condition it is delivered to the sulphur refinery at San Francisco.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act, 1868.

At the Clerkenwell Police Court, on Friday, the 28th ult., George Theodore Imeson, of 172, Caledonian Road, London, N., was charged with having, on the 20th of July, sold to Mr. Templeman, the Assistant Secretary of the Chemists and Druggists' Trade Association of Great Britain, a preparation of opium not labelled with the name of the seller.

Mr. Glaisyer appeared for the prosecution, and Mr. Attenborough, barrister, defended.

The case was under the 17th Section of the Pharmacy Act, 1868, which provides that it shall be unlawful to sell any poison either by wholesale or retail unless the box, bottle, or wrapper in which such poison is contained be distinctly labelled with the name of the article, the word "poison," together with the name and address of the seller of the same. On the 20th ult., Mr. Templeman went to the shop, 172, Caledonian Road, and there purchased from the defendant personally two pennyworth of laudanum. The bottle containing the poison was labelled "Laudanum, Poison. Saunders and Co., Chemists and Dentists, 172, Caledonian Road, London, N., Post and Money Order Office." The defendant was also the postmaster and he was rated as occupier of the premises, but his name does not appear on the Register of Chemists and Druggists, and he has therefore no right to sell poisons.

Mr. Glaisyer then directed the attention of the magistrate to the decision of Mr. Justice Grove and Mr. Justice Lopes, in the case of Templeman *v.* Trafford, who held that the seller within the meaning of the Act was the person who had actual control of the shop where the sale took place.

Mr. Attenborough, in defence, quoted from the case of Templeman *v.* Trafford, which he argued was not at all applicable to the present one, inasmuch as in that case there was no name over the door of the shop, the poison was labelled with the name of a chemist residing at some distance from the shop where the poison was sold. Mr. Imeson, as an unregistered person, might have infringed another section of the statute by selling poisons, but he contended that the requirements of the section under which these proceedings were taken had been complied with, since the name Saunders and Co. appeared on the facie board and also on the bottle, and that enabled them to trace the sale of poisons to that address, the prosecutor had failed to prove that such a firm as Saunders and Co. did not exist.

The Magistrate: We have heard that a Mr. Higham lived at that address, then came the defendant, but there has been no mention of Saunders and Co. residing there. He was clearly of opinion that there had been an infringement of the Act, and the defendant must pay the full penalty of £5 and costs.

Mr. Glaisyer applied for extra costs, which were not allowed.

Obituary.

Notice has been received of the death of the following:—

On the 20th of June, Mr. Charles Wood, Chemist and Druggist, Market Place, Wigan. Aged 37 years.

On the 18th of July, Mr. George Long, Pharmaceutical Chemist, High Street, Peckham, S.E. Aged 52 years.

On the 20th of July, Mr. Joseph Wright, Chemist and Druggist, Bridge Street, Leeds. Aged 49 years.

Correspondence.

The Future of Pharmacy.

Sir,—The question, as it appears to me, is, How is a chemist to get his living, maintain the dignity of his profession, and compete with the numerous stores now in existence, these stores being supplied by the same people that supply us, but on very different terms?

I had given to me the other day, confidentially, a list, which is a piece of ordinary ruled paper, with the articles and prices written on both sides; made out by a very influential wholesale drug house, whose name I must withhold, but the principals of which have been brought before us in a very prominent manner, and I presume it is for the sake of their reputation amongst chemists generally that they withhold their name from the list which is specially made out for stores' orders. Some of the articles I will give you, with prices:—

Dill Water	8 oz.	bottles	3s. 6d.	per dozen.
Essence of Ginger . .	1	,,	4s.	,,
,, . .	2	,,	7s.	,,
Essence of Senna . .	4	,,	6s.	,,
,, . .	8	,,	11s. 6d.	,,
Glycerine, B.P. . .	2	,,	3s.	,,
,, . .	4	,,	5s. 6d.	,,
Vin. Ipecac.	2	,,	3s. 9d.	,,
,, ...	4	,,	6s. 6d.	,,
Spirits of Camphor, Nitre and Sal. Volatile	2	,,	6s.	,,
,,	4	,,	10s. 6d.	,,
Com. Conc. Sarsaparilla	4	,,	10s.	,,
Cough Linctus . . .	4	,,	4s. 6d.	,,
,, . . .	8	,,	8s.	,,

All less 10 per cent. discount.

Castor oil, 4 oz., 2s. 6d.; 8 oz., 4s. 6d.; 10 oz., 5s. 6d.; 12 oz., 6s.; 16 oz., 8s., per dozen.

Cod liver oil, 8 oz., 10s. 6d.; 16 oz., 18s., per dozen.

These are only a few from a list of sixty-three, and with the ordinary receipts of a chemist and druggist, I think it is impossible for him to compete with these prices. It seems to me, that when we, as a body, find a wholesale house of any description supplying stores, and necessarily giving them the advantage over us, we should, so to speak, "Boycott" that firm. I for one, would not, if I knew it, spend sixpence of my money with any firm that, to my knowledge, supplied stores, and would strongly recommend this plan to the trade generally. From observing the trade advertisements in stores' lists, we should find a great many of those who did supply them. If this plan could be unanimously adopted, wholesale houses would find that a fair and legitimate trade amongst chemists and druggists was far more satisfactory and remunerative than supplying stores at large discounts.

We cannot blame stores, but the people who supply them at special terms and thus giving them the great advantage of offering goods to the public at the same prices as we buy them, or very nearly so, and until we can in some way let those firms find that we will not deal with them, stores will flourish.

Perhaps these few remarks may give rise to some idea that will be beneficial to us in the future of pharmacy.

Wulfruna.

Magister.—You do not appear to be aware that the examination criticized by you was conducted by the College of Preceptors, whose papers you speak of approvingly.

Communications, Letters, etc., have been received from Messrs. W. I. Richardson, Thompson, I. Pike, W. J. McIntosh, J. H. Garrett, Aquam.

THE INTERNATIONAL ELECTRIC EXHIBITION.

(*Continued from page* 102.)

The next Englishman to tread in Mr. Swan's steps in this field was Mr. St. George Lane-Fox. The following description of this inventor's lamp by the Paris Committee is very full and clear, but further details as to the manner in which the contacts are made will be found of interest and will therefore be given after the description. "The Lane-Fox lamp is ovoid in shape, the neck being in length intermediate between the two lamps last described (Swan and Maxim). The carbon is in the form of a horseshoe, and is circular in cross-section. It is made from the root of an Italian grass, largely used in France for making brooms. After carbonization the filaments are classified according to their resistances. They are then heated in an atmosphere of coal gas, by which carbon is deposited upon them, as in the filaments of the lamps last described. The filament in the lamp is supported by platinum wires, to which it is attached by sleeves of carbon encircling both. These wires pass through tubes in the top of a hollow glass stem. Just below the extremities of these tubes are two small bulbs containing mercury, forming the contact between the platinum wire sealed into the glass above and the copper conductor which enters from below. These conductors are held in place by plaster, which fills the base of the lamp."

The filaments are joined to short cylinders of carbon or graphite by means of holes drilled a little way into them; these holes are filled up with a cement composed of genuine Indian or Chinese ink and finely divided plumbago. At the other end of the cylinders holes are drilled to meet the ends of the filaments, but the inventor states that this is not absolutely necessary. In these latter holes short lengths of platinum wire are inserted, cemented as before; each length of platinum wire need not exceed $\frac{1}{4}$ of an inch in length. The other ends of the platinum wires are fused into tubes of lead glass and the wire ends come into the small glass globes filled with mercury. The mercurial contacts are arranged as stated by the committee.

The Italian grass from which the filaments are manufactured is stated by the inventor to be the *Andropogon Ischæmum* or *Chrysopogon Gryllus*. The grass is prepared by boiling in a 5 per cent. solution of caustic soda or potash; the outer skin is thus loosened and scraped off. The fibre is straightened by stretching it while still damp, and the straightened fibre is bound on a block of carbon, buried in plumbago in a sealed crucible and the crucible and its contents raised to a white heat. The fibres are thus ready for mounting as before described. If the resistance of the carbonized fibres proves to be too high Mr. Lane-Fox ingeniously incandesces them in a "Woulfe's" bottle contrivance through which a stream of coal gas or hydrocarbon vapour is passing continuously. The filaments are in connection with a measuring apparatus, and when the resistance is found to be nearly right, the filaments are mounted in their holders and the process repeated until the resistance reaches the exact figure necessary.

The Lane-Fox lamp was found by the Paris Committee to have a mean resistance cold of 55 ohms; at 16 candles this resistance became reduced to 27·4 ohms, and at 32 candles to 26·59 ohms. The current required when yielding 16 candles was 1·593 ampères with an electromotive force of 43·63 volts; at 32 candles the current was 1·815 ampères and the electromotive force 48·22 volts; 10·61 16-candle lamps were yielded per horse-power and 8·65 32-candle lamps, being 173·58 and 276·89 candles per horse-power.

The Lane-Fox lamp is worked by the Anglo-American Brush Electric Light Company. The luxurious richness of the installations of Lane-Fox lamps in the Alhambra Court at the Crystal Palace made the Brush Company's exhibit one of the most popularly attractive sights of the exhibition. The display was certainly an impressive demonstration of the ornamental capabilities of the incandescent electric lamp, such as cannot be imagined by those who had not the fortune to see it.

The next lamp that is commercially available to the public is the Maxim lamp, owned by the Maxim-Weston Electric Light Company, formerly known as the Electric Light and Power Generator Company. This lamp is of American origin, and is not yet so well known in this country as the preceding lamps; it, however, appears to be making its way slowly. It is one of the four lamps reported on by the Paris Committee. The following is the committee's description of the lamp. "The Maxim lamp is also globular in form. It has a short neck; within the neck rises a hollow cylinder of glass, supporting upon its summit a column of blue enamel, through which passes the conducting wires of platinum which carry the carbon. The filament is made of cardboard cut by a punch in the form of an M, in section, therefore, rectangular, and several times as broad as it is thick. It is carbonized in a mould, through which a current of coal gas is passed. After carbonization the filament is placed in an attenuated atmosphere of hydrocarbon vapour and heated by the current. The vapour is decomposed and its carbon is precipitated on the filament. In this way not only are the inequalities obliterated, but the resistance of the filaments may be equalized and brought to any standard required." The committee found the cold resistance of the Maxim lamp to range from 63 to 84 ohms, the mean resistance of the ten specimens tested being 72 ohms. The hot resistance when giving a light of sixteen candles was 41·11 ohms mean and 39·60 ohms at thirty-two candles. The current in ampères when yielding sixteen and thirty-two candles was 1·38 and 1·578 respectively. The electromotive force in the same order was 56·49 and 62·27 volts. These figures give 9·48 16-candle and 7·50 32-candle lamps per horse-power, or a total of 151·27 and 239·41 candles per horse-power in the two cases.

As a result of their experiments the committee come to the following four conclusions:—

1. The maximum efficiency of incandescent lamps in the present state of the subject, and within the experimental limits of this investigation, cannot be assumed to exceed three hundred candle lights per horse-power of current.

2. The economy of all lamps of this kind is greater at high than at low incandescence.

3. The economy of light production is greater in high resistance lamps than in those of low resistance, thus agreeing with the economy of distribution.

4. The relative efficiency of the four lamps examined, expressed in carcel burners of 7·4 sper-

maceti candles each, produced by 1 horse-power of current, is as follows:—(*a*) At sixteen candles, Edison, 26·5; Swan, 24; Lane-Fox, 23·5; and Maxim, 20·4. (*b*) At thirty-two candles, Edison, 41·5; Lane-Fox, 37·4; Swan, 35·5; and Maxim, 32·4. To double the light given by these lamps the current energy was increased, for the Maxim and Lane-Fox lamps 26 per cent., for the Edison lamp, 28 per cent., and for the Swan lamp, 37 per cent.

The foregoing are the only incandescent lamps of which, up to the present time, exhaustive tests have been published. It will, however, perhaps complete the subject-matter better if a brief description be given of the general notions involved in some of the more recently invented lamps which have been sold to various public companies, but of which nothing further is at present known than is contained in the respective inventors' patent specifications.

Mr. William Crookes, F.R.S., who has sold his lamp to the Gülcher Electric Light Company, takes cellulose, which he purifies by soaking in hydrofluoric acid, etc. He also claims the use of certain substances which are capable of absorbing the residual gas; he mentions thorina and alumina as suitable for this purpose. It is stated in the specification, No. 1422, 1881, that alumina absorbs residual traces of aqueous vapour. The method of utilizing this property is thus given:—After exposing the substance to the action of aqueous vapour the containing bulb is to be exhausted in the usual way until the exhaustion reaches, say, the one ten-thousandth of an atmosphere. On applying heat to the part of the glass containing the alumina occluded aqueous vapour is given off from the alumina. On re-exhausting as completely as possible a mere trace of vapour is left in the bulb; as the heated alumina cools down this residual trace of vapour is absorbed, thus rendering the vacuum practically complete. Mr. Crookes says that by operating in this way it is easy to push the exhaustion to a degree that would be impracticable by the use of a pump only. The vacuum thus produced will prevent an induction spark passing that would strike through several inches of air. The methods by which the purified cellulose is formed into filaments constitutes another patent, No. 2612, 1881. In this specification several different ways are given of treating the purified cellulose with an ammoniacal solution of cupric hydrate called cuprammonia, a well-known solvent of cellulose. In the first method the cellulose is taken in a manufactured form as thread, paper, etc. The material is passed through or dipped into the solvent for a few moments until the cellulose is acted upon to such an extent as wholly or partially to destroy its intimate structure, but not sufficiently to produce disintegration or solution. When sufficiently acted upon the material is allowed to dry by simple exposure to the air. The copper that remains behind is extracted with dilute acid; after extraction the material is washed thoroughly with water and dried between sheets of blotting paper.

Another process is to allow a cuprammonia solution of cellulose to evaporate in a shallow dish, with an accurately levelled plane bottom. When the skin or film left has acquired a sufficient consistency it is treated with dilute acid to extract the copper, thoroughly washed with water and dried under pressure between sheets of blotting paper.

The filament is prepared from the above material by cutting or punching out an adequate portion. The ends of the filament are strengthened by electro-depositing nickel or copper on them, and the junction between the conducting wires and the filament are painted with a thick syrupy cuprammonia solution of cellulose; after drying and carbonizing a good junction will be obtained possessing good conductivity from the finely divided metallic copper present. The carbonization is to be effected slowly in a gas muffle furnace, the filaments being buried in powdered charcoal and placed under moderate pressure during the operation, coal-gas is passed through the iron box in which the filaments are carbonized during the whole operation. If the filament after carbonization does not possess the right resistance or is imperfect, it is improved by heating it in a vacuous vessel containing a quantity of a high boiling point hydrocarbon, of which the vapour tension at ordinary temperature is low, such as naphthaline, or xylol or chloroform. These hydrocarbons, although present in quantity, emit an attenuated vapour, which is slowly decomposed and deposits carbon on or in the pores of the filament in a good conducting graphitoidal form. The manner in which the filament is mounted in its glass globe forms the subject-matter of another patent, 3799, 1881. This patent specification contains an interesting description of the manner of forming the glass envelope, which, however, could not be intelligibly described without the accompanying diagrams. The most notable feature is the device of using a cored wire conductor for sealing into the lamp. It is difficult to make a good junction between the glass and the metal except in the case of platinum; and with thin conducting wires of platinum the low conductivity of the metal causes it to heat when large currents are used, and to crack the glass or cause a leak at the junction. Mr. Crookes gets over this difficulty by using a compound wire having a core of copper, silver, gold, or other good conductor, and a platinum sheathing, so that there is the advantage either of using a cheaper metallic conductor or a metallic conductor of better conductivity, without any increased difficulty in making it form a good junction with the glass.

The patent specification of Tom Ernest Gatehouse, 3240, 1881, appears to be an attempt to use platinum as an incandescing material, the metal being kept from fusing by an alternative circuit of carbon, the principle taken advantage of being the familiar one that metals increase in resistance with elevation of temperature, while carbon, on the contrary, diminishes in resistance under these conditions. Upon these facts Mr. Gatehouse constructs a current regulator. Chatterton's compound* is used in filling the neck of the containing globe. This lamp is said to have been acquired by one of the numerous electric lighting companies that have been formed during the last few months.

The remaining incandescent lamp it is proposed to notice is the one invented by Mr. Desmond Gerald Fitz-Gerald. Specification No. 3890, 1881. The filament of the Fitz-Gerald lamp is formed of Swedish filter paper gelatinized by the action upon it of concentrated solution of chloride of zinc of specific gravity 1·876 or thereabouts. When the material is sufficiently gelatinized it is thoroughly washed with water acidulated with hydrochloric

* A mixture very familiar to telegraph engineers, composed of Stockholm tar, resin and gutta percha.

acid, next with a dilute solution of ammonia, and finally with water, then it is left to thoroughly dry and when ready for use is said to be very tenacious. The prepared filaments are carbonized in the usual way.

The carbonized filaments are cemented into short lengths of copper tube, $\frac{1}{4}$ of an inch being a suitable length; the cement used is a mixture of lampblack and platinum black made into a paste with water, sugar solution or starch; after drying, the cement tubes carrying the filament are heated to a temperature of not more than 1900° F., being protected from the air in the meantime.

Platinum conducting wires are connected with these tubes and are fused into the glass in the usual manner. The hollow in the base of the lamp is first filled in with a minute quantity of melted gum copal, and then fully secured by means of an infusible cement composed of litharge and glycerine diluted with about two-thirds its bulk of water; this cement is said to become very hard and impervious. The details of the lamp connections can scarcely be understood without the proper diagrams.

Arrangements are made to ignite a short length of magnesium ribbon in the glass bulb in order to facilitate the removal of the residual oxygen. The Fitz-Gerald lamp is owned by the Phœnix Electric Light Company, and has been exhibited at Westminster during the few last weeks.

The future of the incandescent electric lamp looks very promising, though the whole subject is yet in its infancy. Still the progress that has been made is truly astonishing and augurs extremely well for the immediate future of this young creation of the nineteenth century. It was intended to discuss the theoretical bearings of the incandescent lamp more than has been done, but the necessary descriptive matter has taken up such an amount of space as to make this quite out of the question.

NOTE ON CONVALLARIA MAJALIS.*

BY A. LANGLEBERT.

Recent communications made to the Academy of Sciences and Academy of Medicine, by Professors Vulpian and Sée have attracted the attention of the medical profession to a new remedy derived from the lily of the valley (*Convallaria majalis*). Without dilating upon the botanical characters of this beautiful little annual, belonging to the sub-order Asparageæ, I will briefly recapitulate its chemical composition.

The action of this medicament appears to be due to a glucoside and an alkaloid. Valz, in 1830, isolated from it two glucosides, "convallamarin" and "convallarin." In 1865, Stanislas Martin obtained an alkaloid, "maïaline," an acid, "maïalic acid," an essential oil, a yellow colouring matter and wax. This plant, therefore, contains several principles that are themselves subject to modification. In fact, under the influence of dilute acids, convallamarin splits up into sugar and "convallamaretin," and convallarin into sugar and "convallaretin." The chemical composition being known, it was necessary to determine the seat of the active principles, it being easy to foresee that the effects would be different according to the parts of the plant employed. The experiments made hitherto have indicated that all the activity resides in convallamarin and maïaline, convallarin appearing to be nearly inert.

Already for a long time the *Convallaria majalis* has attracted the attention of the scientific world. Cazin tried the flowers under the form of an electuary and obtained abundant stools; the root produced emeto-cathartic effects. Schultze prepared an alcoholic extract of the flowers, which was bitter and purgative with a dose of two grains.

Wouters, Peyrille, Cartheusen and Klein made it out to be a purgative analogous to scammony and aloes. I wish to emphasize this point, because one of the difficulties met with is the elimination, at least partially, of the purgative principle. The extract actually prepared is exempt from it.

In idiopathic epilepsy, headaches and convulsions, Senckenberg, father and son, employed it in doses of from 1 to 4 grams. Hitherto, it would appear, the action on the heart was not even suspected.

In 1880, some Russian physicians experimented with an infusion of the plant, but without sensible results.

Recently the *Convallaria majalis* has been tried by Professor Sée in his clinical practice at the Hôtel Dieu, physiological researches being made simultaneously in the laboratory by Messrs. Bochefontaine and Hardy. Alcoholates and tinctures of the entire plant and of the various parts were prepared, but the results upon the heart were not conclusive. Infusions, even in large doses (6 or 7 grams of the plant), were not uniformly successful. It became necessary, therefore, to prepare extracts of the entire plant and each of its parts, taking into account the action of the menstruum upon the active principles contained in the plant.

The aqueous, alcoholic and hydroalcoholic extracts prepared from the roots did not give the results sought for. In my opinion, the emeto-cathartic action which was observed in a series of extracts prepared by me, was to be attributed to the presence of too large a proportion of the roots.

The aqueous, alcoholic and hydroalcoholic extracts of the leaves are three times less active than the extract actually prepared. Moreover, the aqueous and alcoholic extracts of the root and leaves, whilst fulfilling the therapeutic indications, possessed emetic and purgative properties if the dose given were too high.

The extracts prepared from the flowers and stalks, gave good results, especially with animals, in which the cardiac phenomena observed were very remarkable; they were unaccompanied by emetic or purgative effects, but with very slight diuresis.

From the foregoing facts it would appear that each part of the plant employed produces a slightly varied effect. After several trials made with the flowers, stalks, leaves and roots, the best results were obtained with an aqueous extract prepared from the flowers and stalks of the *Convallaria majalis*, with the addition of a third of their weight of roots and leaves.

This extract, deprived in great part of the resinous purgative principle, is solid in consistence, shining black, possesses a very bitter taste, is soluble in all proportions in water and alcohol, and has an agreeable persistent odour. It is used in the preparation of an aromatized syrup, having a free bitterness without after-taste, and containing 50 centigrams of extract to a tablespoonful. It is under this form

* *L'Union Pharmaceutique*, xxiii., 338.

and in doses of 2, 3, or 4 spoonfuls that the medicament is prescribed in the treatment of cardiac affections.

EXPERIMENTAL RESEARCHES UPON THE CONVALLARIA MAJALIS.*

BY G. SÉE.

The lily of the valley has been known from time immemorial among the Russian peasants as a certain remedy for dropsy. This popular belief became in 1880 the subject of experiment by Messrs. Troitzky and Bojojawlensky, but insufficient was published to attract attention to the subject. The statements, however, being supported by Professor Botkin, of St. Peterburg, impressed the author, who took the first opportunity for their verification, it being necessary to procure the plant in flower to determine the active part.

The Russian physicians had spoken of infusions, without saying whether they were prepared from the flowers, leaves, stalks, roots, or entire plants. The various parts of the plant were therefore tried under the form of infusions, aqueous or alcoholic macerations, and lastly of extracts. The infusion of the flowers was without effect, even in doses equal to five or six grams of the flowers, whilst the tinctures and even the alcoholatures were infinitely less active than the extracts, which M. Sée classes as follows, according to their order of merit:—(1) aqueous extracts of the leaves, which require a dose three times as large as the extracts from other parts of the plant; (2) extracts of the flowers, which exercise upon animals a very energetic action, and upon man a much less intense one; (3) extracts of the entire plant, including flowers, stalks, and roots.

Valz, in 1830, obtained from the aqueous extract of the dried flowers and roots the toxic principle called "convallamarin;" the alcoholic extract yields "convallarin," which is of little importance. The former principle is a glucoside, splitting up, under the influence of acids, into sugar and convallamaretin.

M. Hardy, demonstrator of chemistry in the laboratory of the Hôtel-Dieu, has obtained convallamarin in the amorphous state. It was obtained from extracts of the plant, by Dragendorff's process; treating the acidulated aqueous extract with alcohol and then with chloroform or amylic alcohol. This principle has an activity comparable to that of pure digitaline, with which experiment shows it to have points of analogy as well as of difference.

In order to arrive at the therapeutic dose of the extracts to be given to man, preliminary trials were carefully made first upon animals. By an approximative calculation, based upon corporeal weight, the dose useful in cardiac disease was determined. It may be thus formulated: 1 gram to 1½ or even 2 grams of extract of the flowers or of the entire plant; extract of the leaves is only active with double this dose.

EXTRACT OF MALT.†

BY THOMAS T. GOODALE, PH.G.

In preparing extract of malt, cleanliness is of primary importance. The vessels should be thoroughly washed in some alkaline solutions, such as solution of soda or potash, to prevent any substance from adhering to them, and, when not in use, should be filled with lime water. If these precautions are neglected, acetification is sure to follow, and the preparation is spoiled. Care must also be taken that the malt be fresh, as it sours and becomes unfit for use if it has been crushed more than three or four days. The grain must be reduced to a moderately fine state, and the best mode is that which crushes it and loosens the husk from the fleshy part without separating the two. Each shell then forms a filter through which the clear liquor percolates, leaving behind any matter which might be mechanically taken up. When ground in a mill, the grain is so disintegrated that it is apt to set during the process of extraction, and form a mucilaginous magma which retains much of the liquor. This cannot be removed except by repeated washings; a very dilute extract is then produced, which is liable to acetification in the succeeding treatment. In order to obtain a concentrated and bright liquor, the saccharine and amylaceous matters must be extracted with the smallest amount of water, and maintained at a proper degree of heat. The grain will be completely exhausted by one mashing, if successfully conducted. Failure may result from two causes: when a mucilaginous mass is formed in consequence of too elevated a temperature, or when the grain is too fine, the liquor cannot be drawn off freely, and the grain is, therefore, not thoroughly exhausted. If, on the other hand, the temperature is too low, the starch is not converted into dextrin and glucose, but is carried off in suspension. The washing apparatus which was found most convenient consists of a tub similar to that used by brewers, smaller at the bottom than at the top, with a finely perforated bottom fitted to it. In the side, between the true and false bottoms, is placed a faucet. Fitting into the perforated bottom, and passing through the cover, is a mixer, which is an upright shaft having cross-bars attached, running at right angles to it. A cog-wheel fitted to the top of the shaft, together with a crank, communicates power to it. A cover made of heavy felting was adjusted to the tub. Wood and felt being both non-conductors, any desired temperature can be constantly and perfectly maintained for many hours. Care must be taken to keep the heat of the mash at 160° F., the conversion of starch into dextrin and glucose being best effected at that degree. The freshness, hardness, and dryness of the grain exert an influence on the temperature. When very dry, heat is generated, and the conversion of the starch causes a still greater elevation of the temperature. Boiling water is poured into the tub, and when the heat has fallen to 165° F., the malt is gradually added and thoroughly stirred in. The temperature is now brought to 160° F., and the tub is closely covered to maintain the heat. After stirring a short time, the mash is allowed to remain at rest for two hours. At the end of this time, the faucet is carefully turned until it is half open. The liquid which flows out should be perfectly bright and clear, and great care should be used to prevent fine particles of grain or any solid matter from passing out. After drawing all the liquid from the tub, a fresh quantity of water heated at 160° F. is sprinkled on the grain, allowed to remain about an hour, and then drawn off as before. If the grain is not exhausted, this operation must be repeated, but nothing of value will remain after two macerations if they have been properly conducted. When three macerations are necessary, the resulting liquor is so dilute that acetification is apt to take place before it is evaporated. In practice, in order to obtain at once a very concentrated extract which should contain all the valuable properties of the grain, the liquid obtained from the first washing is returned to the tub and drawn off in a hour. It is then only necessary to sprinkle on sufficient hot water to force out the liquor held by the grain. If the process has been successful, the extract will be the exact colour of the grain used, will have a good head, be finely flavoured, and effervesce. When the temperature has been too high, the white head has a tinge of brown, and the colour of the extract deepens in exact proportion to any excess of heat. If, on the contrary, the temperature has not been high enough, the liquor is less bright and lively in flavour. When the heat has been very low, the characteristic head will not stand, but flies off immediately, and the liquor will be thick and mucilaginous, and quickly spoil when exposed to the air.

* Abstract of a paper read before the Academy of Medicine (*L'Union Pharmaceutique*, xxiii., 337).

† Abstract of a thesis presented to the Massachussets College of Pharmacy (Boston). From *New Remedies*, March, 1882.

This process differs greatly from Mr. Ebert's, by which the malt is digested for a short time at a temperature of 125° F., and then strained. The liquor obtained contains the diastase. The residue is boiled with fresh water, and strained, and the resulting liquor contains the starch. The two solutions are then mixed and kept at a temperature of 160° F. until the starch is completely changed into grape sugar, which can be readily ascertained by the iodine test. If a higher degree of heat is used, the diastase of the grain is coagulated, and becomes insoluble and inactive. After straining and filtering, the liquor must be carefully evaporated to the proper consistence. The importance of having the liquor perfectly clear and bright was shown by a series of eight experiments as follows.

Experiment No. 1.—The liquor was pale and not very bright. It was placed in a shallow vessel over a water-bath, and constantly stirred. The albuminous matter which made its appearance during the operation was removed, and the evaporation continued until an extract of the consistence of honey was obtained. It was light brown in colour, with a sweet taste, and had the odour of malt. At the end of two weeks it showed no change, but in four weeks, a thin crust had made its appearance. After eight weeks, the mass had separated into two distinct layers. The upper one, or crust, which formed about one-third of the whole, was a shade lighter in colour than the original extract, and quite tough and pliable. It had a starchy appearance and taste, and, when tested with iodine, gave the blue reaction characteristic of starch. The lower layer was a trifle lighter and more liquid than the original extract, and had an agreeable sweet taste and odour. With iodine, it gave negative results, showing the absence of starch. These layers were separated and again examined in four weeks. The crust had grown somewhat harder, but otherwise remained the same. The lower layer showed no change. The peculiar behaviour shown in this case was thought to be due to the separation of the solid and starchy matter of the grain, which had been held in suspension, but which separated when the liquor was evaporated.

Experiments Nos. 2, 3 *and* 4.—These three lots were made in the same manner as No. 1, except that particular care was taken to obtain the liquor perfectly clear and bright. The same process of concentration was strictly followed. When finished, all presented the same appearance, and exactly resembling the lower layer of No. 1, in colour, taste, and odour. At the end of eight weeks, all remained light-brown clear extracts. The liquor used in all the preceding experiments was made in a mash-tub.

Experiments Nos. 5 *and* 6.—The liquor used in these experiments was made by Ebert's process. When first strained, it had a pale starchy appearance. Being shaken with paper-pulp and again strained, a perfectly clear, bright colour was obtained. The method of evaporation was precisely the same as in previous experiments, and the product resembled in every particular those resulting from Nos. 2, 3 and 4. Examination at the end of eight weeks showed no change.

Experiment No. 7.—The liquor used in this experiment was made by Ebert's process, but was merely strained, not brightened. At the end of eight weeks, the peculiar formation noted in No. 1 had made its appearance. After separation, the lower layer remained unchanged, and presented every characteristic of a good extract.

Samples from Nos. 2, 3, 4, 5 and 6 when tested for starch gave negative results.

These experiments, then, proved the correct use of the theory that the peculiar formation noticed when turbid liquors were used, was due to the presence of the solid and starchy matters of the grain, which had passed out in suspension; and that no such formation will take place when the liquor is perfectly clear and bright. Filtering, which is necessary in Ebert's method, renders the process impracticable for large lots, as it is long and tedious.

When made in a mash-tub, the liquor is obtained at once perfectly bright and clear, and is ready to evaporate.

Having obtained a bright liquor, which is necessary, the next step was to find a process by which this liquor could be evaporated in considerable quantities at once, and, at the same time, be made to yield a preparation of a light and uniform colour. When evaporated in the ordinary manner in an open pan, good results can be obtained by constant stirring and careful regulation of the heat, provided the quantity of liquor is small. In making large lots, the long-continued heat necessary to reduce so much liquid produces an extract very dark in colour, and sometimes black. This process, is, therefore, impracticable. The vacuum-pan presented itself as a ready solution of the problem, since, by it, a very bright sweet extract can be made, which, in taste, odour, and particularly in colour, is all that can be desired. This method, however, was abandoned, as the aim was to find some process which would not require complicated or expensive apparatus. The plan of evaporating in very shallow pans at a low temperature was then tried. The clear liquid was poured into tin pans $\frac{3}{4}$ of an inch in depth. These were then placed in a drying closet having a heat 80° to 90° F. The result was but little inferior to what was sought, namely, a sweet extract entirely free from any burnt appearance or taste, with an odour resembling fresh bread. The amount of room necessary to carry out this plan led to its abandonment. The fact that the exposure of a very large surface to the air greatly facilitates evaporation, then led to the adoption of an apparatus by which this advantage was secured, and a very low degree of heat could be employed. There being no ceiling to the room in which the experiment was conducted, two wooden uprights, 12 inches wide, which reached nearly to the bottom of a jacketed kettle underneath, were fastened to adjacent floor-beams above. A wooden roller passed from one upright to the other near the bottom, while near the top two rollers were placed parallel to each other. Over these rollers, a band of cloth was passed, forming, as it were, a letter V closed at the top. Power was communicated by means of a crank attached to one of the upper rollers. The kettle being filled with the clear liquor, steam was turned on until the temperature reached 80° to 90° F., and the heat was kept at this point until the operation was finished. The belt was now set in motion, and passing through the liquor, brought the warmer portions to the surface, and carried a considerable part with it as it passed over the rollers. By this method, a large quantity of liquor can be quickly reduced to a small bulk by a low heat, and with little labour. The rapidity of the evaporation is increased by directing a current of air upon the band, and is also, of course, somewhat in proportion to the length of the band and the amount of surface thus exposed. This process yielded a very satisfactory product, very light in colour, and free from any burnt taste. When compared with lots made in the ordinary manner, its superiority was very marked. Here, then, was a method which gave good results, required only just sufficient heat to warm the liquor, and was easy in manipulation, while the apparatus was inexpensive and occupied but little room.

A freezing process next presented itself as possessing two great advantages, namely, the entire absence of heat during concentration, which would render the formation of caramel impossible, and the great preservative power of cold. The operation was conducted as follows:—The clear liquid, when cold, was frozen in an ordinary ice-cream freezer. The ice-cake was then broken, placed in a strong canvas bag, and firmly pressed in a tincture press. The ice-cake remaining in the press was of a pale straw colour. The liquid expressed was again frozen and pressed, and the process continued until a thick syrupy liquid was obtained. This was placed in shallow pans in a warm drying closet, and in about an hour was of the proper consistence. The finished extract was superior in appearance to any which I have yet seen, but the yield was less than in previous experiments, the ice-cake retaining some of the liquor. In subsequent experiments, the ice-cake was divided into several portions; these were put into separate bags, and iron plates placed between them. All were then pressed until the liquor ran white. The ice-cake remaining should be colourless. The liquor was again frozen and again pressed in the same way until the product could no longer be frozen; it was then finished in the drying closet as before. The yield was now satisfactory.

We have then two methods of concentration, each possessing its own special advantages. The first, in which a large evaporating surface is obtained by means of a belt of cloth, recommends itself by the simplicity of the apparatus and its economy in time and labour, while the finished product is of good appearance. The readiness with which this method may be employed in every store, will probably render it the most useful, The second, or freezing process, has the advantage of giving an exceptionally superior product free from all colour except that obtained from the grain.

To sum up, in order to prepare a good malt extract, the best malt must be used, a uniform and proper temperature must be maintained during the washing process, care must be used in drawing off the liquor, to prevent the solid matter of the grain from passing out, the exhaustion of the grain must be accomplished with as little water as possible, and the concentration must be effected rapidly at a low heat. By careful attention to these details, an extract will be obtained, which will be handsome in appearance, and contain all the valuable properties of the grain.

QUASSIIN.*

BY A. CHRISTENSEN.

The literature upon the chemical constituents of quassia wood is very inconsiderable. In 1806 Thomson† mentioned that by digesting quassia wood with water and evaporating he obtained a very bitter substance, which when warm was soft, and became brittle upon cooling, and which, in his opinion consisted principally of the pure bitter constituent; it gave a slight precipitate with tincture of galls. In 1811 it was stated by Pfaff‡ that the bitterness was completely extracted by cold water. In 1826 Buchner introduced 1 grain of the alcoholic extract into a wound in a rabbit, which was followed by the death of the animal. Another investigation of the extract by Keller§ contains nothing of importance.

Quassiin was first prepared by Winckler|| in 1835 as follows. Three ounces of quassia wood were extracted with 2 pounds of 80 per cent. alcohol. After evaporation in a water-bath the residue was dissolved in water, and the solution filtered and evaporated to the consistence of an extract. The extract was exhausted with absolute alcohol, evaporated almost to dryness, and then again exhausted with boiling water. The light-yellow solution, decolorized by animal charcoal, left after slowly evaporating crystals of quassiin. Winckler described this substance as crystalline, difficultly soluble in water and freely in alcohol, faintly alkaline, giving a precipitate with tannic acid, and as being obtained crystalline most easily from water.

Subsequently Wiggers¶ prepared quassiin by repeatedly boiling 8 pounds of quassia wood with water, evaporating the filtered decoction to 6 pounds, cooling, adding lime and allowing the mixture to stand a day with frequent shaking, filtering, evaporating nearly to dryness and then boiling with 90 per cent. alcohol. From the solution, which according to Wiggers contained, besides quassiin and colouring matter, some sodium chloride and potassium nitrate, the alcohol was distilled off and it was then evaporated to dryness. The residue was dissolved in the least possible quantity of alcohol and mixed with a considerable quantity of ether, which separated much colouring matter. The filtrate was now again evaporated, and dissolved in absolute alcohol and ether and this repeated until the residue was colourless and free from saline matter. Lastly the ethereal solution was poured into a small quantity of water and left to evaporate spontaneously.

Wiggers found for quassiin the formula $C_{20}H_{25}O_6$. According to him it loses 1·3 per cent. of water at 100° C., and 0·37 per cent. more upon fusing. The melting point, he says, lies a little above that of the resin. He found it dissolve in 220 parts of water at 12° C., and it did not neutralize acids. It crystallized by spontaneous evaporation from a solution in alcohol and ether which was mixed with water, and also when a warm saturated alcoholic solution was mixed with boiling water and allowed to cool. The quassiin of Wiggers was precipitated by tannic acid, but not by metallic salts.

In commencing the present investigation, Herr Christensen first directed his attention to find a new method of preparation, since the methods of Winckler and Wiggers yielded it in a very impure condition and the operations for its purification would involve considerable loss. The author tried two methods that are available in the extraction of several bitter substances: (1) treatment of a solution of the watery extract with bone black and exhaustion of this with alcohol; and (2) precipitation of the watery extract with tannic acid, decomposition of the washed precipitate, extraction with alcohol, etc. In both cases, by evaporating slowly, he obtained tabular crystals, having an intensely bitter taste, leaving on combustion no ash, difficultly soluble in water and fairly soluble in alcohol. The solutions gave with tannic acid a dense white precipitate.

Notwithstanding that the quassiin is tolerably completely removed by bone black, as is shown by the fact that the filtrate tastes only slightly bitter, the tannic acid method has the advantage that it yields the purer product. The following method was adopted by the author for the preparation of quassiin:—

Five kilos of quassia were boiled several hours with two successive quantities of water. The united filtrates were evaporated, at first over an open fire, subsequently on a water-bath, to 1½ litres. After cooling this was filtered and the filtrate precipitated with tannic acid, taking care to keep the reaction neutral or faintly acid by the addition of carbonate of soda, since the compound of quassiin with tannic acid, like many similar compounds of bitter substances with that acid, is very soluble in it. The precipitate, after the addition of well-washed pipe-clay is easily collected and removed by filtration. The precipitate after being repeatedly washed was mixed whilst moist with a considerable quantity of freshly precipitated lead carbonate, and evaporated to dryness in small portions, with frequent stirring, upon a water-bath. The mixture was extracted four times with alcohol, the alcohol distilled off and the residual liquid evaporated until the separation of crystals of quassiin, which were washed and dried between filter-paper. The filtrate yielded more crystals upon further evaporation, and some more quassiin was separated by shaking it with chloroform. Lastly, the quassiin was recrystallized from ether-alcohol and water.

In the place of lead carbonate, calcium hydrate also was used for the decomposition of the tannic acid compound, and an alcoholic solution obtained that was not so much coloured, but the yield was smaller.

§ Buchner's 'Repertorium,' ii.

|| Buchner's 'Repertorium,' liv. (1837), 85, and lxv. (1839), 74.

¶ *Annalen der Pharmacie*, xxi. (1837), 40.

Upon evaporating the watery extract of quassia wood, a considerable precipitate separated as a smeary mass. This was treated with freshly precipitated lead carbonate, evaporated almost to dryness and extracted with 84 per cent. alcohol. After the alcohol had been distilled off, and the liquid sufficiently evaporated, some quassiin separated, but in an impure condition.

Quassiin is very freely soluble in chloroform, and by shaking an aqueous solution of it with chloroform it can be nearly entirely removed. The author therefore tried to obtain the quassiin from the aqueous extract of quassia wood by simply shaking this with chloroform; but the practical difficulty was met with that the chloroform does not completely separate it, and a pasty, slimy mass was formed, the consistence of which was not altered even upon warming. After the chloroform had been distilled off a very impure residue was left, from which the quassiin was only obtained by repeated recrystallizations from ether-alcohol mixed with a little water. Neither can direct exhaustion of the quassia wood by chloroform be adopted in the preparation of the quassiin, since much resin is taken up with it, and this can only be separated by the ether-alcohol method, which involves considerable loss. The last two experiments show, however, that quassiin exists as such in the wood, and is not a product formed during the treatment.

The quassiin, obtained as above described with tannic acid, was purified by recrystallization from the smallest possible quantity of warm alcohol, in which it is so much more soluble than in cold that the solution solidifies into a paste upon cooling. After the crystals had been washed with dilute alcohol and dried between filter-paper and then over sulphuric acid they were white and gave a colourless solution. They were recrystallized once more by the addition of boiling water to a hot concentrated alcoholic solution; the crystals that separated on cooling showed the same melting point as those of the first crystallization and were used in the further experiments.

With respect to the proportion in which quassiin occurs in the wood, the author obtained from 18 kilos of Jamaica wood (*Picræna excelsa*) 12 grams of impure substance, equal to 0·6 per 1000. But in treating a subsequent consignment, both of Jamaica and Surinam wood, he found to his surprise that in repeated experiments upon considerable quantities of both kinds he could obtain scarcely any quassiin. A sample of *Quassia amara* wood, that yielded 2·8 per cent. of extract, and one of *Picræna excelsa* wood, that yielded 2·6 per cent., yielded no quassiin. The sample of *Picræna excelsa* wood that gave 0·6 per 1000 of quassiin yielded 3·2 per cent. of extract. The author is unable to explain the cause of this difference; but if the value of quassia wood is dependent upon the proportion of quassiin it contains, the results do not afford much justification for the exclusion of the Jamaica wood from some pharmacopœias.

Pure quassiin forms very thin rectangular double refracting crystalline scales. It has an intensely bitter taste, is without smell, permanent in air, and gives neutral solutions with alcohol, water, etc. It melts at 205° with slight puffing—possibly due to the giving off of water—to a yellow resin-like mass, which upon solution and recrystallization is recognized as unaltered quassiin.

Water, left in contact with finely powdered quassiin several days, with frequent shaking, at 15° C., dissolved 1 part in 1230. A warm saturated solution left forty-eight hours at 15° C., with frequent shaking, contained 1 part in 735. Boiling water dissolves quassiin with difficulty, but much more freely than cold. In alkalies it dissolves with a yellow colour very readily upon boiling and separates unaltered on the addition of acids, becoming again colourless. It is dissolved by alkalies in the cold somewhat more easily than by water, turbidity resulting upon neutralizing the liquid with acids. Boiling alcohol dissolves it very freely, but cold alcohol much less so, 1 part of quassiin requiring 30 parts of 84 per cent. alcohol at 15° C. In ether and petroleum spirit it dissolves with difficulty, but very freely in chloroform, of which 2·1 parts dissolve 1 part of quassiin. A solution in chloroform is dextrogyre, the specific rotation being $\alpha_D + 37{\cdot}8$.

Quassiin contains no nitrogen. After being dried to a constant weight over sulphuric acid, it did not alter in weight when exposed for an hour to a current of dry air at 100° C., and gave upon analysis results corresponding with the formula $C_{31}H_{42}O_9$.

	Calculated.	Found.
C	66·66	66·90
H	7·52	7·44
O	25·82	25·65

An aqueous solution of quassia is not rendered turbid by metallic salts. A saturated alcoholic solution gives no precipitate with a similar solution of neutral lead acetate, and upon evaporation the quassiin separates unaltered. Other saturated alcoholic solutions of metallic salts behaved similarly. Tannic acid produces in aqueous and alcoholic solutions of quassiin a white precipitate which is soluble in acids and in caustic and carbonated alkalies.

Dilute hydrochloric and sulphuric acids dissolve quassiin in the cold somewhat more freely than water, but 5 to 10 per cent. solutions, even after being heated in sealed tubes to 125° for an hour, did not reduce alkaline cupric tartrate, showing that quassiin is not a glucoside.

By treatment of quassiin with a 3 per cent. solution of sulphuric acid a new compound was obtained, crystallizing in fine needles, and having only a slightly bitter taste. It melted at 237° C., did not lose all its water of crystallization (four molecules) till 110° C., and when anhydrous gave upon analysis results corresponding with the formula $C_{31}H_{38}O_9$. It was very sparingly soluble in water, required 180 parts of alcohol at 15°, dissolved very freely in caustic potash and caustic soda, and gave no precipitate with tannic acid. There was also a formation of resinous matter that could not be crystallized and possessed an intensely bitter taste.

A strong solution of quassiin in chloroform decolorizes bromine, with formation of hydrobromic acid. The author obtained a bromine compound as a white amorphous mass, with a taste even more bitter than that of quassiin; this compound dissolved in alkalies with an intense yellow colour, distinctly produced by the smallest traces, and at the same time lost its bitter taste almost completely.

An experiment made to test statements as to the occurrence of an essential oil in quassia wood gave negative results, a small quantity of solid white substance that collected on the surface of the aqueous distillate proving to consist of free fatty acid.

"MANICURE."*

A number of persons at New York and at frequented summer resorts have for some time past been doing a profitable business in the treatment of the hands and finger-nails of those who consider themselves to be in need of such service. In a recent number of the *Art Interchange*, published in that city, the editor gives the following reply (in substance) to a correspondent who wishes information concerning the methods and materials employed. It is not unlikely that some of our readers may find it profitable to prepare the materials requisite, and give the necessary directions for their use.

For cosmetic gloves, take chamois or castor—the best quality is not necessary—three sizes larger than the person ordinarily wears; rip them open and spread them with the pastes below described. If you call at the lady's house and examine her hands, and learn what they need

* From *New Remedies*, June, 1882.

and the number of her gloves, you can prepare accordingly, and order gloves to be worn at night. The following is a useful prescription for whitening the hands, to be preceded by baths and washes, to be described further on.

Cosmetic Paste, No. 1.—Myrrh, 1 ounce; honey, 4 ounces; yellow wax, 2 ounces; rose water, 6 ounces; glycerin added according to thickness of paste, just enough to make it spread easily. Melt the wax in a dish over boiling water, add the myrrh while hot; beat up together, then add honey and rose water; beat again, and lastly add glycerin from a teaspoonful up; spread over the inside of the gloves; then sew them up; they are ready for use.

Cosmetic Paste, No. 2.—Two teaspoons of oil of sweet almonds; one ounce of rose water, thirty-six drops tincture benzoin; one teaspoonful glycerin; yolks of two fresh eggs; one teaspoonful of rice flour. Beat to a paste, and line gloves, or rub on hands, and wear close-fitting gloves over it at night.

Cosmetic Paste, No. 3.—One teaspoonful of the best pine tar; 1 pint pure olive oil. Melt in tin cup over boiling water. This can be kept on hand, and, if preferred, may be perfumed with rose water. To be spread on hands and worn with gloves. One application will not be sufficient; the beautifying of the skin is a work of more or less time, according to its condition.

Ground barley, the white of an egg, 1 ounce of honey, and a teaspoonful of glycerin spread thickly inside gloves, and worn at night, is a useful recipe for the hands.

Another recipe for whitening the hands, and an inexpensive one to prepare, is composed of home-made soft soap, half a pound; salad oil, 1 gill; mutton tallow, 1 ounce; boil together, then add, when away from fire, spirits of wine, 1 gill; ambergris or some other perfume, according to fancy; benzoin would answer. Spread on gloves and wear at night.

For ordinary use to keep the hands white where they are used in house work, bran mittens are excellent. Make good-sized mits of cloth, fill with wet bran or oatmeal first, washing the hands with vinegar and glycerin, or lemon-juice and glycerin rubbed in afterward; then put the bran mittens on; tie closely at wrist and wear them every night, or at regular intervals as needed.

Alum added to white of egg and rose water is good for making the flesh firm; a trifle of glycerin added is an improvement.

Colour for Finger-tips.—A pinkish tint is thought to be desirable for the tips of the fingers; it can be attained by the use of the following: ½ ounce of alkanet root chippings soaked for a week in alcohol diluted with water will give a lovely stain for the finger-tips; apply by dipping a bit of raw cotton in the mixture, and touching the finger-tips with it.

Polish and Colour for the Nails.—Rub the nails, which must first be carefully trimmed with sharp scissors, with equal parts of cinnabar and fine emery powder, and afterwards with scented oil of almonds.

To Remove Spots.—Pitch and myrrh melted together and laid over the nails over night will soon cause white specks to disappear. Butter or cream will remove the pitch in the morning.

For Removing Discolorations.—Two ounces of fine almond soap (white soap is always best) dissolved in 2 ounces of lemon-juice, to which must be added 1 ounce of oil of almonds and a trifle of carbonate of potash and one teaspoonful of glycerin, stirred up until like soap, is excellent to wash the hands with occasionally, but it must not be used where the skin is chapped or abraded.

A fine toilet salve, and useful for chapped surfaces, is made with 2 ounces of oil of almonds, 1 drachm each of wax, spermaceti, and glycerin, melted together and perfumed by 2 ounces of rose-water and ½ ounce of orange-flower water.

Fine pumice stone smoothed and rounded is exceedingly useful for smoothing the palms of the hands, and the fingers. As a first step in beautifying the nails, lather well with warm soap suds from a pure white soap; dry, and while the nails are softened, trim carefully, push down the skin all around to show the shape of the nails and the little half moon at the base of the nails; remove hangnails, and then polish and cover with powder described for the purpose. It would be well to treat the hands at the first, and then remove specks from nails and finally polish. The polishing may afterwards be done by the lady at home, if desired. Use different prescriptions, according to state of hands. Bran in warm water and vinegar is useful for a wash; make into lather with fine white soap, and rub the hands well with the bran. Indian meal and oatmeal are also goods for a preparatory bath before trimming and polishing nails and using cosmetic preparations. The various cosmetics can be sold at prices according to their first cost. The washing cosmetic with potash need only be used once or twice, and is useful after the bran bath or before; the cosmetic gloves may follow for night use. Always use pure white soaps; almond soap, glycerin and lettuce-oil soap, are to be recommended; also the oatmeal and pumice soaps where the skin will bear the latter.

THE FORENSIC-CHEMICAL DETERMINATION OF GELSEMINE IN ANIMAL LIQUIDS AND TISSUES.*

BY EDWARD SCHWARZ, M.D.

The author briefly reviews the investigations of H. Kollock (*Amer. Jour. Phar.*, 1855, p. 263), C. L. Eberle (*Ibid.*, 1869, p. 35), Professor Wormley (*Ibid.*, 1870, p. 1), and Dr. C. A. Robbins (*Ibid.*, 1876, p. 191). Professor Wormley's more recent investigation (*Ibid.*, 1877, p. 150), appears to have escaped his attention. The method recommended by Dragendorff (*Jahresbericht für Pharmacie*, 1878, p. 640), was used for the preparation of the two important principles; gelsemic acid was obtained from the acidulated solution by agitation with chloroform, and gelsemine by agitating the liquid rendered alkaline by ammonia with benzol.

The chloroform solution, on evaporation, left a crystalline residue, which dissolved partly in water, with a yellow colour, and showed a strong blue fluorescence. The small insoluble portion was dissolved in alcohol. Both solutions, placed over sulphuric acid, yielded crystals; those from the watery liquid were light yellow-brown fine needles, being comb-like, attached to a larger prismatic crystal. These crystals showed all the reactions of æsculin except that they acquired a greenish colour with ferric chloride, due probably to the presence of æsculetin. The crystals from the alcoholic solution emanated from a central point, and were branching in a tree-like manner; in the deeper part of the vessel several thornapple-like aggregations of crystals were observed. The amount obtained from 50 grams of the root was so small that accurate investigations could not be made; moreover, the presence of æsculin seemed to interfere with the reactions of this substance.

The benzol solution yielded, on evaporation, a dark brown, resinous mass, which was dissolved in dilute sulphuric acid and precipitated with concentrated soda solution; the precipitate collected, washed and dried formed a white powder, which caked together in boiling water to a brown mass, and showed the behaviour of gelsemine. The filtrate agitated with chloroform, yielded a pale, rose-coloured substance, having the same behaviour. The total yield weighed between 0·2 and 0·3 gram.

Another experiment made with the powdered root proved that the acidulated liquid yields to amylic alcohol

* Abstract from an Inaugural Essay presented to the University of Dorpat, and communicated by the author. From *The American Journal of Pharmacy*, August, 1882.

considerable æsculetin, recognizable by the dark green colour with ferric salts, and by the blue-green fluorescence in aqueous solution, which is destroyed by potassa. The residue also gave distinct alkaloidal reactions with bismuth-potassium iodide, picric acid, and iodine.

The following tests were made with æsculin and æsculetin, not with the similar principle obtained from gelsemium.

To the well-known reaction of æsculin and æsculetin must be added their behaviour to *Langley-Koehler's test*, which is very similar to that of picrotoxin,* except that the colour with æsculin is deeper brown, and with æsculetin, red-brown. Æsculin and brucine have also a similar reaction, namely, to *chlorine water* (red colour). *Gold chloride* is reduced by æsculin, the colour depending on the concentration and temperature of the liquid; it yields, with aqueous solutions of æsculetin, a raspberry-red colour. *Potassium ferridcyanide* does not affect æsculin, but, on boiling, colours æsculetin solutions red-brown. The same reagent, *with ferric chloride*, gives with both an intense green-blue colour, and gradually causes a blue precipitate. Solution of *copper sulphate* remains blue with æsculin, but turns green with æsculetin.

A solution of 0·5 gm. æsculin in 50 c.c. of water was given to a cat without producing abnormal symptoms; the acid urine let after two hours had a strong fluorescence. Another cat took 0·1 gm. æsculin. The aqueous solution of the fæces of the first and second day was strongly fluorescent; from the third day, æsculin could not be detected. The urine was likewise fluorescent on three days, but not on the fourth day until after it was rendered alkaline; chloroform extracted from it æsculin.

Subcutaneous injections of æsculin, ·0066 and ·0003 gm., were made to two frogs, and these were afterwards placed in distilled water, which for nine days became fluorescent.

The author concludes, from these experiments, that

1. Æsculin is without decided action upon the animal organism.
2. It rapidly enters the second ways from the stomach and intestines.
3. It is not decomposed within the body, and
4. Is rapidly excreted through the kidneys.
5. A prolonged time is required for its complete excretion.
6. Powdered æsculin is partly eliminated with the fæces, probably owing to its sparing solubility.

The "animal quinine" obtained by Bence Jones from the kidneys of higher animals, which, however, has not been observed by Dragendorff, is not fluorescent in alkaline solutions.

The experiments with the alkaloid were made with such prepared by the author, and with pure gelsemine made by Merck. If merely moistened with sulphuric acid and then brought in contact with a minute drop of solution of potassium bichromate, the colour produced and the changes closely resemble those observed with strychnine; but if, as suggested by Robbins, the alkaloids are dissolved in strong sulphuric acid, and the bichromate added to the solution, gelsemine yields a cherry-red colour, changing to dingy grey-brown, and green spots or streaks are not unfrequently observed, due to absorption of moisture. Strychnine becomes violet-blue, then cherry-red, finally brick-red, the latter colour lasting more than a day. Quebrachine becomes slowly violet-blue, and, after a long time, acquires a red tint; but, if dissolved in trihydrated sulphuric acid, no reaction is observed with potassium bichromate, as is also the case with curarine; but under the same condition the cherry-red colour of gelsemine changes to an intense green or bluish-green.

On substituting manganese binoxide for the bichromate, almost identical results are obtained; but using concentrated sulphuric acid, the colorations of gelsemine, and particularly of quebrachine, are much darker and handsomer. With the bihydrated acid, quebrachine gives only a slight violet colour; in the presence of trihydrate the dark green colour of gelsemine appears slowly, and, with a greater dilution of the acid, the blue-violet colour of strychnine in the beginning is more and more replaced by cherry-red.

The same reactions, made by ceric oxide, yield lighter and less intense colorations, the green from gelsemine having a bluish tint.

The weakest colorations are produced by lead peroxide only in presence of a trace of nitric acid; the tint from gelsemine is grass-green.

The reaction best adapted for gelsemine is sulphuric trihydrate and one of the four reagents, when the final colour by gelsemine is green, and by strychnine, brick-red.

Concentrated sulphuric acid dissolves gelsemine with a yellow-brown colour; quebrachine, similar; strychnine, colourless.

Sulphuric acid containing iron shows no reaction with gelsemine and strychnine; a blue-violet colour with quebrachnine.

Froehde's reagent: With gelsemine, roe-brown to red-brown, gradually yellowish-green (a very similar reaction was observed by Graebner with ptomaines); strychnine, no change; geissospermine and quebrachine, blue.

Selen-sulphuric acid, with gelsemine, no reaction.

Sugar and sulphuric acid: Gelsemine, cherry-red; but fats, biliary acids, aconitine, codeine, and delphinidine give the same colour; strychnine, no red colour; quebrachine, intense cherry-red.

Brouardel-Boutmy's reagent (potassium ferridcyanide and ferric chloride): Gelsemine and quebrachine, intensely green; strychnine and aspidospermine, no reaction. Ptomaines obtained from the stomach and intestines, no reaction; but if isolated from the liver, kidneys, etc., by agitation of the alkaline liquid with benzol or chloroform, a slight green colour is produced, and the older the corpse the more frequently are such ptomaines obtained.

Chlorine water to acid solution: Gelsemine yields yellowish turbidity and slight fluorescence; after a while a yellowish-white precipitate, which is produced yet in solutions of 1 in 1000 and is dark coloured from impure alkaloid; the supernatant liquid is not fluorescent. Strychnine has a very similar behaviour; likewise, though less delicate, quebrachine.

Boiling with perchloric acid: Gelsemine, slightly yellow; strychnine, red.

Sulphuric bihydrate, with fragment of potassium chlorate and boiling: Gelsemine and aspidospermine, clear; strychnine, red-brown to black-brown solution.

Selmi's reagent (iodic acid suspended in sulphuric acid): Gelsemine and strychnine, rose-coloured; brucine and aspidospermine, brick-red; quebrachine, dark violet. On warming, the colour becomes darker, and finally disappears.

Potassium-bismuth iodide gives a red-brown precipitate with ·000025 gram gelsemine; phosphomolybdic acid, a precipitate with the same amount. Precipitates with ·00005 gram gelsemine are caused by iodine, potassio-mercuric iodide, bromine (yellow), phosphotungstic acid (white), and tannin; with ·0001 gram gelsemine, by potassio-cadmic iodide (white) and picric acid (yellow), and a turbidity merely by the chlorides of gold and mercury.

The author then refers to the physiological experiments made with gelsemium by Professor Ott (1875) and Dr. Moritz (1878), with whose results his own observations agree. He details his experiments for th detection of

* Mix powdered picrotoxin with 3 or 5 parts of pure saltpetre; add 1 or 2 drops of strong sulphuric acid; mix, and add rapidly soda solution to strong alkaline reaction, when the mixture becomes transiently brick-red.—EDITOR *A. J. P.*

æsculin (gelsemic acid) and gelsemine, made with food, blood, and urine, both fresh and putrid, and with poisoned cats, and closes with the following deductions:

After poisoning with gelsemium in lethal doses, æsculin and gelsemine may be isolated by Dragendorff's method (removal of fat by petroleum benzin, extraction of æsculin from the acid solution by chloroform, and extraction of gelsemine from the alkaline liquid by benzol), and both may be recognized as such.

Æsculin may be found in all organs, and gelsemine in the stomach, intestines, blood, and liver.

After the subcutaneous application of rapidly fatal doses of gelsemine, the alkaloid can be detected in the corpse only in mere traces, and not with certainty; it is best to search for it in the liver.

Putrefaction, accompanied by alkaline reaction, does not alter gelsemine, but decomposes æsculin; both principles are not altered if the reaction remains acid.

The poisonous action of gelsemium does not depend on æsculin.

Gelsemine and æsculin rapidly pass from the stomach and intestines into the blood, and are excreted through the urine. The resorption is also rapid on subcutaneous application.

For the complete excretion of æsculin through the urine a longer time is required, so that after a single dose it may be recognized in the urine for several days.

If, in forensic analysis, gelsemine is supposed to have been found, the presence of æsculin should be determined for deciding the question whether gelsemine alone or gelsemium root had been administered.

Under certain conditions gelsemine shows the same reaction with sulphuric acid and potassium bichromate as strychnine. For distinguishing it from the latter, the following properties are useful:—

I. The reactions. 1. To concentrated sulphuric acid; 2. To sulphuric trihydrate and potassium bichromate (or ceric oxide or peroxide of manganese, or of lead); 3. To Brouardel-Boutmy's reagent; 4. To sugar and concentrated sulphuric acid.

II. The action upon the animal body; and

III. Its association in the root with æsculin.

It is distinguished from quebrachine, 1. By not being extracted by chloroform from acid solutions by the reactions; 2. With sulphuric acid and potassium trihydrate; 3. With Froehde's reagent; 4. With sulphuric acid containing iron; 5. By the absence of æsculin from quebracho bark.

The mode of isolation, the reaction with Froehde's reagent, and the association with æsculin in the drug serve to distinguish gelsemine from geissospermine.

For distinguishing it from aniline and curarine consult Dragendorff, 'Ermittelung der Gifte.' Relations analogous to those existing between strychnine on the one side and curarine and aniline on the other are likewise observed between gelsemine and the last two alkaloids.

PREPARATION OF ESSENCE OF RENNET FROM FRESH STOMACHS.*

BY DR. J. NESSLER.

In this paper the author communicates the results of some experiments made with the object of comparing the activity of essence of rennet made according to Soxhlet's method from dried stomachs† and that of essence made from fresh stomachs.

The experiment showed that, using corresponding quantities of dried and fresh stomach, the latter yielded the more active preparation. It was found, moreover, that the activity of the preparation from a fresh stomach could be increased by the removal of mucus, which not only made it more bulky, but prevented it from diffusing the milk so readily, and that this removal could be effected without injury by means of blotting paper. Preparations made from the top layer of the inside of the stomach, scraped off with a knife, proved much more active than others for which the residuum was used, but the residuum contained too much ferment to permit it to be left unused.

The author gives the following instructions for the preparation of an essence of rennet from fresh stomachs. Chop up a fresh calf's stomach as finely as possible, pour upon it two litres of water in which 100 grams of common salt has been dissolved, and shake well. After twelve hours add 200 c.c. of 90° alcohol, and allow the whole to stand, with frequent stirring, in a closed flask for three weeks, then decant, and add sufficient blotting paper to cover it. After several weeks, during which the vessel must be kept well closed, the essence of rennet is drawn off into bottles and preserved. A liquor prepared in this way was, when fresh, capable of curdling 6000 times its volume of milk, and, being kept in a well-corked bottle, it was found, after two years, to have diminished in activity only from 1 in 6000 to 1 in 5451.

The author adds that distilled or rain water gives a more active essence than spring water, and that it is advantageous to mince the stomach as finely as possible.

SOLAR APPARATUS.

It will be remembered that M. Mouchot, a short time ago,* devised an apparatus for utilization of solar heat, and that M. Pifre made some important improvements on it. Very different views have been taken as to the practical utility of such an apparatus. Some help towards a right judgment now comes from Montpellier, where a French Government Commission has been experimenting with the apparatus for a year (1881). Another commission has experimented at Constantine, in Algeria, but the results are not yet published. The apparatus was of the known form—a concave mirror, with blackened boiler in the axis, surrounded by a glass envelope. The steam from the boiling water was condensed in a coiled tube cooled by water. The weight of water distilled in an hour indicated the amount of heat utilized; and observations with an actinometer from hour to hour showed the amount of incident heat. The rates of these two quantities was a measure of the economic efficiency of the apparatus. The temperature and moisture of the air, etc., were also carefully noted. The number of days of observation was one hundred and seventy-seven, and of observations nine hundred and thirty, and water was distilled to the amount of 2725 litres. Without entering much into numerical detail, we may state that while the heat utilized in the most favourable circumstances per square metre per hour would be about equal to that utilized from 240 grams of coal (supposing about a half to be utilized)—even the half of this is not attainable in our climate. The sun does not shine continuously enough for practical utilization of the apparatus. In very dry and hot climates the possibility of utilization would depend on various circumstances, such as the degree of difficulty of procuring fuel, the price and facility of transport of solar apparatus, etc. We note in the report (by M. Crova) that the efficiency of the apparatus is not proportional to the heat intensity of the solar radiations, and hardly ever varies in the same sense. The absolute quantity of heat utilized, on the other hand, depends essentially on the temperature of the air; the higher this is, and the less consequently the cooling, the greater the amount of heat utilized.—*Times.*

REPORT OF THE SCIENCE AND ART DEPARTMENT ON SCIENCE TEACHING.

THE twenty-ninth Report of the Science and Art Department shows that during the year 1881 the expenditure under that head amounted to £340,025 14*s.* 10*d.*, and that although the number of schools examined was rather less than in the year 1880 the number of persons under instruction at them was larger than in the previous year. The term "science school" is employed in a somewhat wide sense in the Report, as indicating each separate institution in which science is taught in connection with the Science and Art Department. The school may consist of but one class in a particular branch of science, meeting in the evening in an elementary school or some other building used for a different purpose during the day, or it may occupy a building or part of one belonging to the school with day and evening classes, and a more or less complete curriculum of studies in several branches of sciences. No very precise classification of the different kinds of schools established under the system of aid granted by the Department can be made, but the following statement furnishes a fair general idea. There are about 300 science schools which are held in buildings which are either entirely the property of the schools or in part definitely appropriated to them and these schools have every element of permanency. About 320 science schools are parts of or adjuncts to educational institutions of a character more extended and general in its scope. They may also be looked upon as of a permanent character and depending more on local organizations than on the teacher. In addition, there are some 580 schools or classes which depend more on the teachers through whose energy these schools have come into operation than upon any permanent local organization. They are usually superintended by committees, but are generally held in rooms hired for the purpose, and though they may have been in operation for many years, and would probably be continued, there is a possibility that by the death or removal of the teachers from any of them they might be in many cases closed. Lastly, there are about 260 classes of a more ephemeral character, a certain number of which come to an end every year, while others are commenced. It is found that they often lead to the establishment of permanent institutions for science teaching, but even where this has not been the case these schools have been productive of good while they lasted.

The number of separate classes examined in 1881 was 4839, and the number of students who came up for examination from them was 38,837. In addition there were 5804 self-taught students and pupils in classes not entitled to claim payment on results. The number of papers which passed was rather larger than in the previous year, and the number of candidates in the honours division of the examination was 1342, of which 91 passed in the first class, and 395 in the second class.

It is considered that the general reports of the examiners give a favourable impression of the progress of the schools, but on referring to the published extracts from the examiners' reports it is not difficult to perceive that bad teaching is still too prevalent and that there is much reason for suspecting the existence of a cramming system, designed only to secure the benefit arising from success in the examinations. This is especially pointed to in the reports of Professors HUXLEY and GUTHRIE, Dr. MICHAEL FOSTER, Dr. RUSSELL and Mr. THISELTON DYER, and the circumstance appears to have been regarded as so obviously suggestive of a want of proper qualification on the part of the certificated science teachers that Colonel DONNELLY devotes considerable space to a kind of apology for the defects of the teachers. He seeks to answer the constantly repeated criticism of the action of the Department that it does not demand a higher qualification from the teacher before he is allowed to teach by pointing out that the Department does not give any certificate of qualification to teach, but merely states that a certain person, having passed a certain examination, is qualified according to the rules to earn payments on the results of his instruction as measured by examinations. This is scarcely a satisfactory answer, especially when it is remembered that Colonel DONNELLY does not dispute the existence of much bad teaching. It is discouraging to find this virtual admission that a vicious system is being propagated throughout the country, instead of that thorough study of subjects which can alone justify support by the State and the large expenditure that is incurred.

There can indeed be little doubt in the mind of anyone conversant with the past action of the Department, that certificates of qualification to teach various subjects are granted too readily and upon insufficient grounds and that much harm is being done in this way. Colonel DONNELLY, indeed, mentions a circumstance which appears to illustrate this point and to show that, in spite of the admirable body of distinguished men of science acting as examiners, there is a tendency, even among highly trained and good teachers, to make the passing of the examinations the chief object of their work rather than the sound instruction of their pupils. No doubt the power to teach is to a great extent a special faculty, distinct from the power to learn and to pass an examination, but that is not a sufficient reason for granting certificates of qualification to teach without applying some test by which the possession of the teaching faculty can be ascertained, and it is a fact that points in the opposite direction. We are inclined to believe that, under existing conditions, it does pay to prepare students for defeating examiners, and that the efforts made in this direction are only too successful. It may be a satisfaction to know that those who fail to do so do not obtain any State money, but it is not the less certain that infinite mischief is done by those who succeed.

The number of centres at which examinations were held last year was in the provinces 987 and in the metropolis 111. The total amount paid to teachers on results was £43,519 2*s.* 9*d.*, or at the rate of 14*s.* 2*d.* for each student under instruction. These payments were made to 1762 teachers, and the average payment per teacher was £24 13*s.* 11*d.* But there was a very great inequality in the amounts of payment to schools, as will be evident from one or two instances taken at random from the returns. Thus, an orphan school at Stockport presented one hundred students for examination in seven subjects, with the result that payment was made amounting to £301, or rather over £3 per head of the children. Another school at Warrington, presenting the same number for examination, only obtained £27. Another school in Bristol presenting one hundred and eighteen for examination in fourteen subjects gained £413. Hence it is evident that this system may be worked in such a way as to form a very considerable addition to the income of a school, and it becomes very important to guard against the possibility of this being effected by such means as we know examiners are very generally coming to acknowledge that they cannot adequately deal with.

During the past year the grants towards purchases of apparatus, diagrams and examples amounted to £497 13*s.* 2*d.*, being a decrease of more than £210 on the previous year. At the Normal School of Science and Royal School of Mines there were last year 46 regular and 139 occasional students. At the Royal College of Science for Ireland there were 16 regular and 20 occasional students. The lectures at South Kensington Museum were attended by 3788 persons. The evening lectures to working men at the Royal School of Mines were attended by 1472 persons, or 328 less than last year, and 211 science teachers attended the special courses of lectures provided for their instruction in the new science schools at South Kensington. The lectures in connection with the Department in Dublin were attended by about 850 persons. Therefore, the total number of persons who received instruction as students, or by means of lectures, in connection with the Science and Art Department in 1881 was 984,820, showing an increase as compared with the previous year of nearly 9 per cent.

THE CONFERENCE MEETING.

On Tuesday next, as most of our readers are aware, the Nineteenth Annual Meeting of the British Pharmaceutical Conference will commence in Southampton, and it may be convenient for some intending visitors to have a brief recapitulation of the programme of the proceedings, so far as it has been made known. The sittings are to be held in the Watts Memorial Hall, on Tuesday the 22nd and Wednesday the 23rd inst., commencing at 10.30 a.m. each day. At 1 p.m. on each day there will be an adjournment until 2.30 p.m., for the purpose of luncheon, and the business proceedings will terminate about 5 p.m. on Wednesday. On Thursday the visitors are invited by the members of the Local Committee to accompany them upon an excursion to the Isle of Wight, visiting Ryde, Ventnor, Brading and the Landslip.

Last week we were enabled, by the courtesy of the Honorary Secretaries, to print a list of papers that have been received or promised for reading, subject to the approval of the Executive Committee. To these are now added—

22. Note on a Reaction of Glycerine and other Polyhydric Alcohols. By W. R. Dunstan, F.C.S.

23. On Tumefaction as an Aid to the Identification of the Varieties of Maranta Starch. By W. H. Symons, F.R.M.S., F.C.S.

Although rather late, it may be useful to repeat that information respecting hotel accommodation and similar matters will be willingly given to intending visitors by the Honorary Local Secretary, Mr. O. R. Dawson, Belle Vue Road, Southampton.

The meeting, in the same town, of the British Association, under the Presidency of Dr. C. W. Siemens, promises this year to be a very interesting one, and as is usually the case will induce many of the visitors to the Pharmaceutical Conference to prolong their stay for some days more.

A NEW PHARMACOPŒIA FOR GREECE.

We learn from an esteemed correspondent, Professor Xavier Landerer, of Athens, that a Commission has just been entrusted by the Government with the task of elaborating a new Greek Pharmacopœia. The first official Greek Pharmacopœia made its appearance in the year 1837, and was compiled by John Bouros, Xavier Landerer and Josef Sartorios. In 1868, this work was reprinted, with an Appendix, by Professor Landerer, describing the more recent remedies and containing an etymological dictionary of names of botanical, zoological and mineral substances, and a list of antidotes. This work is still in common use throughout Greece, as well as in Asia Minor, and also to some extent in Constantinople; but in Turkey Dorvault's *L'Officine* is the work usually consulted.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Wednesday, August 2, in the College of Physicians, Kildare Street, at three o'clock.

The President, Professor Charles Tichborne, in the chair.

The other members present were:—The Vice-President, Dr. Aquilla Smith, and Messrs. Allen, Bennett, Brunker, Dr. Collins, Messrs. Doran, Draper, Grindley, Hodgson, Sir George Owens, Messrs. Payne, Pring, Simpson, Dr. Whittaker, Messrs. Lester and Wells.

Mr. Hugh Fennell, Registrar, read the minutes of the last meetings, which were confirmed.

The President congratulated the meeting on the presence, for the first time amongst them, of two newly elected members of the Council, Mr. Lester and Mr. Wells.

The first business on the paper was the election of an Examiner in Practical Pharmacy. There were two candidates.

Dr. Collins moved that—

"Mr. Charles Evans, M.P.S.I., be elected."

Mr. Draper seconded the motion.

Mr. Allen moved that—

"Dr. William Whitla, L.A.H.I., M.P.S.I., be elected."

Mr. Pring seconded the motion.

Dr. Whittaker hoped that by this election the Council would show that they were desirous of making the Society a national and not a metropolitan society. They had already three examiners belonging to Dublin. Dr. Whitla, besides being thoroughly conversant with practical pharmacy, had published a book. He had been in his (Dr. Whittaker's) establishment for years. He did not know Mr. Evans personally, but he wished he had some higher qualification than being a member of the Pharmaceutical Society of Ireland. Excuse him, he would say that it was not a very high qualification, although he hoped it would yet become such. [Certain members of the Council protested against Dr. Whittaker's remarks.] The Belfast members had tried to do all they could for the Society. There was no doubt as to Dr. Whitla's qualifications, and his being a medical man was rather in his favour than otherwise.

Dr. Collins said it was to carry out the principle mentioned of making the Society as much a national one as possible, that Sir George Owens and himself had wished to elect Mr. Harrington, of Cork, at the previous meeting.

The President said he had received a letter in reference to the election, in favour of Mr. Evans, from a member of the Council, who was unable to attend, and he thought he should read it.

Mr. Draper did not think such a letter ought to be read.

The Vice-President said if a member could not make it his convenience to attend the election he had no right to have his letter read.

Mr. Draper said he made the objection not knowing who the writer was.

The President: It is Mr. Hayes.

The Vice-President observed, that as both candidates were members of the Pharmaceutical Society, he did not think any disrespect was involved in the observation made by Dr. Whittaker. He was aware that Dr. Whitla had produced a work on pharmacy, which possessed a great deal of merit. He was not personally acquainted with Mr. Evans, but he knew that he represented the oldest compounding establishment in the city, which was at present more than a century old; and if there had been no other candidate he would vote for him, as he was sure he would make a very suitable examiner. He quite concurred in the observation that the examiners should not be exclusively Dublin men.

Mr. Payne, in supporting the candidature of Dr. Whitla, said that gentleman was a thoroughly practical man, and in addition to being a pharmaceutical chemist was an apothecary. He thought all the members of the Council would admit that in past times the apothecaries had conducted pharmacy in a satisfactory manner. One of the strongest points in his favour was that he in no way prepared pupils for examination in the city. He was sure no examiner would wish to examine his own pupils. No member of the Council who prepared pupils should be an examiner.

Sir George Owens said Mr. Evans was fully equal to the post he sought, and he could vouch for him that after he should be elected he would never take or teach a pupil in the city.

Mr. Draper said he never had the faintest idea that Mr. Evans took pupils. If he thought he did he should withdraw his support from him.

Mr. Payne said he thought the Registrar had a certificate from Mr. Evans.

Mr. Fennell said it was a certificate from Dr. John Evans, of having been engaged in compounding in his establishment for two years.

The President said he could contradict the imputation that Mr. Evans took private pupils. The certificate referred to was that of a Mr. Hardy, who went to Mr. Evans's brother to put in two years' pharmacy.

Dr. Montgomery said the taking of apprentices was not the same thing as grinding, and it rather added to Mr. Evans's ability to be a good examiner.

The President said it was not necessary to carry the discussion further. He merely wished to say that he knew both of the candidates, and they were both excellently qualified. He should be very glad to have Dr. Whitla as an examiner in materia medica, which was the subject on which he had written, but in the present instance he thought Mr. Evans would be the right man in the right place. He was a properly educated pharmaceutical chemist, and practically engaged in compounding; Dr. Whitla was a practising physician.

The Council then divided on the motion for the election of Mr. Evans with the following result:—

For the motion—Sir George Owens, Dr. Montgomery, Messrs. Hodgson, Brunker, Draper, Lester, Doran, Bennett, Dr. Collins and the President,—10.

Against it—Dr. Whittaker, Messrs. Allen, Pring, Simpson, Grindley, Wells, Payne, and the Vice-President,—8.

The President declared Mr. Evans duly elected.

The Registrar read a letter from Mr. George A. Webb, of 141, York Street, Belfast, stating that he was surprised at seeing it reported in the proceedings of the Council that a member had said that he (Mr. Webb) stated that while Mr. Carse was in his establishment he attended "pretty regularly." He had no recollection of having used such words. On the contrary, while Mr. Carse was with him his attendance was regular, and he exceeded his time by six weeks.

Mr. Payne said it was possible that he had made a mistake in using the words "pretty regularly."

The Registrar read a letter from a member of the Society in Waterford, protesting against Mr. Savage, of Dublin, being allowed to keep an open establishment for compounding in that city, even by means of a qualified assistant.

Mr. Brunker said this matter was considered at a former meeting of the Council, and the explanation then given by the representative of the late Mr. Savage was deemed satisfactory. The deceased Mr. Savage was an apothecary, and his executor was carrying on his business with the aid of a qualified assistant. The Council could not interfere in the case, and if the writer of the letter had anything to complain of he should apply to the Apothecaries' Hall.

The President said the proper reply would be to say that the case has been already considered, and that there was no information before the Council at present that would warrant interference.

Mr. Brunker said he would go further to say that the Council had no power to interfere under clause 32.

The Vice-President: There might be a hundred shops kept open in the same way. There should be some limit to it. Clause 32 did not put any limit to the time during which an establishment might be kept open by a hired assistant, and was therefore defective.

Mr. Brunker said clause 32 did not apply to a licensed apothecary.

Dr. Whittaker asked whether a lady had not been carrying on one of the first businesses in Dublin for years?

The President:—But she engaged a qualified man. She is the widow of an apothecary.

The Vice-President asked whether the deceased in the present case was a registered pharmaceutical chemist.

Mr. Brunker: No; an apothecary.

Dr. Collins said the Council had always allowed executors to carry on the business of deceased members of the Society by a suitable person and for a moderate time while they could dispose of the interests, but he did not think they had been allowed to go on as this man was doing. Still, if either this Society or the Apothecaries' Hall brought him into a court of justice the probability was that clause 32 would be relied on, even for an apothecary's executor.

The Vice-President said a legal opinion on the case ought to be taken.

On the motion of Mr. Payne the letter was referred to the Law Committee with instruction to take a legal opinion on it; and the Registrar was directed to inform the writer of the course which had been taken.

A letter was received from Dr. Stannus Hughes, Registrar of the College of Surgeons, intimating that as soon as the Council of the College had before them the amendments which the Council of the Pharmaceutical Society proposed to have made in the Sale of Poisons Act, they would take them into consideration.

On the motion of Mr. Bennett, seconded by Mr. Doran, a report of the Law Committee was adopted.

Mr. Allen moved the following resolution:—

"That for the use of the Examiner in Pharmacy a collection of prescriptions shall be formed, which shall be pasted in a book, or books, and placed, when not in use, under the care of the Registrar, and treated as confidential."

He would be glad to see the examination of the Society made very much better. It was rather under the standard of the Minor examination in England, and he should be glad to see it brought up to it. The English Pharmaceutical Society had a collection of 3000 prescriptions, got together by Mr. Joseph Ince, which included every variety of writing and different styles of Latin.

Mr. Pring seconded the motion.

Dr. Whittaker said he would not oppose the motion, but he thought it unfortunate that it should be called for. The motion of Mr. Allen was almost absurd on the face of it. He (Dr. Whittaker) would know what practical information a man possessed almost as soon as he saw him take a pestle in his hand. Botany and chemistry and materia medica were all very well, and yet there were practical pharmacists who knew mighty little about these things and yet could read prescriptions well and do their work well.

Dr. Collins was of opinion that it would be desirable to have such a collection of prescriptions as was proposed by Mr. Allen. It would be an advantage for the examiner to have other prescriptions besides his own.

The President said he agreed with Dr. Collins. It would be easy for the candidates to get prescriptions which had been written by the Examiner. A large variety would afford a much more effectual test. Besides, Mr. Allen did not want to dictate to the examiners. They could write prescriptions themselves also.

Dr. Montgomery said he believed Mr. Allen did not intend to interfere with the examiners. He (Dr. Montgomery) had had a large experience as an examiner and when conducting an examination he always selected from a collection of from 300 to 400 prescriptions.

Mr. Payne was in favour of the collection of prescriptions. It should embrace prescriptions written in every part of Ireland.

The motion was then put and carried unanimously.

Mr. Allen said that in order to carry out the resolution just passed it was necessary for him to move:—

"That the members of the Society be invited to send prescriptions and that the committee appointed to visit the examinations shall receive, examine, and arrange the collection."

Mr. Pring seconded the motion, which was unanimously agreed to.

The Registrar stated that he had received a letter from Mr. A. Chapman, pharmaceutical chemist, of Belfast, forwarding one which he (Mr. Chapman) had received from Dr. Meredith and Dr. Dunne, the secretaries of the Royal University, informing him that a certificate signed by a licentiate apothecary attached to a recognized hospital would be accepted by that university. Mr. Chapman asked the Registrar (Mr. Fennell) was it only a licensed apothecary that could give a certificate which would be accepted by the Royal University.

Dr. Whittaker said the Council should ask the Royal University to recognize their licentiates as competent to give certificates in pharmacy. He moved that the attention of the authorities of the Royal University be called to the fact that as far as regards the compounding of medicines the privileges of the Apothecaries' Hall had been united with those of the Society, and that pharmaceutical chemists were qualified by law to compound medicines, and that the Council should ask the authorities of the Royal University to accept the certificates of qualified members of the Society as on a par with those of members of the Apothecaries' Hall.

The President said that as the subject was not on the paper of business it was better to give a notice of motion respecting it.

The Registrar laid on the table the report of the examiners.

Mr. Brunker, as one of the visitors who had attended the examination, said that the candidates were of a good stamp, but he thought the arrangements made for the holding of the examination most unsatisfactory. The time given to the examiners was also insufficient. They would like to have two days, one for papers and one for *vivâ voce.*

The President said he had directed Mr. Fennell to supply the examiners with everything that they required.

On the motion of Dr. Whittaker, seconded by Mr. Hodgson, the consideration of the recommendations of the Pharmacy Act Amendment Committee was postponed.

Mr. Payne said he had to hand in his resignation. He could not remain on the Council when it was the opinion of some members that three weeks was a sufficient time to learn compounding in, and when the Council had endorsed that view by the course which it had that day taken with respect to the election of the examiner.

Mr. Brunker trusted that the Council would not receive Mr. Payne's resignation. He was sure that when Mr. Payne thought over the subject he would see that it was scarcely wise to retire merely because everything was not done according to his own ideas. If everyone did that they would have no Council.

Dr. Whittaker also handed in his resignation. He said he did so with regret, but he did not believe that he could do any good by remaining. He was afraid he was not met in the spirit in which he should be met, having regard to the services which he had rendered to pharmacy. He believed they wished to make the Society a Dublin Society.

The President said he thought Dr. Whittaker was hardly justified in in saying that, when four members of the Society from Belfast had been put on the Council, which numbered, in all, only twenty-one members, and having regard to his (President's) anxiety to get the North of Ireland represented on that Council. Dr. Whitla, it was true, had resigned, but he was sure that they would all be glad of the first opportunity of seeing him back again.

Dr. Whittaker said he merely believed that what he had stated was the case.

Mr. Pring said that he had been disappointed at the result of the election, as well as Mr. Payne and Dr. Whittaker. But they had been fairly beaten, and, therefore, they should not resign. But there were one or two notices of motion to come on with respect to the bye-laws and if these should not be carried, he (Mr. Pring) would resign.

Mr. Brunker said that five Dublin members of the Council had voted for Dr. Whitla; while two country members had voted for Mr. Evans.

The President said he would not accept the resignations. If the gentlemen desired to resign, they could, after good consideration, forward their resignations to him.

The Council then adjourned.

Provincial Transactions.

CHEMISTS' AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Executive Committee of this Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on August 9, 1882, at 1 p.m.

Mr. Robert Hampson (London), President, in the chair.

Mr. John Harrison (Sunderland), Vice-President.

Present—Messrs. Arblaster (Birmingham), Barclay (Birmingham), Bell (Hull), Churchill (Birmingham), Cross (Shrewsbury), Davis (Leamington), Ellinor (Sheffield), Holdsworth (Birmingham), Jones (Llanrwst), Laird (Edinburgh), Maltby (Lincoln), Mason (Liverpool), Parker (Nottingham), Paterson (Aberdeen), and the Solicitor of the Association.

Communications were read from Messrs. Mackenzie, Stead, Walker, and Williams, regretting their inability to attend.

The minutes of the previous meeting of the Executive were read and confirmed.

It was moved by Mr. Laird, seconded by Mr. Ellinor, and unanimously resolved:—"That the officers of the Association, together with Messrs. Andrews, Arblaster, Barclay, Bell, Cross, Davis, Jervis, Holdsworth, Maltby, Mason, Stead, Symes and Walker form a Law and Parliamentary Committee for the ensuing year."

It was moved by Mr. Cross, seconded by Mr. Mason, and unanimously resolved:—"That the officers of the Association, together with Messrs. Arblaster, Barclay and Holdsworth, form a Finance Committee for the ensuing year."

It was moved by Mr. Bell, seconded by Mr. Paterson, and unanimously resolved:—"That the officers of the Association, together with Messrs. Andrews, Arblaster, Bell, Cross, Davis, Jervis, Ellinor, Holdsworth, Jones, Maltby, Mason, Parker, Stead, Symes, Walker and Williams form a General Purposes Committee for the ensuing year."

It was moved by Mr. Cross, seconded by Mr. Davis, and unanimously resolved:—"That Mr. Henry Glaisyer be re-appointed Solicitor to the Association for the ensuing year."

It was moved by Mr. Bell, seconded by Mr. Harrison, and unanimously resolved:—"That Mr. W. F. Haydon be re-appointed Secretary to the Association on the same terms as before."

It was moved by Mr. Bell, seconded by Mr. Ellinor, and unanimously resolved:—"That Professor Attfield be re-appointed Analytical Referee to the Association for the ensuing year."

It was moved by Mr. Mason, seconded by Mr. Arblaster, and unanimously resolved:—"That Messrs. Lloyd's Banking Company be re-appointed Bankers to the Association for the ensuing year."

It was moved by Mr. Cross, seconded by Mr. Davis, and unanimously resolved:—"That Messrs. Laundy and Co., Public Accountants, be re-appointed Auditors to the Association for the ensuing year."

Mr. Paterson said that he thought the Assistant Secretary might make a journey to Scotland with a view of taking proceedings against unregistered traders under the Pharmacy Act.

The Secretary said that in May last, he had written to the Honorary Secretary of the Scottish Branch of the Association, asking to be supplied with the names of a few unregistered traders, residing in Scotland, who were openly selling arsenical sheep dip, but that he had not yet received such a list.

On the suggestion of Mr. Barclay, the Secretary was instructed to again write to the Secretary of the Scottish Branch respecting his (the Secretary's) former application.

The Secretary said that some months since, it had come to the knowledge of the Committee of the Scottish Branch of the Association that an application was about to be made by the Edinburgh University Court to Her Majesty in Council, for powers to make attendance in practical classes in physiology, pathology, and materia medica imperative, and that the instruction accepted as equivalent to a course of practical materia medica be apprenticeship for not less than two years in compounding and dispensing drugs under a registered medical practitioner or a member of the Pharmaceutical Society of Great Britain. This ordinance would have precluded chemists and druggists who were not members of the Pharmaceutical Society from educating students in materia medica. A memorial was consequently transmitted to the Secretary of the University Court on the subject, to which memorial the faculty of medicine had replied as follows:—"The memorial of the Scottish Branch of the Chemists and Druggists' Trade Association urges that a certificate of two years' apprenticeship with a registered chemist and druggist should be received by the University as equivalent to a certificate of apprenticeship for a similar period with a member of the Pharmaceutical Society of Great Britain. The faculty of medicine, only after some hesitation, included the latter among the means of instruction alternative to a recognized class of practical materia medica, on the ground that a certain number, which can only be a small one, of candidates for degrees in medicine may, in the laboratory of a pharmacist, have acquired practical instruction in many of the subjects taught in this class, at a time when they did not contemplate qualifying themselves for the profession of medicine. It appeared unnecessary to require such students to attend a class of practical materia medica, even although the instruction in this class would be of a more systematic, wide, and academic character than in the establishment of a pharmacist. It was recommended that apprenticeship should be restricted to a member of the Pharmaceutical Society of Great Britain, because the fact of such membership affords a guarantee that an education had been undergone which renders the members of this Society in many respects qualified to give such instruction to their apprentices as a university might be justified in recognizing. The education of registered chemists and druggists is, however, of the most varying description, and the title fails to afford a guarantee of equal value to the title of member of the Pharmaceutical Society of Great Britain. At the same time, taking into consideration the fact that the alternative qualification of apprenticeship to a pharmacist would affect only a limited number of students, and that the class of students so affected would generally be one whose pecuniary resources are limited, the faculty of medicine would be willing to coincide in the suggestion of the Chemists and Druggists' Trade Association. The University Court consider it desirable to adopt it."

The Executive considered in committee the advisability of defending a member of the Association against whom an action was threatened for the alleged infringement of a trade mark for liver mixture, and decided to defend on the grounds that the words liver mixture had been for many years of common use in the trade, and that it was not advisable in the interest of the trade that any person or firm should claim a monopoly over such common terms.

The President said that the next subject on the agenda paper was:—"To consider the advisability of giving effect to the following resolution, passed by the Executive at their last meeting:—'That it be a recommendation to the incoming Executive to communicate with the Government on the question of the sale of patent medicines containing scheduled poisons.'" The discussion on this matter was also taken in committee.

It was moved by Mr. Barclay, seconded by Mr. Holdsworth:—"That a deputation be appointed by the Executive to wait upon the Government to ask that the sale of patent medicines containing scheduled poisons may be put under the same regulations as the sale of other scheduled poisons," to which Mr. Paterson moved, as an amendment, and Mr Bell seconded, "The previous question."

On being put to the vote, 10 voted for the amendment and 4 against it; it was consequently carried.

On the motion of Mr. Barclay, seconded by Mr. Jones, it was resolved:—"That the Finance Committtee be authorized to appoint local secretaries in all towns in England and Wales containing six or more chemists and druggists, and that the same Committee be empowered in conjunction with the Scotch Committee of the Association to appoint local secretaries in Scotland."

Several communications were read from members of the Association, and the Secretary was instructed as to the manner in which he should deal with the same.

DOVER CHEMISTS' ASSOCIATION.

At a meeting of the above Association the following note was read:—

A Dispensing Solution of Acetate of Potash.

BY J. F. BROWN.

From its proneness to deliquescence, this salt often gives trouble to the dispenser; and I thought it might be worth while to suggest the following formula for a dispensing solution, which is easily made, permanent, and of convenient strength.

Weigh into an evaporating dish half a pound (av.) and 68 grains of acetic acid, B.P.; then add in successive portions 3¾ ounces, or quant. suff., potassium carbonate, until the solution, having been gently heated to expel carbonic acid, is neutral to test paper; evaporate further if needful, to make the measure exactly 8 fluid ounces, and filter. Two minims contain 1 grain. A fluid drachm contains 30 grains and a fluid ounce 240 grains.

Proceedings of Scientific Societies.

KENTUCKY PHARMACEUTICAL ASSOCIATION.

Some New Preparations of the Hypophosphites containing Iron.*

BY C. LEWIS DIEHL.

Several years ago I was requested by a physician to prepare for one of his patients a pleasant combination of the hypophosphites of iron and quinia, if possible, in the form of an elixir, and in as nearly a neutral condition as practicable. After some experiments I succeeded in making a very acceptable preparation—in fact, an elegant elixir, containing in each fluid drachm one grain of each of the salts named, in perfectly neutral combination. The successful production of this preparation led me to apply the chemical facts involved to the production of other combinations of hypophosphites containing iron, some of which have been received with decided favour by the physicians whose attention I have been able to invite to them. Thinking that possibly these preparations may merit more extended use, and that at all events they are interesting combinations, I have concluded to make known their formulas and the methods of their preparation in the following.

In the preparations prepared by me the ferric salt is used, as in Professor Procter's formula,* but instead of effecting its solution by means of hypophosphorous acid, citrate of potassium is employed, a handsome greenish and perfectly neutral solution being formed. The quantity of the citrate necessary for this purpose is about equal to that of the dry ferric salt, but the latter is preferably prepared freshly and dissolved while still moist. The citrates of ammonia or sodium would answer the purpose of solvent as well as the potassium salt, which was selected only because it is always at hand, and because the ammonium and sodium salts are not known to possess any advantage. For the preparation of the ferric hypophosphite any of the soluble salts of the hypophosphorous acid will answer, but I have selected the hypophosphite of calcium, with ferric chloride as precipitant, for the reason that it is the salt most commonly kept in quantities, and because it is the cheapest. Certain precautions must, however, be observed to secure the perfect precipitation of ferric hypophosphite, for if too much or an insufficient quantity of ferric chloride be added, a portion of hypophosphite remains in solution and is lost during the washing of the precipitate, which must be done with the smallest possible quantity of water. It may be well, therefore, to give particular consideration to the

Preparation of the Ferric Hypophosphite.—Dissolve 150 grains of the hypophosphite of calcium in four fluid ounces of distilled water, if necessary, by the aid of gentle heat, and filter the solution. To the cold solution carefully add solution of ferric chloride so long as a precipitate is produced. Collect the precipitate upon a close muslin cloth, drain well, and express firmly; then pour upon the magma one fluid ounce of distilled water, and express again. The magma may then at once be dissolved by the aid of citrate of potassium.

When precipitating this compound it is best to add the ferric chloride in small portions at a time and to stir the liquid constantly. Then allow the precipitate to subside, so that the supernatant liquid may become clear before adding the next portion of ferric chloride. Toward the last a small portion of the clear supernatant liquid is removed after each addition and tested with diluted ferric chloride solution, allowing it to stand for several minutes if no immediate turbidity occurs. If the liquid remains clear after several minutes' standing, the precipitation may be regarded as complete, and the straining and washing may go on as above directed. The product is equal to 128 grains of dry ferric hypophosphite.

Having thus explicitly given the method of obtaining the magma of ferric hypophosphite, these directions do not need repetition in the formulas for the different preparations given below. As regards its solution by the aid of citrate of potassium, it is only necessary to triturate the magma with the specified quantity of the latter, when partial solution will occur, and complete solution follows upon the addition of water, or of the solution of the other hypophosphites.

I. *Improved Syrup of the Hypophosphites with Iron.*—Take of hypophosphite of calcium 256 grains; hypophos-

* Read at a meeting of the Kentucky Pharmaceutical Association.

* Parrish's 'Pharmacy,' third edition, 1864, pp. 429, 430.

phite of sodium 192 grains; hypophosphite of potassium, 128 grains; ferric hypophosphite (represented in the magma obtained from 128 grains of hypophosphite of calcium), 96 grains; citrate of potassium, 96 grains; white sugar 13 troy ounces; orange flower water, 1 fluid ounce; distilled water, a sufficiency. Dissolve the calcium, sodium, and potassium hypophosphites in 7 fluid ounces of the water, if necessary, by the aid of a gentle heat, and filter the solution. Triturate the magma of the ferric hypophosphite with the citrate of potassium, add the solution of the other hypophosphites, and when complete solution is effected, the orange flower water and sufficient distilled water to make the whole measure 9 fluid ounces. In this dissolve the white sugar, without heat, and filter the resulting syrup through paper. A fluid drachm of this syrup contains 2 grains of the calcium, a grain and a half of the sodium, one grain of the potassium, and three-fourths of a grain of the ferric hypophosphite.

II. *Syrup of Hypophosphite of Iron.*—Dissolve 128 grains of ferric hypophosphite (represented in the magma) from 150 grains of hypophosphite of calcium, by the aid of 128 grains of citrate of potassium, in 1 fluid ounce of orange flower water, and sufficient distilled water to make the solution measure nine fluid ounces. In this dissolve 13 troy ounces of white sugar, and filter the resulting syrup. One fluid drachm of this syrup contains one grain of the ferric hypophosphite.

III. *Elixir of Hypophosphite of Iron.*—In the 9 fluid ounces of solution of ferric hypophosphite, obtained as above (II.), dissolve 4 troy ounces of white sugar, and add 5 fluid ounces of alcohol, in which 8 drops of fresh oil of orange have been previously dissolved; then filter. The strength of this is the same as that of the syrup, over which it probably possesses no advantage.

IV. *Elixir of Hypophosphite of Iron and Quinine.*—Make a solution of ferric hypophosphite, as under II., but bring it only to the measure of 7 fluid ounces, and dissolve 4 troy ounces of white sugar in it. Triturate 128 grains of sulphate of quinine with 5 fluid ounces of strong alcohol, add a solution of 30 grains of hypophosphite of calcium in ½ fluid ounce of distilled water, and shake the mixture occasionally for an hour. Then filter, and wash the filter with sufficient strong alcohol to make the filtrate measure 7 fluid ounces. In this dissolve 8 drops of fresh oil of orange, add it to the solution of ferric hypophosphite, mix well and filter. A fluid drachm of this elixir contains 1 grain of the hypophosphite of quinine and 1 grain of ferric hypophosphite.

V. *Elixir of Hypophosphite of Iron, Quinine and Strychnia.*—This is the above elixir (IV.) containing $\frac{1}{128}$ grain of hypophosphite of strychnia in the fluid drachm, and is made by triturating 1 grain of sulphate of strychnia with the sulphate of quinine and alcohol, and increasing the quantity of hypophosphite of calcium by 1 grain.

VI. *Elixir of Calisaya with Hypophosphites.*—This is the "elixir of calisaya" proposed by me in 1866, containing hypophosphites in such proportion that two teaspoonfuls represent one teaspoonful of "improved syrup of the hypophosphites with iron" (I). It is therefore necessary to reproduce the formula for the elixir of calisaya, as modified for this purpose.

Take of calisaya bark, 24 troy ounces; curaçoa orange peel, 16 troy ounces; coriander, 4 troy ounces; cinnamon, 3 troy ounces; cardamom, 1½ troy ounces; anise seed, 1 troy ounce; cocoa (Baker's), 8 troy ounces. Having reduced these ingredients to a moderately fine powder, displace them with a mixture of one volume of strong alcohol and three volumes of distilled water, until 2 gallons of percolate are obtained.

Meanwhile prepare from 6 pints of solution of tersulphate of iron, hydrated sesquioxide of iron by the formula of the Pharmacopœia, measure the magma, and add to every 4 volumes 1 volume of strong alcohol; then add of this mixture sufficient to the percolate, obtained as above, to deprive it of its cinchotannic acid. The absence of the latter is readily ascertained by the addition of a drop of muriated tincture of iron to a filtered portion of the liquid, which should not be coloured by such addition. Should coloration result, the intensity or faintness will serve as a guide to the further addition of the ferric oxide. As soon as de-tannation is effected, filter the whole through a *double* muslin cloth, express the residue under a press, filter this portion, add to that first obtained, and measure the united filtrate. Add to the residual magma on the cloth sufficient of the above described mixture of alcohol and water to make, when again expressed and filtered, the united filtrates measure 3 gallons. Now triturate 2 fluid drachms of fresh oil of orange with 4 troy ounces of prepared chalk, incorporate this with the 3 gallons of de-tannated "cinchona liquor," and agitate occasionally for twenty-four hours, and then filter.

The "cinchona liquor" so obtained is just twice the strength of the "elixir of calisaya," above referred to, and when mixed with an equal volume of "improved syrup of the hypophosphites with iron" forms the "elixir of calisaya with hypophosphites."

VII. *Elixir of Calisaya and Hypophosphites with Strychnia* may be made by dissolving 1 grain of strychnia by the aid of a few drops (or just sufficient) of hypophosphorous acid in one fluid drachm of distilled water, and adding sufficient of the above elixir (VI.) to make 1 pint A dessertspoonful contains 1·64 grain of strychnia.

Parliamentary and Law Proceedings.

Poisoning by Opium.

On Wednesday, August 9, an inquest was held at Millfield, Sunderland, upon the body of Dr. Joseph Parker Crossby, aged 44 years, medical officer of the Sunderland Workhouse, who was found dead in bed on Monday morning.

Mrs. Crossby testified that the deceased, who slept alone, was in the habit of taking morphia pills at night. He had complained of heart disease for years. He appeared all right on Sunday.

Dr. Drinkwater said he met Dr. Crossby (who had given evidence in a manslaughter case at Durham Assizes on Saturday) coming from the Workhouse on Saturday night. He was very much excited, nervous and shaky. When he was hastily called in on Monday morning, he judged deceased had been dead two hours. In his opinion death arose from an overdose of opium, but there was no indication of an intentional poisoning.

The jury returned a verdict in accordance with this testimony.

Important Excise Prosecution.

At the Lambeth Police Court on Tuesday, Mr. W. Bush, wholesale chemist, Artillery Lane, City, and Ash Grove, Hackney, appeared to summonses issued against him by the Inland Revenue for having, as alleged, used a still without a licence for compounding spirits, and for retailing spirits without a licence, and for separating gum resin from methylated spirits mixed with gum resin.

Mr. N. J. Highmore, barrister, prosecuted on behalf of the Inland Revenue; and Mr. Edward Pollock appeared for the defendant.

Mr. Highmore said he would take first the offence of "using a still" and "for separating gum resin from methylated spirits mixed with gum resin."

He called Mr. R. W. Parry, supervisor of Excise, who said he visited the premises of the defendant in Hackney. The ordinary still licence was produced. The defendant had no licence to distil spirits. Witness found six stills, varying from 30 to 1000 gallons. There were likewise three or four smaller stills. He found methylated spirit running from the worm end of some of the stills. He asked a man what they were distilling, and he replied "A varnish or finish." A Mr. Wooton told him the same, and that the operation was performed in order to rectify the spirit from the gum. He took samples and handed them to the analyst at Somerset House. Witness made a search, and close to the stills found ten drums containing 110 gallons of methylated spirit, from which the gum resin had been extracted by the stills at work. On July 28, he again called in conjunction with Mr. Harper, who had been with him on the first day. Mr. Holmes, one of the analysts of Somerset House, was with them. There was no distilling going on then. Witness explained to Mr. Bush, jun., the nature of the offence and the law. He requested witness not to remove the spirit until Mr. Bush, sen., came, and he said he would not. When the defendant came and was told of the affair, he said it was the practice of the trade to separate gum from the "finish," and that he was ignorant of the law on the subject.

In cross-examination, the witness said he had not heard of such a practice as that of the defendant's being carried on before by the trade. There was no desire by the defendant to conceal anything.

Mr. John Harper, supervisor of Excise, corroborated; and Mr. John Holmes, analyst, spoke as to having examined the samples, and found them to be methylated spirits, and the solid matter in the stills he found to be gum resin.

Mr. Pollock said with regard to the separation having been carried on he would not dispute, but pointed out that everything had been done by the defendant in an open manner. The defendant likewise had acted in ignorance of the law.

Mr. Chance asked if the facts were admitted, and Mr. Pollock replied in the affirmative, but contended that within the meaning of the Act it was not a distillation of spirits going on, but it was methylated spirits. A long discussion arose over points raised by Mr. Pollock, especially upon the one as to what was meant by "spirits," the learned counsel pointing out that in many articles "spirits" were used.

Mr. Chance said he should well consider the points raised before giving his decision.

The other summonses against the defendant were then proceeded with—the first being for his having carried on the trade of a compounder of spirits, and for compounding spirits without a licence.

Mr. Highmore said the defendant would be bound to have taken out a licence as a compounder quite distinct from that of a distiller. The defendant was the maker of compounds for spirits and liqueurs, and he would show such essences contained "spirit." Under such a business it was likewise required there should be an "entry" of the premises, and a very strict survey. None of these had been complied with.

Mr. Parry, the supervisor, gave evidence in support of the learned counsel's statement, and the evidence of the analysts was given stating that in their opinion the "essences" were "spirits."

Mr. Pollock said that the defendant had carried on the business for many years, and he had in his possession the circulars of many others who for a long period had carried on a similar business. At the Exhibitions from 1851 downwards, medals had been awarded for these "essences" and no proceedings had been taken.

Mr. Highmore said such a trade might not have been known to the authorities, or perhaps the article had been manufactured by a "licensed" compounder. If it had been known the authorities would have interfered.

Mr. Chance said there were certainly many important points to be considered, and he should take time to give his decision upon them. He could hardly understand how these matters had gone on without being known to the authorities.

Mr. Pollock observed that even the Prime Minister must have known it.

The cases were then adjourned.

Alleged Poisoning by Belladonna.

Mr. Carttar, Coroner for West Kent, held an inquest on Monday, at Plumstead, on the body of Henry John Cetewayo Kitchingham, aged two years and seven months. On Thursday the child was playing in the garden of 3, Wellesley Terrace, Anglesea Road, Plumstead, where its parents lodged, and was seized with vomiting, and getting worse he was taken to Dr. Ingledew's surgery, where it was found he was suffering from inflammation of the stomach and intestines, due to some irritant poison.

Mrs. Reeves, landlady of the house, said she noticed some of the children who were playing with the deceased come in with some flowers and a weed like that produced, which she remarked at the time was very poisonous, and threw it on the fire. A wooden fence separated her back garden from that of No. 2, and the flowers and weed, she believed, had been plucked through the fence, as she had no such flowers or weed in her garden.

When the jury viewed the body they also inspected the next garden, and amongst some scarlet runners the Coroner drew their attention to some deadly nightshade or belladonna, the berries of which were green.

Dr. Ingledew said the weed produced was nightshade, and from a *post-mortem* examination he attributed death to the deceased having eaten some of the berries.

Mrs. Henderson, the neighbour, produced some of the weed and said she had since cleared her garden of it.

The jury returned a verdict of death from accidentally eating berries of deadly nightshade.—*Standard.*

Reviews.

The Manual of Colours and Dye Wares. Second Edition. By J. W. Slater. London: Crosby, Lockwood and Co.

In this little manual of two hundred and thirty-four pages, the dyer, calico printer and drysalter will find a fair amount of really valuable information, given in a brief and thoroughly practical form, under an alphabetical arrangement favourable for easy reference.

The particulars given embrace the results of recent researches on colouring matters, the modes of testing dye wares, the strength of acids, etc., together with some useful tables of French weights and measures reduced to their English equivalents, and hydrometer tables of Baumé and Twaddell, compared with the actual gravities to which they correspond. Soaps and mordants are well described, and the chemical properties of dye wares correctly stated. The latter descriptions might in some cases have been elaborated with advantage, but what is stated appears to be singularly correct. The only errors are a few misprints, such as the proper names of inventors or manufacturers:—"Perkins," "Lewinstein," "Fel" and "Bayer," standing for Perkin, Levinstein, Fol and Baeyer; and "Bismark brown" is not a true rendering of the colour named after the great German Chancellor. "Mythylic alcohol" is another mistake, and on page 162, for "permanganate" read "ferrocyanide." Excepting these clerical errors, and another (on page 131), where it is said that "Tin (or iron) dissolved in nitric acid is more readily deposited upon cotton than if hydrochloric acid were the solvent," the book throughout seems thoroughly trustworthy, and we feel pleasure in recommending it to the notice of dyers and others interested in the technical branches treated of in this useful little manual.

Remarks on Certain Medical Principles and Publications. By Dr. Joseph Hamernik, Prague. Translated from the German by F. Marks. London: E. W. Allen. 1882.

This pamphlet belongs to a class of literature that is sufficiently represented by indigenous productions to have enabled the English community to have dispensed with imports of it from foreign lands. Its principal characteristic is a maximum of assertion and a minimum of proof. When doctors disagree ordinary mortals do not usually volunteer to decide, still, if they are appealed to they might require something more than three dozen pages of dogmatism before giving a verdict against all that is "orthodox" in medicine. The author is evidently not troubled with doubt. Vaccination is denounced by him as worse than useless, without the reader being favoured with the evidence leading to that conclusion. He is told cow pox has no connection whatever with small pox, and that "in the event of an attack of small pox it is of no manner of importance whether the patient is vaccinated or not." Though he may find this difficult to reconcile with a statement on the opposite page that "persons are most liable to be attacked by small pox in the years immediately succeding vaccination." Vaccinators with original cow-pox lymph are described as "for the most part charlatans, who produce the pustulation in the udder of the calf or cow by solutions or ointment of tartar emetic, and drive a fraudulent trade in it." All aperients are said to be superfluous and mischievous, and Hunyadi-Janos water is specially singled out for condemnation, apparently because of its dissimilarity to ordinary drinking water. "Disinfection does nothing in the way of preventing disease or rendering it milder." And so on, *usque ad nauseam.*

Notes and Queries.

[737]. Extractum Cinchonæ Liquidum.—On several occasions whendispensing the above preparation, contentions have arisen, sometimes with the patient, sometimes with the prescriber, as to the proper appearance of mixtures in which it has been ordered. The patient is continually complaining that the medicine is not like the last, made up elsewhere; and the doctor himself sometimes will hardly be satisfied with the explanation one has to offer, even though one goes deeply into the subject and harangues him for half an hour on the great difference observable in it as obtained from different establishments, and as prepared from different species of cinchona.

One exhausts one's knowledge of materia medica and wastes one's breath to very little purpose: the mixture has been made before at a first rate West End house; mine is not like it, as it ought to be, and there's an end of the argument.

This strikes me as being so very unsatisfactory, that I am now led to seek the consolatory comments of some kind brother pharmacist.

Three samples of ext. cinch. liq., obtained from well known sources, gave the following divergent results. The experiments being carried out in 1-ounce phials, and 20 minims of the extract added to each, then allowed to stand twelve hours.

No. I.

With distilled water only.

Colour of mixture golden-brown. The precipitate occupied about one seventh of thephial, of a dirty yellowish brown. It shook up easily. Supernatant liquid clear, amber-colour.

With 5 grs. amm. carb.

Colour of mixture dirty yellow-brown. The precipitate occupied about one fifth of the phial. A pale mud-colour; fine, and easily shaken up; supernatant liquid opaque, light brown.

No. II.

With distilled water only.

Colour of mixture purplish liver-colour. The precipitate occupied a. fourth of the phial. Dingy purple; softly flocculent; shook up well, but soon began to come down again. Supernatant liquid clear and rather darker than No. 1.

With 5 grs. amm. carb.

Colour of mixture pale brick-red. The precipitate occupied a third of the phial. Sand-red colour. In large flakes and slightly granular. Not mixing thoroughly when shaken, and beginning to fall at once. Supernatant liquid clear, bright orange.

No. III.

With distilled water only.

Colour of mixture bright brown. The precipitate scarcely more than covered the bottom of phial. Dense, and not shaking up so easily; dark brown. Supernatant liquid opaque, dark brown.

With 5 grs. amm. carb.

Colour of mixture nearly black by reflected light. The precipitate very dark brown; small; dense, with some inclination to stick to the glass. Supernatant liquid opaque, dark brown.

[738]. "Lin. Scorpii."—Can any reader of the Journal favour me with the formula of the above, as I am unable to find any mention of it in any book of formulæ? F. Herington.

Obituary.

T. B. STEAD.

It is with regret that we have to record the death of Mr. T. B. Stead, chemist and druggist, of 20, Upperhead Row, Leeds, which took place on the 14th inst. at his residence, Roundhay. Mr. Stead had been ailing for some time, but his illness did not assume a serious form until last week. On Tuesday last he consulted Dr. Horsfall as to his condition, and that gentleman advised him to take a few days' rest. Mr. Stead gradually became worse, congestion of the brain set in, and he died on Monday. Mr. Stead held the position of President of the Leeds Chemists' Association at the time of his death, having been one of its founders just twenty years ago. His sound sense, genial manner and willingness to work for public objects had secured for him the esteem of his brethren in the ranks of pharmacy. He represented the Leeds district on the Executive Committee of the Chemists and Druggists' Trade Association, and was a regular attender of its meetings in Birmingham. The deceased gentleman represented the West Ward in the Town Council from 1872 until November last, when he did not seek re-election. During his connection with the Corporation he rendered much useful service as a member of several important committees. He was the means of bringing to light many of the anomalies which existed in the collection of the rates in the townships, and on the formation of the committee for levying the rates over the borough he was appointed its chairman, an office which he held until his retirement from the Council. For many years he was a member of the board of overseers of the township of Leeds. As a thorough-going politician he actively engaged in many parliamentary and municipal contests, always displaying a generous spirit, which gained for him the admiration of his opponents, as well as the esteem of those who worked with him. He leaves a widow, a son, and daughter.

Notice has also been received of the death of the following:—

On the 21st of July, Mr. Robert Lambert, Chemist and Druggist, Haworth. Aged 78 years.

On the 22nd of July, Mr. Sydney Herbert Witherington, Chemist and Druggist, Wandsworth Road, S.W. Aged 44 years.

On the 28th of January, Mr. Thomas Howie Hopper, Chemist and Druggist, High Street, Hawick. Aged 64 years.

On the 29th of July, Mr. Alexander Holroyd, Chemist and Druggist, Widnes. Aged 39 years.

On the 29th of July, Mr. Thomas Andrews, Chemist and Druggist, Shrewsbury. Aged 50 years.

On the 31st of July, Mr. William Symes Pryer, Pharmaceutical Chemist, Axminster. Aged 75 years. Mr. Pryer had been a Member of the Pharmaceutical Society since 1853.

On the 6th of August, Mr. Richard Bird Mitchell, Chemist and Druggist, Chulmleigh. Aged 49 years.

On the 11th of August, Mr. William Ruston, Chemist and Druggist, Grey Street, Newcastle-on-Tyne. Aged 39 years.

Correspondence.

The Future of Pharmacy.

Sir,—If your correspondent "Wulfruna" will make a simple calculation he will find that the prices he quotes in your last issue are not, after all, anything "special," but the usual wholesale price, with a fair profit for bottling, etc., and if there were a demand among retail chemists for packed drugs of that description I have no doubt they would be supplied on quite as reasonable terms. There is a firm of grocers in the immediate vicinity of my shop who retail many of the articles at the same and in some cases less than the price "Wulfruna" quotes.

Why we should "Boycott" those firms who supply stores I cannot understand, for if a wholesale chemist publishes a list of prices at which he is prepared to supply drugs to all *bonâ fide* wholesale buyers it should not concern him who those buyers are, so long as they have the money to pay for their goods. I doubt if your correspondent could point to any wholesale firm in London which would refuse a good ready money order from any of the London stores.

It is not by any such pettish actions as those advocated by "Wulfruna" that the questions of co-operation are to settled or pharmacy advanced to that professional dignity "Wulfruna" would see it occupy. It is within the power of Parliament only to give us the necessary legislation that will raise pharmacy above the level of other competitive trades, and until that legislation is granted we must be content either to hand over a large portion of our business to the grocers and the stores, or to try and compete with them. For myself, I prefer the latter course.

H. S.

Sir,—I beg to make a few remarks in the Journal on the above subject. It is a burning question amongst us, and any practicable suggestion likely to be beneficial would undoubtedly be welcomed by the whole profession.

We have just had before us Professor Attfield's excellent scheme, which was pretty generally approved. Being myself an outsider,—a country druggist,—I could not take the liberty of intruding on your space with my opinion. I was, however, glad to see that a very great majority endorsed that scheme. But in the meantime the "stores" are our *bête noire*, and we have suggestions without end as to our attitude towards them. It is the letter of your correspondent "Wulfruna" on the stores and their treatment, in last week's issue, under the heading "The Future of Pharmacy," which induces me to write you.

His ideas appear to me to be impracticable and inconsistent. He advocates "Boycotting" firms supplying stores, though he is of opinion that "we cannot blame stores." We cannot. So long as they avoid infringing the law they are perfectly legitimate concerns. It cannot be maintained that there is any difference in, *e.g.*, the glycerine, B.P., which the chemist sells at, say 3*d.* per oz. (the Liverpool chemists' price list), and the glycerine, B.P., 4-oz. bottle at 6*d.*, Lewis's price. The truth is the profits of the chemist and druggist have been too high. The prices "Wulfruna" quotes from the list of a wholesale house supplying stores,—the lowness of these prices is apparently the principal occasion of his letter,—are quite as high as he himself would buy at from any wholesale house. In most instances they are, I think, higher. But whatever these prices might be, they would be probably the same to everybody for the same quantity and terms. It is a matter of competition. The stores employing a larger capital require less percentage of profit. I have a general dealer next door to me selling at store prices. Amongst other drysalteries he sells 3-oz. bottles castor oil, at 3*d.* each; 4-oz. bottles at 4*d.*; cream of tartar, 1*s.* 4*d.* per lb.; tartaric acid, 2*s.* per lb.; seidlitz powders, 10*d.* per box; extract of meat (Company's), 1*s.* 3*d.* for 2-oz. pot; toilet soaps, about 33 per cent. off usual retail prices. I must then either sell at these prices or not sell these articles at all, for even at these prices he makes as much per cent. on his turnover as he finds necessary to the profitable carrying on of his business. How could we "Boycott" firms supplying him? We could not "Boycott" castor oil nor extract of meat. We cannot blame the stores so long as they deal honestly, nor the public for laying out their money economically. The chemist and druggist himself is, I think, to blame. He has, in the business of distributing "patent medicines and perfumery," "homœopathic medicines," "toilet requisites," etc., put a fictitious value on his services. But he can now bring his professional education to bear. "Knowledge is power." This is true, whether the knowledge be business or scientific. If "Wulfruna" (I speak generally) be placed in a situation where nothing more is required than a distributing capacity, he must either accommodate himself to his environment, or shut up. If his scientific ability merit it he will find scope and obtain customers in spite of "cutting" stores. It is not by "Boycotting" wholesale houses that we may improve our position. That could only be done by a demand for more skilled labour on the part of the medical faculty and the public, and the supply of that labour.

The law relating to the practice of pharmacy may require amendment, but reform is much required within the ranks of chemists and druggists. Instead of the charlatanry, chicanery and huckstering, which so widely prevail, let us cultivate a purer pharmacy.

It will eventually come, throughout the country, to what it has already come to in many places. Those most fitted for pharmacists have survived, and their businesses have become more truly pharmaceutical than ever. Those most fitted by education and position to become traders have, by speculation, untiring energy and economy, developed stores into a financial success. The weak have gone to the wall.

W. B.

Leeches.

Sir,—In the matter of leech keeping I am sorry to have to say that my experience differs very greatly from that of Mr. Lamble, my conviction being that in order to ensure the keeping of leeches in perfect health you will have to change their water very often indeed. So far as mine are concerned I have found that they have flourished the most vigorously when the water was changed every day, and that they soon began to stagnate when neglected for a few days, not to speak of weeks or months. I should like to hear from Mr. Lamble how he gets over the difficulty of vegetation on the surface of the water and sides of the aquarium.

Aquam.

W. Miller.—Nos. 1, 3 and 5 are named correctly. 2. *Hypericum perforatum.* 4. *Anthemis Cotula.* 6. *Teucrium Scorodoma.*

J. J.—We know of no reason why the two substances mentioned should form a dirty brown mass.

R. F.—Numerous forms for coating pills have been already published, and may be found by reference to the Index.

Vin. Aurant.—We think that there can be no doubt that the wine has undergone acetification.

A. B. C. is thanked for his communication.

Communications, Letters, etc., have been received from Messrs. Morley, Macdermot, Benest, Garrett, Dobson, Thompson, Aquam.

The Pharmaceutical Journal.

SATURDAY, AUGUST 26, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

BRITISH PHARMACEUTICAL CONFERENCE.

SOUTHAMPTON has during the past week been the rendezvous of such pharmacists as have been able and had the inclination to avail themselves of the opportunity afforded by the annual meeting of the British Pharmaceutical Conference to vary the monotony of the ordinary routine of their lives by friendly intercourse with their *confrères.* The Conference commenced on Tuesday, at half-past ten o'clock, in the WATTS Memorial Hall, under the presidency of Professor ATTFIELD, F.R.S., the visitors being welcomed, in a few well-chosen words, by Mr. RANDALL, speaking in the name of the local pharmacists. The audience was not so large as on some similar occasions in previous years, and did not nearly fill the area of the handsome hall in which the Conference met; whilst the general attendance appeared to be below the average, and this is confirmed by the number of signatures in the book placed at the entrance.

After a formal reception of the delegates present from various societies, the business of the meeting was commenced by the reading of the Report of the Executive Committee. The Report referred to the alterations that were introduced into the last 'Year-Book' and to the subject of grants in aid of original scientific research. It also mentioned the resignation of one of the General Secretaries, Mr. M. CARTEIGHE, in consequence of his accession to the Presidency of the Pharmaceutical Society of Great Britain, and stated that the consequent vacancy had been temporarily filled, at the request of the Committee, by Mr. SIDNEY PLOWMAN. From the Financial Statement it appeared that during the past year the expenditure had exceeded the income by about £65, which was partly due to a falling off in the number of members from whom subscriptions had been received. In alluding to this deficiency the President remarked that the introduction of the Parcels Post System would lessen the expense of distributing the 'Year-Book' in future, and he expressed an opinion that an appeal to the registered chemists and druggists who are not already members of the Conference should be followed by an increase of members sufficient to prevent a deficit in future years; further, that although the Committee had felt compelled to defer for the present, for financial reasons, the compilation of the General Index which had been suggested, the postponement would only be of short duration.

The Address of the President was undoubtedly the most important feature of the meeting. The Conference has been privileged in previous years to hear admirable addresses from different presidents, but in no previous year has a more marked impression been produced. As the Address is printed *in extenso* in another part of this Journal, it is not necessary to summarize it here, neither will this be the best opportunity for its criticism. As remarked by one of the speakers, it will doubtless be read with pleasure by all English speaking pharmacists, and the decided opinions expressed, couched in language that admits of little misunderstanding, will probably evoke a considerable amount of discussion. Indeed, that it has already attracted attention outside the pharmaceutical circle is evidenced by the fact that the *Times* has already devoted a leading article to the discussion of some of its topics. It will be sufficient to say here that the Address was admirably delivered and was listened to with that silent attention which is sometimes better evidence of interest than the most boisterous applause.

The first papers read consisted, as usual, of reports of work undertaken at the request, and with the aid, of the Conference. The first was a "Report on the Differences between the Essential Oils of Cinnamon and Cassia," by Mr. A. H. JACKSON. The reporter stated that, tested from a physical standpoint, the oils possess distinctive and characteristic odours and that the cinnamon oil has a more fiery taste than the cassia, but that neither the relative densities nor the refractive energies are sufficient guides in distinguishing mixtures of these oils, though the density of the oil of cassia was found to be somewhat greater than that of the oil of cinnamon. The chemical examination seemed to show that the constituent or constituents in which the oils differ from each other are present only in extremely small proportion. The next report was by Mr. A. W. GERRARD, "On the Alkaloidal Value of Belladona Plants," which was a continuation of a report on the same subject presented last year. The experiments referred to in the present report were made upon uncultivated plants in their first year's growth, from a chalk soil in Yorkshire and from a leaf mould in Sussex, and also upon cultivated plants in their second year's growth, gathered in May, June and July, or before flowering, whilst in flower, and whilst in fruit. The results obtained with the wild plants indicated that belladonna in the first year of its growth contains a very small proportion of alkaloid, but to that extent they were confirmatory of previous deductions by the author that the formation of alkaloid in the plant is favoured by a chalky soil. Experiments with the cultivated plant showed that the plant becomes most rich in active principles at the period of flowering and that the proportion is maintained in the fruiting season; further, that there is a simultaneous development of alkaloidal matter in the root and in the leaf, the former not being exhausted to strengthen the latter. A slight discussion followed, in the course of which Mr. HOLMES remarked that he had observed that belladonna grows more luxuriantly in calcareous soils, which might perhaps account for its being richer in alkaloid. At the close of this discussion the Conference adjourned to luncheon, which was provided in an adjoining room.

On resuming, the first paper read was entitled "A New Styptic of Indigenous Growth," and contained some observations of Professor QUINLAN upon the hæmostatic properties of the leaves of the *Plantago lanceolata*, or ribgrass. Notwithstanding the form of its title, the paper contained some interesting quotations from SHAKSPERE and CULPEPPER, proving that the ribgrass long ago had a great reputation as a styptic. Professor QUINLAN exhibited some pharmaceutical preparations of the plant, but it would appear that for external application the dried leaves are effective or the fresh leaves in a paste such as would be produced by mastication. It is not quite clear in what manner the leaf acts, but some experiments appeared to show that it is devoid of any kind of tannin, and it was suggested by Professor TICHBORNE that if there were an astringent principle present it might be allied to the catechuic acid compounds. Mr. BORLAND said that *Plantago lanceolata* had long been used in the district in which he lived to stanch the bleeding of wounds, but he had hitherto thought that it was merely because they formed a convenient covering of a wound.

A *résumé* was then given by Mr. W. A. SHENSTONE of "Some Experiments on English Oil of Lavender," which had been undertaken to test statements made by foreign chemists to the effect that oil of lavender sometimes deposits in cold weather a camphor, identical with common camphor, and that the oil contains a hydrocarbon boiling at a very high temperature (200°–210° C.). Mr. SHENSTONE was unable to confirm either of these statements, the oil used by him evidently not containing any notable quantity of crystalline constituents, whilst the distillate collected about the temperature mentioned contained a large amount of oxygen. It would also appear from the independent experiments of the author and M. BRUYLANT that the English and foreign oils of lavender differ very considerably in the amount of terpene which they contain. It may be remarked, in passing, that Mr. SHENSTONE'S *résumé* was evidently appreciated by the audience, and it is worth consideration whether it would not be better, as a rule, to summarize papers containing a large number of details that cannot be followed in the reading and to present the general results in such a form that they can be readily grasped, and, if necessary, discussed. No person in the habit of attending scientific meetings like the Conference can have failed to observe the weariness that becomes evident in the audience during the reading of even valuable papers, the drift of which is obscured by the multitude of details.

Next Mr. PARKER read a meritorious paper upon "Terpin Hydrate: its Preparation and Crystallography," which had been suggested by the occurrence of some crystals in a jar of furniture oil, supposed to have been compounded chiefly of linseed oil, turpentine, butter of antimony and methylated spirit. The author does not seem to be aware that the formation of such crystals in furniture polish is by no means a new experience; but it may be mentioned that in the early days of the School of Pharmacy, Bloomsbury Square, the conditions under which the formation of such crystals took place was the subject of many experiments in the laboratory, though without any satisfactory result being arrived at. Besides an elaborate description of the crystallography of terpin hydrate, the paper contained details as to its preparation and physical properties, and it mentioned the interesting fact that it is probable that terpin hydrate may be made to yield several aromatic oils by the action upon it of dehydrating substances under suitable conditions.

The next paper was on "A New Method of Making the Volumetric Solution for Estimating Hardness of Water," by Professor TICHBORNE. The novelty consists in the use of an oleate of soda, the preparation of which he describes, in the making of the soap solution. Dr. SYMES then read "Some Notes on Brazilian Drugs," in which he described a gum derived from the *Acacia Angico*, known in Brazil under the name of "resin de angico," and said to be useful for chest complaints. Another drug referred to was a species of elemi, named "almesca," differing in some respects from the elemi of commerce. The last drug described was a bark named "casca de guassatunga," from which in Brazil an alcoholic tincture is prepared said to be useful in the treatment of snake-bites.

The chair was now taken by Mr. GROVES, whilst a paper was read by the President, entitled "Half-an-hour with a Few Sheets of the New Pharmacopœia of the United States." The sheets upon which the remarks were based had been placed at the disposal of Professor ATTFIELD by the courtesy of Professor P. W. BEDFORD, President of the American Pharmaceutical Association, who is also a member of the United States Pharmacopœia Committee. The work is printed in large octavo, and the division into the two classes of "Materia Medica" and "Preparations," which obtains in the last edition, is abandoned in favour of one simple alphabetical arrangement like that of the British Pharmacopœia. The system of chemical nomenclature advocated by Professor ATTFIELD is again followed, and the author of the paper justly claimed that this proved that it was practicable and serviceable in the medicine and pharmacy of an English-speaking people. The old system of weights and measures is abandoned and the formulæ are, as a rule, expressed in parts by weight, but in cases where particulars of volume as well as of weight are required the metric decimal system is employed. The Pharmacopœia opens with a new class of preparations, termed "Abstracts," which are alcoholic extracts mixed with sufficient sugar of milk to make one part of the preparation represent two parts of the original drugs. The class includes abstracts of aconite, belladonna, conium, digitalis, hyoscyamus, ignatia, jalap, nux vomica, podophyllum, senega and valerian. A list of the additions and omissions was given, which cannot be referred to here further than to notice that "aconitia" is omitted, notwithstanding the assistance afforded to the Pharmacopœia Committee by Dr. Wright in respect to a definition of that substance. Further, the doses of drugs are now given, temperatures are stated in Centigrade degrees with Fahrenheit equivalents in brackets, chemical formulæ are inserted as in the British Pharmacopœia, and the molecular weight is appended to each formula. The interest excited by this paper was increased by the fact that Professor Redwood took the opportunity of stating that the preparation of a new edition of the British Pharmacopœia is now in contemplation. He said that he had little doubt that in it the same system of nomenclature would be adopted as in that of the United States, but he spoke with less certainty as to the adoption of the plan of indicating quantities in parts by weight, although he approved of the system and had himself worked it out years ago. He remarked that with respect to the Pharmacopœia of this country a greater conservatism was exercised by the Medical Council than by the body that controlled the United States Pharmacopœia, since it did not introduce any unproved remedies. The reading of this paper brought the first day's business to a close.

In the evening a visit was made to the picturesque ruins of Netley Abbey by upwards of sixty members and visitors, carriages having been provided by the Local Committee. The pleasure of the excursion was slightly marred by atmospheric influences, the splendid view of Southampton Water and the opposite coast being nearly destroyed by the driving rain and mist; but notwithstanding this untoward circumstance the trip proved a very enjoyable one, and much interest was excited by the ruins.

On Wednesday morning the proceedings were resumed by the reading of a paper on "Some Reactions of Arsenic," by Messrs. Naylor and Braithwaite. The first portion of the paper was devoted to the results of some experiments made to test a statement of M. Patrouillard, and introduced into some text-books, to the effect that arsenic acid is easily reduced to arsenious acid by the action of oxalic acid. The authors failed to obtain any confirmation of this statement and expressed an opinion that oxalic acid exerts no reducing action under the conditions described by M. Patrouillard. The remainder of the paper was devoted to an account of the method followed in employing the copper-test, which is based upon the fact of the solubility of cupric arsenate in the double tartrate of potassium and sodium, and to a description of the decomposition which takes place between arsenious acid and mercuric salts.

The next paper read was entitled "Some Results of the Action of the Digestive Ferments on Drugs," and was by Mr. G. Brownen. It described the effect produced by solutions of the gastric ferment and pancreatic solutions upon a number of drugs and their preparations. The results obtained suggest that this field of investigation will prove not only interesting but important to the physiologist, though evidently the value of such experiments will be increased in proportion as the conditions under which they are performed resemble those which occur in the human economy. It was pointed out in the discussion which followed that those conditions are very difficult to imitate, especially such of them as obtain in cases of disease, and it was objected by Mr. Plowman that the temperature at which the experiments were conducted (50° C.) exceeded that of the human body. Some little amusement was caused by the prohibition by the President of any reference to such a subject as "vital force" and by the difficulty some of the speakers experienced in their attempts to avoid the veto.

Mr. E. M. Holmes commenced his "Remarks on the Root of *Aconitum Napellus* and Allied Species" by pointing out that although aconite has long been in use in medicine, and is recognized as one of the most powerful of medicinal agents, its internal administration in this country is not so great as might have been expected. This he considers to be possibly due to variation in the strength of official preparations, and without attributing this variability altogether to the non-recognition in the Pharmacopœia of well-known facts, he says that it appears certain that the requirements of the Pharmacopœia might be complied with and yet preparations of very variable strength be the result. He points out that the figure of the root referred to in the Pharmacopœia is totally inadequate to distinguish the root of *Aconitum Napellus* from that of other less poisonous species, and that the roots imported from Germany are collected by peasants not possessed of any botanical knowledge and sold without any guarantee as to the time of their collection. The difficulty is increased by the fact that the numerous aconites are closely allied, the varieties running one into another, whilst a complete series of the members of the genus is hardly to be found for reference in any botanical garden or museum. He, therefore, considered it worthy of inquiry whether the aconites available for pharmaceutical preparations might not be characterized for practical purposes by the effect produced by them when chewed. He found that the roots of several species did not cause a tingling sensation upon the tongue, including some plants which presented the specific characters of *Aconitum Napellus*, though easily distinguishable from it by habit. But all the aconites in which this variation occurred were observed to flower later than the typical *Aconitum Napellus.* He expresses the opinion, therefore, that the only way to secure aconite of good and uniform quality is to limit the official drug to home-grown aconite, flowering in May and June and gathered while the plant is in flower. He remarks, in conclusion, that aconite is very easy to cultivate and that, considering the small quantity used, there is no reason why any chemist who has a small piece of garden should not grow his own aconite root. Contrary to what might have been expected after the reading of so practical a paper, no discussion followed, and it may be remarked that the comments made upon the papers read at this meeting, as a whole, were far fewer than in previous years.

"Ammoniated Extract of Ergot and a Process for its Preparation" was the title of the next paper read, which was contributed by Mr. A. W. GERRARD. The process consists in macerating 10 parts of crushed ergot for eight or ten hours with frequent stirring in 50 parts of cold water containing ½ per cent. of strong solution of ammonia, straining through flannel, washing the ergot from time to time with more ammoniacal water till exhausted, evaporating the strained liquor to five parts (any scum or fat arising to the surface being removed), treating the cooled extract with an equal volume of aromatic spirit of ammonia, decanting the clear portion after subsidence, filtering the remainder through felt or flannel and washing the residue with sufficient spirit to bring the volume of the extract to ten parts. One part of the extract, which thus prepared is darker in colour than the ordinary form, contains the soluble matter of one part of solid ergot; the average specific gravity is 1000, and the dose is the same as that of the ordinary liquid extract. The advantages claimed for the preparation are that the ammonia not only by its solvent power insures a complete exhaustion of the active principles of the drug, but by its presence in the medicine induces a rapid action by acting as a nervous stimulant. In the discussion which followed it was suggested that the ammonia by forming a soap took up a portion of the oil present in ergot, and thus facilitated the permeation and consequent exhaustion of the drug. The official formula found several defenders, Mr. GREENISH being of opinion that water extracts all the active principle from ergot if the oil be previously removed. On the other hand, Dr. QUINLAN said that in practice he had found ammonia in a preparation of ergot to be useful as a corrective.

Mr. SYMONS then read a paper on "Tumefaction as an Aid to the Identification of the Varieties of Maranta Starch." It contained the results of experiments made by treating different starches with solutions varying from 0·5 to 1·5 per cent. of caustic soda and also by submitting them to various degrees of heat until tumefaction took place. He found that when potato, oat, Natal, tous-les-mois, wheat, Bermuda, sago, maize, cassava, St. Vincent, and rice starches were treated with caustic soda for ten minutes, they required for their complete tumefaction solutions increasing in strength in the order mentioned, from potato with a 0·8 solution to rice which required a 1·3 solution. When tumefied by heat and arranged according to the degree of temperature required, the order of the starches was nearly the same, with the exception of oat and cassava. It is worthy of remark that when using the alkaline method of tumefaction the order of the starches bears out a conjecture recently put forward in this Journal by the author, that the higher the temperature at which a starch grows the higher is its point of tumefaction.

The next paper read was on "The Purity of Commercial Salts of Gold," by Mr. F. W. BRANSON. It gave the result of the examination of some fifteen-grain tubes of commercial salt of gold, eight of which were found to be correct within reasonable limits, whilst four showed a deficiency of 8 per cent. in weight or 5 per cent. in metal. The latter, although obtained from a reputable house, bore neither trade mark, seller's name nor guarantee label.

In the paper next read, on "The Iodides of Bismuth," by Messrs. F. W. FLETCHER and H. P. COOPER, the authors described a new compound of bismuth, a very basic yellow iodide, represented by the formula $BiI_3.5Bi_2O_3$ or $3BiOI.4Bi_2O_3$, met with whilst testing metallic bismuth for lead.

The last paper read before the adjournment for luncheon was a note on "Microscopic Organisms in certain Inorganic Solutions," and contained the details of some experiments made as to the formation of a green vegetable growth in bottles containing solutions of sodium phosphate, magnesium phosphate, and calcium sulphate, kept in the laboratory of the Yorkshire College of Science.

The Conference reassembled at 2.30 p.m. when a paper by Mr. D. B. DOTT on "The Solubility of Morphia Salts" was read. It consisted principally of an adverse criticism of two papers on a similar subject by Professor POWER and Mr. J. U. LLOYD, and incidentally the author mentioned that he is engaged upon the compilation of a table of the solubility of morphia salts, the determinations being made at 60° F. In discussing this paper Mr. R. H. PARKER suggested that it would be advantageous to establish standard conditions under which solubilities should be taken, since the solubility of many substances is much affected by varying circumstances. Mr. J. WILLIAMS said that he looked upon solubility as being closely associated with the power of crystallization, illustrating his remark by a reference to the compounds of caffeine recently described by M. Tanret, which he does not consider to be definite chemical compounds, but mixtures. Mr. P. W. Squire also pointed to the necessity of distinguishing between the point of solubility and the crystallizing point.

In some "Notes on the Pharmacy of Cinchona," Mr. R. W. Giles called attention to the unsatisfactory results that have followed the "fearful deterioration of Calisaya bark," both pharmacy and medical practice having been prejudiced through the consequent substitution of quinine for pharmaceutical preparations of the bark. He recommends that all pharmacists should keep in stock Indian or other non-official bark of sufficient alkaloidal value and that when opportunity offers they should educate the medical profession to the use of it. He considers that the standard adopted for the cinchona of pharmacy should be an alkaloidal and not a quinine standard, that it should be a mean and not an extreme one, and that it should admit barks from all sources. Further, he described a process for the determination of the alkaloidal value of cinchona bark which, he said, though simple and easy of manipulation, gives results near enough for pharmaceutical purposes. He expressed a preference for a fluid extract as a pharmaceutical preparation, but said that a fluid extract of cinchona worthy of its name was still a desideratum. In the discussion of this paper, Mr. Welcome recommended that the standard of a pharmaceutical bark should be fixed at 2 per cent. of quinine with a proper proportion of the other cinchona alkaloids. Mr. Southall spoke favourably of the decoction, which he said was largely used in the Birmingham district, and Dr. Symes said it was also a favourite preparation in Liverpool. On the other hand, Mr. Ekin reminded the Conference that he had found the decoction to be the preparation weakest in alkaloid. The discussion afforded Mr. Hampson the opportunity of saying that changes in the Pharmacopœia would be best effected, when necessary, under the advice of practical pharmacists, and that the Pharmaceutical Society of Great Britain or the British Pharmaceutical Conference ought to be represented in the Pharmacopœia Committee in virtue of legal enactment.

"A Note on the Action of Glycerine upon some Salts of Iron," by Mr. G. F. Schacht, described the results of some experiments arising out of an alteration observed in a mixture made from the following prescription:—"Tinct. ferri perchloridi, ʒiss; glycerini, ʒvj; aquæ, ad ℥vj." The mixture, when first prepared, was of a pale sherry colour and possessed an astringent metallic taste; but the colour afterwards nearly disappeared and the taste became sweet and metallic, but not astringent. The change was due to the reduction of the iron from the ferric to the ferrous condition and experiments showed that this reduction takes place in the presence of ethyl alcohol, glycerine, and probably some other alcohols. Conversely, glycerine appears to retard though not absolutely to prevent the oxidation of the proto-salts. The President said that this action of alcohol upon a per-salt of iron had been long known, an ethereal spirit of chloride of iron prepared in this way having been formerly official in a continental Pharmacopœia.

In a "Note on a Reaction of Glycerine and Polyhydric Alcohols," Mr. W. R. Dunstan recorded the observation that the acid solution obtained by the addition of glycerine to an aqueous solution of sodium biborate becomes alkaline when heated. The reaction is also given by many other polyhydric alcohols and by certain sugars.

The interest excited by the introduction of Professor Barff's "Boro-glyceride" has induced Mr. D. Hooper to make some experiments upon the "Solubility of Boric Acid in Glycerine." He finds that at zero 100 parts of glycerine dissolve 20 parts of boric acid, that at 100° C. the quantity dissolved is increased to 72 parts, and that between these two temperatures the solubility is represented by an almost straight line.

Mr. B. S. Proctor, having been somewhat sceptical as to the cause of the non-appearance of the results of oxidation in a commercial sample of liquor of iodide of iron, was induced to examine it, and the results furnished the subject of the next paper read. He proved the presence of phosphoric acid by its separation as ferric phosphate and that of oxalic acid by its separation as ferrous oxalate. The liquor also did not contain the quantity of iodide of iron required to make a syrup of full strength, when used according to the directions accompanying it. At the conclusion of his paper Mr. Proctor somewhat cynically suggested that if any pharmacist feels impelled to any other expedient than that of keeping his solution in contact with an iron wire he had better at least know what he is doing, and add the adulterations himself rather than buy the liquor ready adulterated, not knowing what it contains. Mr. Fletcher expressed a doubt whether any manufacturer who had a reputation to lose would add such a substance as oxalic acid, and, referring to the acidity of the liquor which had been mentioned by Mr. Proctor, said that it might be due to free hydriodic acid which is always formed. The usual *pro* and *con.* statements with respect to the permanence of syrup of iodide of iron and the effect produced by iron wire or light were made by different speakers, and Professor Tichborne expressed an opinion that a frequent cause of failure was that the heat was not continued long enough in making the solution of iodide of iron to sufficiently remove the hydriodic acid formed.

A "Report on the Strength of Commercial Samples of Tincture and Liquid Extract of Opium," by Mr. J. Woodland, was then read. Fourteen samples of tincture had been examined, and taking the percentage of morphia present as a criterion, eight of them appeared to have been prepared from opium exceeding in morphia strength the Pharmacopœia standard; the other six were more or less deficient. Of ten samples of liquid extract of opium none reached the standard, and in one or two cases the percentage of morphia was very low.

The last paper read was a "Report on the Purity of Commercial Samples of Silver Salts," also by Mr. Woodland. It stated that caustic points had been found to contain from 25 to 36 per cent. of potassium or sodium nitrate, crystals of silver nitrate from none to 19 per cent. of the same diluents, and oxide of silver from 13 to 26 per cent. of impurities. It was remarked by the President that potassium nitrate is avowedly added in the preparation of caustic points in order to give them greater toughness, and Mr. J. Williams said that nitrate of lead is used for the same purpose. Both Mr. Williams and Mr. Naylor expressed surprise at the statements with respect to silver oxide and said that it did not usually contain more than 1 or 1½ per cent.

The next business of the Conference would have been to decide as to the place of meeting in 1883; but the President having stated that it was not yet settled what town should be visited by the British Association,—the arrangement with respect to Oxford having fallen through,—it was agreed to leave the decision in the hands of the Executive Committee.

The election by ballot of officers for 1882–83 then took place with the following result:—

President.—Prof. Attfield, Ph.D., F.R.S., F.I.C., F.C.S.

Vice-Presidents.—M. Carteighe, F.I.C., F.C.S., London; J. R. Young, Edinburgh; C. Umney, F.I.C., F.C.S.

Treasurer.—C. Ekin, F.C.S., Hounslow.

General Secretaries.—F. Baden Benger, F.C.S., Manchester; S. Plowman, F.I.C., London.

Other Members of Executive Committee.—Alexander Kinninmont, F.C.S., Glasgow; J. C. C. Payne, Belfast; W. A. H. Naylor, F.C.S., London; R. Chipperfield, Southampton; P. W. Squire, F.L.S., F.C.S., London; G. S. Taylor, F.C.S., London; J. C. Thresh, D.Sc., F.C.S., Buxton; F. W. Fletcher, F.C.S., London.

Auditor.—James Spearing, Southampton.

Nothing now remained for the Conference to do but to record its sense of indebtedness to those friends who had contributed in various ways to make the meeting a success. First, the cordial and well-deserved thanks of the non-resident members were accorded to the Local Committee, and especially to Messrs. Randall, Chipperfield and Dawson, for the successful way in which they had carried out the arrangements. Then a vote of thanks was passed to General Cooke, Director-General of the Ordnance Survey Department, for his kindness in affording facilities to the members to visit the Ordnance Survey Offices and inspect the operations going on there. Last of all came an enthusiastic vote of thanks to the President, for his conduct in the Chair, and the members of the Conference then separated, not without some misgivings as to the weather for the evening Excursion.

Any fears, however, which might have been entertained during the storm which raged on Wednesday night, as to the condition of the weather on the following day, were fortunately dispelled. The morning was faultless; the sun brilliant and the air delightful. Before half-past eight, the hour fixed for starting, members of the Conference were making a forced march to the pier-head, many, judging from an indescribable expression of "goneness" in their features, having evidently sacrificed breakfast to a heroic determination to be punctual. The steamer engaged for the trip was one of the finest boats in the Isle of Wight Company's service, and about one hundred and twenty excursionists, including a fair proportion of ladies, were on board when, a little before nine o'clock, the signal for departure was given. The run to Ryde was most enjoyable, affording as it did, glimpses of many objects of interest; Netley Hospital, with its magnificent façade, and the ruins of the fine old Abbey close by, well contrasted the spirit of the Past and the Present, and Osborne, so delightfully situated amidst the peaceful beauty of its surrounding, evidenced the gentle spirit of its Royal occupant.

Ryde was reached at 10·30, where a train was waiting to convey the party to Brading. Alighting here, a pleasant stroll through lanes and fields, rich in spoils for the botanists, brought the visitors to the remains of the Roman Villa. An inspection of the mosaic floors, some of which are in very perfect condition, and the many archæological treasures which have been turned up during the excavations, detained the company here until 12·30, when train was taken to Ventnor.

A short distance from the town, on the Bonchurch Road, a substantial luncheon was served on the lawn in front of the residence of Captain Roache, who had kindly thrown open his grounds for the reception of members of the Conference. The majority of the party then made their way through Bonchurch to the Landslip. The magnificent scenery of this spot is too well known to need description; suffice it to say that the expanse of sun-illumined sea on the right hand and the solemn grandeur of the grey crags to the left, intermingled with the varied tints of the luxurious foliage, made up a scene which by those who witnessed it for the first time will never be forgotten, and which by those who had already seen it many times before will ever be remembered with increased delight.

On the road along the cliffs to Shanklin stands the private residence of Mr. Gibbs, of Ryde, and at this point a pleasant surprise awaited the excursionists. Mr. Gibbs, gracefully assisted by his wife, welcomed into his house successive detachments of the party as they arrived; and beneath his hospitable roof every kind of comfort and refreshment was set before them. In the dining room were choice wines and fruits, and in the drawing room, tea, coffee, and other light refreshments. Coming as it did so unexpectedly, and dispensed so courteously and generously, Mr. Gibbs's hospitality constituted one of the most delightful incidents of the trip.

After passing through the village of Shanklin and visiting its celebrated Chine, the party returned by rail to Ryde, and thence by steamer to Southampton, where, at 7.30, high tea was served at the Royal George Hotel. Numerous speeches followed, and at a late hour the company dispersed, unanimous in the opinion that a pleasanter excursion had never been spent by the Conference.

Amongst the members of the Local Committee singled out for special thanks were Mr. Randall, the courteous Chairman, Mr. Dawson, the assiduous Honorary Secretary, and last, but not least, Mr. Chipperfield, the energetic "Acting Manager."

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The Nineteenth Annual Conference commenced its sitting at the Watts Memorial Hall, Vincent's Walk, Southampton, on Tuesday morning, the 22nd inst, at 10.30 a.m., under the Presidency of Professor Attfield, Ph.D., F.R.S., F.I.C., F.C.S. During the Conference about one hundred and twenty persons signed the book.

Welcome to the Conference.

Mr. W. B. Randall (Southampton), Chairman of the Local Committee, said he was deputed by his brother pharmacists to say how pleased they were to see the British Pharmaceutical Conference meet in Southampton. The gentleman who conveyed the invitation to the Conference at York last year mentioned certain disabilities under which they laboured in undertaking this duty, but notwithstanding that, with the help of their brethren in the neighbourhood and of some friends at a distance, they trusted they had been able to make such arrangements as would make members of the Conference comfortable and minister to their enjoyment during their visit. They could not say at Southampton that they were favoured by nature with those mineral treasures which added so greatly to the population and wealth of the localities where they were found, but they might boast, perhaps more than some of those localities, of the beauties of nature, and he ventured to think that this was as good a part of the country to work in, and to enjoy life in, as those parts where there might be more mineral wealth. It was quite certain that the monks of old thought this locality a good one, and they were not bad judges, for they put up Netley Abbey, of which the stately ruins might still be seen. The Government of our own day had much the same feeling, for they erected Netley Hospital close to the ruins of the Abbey. The old Norman kings too must have thought something of the South of England, for they made their hunting grounds in the New Forest, and Her Gracious Majesty the Queen and her lamented Consort appeared to have thought the same when they chose Osborne as one of their royal residences. He might say something too, if time permitted, about the historic associations of Southampton. It was there, he believed, that Canute gave that celebrated rebuke to sycophancy which all would remember, and that lesson in reverence which was now-a-days, he believed, equally needed. In that neighbourhood too, in his early days, ran about a man who had taught some amongst them the close observation of nature, when he recommended them to imitate the industry of the busy bee, and who also taught many of them their first lessons in logic, for his handbook on that science had the honour for some time of being the text-book in one of the universities. He alluded to Dr. Watts, after whom the building in which the Conference was assembled had been called, and on whose father's garden it stood. He would detain them no longer from the address they were anxious to hear, but in the name of the pharmacists of the south-western district, including those residing in the garden of England across the Solent, he bid the British Pharmaceutical Conference welcome to Southampton.

The President, in the name of the Conference, thanked Mr. Randall for the kind words of welcome he had uttered. He begged also to express the hope that, in return, the meeting of the Conference might be the means of doing some good to the pharmacists of Southampton and the district.

Reception of Delegates.

Mr. F. B. Benger (General Secretary) then read the list of delegates from various societies, who were collectively welcomed by the President.

The following is a list of those present:—

From the *Pharmaceutical Society of Great Britain.*—Mr. S. R. Atkins (Vice-President); Messrs. F. Andrews, T. Greenish, F.C.S., F.R.M.S., R. Hampson, W. D. Savage, G. F. Schacht, F.C.S., P. W. Squire, C. Symes, Ph.D., F.C.S. and J. Williams, F.I.C., F.C.S.

From the *North British Branch of the Pharmaceutical Society.*—Messrs. Borland and J. B. Stephenson.

From the *Pharmaceutical Society of Ireland.*—Professor Tichborne, Ph.D., F.I.C., F.C.S. (President); Messrs. W. N. Allen, H. Bennett and Payne.

From *Birmingham.*—Mr. Southall.

From the *Brighton Association of Pharmacy.*—Messrs. Padwick and W. D. Savage, J.P.

From the *Bristol Pharmaceutical Association.*—Mr. G. F. Schacht (President).

From the *Liverpool Chemists' Association.*—Mr. Mason and Dr. Symes.

From the *Leicester Chemists' Assistants and Apprentices' Association.*—Mr. J. W. Clarke.

From the *London Chemists' Assistant's Association.*—Messrs. W. A. Wrenn (President), and C. E. Stuart, B.Sc.

From the *Manchester Chemists and Druggists' Association.*—Messrs. F. Baden Benger, F.C.S., and A. H. Jackson, B.Sc.

From the *Sheffield Pharmaceutical and Chemical Society.*—Mr. J. Preston (President).

From *York.*—Messrs. Clark and Dresser.

Mr. Benger then read the report of the Executive Committee, as follows:—

Report of the Executive Committee.

Since the last general meeting of the Conference at York, your Committee have met on several occasions in London, chiefly for the transaction of business connected with the publication and distribution of the 'Year Book,' the issue of the Blue Lists and other circulars, the collection of members' subscriptions, and the organization of the present meeting.

At a meeting held in December, Mr. Siebold was re-appointed editor of the 'Year Book' for 1882. The manuscript of the forthcoming volume, so far as it can be completed up to this date, has been placed on the table. There remain to be added to it the Introduction, the Bibliographical section, the Transactions of the Conference at this meeting, and the Index.

Members will have observed that in the 'Year Book' for 1881 the various alterations and improvements alluded to in the last Report of your Committee have been carried out. A new section, "Bibliography," comprising titles of books, pamphlets, etc., on chemistry, botany, materia medica, pharmacy, and allied subjects, published between July 1, 1880, and June 30, 1881, has been added. The abstracts are somewhat more condensed than in former years and are more numerous, one of the lists of members—that in which the names were classified under those of the cities and towns in which they reside—has been omitted, and better paper has been employed. The issue of a general index has been postponed for financial reasons.

It being very desirable to enlist the sympathies and secure the friendly co-operation, in Conference matters, of colonial pharmacists as far as possible, steps have been taken to place the Blue List of subjects suggested for investigation in the hands of the principal pharmacists residing in some of the British Colonies. In carrying out this arrangement, the assistance of local Pharmaceutical Associations has been kindly afforded. Your Committee have already been informed of the distribution of the papers sent to Victoria, and twenty-one applications for membership have already been made in consequence.

Letters have been received from Mr. Bosisto, the President, and Mr. Shillinglaw, the Secretary of the Victoria Pharmacy Board, expressive of the cordial interest taken by them in the proceedings of the British Pharmaceutical Conference, and offering to distribute, at any time, Conference circulars free of cost.

One application only for a grant in aid of research has been made, that of Mr. Alfred H. Jackson, B.Sc., of Manchester, The sum of £10 has been placed at this gentleman's disposal for the purchase of materials wherewith to conduct an examination of the essential oils of cinnamon and cassia, with a view to discover some chemical or physical distinctions. Mr. Umney was good enough to undertake the distillation of these oils from the respective barks, thereby guaranteeing their purity, and Mr. Jackson will present a first report to the present meeting. Mr. Gerrard, to whom a grant was voted last year, has continued his investigations on the relative values of wild and cultivated belladonna, and on the activity of the various parts of the plant, and will furnish a further report.

Mr. H. G. Greenish, who was also the recipient of a grant last year to aid his investigation of the principles of *Nerium Oleander*, writes, "The publication of the results that I have hitherto obtained would probably lead only to confusion, as they involve the modification, to a certain extent, of statements made in a 'Preliminary Note,' published in the *Pharmaceutical Journal* some time since and are in themselves but incomplete." The reception of Mr. Greenish's report is therefore postponed.

Your Committee take the opportunity of again reminding members that there are funds ready to be placed at their disposal, to defray the cost of materials used in the investigation of subjects suitable for Conference Reports, and they cannot refrain from an expression of disappointment that so few avail themselves of this assistance.

Your Committee regret the loss of the valuable services of one of the Honorary General Secretaries. Mr. Carteighe, having been elected President of the Pharmaceutical Society of Great Britain, felt it to be his duty to that Society to resign the position as Secretary he held with us.

Mr. Sidney Plowman, F.C.S., having been asked by his fellow members of the Committee to act provisionally as an Honorary Secretary until an appointment could be made, has assented to do so.

Fifty-seven gentlemen have been elected members since the last annual meeting.

Mr. Ekin (Treasurer) read the statement of accounts for the past year, which is printed on page 169.

The President, in moving the adoption of the report, said he trusted the Conference would be satisfied with the work of the Committee during the year. He would remark, in reference to the small deficit which marked the operations for the year, that the Committee did not seek to save money; it desired to spend every penny received. In past years, more by accident than anything else, the Conference had accumulated £300 or £400, which was quite sufficient to stand between it and bankruptcy, and he should be quite satisfied if that amount remained to its credit. As to whether in any year there might be a deficiency of a few pounds, or an increase of a similar amount, need not cause much trouble. If anyone had any misgivings on this point, however, he might reflect with satisfaction that very shortly a post-office parcels post would be in operation, which would save at least 2*d.* per volume in the delivery of the 'Year-Book.' But when the Conference came to ask the registered chemists and druggists of the country who were not already members of the Conference to become so, he thought there would be such an increase of membership as would remove any possible difficulty there might be in the way of finance. With regard to the general index to the 'Year-Books,' to workers at pharmacy it would be a great advantage to have a general index to the whole of the volumes, and two years ago it was suggested that such a general index should be published. The Committee had considered the matter carefully, and were somewhat surprised to find that the production of such a work would cost a considerable sum, and just now they did not happen to have funds in hand for that purpose. He had no doubt that in the course of a year or two such funds would be forthcoming, and one of the first objects to which they would be applied would be the production of the general index.

Mr. W. D. Savage (Brighton) seconded the motion, which was then put and carried unanimously.

The Bell and Hills Fund Gift of Books.

Mr. Ekin said he was happy to be able to state that the Local Committee saw its way to accept the gift of books from the Bell and Hills Fund, and to make arrangements by which they would be available to all the chemists of Southampton. He regretted that it had not been decided a little earlier, so that the books might have been presented on the spot; but the selection had been made, and they would shortly be sent to Southampton.

Mr. Randall said the pharmacists of Southampton accepted this gift with very much pleasure and thankfulness, and they hoped it might lead some day to their having their own place in which to keep and use these books, and even to something beyond that. If it did, it would have done them considerable good, and he must say, in his opinion, the donors of this gift had done great good by giving such practical lessons in the value of a good library.

Mr. Sidney Plowman (General Secretary) then read the following letter from Professor P. W. Bedford, President of the American Pharmaceutical Association:—

"Professor John Attfield, Ph.D.,
"President,
"British Pharmaceutical Conference.

"Dear Sir,—Allow me to congratulate yourself and the Conference on the assured success of the coming meeting at Southampton, and to express my regret that I have to do by letter what I would far rather do in person. I had hoped that ere this I should have had the pleasure of attending one of the gatherings of the British Pharmaceutical Conference, but it is still one of the prospects of the future.

"I trust that in numbers it will be the largest meeting yet held; in papers, most numerous; in discussions, most profitable; in social pleasure, the most enjoyable.

"I recently forwarded to you proof sheets from the corrected plates of the first ninety-six pages of the text of the forthcoming U.S. Pharmacopœia; and, with this, I have the pleasure of sending the succeeding forty-eight pages; all that are as yet in presentable condition.

"It will serve to show yourself and friends of the British Pharmaceutical Conference, that it will be a work worthy of the labour bestowed upon it.

"It is the only copy that has gone outside our Committee, and I take pleasure in sending it to one that has honoured his own land by his worthy work in the cause of pharmacy, and in our own land is as well known by his scientific labours in our profession. Another tie exists: it is the remembrance of the practical sympathy and interest which years ago was extended to those of our profession who saw their College of Pharmacy vanish in the flames.

"The annual meeting of the American Pharmaceutical Association follows close after that of the Conference. I trust that it may be possible for us at that meeting to extend a cordial welcome to some of our fraternity from England.

"May the British Pharmaceutical Conference ever prosper, ever be an active promoter of the true welfare of our profession, and stand as an able exponent of the best talent of pharmacy in England.

"Very sincerely yours,
"P. W. Bedford,
"*President,*
"*American Pharmaceutical Association.*"

Letters expressing regret at not being able to be present had also been received from Mr. Richard

FINANCIAL STATEMENT FOR THE YEAR ENDING JUNE 30, 1882.

The Hon. Treasurer in Account with the British Pharmaceutical Conference.

Audited and found correct, { RICHARD DRESSER / JAMES SPEARING } *Auditors.*

Reynolds, late President of the Conference, Professor Bentley, Messrs. Siebold, Umney, Stanford, Proctor, Young, Taylor, Thresh, Kinninmont, Frazer, and others.

The PRESIDENT then delivered his address as follows:—

THE PRESIDENT'S ADDRESS.

Pharmacy, in every country, has high duties to perform towards the State. The humble handmaid of medicine, she has to aid in maintaining that greatest of physical blessings, health; to aid in restoring those from whom that blessing is temporarily withdrawn; and to aid in soothing the life of those to whom that blessing will never come again. From earth and sea, and the living things they foster, pharmacy draws forth drugs new and old, gives them convenient shape, and distributes them to the community. Ever conservative, she searches the whole globe for supplies of medicaments, well known, well tried, and reliable; ever progressive, she searches the realms of nature and the regions of art for new materials wherewith to aid in combating disease and death. And when she has found her *materia medica*, she is unwearied in elaborating them, and unremitting in her endeavours to place them—by her possibly too competitive and too varied agencies—at the door of every dwelling in the land. Exhaustive research, careful manufacture, thorough distribution: these are the means by which her duties are fulfilled.

Is pharmacy performing those duties with the maximum of efficiency, either in the world generally or in any country particularly? Can she better search, better elaborate, better distribute? Can she in any way better meet the public demands made upon her? Can she better serve mankind, either herself directly, or through the profession of medicine? Is she performing any one of her duties better in some countries than in certain others; and, if so, can the international agencies for the exchange of pharmaceutical information be improved in character or wisely increased in number? Is a community best served, in the matter of pharmacy, by a large number of distributors of elaborated drugs, only a few persons being manufacturers of the preparations; or by a smaller number of distributors, each of whom makes his own preparations? Can the followers of pharmacy show the civilized States of the world, or show the governing body of any one State, how legislative enactments, new or extended, will better enable her to perform her high duties?

These are vital questions—vital to the health and therefore to the happiness of society, vital to pharmacy.

They are questions which may well form the subject of an address on the present occasion to a non-political society of pharmacists—the British Pharmaceutical Conference. For with one exception, the last, which will only receive such a passing notice as previous presidents have given to politics, the questions lie outside the area of legislation and administration. Lying also, as they do, outside the area of that original pharmaceutical research, the promotion of which is the chief object of the Conference, their consideration will form an agreeable relief to our deliberations on more technical matters.

They are questions which should strike home to pharmacists as individuals. For does any follower of pharmacy desire to promote even his own sole interest? Let him remember that the better he performs the duties the public require him to do, and have put him amongst his drugs to do, the greater will be his personal success. Let him reflect that he is only one member of the pharmaceutical body, and that in the degree in which he contributes to the welfare of the whole body does he promote his own welfare. Let him never forget, in short, that in pharmacy, as in every other walk of life, the highest self-interest is to be found in the forgetting of self. The requirements of the public have called him into existence; the requirements of the public maintain him in his position; only in proportion as he meets the requirements of the public will he promote his own interests or raise either himself or his calling.

Collection; Preparation; Distribution.—We must glance at the present condition of the machinery with which we perform our pharmaceutical duties before we can usefully consider possible improvement.

Collection.—In searching for supplies of the old and well tried natural drugs, pharmacy presses into her service natives of many climes and traders of many nationalities. In growing those drugs more or less artificially, she employs thousands of workers in all countries. In making her more strictly artificial saline remedies, she contributes to the support, is often the chief and sometimes the only support, of the chemical industries of Europe and America. And in the exercise of her demands for new remedial agents, she looks to the original researches and discoveries of the traveller, the botanist, the zoologist, the mineralogist, the scientific chemist. Her followers themselves largely conduct original research and discovery; they also largely foster research and discovery by banding themselves into Societies, Associations and Conferences, for the initiation of original pharmaceutical research, for the payment of expenses incurred in research, and for the free publication of the results of research.

Preparation.—To manipulate raw drugs and to manufacture compounded drugs is perhaps pharmacy's most special duty, the work which gives to pharmacy a distinctive stamp amongst man's many vocations. For it is her peculiar art to find the fittest form in which the animal product, the medicinal plant, or the crude mineral shall most directly, easily, and even pleasantly it may be, do the work it is intended to do. From the plant, animal, or mineral which observation or more minute research has shown to have medicinal value, pharmacy must carefully, step by step, and constantly testing progress, eliminate what is valueless, until she is able to say that a simple aqueous infusion or decoction contains all the activity of the raw material. Perhaps she finds that the active matter is only removable by more spirituous fluids, and hence produces a "tincture." May be she proves that the aqueous or spirituous fluid, without harm and with some advantage, may, by the boiling away of the solvent, be concentrated to a soft solid or "extract." Possibly, after much labour, she obtains from the crude drug one or more of the actual principles in which reside its activity; extracting such an alkaloid as quinine, such a substance as salicin, such a body as citric acid, such a salt as cream of tartar. Whether she always extracts the active principle or not, she must ascertain its properties in order that its presence may at any time be verified, or perhaps its purity be demonstrated, and in order that she may avoid mixing antagonistic or incompatible drugs when she distributes compounded drugs to the public.

To accomplish this manufacturing or manipulative work, either all or some of the followers of pharmacy must possess extensive knowledge. They must have sufficient preliminary education and mental training to enable them intelligently to study the scientific books they will have to master, and to comprehend the principles on which their work is based. They must as pupils give a few years to the acquirement of *materia pharmaceutica*, in order that they may be familiar with the standard physical characters, the general medical qualities, and the commercial importance of the many hundreds, if not thousands, of elaborated materials or mixtures of materials which they desire, sooner or later, to prepare for themselves. They must have some knowledge of botany, as well as of animal and mineral products, or they will not be able to judge of the raw materials with which they will have to deal. They must have a fair knowledge of the natural forces and of mechanics, or they will not be able to convert the raw drugs into preparations having the maximum of medicinal activity and convenience of form or shape, with the minimum of unpleasant flavour, odour and appearance. They must have a considerable knowledge of chemistry to enable them to judge of the qualitative character of many drugs, and the quantitative character of most, the purity of the chemical substances which they purchase, the state of activity of preparations that have been long in stock, the compatibility or incompatibility of the components of mixtures they are called upon to prepare. A very large amount of such professional and commercial knowledge must be forthcoming somehow and somewhere from the pharmaceutical body for pharmacists rightly to do their duty to the State, as elaborators, or manufacturers, or compounders of drugs. Whether all pharmacists or only some should possess this knowledge, is a question yet to be discussed. The point up to which division of labour is desirable and beyond which it is undesirable, will be considered subsequently.

Distribution.—In every civilized State somebody must bring drugs within reasonable reach of every household. Very different agents perform this duty. There is, first, the pharmacist proper, who is not only a distributor but a manufacturer or compounder of the pharmaceutical preparations he distributes; the man who can warrant the purity and efficiency of every drug he distributes, either because he has tested it, or because he has made it himself from materials which his professional knowledge tells him to be trustworthy; the only pharmacist, therefore, who can offer a personal guarantee that the medicine prescribed by a physician will, as medicine, have the effect intended. There is next the druggist, who makes few, if any, compounds, trusting for their purity and efficiency to wholesale manufacturers, and who is able to test few, if any, of the articles supplied to him; but who has such experience of pharmacy as well fits him to supply a widespread demand for drugs—especially in suburbs of cities, and in the small towns and the villages of a country. Third in importance as a distributor of drugs, is the general practitioner of medicine, who, if he even has less knowledge of drugs than the druggist just alluded to, supplies an important demand, not only where pharmacists could do the work, but in outlying country districts remote from a druggist's shop of any kind. Fourthly, the distribution of drugs is effected, to some extent in the aggregate, in certain countries, by shopkeepers other than druggists; that is to say, by grocers, drapers, and such vendors, who admittedly know nothing about drugs, and who, except that they buy in bulk from the wholesale dealer or manufacturer, and retail in small quantity, sell the drugs in the state in which they are received. Lastly, drug distribution is, in certain countries, extensively accomplished by the agency of portable proprietary preparations termed "patent," though only so-called, now-a-days, in a *lucus a non lucendo* sense, the composition of most of them being a secret. These compounds pass from the producer to the consumer, either by the agency of the retail dealer, often but not always a pharmacist, or through the post-office. The maker of the patent medicines may or may not be a person having knowledge of drugs, and may not even reside in the country in which his articles are sold, therefore may not be legally responsible for any harm caused by their use or misuse.

The relative numbers of these five classes of drug distributors doubtless vary considerably in different countries, and probably cannot be ascertained for any one country. In Great Britain, for instance, there are some thirteen thousand registered "Chemists and Druggists," but how many of these are in business on their own account, and how many are assistants who have passed the qualifying examination, we do not know; nor do we know how many of those in business on their own account are mere vendors of drugs, and how many can give, respecting all their drugs, the personal guarantee of purity and efficiency already alluded to. There are twenty-three thousand registered practitioners of medicine in Great Britain and Ireland, but how many of them are direct distributors of medicines we do not know. What amounts of drugs are annually sold by grocers, drapers, and other non-pharmaceutical vendors we do not know. Patent medicine stamp duty to the amount of nearly £140,000 was paid into our Inland Revenue in the year ending March 31, 1881, which is equivalent to at least one million of pounds as the present annual payment by the public for secret remedies. But many proprietary medicines are not liable to stamp duty; so that the extent to which drugs are distributed in this way we do not quite know, though it is obviously very considerable.

Thus far the position of pharmacy in relation to the State has been defined, and an outline given of the means or method or machinery—partly haphazard, partly almost naturally evolved—by which pharmacy performs her State functions of collecting, elaborating, and distributing drugs.

Does this existing condition of pharmacy admit of improvement? If so, in what directions?

These are questions of great importance to the community. They are also of the highest importance for the pharmacist, both from the point of view of bounden duty to the State, and from that of obvious self-interest.

That the pharmacy of the present day admits of improvement will probably be admitted by the pharmacists of every State. What human institution does not? But respecting the directions in which improvements may be effected, the period at which they may be introduced, and the rate at which they may be carried out, there will be differences of opinion, especially as regards different States. The pharmacists of each separate nation must therefore separately discuss this question, at all events, as a preliminary step to international discussion at any future time. Our own discussion of the relation of pharmacy to the State will at present be carried on solely from the British standpoint.

Collection; Elaboration; Distribution.—Let us again in this order consider the general direction of possible improvements in our important and honourable State relations: our relations on the one hand to remedial agents, and on the other to our fellow-countrymen, who all, at one time or other, need remedial agents.

Collection, including, as already indicated, commercial investigations and original research.—The therapeutical importance of quinine and morphia have secured attention to the cultivation of the cinchona tree and the opium poppy; but for the vast majority of vegetable drugs, we still have to rely, as regards quality, on the somewhat capricious kindness of unaided nature, and as regards quantity and quality, too often on the good and bad consciences, and perhaps commercial cupidities, of more or less ignorant and irresponsible collectors. Why should not drug farms be more generally established, even in Great Britain? Is land required? Many food farms are being thrown out of cultivation in this country. Would farming other than food farming be likely to be remunerative? Flower farming and fruit farming are among the most lucrative callings in these islands. Could not some pharmaceutical body emulate the Royal Agricultural Society with its Woburn experimental farm? May we not hope that a Lawes will arise in pharmacy, who, founding a Rothamstead, will pioneer us towards the successful scientific cultivation of most of the medicinal plants? The area of pharmaceutical research, in the largest sense of that term, including improved modes of collecting as well as of investigating drugs, could be extended by the State, by societies, and by individuals. But State aid to research of any kind is almost necessarily accompanied by State control, and some peoples are impatient of control, and do their duties to their calling and to the public with the maximum of efficiency in an atmosphere of freedom. State aid in carrying on research in pharmacy would probably be less effective than internal effort, hence improvement in pharmaceutical research by such aid is scarcely to be expected. Internal effort to improve and extend pharmaceutical research may come from societies and from individuals. And already in Great Britain the Pharmaceutical Society and the Pharmaceutical Conference have given good aid to research, especially in affording opportunities for individuals in pharmacy to bring their researches before their fellow pharmacists, to publish researches without expense, and in the case of the Conference to carry on researches at diminished expense. But any really comprehensive scheme of aid to research by societies, as societies, needs far more ample funds than those at the disposal of the bodies just named; and the source of such funds is not obvious so long as two-thirds of the pharmacists of the country stand aloof from the other third in all matters pertaining to the general pharmaceutical welfare, withholding even that small annual subscription which, contributed by the many, would allow of so much good in many directions being accomplished. In the matter of pharmaceutical research by individuals, English pharmacists, even with the limited aid of the Pharmaceutical Society or the Pharmaceutical Conference, are holding their own, let us hope, but not much more. Such men as a Deane, a Morson, or a Squire need no incentive. Force of character and love of truth for its own sake have always and will always bring a few such men to the front, but we can never hope to see many there. The educational endeavours at the headquarters of the Pharmaceutical Society during the past forty years have always included efforts in the direction of the encouragement of research, and associations of students and assistants for the prosecution of investigations, more or less original, have been the immediate outcome, a subsequent result being the enleavening spread of active workers at original research, and men having sympathy with original research, throughout the whole country. The introduction of compulsory examination into British pharmacy in 1868 was expected to result, *inter alia*, in such an impetus to education as would carry large numbers of young pharmacists into the region of original investigation. That such an impulse has not resulted, that the cause of the failure has been detected, and that a remedy has been found and is to be applied forthwith, are now matters of history. Soon again will every young pharmacist in this country have such opportunities for acquiring sound pharmaceutical education as will start him fairly on the road to research; and we may reasonably expect that a certain proportion will continue to travel along that grand highway. Sooner or later, therefore Great Britain, let us hope, will be not only abreast, but ahead, of other countries in the matter of pharmaceutical discovery; that is to say, in the matter of a more extended and trustworthy *materia medica.*

In the matter of the improved collection of drugs, therefore, including the development of the maximum activity of medicinal plants and general control over their growth, and including the prosecution of those branches of original research which shall extend the number and the definiteness of drugs, there is room for great improvement in English pharmacy.

Elaboration.—Is a State best served, as regards pharmacy, by a large number of distributors of elaborated drugs, only a few persons being manufacturers of the preparations, or by, probably, a smaller number of distributors, each however making his own preparations? "A smaller number," because, in any calling, the greater the skill, knowledge, and intelligence of its followers, the greater their reasonable expectations of remuneration, and therefore the fewer that can be supported by the community. Now, in Great Britain, unquestionably, the tendency—at all events during the past fifty years—has been for fewer and fewer of the distributors of drugs to manufacture their own medicinal preparations, the retailer relying for these more and more on wholesale manufacturers. Is this practice likely to promote the interests either of the public or of the pharmacist himself? In dealing with a druggist for drugs, simple or compound, the public expect to be served with what is trustworthy. The vendor is a "chemist" as well as a druggist; therefore, presumably, he can chemically verify the trustworthiness of those of his drugs which have chemically definite characters. But he is a "druggist" as well as a chemist; therefore, presumably, he can guarantee the trustworthiness of his non-chemical drugs and drug-compounds. How can he do this if he has not himself prepared those compounds? For they cannot be assayed chemically. Nay, if he has not himself made them from the raw drugs, and thus by long acquaintance with the latter become thoroughly familiar with them, and a thorough judge of their character, how can he guarantee the quality even of what few drugs he may sell in the raw state? Further, if a druggist has not made his own preparations, and has not tested those he purchases—either because he himself cannot test them, or because they are beyond the grasp of chemical analysis,—is he one whit the superior in pharmacy to his neighbour, the medical practitioner? Possibly both purchase their compounds of the same wholesale dealer. And if such a *soi-disant* druggist is not more of a druggist than the medical practitioner, where is the foundation for the hope that the medical practitioner will some day turn over all his medicine-making to the pharmacist?

Again, if the druggist is only a distributor and not a compounder or elaborator or manufacturer of drugs, has he much more claim to be even a distributor than a grocer or any other trader who buys or distributes drugs? Is the State much better served by one of these distributors than by the other? Let there be no misunderstanding here. The cry of "drugs for the druggist" is a good and wise cry, but only when founded on the druggist's knowledge of drugs, and on his personal guarantee of their efficiency,—a guarantee founded, as before stated, on his having either made or tested all, or practically all, of his preparations. If he merely buys and sells his preparations, without such personal knowledge, he cuts his own professional platform from beneath his feet. Having taken up the ground of a mere trader, can he wonder if other more astute traders beat him on that ground. Neglecting what ought to be his own cherished art of elaborating or compounding his preparations, can he wonder if he has to relinquish that remuneration, those profits, which were born of the times when the druggist was such a manufacturer,—profits which are still enjoyed by those who do so manufacture. Relinquish them he must if he deliberately labours on the lines of mere trade. In these days of over-population and, consequently, keen competition, no other result can ensue. It is a case of reaping what is sown. And the sooner such a man realizes his position and adds to his trade the trades of those who otherwise will supplant him, the sooner will he be saved from ruin. This differentiation between trading retail druggists and manufacturing retail druggists is already going on. Afterwards there will be another. Some day what remains of the trading retail druggist's trade in drugs will flow away from him to the counter of the manufacturing retail druggist, even though the latter be charging higher prices; for in proportion as purchasers find they cannot judge for themselves, they will go to those who can judge for them. Then if the trader has cultivated other trades, he will have them to fall back upon. Fortunately, in the long run the fittest must survive: the fittest tradesman who is only a tradesman, and the fittest pharmacist who is a tradesman and a professional man too. Does the pharmaceutical apprentice of to-day desire future pharmaceutical success? Let him master the principles of his art. Let him practically learn how, by the aid of chemistry and botany, to test the quality of most of the articles he works with, and how to manufacture what cannot be tested.

Broadly, as a matter of self-interest and sound policy, the preparation of medicinal compounds by a few druggists only, and their mere distribution by the many, is a practice to be deprecated. Clearly, too, it is to the interest of the public that every druggist should be really, as well as nominally, a druggist,—a man who either tests or manufactures every one of his own preparations. All efforts to secure future drug dealing and drug-working to druggists must be founded on personal professional knowledge possessed by every pharmacist. A medical practitioner purchasing drugs at all will surely prefer to obtain them from the neighbouring druggist rather than from a distant source, if he knows that the druggist can give the guarantee of genuineness that he himself cannot provide, and if they can be obtained at a reasonable price. May he not in many cases go further, and give up dispensing bodily, if in the matter of trustworthiness of materials the druggist can beat him, and if, of course, neither he nor his patient suffer too severely in pocket? For the practitioner will thus get that personal guarantee which should be the druggist's most treasured possession, a guarantee which must, in the nature of things, be stronger when afforded by a neighbour than when offered by the distant dealer, especially when in the latter case it is only afforded at second hand by a price list or a traveller. Contrast the value of the guarantee of a retailer who is also a maker, with that of a druggist who can only trust to the respectability of a maker separated from him by two or three different agents and by scores or hundreds, if not thousands, of miles. Some preparations will doubtless always be better made by one man than by another, or by few persons rather than by many. Let us do nothing to damp the ardour of discoverers, inventors, or originators, in great things or in small. And let us always welcome to our shores anything of excellence that may be offered to us by other countries. But if pharmacy has anything to do with the health and welfare of a State, and if that health and welfare are affected by the personal skill, knowledge, and ability of the pharmacist, let us avoid those false but specious principles, and those false and more specious practices, which would sink pharmacists to the level of mere traders, mere dealers, mere agents, worthy and honourable enough in their sphere though such men might be.

In the matter, then, of the elaboration of drugs by all druggists, as against elaboration by a few druggists and distribution by the many, there is room for great improvement in English pharmacy; for it would be idle to deny that the preparation of his own compounds is the exception rather than the rule with the British pharmacist. No doubt druggists who are manufacturers as well as retailers of the preparations on their shelves may readily enough be found; but it is a fact that many druggists scarcely make even their own pills, but purchase them of wholesale makers (or even only of dealers) who reside, it may be, in quite another county, possibly in another country or in another continent altogether. What can such a druggist know of the quality of such articles? He urges the respectability of their maker. But how much can he know of the characters of makers separated from him by an ocean? After a time prominent makers may be severely pressed by more obscure manufacturers, and he may be dealing with some of the latter, whose probity, with a sense of responsibility naturally diminished by distance, may have given way. In purchasing preparations cheaper, as such a druggist thinks, than he can make them himself, and, still sadder to say, perhaps better looking, is he not buying pottage with the coinage of birthrights? Is he not dealing disastrously with his own interests, and with those of the State, in which he is after all but a steward?

Into the question of improvements in the elaboration of particular drugs it is not desirable now to enter; first, because it is dealt with in the list of subjects for research annually issued by the British Pharmaceutical Conference; secondly, because the spirit of emulation will not permit it to pass out of sight; and, thirdly, because it would be unwise to dwarf the importance of the main question just considered.

Distribution.—Given a body of pharmacists, each member of which can, respecting his drugs and drug compounds, supply either the analytical or the synthetical guarantee of efficiency and trustworthiness, then a State is best served by drug distribution being limited, on the whole, to such a body. Limited as a rule. For just as some drug compounds will probably always best be prepared by the few and distributed by the many, so the distribution of drugs to dwellings remote from towns will probably always have to be accomplished by mere distributors. The main limitation of drug supply to the public should, however, be to qualified druggists—men who prepare as well as distribute. The public in a sparsely populated district might purchase drugs of a mere distributor rather than do without them, especially if the real manufacturer were not far off, and whose personal guarantee were available at the cost of a long walk or a drive, or a short railway journey—just as the services of a solicitor's confidential clerk, or of a medical practitioner's assistant, will be accepted in the absence of those of the principal. Bearing in mind, however, the importance in pharmacy of the influence of the personal guarantee, and that this influence becomes weaker and weaker the more it is stretched, the distribution of drugs should, obviously, in the interests of the public and of pharmacy itself be confined, as a rule, to those who can afford such a personal guarantee—to those who, let me reiterate, either compound or test every drug they distribute. In the matter of pharmacy a State will, year by year, be better and better served to the extent to which there obtains a pharmaceutical policy that provides for the growth, not of those already named as mere distributors of drugs, but of druggists who are manufacturers and distributors too.

The third-named agent of drug distribution, the medical practitioner, cannot be, and probably never desires to be, a competent pharmacist. He has never professed to be anything more than a distributor of drugs, and as year by year the demands upon his medical, surgical and sanitary skill become, as they do, greater and greater, he will probably find his pecuniary interests, his tastes, and his aspirations for social position, prompting him to relinquish drug distribution altogether. Let pharmacists take care previously to prepare themselves for the work that will then fall into their hands; for whatever be the period when such a state of things comes to pass, it will be the outcome of a public demand for more and better work all round, from the pharmaceutical as well as from the medical practitioner; nay, the period of the demand will be greatly accelerated by the promise and power of the potential supply. Doubtless the country doctor will always carry, or hold himself ready to carry, in his pocket, his saddle-bag, or his carriage, agents which heal as well as agents which hurt, agents to inject into the flesh as well as those with which it may be incised, agents in the form of the soothing pill or the stimulating spirit. But for the compounding of even these he will look to the pharmacist proper, who with due and dignified responsibility will be near at hand to supply fresh and trustworthy fluids, convenient combinations, and palatable preparations, and who will receive adequate but not extravagant remuneration.

Respecting the distribution of drugs by retail vendors other than competent and trustworthy druggists, it is open to very serious question whether a State does not get more harm than good by such a practice. Such vendors can offer no personal guarantee either of the purity or the efficiency of their drugs. The practice may perhaps be tolerated for a time in a country where the machinery for the supply of druggists who are compounders as well as distributors is incomplete. But in a State in which all the druggists are competent for their work, the supply of medicinal agents by vendors other than druggists should only be permitted in districts where population is below a given number per square mile, and then only in unbroken packets supplied by a not far distant registered and responsible pharmacist. With non-pharmaceutical vendors of drugs must be classed co-operative stores. For personal responsibility respecting either raw or compounded drugs is scarcely compatible with the co-operative system. The companies who own co-operative stores do not make their own drug compounds. They are mere distributors. They could not well do or be anything else. At first sight it would appear that such an undesirable condition of things for the welfare of the public might be remedied by the employment at such stores of a staff of properly qualified pharmacists; men who could not only discriminate between good and bad raw drugs, but who could and would test all supplied drugs admitting of assay, and who could guarantee the quality of all other preparations because they had made them. There is, however, a good reason why such a remedy could not work, for then the cost of, and hence the prices charged for, dispensing prescriptions would necessarily be pretty much those of ordinary retail shops, and the inducement for the public to deal at stores rather than at shops would cease. Besides, long before such a remedy can be applied, society will probably find that money saved at co-operative stores, having to be expended in those rates and taxes, and in those many services now paid for by shopkeepers, there will be a balance of State advantages in leaving trade to the trader, and certainly in leaving the half-trade, half-profession of pharmacy to the pharmacist.

Respecting the distribution of drugs in the form of proprietary preparations, especially those called patent medicines. The question here must be not so much what improvements can be effected in this mode of distributing drugs to the inhabitants of a country, as, can the inexorable demand for simple medicinal remedies by the public be supplied in any better form than that of patent medicines. For the demand for simple remedies by all persons, and the habit of prescribing simple remedies by all persons for themselves, or for one another, are matters which always have lain outside, and always will lie outside, medical practice by professional men, a demand and a habit the source of which lies deep down among the springs of human nature, and of the common sense of free people. They therefore scarcely admit of criticism, and do not admit of carping, cavilling objection. The demand and the habit exist naturally in this country, and must be dealt with wisely. They scarcely admit even of definition, or of the drawing of any line up to which they may go, and beyond which they may not go. This much would seem certain, however, that if a mother for a child or a friend for a friend may prescribe a remedy which has proved serviceable under similar circumstances, surely a druggist, who is daily dealing with remedies from year's end to year's end, may prescribe simple remedies too. If one druggist will not do so, we may be quite sure another will; and that to the extent to which druggists generally do not or cannot prescribe simple remedies, to that extent patent medicine owners will step in and supply the irrepressible demand. Some medical men decry the habit of prescribing by druggists; but is the demand for simple remedies by channels other than the medical man's prescription thereby curtailed? Probably not. On the other hand, do not such medical men, and those druggists who from various motives follow the medical lead, thereby play directly into the hands of the proprietors of patent medicines? In the United States the practice of medicine is largely separated, and most wisely separated, from the practice of pharmacy. But besides this, the open recommendation of simple remedies by druggists is discouraged. With what result? In no country is traffic in secret remedies more rife. It is of course wrong for the pharmacist to meddle with pathology, attempting to diagnose while knowing nothing about the human frame. I trust no one will construe what I have said into support of quackery. But whenever and wherever a druggist is free to sell a patent medicine, he surely should be free to sell and be able to sell a simple remedy prepared by himself, by the aid of that special pharmaceutical knowledge and skill which are the guarantee that he is something more than a mere drug distributor. The inability to recommend remedies characteristic of the mere seller of drugs, and the professional jealousy which would stop a qualified pharmacist from recommending them, have probably done more to foster the present enormous demand for secret remedies than all other causes put together. The reduction of what is sometimes termed the patent medicine evil will probably be effected, chiefly, by that gradual extension of pharmaceutical knowledge amongst our future pharmacists, which will enable them to supply from their own shelves simple remedies for those tiresome minor maladies for which the public are now driven to patent medicines. The druggist who in this country prescribes simple remedies is a man who has been called into existence by the wants of the community; a useful servant, whom the public are too mindful of their interests ever to discharge. Society distinguishes clearly enough for all practical purposes between this man and the medical practitioner, and well may be left to seek the aid of one or other as required.

For improvement in drug distribution, therefore, we may reasonably look in two directions. First, in the distribution of drugs being limited, in the main, sooner or later, and of course without injuring any one, to druggists, such druggists being compounders as well as distributors of the drugs with which they deal. This will be brought about internally by education, externally by legislation. Internally by the carrying out of that policy to which pharmacists may now be said to be committed, and which may be summed up in the words sound and thorough compulsory pharmaceutical education; externally by appropriate legislative enactments. Improvement will result, secondly, in our having in the place of secret remedies, which are prescribed by persons at a distance, who are irresponsible, the open recommendation of simple remedies by pharmacists who have made the components themselves, and who can guarantee their trustworthiness. This too will be brought about gradually by improved pharmaceutical education, and by that only. It would be unwise to provide for pharmacists any modified medical education. Let there be no pretence of professional medical treatment mixed up with pharmacy. Let the druggist's recommendation of simple remedies be founded on that knowledge and experience which comes of much pharmaceutical familiarity with remedies, and on that common sense and perception in all that pertains to drugs, with which a properly and specially educated pharmacist may be credited. Indeed, any trespassing on the purely medical domain would necessarily sooner or later involve commensurate punishment.

Pharmaceutical Legislation. The old partnership of *Chemists and Druggists. Pharmaceutical Organization.*—A few words must be added on each of these subjects.

Legislation.—As regards legislative enactments that will enable pharmacy better to perform her duties to the State, they must always be of two kinds—each complementary to the other. First, those designed for the well-being of the public; second those which provide for the well-being of the pharmacist. It is to the interest both of the public and the druggist that the sale of poisons should be restricted, it is to the interest of both that the sale of compounded drugs should be restricted. For a State to assert that druggists must be qualified is only, in other words, to proclaim that drugs should not be sold by unqualified persons: the one proposition is involved in the other. It is law that the British druggist must be qualified. The health and welfare of the community has called this law into existence. Why? Because the health and welfare of the community are endangered if this dealer in drugs is not qualified. To this end the law has labelled him alone "chemist and druggist." From this point of view a Pharmacy Act which provides for the qualification of drug vendors without rendering penal the vending of drugs by unqualified persons is simply incomplete. It is no answer to this argument to say that the State, by protecting the title "chemist and druggist," has only adopted means for the proper supply of drugs to those of the public who cannot judge for themselves, and who desire State guidance, and that to go farther than this would be to interfere with freedom. *Caveat emptor* does not apply here, however good the judgment for other things may be. For no ordinary purchaser is able to judge of drugs. It is too bad to expect him even to judge of the qualifications of the vendor solely by the presence or absence of the words "chemist and druggist" in connection with the shop, for the time-honoured coloured show-bottle and a display of senna, rhubarb, etc., forms the commoner test. To provide for the well-being of the public who cannot judge of drugs for themselves something more than the test of title should be allowed. But in truth no such indirect mode of providing the public with qualified druggists will suffice for the public welfare. The only way in which the welfare of the public, so far as it is affected by drugs, can be provided for, and harm to the public, as far as it may come from drugs, be provided against, is not only to enact that druggists must be qualified, but that drugs must not be sold by unqualified persons. This is already enacted for a certain small number of drugs named in a schedule to the Pharmacy Act of 1868, and deemed poisons. So far so good. But all drugs are, more or less, poisons. The sale of all drugs should be thus restricted. If there are any substances sometimes used as drugs, but so harmless, and so generally used for other purposes, that to restrict their sale would be inconvenient to the public, let such drugs alone be scheduled as those which may be sold by unqualified persons. A Pharmacy Act which provides for the qualification of vendors of drugs, but contains no clause preventing the sale of drugs by unqualified persons, is incomplete. And if our own Pharmacy Acts are thus incomplete, the sooner they are rendered complete by an extended Pharmacy Act, the better for the State, the pharmacist, and the public. To get our legislature to take an interest in this matter, and to view it in its proper bearings, should be the only difficulty in the way of obtaining legislative enactments which will better enable British pharmacy to perform her duties to the State. This is no mere matter of class legislation, but a subject of considerable national importance. Let us only take care that the thoroughness of our pharmaceutical education fully demands or warrants such legislation, which it will do when founded not alone on that very inefficient test termed "a pass examination," but also on a properly arranged public curriculum diligently followed for an appropriate period.

Chemists and Druggists.—An address on the relation of pharmacy to the State should include, at all events in Great Britain, some allusion to that part of the implied duty of a pharmacist to his country covered by his use of the designation or title of "chemist." The English pharmacist is a "chemist and druggist." From what has already been stated, it will be clear that the proper standard as regards such a "chemist," is that of a man who is not only a vendor of chemical substances, but who has sufficient professional knowledge of chemistry to enable him to guarantee analytically every one of his drugs and chemical substances that admits of chemical assay. And there are large numbers of pharmacists in this country who can do all this and more. But does the average chemist and druggist of to-day come up to this standard? Is he even a general trading *chemist?* Is he not rather a man who has left to the oilman and the grocer the vending of "soda" and other alkalies, vinegar and other acids, delicate mineral and vegetable dyes and colouring matters, and hosts of such "chemicals," as they are termed; a man who, while calling himself and legally appropriating to himself the title of "chemist," has through his ignorance of chemical substances, allowed chemists, who dare not call themselves chemists, to establish shops for the sale of photographic and other chemicals, and chemical and physical apparatus generally; a man who, through being unable to perform such simple chemical operations as the testing of a fluid excretion for albumen or sugar, has driven from his doors the physic-taking patient afflicted with diseases of the albumenoid or saccharoid type; and a man who has committed these sins of omission, not always because his time was wholly occupied with the pursuit of pure pharmacy. Can such "chemists and druggists" wonder that their calling is declining in this country, when even for chemical guarantees of the genuineness of their goods they must rely on the distant wholesale manufacturer, and for the pharmaceutical attractiveness of prettily coated pills, they find it necessary to go to the other side of the Atlantic? Will the rising generation of pharmacists allow this state of things to continue? No doubt a great deal of the work of the pharmacist of fifty or one hundred years ago has gone never to return, but a vast amount of new work has taken the place of the old. Chemistry is progressing with a rapidity unexampled in the annals of man's avocations. The trade in the materials and apparatus for the study and the practice of chemistry by amateurs, professional men, and manufacturers, is extending year by year. Will trading "chemists" allow this chemist's trade to slip through their hands? At no previous period in the history of this country has the subject of purity of food, drink, drugs, and all other things, occupied so much attention as at present. Never was there a greater demand on the part of the public, not for direct analysis at the request of ordinary purchasers by officials under the Acts relating to adulteration—that Parliamentary scheme (Act of 1875, section 12) has entirely failed—but for the personal guarantees of vendors that articles sold are what they are professed to be. Who so well able to give this guarantee as the "chemist and druggist" who is a chemist as well as a druggist. Such a chemist will extend his trade over the whole commercial area of chemistry, as well as draw to himself those pharmaceutical streams now flowing in channels uncontrolled by pharmacists. There is also minor professional work to be done by the "chemist" in such directions as those already indicated; work chiefly qualitative, and for which the chemist and druggist would perhaps only receive silver fees, but for which he would be remunerated over and over again in the confidence reposed in him by his customers, and by the medical practitioners of the neighbourhood, and in the prestige and status it would win for him.

Organization.—A word respecting organization amongst pharmacists. Organization, in the absence of which any consideration of improvements in the modes of collecting, elaborating, or distributing drugs would be little more than a dream. Organization, without which the duties of chemists and druggists to the State will only be performed in an incomplete and haphazard manner, and without which their own interests will be developed or maintained very imperfectly if at all. Such organization—the work of a generation of philo-pharmaceutic pioneers—exists already in this country as regards about one-third of the chemists and druggists. Had the other two-thirds responded to the general appeals made by their brethren more than once during the past forty odd years, it is safe to aver that not only would the State at this moment be better served by pharmacy, but every pharmacist would be richer in pocket, richer in social position, richer in self-respect. Even now, were the advantages of union and a pathway to union brought home to every pharmacist—which could be well done now that we have a complete Register—there can be little doubt that nearly every druggist having any really important stake in pharmacy would join in forming a Pharmaceutical Society of Great Britain co-extensive with British pharmacy. It would be astonishing, indeed, if after such a special appeal any very large proportion of the druggists in the country were found to care so little for the welfare either of themselves or of the community, or to perceive that welfare so imperfectly, as to hold aloof from such an organization. But our chief hope must rest with our pupils and young men. Cannot some plan be carried out by which all future pharmacists shall become members of one great national society?

Conclusion.—In the course of this address on an aspect of pharmacy complementary to the political, an attempt has been made to set forth the duties of pharmacy to the State in obtaining, elaborating, and distributing drugs; suggestions have been offered by which pharmacy may better perform these duties; hopes thrown out respecting the duty of the State to pharmacy, though this, being a political question, has only been glanced at; and for the thoroughly qualified chemists and druggists of Great Britain generally, a brighter future foreshadowed than might at first sight be anticipated. Amongst the body there are large numbers who can well hold their own with the pharmacists of any country in the world, whether as followers of pure pharmacy or as "chemists" as well as "druggists." All that these are now, the rising generation of pharmacists should strive to become. With a thoroughly united, thoroughly educated, body of pharmacists, in number properly proportionate to the population of the country, each pharmacist a unit in one great society of pharmacists, we may confidently predict for no very distant future a relationship between pharmacy and the State which shall be permanently beneficial to all concerned. We too

" . . . rest in faith
That man's perfection is the crowning flower,
Toward which the urgent sap in life's great tree
Is pressing,—seen in puny blossoms now,
But in the world's great morrows to expand
With broadest petal and with deepest glow."

Mr. Chipperfield said the gentlemen present had all listened with much attention and gratification to the eloquent address just given; an address eminently practical and full of interest both to pharmacists and the general public; and he would fain hope that at least some benefit to the general public might be the outcome of its publication. It had always seemed to him an anomaly and a glaring injustice that while the pharmacist of the present day was bound to acquire an excellent education and to submit himself to a stringent examination he had no legal safeguard and possessed no special privileges in carrying on his vocation. The mere scheduling of a certain number of poisons, and he alone having the right to vend them, was virtually no protection or benefit to him or to the public, and nothing more incontrovertible was ever uttered than the proposition that a Pharmacy Act which provided for the qualification of the legal vendors of drugs, but contained no clause preventing their sale by unqualified persons, was incomplete, it being lame and impotent in the extreme. The great difficulty to his mind hitherto had been to see how persons living in rural and sparsely populated places were to obtain the necessary medicines if only legally qualified pharmacists might vend them; but the suggestion make by the President that unqualified persons should be permitted to supply the consumer with such medicines only in sealed packets supplied by qualified pharmacists completely destroyed that difficulty. It was his pleasure and privilege to propose that a hearty vote of thanks be recorded to the President for his very admirable, eloquent and practical address.

Mr. O. R. Dawson had much pleasure in seconding the vote of thanks. He was quite sure the words uttered that morning would be read by all English-speaking pharmacists with a great deal of pleasure; he hoped that what the President had foreshadowed with regard to legislation would be embodied in the Pharmacy Bill which he hoped it would soon be the duty of the Council to introduce.

Dr. Quinlan wished to say a few words in support of the motion. The address presented a great number of subjects which gave rise to a great deal of reflection, both on the part of the medical profession and also of the pharmacist, for he considered that the interests of these two great callings were inseparable. He had been much struck with the remarks about the collection of drugs, for nothing could be more unsatisfactory in many ways than the manner in which this was now conducted. In fact, it resembled the vicious system of merely asking a candidate what he knew, without any reference to where he had been educated. At present they had to take drugs collected by anybody, and depend on the commercial conscience for their purity, and, with all due respect for that commercial conscience, he might say that anyone who had occasion, as he had, to go through large samples and quantities of drugs, would be convinced of its extreme elasticity. He thought the suggestion made as to the establishment of pharmaceutical gardens was a very good one; they would require a good deal of trouble and skill to be brought to bear, but they would certainly pay. With regard to the practicability there could be no doubt; in the botanic gardens a great number of plants were grown on a small scale, and if a small bed of plants could be grown for the instruction of students, why should not two or three acres be cultivated? The greater certainly included the less. The distribution of drugs was a great difficulty. He had been convinced by long experience that there must be a hard and fast line of separation between the prescribing and compounding of drugs; he believed the two duties must be performed by two entirely distinct classes of persons. There was only one exception to that, and that was in thinly populated districts which would not support a pharmaceutical chemist; there the travelling physician or surgeon, who went thirty, forty, or sixty miles a day, would have to carry about his own drugs, but there was nothing to prevent his getting them from a practical pharmaceutical chemist, who would be able to guarantee their purity either by manufacturing or testing them himself. With regard to the manufacture, there was no doubt that there were some substances which could not be made with economy, except on a large scale; but there was a day within the memory of living men, when the bulk of pharmacists made their own preparations. Those happy days when concentrated infusions and such like things were entirely unknown had gone, and he much wished they would return, and that pharmacists would make their own preparations with the exception of elaborate chemical compounds. He had listened with the deepest regret to the statement that nearly a million a year was spent on patent medicines. People were very fond of dosing themselves, and they would ask for these things, but, in his opinion, a great deal of the blame lay with doctors and chemists, who should endeavour to diffuse truer notions amongst the masses, for it could not be very difficult to persuade them that one article could not cure thirty or forty different complaints; and gradually he hoped they might be able to educate patent medicines off the face of the earth. In conclusion, he alluded to the fact that the Royal University in Ireland required from all candidates for a medical or surgical degree a course of practical compounding and of pharmacy, and it required that this should take place in some regular pharmacy, not in a hospital or dispensary. He thought it extremely important that members of the Irish Pharmaceutical Society should see that they were not left out in the cold with regard to granting these certificates, which he considered they were as much entitled to do as the Irish apothecary. He believed the privilege could be obtained by simply asking for it.

Mr. Hampson wished to thank the President for his very able address, but he feared the hope he had thrown out of getting so much State aid was rather illusory; at all events they might hope, however, to have at some future day the dispensing of medicine protected by the State, and that would be a great step in advance. He must say he had more faith in the good results of educating the people themselves that in anything which was done by the State. When the public became more enlightened on these matters it would go to the best men it could find in the trade or profession, and until that came about he feared there would not be any great change. In London he feared that instead of making any advance in the way of getting the dispensing of prescriptions, they were rather going backwards; the medical man seemed to look for his profit to the retailing of medicine and giving it in the cheapest possible form.

Mr. ATKINS wished to add his testimony to the value of the address. Professor Attfield had paid a high compliment to the Pharmaceutical Conference in preparing so thoughtful and admirable an address, and the highest compliment those present could pay it in return would be not to attempt to criticize it in detail, but rather to peruse it carefully, and form their conclusions upon it. It had been his privilege to listen to many presidential addresses, but he did not know that he had listened to one which appeared so suggestive and likely to evoke a very large amount of controversy. The very highest tribute which could be paid to it was that it would bring out the points of difference in the pharmaceutical world. The division of the subject was admirable—collection, preparation and distribution were three points which could be at once fixed in the mind. He thought the suggestion of drug farms in this country a very happy one; it might be merely visionary, but he hoped it would prove to be practical, and that it would become practicable to produce on a large scale anything which the climate would admit. He hardly agreed with Professor Attfield as to the necessity or desirability of every chemist making all his own preparations. He quite agreed with him that the knowledge requisite to do it ought to be there, but it seemed to him the tendency of the age was rather to produce the best article under the most perfect conditions, such as could only be attained in large manufactories where there were the best appliances and the most complete division of labour. Still he thoroughly agreed that the knowledge requisite to produce all these preparations ought to be possessed by pharmacists, and if they did not all possess it now, it should be their earnest aim that their sons and successors should possess it.

Professor TICHBORNE also desired to express the pleasure with which he had listened to the address, and remarked that the subject referred to by Dr. Quinlan had engaged the attention of the Council of the Irish Pharmaceutical Society at its last meeting, and measures were being taken to secure if possible that the education of the pharmacist in Ireland should be available for conferring the qualification in the compounding of drugs required of medical men.

The vote of thanks was then put by Mr. GROVES, and carried unanimously.

The PRESIDENT, in response, thanked the meeting for the resolution. He said he had endeavoured, in the words of his predecessor, to give a good, straight look at things as they were, and he had also endeavoured to give a common-sense view of things as they should be. What he had said he simply put forward as his own opinions, and he had been abundantly compensated for any trouble he had taken in preparing the address by the manner in which it had been received.

(To be continued.)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the above Association commenced on Wednesday, August 23, at Southampton, under the Presidency of C. William Siemens, D.C.L. (Oxon.), LL.D. (Glasc. and Dubl.), Ph.D., F.R.S., F.C.S., Member Inst. C.E., who delivered the following opening address:—

THE PRESIDENT'S ADDRESS.

In venturing to address the British Association from this chair, I feel that I have taken upon myself a task involving very serious responsibility. The Association has for half a century fulfilled the important mission of drawing together, once every year, scientists from all parts of the country for the purpose of discussing questions of mutual interest, and of cultivating those personal relations which aid so powerfully in harmonizing views, and in stimulating concerted action for the advancement of science.

A sad event casts a shadow over our gathering. While still mourning the irreparable loss science has sustained in the person of Charles Darwin, whose bold conceptions, patient labour, and genial mind made him almost a type of unsurpassed excellence, telegraphic news reached Cambridge, just a month ago, to the effect that our Honorary Secretary, Professor F. M. Balfour, had lost his life during an attempted ascent of the Aiguille Blanche de Penteret. Although only thirty years of age, few men have won distinction so rapidly and so deservedly. After attending the lectures of Michael Foster, he completed his studies of biology under Dr. Anton Dohrn at the Zoological Station of Naples in 1875. In 1878 he was elected a Fellow, and in November last a member of Council of the Royal Society, when he was also awarded one of the Royal Medals for his embryological researches. Within a short interval of time Glasgow University conferred on him their honorary degree of LL.D., he was elected President of the Cambridge Philosophical Society, and after having declined very tempting offers from the Universities of Oxford and Edinburgh, he accepted a professorship of Animal Morphology created for him by his own University. Few men could have borne without hurt such a stream of honourable distinctions, but in young Balfour genius and independence of thought were happily blended with industry and personal modesty; these won for him the friendship, esteem, and admiration of all who knew him.

Since the days of the first meeting of this Association in York in 1831, great changes have taken place in the means at our disposal for exchanging views, either personally or through the medium of type. The creation of the railway system has enabled congenial minds to attend frequent meetings of those special societies which have sprung into existence since the foundation of the British Association, amongst which I need only name here the Physical, Geographical, Meteorological, Anthropological, and Linnean, cultivating abstract science, and the Institution of Mechanical Engineers, the Institution of Naval Architects, the Iron and Steel Institute, the Society of Telegraph Engineers and Electricians, the Gas Institute, the Sanitary Institute, and the Society of Chemical Industry, representing applied science. These meet at frequent intervals in London, whilst others, having similar objects in view, hold their meetings at the University towns, and at other centres of intelligence and industry throughout the country, giving evidence of great mental activity, and producing some of those very results which the founders of the British Association wished to see realized. If we consider further the extraordinary development of scientific journalism which has taken place, it cannot surprise us when we meet with expressions of opinion to the effect that the British Association has fulfilled its mission, and should now yield its place to those special societies it has served to call into existence. On the other hand, it may be urged that the brilliant success of last year's Anniversary Meeting, enhanced by the comprehensive address delivered on that occasion by my distinguished predecessor in office, Sir John Lubbock, has proved, at least, that the British Association is not dead in the affections of its members, and it behoves us at this, the first ordinary gathering in the second half century, to consider what are the strong points to rely upon for the continuance of a career of success and usefulness.

If the facilities brought home to our doors of acquiring scientific information have increased, the necessities for scientific inquiry have increased in a greater ratio. The time was when science was cultivated only by the few, who looked upon its application to the arts and manufactures as almost beneath their consideration; this they were content to leave in the hands of others, who, with only commercial aims in view, did not aspire to further the objects of science for its own sake, but thought only of benefiting by its teachings. Progress could not be rapid under this condition of things, because the man of pure science rarely pursued his inquiry beyond the mere enunciation of a physical or chemical principle, whilst the simple practitioner was at a loss how to harmonize the new knowledge with the stock of information which formed his mental capital in trade.

The advancement of the last fifty years has, I venture to submit, rendered theory and practice so interdependent, that an intimate union between them is a matter of absolute necessity for our future progress. Take, for instance, the art of dyeing, and we find that the discovery of new colouring matters derived from waste products, such as coal-tar, completely changes its practice, and renders an intimate knowledge of the science of chemistry a matter of absolute necessity to the practitioner. In telegraphy and in the new arts of applying electricity to lighting, to the transmission of power, and to metallurgical operations, problems arise at every turn, requiring for their solution not only an intimate acquaintance with, but a positive advance upon, electrical science, as established by purely theoretical research in the laboratory. In general engineering the mere practical art of constructing a machine so designed and proportioned as to produce mechanically the desired effect, would suffice no longer. Our increased knowledge of the nature of the mutual relations between the different forms of energy makes us see clearly what are the theoretical limits of effect; these, although beyond our absolute reach, may be looked upon as the asymptotes to be approached indefinitely by the hyperbolic course of practical progress, of which we should never lose sight. Cases arise, moreover, where the introduction of new materials of construction, or the call for new effects, renders former rules wholly insufficient. In all these cases practical knowledge has to go hand in hand with advanced science in order to accomplish the desired end.

Far be it from me to think lightly of the ardent students of nature, who, in their devotion to research, do not allow their minds to travel into the regions of utilitarianism and of self-interest. These, the high priests of science, command our utmost admiration; but it is not to them that we can look for our current progress in practical science, much less can we look for it to the "rule of thumb" practitioner, who is guided by what comes nearer to instinct than to reason. It is to the man of science, who also gives attention to practical questions, and to the practitioner, who devotes part of his time to the prosecution of strictly scientific investigations, that we owe the rapid progress of the present day, both merging more and more into one class, that of pioneers in the domain of nature. It is such men that Archimedes must have desired when he refused to teach his disciples the art of constructing his powerful ballistic engines, exhorting them to give their attention to the principles involved in their construction, and that Telford, the founder of the Institution of Civil Engineers, must have had in his mind's eye, when he defined civil engineering as "the art of directing the great sources of power in nature."

These considerations may serve to show that although we see the men of both abstract and applied science group themselves in minor bodies for the better prosecution of special objects, the points of contact between the different branches of knowledge are ever multiplying, all tending to form part of a mighty tree—the tree of modern science—under whose ample shadow its cultivators will find it both profitable and pleasant to meet, at least once a year; and considering that this tree is not the growth of one country only, but spreads both its roots and branches far and wide, it appears desirable that at these yearly gatherings other nations should be more fully represented than has hitherto been the case. The subjects discussed at our meetings are without exception of general interest, but many of them bear an international character, such as the systematic collection of magnetic, astronomical, meteorological, and geodetical observations, the formation of a universal code for signalling at sea, and for distinguishing lighthouses, and especially the settlement of scientific nomenclatures and units of measurement, regarding all of which an international accord is a matter of the utmost practical importance.

As regards the measures of length and weight it is to be regretted that this country still stands aloof from the movement initiated in France towards the close of last century; but, considering that in scientific work metrical measure is now almost universally adopted, and that its use has been already legalized in this country, I venture to hope that its universal adoption for commercial purposes will soon follow as a matter of course. The practical advantages of such a measure to the trade of this country would, I am convinced, be very great, for English goods, such as machinery, or metal rolled to current sections, are now almost excluded from the continental market, owing to the unit measure employed in their production. The principal impediment to the adoption of the metre consists in the strange anomaly that although it is legal to use that measure in commerce, and although a copy of the standard metre is kept in the Standards' Department of the Board of Trade, it is impossible to procure legalized rods representing it, and to use a non-legalized copy of a standard in commerce is deemed fraudulent. Would it not be desirable that the British Association should endeavour to bring about the use in this country of the metre and kilogram, and, as a preliminary step, petition the Government to be represented on the International Metrical Commission, whose admirable establishment at Sèvres possesses, independently of its practical work, considerable scientific interest, as a well-found laboratory for developing methods of precise measurement?

Next in importance to accurate measures of length, weight, and time, stand, for the purposes of modern science, those of electricity.

The remarkably clear lines separating conductors from non-conductors of electricity, and magnetic from non-magnetic substances, enable us to measure electrical quantities and effects with almost mathematical precision; and, although the ultimate nature of this, the youngest scientifically investigated form of energy, is yet wrapt in mystery, its laws are the most clearly established, and its measuring instruments (galvanometers, electrometers, and magnetometers) are amongst the most accurate in physical science. Nor could any branch of science or industry be named in which electrical phenomena do not occur, to exercise their direct and important influence.

If then, electricity stands foremost amongst the exact sciences, it follows that its unit measures should be determined with the utmost accuracy. Yet, twenty years ago, very little advance had been made towards the adoption of a rational system. Ohm had, it is true, given us the fixed relations existing between electromotive force, resistance and quantity of current; Joule had established the dynamical equivalent of heat and electricity, and Gauss and Weber had proposed their elaborate system of absolute magnetic measurement. But these invaluable researches appeared only as isolated efforts, when, in 1862, the Electric Unit Committee was appointed by the British Association, at the instance of Sir William Thomson, and it is to the long-continued activity of this Committee that the world is indebted for a consistent and practical system of measurement, which, after being modified in details, received universal sanction last year by the International Electrical Congress assembled at Paris.

At this Congress, which was attended officially by the leading physicists of all civilized countries, the attempt was successfully made to bring about a union between the statical system of measurement that had been followed in Germany and some other countries, and the magnetic or dynamical system developed by the British Association, also between the geometrical measure of resistance, the (Werner) Siemens unit, that had been generally adopted abroad, and the British Association unit intended as a multiple of Weber's absolute unit, though not entirely fulfilling that condition. The Congress, while adopting the absolute system of the British Association, referred the final determination of the unit measure of resistance to an International Committee, to be appointed by the representatives of the several Governments; they decided to retain the mercury standard for reproduction and comparison, by which means the advantages of both systems are happily combined, and much valuable labour is utilized; only, instead of expressing electrical quantities directly in absolute measure, the Congress has embodied a consistent system, based on the Ohm, in which the units are of a value convenient for practical measurements. In this, which we must hereafter know as the "practical system," as distinguished from the "absolute system," the units are named after leading physicists, the Ohm, Ampère, Volt, Coulomb, and and Farad.

I would venture to suggest that two further units might, with advantage, be added to the system decided on by the International Congress at Paris. The first of these is the unit of magnetic quantity or pole. It is of much importance, and few will regard otherwise than with satisfaction the suggestion of Clausius that the unit should be called a "Weber," thus retaining a name most closely connected with electrical measurements, and only omitted by the Congress in order to avoid the risk of confusion in the magnitude of the unit current with which his name had been formerly associated.

The other unit I should suggest adding to the list is that of power. The power conveyed by a current of an Ampère through the difference of potential of a Volt is the unit consistent with the practical system. It might be appropriately called a Watt, in honour of that master mind in mechanical science, James Watt. He it was who first had a clear physical conception of power, and gave a rational method of measuring it. A Watt, then, expresses the rate of an Ampère multiplied by a Volt, whilst a horse-power is 746 Watts, and a Cheval de Vapeur 735.

The system of electro-magnetic units would then be:—

				C.G.S. Units.
(1) Weber, the unit of magnetic			quantity	$=10^8$
(2) Ohm	"	"	resistance	$=10^9$
(3) Volt	"	"	electromotive force	$=10^8$
(4) Ampère	"	"	current	$=10^{-1}$
(5) Coulomb	"	"	quantity	$=10^{-1}$
(6) Watt	"	"	power	$=10^7$
(7) Farad	"	"	capacity	$=10^{-9}$

The word energy was first used by Young in a scientific sense, and represents a conception of recent date, being the outcome of the labours of Carnot, Mayer, Joule, Grove, Clausius, Clerk-Maxwell, Thomson, Stokes, Helmholtz, Macquorn-Rankine, and other labourers, who have accomplished for the science regarding the forces in Nature what we owe to Lavoisier, Dalton, Berzelius, Liebig, and others as regards chemistry. In this short word energy we find all the efforts in nature, including electricity, heat, light, chemical action, and dynamics, equally represented, forming, to use Dr. Tyndall's apt expression, so many "modes of motion." It will readily be conceived that when we have established a fixed numerical relation between these different modes of motion, we know beforehand what is the utmost result we can possibly attain in converting one form of energy into another, and to what extent our apparatus for effecting the conversion falls short of realizing it. The difference between ultimate theoretical effect and that actually obtained is commonly called loss, but, considering that energy is indestructible, represents really secondary effect which we obtain without desiring it. Thus friction in the working parts of a machine represents a loss of mechanical effect, but is a gain of heat, and in like manner the loss sustained in transferring electrical energy from one point to another is accounted for by heat generated in the conductor. It sometimes suits our purpose to augment the transformation of electrical into heat energy at certain points of the circuit when the heat rays become visible, and we have the incandescence electric light. In effecting a complete severance of the conductor for a short distance, after the current has been established, a very great local resistance is occasioned, giving rise to the electric arc, the highest development of heat ever attained. Vibration is another form of lost energy in mechanism, but who would call it a loss if it proceeded from the violin of a Joachim or a Norman-Neruda?

(To be continued.)

THE "TIMES" ON PROFESSOR ATTFIELD'S ADDRESS TO THE BRITISH PHARMACEUTICAL CONFERENCE.

On Thursday last the *Times* contained in its editorial columns the following remarks on the address by Professor Attfield, printed on another page:—

"The Pharmaceutical Conference is a gathering of men whose doings and discussions should have no little interest for the general community. The dispensing chemist is not exactly a State functionary, but he is an important public servant. In the modern division of professional labour he is the necessary intermediary between the doctor and his patient. The doctor prescribes, the chemist compounds, the patient swallows. Armed with a slip of paper often not too legibly written and never intelligible to non-professional readers, the patient quits the physician's consulting room and goes to the chemist's shop. He is compelled to trust the latter to give him what the doctor has ordered. Doctor and patient, in fact, are entirely in the chemist's hands. The patient does not even know what it is the doctor has ordered, the doctor cannot tell that his orders are carried out. Even if the prescription is duly dispensed according to order, there is still not a little to be taken on trust. The drugs may be old or weak, or they may be of inferior quality. The case supposed, moreover, represents the *minimum* amount of trust ordinarily reposed by the public at large in the dispensing chemist. There must be times and occasions when the dispenser is ignorant, inadvertent, or shifting: when he either makes a sheer mistake, or is tempted to substitute one drug for another with which he happens to be unprovided. There are others when he is induced or even forced by the importunity of his customers to prescribe as well as dispense. There is still, in fact, a good deal of old-world simplicity, not to say superstition, in the popular resort to medical advice. Many good people in country places think nothing of a doctor who does not dose them well, and they discern no material difference in skill between the doctor himself and the chemist who gives them a draught and the old woman who mixes them a dose of simples. Indeed, a very little medical knowledge goes a very long way in country districts, and it is no wonder, therefore, that the chemist is often called upon to do the work of the medical man. All this, however, serves to show the importance to the community of a healthy and elevated tone of the pharmaceutical calling. There is no legal impediment to the sale of drugs, other than certain specified poisons, by anyone. It is true that no one is allowed to call himself a pharmaceutical chemist or to practise the calling of a chemist and druggist unless he is duly registered under conditions which attest his qualification to dispense medical prescriptions, but this statutory limitation does not prevent the sale of uncompounded drugs by any retail trader, nor does it in any way preclude a dispensing chemist from prescribing on his own account. All that the law requires is that 'persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business, and to that end . . . . should be duly examined as to their practical knowledge.' These words, which are taken from the preamble to the Pharmacy Act, 1868, represent in summary the exisiting relations of pharmacy to the State. As such they form a convenient starting point for commenting on the address on that subject, delivered at Southampton, on Tuesday, by Professor Attfield, as President of the Pharmaceutical Conference for the present year.

"Professor Attfield considers that legislation in respect of pharmacy is at present in a very unsatisfactory state; but he does not offer any very definite suggestion for its improvement beyond the remark that, instead of scheduling certain drugs as poisons and placing restrictions on their sale, the law should rather schedule only such drugs as may safely be sold by unqualified persons. As, according to the same authority, 'all drugs are more or less poisons,' it is a little difficult to see how such a provision could be made to work in practice. On the whole, we are rather disposed to think, in spite of Professor Attfield, that the law does all that it can or need do at present; the rest may fairly be left to the corporate efforts and feeling of the members of the pharmaceutical calling and to the common sense of the public at large. Very possibly the schedule of poisons given in the Act needs revision and extension; but the Act empowers the Pharmaceutical Society, with the approval of the Privy Council, to enlarge it from time to time. But beyond this, all that the law need require, and probably all that it can practically enforce, is that persons who profess to compound medical prescriptions should be properly qualified to do so, and that their qualification should be publicly registered. No one, of course, would like to think that a prescription sent to the chemist's ran the risk of being made up by a man whose pharmaceutical skill was on a par with that of the chemist's apprentice in 'Pickwick.' The Pharmacy Act precludes such a catastrophe, and for the rest it is safer, perhaps, to trust to such indirect influences as are independent of positive legislation, and more or less outside its sphere. It is highly desirable, of course, that pharmaceutical chemists should be men of high character and good education, and such we understand to be the aim of the Pharmaceutical Conference. But the business of a dispensing chemist is in one sense a trade like any other, and as such it is subject, like any other trade, to the stimulating influence of competition and to the natural conditions of supply and demand. Professor Attfield desired that the chemist and pharmacist should be in reality as well as in name a druggist also—that he should be skilled in the preparation of drugs from the raw material as well as in the compounding of them. This is, no doubt, desirable in itself, but the tendency of modern commerce and industry is to division rather than to concentration, and it is not easy to see how the tendency is to be counteracted. The suggestion that pharmacists should be encouraged to recommend simple remedies compounded by themselves is a good deal more questionable. The practice is common enough, and it could not be easily checked, but certainly it hardly calls for direct encouragement. 'Let there be no pretence of professional medical treatment mixed up with pharmacy,' says Professor Attfield sensibly enough; but it is a little difficult to reconcile this principle with the remark which follows, to the effect that 'the druggist's recommendation of simple remedies should be founded on that knowledge and experience which come of much pharmaceutical familiarity with remedies, and on that common sense and perception in all that pertains to drugs with which a properly and specially educated pharmacist might be credited.'

"The fact is that there is no little variance between theory and practice in this matter. The theory, of course, is that to the doctor only should belong the power of prescribing remedies, and that the pharmacist has nothing to do but compound them. The physician is the man of science; the pharmacist is merely his instrument. Such is, no doubt, the ideal relation between the two, especially as regarded from the physician's point of view. But the popular mind does not always move in this elevated region, and popular practice is still almost as impatient of the solemn '*ordonnances des médecins*' as it was in the time of Molière. In scores of simple cases the chemist's advice is almost as good, or, at any rate, it is thought to be almost as good, as the doctor's; and, what is more to the point, it is a good deal cheaper to obtain. If chemists oftentimes do harm by prescribing, it must nevertheless be remembered that as often as not the real fault lies with the applicant for their advice. A man often goes to the chemist's shop not so much for specific advice as for the purpose of obtaining a remedy that he wants, or thinks he wants. He is hoarse, and thinks a gargle will do him good; he is bilious, and asks for a simple purgative or a saline draught; and the chemist has nothing more to do than to give him a remedy which he has compounded scores of times at the doctor's bidding in similar cases. Where is the line to be drawn? Common sense alone can draw it, and the common sense must quite as often be that of the patient himself as of the chemist to whom he applies. We are afraid that such a lax view as this of the duties and functions of the pharmacist will be regarded as flat heresy by the medical profession. We can only say that medical men are not wholly disinterested in the matter, and we may add that when the patient finds his way to the chemist's shop it is very often the doctor who has first shown it to him. There was a time when the doctor, especially the country doctor, was his own pharmacist. To this day the licence of the Apothecaries' Company is a qualification for the practice of medicine. The practice of medical men compounding their own drugs is by no means extinct, though it is discouraged and discountenanced by the medical profession at large. It has its good and its bad side, no doubt, and very likely the evil preponderates. But if medical men insist on abandoning the practice of pharmacy, it is certain that in many cases the pharmacist will have to supply their place. The practice of consulting pharmacists exists, and, human nature being what it is, we doubt if it is possible to do very much in the way of checking it. Medicine, in one sense, is a science or a whole assemblage of sciences demanding the highest skill and the widest experience for their mastery and practice; in another sense, it is an art of which almost every man considers himself to have at least a smattering. The higher sphere properly belongs to the physicians; if the pharmacists have gained a footing in the lower, it is only because they have thereby satisfied a popular need."

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Gerrard, Parker, Hooper, Brown, Dott, Mason, Bush and Co., Hearon and Co., Johnston, Hart, Quinlan, Lamble, Della Rosa, G. A. C., Observer, Nectandra, Wulfruna, Syrupus, Specific Gravity, Associate, North.

"THE MONTH."

Although August must decidedly be reckoned among the "dead" months of the year, it shares with September the fortune of being galvanized into some appearance of life by various *soi-disant* scientific meetings. Three such meetings have taken place during the past month, all of them more or less interesting to the pharmacist: the British Medical Association has met at Worcester, and the British Pharmaceutical Conference and the British Association for the Advancement of Science at Southampton.

First in order of date came the meeting of the British Medical Association, which possessed additional interest from the fact that it marked the expiration of fifty years since the establishment of the Association, under the name of the "Provincial Medical and Surgical Association," in the same old city of Worcester in 1832. Then the Association numbered 140 members; now it numbers 9500. But it made comparatively slow advance in its early history, only numbering about 2000 members at the end of its twenty-fifth year; in fact, the medical profession generally exhibited relatively little appreciation of the advantages involved in membership of the organization until about sixteen years ago, when Mr. Ernest Hart was appointed Editor of the Journal of the Association, since which time its progress has been very rapid. It was natural that Dr. W. Strange, the President for the year, should in his address contrast the position of medicine at the epoch of the birth of the Association and now, and the first portion of it was devoted to the "Revival of Medicine," as part of the outburst of the forces of thought and research after the repression due to the effects of a long period of war, whilst the second was entitled "The Survival of Medicine." The orator credited medical literature with being one of the chief of the forces that have operated to bring about great changes during the last fifty years, but in acknowledging the valuable services rendered by the *Lancet* he used a decidedly double-edged metaphor. After comparing that journal in its earlier years to a wasp buzzing about the drones of the medical hive, when he came to speak of it after its enlargement in 1831, he altered the figure. "We may now liken it to a weasel, or a still more unsavoury animal, the polecat, biting, scratching, driving out of their holes, with venomous scurrility, the 'bats,' as it called the hospital surgeons and councillors of the Royal College, and hanging them up, like vermin on a barn-door, to general obloquy. This was the function of the *Lancet*." The *Lancet* of to-day is naturally not quite pleased with this simile, although one certainly in accord with Dogberry's statement that "comparisons are odorous," and it quotes with some complacency a suggestion that weasels and polecats are not usually engaged in nailing bats to barn-doors; but it is willing to forgive this and much more in consideration of the kind manner in which Dr. Strange spoke of the late Mr. Wakley, and it assures its readers that the spirit in which that gentleman conducted the *Lancet* "is religiously, it may be said filially, preserved under the present Editor." If Dr. Strange's eulogy is of rather uncertain sound, the same cannot be said of his condemnations, as for instance, when he attacks the well-known "nuisance of modern medical literature," that "many a fresh investigator will treat his subject as if no one had ever done anything in it before." His utterances, also, respecting some of the evils attending modern consultations are no less sharp than true. "As regards consultants," he asks, "do we not recognize a solemn farce when Mr. A. or Mrs. B. returns from consulting, say some metropolitan celebrity, and tells us that Dr. C. has laid down all the rules for his or her future life, and indicated this or that health-resort as essential to recovery; and all in ten minutes' time and for a fee of one guinea? The issues of life and death, in the case of a stranger never seen before, solved in a ten or fifteen minutes' interview, and all for one guinea!" The "Address in Medicine" was delivered by Dr. W. F. Wade, and the "Address in Surgery" by Professor W. Stokes.

Next in order of time came the meeting of the British Pharmaceutical Conference, but the full report of the proceedings in another part of the Journal renders further notice here unnecessary. Then came the meeting of the British Association, with its sections covering all the fields of science. Amongst the topics dealt with by Dr. Siemens in his presidential address was that of artificial lighting, upon which he could speak with authority, consequent upon the work that he has done in improving the methods of lighting by both gas and electricity. It is therefore interesting to note that he thinks "gas lighting will hold its own as the poor man's friend." Its convenience as a lighting and heating agent constitutes gas "an institution of the utmost value to the artizan," and he considers "the time is not far distant when both rich and poor will largely resort to gas as the most convenient, the cleanest, and the cheapest of heating agents, and when raw coal will be seen only at the colliery or the gasworks." In a paper read before the Mechanical Science Section, Mr. William Sugg expressed a similar opinion as to the future of gas and said that at present the greatest hindrance to improvements was met with in those members of the public who supply themselves with the lowest priced burners and stoves they can buy and then blame the quality of the gas. He believes that if the consumers of gas would only acquire a moderate amount of information as to its properties, they would be enabled to use it with greater economy and comfort to themselves, and he considers that the easy manner in which gas can be made to produce either the light of a rushlight or the blaze of a thousand candles by a mere turn of the wrist, joined to the readiness by which it can be conveyed from one place to another, will always insure for it a large and increasing demand. Indeed there can be little doubt as to the future of gas, and the growing importance of the long list of substances mentioned by Dr. Siemens, which are looked upon at present as by-products in its manufacture, renders it probable that the time is not far distant when these will become the principal objects of the distillation of coal, and "gas" will take their place as a by-product. The address of the President of the Chemical Section, Professor G. D. Liveing, had for its subject the advance made in the dynamics of chemistry. In the Botanical Department of the Biological Section, Professor Lawson delivered an address on the progress of systematic botany during the last eight years.

In the Mechanical Science Section, also, a most interesting paper on "Recent Progress in Telephony" was read by Mr. W. H. Preece, of the General Post Office. Only six years have elapsed since the telephone was first mentioned to a British audience, at Glasgow, by Sir William Thompson, and now it is in practical use, more than a million and a half sterling is invested in its working in this country alone, and it is earning an annual revenue of more than £100,000. It is worthy of note that the original telephone receiver of Bell has scarcely been improved upon. The principal difficulty attending the use of the telephone is not due to any defect in the instrument itself, but to disturbing influences external to it. It is so sensitive that the minute quantity of electricity which makes up the currents is easily absorbed by competing conductors. When two or more telephone conductors run side by side, what is said on one can be overheard on the others, and when a telephone wire extends alongside telegraph wires every current on the telegraph circuit is repeated in the telephone, giving rise to a hissing bubbling sound which on busy lines entirely drowns speech. The only remedy for this evil at present found practically effective is to employ a complete metallic circuit, so contrived that the two wires are in very close proximity to each other or that they twist round each other so as to maintain a mean average equality of distance between themselves and the disturbing wires. The telephone has established beyond doubt the fact that currents of electricity actually traverse the earth's crust. Several cases are on record in which telephone circuits miles away from any telegraph wires, but in a line with the earth terminals, have picked up telegraphic signals. When, too, an electric light system uses the earth it stops all telephonic communication in the neighbourhood; on one day the whole telephonic communication of Manchester broke down from this cause, and on another occasion, in the city of London, the effect was so strong as not only to destroy telephonic communication but to ring the bells also. A telephone circuit in connection with the earth gives distinct evidence of every visible flash of lightning and there have been several cases of persons being knocked down while experimenting during a thunderstorm, though no personal injury has been sustained. In England the use of double wires diminishes danger from this source to a minimum, but on the continent and in America, where single wires are used, telephones are invariably protected by a lightning arrester.

An extremely interesting experiment has recently been made as to whether it is possible to communicate by means of electricity across seas and channels without the aid of wires. Large metal plates were immersed in the sea on opposite sides of the Solent, one set at Portsmouth and Ryde, six miles apart, and another set at Hurst Castle and Sconce Point, one mile apart. The Portsmouth and Hurst Castle plates were connected by a wire passing through Southampton, the Ryde and Sconce Point plates by a wire passing through Newport, the circuit being completed by the sea. The experiment was so far successful that signals were passed easily so as to be read by the Morse system, but communication by telephone was not found practicable.

The well-known theory of Dr. Andrews, that the liquid and gaseous states of matter are continuous, has been questioned by more than one observer, and Dr. J. B. Hannay, as the result of several hundreds of experiments wherein hydrogen was compressed over various liquids in which it is insoluble, has arrived at the conclusion that the two states are not more continuous than are the solid and liquid states, but are separated by an isothermal passing through the critical point. He points out (*Nature*, August 17) that by Andrews's method, where the liquid is in contact with its own vapour, the critical point is the only period when the direct passage from liquid to gas is visible, whilst the employment of hydrogen for retaining a free surface allows of the observation of the passage at any pressure, and he states that it takes place as suddenly at two hundred atmospheres pressure as the critical pressure. In fact he considers that the irregularities observed by Dr. Andrews in the vicinity of the critical point rather lend support to the view that a change of state takes place there. He states the change thus:—"The cohesion of the liquid state is weakened as the thermal motion increases, till the repulsion is in excess of the attraction and the gaseous state ensues." So far from the gaseous state of matter being continuous and indistinguishable, he considers that the liquid limit or absolute boiling point is the only fixed point among the properties of matter, and he proposes to give to it the name of the "cohesion limit."

It is known that metals can be volatilized, but in order to effect this in air or gas at the ordinary pressure, high temperatures are required, the employment of the electric arc being frequently necessary. Some experiments have been made by M. Demarçay to ascertain whether the temperature at which volatilization takes place is affected by diminishing the pressure. He reports (*Comptes Rendus*, xcv., 183) that so far as he has gone he finds that only a comparatively low temperature is required. When a metal is heated in a vacuum there is generally at the commencement a disengagement of gas which ceases after a time varying with the metal, and then a blackish layer is deposited upon a cool surface, which eventually takes a metallic aspect. The temperatures required for volatilization of the metals experimented with were—cadmium, 160° C.; zinc, 184° C.; antimony and bismuth, 292° C.; lead and tin, 360° C. If proper precautions are not taken, a thin layer of sub-oxide is formed on the surface of the metal when it is first heated, and this being less volatile than the metal prevents the volatilization until a temperature is reached much higher than those mentioned. A fissure appears then to be formed in the superficial coating of sub-oxide, and the deposit of volatilized metal commences suddenly. The author purposes to extend his experiments to platinum and iron.

Last month reference was made to experiments which appeared to show a relation between the molecular weights and melting points of certain groups of compounds. A paper communicated to the Academy of Sciences by M. Raoult (*Comptes Rendus*, xcv., 187) points to the existence of a physical constant at the other end of the scale. M. Raoult's experiments were made to determine the extent to which the freezing point of a liquid is lowered by the solution in it of various substances. Using chemically pure benzine, freezing at 4·96° C., he dissolved in it definite proportions of a series of compounds belonging to the groups of hydrocarbons, ethers and aldehydes. It was found that the coefficient of depression (*i.e.* the lowering of the point of congelation due to 1 gram of substance dissolved in 100 grams of benzine) varied considerably, but that if this coefficient of any of these bodies were multiplied by the molecular weight, the product was approximately constant, always being close to the number 50. The author deduces the law that acetones, ethers, hydrocarbons, and their derivatives, when dissolved in benzine in quantities proportional to their molecular weight, all lower the point of congelation of that liquid nearly the same number of degrees. At present it would appear that this property is independent of the nature, number or arrangement of the atoms composing the dissolved molecules.

In the *Scientific American* for August 12, there is a very interesting description of the arrangements for the supply of water to the city of Rochester in New York State. The city has two sources of supply, the water for fire and manufacturing purposes and the distribution of power being taken from the Genesee river, and the sweet water from Hemlock Lake, about thirty miles distant. The water is conveyed from the lake in iron pipes to a storage reservoir, and from thence to a distributing reservoir which is 117 feet below the level of the storage reservoir. This difference in level is taken advantage of for the purpose of thoroughly aërating the water before it is distributed into the city during warm weather, which is done by means of a fountain placed in the middle of the distributing reservoir. The fountain consists of a 24-inch pipe, turned vertically upwards, enlarged near the top to a diameter of 3 feet, and closed by means of a dome-shaped head provided with twenty-one orifices which may each be reduced in diameter or closed as desired. Through these orifices the whole of the sweet water for the supply of the city issues in jets, and is thus thoroughly exposed to the action of the atmosphere. The fountain is said to be visible in clear weather for a distance of many miles, and when all the orifices are closed except the centre one, and that is reduced to a diameter of 3 inches, the jet of water rises to the height of nearly 110 feet above the surface of the water in the distributing reservoir, or within 7½ feet of the elevation of its source in the storage reservoir 8¾ miles distant. The amount of water supplied daily in this way from Hemlock Lake is about three million gallons.

So many alkaloidal compounds have now been obtained from cinchona barks that the terminology has become sufficiently perplexing to render the elimination of any surplus names welcome. Some months ago Dr. Hesse described (*Pharm. Journ.*, [3], xii., 179), under the name "cinchamidine," an alkaloid obtained from the mother-liquor during the purification of homocinchonidine sulphate. He afterwards expressed an opinion (*Pharm. Journ.* [3], xii., 904), that this base was probably identical with Messrs. Forst and Böhringer's hydrocinchonidine, prepared by them from pure cinchonidine, but the formula calculated by him from the results of an analysis of the acid platino-chloride differed by 1 atom of carbon from that given by the other observers. Subsequent experiments have, however, induced Dr. Hesse to think that the excess of carbon was due to the presence of some neutral platinochloride in the salt analysed, and he now adopts for the alkaloid the formula of $C_{19}H_{24}N_2O$ and also the name "hydrocinchonidine" (*Annalen*, ccxiv., 1), since it appears to stand in the same relation to cinchonidine as hydroquinine does to quinine. Hydrocinchonidine is said to occur frequently in commercial preparations of cinchonidine and homocinchonidine, and Dr. Hesse describes several of its salts.

Further, Messrs. Forst and Böhringer have arrived at the conclusion (*Berichte*, xv., 1656) that the hydroconchinine separated by Dr. Hesse from the mother-liquors of quinidine (conchinine) sulphate is identical with the alkaloid obtained by them in the oxidation of quinidine by means of potassium permanganate, and called by them "hydroquinidine" ($C_{20}H_{26}N_2O + 2\frac{1}{2}H_2O$). They state that they have found hydroquinidine in samples of quinidine sulphate from various sources, and it would therefore appear to be a constant companion of quinidine in cinchona barks, just as cinchotine is of cinchonine, hydrocinchonidine of cinchonidine and hydroquinine of quinine. When an aqueous solution of the neutral sulphate is evaporated slowly, crystals are obtained containing 12 molecules of water of crystallization.

On the other hand Messrs. Forst and Böhringer have added to the cinchona terminology (*Berichte*, xv., 1659) the term "chitenidine," which they apply to an alkaloidal compound resembling chitenine that is formed, together with hydroquinidine and formic acid, in the oxidation of quinidine. This body had previously been observed, but not investigated, by Skraup. It is rather freely soluble in hot water, not so soluble in cold water, and still more difficultly soluble in alcohol. Its solution in dilute sulphuric acid has a blue fluorescence, which disappears upon the addition of hydrochloric acid. It is represented by the formula $C_{19}H_{22}N_2O_4 + 2H_2O$.

Professor G. Planchon, in the *Journal de Pharmacie*, this month, throws some fresh light on the source of cuprea bark. A microscopical examination of the specimens supplied to him by M. Triana showed that the barks derived from Bucaramanga, in the north, and from Llanos, the southern district, both present the same characters and are evidently both furnished by *Remijia pedunculata*. The cinchonamine bark of M. Arnaud presents different microscopical characters, and is referred by M. Planchon to *R. Purdieana*. He remarks that a microscopical examination has never yet deceived him in the solution of like problems. A singular confirmation of the value of this method of research occurs in the form of a postscript to M. Planchon's article, in which he states that since it was written M. Triana has received information to the effect that the cinchonamine bark does not come direct from Bucaramanga, but only passes through it, being collected near Antioquia on the other side of the Magdalena river. Further, that a large exporter of the cuprea bark has recognized the southern bark as the produce of *R. pedunculata*.

The products of the distillation of brucine with potash have been studied by M. Koninck (*Comptes Rendus*, xcv., 298). The crude product consisted of an oily mixture, presenting considerable analogy to the crude chinoleine resulting from the decomposition of cinchonine by potash. A considerable quantity of this oil was submitted to fractional distillation. The fractions between 90° and 140° C. were small and contained neutral and basic products; those between 140° and 160° contained a small quantity of a pyridic base, insoluble in water and having the composition of lutidine. Three fractions between 165° and 200° contained, the first a base presenting the principal characters of β-lutidine, the second a collidine probably identical with α-collidine, and the third a base identical with β-collidine, all three of which have been obtained from the chinoleine derived from cinchonine.

One of the reports to the Scientific Grants Committee of the British Medical Association, presented at the recent meeting at Worcester, contained a *résumé* by Dr. G. Thin of some of the results of his investigation upon the "Pathology of Parasitic Diseases of the Skin." With regard to the fungus of ringworm (*Trichophyton tonsurans*) he is of opinion that it is not a form of a common fungus, as has been supposed by some observers. He found that it could be cultivated artificially when moistened by vitreous humour, but when completely immersed in vitreous humour there was no evidence of its growth. This would appear to explain what takes place when in the treatment of ringworm recourse is had to applications which provoke inflammation, *i.e.*, an effusion of serum around the follicles, in which the *Trichophyton* cannot develope. In ringworm of the scalp, Dr. Thin says considerable caution is necessary in the choice of an application for provoking this curative inflammation; but in ringworm of the body, the parasite is so well within reach that it can be easily destroyed by one application of tincture of iodine and subsequent scrubbing with soap and water. With respect to *Microsporon furfur*, the fungus of pityriasis, and *Achorion Schœnleinii*, the fungus of favus, he has only obtained negative results. The destruction of the hair in *Alopecia areata* he considers to be due to minute bodies of definite and fixed shape and size, which are found in and on the hairs. They are distinct from the granular elements in hairs and are neither oily particles nor crystals, but have the refractive properties of and are bacteria (*Bacterium decalvans*). The disappearance of the hair, resulting in baldness, is due to a breaking up of the hair shaft by the multiplication in it of these organs.

The phenomena attending the preparation of a very alcoholic American-Indian beverage, called "chicha," from ungerminated maize, have been investigated by M. Marcano (*Comptes Rendus*, xcv., 345). The peculiarity consists chiefly in the active fermentation which goes on in a mass consisting nearly exclusively of starch that has not undergone any alteration except that produced by a short boiling with water. It was ascertained that this fermentation is coincident with the reproduction of well-defined vibrionic organisms, which were found on the outer pellicle of the maize grains, and also of the stalk. These organisms proved capable of resisting the action of boiling water during several minutes; they appeared to be most active at a temperature between 40° and 50°C., at which temperature they caused the fermentation of mannite, sugar of milk, saccharose and glucose. They seem to act directly upon young starch, such as occurs in the embryo of the grain; but also attack mature starch, though more slowly. In both cases there is a production of dextrine, carbonic acid gas, and alcohol.

An infusion of the curious scarlet seeds of the *Abrus precatorius* has long been used in the interior of Brazil as a popular remedy in the treatment of ophthalmic disorders. In some experiments made by Dr. de Wecker (*Comptes Rendus*, xcv., 299) to test the action of this remedy he found that a weak cold infusion, made from the powdered seeds, when applied as a lotion, rapidly produced a purulent ophthalmia of intensity corresponding to the number of applications made. The factitious ophthalmia thus produced disappeared in the course of ten days or a fortnight without any therapeutic intervention or danger to the cornea, and Dr. de Wecker is of opinion that this property possessed by the seeds of provoking a very intense ophthalmia of short duration could be utilized in ocular therapeutics in the treatment of granulations, conjunctival diphtheria, etc. The leaves of the plant are also used in the east as a remedy in croupal cough.

Dr. J. Ott describes, in *New Remedies* (p. 226), the physiological action of *Astragalus mollissimus*, one of the "loco" or crazy weeds of the Western States. Animals eat this plant when grass is scarce, and having once tasted it, they leave the sweetest grasses to eat the "loco." Two other plants are eaten by them in the same way, viz., *Oxytropis Lamberti* and *Sophoria sericea*. He finds that the astragalus is a powerful mydriatic, that it increases the flow of saliva, has a spinal tetanic action, a stupefying action on the brain, and reduces the force and frequency of the heart, killing mainly by arresting its action.

Evidence is brought forward in the *British Medical Journal* (p. 178) that the official solution of atropine of the British Pharmacopœia is liable to produce glaucoma, and that a very much weaker solution would serve to produce mydriasis or dilatation of the pupil. Dr. Ringer is of opinion that a solution formed by diluting the Pharmacopœia liquor with two or three hundred times its bulk of water would be sufficiently strong.

Dr. J. Lattey, writing to the same journal (p. 199), states that salicin possesses the peculiar property of relieving after-pains when opium is quite useless. He gives 15 grains for a dose, repeated every two hours until the pain ceases. He states he has never had to give more than three doses, two being usually effectual.

Dr. D. H. Cullimore records, in the *Lancet* (p. 216), a case of hydrophobia successfully treated by aconite, administered in conjunction with bromide of potassium and tincture of cinchona.

Dr. F. Hutchinson, of Scarborough, calls attention, in the *British Medical Journal* (p. 209), to the value of the local application of tincture of iodine in erysipelas, the effect in a case which came under his notice appearing to be almost magical. He does not attempt, however, to explain the action of the drug.

Dr. Schafer, in the *Berlin. klein. Wochenschrift* (*Therap. Gazette*, p. 266), has described a new use for Calabar bean. Having observed that it causes tetanus of the muscular coats of the intestines in animals, he tried it in cases of obstinate constipation dependent on atony of the coats of the bowels. The strength he used was, ext. physostigma, 0·05 gram; glycerine, 10·00 grams. A dose of six drops every three hours during the day gave relief in twenty-six hours.

Messrs. Heckel, Mourson and Schlagdenhauffen have sent to the French Academy (*Comptes Rendus*, xcv. 196) an account of the physiological action of globularine, $C_{15}H_{20}O_8$, and globularetine. The former in doses of 0·15 to 0·56 gram acts somewhat like theine; but in doses of 0·65 gram it produces toxic symptoms, lowering the pulse and the temperature and causing vertigo, headache, shivering, pain in the limbs, etc. It is this principle which has given to *Globularia* the reputation of having poisonous properties, and in consequence of which it obtained the name of *Frutex terribilis*. The globularetine, C_9H_6O, or resin of *Globularia*, is the purgative principle, but its action is less than that of the decoction of the plant, probably because in a natural state it is combined with mannite. It acts more rapidly as a purgative if dissolved in an alkaline solution. It resembles chrysophanic acid and aloin in the character of its effects, the dose varying from 0·125 gram to 1 gram. It also has a powerful action on the kidneys, raising the amount of solid matter excreted one-third above the normal quantity. Globularetine is very difficult to obtain in a state of purity, being always accompanied by a volatile principle which has a diuretic action.

According to Merck's Trade Report, experiments made by Dr. Hiller in the Charité at Berlin have shown that perfectly pure colocynthin is an excellent purgative, entirely devoid of the toxic and drastic effect produced by extract of colocynth. It is administered internally in doses of 1½ to 6 grains. It is a yellowish-white powder of a purely bitter taste, very soluble in water and alcohol.

Dr. Meredith, in the *Birmingham Medical Review*, recommends oil of peppermint as an external application for allaying the neuralgic pain so often complained of in cases of *Herpes zoster*. He has used it with great relief to the patient even when the eruption was out in a fresh florid condition (*Practitioner*, p. 134). He thinks that the value of this remedy in relieving neuralgic pain deserves to be better known.

Dr. E. Thompson recalls attention, in the *Lancet* (July 29, p. 136), to the use of the giant puff-ball, *Lycoperdon giganteum*, as a local hæmostatic. He states that it forms a most soft and comfortable surgical dressing, and that the powder it contains seems to possess antiseptic and anodyne properties. The mature plant is used. At this period it is about the size of a child's head and is covered with a thin skin; the latter is removed, and the capillitium and spores which form a dusty mass are used. Mr. Fagan, a leading surgeon in Belfast, found that it at once restrained bleeding from arteries in the bone in the neighbourhood of the orbit, after the failure of other means. The researches of Hayem (*Lancet*, p. 146), on the reason of the coagulation of the blood, show that the hæmostatic action of the puff-ball, as well as of all other spongy or powdery substances, depends upon the fact that healthy blood deposits hæmatoblasts or minute corpuscles on any foreign substance introduced into a vein, which become adhesive points for the subsequent attachment of particles of fibrin. This action, however, also takes place when the vessels themselves assume abnormal conditions, as when cut or altered by disease. The hæmatoblasts undergo change and become confluent more rapidly under the influence of warmth, which explains the power of warm water to arrest hæmorrhage. The hæmorrhagic tendency is believed to depend upon the absence from or small quantity of hæmatoblasts in the blood, since transfusion of blood has been found to arrest hæmorrhage in such cases.

MM. Weber and Thomas, of the French army (*Lancet*, p. 152), state that they have prepared tow in a chemically pure state, of perfect whiteness, soft, very elastic and readily absorbent, easily impregnated with antiseptics, and cheap. It is obtained by treating ordinary tow with caustic soda, and afterwards washing with solution of hypochlorite of soda to bleach it, the alkali being subsequently removed by hydrochloric acid. The cost of the tow is stated to be 1½ fr. to 1¾ fr. per kilo, or when carbolized 2 fr. to 2½ fr. per kilo. To impregnate it with carbolic acid, a solution of 3 parts of the acid in 2 of alcohol is sprinkled on sheets of filter paper laid between sheets of tow and placed in a closed box. In forty-eight hours the acid is said to pass entirely into the tow. The tow is thus made to contain 10 per cent. of carbolic acid.

The medical papers are now largely discussing phthisis from various aspects, and it is within the limits of possibility that the pharmaceutical chemist may be called upon to provide test solutions for detecting the *Bacillus tuberculosus*. It may be as well for him to know therefore that Dr. H. Gibbes, Curator of the King's College Museum, London, publishes, in the *Lancet* (p. 183), a new method of detecting the *Bacillus tuberculosus* in phthisical sputa, which he says he has found more successful than either Koch's or Ehrlich's process. The solutions he uses are those of magenta crystals and chrysoidin, and the formula given is:—Magenta crystals, 2 grams; pure aniline, 3 grams; alcohol, specific gravity ·830, and distilled water, 20 cubic centimetres. The aniline is dissolved in the spirit and then rubbed up with the magenta in a glass mortar, adding the spirit gradually until all is dissolved, then adding the water slowly while stirring. The solution should be kept in a stoppered bottle. The solution of chrysoidin is a saturated one in distilled water, a crystal of thymol being added to preserve it. Dilute nitric acid, made of 1 part of commercial acid and 2 of distilled water, is used to remove the excess of colour after using the magenta stain. According to Dr. Gibbes the bacilli, when mounted, can be detected with daylight by an ordinary ¼ inch objective, and a ⅛ dry glass will show with the same illumination that they are rows of spherical bodies.

In the *Medical Times and Gazette* (p. 165), appears an official report from Surgeon-Major T. Edmonston Charles, of the Indian army, recommending the use of coca for assuaging thirst during great exertion in hot countries. He is so satisfied as to its thirst-assuaging powers that he remarks, "Had our troops been provided with this leaf in Afghanistan, instead of the disaster after Maiwand our military historians would have had to chronicle a strategic movement to the rear on Candahar. Had the Russian detachment possessed this leaf they would have reached Khiva over the route they were sent to cross instead of having been forced to relinquish the attempt and retire demoralized with their ranks thinned by death in consequence of want of water." He states also that he has seen an infusion of coca relieve the intense headache of nervous exhaustion, ward off the failure of nerve power during prolonged fever, and enable patients to struggle through other exhausting diseases. That coca does possess valuable properties in the fresh state there can be but little doubt, or it would not be so extensively used in Bolivia and Peru, but the leaves as imported into this country do not generally seem to possess the activity with which they are credited by Dr. Charles. Even in Bolivia "coca fresca" is always used, the leaves, as the writer is assured by a resident in Bolivia, being never kept for more than three months. How far the activity of the drug may be due to a volatile oil, as in coffee, has yet to be determined, but a tincture prepared from the fresh leaves by a careful pharmacist would be fitter for experiment than the dried leaves. The coca plant is now being cultivated in Ceylon, and if the experiment be tried, as Dr. Charles suggests, with the Indian contingent sent to Egypt, some interesting results may be obtained.

The stacte of Scripture has been generally referred to liquid storax. But Mr. Heathcote, of Inhambane, in Africa, points out that the native name for a resin found on the east coast and which is fragrant when pounded and burnt, or even when boiled in water, is stakate and staka. Of the tree yielding this resin, which he describes as a kind of copal, he has discovered a forest 200 miles long, running parallel with the coast and midway between it and the first range of mountains, and about 100 miles from Inhambane. This copal tree is remarkable for its enormous height, so that the trees look with respect to the others like an ordinary tree in a hayfield (*Nature*, p. 351). Mr. Heathcote has collected about six tons of the resin.

Whether the present mode of cultivating lavender (*i.e.*, growing it for four years only) is the best may be open to question, seeing how often old and large plants are covered with blossom. The *Gardeners' Chronicle* (p. 262) mentions two hedges of lavender, in the terrace-garden at Pusey Park, Faringdon, which are literally sheeted with blossom. The hedges are four feet or so in width, and make a free growth every summer, but they are cut back every September to a width of twenty inches or so, and break out again into profuse growth in spring.

Dr. Paul Sorauer, of Proskau, Silesia, has originated the idea of forming an international association of the botanists and entomologists most competent to study the diseases of plants and the means by which they may be obviated or cured (*Gardeners' Chronicle*, p. 176). Among the objects proposed are the collection of statistics respecting plant diseases under differences of locality, soil, climate, etc., observations on the power of particular varieties to resist disturbing influences, and experiments with a view to discover the best varieties of plants to be cultivated in different localities. Growers of henbane and lavender will doubtless be glad to forward observations to Dr. Sorauer, if they can only obtain in return information as to the best means of obviating the fungus disease in the lavender and of destroying the insect enemies of the henbane.

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from page* 130.)

FERRI TANNAS (*Tannate of Iron*).

Solution of chloride of iron (ferric; specific gravity, 1·480–1·484)	35
Tannic acid	30
Alcohol (stronger)	12
Water of ammonia	q.s.
Distilled water	q.s.

Dilute the solution of chloride of iron with 200 parts of distilled water; precipitate completely with water of ammonia, collect the precipitate, wash it well, and mix it with a solution of the tannic acid in 40 parts of distilled water. Macerate for a few hours, and then add the alcohol. Collect the precipitate upon a strainer, wash it, and dry it.

It should be a coal-black powder.

PLUMBI TANNAS (*Tannate of Lead*).

Solution of subacetate of lead	100
Tannic acid	38
Distilled water	q.s.

Dilute the solution of subacetate of lead with 500 parts of distilled water, and add to it the tannic acid, previously dissolved in 500 parts of distilled water. Let the mixture stand a few hours, collect the precipitate upon a filter, wash it with about 500 parts of cold distilled water, and dry it at 25°–30° C. (77°–86° F.).

TINCTURA ALEXIPHARMACA HUXHAMI (*Huxham's Compound Tincture*).

Huxham's Tincture (of Bark).

Red cinchona (Javanese or East Indian), in coarse powder	48
Orange peel, deprived of the inner white layer	36
Serpentaria, bruised	9
Saffron, finely cut	4
Stronger alcohol	240
Water	240

Macerate for seven days, express, and filter.

TINCTURA ANTASTHMATICA (*Anti-Asthmatic Tincture*).

Licorice root, cut and bruised	12
Iris (blue flag) root	6
Squill, dried and bruised	3
Saffron, finely cut	2
Alcohol	214
Benzoic acid	1
Sugar	18

Macerate the first four ingredients with the alcohol during fourteen days; then express and dissolve in the strained liquid the acid and sugar. Finally filter.

TINCTURA ANTIFEBRILIS WARBURGI (*Warburg's Fever Tincture*).

(Abbreviated Formula.)

Tincture of orange peel	5
Compound tincture of aloes	20
Stronger alcohol	15
Spirit of camphor	2
Sulphate of quinine	1

Dissolve the sulphate of quinine in the alcohol, and add the other liquids.

N.B.—Tincture of orange peel (Pharm. Neerl.) is prepared by macerating 1 part of sweet orange peel (only the outer yellow portion) with 6 parts of alcohol for fourteen days.

Compound tincture of aloes (Pharm. Neerl.) is prepared by mixing equal parts of tincture of aloes (aloes 1, alcohol 8), tincture of myrrh (myrrh 1, stronger alcohol 8), and tincture of saffron (saffron 1, alcohol 8).

Spirit of camphor (Pharm. Neerl.) is composed of camphor 1, stronger alcohol 12 parts.

TINCTURA CHINOIDINI (*Tincture of Chinoidin*).

Purified chinoidin, in fine powder	2
Hydrochloric acid	1
Alcohol	17

Dissolve the chinoidin in the alcohol and acid, and filter.

TINCTURA DIGITALIS ÆTHEREA (*Ethereal Tincture of Digitalis*).

Digitalis, dried and in coarse powder	2
Ether	5
Stronger alcohol	15

Macerate during seven days, express, filter (avoiding loss by evaporation), and preserve the filtrate in a dark place.

TINCTURA GELSEMII (*Tincture of Gelsemium*).

Gelsemium, in powder	1
Alcohol	10

Macerate during three days, express and filter.

TINCTURA HYRACEI (*Tincture of Hyraceum*).

Cape hyraceum	1
Distilled water	6
Stronger alcohol	2

Macerate the hyraceum during six days with the distilled water. Then add the alcohol and filter.

[We quote this, *not* for the purpose of advising its use, but to attach to it a criticism. We think the time has arrived when the unscientific, empirical use of excrementitious medicines should finally be abandoned.—ED. N. R.]

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 2, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPERTIES OF ANTISEPTICS.

THE literary history of antiseptics is a long string of contradictions. Almost without exception the virtues of every substance vaunted as an antiseptic have been challenged; nearly every investigator has had his pet antiseptic which he has "proved" by experiment to be better than any other, and even such a body as carbolic acid has been declared on the one hand to be an energetic germicide, and on the other as only producing unfavourable conditions for the development of germs. Some explanation of this is no doubt to be found in the varying conditions under which experiments have been made by different investigators, as well as in the unwarranted inferences that have been frequently drawn from the results obtained. Some experiments recently made by M. LE BON appear also to show that not only the antiseptic itself, but the condition of the substance upon which it is used, exercises a powerful influence upon the result obtained and has to be taken into consideration. For instance, an aqueous liquor containing one-tenth of its weight of minced flesh gives off at the commencement of putrefaction an odour that is very fetid, but which is destroyed by a relatively small quantity of an antiseptic. If, however, the putrefaction be allowed to go on, after about two months there will be developed in the same liquid new bodies, having a special odour, which requires at least double the quantity of the same antiseptic for its destruction. Again, if the relative power of antiseptics be estimated by taking as a basis their disinfecting properties upon a given weight of such a liquid as that mentioned, it would appear, according to M. LE BON, that amongst the most powerful disinfectants are potassium permanganate, chloride of lime, sulphate of iron acidified by acetic acid, carbolic acid and the glyceroborates of sodium and potassium. He found, for instance, that to disinfect 10 c.c. of the flesh liquid it required 500 c.c. of saturated aqueous solution of salicylic acid, 80 c.c. of a saturated solution of carbolic acid, 80 c.c. of a 10 per cent. solution of glyceroborate of sodium, and only a few drops of a 1 per cent. solution of potassium permanganate. But there is no parallelism between the disinfectant action of an antiseptic and its action upon microbes, for potassium permanganate, which is one of the most powerful disinfectants, was found to exercise no appreciable action upon them, whilst alcohol, which hinders for a long time their development, exercises upon the products of putrefaction only a very slight disinfectant action. There would seem, therefore, to be no relation between the power of preventing the initiation of putrefaction and that of arresting it when it has appeared. Alcohol and carbolic acid, which are preservative agents *par excellence*, have only a very feeble action upon putrefaction that has commenced. In fact, with the exception of a very small number of powerful poisons, such as bichloride of mercury, the greater number of reputed antiseptics have scarcely any action upon bacteria. This is notably the case with carbolic acid, which, curiously enough, M. LE BON considers to be one of the best mediums that can be employed to preserve living bacteria.

Another experiment illustrating the difference that may exist unsuspected in the same substances treated antiseptically at different periods was made by introducing frogs into a flask at the bottom of which was a thin layer of the flesh liquor before mentioned. It was observed that at the commencement of the putrefaction the liquid, although rich in sulphuretted hydrogen, possessing an extremely fetid odour, swarming with bacteria and very virulent when injected under the skin, exercised no appreciable action upon the animals respiring in it; but the same liquid at the end of two months, though no longer possessing virulent properties when injected under the skin, killed in a few minutes the animals who had to breathe in it. There is, therefore, no parallelism between the virulent power of a putrefying body and the toxic power of the volatile compounds that are given off from it; indeed the two properties seem to be inverse the one of the other. M. LE BON reports that the extremely toxic nature of the volatile products of putrefaction were on more than one occasion demonstrated upon himself and other persons who happened to enter his laboratory during the course of his experiments.

The inferences that may be drawn from the results obtained by M. LE BON, as to the circumspection required in estimating the value of antiseptics, are to some extent confirmed by observations recently made by Herr HERZEN upon the varying influence of boracic acid upon different fermentations. He reports that whilst the conversion of starch into glucose by means of the salivary or pancreatic ferment is not influenced by boracic acid, even when the menstruum is a saturated solution, the conversion of glucose into alcohol is favoured by the presence of boracic acid even in very minute quantity. On the other hand only a very small quantity of boracic acid is necessary to completely prevent the conversion of alcohol into acetic acid. In respect also to the fermentations of albuminoid bodies boracic acid shows a marked difference in its behaviour, the conversion of albumen and fibrin into peptone and tryptone by means of pepsine and trypsine being remarkably accelerated by it, whilst putrefactive fermentation is entirely prevented.

THE INLAND REVENUE REPORT.

The Report of the Commissioners of Her Majesty's Inland Revenue for the year ending the 31st of March last, which has just been issued, contains the usual report of the Principal of the Laboratory. From it we learn that the work under his superintendence has recently very largely increased, the number of samples examined last year having amounted to upwards of 26,000, or an increase of 8000 as compared with the number mentioned in the last report. This increase is attributed principally to the beer duty and to the new regulations for determining the obscuration of foreign spirits on importation. But besides the analyses made in connection more especially with the Customs and Inland Revenue Departments, there is now a large amount of work done in the Laboratory on behalf of other departments of the State, especially in the examination of samples of goods supplied under contract. The necessity for the service thus rendered to the State may be estimated by the fact that, taking the India Office for an example, out of four hundred and eighty-eight general samples submitted, eighty-seven, or 17 per cent. were reported against. Nearly one-half of the samples of wine analysed fell below the standard, and 68 per cent of the samples of brandy, which by the terms of the contract was required to be derived solely from the fermented juice of the grape, had to be rejected as containing variable proportions of grain spirit. The adulteration of oils, too, has been found to have lately become very general, sophistication being effected in more subtle and ingenious ways than formerly. For the Board of Trade eighty-six samples of lime juice and five hundred and fifty samples of lemon juice had been examined, with the result that 6 per cent. of the lime juice and 16 per cent. of the lemon juice (the latter representing more than 14,000 gallons) were rejected. Most of the rejected lemon juice, though otherwise satisfactory, contained free pulpy matter, having been prepared early in the season when lemons are required for making candied peel, and the squeezing is done expeditiously, so that the juice is looked upon rather as a by-product. The pulpy matter has, however, to be got rid of by filtration before the juice is fit for use on shipboard, and as this operation is tedious, attempts are made to get juice containing pulpy matter passed in order to avoid the inconvenience and expense of clarification.

Another duty performed in the Inland Revenue Laboratory is the examination of samples referred by magistrates for analysis under the 22nd section of the Sale of Food and Drugs Act. Of these during the year there were forty-one, consisting of milk, butter, coffee, bread, oatmeal, beer, mustard and whisky, and in fifteen cases the Laboratory officials were unable to support the certificates of the public analysts. Certain samples of milk were received from Dundee, concerning which the prosecutors did not charge the defendants either with adding water or abstracting cream, but asked for a conviction on the ground that the milk was of inferior quality. The total solids in each case were between 11 and 12 per cent., and the proportion of fat, though low, was not lower than is found in genuine milk of poor quality. On receiving a report to this effect the Procurator Fiscal asked for an opinion as to the liability of persons selling milk of low quality, and in reply the Principal of the Laboratory pointed out that the Act of 1875 is silent on the question of standards, from which he inferred that no penalty is incurred by the sale of milk in the state in which it is yielded by a cow in healthy condition under the usual changes of food and season. Another sample of milk was remarkable for the low amount of "solids not fat" and the high amount of mineral matter, especially chlorides, it contained. In this case the cow was reported to be healthy and well fed and to have been milked in the presence of the analyst. Two samples of coffee, which, according to the certificates of the analyst, contained one 10 per cent. and the other 27 per cent. of chicory were found to be quite free from that substance.

The principal report contains one or two points worthy of mention. The licences issued to patent medicine vendors during the year numbered 18,765, and the amount realized for patent medicine stamps reached £144,884, being an increase of £6,205 on the previous year. A falling off in the consumption of beer is connected, among other causes, with the manufacture of temperance drinks, which has been exceedingly brisk. Although some of these contain no alcohol, others are stated to contain a certain amount of spirit generated by fermentation, and it has been found necessary to insist upon the conditions that such drinks shall not be made from malt and hops or contain more than 3 per cent. of proof spirit.

THE BRITISH ASSOCIATION.

The meeting of the British Association at Southampton has been continued during the past week, and on the whole, though not so numerously attended as some meetings in previous years, it has been fairly successful. The difficulty as to the place of meeting next year, caused by the withdrawal of the invitation from Oxford, has been solved by a resolution accepting an invitation from Southport, the President-Elect being Professor Cayley. A vigorous, though unsuccessful effort was made by a section of the members to secure the acceptance of an invitation to the Association to meet next year in the Dominion of Canada, the invitation having the support of the Governor-General and the Premier of the Dominion. It was decided, however, by a considerable majority, that the Association should meet in Montreal in 1884, the other candidates being Birmingham, Aberdeen and Nottingham.

We are requested by the President of the British Pharmaceutical Conference to say that the title of his Address, printed in the last number of this Journal, is "The Relation of Pharmacy to the State."

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

At a special meeting of the Committee, held at the Church Institute, on August 24, 1882, Mr. E. Yewdall, Vice-President, in the chair:

It was resolved, on the motion of Mr. R. Reynolds, seconded by Mr. P. Jefferson:—"That the Committee of the Leeds Chemists' Association record their sorrow at the death of their President, Mr. T. B. Stead, who was a founder of the Association twenty years ago, and who had been one of its constant supporters ever since. Mr. Stead's sound business-like sense, genial manner, and readiness to work for the general good had secured for him the esteem of his fellow chemists. The Committee respectfully tender to Mrs. Stead and her family the assurance of their sympathy under this bereavement."

The Hon. Secretary, Mr. J. Hellowell, was requested to forward to Mrs. Stead a copy of the above resolution, and to enter the same on the minutes of the Association.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page 177.*)

Additional Delegates who were Present.

We are informed by a correspondent that, in addition to the gentlemen who were mentioned last week as representing various Associations at the Conference, Mr. George Ward, F.C.S., F.I.C., and Mr. F. W. Branson were present as delegates from the Leeds Chemists' Association.

The reading of papers was then proceeded with. The first paper read was the following—

First Report on the Differences between the Essential Oils of Cinnamon and Cassia.

BY A. H. JACKSON, B.SC., PH.C.

This investigation was begun in answer to a question on the Conference Blue List, and the work has been done in the Laboratories of the Owens College, Manchester.

The oils were distilled by Mr. Umney from carefully selected samples of barks:—100 lbs. of the bark of *Cinnamomum Zeylanicum* yielded nearly 8 ounces of the essential oil of cinnamon, and 200 lbs. of the bark, whose source is variously ascribed to the *Cassia lignea*, *Laurus cassia* and *Cinnamomum aromaticum*, yielded nearly 16 ounces of the essential oil of cassia; thus the barks practically yielded $\frac{1}{2}$ per cent. of oil on distillation.

The aim in these experiments was to treat both oils in a similar way, in the hope of separating some product from the one that is either not contained in the other, or is contained in a different proportion, and as a physical examination only involved a very slight consumption of material, the oils were tested from both a physical and a chemical standpoint, although the Conference question only asks for a chemical distinction.

Physical Examination.

Effects on the Senses.—The oils had a pale-brown colour, distinctive and characteristic odours, sweet taste, the cinnamon being more fiery than the cassia.

Effects on Polarized Light.—Gladstone says that oil of cassia has no effect (*Journ. Chem. Soc.*, xvii., 3). The 'Pharmacographia' puts cassia as 0°·1 dextro-rotatory with a column 50 mm. long, and cinnamon as slightly lævo-rotatory; whilst Symes says that cassia has a lævo-rotatory power of 1° and cinnamon none, with a column 100 mm. long.

Relative Densities.—The density was calculated from the formula $\Delta = \frac{m}{w}(Q-\lambda)+\lambda$, where m = the apparent weight in air; Q = density of the water used; λ = density of the air, at the time of weighing, in relation to water at 4° C. as the unit; w = the apparent weight of a volume of water of density; Q equal to the volume of the body. 1st weighings at 17° C.:—Empty flask = 28·466 grams; flask of water = 93·251 grams; water = 64·785 grams; flask of cassia = 95·583 grams; cassia = 67·117 grams; flask of cinnamon = 93·889 grams; cinnamon = 65·423 grams. Therefore, cassia $\Delta = 1{\cdot}0346$; cinnamon $\Delta = 1{\cdot}0086$. 2nd weighings at 14° C.:—Empty flask = 28·466 grams; flask of water = 93·257 grams; water = 64·791 grams; flask of cassia = 95·819 grams; cassia = 67·353 grams; flask of cinnamon = 94·013 grams; cinnamon = 65·547 grams. Therefore cassia $\Delta = \frac{67{\cdot}353}{64{\cdot}791}({\cdot}9993 - {\cdot}0012) + {\cdot}0012 = 1{\cdot}0387$; cinnamon $\Delta = \frac{65{\cdot}547}{64{\cdot}791}({\cdot}9993 - {\cdot}0012) + {\cdot}0012 = 1{\cdot}0109$.

The mean of these two determinations fixes the density of cassia at 1·0366, and cinnamon at 1·0097 in vacuo and compared with water at its maximum density.

The published densities vary somewhat. Thus, that of cassia is put as 1·0297 at 15·5° C. (in Watts's Dictionary); as 1·059 at 11° C. (Watts's Supplement); as 1·066 ('Pharmacographia'); as 1·053 at 15·5° C. (Symes); whilst that of cinnamon is put as 1·035 ('Pharmacographia'); as 1·008 at 25° C. (Gmelin's 'Chemistry'); 1·025 at 15·5° C. (Symes).

Their *Absorption Spectra* were tried with negative results.

Refractive Energy.—The angle (ϕ) of an empty, hollow, triangular prism, was determined by observing the distance through which it had to be rotated in order to see a ray of light reflected from both sides of the angle, which measured—1st reading, 57° 58′; 2nd reading, 58° 5′ 10″; mean, 58° 1′ 35″ = ϕ. The prism was then filled with the essential oils, and the minimum deviation (δ) of a ray of *Na* light measured:—

	Direct Reading.	Prism Reading.
1st experiment .	1° 27′ 0″	319° 24′ 20″
2nd ,, .	1° 25′ 20″	319° 25′ 40″
Mean	1° 26′ 10″	319° 25′ 0″

360° − (319° 25′ − 1° 26′ 10″) = 42° 1′ 10″ = δ for cinnamon.

	Direct Reading.	Prism Reading.
1st experiment .	1° 26′ 40″	317° 29′ 0″
2nd ,, .	1° 26′ 0″	317° 28′ 0″
Mean	1° 26′ 20″	317° 28′ 30″

360° − (317° 28′ 30″ − 1° 26′ 20″) = 43° 57′ 50″ = δ for cassia.

The index of refraction (μ) was calculated from the formula $\mu = \frac{\sin\frac{1}{2}(\delta+\phi)}{\sin\frac{1}{2}(\phi)}$.

$$\mu = \frac{\sin\frac{1}{2}(42^\circ\ 1'\ 10'' + 58^\circ\ 1'\ 35'')}{\sin\frac{1}{2}(58^\circ\ 1'\ 35'')} = \frac{\sin 50^\circ\ 1'\ 22\frac{1}{2}''}{\sin 29^\circ\ 0'\ 47\frac{1}{2}''} = \frac{6424811}{4850110} = 1{\cdot}32446 \text{ for cinnamon.}$$

$$\mu = \frac{\sin\frac{1}{2}(43^\circ\ 57'\ 50'' + 58^\circ\ 1'\ 35'')}{\sin\frac{1}{2}(58^\circ\ 1'\ 35'')} = \frac{\sin 50^\circ\ 59'\ 42\frac{1}{2}''}{\sin 29^\circ\ 0'\ 47\frac{1}{2}''} = \frac{6293863}{4850110} = 1{\cdot}29767 \text{ for cassia.}$$

The specific refractive energy was then equal to $\left(\frac{\mu-1}{d}\right)$ where (d) is the density of the oils at 15·5° C., thus cinnamon $= \frac{1{\cdot}32446-1}{1{\cdot}0107} = {\cdot}32102$, and cassia $= \frac{1{\cdot}29767-1}{1{\cdot}0377} = {\cdot}28685$. This energy is said to be due to the contained cinnamaldehyde.

From these observations it may be inferred that neither the relative densities nor the refractive energies are sufficient guides in distinguishing mixtures of these oils.

Chemical Examination.

These oils consist chiefly of cinnamaldehyde, together with small quantities of cinnamic acid, resins, and unexamined hydrocarbons. The acid and resins are probably due to oxidation of the oil, as they increase in amount with age and exposure. Of the latter, Mulder has examined two, viz., the α-resin, fusible at 60° and soluble in cold alcohol; and the β-resin, fusible at 145°, soluble in hot alcohol, but sparingly so in cold. There is said to be an unexamined camphor in oil of cinnamon, and a stearoptene in oil of cassia ('Pharmacographia'). Rochleder and Hlasiwetz found in oil of cassia a crystalline deposit to which they gave the name of 'benzhydrol,' and the formula $C_{14}H_{15}O_{2\frac{1}{2}}$ (Wurtz's 'Dictionary'). Bizio says that cinnamon becomes turbid at 20° from a deposition of camphor; and Margueron that it freezes several degrees below zero, and then melts at 5° (Gmelin's 'Chemistry,' vol. xiii.). In Gerhardt's edition of Liebig's 'Chemistry,' essence of canelle is said to solidify at $-5°$, and to leave crystals at $-20°$.

Fractional Distillation.—All temperatures measured with a centigrade thermometer. A portion of the oil of cassia, being neutral but turbid, was added to some fused $CaCl_2$ and ether; then decanted and the ether distilled off, after which the temperature rose to 218° and half the oil came over, leaving a solid black residue. This distillate was separated into six parts by heating in a small retort:—

1st. Distilled under 220°, small portions of a yellow and a light brown liquid which do not mix.

2nd. Distilled about 225°, brown liquid.

3rd. Distilled at 242° to 244°, large portion of brown liquid.

4th. Distilled at 245°, pale yellow, about half the bulk of the brown and more fragrant.

5th. Distilled about 250°, yellowish-brown liquid from which fragrant and acicular crystals separated out after some weeks.

6th. Distilled above 255°, small portion of dark brown liquid. Residue, a brownish-black solid, from which white fumes arose on strongly heating, but nothing more came over.

Bertagnini's Method.—This was thought to be productive of a better result than the method of fractionation. So that a portion of the cassia was shaken, in small quantities at a time, with a saturated solution of potassium bisulphite, whereby a white magma and a small lot of yellowish liquid separated out; this was filtered and washed with methylated spirit by the aid of a Bunsen pump; the residue, on the filter, supposed to be a crystalline mass of cinnamaldehyde and potassium bisulphite was put aside for further investigation. To the filtrate were added water and sodium chloride; a very small quantity of oil separated out and floated on the surface. The supernatant oil, removed by a separating funnel, was treated with fused potassium carbonate to remove water, then dissolved out by anhydrous ether; after evaporation of the ether there was left a clear, brown oil, smelling of sawdust and patchouli (30); a pipette, which had been first tried for the removal of the supernatant oil, was washed with methylated spirit and then with strong sulphuric acid, whereby a brownish-violet colour was developed.

Some of the oil of cinnamon was treated in the same way and with a similar result. Each oil yielded about three times its weight of the washed, damp, fresh, crystalline magma.

Sometimes the oils did not combine with the potassium bisulphite; and at other times so entirely combined as apparently to leave no yellow liquid (as if there was nothing but cinnamaldehyde present); some of the lots liquefied and apparently separated into their original state immediately after combination. These liquefied mixtures of cassia and bisulphite were put into a retort, with some water, and distilled by passing steam through it; a brown residue (1) was left.

To the distillate sodium chloride was added and it was re-distilled; from the opalescent distillates a few drops of a yellow liquid separated, floating on the surface and smelling of oil of bitter almonds.

Residue (1). On boiling, some of this clear, brown, fragrant, thick solution with cupric sulphate and caustic soda, it became yellowish-red and turbid; in a little time it separated into a yellowish-brown liquid and a reddish-brown residue, consisting of red cuprous oxide and an oily substance, which, on addition of water, formed a yellow, turbid solution smelling of benzyaldehyde; therefore No. 1 probably contains a glucoside or glucose.

As it is probable that the cinnamaldehyde is the only constituent of these oils which combines with the potassium bisulphite, it is in the filtrate from their magmas that the cause of difference between the oils is likely to be found. But, as the oils are said to consist almost entirely of the cinnamaldehyde, there is but a very small quantity of material, and that largely diluted, left for the investigation.

The PRESIDENT said pharmacists had long wanted to know something of the differences and the causes of the differences between the oils of cinnamon and of cassia, and the Committee had asked Mr. Jackson to endeavour to throw some light on the subject, and he would now propose a vote of thanks to him for the skill with which he had so far accomplished the work. Mr. Jackson had confirmed what had been previously observed, that the specific gravity of cinnamon oil was considerably below that of cassia, for although the specific gravities had been given very differently by different observers, still taking them all it was clear that the specific gravity of cassia was considerably above that of oil of cinnamon. The numbers Mr. Jackson had quoted were for cassia from 1066 to 1030, and for cinnamon from 1035 to 1008; but he himself found the specific gravity of oil of cassia was 1037, while that of cinnamon was 1010. There seemed to be no great difference in the refractive energy. Finally Mr. Jackson said the chief cause of the difference would unfortunately be found in a material which was present in a very small proportion in both these oils, for each of them consisted largely of cinnamaldehyde. This was unfortunate, because though they were anxious that gentlemen should work at such subjects as this, which required special skill and expensive materials, at the cost of the Conference, still there must be a limit, and if they were to spend £10 or so simply to get from one pound of oil only a very small quantity of the material, which then only *might* contain what caused the difference between the two oils, he feared their funds would be exhausted before they arrived at any very satisfactory conclusion.

The vote of thanks was carried unanimously.

The next paper read was—

ON THE ALKALOIDAL VALUE OF BELLADONNA PLANTS AT DIFFERENT PERIODS OF GROWTH.

BY A. W. GERRARD, F.C.S.

At last year's meeting of this Conference I presented my first report on belladonna, the main features of which demonstrated the relative atropine value of cultivated and wild plants. The wild variety was found to be richest in atropine, and, contrary to general opinion, the leaf in both varieties was found to be richer than the root.

In continuation, I have been able to examine this summer two specimens of the first year's growth of the plant; likewise the second year's growth at three periods of development, viz., before, during, and after flowering. The object as regards the second year's plant was to determine at what period it attains its maximum therapeutic value.

Immediately on receipt of the fresh plants, the leaves and roots were separated and well dried, the estimation of the atropine being completed in less than a month from the time of collection. This rapidity of manipulation was considered advisable, to avoid as much as possible the changes plants undergo by keeping.

In the present experiments the process by which the atropine has been estimated differs from that described in my first report, the method of extraction, however, has been the same; the difference is that I have employed a volumetric instead of a gravimetric method.

For this purpose, I titrate the ethereal alkaloidal residue with a centinormal sulphuric acid, 100 parts of which is made to exactly neutralize 1 part of pure atropine. The alkaloid residue being but sparingly soluble in water I dissolve it in alcohol and colour with litmus, so as to clearly indicate the critical point. This method I find both rapid and accurate; to test it, two samples of commercial atropine, and two made by myself from cultivated and wild plants, gave upon titration, figures agreeing within 1 per cent. This result, whilst demonstrating the accuracy of the method, also shows that commercial atropine is a very pure substance.

The first year's plants examined were both uncultivated, one grown in Yorkshire on a chalk soil, the other in Sussex in leaf mould; none of these plants appeared to have flowered, they averaged 6 inches in height and twenty of them yielded on drying 203 grains of leaf and 165 grains of root. These two varieties gave the following results:—

Atropine in 100 *parts Wild Belladonna, First Year's Growth.*

	Roots.	Leaves.
From chalk soil . . .	·21	·23
From leaf mould . . .	·09	·22

The only value of this experiment is to show that the plant in the first year of its growth contains about half the quantity of atropine present in older plants, and practically this is of little importance, as on account of its small growth it is never collected for the druggist's use. The result also helps to confirm what I have stated in my previous paper, viz., that a chalky soil favours the formation of atropine.

Examination of Second Year's Plant.

The cultivated kind only was subjected to analysis. It was grown by Mr. Ransom, of Hitchin, and gathered in the months of May, June and July, June being the month when it is usually collected for the druggist's use, and would be expected to have arrived at maturity. The plants I received averaged 3 feet in height. The May plant, though not fully developed, had the most luxuriant crop of leaves. On the June plants the flowers were abundant, but the leaves were small. The July plant was covered with unripe fruits and small leaves.

Atropine in 100 *parts Cultivated Belladonna, Second Year's Growth.*

When collected.	Leaves.	Roots.
May	·25	·21
June	·36	·32
July	·34	·32

This result shows that the plant before flowering is not rich in active principles, but it appears that at the period of flowering the full development is reached and maintained into the fruiting season. Especially worthy of attention is the increase in the June yield of atropine, it being one-third more than obtained from the May plant. The experiment also shows a simultaneous development of root and leaf, and not the exhaustion of the former to strengthen the latter. The inference from this is that root and leaf should be gathered at the same period.

Throughout these experiments, as on former occasions, the leaves have uniformly yielded more atropine than the roots.

The PRESIDENT said this was a strictly pharmaceutical report, and considering the powerful effect of such alkaloids as atropine on the human system any researches on such bodies was of extreme importance. He gathered that in speaking of atropine Mr. Gerrard alluded to what he defined last year rather as a double alkaloid, as he said he would not tie himself to the statement that the alkaloid he obtained was chemically pure atropine.

Mr. GERRARD said he used the term atropine in the general sense, as usually accepted.

Mr. NAYLOR asked if these results were to be considered as commensurate with those obtained last year, because one would rather suppose, inasmuch as he had employed a different method for estimating the total alkaloid, there would be some slight deviation. The process of manipulation was very much shortened and therefore it was probable that by the former process there would be a greater amount of loss.

Mr. EKIN said this was of course only a preliminary report, and as he understood that Mr. Gerrard was going to continue the subject he would ask him if he thought it worth while to examine further the accuracy of the sulphuric acid determination. It certainly had the merit of extreme simplicity, but it might be worth further investigation as to whether it really did indicate the amount of alkaloid. Mr. Gerrard had told them that what he understood by the name alkaloid, as generally received, was a mixture, and that of itself introduced a little uncertainty, but this would be much increased if there were any doubt thrown on the method of determination. In such a very delicate operation the indications of litmus would be hardly sufficiently delicate. He would suggest to Mr. Gerrard, if he continued this method of estimating the alkaloids, whether he would not find methyl orange or some similar body give much narrower indications than were possible with litmus. He hoped they would be careful in drawing deductions as to the difference in quality of plants grown on cultivated soil and in their natural state from so comparatively small a number of experiments.

Mr. MARTINDALE asked if the volumetric test by sulphuric acid would not reckon the uncrystallizable alkaloid as well as the crystallizable atropine, and thus lead to error. Some manufacturers found that a great deal of uncrystallizable alkaloid was produced.

Mr. PLOWMAN would be glad if Mr. Gerrard would explain exactly what he meant by saying that he used a centinormal solution, 100 parts of which would exactly neutralize 1 part of pure atropine. With reference to Mr. Naylor's remarks, it was only fair to notice that the gravimetric operation would hardly be practicable for estimating an amount of atropine such as was described by Mr. Gerrard last year. Some modification must be adopted in order to get any results at all.

Mr. HOLMES said it was interesting to note the statement that belladonna grown on chalky soil yielded more alkaloid than that grown on other soil. He had seen the plant growing on calcareous and on non-calcareous soil, and he had found that when growing on chalky or calcareous soil it was far more luxuriant, which might account for the presence of more alkaloid.

A vote of thanks having been passed to Mr. Gerrard for his paper,

Mr. GERRARD, in reply, said he spoke of the total alkaloids because there was some uncertainty whether the product obtained was one definite substance or not. There was this difference between the process now employed and the one he adopted last year, that there was not so much mechanical loss involved in the present process, because there were not so many operations in it. In working out long processes, involving several precipitations and recrystallizations, there must be a mechanical loss, and therefore the percentages now given would be somewhat higher than those given before. Nevertheless, they were not very much so. The process he followed before was to obtain the alkaloid in as pure a state as possible, and to weigh it as alkaloid, and to do that, he ensured the thorough exhaustion of the mother-liquor of atropine, endeavouring, as far as possible to avoid mechanical loss. In reply to Mr. Ekin, who doubted whether the residue he obtained would be all alkaloid, he might say that the residue was not all alkaloid, but it was not all neutralized by sulphuric acid. All which was neutralized by the sulphuric acid he assumed to be alkaloid, and he believed it to be nothing else; because when ammonia was used to treat an extractive substance it liberated merely alkaloidal hydrates, and the sulphuric acid simply took them out together with colouring matters and some resins; but these latter would not neutralize sulphuric acid, therefore, he had a right to assume that what the sulphuric acid neutralized was alkaloid. Mr. Martindale had spoken of uncrystallizable substances, not atropine, in the alkaloidal residue. He had worked a good deal with alkaloids and on atropine, and he had always found what was usually called the uncrystallizable residue by further manipulation to be capable of crystallization, and if the sulphuric acid solution of his alkaloid was again precipitated the alkaloid could be easily extracted by pure ether in a crystalline state.

An adjournment for luncheon then took place.

(To be continued.)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The President's Address.

(Concluded from page 179.)

Electricity is the form of energy best suited for transmitting an effect from one place to another; the electric current passes through certain substances, the metals, with a velocity limited only by the retarding influence caused by electric charge of the surrounding dielectric, but approaching probably under favourable conditions that of radiant heat and light, or 300,000 kilometres per second; it refuses, however, to pass through oxidized substances, glass, gums, or through gases except when in a highly rarefied condition. It is easy, therefore, to confine the electric current within bounds, and to direct it through narrow channels of extraordinary length. The conducting wire of an Atlantic cable is such a narrow channel; it consists of a copper wire, or strand of wires, 5 mm. in diameter, by nearly 5000 kilometres in length, confined electrically by a coating of guttapercha about 4 mm. in thickness. The electricity from a small galvanic battery passing through this channel prefers the long journey to America in the good conductor, and back through the earth, to the shorter journey across the 4 mm. in thickness of insulating material. By an improved arrangement the alternating currents employed to work long submarine cables do not actually complete the circuit, but are merged in a condenser at the receiving station after having produced their extremely slight but certain effect upon the receiving instrument. So perfect is the channel and so precise the action of both the transmitting and receiving instruments employed, that two systems of electric signals may be passed simultaneously through the same cable in opposite directions, producing independent records at either end. By the application of this duplex mode of working to the Direct United States cable under the superintendence of Dr. Muirhead, its transmitting power was increased from twenty-five to sixty words a minute, being equivalent to about twelve currents or primary impulses per second.

The minute currents here employed are far surpassed as regards delicacy and frequency by those revealed to us by that marvel of the present day, the telephone. The electric currents caused by the vibrations of a diaphragm acted upon by the human voice, naturally vary in frequency and intensity according to the number and degree of those vibrations, and each motor current, in exciting the electro-magnet forming part of the receiving instrument, deflects the iron diaphragm occupying the position of an armature to a greater or smaller extent according to its strength. Savart found that the fundamental *la* springs from 440 complete variations in a second, but what must be the frequency and modulations of the motor current and of magnetic vibrations necessary to convey to the ear, through the medium of a vibrating armature, such a complex of human voices and of musical instruments as constitutes an opera performance. And yet such performances could be distinctly heard and even enjoyed as an artistic treat by applying to the ears a pair of the double telephonic receivers at the Paris Electrical Exhibition, when connected with a pair of transmitting instruments in front of the footlights of the Grand Opera. In connection with the telephone, and with its equally remarkable adjunct, the microphone, the names of Riess, Graham Bell, Edison and Hughes will ever be remembered.

Regarding the transmission of power to a distance the electric current has now entered the lists in competition with compressed air, the hydraulic accumulator, and the quick running rope as used at Schaffhausen to utilize the power of the Rhine fall. The transformation of electrical into mechanical energy can be accomplished with no further loss than is due to such incidental causes as friction and the heating of wires; these in a properly designed dynamo-electric machine do not exceed 10 per cent., as shown by Dr. John Hopkinson, and, judging from recent experiments of my own, a still nearer approach to ultimate perfection is attainable. Adhering, however, to Dr. Hopkinson's determination for safety's sake, and assuming the same percentage in reconverting the current into mechanical effect, a total loss of 19 per cent. results. To this loss must be added that through electrical resistance in the connecting line wires, which depends upon their length and conductivity, and that due to heating by friction of the working parts of the machine. Taking these as being equal to the internal losses incurred in the double process of conversion, there remains a useful effect of $100-38=62$ per cent., attainable at a distance, which agrees with experimental results, although in actual practice it would not be safe at present to expect more than 50 per cent. of ultimate useful effect, to allow for all mechanical losses.

In using compressed air or water for the transmission of power the loss cannot be taken at less than 50 per cent., and as it depends upon fluid resistance it increases with distance more rapidly than in the case of electricity. Taking the loss of effect in all cases as 50 per cent., electric transmission presents the advantage that an insulated wire does the work of a pipe capable of withstanding high internal pressure, which latter must be more costly to put down and to maintain. A second metallic conductor is required, however, to complete the electrical circuit, as the conducting power of the earth alone is found unreliable for passing quantity currents, owing to the effects of polarization; but as this second conductor need not be insulated, water or gas pipes, railway metals or fencing wire, may be called into requisition for the purpose. The small space occupied by the electro-motor, its high working speed, and the absence of waste products, render it specially available for the general distribution of power to cranes and light machinery of every description. A loss of effect of 50 per cent. does not stand in the way of such applications, for it must be remembered that a powerful central engine of best construction produces motive power with a consumption of two pounds of coal per horse-power per hour, whereas small engines distributed over a district would consume not less than five; we thus see that there is an advantage in favour of electric transmission as regards fuel, independently of the saving of labour and other collateral benefits.

To agriculture, electric transmission of power seems well adapted for effecting the various operations of the farm and fields from one centre. Having worked such a system myself in combination with electric lighting and horticulture for upwards of two years, I can speak with confidence of its economy, and of the facility with which the work is accomplished in charge of untrained persons.

As regards the effect of the electric light upon vegetation there is little to add to what was stated in my paper read before Section A last year, and ordered to be printed with the report, except that in experimenting upon wheat, barley, oats, and other cereals sown in the open air, there was a marked difference between the growth of the plants influenced and those uninfluenced by the electric light. This was not very apparent till towards the end of February, when, with the first appearance of mild weather, the plants under the influence of an electric lamp of 4000 candle power placed about 5 metres above the surface, developed with extreme rapidity, so that by the end of May they stood above 4 feet high, with the ears in full bloom, when those not under its influence were under 2 feet in height, and showed no sign of the ear.

In the electric railway first constructed by Dr. Werner Siemens, at Berlin, in 1879, electric energy was transmitted to the moving carriage or train of carriages through the two rails upon which it moved, these being sufficiently insulated from each other by being placed upon well creosoted cross sleepers. At the Paris Electrical Exhibition the current was conveyed through two separate conductors making sliding or rolling contact with the carriage, whereas in the electric railway now in course of construction in the north of Ireland (which when completed will have a length of twelve miles) a separate conductor will be provided by the side of the railway, and the return circuit completed through the rails themselves, which in that case need not be insulated; secondary batteries will be used to store the surplus energy created in running downhill, to be restored in ascending steep inclines, and for passing roadways where the separate insulated conductor is not practicable. The electric railway possesses great advantage over horse or steam-power for towns, in tunnels, and in all cases where natural sources of energy, such as waterfalls, are available; but it would not be reasonable to suppose that it will in its present condition compete with steam propulsion upon ordinary railways.

The deposition of metals from their solutions is perhaps the oldest of all useful applications of the electric current, but it is only in very recent times that the dynamo current has been practically applied to the refining of copper and other metals, as now practised at Birmingham and elsewhere, and upon an exceptionally large scale at Ocker, in Germany. The dynamo machine there employed was exhibited at the Paris Electrical Exhibition, its peculiar feature being that the conductors upon the rotating armature consisted of solid bars of copper 30 mm. square, in section, which were found only just sufficient to transmit the large quantity of electricity of low tension necessary for this operation. One such machine consuming 4-horse-power deposits about 300 kilograms of copper per twenty-four hours; the motive power at Ocker is derived from a waterfall.

Electric energy may also be employed for heating purposes, but in this case it would obviously be impossible for it to compete in point of economy with the direct combustion of fuel for the attainment of ordinary degrees of heat. Bunsen and Ste.-Claire Deville have taught us, however, that combustion becomes extremely sluggish when a temperature of 1800° C. has been reached, and for effects at temperatures exceeding that limit the electric furnace will probably find advantageous applications. Its specific advantage consists in being apparently unlimited in the degree of heat attainable, thus opening out a new field of investigation to the chemist and metallurgist. Tungsten has been melted in such a furnace, and 8 pounds of platinum have been reduced from the cold to the liquid condition in twenty minutes.

The largest and most extensive application of electric energy at the present time is to lighting, but, considering how much has of late been said and written for and against this new illuminant, I shall here confine myself to a few general remarks. Joule has shown that if an electric current is passed through a conductor the whole of the energy lost by the current is converted into heat; or if the resistance be localized, into radiant energy comprising heat, light, and actinic rays. Neither the low heat rays nor the ultra-violet of highest refrangibility affect the retina, and may be regarded as lost energy, the effective rays being those between the red and violet of the spectrum, which in their combination produce the effect of white light.

Regarding the proportion of luminous to non-luminous rays proceeding from an electric arc or incandescent wire, we have a most valuable investigation by Dr. Tyndall, recorded in his work on 'Radiant Heat.' Dr. Tyndall shows that the luminous rays from a platinum wire heated to its highest point of incandescence, which may be taken at 1700° C., formed $\frac{1}{24}$th part of the total radiant energy emitted, and $\frac{1}{10}$th part in the case of an arc light worked by a battery of fifty Grove's elements. In order to apply these valuable data to the case of electric lighting by means of dynamo currents, it is necessary in the first place to determine what is the power of fifty Grove's elements of the size used by Dr. Tyndall, expressed in the practical scale of units as now established. From a few experiments lately undertaken for myself, it would appear that fifty such cells have an electromotive force of 98·5 volts, and an internal resistance of 13·5 ohms, giving a current of 7·3 ampères when the cells are short-circuited. The resistance of a regulator such as Dr. Tyndall used in his experiments may be taken at 10 ohms, the current produced in the arc would be 4 ampères (allowing 1 ohm for the leads), and the power consumed 160 watts; the light power of such an arc would be about 150 candles, and comparing this with an arc of 3308 candles produced by 1162 watts, we find that 7·3 times the electric energy produce 22 times the amount of light measured horizontally. If, therefore, in Dr. Tyndall's arc $\frac{1}{10}$th of the radiant energy emitted was visible as light, it follows that in a powerful arc of 3300 candles, fully one-third are luminous rays. In the case of the incandescence light (say a Swan light of 20 candle power) we find in practice that nine times as much power has to be expended as in the case of the arc light; hence $\frac{1}{27}$th part of the power is given out as luminous rays, as against $\frac{1}{24}$th in Dr. Tyndall's incandescent platinum—a result sufficiently approximate considering the wide difference of conditions under which the two are compared.

These results are not only of obvious practical value, but they seem to establish a fixed relation between current, temperature, and light produced, which may serve as a means to determine temperatures exceeding the melting point of platinum with greater accuracy than has hitherto been possible by actinimetric methods in which the thickness of the luminous atmosphere must necessarily exercise a disturbing influence. It is probably owing to this circumstance that the temperature of the electric arc, as well as that of the solar photosphere, has frequently been greatly over-estimated.

The principal argument in favour of the electric light is furnished by its immunity from products of combustion, which not only heat the lighted apartments, but substitute carbonic acid and deleterious sulphur compounds for the oxygen upon which respiration depends; the electric light is white instead of yellow, and thus enables us to see pictures, furniture and flowers as by daylight; it supports growing plants instead of poisoning them, and by its means we can carry on photography and many other industries at night as well as during the day. The objection frequently urged against the electric light, that it depends upon the continuous motion of steam or gas engines, which are liable to accidental stoppage, has been removed by the introduction into practical use of the secondary battery; this, although not embodying a new conception, has lately been greatly improved in power and constancy by Planté, Faure, Volckmar, Sellon, and others, and promises to accomplish for electricity what the gas-holder has done for the supply of gas and the accumulator for hydraulic transmission of power.

It can no longer be a matter of reasonable doubt, therefore, that electric lighting will take its place as a public illuminant, and that even though its cost should be found greater than that of gas, it will be preferred for the lighting of drawing-rooms and dining-rooms, theatres and concert-rooms, museums, churches, warehouses, showrooms, printing establishments and factories, and also the cabins and engine-rooms of passenger steamers. In the cheaper and more powerful form of the arc light, it has proved itself superior to any other illuminant for spreading artificial daylight over the large areas of harbours, railway stations, and the sites of public works. When placed within a holophote the electric lamp has already become a powerful auxiliary in effecting military operations both by sea and land.

The electric light may be worked by natural sources of power such as waterfalls, the tidal wave, or the wind, and it is conceivable that these may be utilized at considerable distances by means of metallic conductors. Some five years ago I called attention to the vastness of those sources of energy, and the facility offered by electrical conduction in rendering them available for lighting and power-supply, while Sir William Thomson made this important matter the subject of his admirable address to Section A last year at York, and dealt with it in an exhaustive manner.

The advantages of the electric light and of the distribution of power by electricity have lately been recognized by the British Government, who have just passed a Bill through Parliament to facilitate the establishment of electrical conductors in towns, subject to certain regulating clauses to protect the interests of the public and of local authorities. Assuming the cost of electric light to be practically the same as gas, the preference for one or other will in each application be decided upon grounds of relative convenience, but I venture to think that gas-lighting will hold its own as the poor man's friend.

Gas is an institution of the utmost value to the artizan; it requires hardly any attention, is supplied upon regulated terms, and gives with what should be a cheerful light a genial warmth, which often saves the lighting of a fire. The time is moreover not far distant, I venture to think, when both rich and poor will largely resort to gas as the most convenient, the cleanest, and the cheapest of heating agents, and when raw coal will be seen only at the colliery or the gasworks. In all cases where the town to be supplied is within say thirty miles of the colliery, the gasworks may with advantage be planted at the mouth, or still better at the bottom of the pit, whereby all haulage of fuel would be avoided, and the gas, in its ascent from the bottom of the colliery, would acquire an onward pressure sufficient probably to impel it to its destination. The possibility of transporting combustible gas through pipes for such a distance has been proved at Pittsburg, where natural gas from the oil district is used in large quantities.

The quasi monopoly so long enjoyed by gas companies has had the inevitable effect of checking progress. The gas being supplied by meter, it has been seemingly to the advantage of the companies to give merely the prescribed illuminating power, and to discourage the invention of economical burners, in order that the consumption might reach a maximum. The application of gas for heating purposes has not been encouraged, and is still made difficult in consequence of the objectionable practice of reducing the pressure in the mains during daytime to the lowest possible point consistent with prevention of atmospheric indraught. The introduction of the electric light has convinced gas managers and directors that such a policy is no longer tenable, but must give way to one of technical progress; new processes for cheapening the production and increasing the purity and illuminating power of gas are being fully discussed before the Gas Institute; and improved burners, rivalling the electric light in brilliancy, greet our eyes as we pass along our principal thoroughfares.

Regarding the importance of the gas supply as it exists at present, we find from a Government return that the capital invested in gasworks in England, other than those of local authorities, amounts to £30,000,000; in these 4,281,048 tons of coal are converted annually, producing 43,000,000,000 cubic feet of gas, and about 2,800,000 tons of coke; whereas the total amount of coal annually converted in the United Kingdom may be estimated at 9,000,000 tons, and the by-products therefrom at 500,000 tons of tar, 1,000,000 tons of ammonia liquor, and 4,000,000 tons of coke, according to the returns kindly furnished me by the managers of many of the gasworks and corporations. To these may be added say 120,000 tons of sulphur, which up to the present time is a waste product.

Previous to the year 1856—that is to say, before Mr. W. H. Perkin had invented his practical process, based chiefly upon the theoretical investigations of Hoffman, regarding the coal-tar bases and the chemical constitution of indigo—the value of coal-tar in London was scarcely a halfpenny a gallon, and in country places gasmakers were glad to give it away. Up to that time the coal-tar industry had consisted chiefly in separating the tar by distillation into naphtha, creosote, oils, and pitch. A few distillers, however, made small quantities of benzene, which had been first shown—by Mansfield, in 1849—to exist in coal-tar naphtha mixed with toluene, cumene, etc. The discovery, in 1856, of the mauve or aniline purple gave a great impetus to the coal-tar trade, inasmuch as it necessitated the separation of large quantities of benzene, or a mixture of benzene and toluene, from the naphtha. The trade was further increased by the discovery of the magenta or rosaniline dye, which required the same products for its preparation. In the meantime, carbolic acid was gradually introduced into commerce, chiefly as a disinfectant, but also for the production of colouring matter.

The colour industry utilizes even now practically all the benzene, a large proportion of the solvent naphtha, all the anthracene, and a portion of the naphthalene resulting from the distillation of coal-tar; and the value of the colouring matter thus produced is estimated by Mr. Perkin at £3,350,000.

The demand for ammonia may be taken as unlimited, on account of its high agricultural value as a manure; and, considering the failing supply of guano and the growing necessity for stimulating the fertility of our soil, an increased production of ammonia may be regarded as a matter of national importance, for the supply of which we have to look almost exclusively to our gasworks. The present production of 1,000,000 tons of liquor yields 95,000 tons of sulphate of ammonia; which, taken at £20 10*s*. a ton, represents an annual value of £1,947,000.

The total annual value of the gasworks by-products may be estimated as follows:—

Colouring matter	£3,350,000
Sulphate of ammonia	1,947,000
Pitch (325,000 tons)	365,000
Creosote (25,000,000 gallons) . .	208,000
Crude carbolic acid (1,000,000 gallons)	100,000
Gas coke, 4,000,000 tons (after allowing 2,000,000 tons consumption in working the retorts) at 12*s*.	2,400,000
Total . . .	£8,370,000

Taking the coal used, 9,000,000 tons, at 12*s*., equal

£5,400,000; it follows that the by-products exceed in value the coal used by very nearly £3,000,000.

In using raw coal for heating purposes these valuable products are not only absolutely lost to us, but in their stead we are favoured with those semi-gaseous by-products of the atmosphere too well known to the denizens in London and other large towns as smoke. Professor Roberts has calculated that the soot in the pall hanging over London on a winter's day amounts to fifty tons, and that the carbonic oxide, a poisonous compound, resulting from the imperfect combustion of coal, may be taken as at least five times that amount. Mr. Aitken has shown, moreover, in an interesting paper communicated to the Royal Society of Edinburgh, last year, that the fine dust resulting from imperfect combustion of coal is mainly instrumental in the formation of fog; each particle of solid matter attracting to itself aqueous vapour; these globules of fog are rendered particularly tenacious and disagreeable by the presence of tar vapour, another result of imperfect combustion of raw fuel, which might be turned to much better account at the dye-works. The hurtful influence of smoke upon public health, the great personal discomfort to which it gives rise, and the vast expense it indirectly causes through the destruction of our monuments, pictures, furniture, and apparel, are now being recognized, as is evinced by the success of recent Smoke Abatement Exhibitions. The most effectual remedy would result from a general recognition of the fact that wherever smoke is produced, fuel is being consumed wastefully, and that all our calorific effects, from the largest down to the domestic fire, can be realized as completely and more economically, without allowing any of the fuel employed to reach the atmosphere unburnt. This most desirable result may be effected by the use of gas for all heating purposes with or without the addition of coke or anthracite.

The cheapest form of gas is that obtained through the entire distillation of fuel in such gas producers as are now largely used in working the furnaces of glass, iron, and steel works; but gas of this description would not be available for the supply of towns owing to its bulk, about two-thirds of its volume being nitrogen. The use of water-gas, resulting from the decomposition of steam passing through a hot chamber filled with coke, has been suggested, but this gas is also objectionable, because it contains, besides hydrogen, the poisonous and inodorous gas carbonic oxide, the introduction of which into dwelling-houses could not be effected without considerable danger. A more satisfactory mode of supplying heating separately from illuminating gas would consist in connecting the retort at different periods of the distillation with two separate systems of mains for the delivery of the respective gases. By resorting to improved means of heating the retorts with gaseous fuel, such as have been in use at the Paris gasworks for a considerable number of years, the length of time for effecting each distillation may be shortened from six hours, the usual period in former years, to four, or even three hours, as now practised at Glasgow and elsewhere. By this means a given number of retorts can be made to produce, in addition to the former quantity of illuminating gas of superior quality, a similar quantity of heating gas, resulting in a diminished cost of production and an increased supply of the valuable by-products previously referred to.

The greater efficiency of gas as a fuel results chiefly from the circumstance that a pound of gas yields in combustion 22,000 heat units, or exactly double the heat produced in the combustion of a pound of ordinary coal. This extra heating power is due partly to the freedom of the gas from earthy constituents, but chiefly to the heat imparted to it in effecting its distillation. Recent experiments with gas-burners have shown that in this direction also there is much room for improvement.

The amount of light given out by a gas flame depends upon the temperature to which the particles of solid carbon in the flame are raised, and Dr. Tyndall has shown that of the radiant energy set up in such a flame, only the $\frac{1}{25}$th part is luminous; the hot products of combustion carry off at least four times as much energy as is radiated, so that not more than one hundredth part of the heat evolved in combustion is converted into light. This proportion could be improved, however, by increasing the temperature of combustion, which may be effected either by intensified air currents or by regenerative action. Supposing that the heat of the products of combustion could be communicated to metallic surfaces, and be transferred by conduction or otherwise to the atmospheric air supporting combustion in the flame, we should be able to increase the temperature accumulatively to any point within the limit of dissociation; this limit may be fixed at about 2300° C., and cannot be very much below that of the electric arc. At such a temperature the proportion of luminous rays to the total heat produced in combustion would be more than doubled, and the brilliancy of the light would at the same time be greatly increased. Thus improved, gas-lighting may continue its rivalry with electric lighting both as regards economy and brilliancy, and such rivalry must necessarily result in great public advantage.

In the production of mechanical effect from heat, gaseous fuel also presents most striking advantages, as will appear from the following consideration. When we have to deal with the question of converting mechanical into electrical effect, or *vice versâ*, by means of the dynamo-electrical machine, we have only to consider what are the equivalent values of the two forms of energy, and what precautions are necessary to avoid losses by the electrical resistance of conductors and by friction. The transformation of mechanical effect into heat involves no losses except those resulting from imperfect installation, and these may be so completely avoided that Dr. Joule was able by this method to determine the equivalent values of the two forms of energy. But in attempting the inverse operation of effecting the conversion of heat into mechanical energy we find ourselves confronted by the second law of thermodynamics, which says that whenever a given amount of heat is converted into mechanical effect another but variable amount descends from a higher to a lower potential, and is thus rendered unavailable.

In the condensing steam-engine this waste heat comprises that communicated to the condensing water, whilst the useful heat, or that converted into mechanical effect, depends upon the difference of temperature between the boiler and condenser. The boiler pressure is limited, however, by considerations of safety and convenience of construction, and the range of working temperature rarely exceeds 120° C., except in the engines constructed by Mr. Perkins, in which a range of 160° C., or an expansive action commencing at fourteen atmospheres, has been adopted with considerable promise of success, as appears from an able report on this engine by Sir Frederick Bramwell. To obtain more advantageous primary conditions we have to turn to the caloric or gas-engine, because in them the coefficient of efficiency expressed by $\frac{T-T'}{T}$, may be greatly increased. This value would reach a maximum if the initial absolute temperature T could be raised to that of combustion, and T′ reduced to atmospheric temperature, and these maximum limits can be much more nearly approached in the gas-engine worked by a combustible mixture of air and hydrocarbons than in the steam-engine.

Before many years have elapsed we shall find in our factories and on board our ships engines with a fuel consumption not exceeding one pound of coal per effective horse-power per hour, in which the gas producer takes the place of the somewhat complex and dangerous steam boiler. The advent of such an engine and of the dynamo-machine must mark a new era of material progress at least equal to that produced by the introduction of steam power in the early part of our century. Let us consider what would be the probable effect of such an engine upon that most important interest of this country—the merchant navy.

According to returns kindly furnished me by the Board of Trade and 'Lloyd's Register of Shipping,' the total value of the merchant shipping of the United Kingdom may be estimated at £126,000,000, of which £90,000,000 represent steamers having a net tonnage of 3,003,988 tons; and £36,000,000 sailing vessels, of 3,688,008 tons. The safety of this vast amount of shipping, carrying about five-sevenths of our total imports and exports, or £500,000,000 of goods in the year, and of the more precious lives connected with it, is a question of paramount importance. It involves considerations of the most varied kind: comprising the construction of the vessel itself, and the material employed in building it; its furniture of engines, pumps, sails, tackle, compass, sextant, and sounding apparatus, the preparation of reliable charts for the guidance of the navigator, and the construction of harbours of refuge, lighthouses, beacons, bells, and buoys, for channel navigation. Yet notwithstanding the combined efforts of science, inventive skill, and practical experience—the accumulation of centuries—we are startled with statements to the effect that during last year as many as 1007 British-owned ships were lost, of which fully two-thirds were wrecked upon our shores, representing a total value of nearly £10,000,000. Of these ships 870 were sailing vessels and 137 steamers, the loss of the latter being in a fourth of the cases attributable to collision. The number of sailing vessels included in these returns being 19,325, and of steamers 5505, it appears that the steamer is the safer vessel, in the proportion of 4·43 to 3·46; but the steamer makes on an average three voyages for one of the sailing ship taken over the year, which reduces the relative risk of the steamer as compared with the sailing ship per voyage in the proportion of 13·29 to 3·46. Commercially speaking, this factor of safety in favour of steam-shipping is to a great extent counterbalanced by the value of the steam-ship, which bears to that of the sailing vessel per net carrying ton the proportion of 3 : 1, thus reducing the ratio in favour of steam-shipping as 13·29 to 10·38, or in round numbers as 4 : 3.

In considering the question how the advantages thus established in favour of steam-shipping could be further improved, attention should be called in the first place to the material employed in their construction, A new material was introduced for this purpose by the Admiralty in 1876–78, when they constructed at Pembroke dockyard the two steam corvettes, the *Iris* and *Mercury*, of mild steel. The peculiar qualities of this material are such as to have enabled shipbuilders to save 20 per cent. in the weight of the ship's hull, and to increase to that extent its carrying capacity. It combines with a strength 30 per cent. superior to that of iron such extreme toughness that in the case of collision the side of the vessel has been found to yield or bulge several feet without showing any signs of rupture, a quality affecting the question of sea risk very favourably. When to the use of this material there are added the advantages derived from a double bottom, and from the division of the ship's hold by means of bulkheads of solid construction, it is difficult to conceive how such a vessel could perish by collision either with another vessel or with a sunken rock. The spaces between the two bottoms are not lost, because they form convenient chambers for water ballast, but powerful pumps should in all cases be added to meet emergencies.

If to the improvements already achieved could be added an engine of half the weight of the present steam engine and boilers, and working with only half the present expenditure of fuel, a further addition of 30 per cent. could be made to the cargo of an Atlantic propeller vessel—no longer to be called a steamer—and the balance of advantages in favour of such vessels would be sufficient to restrict the use of sailing craft chiefly to the regattas of this and neighbouring ports.

The admirable work on the 'British Navy,' lately published by Sir Thomas Brassey, the Civil Chief Lord of the Admiralty, shows that the naval department of this country is fully alive to all improvements having regard to the safety as well as to the fighting qualities of Her Majesty's ships of war, and recent experience goes far to prove that although high speed and manœuvring qualities are of the utmost value, the armour plate which appeared to be fast sinking in public favour is not without its value in actual warfare.

The progressive views perceptible in the construction of the navy are further evidenced in a remarkable degree in the hydrographic department. Captain Sir Frederick Evans, the hydrographer, and Vice-President of the British Association, gave us at York last year a very interesting account of the progress made in that department, which, while dealing chiefly with the preparation of charts showing the depth of water, the direction and force of currents, and the rise of tides near our shores, contains also valuable statistical information regarding the more general questions of the physical conditions of the sea, its temperature at various depths, its flora and fauna, as also the rainfall and the nature and force of prevailing winds. In connection with this subject the American Naval Department has taken an important part, under the guidance of Captain Maury and the Agassiz father and son, whilst in this country the persistent labours of Dr. William Carpenter deserve the highest consideration.

Our knowledge of tidal action has received a most powerful impulse through the invention of a self-recording gauge and tide predicter, which will form the subject of one of the discourses to be delivered at our present meeting by its principal originator, Sir William Thomson.

The application of iron and steel in naval construction rendered the use of the compass for some time illusory, but in 1839 Sir George Airy showed how the errors of the compass, due to the influence experienced from the iron of the ship, may be perfectly corrected by magnets and soft iron placed in the neighbourhood of the binnacle, but the great size of the needles in the ordinary compasses rendered the correction of the quadrantal errors practically unattainable. In 1876, Sir William Thomson invented a compass with much smaller needles than those previously used, which allows Sir George Airy's principles to be applied completely.

Sir William Thomson has also enriched the art of navigation by the invention of two sounding machines; the one being devised for ascertaining great depths very accurately in less than one-quarter the time formerly necessary, and the other for taking depths up to 130 fathoms without stopping the ship in its onward course. In both these instruments steel pianoforte wire is used instead of the hempen and silken lines formerly employed; in the latter machine the record of depth is obtained not by the quantity of wire run over its counter and brake wheel, but through the indications produced upon a simple pressure gauge consisting of an inverted glass tube, whose internal surface is covered beforehand with a preparation of chromate of silver, rendered colourless by the sea-water up to the height to which it penetrates. The value of this instrument for guiding the navigator within what he calls "soundings" can hardly be exaggerated; with the sounding machine and a good chart he can generally make out his position correctly by a succession of three or four casts in a given direction at given intervals, and thus in foggy weather is made independent of astronomical observations and of the sight of lighthouses or the shore. By the proper use of this apparatus, such accidents as happened to the mail steamer *Mosel* not a fortnight ago would not be possible. As regards the value of the deep-sea instrument I can speak from personal experience, as on one occasion it enabled those in charge of the cable s.s. *Faraday* to find the end of an Atlantic cable, which had parted in a gale of wind with no other indication of the locality than a single sounding, giving a depth of 950 fathoms. To recover the cable a number of soundings in the supposed neighbourhood of the broken end were taken, the 950 fathom contour line was then traced upon a chart, and the vessel thereupon trailed its grapnel two miles to the eastward of this line, when it soon engaged the cable 20 miles away from the point where dead reckoning had placed the ruptured end.

The time allowed me for addressing you on this occasion is wholly insufficient to do justice to the great engineering works of the present day, and I must therefore limit myself to making a short allusion to a few only of the more remarkable enterprises.

The great success, both technically and commercially, of the Suez Canal, has stimulated M. de Lesseps to undertake a similar work of even more gigantic proportions, namely, the piercing of the Isthmus of Panama by a ship canal, 40 miles long, 50 yards wide on the surface, and 20 yards at the bottom, upon a dead level from sea to sea. The estimated cost of this work is £20,000,000, and more than this sum having been subscribed, it appears unlikely that political or climatic difficulties will stop M. de Lesseps in its speedy accomplishment. Through it, China, Japan, and the whole of the Pacific Ocean will be brought to half their present distance, as measured by the length of voyage, and an impulse to navigation and to progress will thus be given which it will be difficult to over-estimate.

Side by side with this gigantic work, Captain Eads, the successful improver of the Mississippi navigation, intends to erect his ship railway, to take the largest vessels, fully laden and equipped, from sea to sea, over a gigantic railway across the Isthmus of Tehuantepec, a distance of 95 miles. Mr. Barnaby, the chief constructor of the navy, and Mr. John Fowler have expressed a favourable opinion regarding this enterprise, and it is to be hoped that both the canal and the ship railway will be accomplished, as it may be safely anticipated that the traffic will be amply sufficient to support both these undertakings.

Whether or not M. de Lesseps will be successful also in carrying into effect the third great enterprise with which his name has been prominently connected, the flooding of the Tunis-Algerian Chotts, thereby re-establishing the Lake Tritonis of the ancients, with its verdure-clad shores, is a question which could only be decided upon the evidence of accurate surveys, but the beneficial influence of a large sheet of water within the African desert could hardly be matter of doubt.

It is with feelings not unmixed with regret that I have to record the completion of a new Eddystone lighthouse in substitution for the *chef-d'œuvre* of engineering erected by John Smeaton more than one hundred years ago. The condemnation of that structure was not, however, the consequence of any fault of construction, but was caused by inroads of the sea upon the rock supporting it. The new lighthouse, designed and executed by Mr., now Sir, James Douglass, engineer of Trinity House, has been erected in the incredibly short time of less than two years, and bids fair to be worthy of its famed predecessor. Its height above high water is 130 feet, as compared with 72 feet, the height of Telford's structure, which gives its powerful light a considerably increased range. The system originally suggested by Sir William Thomson, some years ago, of distinguishing one light from another by flashes following at varied intervals, has been adopted by the Elder Brethren in this as in other recent lights in the modified form introduced by Dr. John Hopkinson, in which the principle is applied to revolving lights, so as to obtain a greater amount of light in the flash.

The geological difficulties which for some time threatened the accomplishment of the St. Gothard Tunnel have been happily overcome, and this second and most important sub-Alpine thoroughfare now connects the Italian railway system with that of Switzerland and the south of Germany, whereby Genoa will be constituted the shipping port for those parts.

Whether we shall be able to connect the English with the French railway system by means of a tunnel below the English Channel is a question that appears dependent at this moment rather upon military and political than technical and financial considerations. The occurrence of a stratum of impervious grey chalk, at a convenient depth below the bed of the Channel, minimizes the engineering difficulties in the way, and must influence the financial question involved. The protest lately raised against its accomplishment can hardly be looked upon as a public verdict, but seems to be the result of a natural desire to pause pending the institution of careful inquiries. These inquiries have been made by a Royal scientific Commission, and will be referred for further consideration to a mixed Parliamentary Committee, upon whose report it must depend whether the natural spirit of commercial enterprise has to yield in this instance to political and military considerations. Whether the Channel Tunnel is constructed or not the plan proposed some years ago by Mr. John Fowler of connecting England and France by means of a ferry boat capable of taking railway trains would be a desideratum justified by the ever-increasing intercommunication between this and continental countries.

The public inconvenience arising through the obstruction in traffic by a sheet of water is well illustrated by the circumstance that both the estuaries of the Severn and of the Mersey are being undermined in order to connect the railway systems on the two sides, and that the Frith of Forth is about to be spanned by a bridge exceeding in grandeur anything as yet attempted by the engineer. The roadway of this bridge will stand 150 feet above high-water mark, and its two principal spans will measure a third of a statute mile each. Messrs. Fowler and Baker, the engineers to whom this great work has been entrusted, could hardly have accomplished their task without having recourse to steel for their material of construction, nor need the steel used be of the extra mild quality particularly applicable for naval structures to withstand collision, for, when such extreme toughness is not required steel of very homogeneous quality can be produced, bearing a tensile strain double that of iron.

When the British Association met at Southampton on a former occasion, Schönbein announced to the world his discovery of gun-cotton. This discovery has led the way to many valuable researches on explosives generally, in which Mr. Abel has taken a leading part. Recent investigations by him, in connection with Captain Noble, upon the explosive action of gun-cotton and gunpowder confined in a strong chamber, which have not yet been published, deserve particular attention. They show that while by the method of investigation pursued about twenty years ago by Karolye (of exploding gunpowder in very small charges in shells confined within a large shell partially exhausted of air), the composition of the gaseous products was found to be complicated and liable to variation, the chemical metamorphosis which gun-cotton sustains, when exploded under conditions such as obtain in its practical application, is simple and very uniform. Among other interesting points noticed in this direction was the fact that, as in the case of gunpowder, the proportion of carbonic acid increases, while that of carbonic oxide diminishes with the density of the charge.

Messrs. Noble and Abel are also continuing their researches upon fired gunpowder, being at present occupied with an inquiry into the influence exerted upon the chemical metamorphosis and ballistic effects of fired gunpowder by variation in its composition, their attention being directed especially to the discovery of the cause of the more or less considerable erosion of the interior surface of guns produced by the exploding charge—an effect which, notwithstanding the application of devices in the building up of the charge specially directed to the preservation of the gun's bore, has become so serious that, with the enormous charges now used in our heavy guns, the erosive action on the surface of the bore produced by a single round is distinctly perceptible. As there appeared to be *primâ facie* reasons why the erosive action of powder upon the surface of the bore at the high temperatures developed should be at any rate in part due to its one component sulphur, Noble and Abel have made comparative experiments with powders of usual composition and with others in which the proportion of sulphur was considerably increased, the extent of erosive action of the products escaping from the explosion vessel under high tension being carefully determined. With small charges a particular powder containing no sulphur was found to exert very little erosive action as compared with ordinary cannon powder; but another powder, containing the maximum proportion of sulphur tried (15 per cent.), was found equal to it under these conditions, and exerted very decidedly less erosive action than it, when larger charges were reached. Other important contributions to our knowledge of the action of fired gunpowder in guns, as well as decided improvements in the gunpowder manufactured for the very heavy ordnance of the present day, may be expected to result from a continuance of these investigations. Professor Carl Himly, of Kiel, having been engaged upon investigations of a similar nature, has lately proposed a gunpowder in which hydrocarbons precipitated from solution in naphtha take the place of the charcoal and sulphur of ordinary powder, this powder has amongst others the peculiar property of completely resisting the action of water, so that the old caution, "Keep your powder dry," may hereafter be unnecessary.

The extraordinary difference of condition, before and after its ignition, of such matter as constitutes an explosive agent leads us up to a consideration of the aggregate state of matter under other circumstances. As early as 1776 Alexander Volta observed that the volume of glass was changed under the influence of electrification, by what he termed electrical pressure. Dr. Kerr, Govi, and others, have followed up the same inquiry, which is at present continued chiefly by Dr. George Quincke, of Heidelberg, who finds that temperature, as well as chemical constitution of the dielectric under examination, exercises a determining influence upon the amount and character of the change of volume effected by electrification; that the change of volume may under certain circumstances be effected instantaneously as in flint glass, or only slowly as in crown glass, and that the elastic limit of both is dimished by electrification, whereas in the case of mica and of guttapercha an increase of elasticity takes place.

Still greater strides are being made at the present time towards a clearer perception of the condition of matter when particles are left some liberty to obey individually the forces brought to bear upon them. By the discharge of high tension electricity through tubes containing highly rarefied gases (Geissler's tubes), phenomena of discharge were produced which were at once most striking and suggestive. The Sprengel pump afforded a means of pushing the exhaustion to limits which had formerly been scarcely reached by the imagination. At each step the condition of attenuated matter revealed varying properties when acted upon by electrical discharge and magnetic force. The radiometer of Crookes imported a new feature into these inquiries, which at the present time occupy the attention of leading physicists in all countries.

The means usually employed to produce electrical discharge in vacuum tubes was Ruhmkorff's coil; but Mr. Gassiot first succeeded in obtaining the phenomena by means of a galvanic battery of 3000 Leclanché cells. Dr. De La Rue, in conjunction with his friend, Dr. Hugo Müller, has gone far beyond his predecessors in the production of batteries of high potential. At his lecture "On the Phenomena of Electric Discharge," delivered at the Royal Institution, in January, 1881, he employed a battery of his invention consisting of 14,400 cells (14,832 volts), which gave a current of 0·054 ampère, and produced a discharge at a distance of 0·71 inch between the terminals. During last year he increased the number of cells to 15,000 (15,450 volts), and increased the current to 0·4 ampère, or eight times that of the battery he used at the Royal Institution.

On the occasion of his lecture, Dr. De La Rue produced, in a very large vacuum tube, an imitation of the aurora borealis; and he has deduced from his experiments that the greatest brilliancy of aurora displays must be at an altitude of from 37 to 38 miles—a conclusion of the highest interest, and in opposition to the extravagant estimate of 281 miles at which it had been previously put.

The President of the Royal Society has made the phenomena of electrical discharge his study for several years, and resorted in his important experiments to a special source of electric power. In a note addressed to me, Dr. Spottiswoode describes the nature of his investigations much more clearly than I could venture to give them. He says: "It had long been my opinion that the dissymmetry shown in electrical discharges through rarefied gases must be an essential element of every disruptive discharge, and that the phenomena of stratification might be regarded as magnified images of features always present, but concealed under ordinary circumstances. It was with a view to the study of this question that the researches by Moulton and myself were undertaken. The method chiefly used consisted in introducing into the circuit intermittence of a particular kind, whereby one luminous discharge was rendered sensitive to the approach of a conductor outside the tube. The application of this method enabled us to produce artificially a variety of phenomena, including that of stratification. We were thus led to a series of conclusions relating to the mechanism of the discharge, among which the following may be mentioned:—

"1. That a stria, with its attendant dark space, forms a physical unit of a striated discharge.

"2. That the origin of the luminous column is to be sought for at its negative end.

"3. That the time occupied by electricity of either name in traversing a tube is greater than that occupied in traversing an equal length of wire, but less than that occupied by molecular streams (Crookes's radiations) in traversing the tubes.

"4. That the brilliancy of the light with so little heat may be due in part to brevity in the duration of the discharge.

"5. That striæ are not merely loci in which electrical is converted into luminous energy, but are actual aggregations of matter.

"This last conclusion was based mainly upon experiments made with an induction coil excited in a new way —viz., directly by an alternating machine, without the intervention of a commutator or condenser. This mode of excitement promises to be one of great importance in spectroscopic work, as well as in the study of the discharge in a magnetic field, partly on account of the simplification which it permits in the construction of induction coils, but mainly on account of the very great increase of strength in the secondary currents to which it gives rise."

These investigations assume additional importance when we view them in connection with solar—I may even say stellar—physics, for evidence is augmenting in favour of the view that interstellar space is not empty, but is filled with highly attenuated matter of a nature such as may be put into our vacuum tubes. Nor can the matter occupying stellar space be said any longer to be beyond our reach for chemical and physical test. The spectroscope has already thrown a flood of light upon the chemical constitution and physical condition of the sun, the stars, the comets, and the far distant nebulæ, which have yielded spectroscopic photographs under the skilful management of Dr. Huggins, and Dr. Draper, of New York. Armed with greatly improved apparatus the physical astronomer has been able to reap a rich harvest of scientific information during the short periods of the last two solar eclipses; that of 1879, visible in America, and that of May last, observed in Egypt by Lockyer, Schuster, and by continental observers of high standing. The result of this last eclipse expedition has been summed up as follows:—"Different temperature levels have been discovered in the solar atmosphere; the constitution of the corona has now the possibility of being determined, and it is proved to shine with its own light. A suspicion has been aroused once more as to the existence of a lunar atmosphere, and the position of an important line has been discovered. Hydrocarbons do not exist close to the sun, but may in space between us and it."

To me personally these reported results possess peculiar interest, for in March last I ventured to bring before the Royal Society a speculation regarding the conservation of solar energy, which was based upon the three following postulates, viz.:—

1. That aqueous vapour and carbon compounds are present in stellar or interplanetary space.

2. That these gaseous compounds are capable of being dissociated by radiant solar energy while in a state of extreme attenuation.

3. That the effect of solar rotation is to draw in dissociated vapours upon the polar surfaces, and to eject them after combustion has taken place back into space equatorially.

It is therefore a matter of peculiar gratification to me that the results of observations here recorded give considerable support to that speculation. The luminous equatorial extensions of the sun which the American observations revealed in such a striking manner (with which I was not acquainted when writing my paper) were absent in Egypt; but the outflowing equatorial streams I suppose to exist could only be rendered visible by reflected sunlight, when mixed with dust produced by exceptional solar disturbances or by electric discharge; and the occasional appearance of such luminous extensions would serve only to disprove the hypothesis entertained by some, that they are divided planetary matter, in which case their appearance should be permanent. Professor Langley, of Pittsburg, has shown by means of his bolometer, that the solar actinic rays are absorbed chiefly in the solar instead of in the terrestrial atmosphere, and Captain Abney has found by his new photometric method that absorption due to hydrocarbons takes place somewhere between the solar and terrestrial atmosphere. In order to test this interesting result still further, he has lately taken his apparatus to the top of the Riffel with a view of diminishing the amount of terrestrial atmospheric air between it and the sun, and intends to bring a paper on this subject before Section A. Stellar space filled with such matter as hydrocarbon and aqueous vapour would establish a material continuity between the sun and his planets, and between the innumerable solar systems of which the universe is composed. If chemical action and reaction can further be admitted, we may be able to trace certain conditions of thermal dependence and maintenance, in which we may recognize principles of high perfection, applicable also to comparatively humble purposes of human life.

We shall thus find that in the great workshop of nature there are no lines of demarcation to be drawn between the most exalted speculation and commonplace practice, and that all knowledge must lead up to one great result, that of an intelligent recognition of the Creator through His works. So then, we members of the British Association and fellow-workers in every branch of science may exhort one another in the words of the American bard who has so lately departed from amongst us:—

"Let us then be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labour and to wait."

Parliamentary and Law Proceedings.

Poisoning by Washing Soda.

Mr. Carttar, West Kent Coroner, held an inquest on Saturday, August 26, at Greenwich, on the body of Sarah Ann Houess, five years of age.

The evidence of the mother was that on Wednesday she left the child at home by herself, and during her absence the child drank some water from a kettle on the hob, in which witness had placed a handful of common soda to cleanse it before leaving home. On her return she gave the child some magnesia, and she vomited, and did not appear much the worse, but the next day the symptoms were alarming and she went to the relieving officer and obtained an order for medical attendance. On Dr. Hartt seeing the child he found her in a dying state and gave no hopes of her recovery, and she died on Thursday afternoon. The child was in the habit of drinking from the kettle.

Dr. Hartt, the parish surgeon, said the appearances of the child were consistent with alkaline poisoning, and the child must have suffered great pain. Three ounces of common soda dissolved in water had been known to kill an adult, and the deceased was presumed to have taken about an ounce.

The jury returned a verdict that the deceased died from drinking common washing soda and water from a kettle by misadventure.

Children Poisoned by Laburnum Pods.

Dr. Scott, of Barnsley, has had under his care three children who narrowly escaped being poisoned by eating laburnum pods, in Loche Park, Barnsley. The lads, named Fisher, Siddons, and Adams, reside in Winn Street and Heeles Street. They went to the park, and seeing the pods on some laburnum trees, they mistook them for wild lints and ate a quantity of them. Fisher, who is about seven years of age, ate the most pods and was taken seriously ill on his way home. When he reached a field near the Agness Colliery he was unable to proceed further, and falling down exhausted, he was discovered two or three hours afterwards in an insensible condition. For some time he was not expected to recover. The other two lads were not so seriously affected as Fisher, but were ill for some time.—*Yorkshire Post.*

Poisoning by Spirit of Salt.

On the 24th ult., Mr. Collier held an inquest at Hackney on the body of George Childs, a butcher's assistant, aged 77. From the evidence it appeared that the deceased had been much distressed by the expectation that an allowance he received weekly from the parish would be stopped. He was seen to drink something that was smoking from a cup and immediately began retching. Medical assistance was obtained, but deceased died the same night, the doctor attributing the death to poisoning by spirit of salt.

The jury returned a verdict that deceased committed suicide whilst suffering from temporary insanity.

The Future of Pharmacy.

Sir,—If "H. S." and "W. B." consider themselves merely *distributors* of drugs, then, doubtless, they have been considerably overpaid. It is no use waiting, as "H. S." suggests, for an Act of Parliament to raise our status, neither the present nor any future Government will grant us the sole right of dealing in non-poisonous preparations, and if we are to follow the advice of "H. S." and sink to the level of the grocer and the huckster, then we might as well give up the "poison" trade and become general dealers at once, without any special training or examination, for pecuniarily the poison trade could be very well spared. Any amelioration of our condition must come from ourselves and must be the result of our own combined and undivided efforts; we must teach the public that the pharmacist and the retailer (pure and simple) of drugs are distinct persons. But how can reform proceed from a body of men so many of whom have not nearly so much *esprit de corps* as a crossing sweeper and whose sole aim and purpose is, like that of the historic quaker, to make money somehow, honestly if they can, but anyhow to make it? Often when trying to persuade others to join the Society or contribute to the Benevolent Fund I am asked, "Why should I join or support such a Society whilst so many men who are officially connected with it are robbing me of my living by supplying all my neighbours with my particular class of goods?" I am quite sure that in this district at all events one of the main reasons for so few men joining us is the bad odour into which these men have dragged the Society. As to its being "pettish" to Boycott people who cater for grocers, stores, etc., I could tell "H. S." of one wholesale house whose loss of trade was such as to compel it to give up supplying stores. I could also tell him of more than one wholesale house who would refuse to supply them at any price. I do not wonder, if "H. S." be largely engaged in this class of trade, that (pecuniarily at all events) he is well satisfied with his position. I saw an order some time ago for 50 gallons of "paregoric without opium," which was supplied to a chemist at 1*s*. 3*d*. per lb., and by him sold to grocers, provision dealers, etc., for retail, at 2*s*. 8*d*. and 3*s*. per lb. The county analyst, it is true, objected to some of it, but these analysts are at times very fastidious. The police records have repeatedly shown the class of goods supplied by men whose position and education ought to place them far beyond every suspicion of such rascality. These men ought to be treated as the medical profession treat quacks and owners of "6*d*. dispensaries"—ostracize them altogether, have nothing to do with them, and show the public that though these individuals be with us, they are not of us; that while we do not forget that we are tradesmen, we remember that we are something better than mere retailers, and that the lives of our customers and the honour of our craft are worth more in our estimation than the mere acquisition of riches by means which would put even "the heathen Chinee" to shame.

131, *Embden Street, Manchester*. J. Hart.

Sir,—I think few of the readers of our Journal will disagree in the main with the two letters, signed respectively H. S. and W. B., but there are one or two points in that of the latter to which I beg to offer a protest. Firstly, the assertion that the profits of the chemist and druggist have been too high. Fifty years ago they may have been so, but of late years, No! If they have been, how is it that many, I might, I think, say most, have failed to make more than a living, possibly a comfortable one, but not sufficient for them to rest from their arduous labours?

Again, W. B. says his cutting neighbour makes as much per cent. on his turnover as is necessary to carry on his business. Very likely; but suppose he sold nothing but chemists' articles; how would he get on? For are there no profits in the drysaltery trade? There are; but the public does not know so well how much is got out of drysaltery. Not that I mean to say the profits are exorbitant; for where I sell a pound of Epsom salts my drysaltery neighbour will perhaps sell a hundredweight of soda, and why should he not get as much profit?

But fearing I am trespassing too much on your space, I would just say that I think if we were to write and work more in the direction of getting doctors to give up dispensing and yield us that most legitimate part of our business, we, on our part giving up counter prescribing, I say if we were to work more for this end, we should be doing more towards brightening the prospect of the future of pharmacy than the almost, if not quite useless discussions as to stores and cutting grocers will achieve.

G. A. C.

Leeches.

Sir,—My experience of leech keeping coincides very much with Mr. Lamble's; I only change the water once in six or nine months, and keep them in a shaded place. I also keep them well supplied with water plants, those I have found most suitable being the American water weed (*Anacharis alsinastrum*), and the pond weed (*Potamogeton natans*). During the last twelve months the "death rate" did not average one per month. I prefer to get the "weeds" from some pit or canal, rather than purchase them, as then they are invariably rich in the lower forms of life, and with a 1-inch lens or a good "platyscopic" "Aquam" may spend many a pleasant hour in watching the movements of the water flea or the cyclops, and studying the different forms of fresh water polype. I have also found the last two seasons that the leeches have deposited their ova on the sides of the glass, from which in due time a fresh generation of leeches has been developed; there ought to be from 3 to 4 inches of shingle at the bottom of the aquarium.

Manchester. J. Hart.

P.S.—For the past two or three weeks, from a variety of circumstances, I have not been able to keep up my supply of plant life, and the mortality, as a consequence, has rapidly increased.

Sir,—Allow me to say that my experience in keeping leeches agrees with Mr. Lamble's, and corroborates the conclusions he arrives at. For the last three years I have lost scarcely any leeches. I keep them in an aquarium on the counter, have no plants in the water, only sand and a few smooth pebbles. I change the water very seldom, only once in two or three months, unless a leech should die, or from any cause the water smells decidedly fetid; but, as a rule, for a long time the water has only a brackish smell, which I take no notice of. I sometimes clean down the inside of aquarium in the same water and leave it unchanged. I conclude that the leeches' natural *habitat* is in quiet undisturbed semi-stagnant waters. I only buy the best leeches. I may say that the water I use is similar to that used by Mr. Lamble, as I am a near neighbour. The character of the water may probably make a difference elsewhere. Observer.

"*North*."—The point was fully discussed in this Journal about five years ago. See especially the opinion of Professor Redwood upon the meaning of symbols used in prescriptions (*Pharm. Jour.*, [3], viii., 471).

W. Johnston.—The plants sent are greatly in excess of the number we can undertake to name as a rule. In future the number must be limited to six. Those now sent are—1. *Tussilago Farfara*. 2. *Alchemilla vulgaris*. 3. *Angelica sylvestris*. 4. *Ægopodium Podograria*. 5. *Heracleum Sphondylium*. 6. *Lapsana communis*. 7. *Epilobium montanum*. 8. *Geranium robertianum*. 9. *Stellaria graminea*. 10. *Galium verum*. 11. *Lychnis vespertina*. 12. *Rumex Acetosa*. 13. *Torilis Anthriscus*. 14. *Centaurea nigra*. 15. *Scabiosa succisa*. 16. *Geum urbanum*. 17. *Prunella vulgaris*. 18. *Geranium dissectum*. 19. *Achillea ptarmica*. 20. Send specimen with stem leaves.

Communications, Letters, etc., have been received from Messrs. Della Rosa, Fletcher, Schacht, Woodland, Lubberly Lout, Wopper.

MADAGASCAR DRUGS.

BY E. M. HOLMES, F.L.S.

(*Concluded from page* 123.)

LEAVES AND FLOWERS.

FAMAMO, *Mundulia Telfairii*, Boj.—This drug consists of leaflets, mostly detached from their rachis, which bears scars of having borne four or five opposite pairs of leaflets. The leaflets are entire, slightly unequal at the base, about the size and shape of Tinnevelly senna, but more rigid and with many slender lateral veins placed at a very acute angle to the midrib. They have no odour; they taste somewhat like senna, but have an acrid after-taste. The young twigs are woody, with a pale brown bark having darker longitudinal stripes (See Famamo root, before, p. 121).

FANJANONANDRA.—This drug consists of the leafy shoots of *Anthospermum plicatum*, H.B., a heath-like rubiaceous undershrub. The leaves are opposite, about ¾ inch long, a line in breadth, decurrent and having opposite subulate stipules. When examined with a lens they are seen to have two lines at the back, which indicate the three close longitudinal plaits of the leaf, more easily seen on transverse section. Under a Coddington lens the leaf is seen to be studded with minute immersed oil glands. The taste is very bitter and aromatic, but not perceptibly astringent, and any hæmostatic power it possesses is probably owing to its essential oil. The Malagasy name means "stoppage of blood," and the drug is used for that purpose.

HARONGA.—This consists of the leaves or twigs of *Haronga Madagascariensis*, Choisy (Hypericaceæ). The leaves are opposite, smooth, short-stalked, oblong, entire, with prominent veins underneath, which are placed at almost a right angle to the midrib. The taste is very astringent. In Madagascar the leaves are used, as well as those of the Harongana kelifodia (*Psidium pomiferum*), in diarrhœa and dysentery. In Mauritius (according to Bouton, *l. c.*, p. 19) the yellow juice which flows from the incised stems is used as an application to ringworm and a skin disease called Tampane.

NIFIN AKANGA. (*Commelyna Madagascariensis*).—Bracts heart-shaped, seven veined, enclosing small blue flowers more conspicuous than the linear subulate leaves. Used in malarial diseases and as an application to recent sores, but possesses no marked taste or odour.

RAMBIAZANA.—The leaves are alternate, narrowly oblanceolate, entire, with three principal veins; about 1 to 2 inches long and ¼ to ½ inch broad, tapering much below, the leaves and stems being densely covered with down, which on the veins and stem is of a yellowish tint. The taste is aromatic and slightly bitter. The flowers are minute and in small corymbs, and apparently belong to the Compositæ, and, so far as can be judged from the imperfect material, an undescribed species of *Vernonia*. The plant is said to be emetic and expectorant.

SANGAN (*Sangan andivolahy*).—This consists of the flowers and unilateral flower-spikes of *Hyptis pectinata*, Poit. (Labiatæ), an undershrub, growing 6 or 7 feet high. The dried florets, which are not much larger than those of santonica, have a very bitter, slightly aromatic taste, resembling that of white horehound, for which it might perhaps form a substitute in Madagascar.

HANIDRAISÒA.—The leafy twigs of *Aphloia theæformis*, Benth. (Flacourtiaceæ). It is known to possess emetic properties. This plant is also called Voa-fotsy, and is said to be used in strangury or suppression of urine, in which emetics are known to be useful, probably by reflex action; also in dropsy and gonorrhœa.

The leaves are slightly bitter and astringent and have a flavour like that of tea. They are ovate, leathery, smooth, ¾ to 3 inches long, shortly stalked and serrate in the upper half.

TSIAVARAMONINA.—Leaves hispid, scabrous, crenate, alternate. Used with Hanisandroa for condylomata and other syphilitic tumours. Taste and odour not marked.

FRUITS AND SEEDS.

LANDEMO or TENDEMILAHY.—The fruits of *Anthocleista Madagascariensis*, Baker (*Journ. Bot.*, June, 1882, p. 173). These are small ovate fruits, with a dark brown wrinkled surface. A transverse section shows the fruit to be four-celled, the walls being soft and spongy. The taste is pleasantly bitter. The fruits are about the size of a hazel nut, but when mature are stated by Baker to be 1¼ inch long. These, as well as the leaves, are used in malarial fever.

SÈNA SÈNA.—Consists of dark brown fruits about the size of a walnut, the pericarp being dry and covered with rigid prominences or papillæ. It contains several (4 to 8) seeds, of the shape and size of the seeds of the Baobab tree, being convex on one side, and having the two other sides meeting at an angle. The seeds are immature, but appear to have ruminated albumen and a structure like that of the Anonaceæ. The fruits are used in coughs and catarrh, especially for children, one fruit being scraped for a dose. Judging from the warm aromatic taste of the seeds they probably act as a stimulant to the mucous membrane, like those of *Xylopia æthiopica*, A. Rich.

The fruit bears a strong resemblance to that of *Melodorum verrucosum*, in the Kew Museum, but that fruit is pear-shaped and contains plano-convex seed.

TAÌMBÒRON TSILOZA (*Chenopodium ambrosioides*, Lin.).—Used in Madagascar, as in other countries, as an anthelminthic, chiefly for round worms.

TANGENA.—A root named Titsarana and said to be the root of the Tangena, has a blackish, easily separable, scaly bark, the central portion of which is reddish and micaceous; the wood is whitish and porous, the medullary rays being visible to the naked eye as slender radiating lines. It has no perceptible taste.

TÀNANTÀNAMA-FOTSY (*Curcas purgans*, L.).—The seeds of this plant are well known to possess purgative and emetic properties. In Madagascar it is, however, chiefly used externally as a hæmostatic, a practice which is not unknown in India, where the milky juice is applied to wounds and in drying covers them with a varnish like collodion (*Pharm. Journ.*, [3], v. 1028; vii., 730). The hæmostatic property of the plant probably deserves more attention than it has hitherto received.

TÀNANTÀNA-MÀNGA (*Ricinus communis*, L.).—The seeds of the Madagascar plant are very small, being only about 5 or 6 lines long and 3 broad; they have a greyish tint. The oil is obtained from the seeds by boiling them.

TANTÈRAKALA (*Embelia micrantha*, Alp.).—These fruits are about the size of a red currant or black pepper. They have a wrinkled reddish-black husk or skin, which, when removed, is found to contain a single seed, which like others of the genus is readily distinguished by being marked with white dots formed apparently by the infolding of the endopleura into the horny albumen; the lower half of the seed has a cup-shaped cavity. The taste is slightly acrid or pungent. In Madagascar the fruit is given for worms, the wood of the shrub being administered as a tonic. In the Mauritius, where it is called Liane Poilly,* after M. Grillot Poilly, who made known its value in nephritis, of which he was cured by a native by means of a decoction of the plant.

The fruits of another species, *E. Ribes*, Burm., are used in India as a remedy for the tapeworm, in the dose of a teaspoonful for a child and a dessertspoonful for an adult twice a day, and according to Dr. Dymock with success, the worm being expelled dead (*Pharm. Journ.*, [3], vii., p. 3; Dutt, 'Hind. Mat. Med.,' p. 183).

VÀTOLÀLAKA.—The grey seeds of *Cæsalpinia Bonducella*, Roxb., used by natives as parturient and emetic. In the Mauritius the leaves and seed of this plant are used for gonorrhœa and allied diseases, and the seeds powdered and mixed with pepper are used as a febrifuge. The Mauritius name† is "Sogar gota," and the French "Cadoque" (Bouton, 'Fl. Méd. de Maurice,' p. 43). This author appears to have followed Bojer in confounding this species with *C. Bonduc*, which has yellow seeds.

The dose used in Madagascar for promoting expulsion of the placenta is the kernel of one seed, scraped and drunk in water.

VÈRAKA.—The fruits of *Schrebera Golungensis*, Baker. These are fig-shaped, woody, about 1½ inch long, and ⅝ inch broad in the widest part, dehiscing loculicidally into two valves, the dissepiments remaining attached to the valves. They have neither taste nor odour, and unless the seeds, which are not present, possess some marked properties, it is difficult to understand how the fruit can be of any service in dyspepsia or malarial diseases, for which, according to Dr. Parker, it is used, as well as for abscess.

VOANTAMÈNAKA-VAVY.—*Quisqualis* species. The drug consists of the fruit, which differs from that of *Quisqualis indica*, L., in having a short stalk ¼ inch long, in its more oval or globular shape, not tapering gradually towards the end, and in its pale brown colour.

It is stated by Dr. Parker (p. 669) to be used for flat worms of different kinds. For this purpose it is quite probable that it may be an effectual remedy, *Q. indica* being used in China, India and the East generally for lumbrici, four or five seeds being given to children to eat (Hanbury, 'Science Papers,' p. 231, fig. 3; Dr. Porter Smith, 'Chinese Mat. Med.,' p. 182; 'Ind. Pharm.,' p. 90). It is worthy of note, however, that Bouton ('Fl. Méd. de Maurice,' p. 53) states that in a larger dose than above mentioned the seeds of *Q. indica* produce spasms and other disagreeable symptoms.

ALOES.

Madagascar aloes presents an appearance resembling a black extract, but is brittle, like pitch. The powder is of a pale dull brown, with a slight greenish tint. The surface and the fracture have a glassy lustre. In odour and taste it resembles Cape aloes. When a fragment is treated with strong sulphuric acid on a piece of white porcelain it colours the acid yellow at first and then becomes pasty and colours it of a deep crimson. Nitric acid produces no effect upon it. A piece of Cape aloes treated in the same manner does not give a crimson colour with sulphuric acid, but with nitric acid alone, or with nitric acid added after sulphuric acid it gives a dark dull green colour. It would therefore appear probable that it is derived from a different species of aloe, probably the only large species known to grow in Madagascar.

VESICANTS.

The insect used as a vesicant in Madagascar, and which is a species of *Epicauta*, nearly allied to *E. rufficollis*, is rather smaller than the true cantharides, but similar in shape. It has a bluish metallic lustre, resembling that of the common *Meloe majalis*, except that the thorax is of a yellowish brown colour. According to Mr. Waterhouse, it differs from the Indian species, *E. rufficollis*, in having the scutellum yellow, the eyes more separated, the head more square behind, and the sculpture of the head and thorax generally more delicate. It has not as yet received a name.

The remainder of the drugs brought by Dr. Parker do not possess any distinctive taste or odour, or any properties which are worthy of notice.

* Bouton, 'Fl. Méd. de Maurice,' p. 92.

† See Baker ('Fl. Mauritius and Seychelles,' p. 83).

HAILSTORMS AND FORESTS.

The Geneva Correspondent of the *Times* writes, under date September 1:—"Hailstorms, as is well known, often play sad havoc in Switzerland as well as in other parts of Europe. They generally last only a few minutes, but in that time the crops of a whole district may be destroyed, trees stripped of their fruit and leaves, and even potatoes in the ground hacked to pieces. Birds are sometimes killed by the hundred, and a grape-vine touched by a hailstone is ruined for ever. Seven years ago there was a hailstorm in this canton, which in less than five minutes did damage estimated at a million of francs. In some districts there are mutual hail insurance societies as in other countries there are mutual fire insurance societies. In these circumstances everything relating to the phenomena and causes of these visitations is studied with great interest, and papers on the subject read at the late meeting of the association of Swiss Geographical Societies, held this week at Geneva, by Herren Beaumont and Riniker, of Aargau, are attracting considerable attention in scientific circles. The utility of forests as a safeguard against avalanches and a hindrance to *tourments* and snow-drifts has often been pointed out, but it has never before been suggested that forests are a preservation against hailstorms. Such, however, is the opinion of Herr Riniker, who is chief forester of Canton Aargau. He says that where there are forests there are no hailstorms, and in support of this theory he adduces a remarkable fact, for the accuracy of which he and many others can personally vouch. In the south of Aargau there is a little chain of mountains known as the Lindenberge. The Lindenberge are about 20 kilomètres long, of an average height, above sea level, of some 800 feet, and completely covered with wood. About twenty years, ago the forest was divided in two places by wide gaps, with the consequence that the valleys at the foot of the mountains were soon afterwards visited with frequent hailstorms. The hail-charged clouds were seen to traverse the gaps. In 1868 the wider of the two open spaces was closed by a plantation of firs, and since 1871 no hailstorm has crossed the forest. In explanation of this phenomenon Herr Riniker suggests that, as hailclouds are saturated with positive electricity and trees conduct from the earth negative electricity, the meeting of the two currents develops sufficient heat to prevent the complete congelation of the clouds and even to thaw the hailstones contained in them—for the clouds of this description pass very near the earth—and so convert the frozen particles into rain. If further observation should confirm the accuracy of Herr Riniker's conclusions in this regard, the importance of forests in countries where hailstorms are frequent will be greatly increased."

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 9, 1882.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

On a recent occasion we laid before our readers a *résumé* of the Report of the Royal Commission appointed last year to inquire into the working of the Medical Acts. At that time the evidence upon which that Report was based had not been published, but it has this week been issued in the form of a bulky blue book of more than four hundred pages. With respect to the general scope of the Report it will be remembered that it dealt with topics that, apart from their general public interest, were essentially and almost exclusively medical, whilst the subject of counter prescribing, to which numerous attempts at legislation as well as litigious experiences during recent years had given a somewhat factitious importance, was dealt with very curtly, and only by implication, in a single sentence which stated that in the opinion of the Commission it would be undesirable to prevent unregistered persons from practising, but that they should be prevented from representing themselves as being registered, or from assuming titles which would lead the public to believe that they are regular medical men. Of course this would include, and indeed go far beyond the limits of the "counter practice" which has been claimed as being within the right of chemists and druggists, and even this brief reference proves, so far as the Royal Commission reflects public opinion, that the position which has been maintained by chemists and druggists in respect to this question is in harmony with the feeling of the community in general.

It appears that very little evidence was presented to the Commissioners upon the subject of counter prescribing, and even this was mainly incidental to evidence upon the subject of unlicensed practice, using the term in the wide sense of doing all that a qualified practitioner may do. It may be of interest, however, to briefly indicate the nature of even this small amount of evidence.

First in importance, perhaps, should be ranked the evidence of Dr. B. W. Richardson, on account of his appearing as the representative of the British Medical Defence Association. In reply to Professor Huxley, Dr. Richardson said that the "tenour of the wish" of this Association is that every description of practice for gain by persons whose names are not on the Medical Register should be prohibited, and that the majority of the members desired to put a stop to "counter practice," in which feeling they were in accord with the general professional sentiment. He admitted, however, that there exists a difference of opinion upon this point, and that he himself differed from many of his colleagues, since he believed that such suppression was not possible or desirable. An enactment that would prevent a person from getting what help he might choose in a case of illness where, as put by Professor Huxley, "the local doctor, whatever his abilities may be, is a person whose habits are not altogether favourable to clearness of head," Dr. Richardson considered would be a very strong measure, such as would not be likely to pass the House of Commons. The course favoured by this witness was the same as suggested by him some time since, that to a certain extent "counter practice" should receive formal recognition as an absolute necessity, and that "the Apothecaries' Company should take up the whole of that part of medicine." It is worthy of notice that as one of the elements to be taken into account in dealing with the question, Dr. Richardson expressed an opinion that, at the present moment, in a political point of view the chemists and druggists are quite as potent as the medical profession, and that as "they have a Pharmaceutical Society conducting itself uncommonly well in the matter, and with such authority that they are outbidding the profession of medicine" (whatever that may mean), the best course would be "to allow a certain limited measure of counter practice."

Mr. H. Nelson Hardy, President of the Medical Alliance, was unable through illness to attend the Commission, but sent in a long statement on behalf of that Association. In it, under the head "Unqualified Practice," the fact is recalled that in the Government Bill of 1870 was a provision for repealing sections 9 to 24 of the Apothecaries Act, 1815, and the opinion is expressed that the repeal of the 20th or penal section, without the enactment of any equivalent, "would have thrown open the practice of medicine to the fourteen thousand chemists who now keep shops in England and Wales." By the way, it may be remarked that this is far in excess of the number of chemists and druggists keeping open shop, even when Scotland is included. The "equivalent" that Mr. Hardy proposes, if the penal clause be repealed, is to the effect that "Any person registered under the Act who for gain engages in the medical treatment of diseases shall for each offence be liable on summary conviction to a fine not exceeding £20." The statement includes a pretty full abstract of the report of the case of the *Society of Apothecaries* v. *Shepperley*, though whether the writer is satisfied or dissatisfied with the result in that case is hardly evident. Mr. Hardy's absence saved him the necessity of having to explain more in detail how he would suppress "counter practice."

Dr. James Grey Glover, whose connection with the *Lancet* gives additional interest to his opinion, when asked whether he would extend the penal clauses so far as to bring "counter practice" under their cognizance, replied that he would not, although in taking that position he thought he was perhaps not representing general opinion. He believed that counter practice never could be stopped, and that it was not desirable that it should be. But if a chemist and druggist went out to visit and posed as a medical man, and carried on medical practice in the ordinary sense of the word, or in severe cases, he thought a clause should be so constructed as to overtake that kind of practice. Whilst he would do nothing against quackery as such, but leave the utmost freedom to the public to employ whom they please, he would punish the false use of titles very severely. It may be hoped that this rational view will become more and more characteristic of the staff of our esteemed contemporary.

The foregoing will give a fair idea, we believe, of all which is to be found in these "Minutes of Evidence" that applies strictly to what is entitled to be termed "counter practice." There is much besides that refers to irregular medical practice, but some of it is of such a nature as to indicate that one of the most pressing problems to be solved is how best to bring the qualified and registered *mal*-practitioner under control. As might have been expected from the terms of the Report, the whole tenour of the evidence given on the subject of "counter practice" justifies the position taken up by the Pharmaceutical Society in relation to it. It has not been the policy of the Pharmaceutical Society to foster or in any way encourage irregular medical practice, but simply to insist that if a chemist and druggist thinks fit to sell to a customer who demands it a remedy for a simple ailment he is acting within his right and does not render himself liable to a legal penalty. But, as has often been pointed out in these columns, the real remedy against "counter practice" lies in the hands of the medical profession to apply; for there can be little doubt that in proportion as chemists and druggists are entrusted with the work for which they are specially trained, namely the dispensing of the prescriptions of qualified practitioners, they will be less inclined, even in semblance, to encroach on the domain of medical men.

PHARMACEUTICAL GATHERINGS.

At the time of writing this note the Annual Meeting of the German Pharmaceutical Association is being held in the city of Berlin, under the presidency of Dr. Brunnengräber, and it is pleasant to know that invitations to be present at this meeting have been courteously forwarded to several English pharmacists. In Germany the business of the Annual Meeting extends over four days, and besides being associated with a pharmaceutical exhibition it is enlivened by several social gatherings; this year it commenced on Tuesday last and culminates on Friday evening in a visit to the Zoological Gardens, where there are to be a concert, supper, fireworks and ball.

On Tuesday next, the 12th inst., the American Pharmaceutical Association is to commence its Annual Meeting, at Niagara Falls, and although this is also a "far cry," an invitation to British pharmacists from the President, Professor P. W. Bedford, has not been wanting. By the courtesy of Mr. G. S. Seabury, we have been favoured with an early copy of the programme, from which we learn that the proceedings at this meeting also last four days. Concerts and excursions to the "rapids" and other places are to vary the monotony of the business, and the meeting promises to be a very successful one.

Close in succession comes the meeting of the Austrian Pharmaceutical Association in Agram, the principal city of Croatia, the reception of guests commencing on Saturday evening, and the opening meeting taking place on the following day. Here again the local Association extend a cordial invitation to the members of other pharmaceutical associations, and we have no doubt that this welcome might be construed to include the pharmacists of this country. It is proposed to bring this meeting to an end by an excusion to Banjaluka, in Bosnia, on Tuesday, the 19th.

It is worthy of notice that in all these cases there is a fixed tariff for the tickets entitling the holder to partake in the festivities of the meeting. It appears to be considered, and we believe rightly so, that all that is to be expected from the local members is that they should make such arrangements as shall best secure the comfort of their visitors, and see that they are effectually carried out. No doubt in most cases this expectation is exceeded, but at any rate it is left with those most concerned to determine to what extent extra expenses shall be incurred.

THE LIBRARY AND MUSEUM.

We are requested by the Secretary, in order to prevent disappointment, to remind our readers that, in accordance with a resolution of the Council at its meeting in July, the Library and Museum will be closed entirely during September for repairs.

FIRE AT A CHEMIST'S.

We regret to learn that in the course of a destructive fire, which broke out in St. Albans shortly before midnight on the 26th ult., the premises of Mr. Arthur E. Ekins, pharmaceutical chemist, and Local Secretary to the Pharmaceutical Society, were nearly entirely destroyed. The fire appears to have originated in the cellar of an ironmonger next door, in which a large quantity of petroleum and colza and linseed oils was stored.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 192.)

Upon resuming, the first paper read was—

A New Styptic of Indigenous Growth.

BY PROFESSOR QUINLAN, B.A., M.D., M.R.I.A., F.K.Q.C.P., *Senior Physician to St. Vincent's Hospital, Dublin; Professor of Materia Medica and Therapeutics to the Catholic University, and Examiner in the same to the Royal University of Ireland.*

The great advances of chemical and of physical science and their application to medical and surgical purposes have much enlarged the means available for the treatment of disease, and in few departments more than in those connected with pharmacy, which, partly owing to chemical research and partly to botanical discovery, have expanded into an important speciality in the hands of eminent special investigators. It is, however, hardly to be doubted that all this great progress is accompanied by a certain disadvantage in medicine and surgery as well as in pharmacy. In the former we have at our disposal the microscope, chemical tests and other means of precision, which are rapidly giving to several departments of the healing art somewhat of the aspect of exact science; but often we are disposed to lean too much upon those scientific aids and to neglect that minute observation of symptoms by which the old physicians, all unlearned in science, accomplished such wonders of diagnosis. Similarly, in pharmacy, the great advances made by our special inquirers cause us to look towards purely chemical remedies and to overlook many of the valuable old simples which in their day were found so useful; and in discarding which we have (while getting rid of much rubbish) certainly sacrificed some really potent drugs. Many of them are safe, efficacious and accessible; and I propose briefly to bring under your notice one of them, which in its day had a great reputation, but which in latter times has been quite forgotten, with which I accidentally came in contact, and on investigation found very useful.

About a twelvemonth ago I was paying a domestic visit to a rather primitive part of the country, and when walking through the fields was urgently requested by the family of a small cottager to come to the aid of a little child who was stated to be bleeding to death. I found that this young patient was suffering from croup, and that on his windpipe some leeches had been incautiously applied by the cottager's family. Everyone knows the difficulty frequently found in stopping such hæmorrhage in infants; and it is a maxim in such cases that leeches should always be applied in some position where pressure can be resorted to if necessary. In this case the least pressure caused the appearance of immediate suffocation; the child had become quite blanched, and being away from home and not on professional duty I had no surgical appliances about me. I was having a search made for cobwebs and was about to heat a small piece of iron, when a neighbour came in with a large handful of leaves which he chewed and applied to the bleeding spot with immediate success. I recognized the leaves as those of the *Plantago lanceolata*, or ribbed grass; and a number of trials made in hospital and elsewhere satisfied me as to their hæmostatic power, either in the chewed form or in that of the dried leaves, applied to bleeding surfaces. Satisfied as to efficacy, my next effort was to examine whether the observation had been anticipated by others; and I found that while modern writers are silent upon the matter, it is referred to enthusiastically by their predecessors from Pliny down to old Culpepper, "Student in Physick and Astrology." Shakspere alludes to it on several occasions; for example, Romeo, speaking of a wounded shin, says—

"Your plantain leaf is excellent for that"
(Act i., scene 2);

and, again, in reference to a wounded head (in 'Love's Labour Lost')—

"No salve, sir, but a plantain"
(Act iii., scene 1).

Culpepper's 'Herbal,' p. 285, contains the following statement:—

"The juice of the plantain clarified and drank for divers days together stayeth all manner of fluxes, even womans courses when they flow too abundantly. It is good to stay spitting of blood, or the making of foul or bloody water, also too frequent bleeding of wounds."

I may further mention that the Gaelic name of the herb is equivalent to the words "healing plant."

The plantains constitute in themselves a small natural order, and are described in detail in Sowerby's 'English Botany,' vol. vii., pp. 166 to 175, both inclusive. This little order contains two genera, viz., the *Plantago*, which embraces five species; and the *Littorella*, to which we need not further allude. The two herbs which I found useful are the *Plantago lanceolata*, var. *vulgaris* (Sowerby, plate, 1164), and the *Plantago lanceolata*, var. *timbali* (Sowerby, plate, 1165), both of which are simply ribbed grass, and to be met with in every meadow; in fact, as the great Roman naturalist, in lauding them, quaintly says "trodden under every man's foot." After a careful series of experiments I have arrived at the following preparations, which I here exhibit, and for the goodness of which it will be sufficient to say that they have been prepared by Dr. John Evans, State Apothecary and Chemist to the Queen and to the Prince of Wales, 49, Dawson Street, Dublin. They are:—

1. The dried leaves of both species. They are intended for external application, and their action is partly physiological and partly mechanical. In fact it much resembles that of matico, and like it it is somewhat ribbed.

2. A species of external linctus, comprising the leaves pounded in a mortar with glycerine added to preserve them. This is intended to imitate the chewed leaves, and to be available at a time of year when the green leaves might not be forthcoming.

3. The juice with sufficient alcohol to prevent it spoiling. This is intended for internal use. It has a hot astringent taste, but not disagreeable, and somewhat reminds one of that of the cardiac tincture of rhubarb.

4. The juice with glycerine. This was designed for physiological experiment on the capillaries, so as to avoid the fallacy incidental to an alcoholized preparation, and for cases in which alcohol would be unsuitable.

5. The green extract. This is made in the ordinary way, first separating the chlorophyll, then eliminating the albumen, and finally reducing the juice and chlorophyll to the consistence of an extract. With this preparation I have not as yet obtained satisfactory results.

Chemically examined the plantain juice is found not to be a tannin, and to be compatible with both the ferrous and ferric salts, the alkaloids, metallic salts, and the preparations of ergot. For obvious reasons in all the chemical and physiological experiments I employed the plantain juice pure, but its compatibility with well-known astringents and hæmostatics is, of course, an additional recommendation. The juice evaporated to dryness and incinerated yields an ash, containing much phosphate and scarcely any carbonate. If the tail of a gold fish be placed in the field of the microscope at 400 × so as to well display the circulation, and if the juice be applied to the web, after a little the following remarkable effects are observed. The circulation in the larger vessels is not interfered with, but in the capillaries there is a tendency to retardation, almost amounting to stasis. It is thus evident that the juice possesses hæmostatic properties, due to some vegetable principle, which is not a member of the tannin series so common in the vegetable kingdom. It is probably to this principle that the hot astringent taste is due.

This would not be the place to enter into therapeutical details. I will, however, ask the indulgence of the Conference to permit me to say that I have constantly used the leaves, and with the very best results, in cases of external hæmorrhage suitable to styptics. In cases of internal bleeding from the lungs, the kidneys, the bowels, and in menorrhagia I have got fair results from large and repeated doses of the juice, either fresh or fortified with alcohol or glycerine.

I recommend with confidence this ancient and once well-known styptic, so safe, so accessible, and, as I have found, successful. Many valuable lives have been saved, in the absence of surgical appliances, by the impromptu tourniquet of a pocket handkerchief tied round the bleeding limb and twisted with a stick. In like manner it can at least do no harm to furnish the practitioner in an emergency with a means of arresting capillary hæmorrhage, which, should regular medicaments be not forthcoming, can be obtained in the nearest field or rural path in any quantity, and by the most uninstructed persons.

The PRESIDENT, having proposed a vote of thanks to Professor Quinlan, said it would be interesting to know his opinion as to whether styptics acted chemically or physically, and if chemically, whether he thought it possible that one principle or more than one produced the action; if physically, as it would seem to act in the case of the tail of the fish, whether by exosmosis or endosmosis. He might not be able to give much information on these points at present, but from the skill with which he had treated this paper it was to be hoped that he would continue his researches on styptics, so that at some future time he might give the Conference a paper on the general action of styptics.

Professor TICHBORNE said there was no doubt that a great many of these old remedies had been sadly neglected of late years, and very good reasons had now been given why this one should be resuscitated, assuming it proved perfectly efficacious, because it was always at hand. He should like to ask how the succus was prepared, for he observed that it had a very dark colour, and the question occurred to him whether a stone or an iron press or mortar had been used. He would also ask if Professor Quinlan had investigated it for substances allied to catechuic acid or catechu compounds, which did not, under ordinary circumstances, give the strong reactions with iron which were found with ordinary tannic or gallic acid.

Mr. GILES said he might mention, as germane to the subject, another indigenous plant of very common occurrence, which also had valuable properties, viz., *Scrophularia nodosa*, a plant which when applied to that troublesome malady, a boil, in its inflammatory stage, was more effectual in subduing the irritation than anything he had ever met with.

Mr. GERRARD asked if Professor Quinlan had experimented at all with this drug in cases of diarrhœa, to ascertain if it was a good internal astringent as well as external. The paper was interesting, as it added another to the list of astringents which acted as such without the presence of tannin. Professor Quinlan had spoken of the action of the glycerine extract on the capillaries, and of the care he took to avoid the use of alcohol, but he did not see much difference between the addition of ordinary alcohol and glycerine to the preparation, glycerine itself being an alcohol; it was a very powerful body; when applied locally, it abstracted water, and in the pure state acted as an irritant.

Mr. PLOWMAN said a styptic might act chemically, perhaps more particularly in favouring the coagulability of the blood, or it might act by causing contraction of the smaller blood vessels. In the experiment on the tail of the fish, Professor Quinlan did not say whether the smaller blood vessels were contracted or not, or whether the stasis or condition approaching stasis took place without any diminution in the calibre of those smaller vessels. In all probability if there were such an actual diminution in the calibre, the active principle in the styptic would act through the nervous system.

Mr. BROWNEN asked whether any experiments had been made to ascertain the effect of the chewed leaves as compared with whole ones; the process of mastication was the initiatory process of digestion and might possibly set free the styptic agent existing in the leaves, or cause the development of something not present in the natural leaf. If it were so it would facilitate the identification of the styptic body.

Mr. SCHACHT would like to ask one further question, though its solution would not bear on the power of the juice or of the medicinal properties which were said to exist; but it might help to explain the first experiment which brought this matter under Professor Quinlan's attention, namely, the external application of the leaves in mass. Had Professor Quinlan in his microscopical examination directed attention to the leaf itself, to see whether or not it was covered with any special hairy processes which might serve the well-known purpose of distributing the blood over a large surface and thus promoting its more speedy and complete coagulation.

Mr. POLLARD said it was desirable to be as precise as possible in the terms made use of, and it did not seem to him that the word linctus was quite appropriate in this case.

Professor QUINLAN said he quite admitted that, and should be glad of any suggestion which would enable him to get rid of it.

Mr. SOUTHALL said that this interesting paper was very appropriate after the remarks in the President's address on the knowledge or want of knowledge possessed by chemists and druggists of our indigenous plants. If one looked at old herbals the great bulk of the plants were said to possess the same properties, so that one could not gather much information from them; the same set of qualities were attributed to a large number of very different plants. The use of some of these old plants seemed to be now revived, for instance, parsley-piert (*Alchemivll arvensis*) and crouch grass (*Triticum repens*) were not unfrequently used both by herbalists and in pharmacy.

Mr. BORLAND inquired if any investigation had been made as to the season at which these leaves were collected. Attention had already been drawn to the very proper point that regard should be paid to the period at which the collection of the articles of the materia medica was made. He might add that the *Plantago lanceolata* had long been used as a styptic in the part of Scotland from which he came, applied to cut wounds. Farm servants, when they met with any accident, would take one of the long leaves and bind it round the part; but the argument advanced in support of its medicinal action was solely a mechanical one, and he was not aware until now that it was supposed to possess any other property than that of acting as a covering to the wound. He should like to know if the plant was believed to possess these medicinal properties at all seasons of the year when it was found.

Professor QUINLAN said he wished he had heard some of these suggestions before, but he had noted them carefully, and would endeavour to take advantage of them. It appeared to him that the action of the plantain in either the dried or chewed form, but particularly in the dried form, was partly mechanical and partly physiological, but he had no means of saying whether it was also chemical. The first question put by Professor Tichborne was as to how the juice was prepared, and he might say that when he took a bale of leaves to Dr. Evans and told him what he wanted, that gentleman expressed his regret that a powerful hydraulic press which he possessed was out of order. But he told him that even if it had been in order he should have asked him not to use it. It was prepared in a large marble mortar and pestle, worked by two men. He attributed the dark colour to the chlorophyll. He thanked Professor Tichborne for the suggestion about catechuic acid, which had not occurred to him, but he would look into it. Mr. Giles's remark was most valuable, and confirmed the idea he had formed that in throwing over a great mass of rubbish they had at the same time sacrificed a number of very useful remedies, many of which were described in the old book of Nicholas Culpepper, student in astrology and physic, as he described himself. He stated that this was a herb of Venus and not of Mars, but he had not thought it necessary to trouble the Conference with the astronomical portions of his directions. That very morning he had heard from a member of the Conference a remarkable example of one of these old remedies, which had proved immediately efficacious in the cure of some children suffering from chronic whooping cough, one of the most troublesome maladies with which the physician had to deal, and which was almost impossible to cure except by change of air. He should make it his business to look up this local herb, ascertain its scientific name, and investigate its properties. He had not tried the plantago in cases of diarrhœa, but simply as a styptic. With reference to the question of alcohol and glycerine, when he tried any experiments of this kind he always made it a rule to try the effect of the subsidiary agents by themselves; he tried both alcohol and glycerine in the diluted form, and found under the microscope that alcohol caused certain effects which glycerine did not. There was nothing one required to be more careful of in conducting any research than these side effects, which one did not expect. These leaves were collected in May and June, when they were in perfection. He had not examined them microscopically; no doubt if they were so examined something would be found which would account more or less for their mechanical action.

A paper was then read entitled—

Some Experiments on English Oil of Lavender.

BY W. A. SHENSTONE.

Oil of lavender has been the subject of several researches, most of which have been undertaken by foreign chemists, the following being among the chief statements that have been made concerning it.

1. That it sometimes deposits camphor in cold weather, and that the camphor is identical with common camphor. Most of the experimenters who have obtained camphor from this oil, however, have probably done so after the application of some oxidizing process; further, Messrs. Flückiger and Hanbury state in 'Pharmacographia' that they have not been able to ascertain the above fact, and after some experience in the manufacture of the oil, and a good deal of observation during the last ten years, I also have been unable to obtain any confirmation of the first part of this statement, so that I think it is probably erroneous.

2. That it contains a hydrocarbon, isomeric with that from turpentine oil, which is said by Lallemand to boil at so high a temperature as 200° C. to 210° C., and which does not yield a crystalline hydrochloride. It will be seen in the sequel that recent experiments do not confirm these statements concerning the properties of the hydrocarbon in lavender oil.

The most recent contribution to the subject is that of M. Bruylants, an account of which appears in the *Journal de Pharmacie et de Chimie* for 1879.

M. Bruylants working with pure oil of French lavender flowers has obtained from it, by fractional distillation to the amount of 25 per cent., a product which after rectification over sodium he recognized as a terpene by its boiling point, 162° C., its vapour density and its action with iodine. When strongly cooled and treated with hydrochloric acid gas, it yielded a solid hydrochloride. He also believes the oil contains, to the extent of 65 per cent., a mixture of borneol and camphor, being led to this conclusion by the facts that determinations of carbon and hydrogen give numbers which are consistent with such an hypothesis; that after treatment with a mixture of potassium bichromate and dilute sulphuric acid it yielded camphor, and after treatment with phosphorus pentoxide he obtained a mixture of a terpene and cymene. The former in greater proportion however.

As M. Bruylants was unable to separate any solid constituent by applying to the mixture a temperature of − 25° C., and as there are many cases in which the solid constituents of similar oils are separated quite easily by cooling, I am inclined to doubt their presence in this case, especially as M. Bruylants' results are consistent with other explanations. Cymene is not unknown as an apparent constituent of essential oils, so that its isolation by the above method is hardly a sufficient indication of the presence of camphor. And again, since bodies having the same composition as camphor have been obtained by the action of oxidizing agents on several substances, its isolation under these circumstances rather suggests that the above constituent consists of one or more liquid oxygenated bodies which yield camphor when treated with oxidizing agents, and that French lavender oil is in the main a mixture of these and of the above described terpene.

About six years ago Dr. Tilden was kind enough to put into my hands a considerable quantity of fine English oil of lavender, and I devoted a good deal of time to its examination. My results are by no means complete as, unfortunately, all my material was destroyed in a fire which occurred at Exeter in 1878, and I have been deterred from returning to the subject since by pressure of other engagements, and by the very high price of the material. Probably I should not have brought them before the Conference now had not the experiments of M. Bruylants on French oil seemed to me to give an interest to my incomplete work which by itself it hardly possesses.

The quantity of material with which I experimented was rather more than 850 cubic centimetres. When distilled about one-third came over below 185° C., and one-half of the remainder between 185° C. and 207° C. The distillation was stopped at this stage as there was evidence of decomposition. An aqueous liquid, acid to litmus, came over with the distillates. The residue in the retort was finally distilled in a current of carbon dioxide, keeping the temperature low, in order to lose as little of the volatile constituents as possible. The portion distilling below 185° C. was again distilled, ebullition began at about 176° C. and nearly half came over below 180° C. The various portions which distilled above 180° C. were fractionated so as to get as much as possible of the lower boiling product, which was added to the above. During these operations there was constant separation of water, and I may here observe that this occurred throughout my work; portions which had been heated for weeks with metallic sodium still yielding traces of moisture when subsequently distilled.

The result of these operations was that I had a product boiling at 176° C. to 180° C. amounting to nearly one-third of the oil taken, about the same quantity boiling from 200° C. to 207° C., 140 c.c. boiling a few degrees above 180° C., and a black resin amounting to about 25 per cent. of the substance operated on. There is no doubt from the results of a distillation *in vacuo*, subsequently described, that this last was to a great extent a product of decomposition.

The portion which boiled below 180° C. was digested for many days with large excess of metallic sodium, the liquid being from time to time distilled off from a brown solid which separated, steam distillation being employed when necessary to avoid the application of excessive heat. The product was fractionated and the portion which then came over at 170° to 175° C. was subjected to further prolonged treatment with sodium to destroy oxygenated compounds, and finally yielded a liquid which distilled at 167° to 169° C. The quantity of this substance was less than 1 per cent. of the oil taken, and as I could not hope to further purify so small a quantity, I decided to examine it.

I had no apparatus for organic analysis at the time and by Dr. Tilden's kind consent Dr. G. H. Morris made some analyses of it for me. He found that it contained about 3 per cent. of oxygen, but had a vapour density nearly corresponding to that of a terpene of formula $C_{10}H_{16}$. I myself examined the very small quantity which remained from his experiments, and found that the substance was a colourless oil with a camphoraceous fragrant odour, but not that of lavender oil. When well cooled with ice and salt and saturated with hydrochloric acid gas it yielded white needle-like crystals of a hydrochloride, which I collected and dried by pressing between filter paper. I was, however, unable to examine or preserve them as the quantity was too small for purification, and in their then impure state they quickly melted at ordinary temperatures and so disappeared. When treated with hydrochloric acid and subsequently with ferric chloride the oil behaved like a terpene. These results seem to indicate that it was a terpene, but still contained a little of the higher boiling constituents of the oil.*

Unfortunately my examination of the higher boiling fractions was hardly begun before it was brought to a close by the fire previously alluded to. In the course of the separation of the small quantity of terpene, however, I observed that under the action of heat they were modified with the production of water and with an increase of boiling point. In an experiment to test this point I found that a portion of the oil, which boiled at 184° C., after heating for two hours and a quarter with an inverted condenser had its boiling point raised to 192° C., but that subsequent heating had not much effect upon it.† As regards the composition of this part of the oil, it appears to be highly oxygenated. Dr. Morris has made an analysis of a fraction boiling at about 200° C. and he found that it yielded only 83·6 per cent. of carbon and hydrogen, from which it appears to contain about 16 per cent. of oxygen.

I had also fortunately made the following experiments with the view of obtaining, if possible, any solid constituents the oil might contain:—

1. A portion of lavender oil was placed in a distilling flask sealed to a receiver, the arrangement was exhausted by a Sprengel pump till the pressure in the apparatus was equivalent to less than one inch of mercury, and then hermetically closed. The receiver was well cooled and the oil distilled at as low a temperature as possible until only one fourth remained; the residue had the consistence of a syrup and was of a pale colour, but gave no sign of crystallizing after standing for a month, nor did it do so on cooling by means of freezing mixtures.

2. Small portions of the oil of lavender and of one of the higher boiling fractions were cooled with a mixture of solid carbon dioxide and ether. They became exceedingly viscid, but gave no signs of crystallizing, even when minute fragments of camphor were added to them. It is difficult to believe, after these experiments, that the oil contains any notable quantity of crystalline constituents.

From the independent experiments of M. Bruylants and myself it seems that the English and foreign oils differ very decidedly in the amounts of terpene they contain; that in each case it is a terpene yielding a crystallizable hydrochloride which is present; and that probably neither of the oils contains much crystalline constituent, but that both, and this applies particularly to the English oil, are chiefly composed of one or more liquid oxygenated bodies, which there is reason to believe yield camphor on oxidation, and which appear to undergo some degree of change during distillation. The statement in the books that lavender oil contains a hydrocarbon boiling at 200° to 210° C. is doubtless incorrect, as Dr. Morris's analysis shows that the distillate collected at near that temperature contains a large amount of oxygen. The further study of the oxygenated constituents will probably be most conveniently conducted with the English oil, as in that it is mixed with less hydrocarbon than in the foreign product.

In conclusion, I can only regret that I have not a more complete account of this matter to bring before the members of the Conference.

* It is not, of course, certain that this substance had not been produced from other constituents of the oil during distillation. Its resemblance to the terpene obtained by M. Bruylants, however, inclines me to the belief that it was not so.

† Professor Letts, who has very kindly shown me some unpublished notes of experiments on lavender oil, has also observed this rise of boiling point under the influence of heat.

The PRESIDENT, having proposed a vote of thanks to Mr. Shenstone, which was carried unanimously,

Mr. JACKSON asked if Mr. Shenstone had examined the optical properties of the terpene from French and English oils before assuming that they were the same.

Mr. SHENSTONE said that he did not assume that they were the same. He had not examined the optical properties, though he had intended doing so, because his material was unfortunately destroyed before he arrived at that stage.

The next paper read was on—

TERPIN HYDRATE; ITS PREPARATION AND CRYSTALLOGRAPHY.

BY R. H. PARKER.

This subject was brought under my notice by a sample of crystals of unknown composition, many of them remarkably well formed, found by my friend, Mr. W. Adams, of Shrewsbury, in a jar of "Furniture Oil," some of which had been sent to a customer who complained that it scratched the furniture; another bottle, carefully strained, was sent out, but it also come back in about a month with a note stating that it contained "bits of glass." The stock jar on examination was found to contain a considerable quantity of the crystals in question. The exact formula from which the furniture oil was made could not be referred to with certainty; it was probably made from one consisting chiefly of linseed oil, turpentine, butter of antimony and methylated spirit. A sample made according to this formula, however, has given no crystals during four years.

An examination of the substance proved it to be entirely volatile, and its elementary composition was soon found to be limited to C, H and O. When searching for nitrogen by heating with soda-lime, the production of a highly aromatic camphoraceous odour was observed. Further information as to the nature of the substance was sought by ultimate analysis. Several well-formed colourless crystals, evidently very pure, were selected, carefully wiped and powdered. ·1878 gram gave ·1995 H_2O and ·4375 CO_2; ·1787 gave ·1897 H_2O and ·4163 CO_2. Having observed its relation to ordinary solvents, a search among bodies approaching this composition suggested that the substance in question was terpin hydrate. On comparison, a specimen of that substance was found to possess the same crystalline form and produced the same peculiar odour when heated with soda-lime. The percentage of carbon found was too high, probably due to the specimen not being absolutely pure. The following are the figures obtained:—

	1.	2.	$C_{10}H_{18}(OH)_2,H_2O$.
C. . . .	63·53	63·53	63·16
H. . . .	11·80	11.79	11·58

The attempt to produce the substance from the furniture oil having failed, the ordinary process was adopted, *i.e.*, a mixture of turpentine, nitric acid and alcohol. Processes are recorded by Wiggers, Deville, Berthollet, Tilden and others giving different proportions of ingredients and stating numerous conditions probably conducive to the formation of terpin hydrate, but neither details the exact method of mixing the ingredients or states what conditions really assist its formation.

Strong nitric acid, as is well known, acts violently on turpentine and on alcohol, the products varying with the temperature and strength of the acid; the latter and the order of mixing are most important points to observe in the manufacture of terpin hydrate.

My first experiments were made with nitric acid, specific gravity 1·42; a mixture of five volumes of turpentine with two of methylated spirit was kept cool while two volumes of acid were stirred in; this was agitated occasionally for a few days, poured into a shallow dish and a little spirit added at intervals. A dark brown mixture resulted separating into two layers, but no crystals appeared during many months.

In the next series the action of the acid on the turpentine was encouraged by floating the spirit on the oil, and pouring the acid through a funnel-tube to form a third layer at the bottom of the vessel, in this case the strong acid was in direct contact with the turpentine. The temperature rose rapidly, and an explosive ebullition took place, much vapour was disengaged, and the spirit afterwards boiled quietly for some time. A deep red syrupy liquid resulted which showed no tendency to crystallize; it was very soluble in alcohol, the solution bearing considerable dilution with water.

The opposite line of action was next adopted, the acid was diluted with water and mixed with the spirit before adding the oil; this proved to be the correct process and crystals were invariably produced. Nitric acid of specific gravity 1·25 yielded most satisfactory results, when stronger than specific gravity 1·3, no terpin was formed.

Attention was now directed to the conditions most favourable to the production of crystals. Insolation did not appear to influence the result to any important extent. Crystals appeared sooner and in greater abundance in shallow than in deep layers of liquid; the depth should be about a centimetre. Slight occasional rotation of the vessel hastened the appearance of crystals.

The production of *colourless* crystals was favoured by the use of rectified in the place of methylated spirit, of freshly distilled turpentine in preference to that which has been long exposed to air and by the exclusion of air from contact with the mixed ingredients. The latter condition was arrived at by placing a circle of glass, accurately fitting the vessel, so as to touch the surface of the liquid. The advantages gained by this precaution and by the use of rectified spirit were not sufficiently great to warrant their adoption in a manufacturing process. The exclusion of air seemed to favour the production of a larger proportion of crystals.

The following is the process finally adopted:—

Preparation of Terpin Hydrate.

Mix one volume of nitric acid, specific gravity 1·25, with one volume of methylated spirit, cool, place the mixture in a shallow glass dish and float upon it two volumes of oil of turpentine, rotate the vessel occasionally, and in three or four days crystals appear, allow to remain undisturbed for about fourteen days, collect the crystals on muslin, wash with cold water, drain, and dry by exposure to air, re-crystallize, if necessary, from slightly diluted alcohol.

The two layers soon acquire a straw tint, the lower being darker, the colour gradually deepens and after a few weeks becomes deep red. The depth of colour is much less when contact with air is prevented. Most of the terpin hydrate is deposited in the first fortnight. The total produce does not often exceed one-third of the weight of the turpentine taken. When little or no more terpin is produced, the lower layer appears to consist of a mixture of nitric acid and alcohol saturated with terpin and containing a small proportion of the upper layer in solution; this floats when the mixture is diluted with water, while the terpin crystallizes out. The upper layer has a pleasant aromatic odour, decomposes on boiling, but in a current of steam most of it passes over, the distillate being nearly colourless while the residue is very dark red, thick, and heavier than water. The successive portions of distillate varied in specific gravity at 17° C. as follows:—

No. 1	0·896
No. 2	0·900
No. 3	0·910
No. 4	0·921

In odour, the last is similar to but more rank than the first, there is no resemblance either to that of terpinol or the original terpene.

In another experiment, after the terpin had been deposited, the acid layer (*a*) and oily layer (*b*) were separated.

A fresh quantity of turpentine was floated on the acid layer (*a*) and an average crop of crystals was obtained; the upper layer was again replaced by fresh turpentine from which also a large proportion of terpin was in due time produced.

The oily layer (*b*) was floated on a fresh mixture of acid and alcohol, but no crystals appeared for six weeks, and after that time, only a small quantity.

The results I have obtained agree, in the main, with Tilden's (*Journ. Chem. Soc.*, 1878), except that I find the use of a weaker acid necessary, and omit the subsequent additions of methylated spirit.

The theory given by that author accounting for the production of terpin by the intermediate formation of a compound of terpinol with ethyl nitrate,

$$C_{10}H_{16} + C_2H_5OH + NO_2OH = C_{10}H_{18}O \left\{ \begin{matrix} OC_2H_5 \\ NO_2 \end{matrix} \right.$$

$$C_{10}H_{18}O \left\{ \begin{matrix} OC_2H_5 \\ NO_2 \end{matrix} \right. + 2H_2O = C_{10}H_{18} \left\{ \begin{matrix} OH \\ OH \end{matrix} \right. + C_2H_5OH + NO_2OH$$

is satisfactory, except that it does not explain the fact that only one-third of the terpene is hydrated.

Crystallography of Terpin Hydrate.

The crystals which are first produced in the preparation of this substance are often extremely well formed, and if simply wiped, avoiding washing with water, the faces are remarkably brilliant. They consequently afford an excellent opportunity for the study of its crystalline form, which is a combination of the rhombic octahedron and prism in which the faces of the former are dominant; those of the latter are often much reduced but never disappear. Fig. 1 illustrates the average form, which,

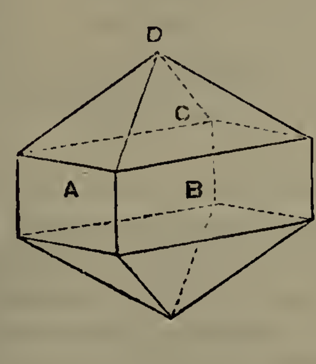

Fig. 1.

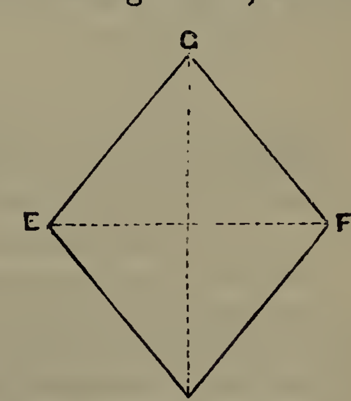

Fig. 2.

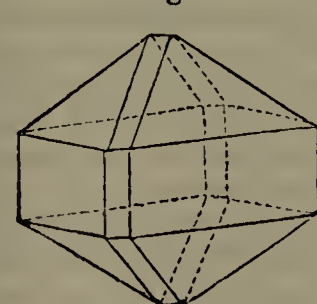

Fig. 3.

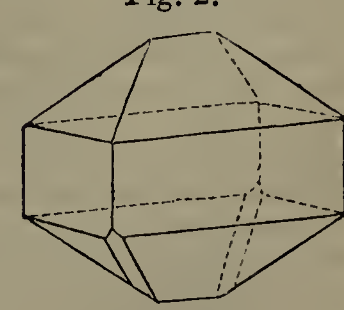

Fig. 4.

however, is not often completely developed; the prism faces are frequently much extended, producing a more or less elongated prism, while they are sometimes reduced to quite a narrow face, forming a nearly closed octahedron. Fig. 2 illustrates the horizontal section. Occasionally the macrodiagonal edge (G and H, Fig. 2) is replaced by a narrow face which is shown in Fig. 3, carried round the complete crystal. These faces are but slightly developed and in the crystal as first formed they are seen on the pyramid in a few cases and never on the prism. After recrystallization from alcohol, the macrodiagonal face may be observed on the prism, more frequently on the pyramid, and occasionally on both.

The most important modification of form to which the crystal is subject consists in decrements from one or more faces of the prism and pyramid; in fact nearly all are more or less modified in this way, the prism becoming more or less flattened, and the solid angle at the apex being reduced to a horizontal edge forming a dome instead of a pyramid. Fig. 4, which illustrates these changes and also the appearance of the macrodiagonal face on the lower side, may be taken as the typical form of terpin hydrate crystals. When produced from alcoholic solution, even slowly, the tendency is to form elongated prisms and needles, but the terminal pyramid is always evident. The brachydiagonal edge (E and F, Fig. 2) does not appear in any case replaced by a face.

The measurements of the opposite angles of prism and pyramid were found, as expected, identical; the macrodiagonal face was found inclined equally to the adjacent faces of the prism.

After a large number of measurements, three of the most perfect and brilliant crystals were selected for final examination with the reflecting goniometer. Five different observations of the solid angle at the apex gave a mean of 105° 6′; nine different observations of the inclination of the pyramid face to that of the prism gave a mean of 127° 33′; a slight error in excess is evident—

$$105° \; 6' + 2(127° \; 33') = 360° \; 12'$$

a closer approximation would therefore be 105° 2′ and 127° 29′. Numerous observations of the prism faces gave as the best results—

macrodiagonal angle E G F = 77° 45′
brachydiagonal angle G E H = 102° 15′

From these measurements the relative lengths of the axes are calculated—

E F :	G H :	vertical axis =
0·8007 :	1 :	0·4951

This result, however, does not quite agree with the parameters given by previous observers (*vide Phil. Mag.*, 1879, p. 132).

Maskeleyne	0·8082 : 1 : 0·4788
Arzruni	0·8072 : 1 : 0·4764

Specific Gravity of Terpin Hydrate.

This appears to vary slightly, the average being 1·09, relative to distilled water at 17·5° C.

Solubility of Terpin Hydrate.

At 20° C. it requires for solution 13 parts of alcohol, specific gravity, ·825; about 350 parts of distilled water; its solubility in alcohol is much increased by heat; boiling water dissolves about 3 per cent. It is slightly soluble in chloroform, carbon bisulphide, ether and benzol, scarcely in turpentine.

This substance well illustrates the conventional character of the term solubility, which I have before pointed out when referring to that of salicin (*Pharm. Journ.* [3], xii., p. 378). A simultaneous series of experiments was made on the solubility of terpin in alcohol and in water, all being maintained at a constant temperature of 20° C. for over forty-eight hours. One part of terpin dissolved in 11 volumes of alcohol with the aid of slight heat did not crystallize, while 1 in 13 without heat did not entirely dissolve, although repeatedly agitated. One part of terpin in 240 volumes of water dissolved by heat, gave a single tiny crystal at the end of forty-eight hours, while 1 in 300 without heat left a considerable amount undissolved. The solubility cannot be taken by the method of evaporation, because terpin is volatile at a dry heat much below 100° C.

The odour observed on heating terpin with lime suggested distillation of such a mixture. Terpin mixed with four or five parts of lime was slowly distilled over a column of lime heated to low redness. A liquid yellowish oil was obtained, having a very powerful aromatic camphoraceous odour, in some degree resembling that of yarrow and cajeput, and yet distinct from them. Sometimes much terpin distils apparently unchanged and solidifies in the condenser. I have not yet arrived at a process by which terpin can be completely converted into this oil, so as to obtain a sufficient quantity for complete examination. It seems, however, probable that terpin hydrate may be made to yield several aromatic oils by the action of dehydrating substances under suitable conditions.

The PRESIDENT said the first feeling on the part of most members on listening to this paper would be one of astonishment that so much science should be made to flow from a bottle of furniture polish; and the second would be that a great deal depended on who drew the cork. He was proud to think that in this instance it had been drawn by an old pupil of his own, and pharmacy should be proud to think that a gentleman engaged as an assistant behind a retail counter could find time and possess the ability to carry out an investigation of this kind. He would propose a vote of thanks to Mr. Parker, who he hoped would continue his researches.

A vote of thanks having been agreed to,

Mr. SHENSTONE said the most interesting point about this communication was the origin of the terpin in the bottle of furniture polish, which Mr. Parker seemed to think was a mixture of linseed oil, spirit of turpentine and butter of antimony. There was a general impression that nothing answered very well for making terpin hydrate excepting nitric acid diluted with alcohol, and now it seemed possible that further investigation might introduce a new body capable of producing terpin hydrate from turpentine, which would be interesting and important, as it might render the explanation of the reaction suggested by Dr. Tilden insufficient.

Professor TICHBORNE said it was his duty some years ago to prepare a considerable amount of terpin hydrate, when he discovered a body called colophonic hydrate, which in its properties bore a considerable resemblance to terpin hydrate, but it differed considerably in one important point, inasmuch as it gave a number of beautiful colour reactions with hydrochloric and sulphuric acid, which terpin hydrate did not. It was a product formed by oxidization from what was known as resin spirit, and there was no doubt a close relation between it and terpin hydrate. In preparing terpin hydrate his experience was that if it were crystallized from fairly strong alcohol, a mass of fine crystals was obtained, but if a solution of 1 part of water to 2 of ordinary spirits of wine were allowed to evaporate spontaneously very magnificent crystals were formed, sometimes approaching ½ inch in length.

Mr. GILES asked how Mr. Parker arrived at the conclusion that the furniture oil had been composed of the ingredients he had mentioned. Was it by analysis or by communication of the formula?

Mr. PARKER said he was unable to arrive at the exact formula from which the polish was made; it occurred in a pharmacy where it was not frequently in demand, being made sometimes from one formula and sometimes from another; the one containing turpentine and butter of antimony seemed to him the most likely one and he made some from that, but no terpin hydrate was formed. It seemed as if the formation of terpin hydrate required a peculiar condition in the mixture; whether a liquid isomer was formed he could not say, for the original sample which was sent out produced another crop of crystals within a month; whereas the specimen he made would not produce crystals under any conditions.

Mr. SHENSTONE asked if there was any possibility of the polish being made from a formula containing nitric acid.

Mr. Parker said it was very unlikely; the preparation of furniture oil with turpentine and butter of antimony was very common, but he did not think any nitric acid would be used knowingly. Professor Tichborne's remarks on colophonic hydrate were interesting, but to his mind the production of beautiful crystals of terpin hydrate seemed due not so much to the solvent as to the presence of other bodies with it. In the first purification of these crystals by means of methylated spirit, the presence of the other bodies was very evident, and in that case only did he obtain a similar crystal. When recrystallized, either from rectified or proof spirit, he found the crystals always exhibited a tendency to assume the form of long prisms or needles.

The next paper read was—

On a New Method of Making a Volumetric Solution for Determining the Hardness of Water.

BY C. R. C. TICHBORNE, F.I.C.,

Analyst, Co. Longford, etc.

It is rather curious to observe that in spite of our constant familiarity with the determination of the hardness in waters, we have never been able to improve, or modify, to any extent the original process of Dr. Clarke, invented nearly half a century ago. We may go even further, and state that we have never been able to throw doubt upon his original investigations and that they stand as he left them. Any so-called modifications are merely nominal, and have been made to suit the modern centesimal mode of expression. The most important proposals have been made in connection with the making of the soap solution and the standard calcium solution used for titration. A few of these modifications are, without doubt, improvements; but none of them touch in the slightest degree the principle of the process. Thus, in making the soap solution, Dr. Clarke used a soap made from animal fats (curd soap), and it has been respectively proposed to use a soft soap made from olive oil, lead soap (*emp. plumbi*), or a soda soap of olive oil (Castile soap). All these three last proposals are undoubtedly better than the original curd soap, as proposed by Dr. Clarke, owing to the very simple fact that the fatty acids in the last three mainly consist of oleic acid, and that the oleates are less prone to separate in cold weather than the corresponding fatty bodies found in the curd soap.

As regards standard hard waters, I had adopted for some time the well-known modification of dissolving an equivalent quantity of powdered selenite. This process leaves nothing to be desired as regards the construction of a calcium solution. It is simple and gives most accurate results, providing there are no crystals of celestine in the selenite,—an experienced geologist will instantly detect them by his eye.

Having premised thus far, it might be asked, Why seek to change, or improve upon the process? Experience shows that the most troublesome part of the method consists in making the soap solution. Soaps are too indefinite in composition to admit of making a reliable solution by merely weighing out a given quantity and dissolving it in a proper quantity of spirit. Assuming that a soap of a definite fatty acid could be always obtained, we find the amount of water to differ so considerably as to render a titration necessary; a titration too, which presents some considerable trouble.

My first idea was that if we took oleic acid and neutralized it with a standard solution of sodium hydrate, the latter base would represent the calcium salts, constituting hardness, equivalent for equivalent. I found, however, in practice that this is not quite so simple a matter as it would appear at first sight, but at the same time it is quite easy to construct a soap solution upon the basis of the soda hydrate consumed by the fatty acid.

The quantivalence of oleic acid may be, and has been, variously viewed. It is generally viewed as a monobasic acid. As acid salts, however, are known, it may with equal propriety be viewed as a bibasic acid; whilst, as will be seen further on, there is every reason to think that tetrabasic compounds of the alkalies exist.

Five cubic centimetres of commercial oleic acid were dissolved in 50 c.c. of spirit of wine, and 1 drop of a ·5 per cent. solution of phenol-phthalein added. A volumetric solution of soda was then run in until a pink indication was obtained. After repeating this experiment two or three times the reaction was found to be not only well defined, but very constant. If litmus were used, not only is it difficult to determine the point of saturation, owing to the gradual transition of colours, but owing to the permanent dissociation of a trace of the oleates when in solution (to which the litmus is amenable), the reagent is not suitable to the experiments detailed. The 5 c.c. of oleic acid exactly worked off at 15·5 of the normal solution of soda of the British Pharmacopœia, which represents 0·62 grams of sodium hydrate. Theory for the oleate having the formula $M'C_{18}H_{33}O_2$ would require 0·6 of hydrate of sodium, assuming the 5 c.c. of acid weigh 4·575 grams.

At this stage of the experiments a curious observation was made when water was substituted for the alcohol. The 15·5 of volumetric solution when added, as I have previously stated, gave a permanent liquid product of a faint pink tinge, showing that the point of neutrality had just been passed. A drop more of the volumetric solution developed a magenta colour, which was permanent as long as the solution was left at this point of saturation. A further equivalent of sodium hydrate was then run in (viz., 15·5 c.c.), when it gradually became colourless again, and at 7·75 c.c. began to pectize; the solution at this stage represented about the consistency of thick mucilage. When the full equivalent was present the solution became a solid jelly. The vessel in which it was obtained might be inverted with impunity. The pectized oleates seem to be permanent and definite compounds. From their behaviour when thrown into alcohol they appear to be hydrated compounds and are perfect colloids. If we push the action further, other compounds are formed which are much more soluble. There seems to be a wonderful analogy between silicic and oleic acid, and the technical application of silicates in soap-making appears to have been one of those chance discoveries which are in advance of scientific knowledge. As I intend to reserve this part of the subject for a separate communication, I have only to consider on the present occasion the practical bearings of these observations.

The measurers of the hardness in water are really the fatty acids, and it is almost immaterial whether we use the monobasic or dibasic salt above mentioned. In these remarks, we retain the old formula of oleic acid, but it is evident that the whole subject requires revision. We find by experiment that very little difference will be obtained, but that as the pectized salt seems to lather more freely, and as the solution seems more permanent I prefer it.* We, however, always depend upon the sharp reaction obtained on adding the soda until the pink solution is developed with phenol-phthalein. This point always represents the proportion of NaHO as equalling pure $C_{18}H_{34}O_2$.

The following is the process:—

As already mentioned, 5 c.c. of oleic acid are measured with a pipette and 50 c.c. spirit added to it in a beaker; 2 drops of phenol-phthalein solution are also added, and immediately a volumetric solution of soda $\left(\frac{NaHO}{1000} - \right)$ is run in until a pink indication is produced. This must

* This remark is not strictly true. I have found specimens of some oleic acids which do not work well, and do not readily pectize, and wherever there is any doubt about the results it is safer to merely add the exact proportion to neutralize the acid, as indicated by phenol-phthalein.

be done accurately, as the success of the process depends upon this measurement. If the gelatinous salt is required, another quantity of soda is then run in. The oleate of soda is then made up to the required measure by the addition of a mixture of equal parts of rectified spirit and distilled water. Each 15·5 c.c. of soda used in the first saturation equals 820 c.c. of volumetric solution of soap.

Thus— $$\frac{n \times 820}{15 \cdot 5} = x$$

n being the number of c.c. of soda solution which the oleic acid works off at, it is to be made up x. Such a solution makes a lather exactly on the original scale of Clarke, and it becomes unnecessary to titrate such a solution against a calcium solution, the soda solution being quite as definite and reliable as a calcium solution. Again, although different oleic acids might differ in purity, such a condition of things introduces no error, as the volumetric soap solution is made up on the saturating power of the acid employed, which alone determines the strength. Oleic acid obtained from the candle manufacturers, and a pure sample from Messrs. Hopkin and Williams, gave me exactly the same results in this respect, although they differed very much in their pectizing properties. The 15·5 c.c. of soda required to saturate 5 c.c. of acid always neutralized in my experiments; but I am not prepared to say that this would be generally the case, and it is difficult to make in different hands a pipette always delivering separately the same amount of an oily fluid like oleic acid, therefore I proceed on the above basis of calculation.

The above process gives a solution 32° c.c. of which when operating on 100 c.c. of water represent 16° of hardness per gallon by Clarke's scale.

The advantages claimed are that the soap solution may be made in five minutes,—requires no titration against a standard water,—and is more permanent than those made from ordinary soaps.

The PRESIDENT moved a vote of thanks to Professor Tichborne, which was carried unanimously. He said this method seemed a practical improvement inasmuch as it started with something quite definite, like soda, instead of something indefinite, like soap or commercial oleic acid. He would ask Professor Tichborne whether a solution made in that way really did keep better,—whether he had observed it for any length of time. It seemed natural for a soap solution when exposed to the air to split up, more or less rapidly, into an alkaline body and an acid oleate, the less soluble oleate being apparently more durable.

Mr. EKIN said he understood Professor Tichborne to say that when he added more alkali to what was a perfectly clear solution of soap he got a pectinized form. Was it not possible that the soap was insoluble in a solution of alkali, and that the pectinization was thus accounted for? The kind of soap he had found keep best was Pear's transparent; when dissolved in spirit it keep very satisfactorily. The method proposed for making a soap solution was perhaps about the most convenient, as it was a ready process that was always at hand. The great difficulty with Clarke's process had always been the trouble with the different kinds of soap.

Professor QUINLAN said he had often had occasion to make use of Clarke's test, and he could bear witness to the extreme trouble of making up the soap solution. This paper seemed to afford a method for readily making up a definite compound which would be very easy to use.

Mr. JACKSON asked if Professor Tichborne had used any other indicator than phenol phthalein, litmus, for instance, and compared results, to see if they were always the same.

Mr. NAYLOR said the method he adopted was to purify the commercial oleic acid by freezing, then to dissolve in that oleic acid some freshly precipitated oxide of lead, and decompose the lead compound in the usual way. He did not quite see why this oleate of soda should be more definite made as Professor Tichborne proposed than by any other method, provided the oleic acid were purified to begin with.

Professor TICHBORNE, in reply to the question put by the President, said there was no doubt that this solution did keep better than those of ordinary soaps. Even Castile soap, which was supposed to be very definite, sometimes contained a great mixture. He did not claim that this solution would keep perfectly; like all soap solutions, after being kept some time, there was a kind of silky crystalline appearance upon it, which it was impossible to avoid; but it was quite different to what occurred when a soap was used which contained a large proportion of stearic and palmitic acids. Sometimes there was a deposit in the bottle, which would prevent any reliable work being done. One of his reasons for thinking that the gelatinous body which pectized with the two equivalents of soda was a definite compound was based on the fact that if it were placed in a dialyser it acted very like a definite compound. He was not prepared at present to say that it was, but he thought this much more likely than that it was insoluble in caustic soda; because if another equivalent were added still more soluble compounds were obtained; the gelatinous appearance passed away, and by the addition of another equivalent of sodium a perfectly soluble compound was produced. The use of litmus as a test was not applicable; in the first place it was extremely difficult with such a thing as that to watch the reaction, the transition of litmus was so gradual. His experience of litmus was that it was about the worst indicator that could be used. He had observed with students, that what one called the point of neutrality with litmus was quite a different thing from what another did. The indication of litmus was a transition from the deep alkaline blue, through all the shades of violet to bright red with a strongly acid solution. Phenol phthalein was perfectly definite; take any oleic acid you liked, it was always sharp and there was not the slightest variation in the result. Another advantage was that with it a neutral solution was perfectly colourless, like water, but directly a minute quantity of acid was added it developed a strong magenta colour. Lastly, he did not claim that the oleate of soda made by this process possessed any peculiar properties, or was more definite than any other solution; he only put it forward as a convenient mode of manipulating the volumetric solution of oleate of soda, without having to go to the soap, which involved two processes, making the volumetric solution first with soap, and then regulating it.

The next paper read was—

NOTES ON BRAZILIAN DRUGS.

BY CHARLES SYMES.

The drugs which I desire to bring before the notice of this meeting are three in number, and, although practically unknown in this country, I trust they will not be found altogether devoid of interest. They have been received under the respective names of "Resin de Angico," "Almasça" and "Guassatunga." The two former are products of the district of Maranham in the north of Brazil (the locality from whence we obtain the finest copaiba balsam), the latter comes from the south and was obtained in the neighbourhood of Porto Alagre.

Resin de Angico.—This is not a resin but a gum, of a deep brownish-red colour, translucent, and breaking with a bright shining fracture. It occurs in pieces of from 1 to 3 ounces in weight, some of which have portions of bark attached to them. In the 'Formulario ou Gui Medica' of Chirnoviz, it is mentioned as the product of *Acacia Angico,* and is said to be good for chest complaints; the same tree yielding an astringent bark. Mr. Holmes has identified it with a specimen in the Museum of the Pharmaceutical Society, and has kindly furnished me with the small piece of bark which accompanies the specimen of gum. The pieces are very tough, but when broken up and dried at 212° for some hours it loses 12 per cent. of moisture and can then be readily reduced to fine powder. When added to twice its weight of water it forms a thick semisolid magma, and when this quantity of water is increased to eight times its weight, less than one-half dissolves, forming a reddish-brown mucilage with a slightly acid reaction; the remaining jelly-like mass becoming liquid on the addition of a little caustic alkali, thus resembling tragacanth more nearly than it does gum arabic. It dissolves in proof spirit almost as completely as it does in water. The aqueous solution is rendered turbid by the addition of rectified spirit in excess, also by solution of oxalate of ammonia; it is not affected, however, by solutions of perchloride of iron, borax or acetate of lead. As regards its medicinal properties the only remark which accompanied it was similar to that of Chirnoviz,—"usa-se nas molestias do peito," useful in chest complaints, which probably means that it is demulcent; but whether it possesses any special virtues in this respect, or whether it is in any way superior to the remedies of this kind already in use here, remains to be proved. A physician to one of the Liverpool hospitals has promised to determine this point.

Almasca.—This substance, received in sausage-shaped masses of about 12 inches in length and 2 to 3 inches in diameter and covered with dried leaves, is evidently a species of elemi, but it differs in appearance and in some of its characters from the elemi of commerce, from the Brazilian elemi of the Hanbury collection and also from that of Dr. Pereira at Bloomsbury Square. Except that it is more recent, and therefore much softer, it more nearly resembles the Brazilian elemi of Martin's collection, and Mr. Holmes is of opinion that it is produced by the same species, probably by *Icica heptophylla.* It comes from the same district as gum angico, but without any particulars of its use there. The term almasça indicates mastic, but from this it differs very materially. It is a soft grey looking resin, with whitish crystalline masses diffused more or less frequently through it, and possesses an aromatic, fragrant and somewhat penetrating odour. Chloroform, ether and absolute alcohol dissolve it without the application of heat; it also dissolves in boiling spirits of wine, specific gravity ·0838; but at ordinary temperatures this breaks it up into a thick milky looking liquid, dissolving only 65 per cent., the remaining portion corresponding in its various characters with the substance known as *amyrin.* This may be purified by solution in boiling rectified spirit, from which on cooling, it separates in white crystalline masses.

Flückiger and Hanbury examined Manila elemi and found it to contain 20 per cent. only of this substance. They also obtained by distillation as much as 10 per cent. of a volatile oil which, examined with Wild's polaristrobometer, was found to be strongly dextrogyrate; whilst a sample of oil of elemi examined by H. St.-Claire Deville was found to be strongly levogyrate. I have distilled a portion of this substance and have only obtained 7·3 per cent. of a colourless volatile oil, with an odour reminding one of fennel, and which corresponds with that of the 'Pharmacographia' in that it is soluble in bisulphide of carbon and gives a deep orange colour with strong sulphuric acid, but on careful examination I found it to be *optically inactive.*

Elemi is at present little used in medicine, but it seems to possess properties worth the attention of the medical profession and pharmacists.

Guassatunga.—On a recent vist to the south of Brazil, Mr. Joseph Hallewell found in use there a popular native remedy for snake-bite in the form of an alcoholic tincture of a golden yellow colour, put up in small bottles, with a label in Portuguese as follows:—"Para mordedeura de cobras e outros animaes veneno. Tomas-se uma gota em uma colher d'agua de 10 em 10 minutos de 2 ou de 4 em 4 horas conforme a gravidade de caso, nas criancas metade ou menos. Sobra as mordedura conserva-se panos embebidos em 4 colheres d'agua com 10 gotas." Thus in English,—"For the bites of snakes and other venomous reptiles. One drop to be taken in a spoonful of water every ten minutes for two or four hours according to the severity of the case, for children half or less. Mix 10 drops in 4 spoonfuls of water, in this soak a cloth and apply to the bite or wound."

Assuming this to be a remedy of some amount of activity, Mr. Hallewell procured a small quantity of casca de guassatunga, the bark from which this tincture is prepared. It is the produce of a tree inhabiting the borders of Uruguay and occurs in pieces of from 2 to 4 inches in length, from 1 to 2 inches in width and $\frac{1}{16}$ in thickness, hard and breaking with a short non-fibrous fracture. It is of a fawn colour with a greenish-brown tint diffused irregularly over it, paler on the outer than on the inner surface and possesses a slightly bitter taste.

Treated with ether it yields a bright green resinous substance; with alcohol a golden yellow tincture is obtained, and the marc infused in water yields a brown liquid which on evaporation produces a dark brown extract. Altogether this treatment removes 24 per cent. of its original weight. The tincture, treated with the usual reagents, gave characteristic indications of the presence of an alkaloid and I have, in fact, been able to separate a small quantity of such a body in a crystalline form but only sufficient for examination with the microscope. On the receipt of a further supply I hope by the aid of medical friends to determine more exactly its physiological action and also to make a further investigation of it chemically.

The President said it was obviously desirable in the interest of pharmacy that they should have early information respecting drugs likely to be imported, not merely such statements as could be obtained from price lists, but information concerning their chemical, physical, and botanical properties, such as Mr. Symes had given them in his paper and for which he was entitled to a vote of thanks.

A vote of thanks having been passed,

Mr. Atkins said he thought the line of procedure taken by Dr. Symes was well worth further consideration. If it was found that the natives of distant lands resorted to certain remedies, without any knowledge of the philosophy of their action, it was then very desirable to investigate the properties of those remedies scientifically. A large amount of work might have been already done, but it was in the rough and followed what might be called the rule of thumb. A short time ago he received from a friend, who had gone to the Congo, a plant which was said to have a very specific action as a styptic, and he intended to hand it over to another friend and have it examined. There was a goodly number of generally accepted remedies, which came to them originally only on report as being used for certain diseases by the natives of distant lands, and if the matter were pursued further the number might be considerably increased.

Mr. Groves asked if Dr. Symes had experimented with these drugs on any of the lower animals; but he presumed he would require a licence before operating even on a mouse. It appeared to him to be a great obstacle to science that a simple thing like this which Dr. Symes had been kind enough to bring forward could not be dilated on satisfactorily in consequence of the action of the anti-vivisectionists. A dose of this medicine could not be given to a mouse, although it might do the mouse good, in consequence of the existence of the Act of Parliament.

Mr. Groves, as senior Vice-President, then took the chair while the President read his paper entitled—

Half an Hour with a Few Sheets of the New Pharmacopœia of the United States of America.

BY PROFESSOR ATTFIELD, F.R.S.

In a letter, dated New York, August 4, 1882, sent to the writer, as President of the British Pharmaceutical Conference, by Professor P. W. Bedford, President of the American Pharmaceutical Association, the following paragraph occurs:—"I recently forwarded to you proof sheets from the corrected plates of the first ninety-six pages of the text of the forthcoming Pharmacopœia of the United States. I now have the pleasure of sending the succeeding forty-eight pages. These are all that are, as yet, in presentable condition. They will serve to show yourself and friends of the British Pharmaceutical Conference that it will be a work worthy of the labour bestowed upon it. It is the only copy that has gone outside our Committee."

By way of showing our honorary member our appreciation of his compliment, and in order to give British pharmacists some information respecting this new Pharmacopœia, the following descriptive remarks are offered.

In point of size of page this sixth decennial revision of the United States Pharmacopœia exceeds its predecessor. That was a foolscap octavo, this is a full octavo. The leading names of the preparations are given in larger, plainer, black letters, the names of the components of the formulas are also given in thick type, the quantity of each component now being printed not only in words, which, by the way, are in italics, but, in addition, in figures.

The former division into the two great classes of "Materia Medica" and "Preparations," the latter divided into over sixty sub-classes, is no longer maintained. The work is now, therefore, in uniformity with the one simple alphabetical arrangement of the British Pharmacopœia.

The Chemical Nomenclature.—Four or five years before the fifth decennial revision, that of 1870, was published, I very strongly advocated that system of chemical nomenclature under which names of salts of potash, soda, ammonia, baryta, lime, magnesia, etc., become names of salts of potassium, sodium, ammonium, barium, calcium, magnesium, etc. The system was adopted in the 1870 pharmacopœia (issued in 1872), "to place the work in accord with the progress of chemical science." In acknowledging my endeavours for its introduction, the President of the National Convention presented me with the first copy of the Pharmacopœia sent to this country. I may be pardoned for expressing my gratification at finding that the system is retained in this 1882 revision, showing that the nomenclature has been found to be practicable and serviceable in the medicine and pharmacy of a great English-speaking people.

Weights and Measures.—The Convention for the fifth revision (1870) resolved on the abandonment of measures of capacity, but the Revising Committee were alarmed at the amount of time, labour, and cost involved in the application of the resolution to the whole of the Pharmacopœia, and objected that the execution of such directions entailed the employment of an untried system. The old wine gallon and troy pound with their confusing divisions were, therefore, retained. These are now swept away, and "*parts*," by weight, substituted. Thus:—

Extractum Colocynthidis Compositum.

Compound Extract of Colocynth.

Extract of colocynth, *sixteen parts* . . .	16
Aloes, *fifty parts*	50
Cardamom, in No. 60 powder, *six parts* . .	6
Resin of scammony, in fine powder, *fourteen parts*	14
Soap, dried and in coarse powder, *fourteen parts*	14
Alcohol, *ten parts*	10

Then follow very full directions for preparation.

In cases in which some notice of volume as well as weight is required the metric decimal system is employed. Thus:—

Extractum Ergotæ Fluidum.

Fluid Extract of Ergot.

Ergot, recently ground and in No. 60 powder, *one hundred grammes*	100
Diluted hydrochloric acid, *six grammes* . .	6
Alcohol,	
Water, each, *a sufficient quantity*,	
To make one hundred cubic centimeters .	100

New Preparations.—The first seven pages of the Pharmacopœia (exclusive of prefatory matter, which has not yet come to hand) are almost wholly occupied with a new class of compounds termed Abstracts—Abstracts of aconite, belladonna, conium, digitalis, hyoscyamus, ignatia, jalap, nux vomica, podophyllum, senega, valerian. Thus:—

Abstractum Jalapæ.

Abstract of Jalap.

Jalap, in No. 40 powder, *two hundred parts* .	200
Sugar of milk, recently dried and in fine powder,	
Alcohol, each, *a sufficient quantity*,	
To make *one hundred parts*	100

Moisten the jalap with *one hundred* (100) *parts* of alcohol, and pack firmly in a cylindrical percolator; then add enough alcohol to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the jalap is exhausted. Reserve the first *one hundred and seventy* (170) *parts* of the percolate, distil off the alcohol from the remainder, and mix the residue with the reserved portion. Place the mixture in an evaporating dish, and, having added *fifty* (50) *parts* of sugar of milk, cover it with a piece of thin muslin gauze, and set aside in a warm place where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough sugar of milk to make the mixture weigh *one hundred* (100) *parts*, reduce it to a fine, uniform powder.

Preserve the preparation in a well-stopped bottle.

These "abstracts" are, in short, alcoholic extracts, or, in other words, the dried residue of evaporated tinctures, mixed with sugar of milk and rubbed to powder, and of such a strength that one part represents two parts of the original root, leaf, etc. The exhaustion of the aconite is aided by tartaric acid, the hemlock by hydrochloric acid. For the ignatia and nux vomica the alcohol (having a strength of 91 per cent. by weight) is slightly diluted. Otherwise the directions for their preparation, respectively, are almost identical.

Other additions, to go no farther than the letter A, are acidum boricum, acidum hydrobromicum dilutum, acidum oleicum, acidum salicylicum, æther aceticus, aluminii hydras, ammonii phosphas, amyl nitris, amylum iodatum, apomorphinæ hydrochloras, auri et sodii chloridum.

Aconitia is omitted, atropina retained. The root only of aconite is employed. Alcohol amylicum is omitted. Aloe Socotrina is the only variety recognized. Both varieties of aralia are dismissed. Acidum muriaticum has become acidum hydrochloricum, aqua chlorinii is now aqua chlori, sulphurets are now sulphides.

The doses of drugs were not given in 1870; they are not given in the present Pharmacopœia.

Temperatures are now stated in Centigrade degrees, with the Fahrenheit equivalents in brackets.

Characters, tests, and descriptions generally are given much more fully than before. No chemical symbols were given in the last edition; chemical formulæ, both on the old and new systems, are now given as in the British Pharmacopœia, and the molecular weight is appended to each formula.

Remedies which have come into use during the past decade find due place. Thus a cursory glance at these one hundred and forty-four pages reveal cinchonidine sulphate, codeine, one simple elixir—of orange,—eucalyptus leaves, fluid extract of guarana, extract of malt, fluid extract of pilocarpus.

Critical remarks would, at present, be out of place, but Professor Bedford's statement would seem to be thoroughly well founded, namely, that much labour has been worthily bestowed on this sixth decennial revision of the Pharmacopœia of the United States of America.

The CHAIRMAN said that the hearty thanks of the meeting were due to Professor Bedford for his considerate courtesy in forwarding an early copy of an interesting portion of the new United States Pharmacopœia. The members were also very grateful to Professor Attfield for his paper thereon, though, as he said, they must wait until the work was published in its complete form before criticizing it. Then an evening or two might very profitably be devoted to its discussion. At present he could only say that this new Pharmacopœia seemed to be distinctly in advance of its predecessor.

Professor REDWOOD said the general feeling must be one of gratitude to the President for bringing this subject under the notice of the Conference. As had been already said, this was not the occasion to enter on anything like a critical notice of even what had been thus briefly brought under their notice; when the work came into their hands it would be very greatly appreciated no doubt, especially as a movement was now being made towards the production of a new edition of the British Pharmacopœia, and the opportunity of observing the results of the investigations made on the other side of the Atlantic, and the conclusions arrived at by the able pharmacists there, would be very valuable to those whose duty it would be to prepare a similar work for use in this country. One remark of a general character he might make, viz., that in this country, and especially amongst those who at present had the legal authority to prepare and issue the Pharmacopœia—the Medical Council—there was a far greater amount of conservatism than existed on the other side of the Atlantic; and he had no reason to anticipate that in the new edition of the British Pharmacopœia changes so considerable as those which appeared in the new edition of the American work would be introduced. One principle acted upon in this country was that it was not justifiable to introduce into the Pharmacopœia new preparations which had not been proved in medical practice. Such preparations as "abstracts," to which Professor Attfield had alluded, were an entirely new class, and the principle which had been hitherto acted upon by the Medical Council was that any such preparations ought to come into general use before they were introduced into the Pharmacopœia. There were certain changes alluded to which had been previously adopted, and there were others which he had not the slightest doubt would be adopted in any subsequent edition, such, for instance, as the nomenclature, which he believed was entirely approved of by the Committee of the Medical Council who had charge of the matter. With regard to the weights and measures, that was a point with reference to which he had no doubt some change would be made, possibly in the direction indicated in the American edition, which he himself advocated some years ago, when he worked it out and submitted it to the Pharmaceutical Society, ordering parts by weight. Whether that would be the method adopted he could not anticipate, but it seemed to him under existing circumstances by far the most rational mode of treating the subject. The adoption of a new system of weights and measures, new to medical men in this country and to those pharmacists whose studies had not been in the scientific line, would lead to a great deal of opposition if attempted hastily. In the present edition of the Pharmacopœia metric weights and measures were recognized where they could be applied in processes of volumetric testing, but even the Americans had hesitated to adopt the system entirely. On the whole he should say the plan they had adopted of having parts by weight was the one which would be most likely to meet with general approval. He had only had a hasty glance at these sheets, and did not know that there was anything else he could add. He was quite sure that when the complete work came into their hands it would be very fairly and liberally examined and whatever was thought to be really beneficial, and not too much of the character of untried novelties, would receive full and fair consideration.

The Conference then adjourned until the following morning.

(*To be continued.*)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

PRESIDENTIAL ADDRESS TO THE CHEMICAL SECTION.

BY PROFESSOR G. D. LIVEING, M.A., F.R.S., F.C.S.

If I were asked in what direction chemical science had of late been making the most important advances, I should reply that it was in the attempt to place the dynamics of chemistry on a satisfactory basis, to render an account of the various phenomena of chemical action on the same mechanical principles as are acknowledged to be true in other branches of physics. I cannot say that chemistry can yet be reckoned amongst what are called the exact sciences, that the result of bringing together given matters under given circumstances can yet be deduced in more than a few special cases by mere mathematical processes from mechanical principles, but that some noteworthy advances have in recent years been made, which seem to bring such a solution of chemical problems more nearly within our reach.

To show how large a gap in our ideas of chemical dynamics has been bridged over within the last quarter of a century, I will quote the words of one of the largest minded philosophers of his time, who was one of the earliest promoters of this Association, and its President in 1841: Whewell, in a new and much altered edition of his 'Philosophy of the Inductive Sciences,' published in 1858, says:—"Since Newton's time the use of the word *attraction*, as expressing the cause of the union of the chemical elements of bodies, has been familiarly continued, and has no doubt been accompanied in the minds of many persons with an obscure notion that chemical attraction is in some way a kind of mechanical attraction of the particles of bodies. Yet the doctrine that *chemical* 'attraction' and *mechanical* attraction are forces of the same kind has never, so far as I am aware, been worked out into a system of chemical theory; nor even applied with any distinctness as an explanation of any particular chemical phenomena. Any such attempt, indeed, could only tend to bring more clearly into view the entire inadequacy of such a mode of explanation. For the leading phenomena of chemistry are all of such a nature, that no mechanical combination can serve to express them without an immense accumulation of additional hypotheses." ('History of Scientific Ideas,' ii., p. 13.) And further on he says:—"We must consider the power which produces chemical combination as a peculiar principle, a special relation of the elements not rightly expressed in mathematical terms." (*Ib.*, p. 14).

The influence by which our ideas have gone round so as to be now the very opposite of those of the illustrious thinker whom I have just quoted, so that we should ridicule the thought of looking for an explanation of chemical action on any but mechanical principles, is undoubtedly the progress which has been made in other branches of molecular physics. The indestructibility of matter has long been a formula familiar to chemists, but that the conservation of energy should be as universally true, even in regard to chemical actions, has only in recent years been fully recognized. This is certainly no new principle, it was developed mathematically generations ago; but the realization that it is anything more than an abstraction, that it is the keynote of every rational explanation of physical phenomena, has been the foundation of recent progress in physical science; and if all energy be one, there can be but one code of dynamical laws which must apply to chemistry as well as to all other branches of physics. The development of the mechanical theory of heat, and of the molecular theories which have grown up in consequence of it, have done much to set our minds free from preconceived notions, and to induce us to build chemical theories on something more than unverified conjectures.

But how far can we say that mechanical principles are actually recognized as the true basis of rational chemistry? So far as I know no chemist denies that it is so, and yet how little do our text-books, even the most recent and the most highly reputed, show the predominance of this idea! How very small a portion of such books is taken up with it, how much seems utterly to ignore it or to be couched in language antagonistic to it! We still find chemical combinations described as if they were statical phenomena, and expressions used which imply that two perfectly elastic bodies can, by their mutual action alone, bring each other into fixed relative positions. We still find change of valency described as a suppression of "bonds of affinity," as if a suppression of forces were the usual course of nature, or as if it were possible that the same two forces, acting at the same place and in the same direction, should at one time neutralize one another, and at another time not neutralize one another. We still find saturated compounds spoken of as if the stability of a compound were independent of circumstances, and chemical combination no function of temperature and pressure. Beginners are sometimes helped by the invention of intermediate reactions in explanation of final results, without any reference to the dynamical conditions of the problem, without any consideration whether the fancied intermediate reactions imply a winding-up or a running-down of energy. In fact our long familiar chemical equations represent only the conservation of matter, and to keep always in mind the mechanical conditions of a reaction is as difficult to some of us as it is to think in a foreign language. Moreover, we still find in many of our text-books the old statical notion of chemical combination stereotyped in pictures of molecules. I do not, of course, mean to accuse the distinguished inventors of graphic formulæ of meaning to depict molecules, for I believe that they would agree with me in thinking that these diagrams do not any more nearly represent actual molecules than they represent the solar system; but unfortunately we cannot prevent beginners from regarding them as pictures, and moulding their ideas upon them. They present something easily grasped by the infant mind, and schoolmasters are fond of them, but only those who have each year to combat a fresh crop of misconceptions, and false mechanical notions engendered by them, can be aware how much they hinder, I will not say the advance, but the spread of real chemical science. If it be true that the illustrations of an artist like the late Hablot Browne give to our conceptions of the characters of a story a more definite and permanent, though perhaps a much modified form of what the author of the story intended to portray, it is equally true that the illustrations by which some, even great names amongst us, have tried to make us fancy that we had a true conception of some natural process, have become so fixed in our minds as to prevent our realizing the true meaning of nature.

What, then, is the progress which I think has been made in physical chemistry? In the first place, notwithstanding the slowness with which new ideas replace old familiar images, the molecular theories developed by Clausius, Clerk-Maxwell, and Boltzmann, and by Sir W. Thomson, have been long enough before the world to have greatly loosened the hold upon our minds of many old notions. The rigid, unbreakable, impenetrable atoms of the Epicurean philosophy, made familiar to us by Lucretius, always presented difficulties which were only perhaps exceeded by those of the elastic atmospheres with which modern philosophers fancied them to be surrounded; but now the vortex theory, whether we think it probable or not, at least gives us a standing ground for the assertion that the supposed impenetrability of matter, and the curious compound of nucleus and atmosphere which had been invented to account for elasticity, are not necessary assumptions.

The kinetic theory of gases has analysed for us the different motions of the molecules in a mass of matter, and has facilitated the conception of the part which heat plays in chemical action. Hence we have had of late several attempts to reduce to a form susceptible of mathematical calculation the problems of chemistry. Most of these attempts have proceeded on the well-known mechanical principle that the change of *vis viva* of a system, in passing from an initial to a final configuration, is independent of the intermediate stages through which it may have passed, provided the external conditions are unaltered; and on the principle of the dissipation of energy, that is to say, on the condition that the state of the system, if it be a stable one, must be such that the energy run down in reaching it is a maximum. These principles have been applied successfully to the solution of some particular cases of the equilibrium between a mixture of chemicals by Willard Gibbs, Berthelot, and others. By the first mentioned principle all consideration of the intermediate stages by which the final result is reached is avoided. Quite recently Lemoinne has attacked the same problem on another principle. His principle is that of an equilibrium of antagonistic reactions in a mixture of materials, a mobile equilibrium, such as we are now familar with, dependent on compensating effects; but he does not seem able to solve the problem in any great number of cases. In fact, the difficulty does not now lie so much in expressing mathematically the conditions of the problem, as in the defect of knowledge which depends upon experiment. And it is just in this that I think the outlook most hopeful. In some cases the patient work of weighing, measuring, and comparing, which is necessary to make our theoretic speculations of any substantial value, has been already done for us. The publication, three years since, of Berthelot's 'Essay on Chemical Mechanics,' has given us, in a collected form, a large quantity of data of the first importance, and now I am glad to say that the long labours of another worker in the same field, Thomsen of Copenhagen, are in course of publication in a handy form. I think these two investigators have done more than anyone else of late years towards making it possible to give chemistry the rank of an exact science. But besides the data which they have supplied to us, there are others which are yet wanting. For instance, almost every equation of chemical equilibrium involves an expression depending on the specific heat of the materials. At present we do not know enough of the law of specific heats to be able to give in most cases a probable value to these expressions, but these and other data of the kind do not seem out of our reach, and we may hope that the same ingenuity and patience which has gained for us so much firm ground in thermal chemistry will extend it to the uncertain spots where we have yet no solid foundation.

Further, the laws of dissociation, so ably investigated by Deville, have taught us that the force called chemical affinity, by which we suppose the atoms of unlike matters are held together in a compound molecule, follows precisely the same laws of the force as cohesion by which particles of a similar kind are united in molecules. We have long known that the molecules of sulphur vapour are broken up into simpler molecules by elevation of temperature and condense again when the temperature is reduced. Other elementary substances behave in a similar way. We have within the last two or three years learnt that iodine is in part dissociated by a high temperature from molecules consisting of two chemical atoms into molecules consisting of only one such atom, and the same is true of chlorine and bromine. That some such change must occur in iodine was inferred as long ago as 1864 by the younger Mitscherlich. He argued that iodine is a compound body from the fact that it shows two spectra, one similar in character to those of metallic oxides and the other similar to the spectra of metals, and from the analogy in the behaviour of iodine to a metallic oxide in giving the one spectrum at one temperature and the other at a higher temperature: "from this," he says, "it would follow that iodine at ordinary temperatures and iodine at the temperature of a hydrogen flame must be considered as two different compounds, because the spectrum of iodine formed at ordinary temperatures" (that is, the absorption spectrum of iodine vapour) "is different from that produced in a hydrogen flame." Also "that bromine, though it gives no flame spectrum, gives one spectrum by absorption and another by the electric spark, and must therefore in its ordinary state be regarded as a compound." Also that "the spectra formed by the flames of selenium, tellurium, and phosphorus, and those of sulphur and nitrogen given by feeble electric discharges, all have the character of the iodine flame spectrum, and these metalloids would therefore, if the above expressed supposition with regard to iodine be confirmed, also be compound bodies." (*Phil. Mag.*, 1864, p. 188.) Since the paper from which the foregoing extract is taken was published, not only the metalloids but many metals have been found to give complicated spectra at one temperature and much simpler spectra at higher temperatures. Such are the channelled spectra of sodium and potassium, first described by Roscoe and Schuster, the channelled spectra of silver, bismuth, and other metals described by Lockyer and Roberts, and the ultra-violet channelled spectrum of tin recently photographed by Dewar and myself. Mitscherlich's hypothesis gives us a rational explanation of such multiple spectra produced by the same substance, and it has been accepted, in one form or another, by all spectroscopists since he wrote. Nevertheless, the existence of multiple spectra cannot be taken as a proof of allotropic modification unless the possibility of a chemical combination be excluded. The channelled spectrum which magnesium gives in hydrogen was mistaken by more than one observer for that of some modification of the simple metal, until it was shown that magnesium in nitrogen or other gases does not give it if no hydrogen is present, and that its persistence in hydrogen at high temperatures depends, as does the permanence of chemical combinations, on the pressure of the gas. If, however, homogeneous molecules are dissociated by heat, so also are heterogeneous molecules, formed, as we say by chemical combination, split up by elevation of temperature, to unite again on cooling, or when the pressure is increased within certain limits. Nor is there any essential difference in character between a chemical compound and an element, beyond that of facility of decomposition. If we could not so easily resolve them into their constituents, and were to disregard the difference of their spectra, no one would suppose ammonia to be differently constituted from potassium, or cyanogen from chlorine. Indeed, chemists have long been in the habit of considering the union of two atoms in a molecule of ordinary hydrogen or chlorine as a species of chemical combination; but when we find that the combinations of particles of the same kind are as definite as those of particles of different kinds, and that they are both subject to precisely the same mechanical laws, we are hardly justified in regarding the forces by which they are produced as essentially different. To get rid of a gratuitous hypothesis in chemistry must be a great gain.

But it may be asked, Why stop here? Why may not the chemical elements be further broken up by still higher temperatures? *A priori* and from analogy such a supposition is extremely probable. The notion that there is but one elementary kind of matter is at least as old as Thales, and underlies Prout's hypothesis that the atomic weights of our elements are all multiples of that of hydrogen. This famous hypothesis has gone up and down in the scale of credibility many times during the present century. About seventeen years ago the publication of Stas' new determinations of combining weights, carried out on a scale never before attempted, and with all the refinements which the growth of our knowledge could suggest, was thought to have given it its deathblow. But a reaction has set in since that time. The periodic recurrence of the properties of elements with regular additions to the atomic weights, like octaves in a musical scale, put forcibly before us by Mendelejeff, makes it difficult not to think that there is a simple relation between the atomic weights, though there may be causes producing slight perturbations of such a relation. Quite recently a fresh revision of the combining weights has been made, on the other side of the Atlantic, by Professor F. W. Clarke. He has collected all the determinations made by different observers, and after rejecting such as from defective methods were untrustworthy, has applied to the remainder such corrections as newer experiences have suggested, and then deduced from the corrected numbers the most probable values by the methods of the theory of errors. Professor Clarke has done a piece of work of the highest utility, for which chemists must be grateful; nevertheless, he has not carried the revision so far as it might be carried. He has, to begin with, rightly separated the several sets of observations, and deduced the most probable number from each set by itself, but in combining the various sets for the final determination of the numbers adopted, he has treated the results obtained by different methods, as if they were a set of observations all presumably of equal value, so that the most probable numbers could be deduced by the method of least squares. He has not attempted any discussion of the different methods with a view to an estimate of the relative values of the results obtained by them, nor made any difference between the values of the figures deduced from operations on the large scale employed by Stas and those arrived at on the small scale of other observers. Any sort of handicapping of methods is no doubt a very difficult and delicate operation, and requires more than the judgment of an Admiral Rous, but without it the question whether the numbers adopted are the best obtainable will always be an open one. It is, however, a very noteworthy fact, that in almost every case the numbers deduced from Stas' experiments, taken by themselves, coincide very closely indeed with the most probable numbers derived by the method of least squares from the whole of the recorded estimates. On the whole, Professor Clarke concludes that Prout's hypothesis, as modified by Dumas, is still an open question, that is to say, his final numbers differ from whole multiples of a common unit by quantities which lie within the limits of errors of observation and experiment.

Let us turn again to the evidence afforded by our most powerful instrument for inspecting the inner constitution of matter, the spectroscope. A few years ago Mr. Lockyer supposed that the coincidence of rays emitted by different chemical elements, particularly when those rays were developed in the spark of a powerful induction coil and in the high temperatures of the sun and stars, gave evidence of a common element in the composition in the metals which produced the coincident rays. Such an argument could not be drawn from the coincidences unless they were exact, and the identity of the lines could only be tested by means of spectroscopes of great resolving power. By the use of the well-known Rutherford gratings, Young, in America, had found that most of the solar lines which had been ascribed to two metals were in reality double, and Dewar and I, working on the terrestrial elements in the electric arc, had found the actual coincidences to be very few indeed. These observations, even with Rutherford gratings, were delicate enough; but quite recently M. Fievez, of the Brussels Observatory, has brought to bear on this question, a spectroscope of unexampled power. By combining two of the Astronomer Royal's highly dispersive half prisms with a Rutherford grating of 17,296 lines to the inch, he has obtained a dispersion quadruple that of Thollon's combination of prisms. Bringing this to bear on the sun he has mapped the solar spectrum from a little below C. to somewhere above F., on a scale one-third greater than that of Vogel's map, and has not only confirmed the work of Young, Dewar, and myself, but has resolved some lines which were not divisible by such dispersive power as we had at command. This result cannot fail to shake our belief, if we have any, in the existence of any common constituent of the chemical elements; but it does not touch the evidence which the spectroscope affords us, that many of our elements, in the state in which we know them, must have a very complex molecular structure. I cannot illustrate this point better than by the spectra of two of our commonest elements, magnesium and iron. We have good reason to think the molecule of magnesium to be as simple as that of any chemical element, and we find its spectrum to be one of the simplest, consisting of a series of triplets which repeat each other in a regular way and are probably harmonically related, and of a comparatively small number of single lines, of which also some may be harmonics. The spectrum of iron, on the other hand, presents thousands of lines distributed irregularly through the whole length, not only of the visible, but of the ultra-violet region. Make what allowance you please for unknown harmonic relations and for lines which are not reversible and may not be directly due to vibrations of the molecules, we still have an immense number of vibrations, so that we can hardly conceive any single molecule to be capable of all of them, and are almost driven to ascribe them to a mixture of differing molecules, though we have as yet no independent evidence of this, and no satisfactory proof that any of this mixture are of the same kind as occur in other elements.

M. Fievez's combination is a great advance in resolving power, but Professor Rowland, of the John Hopkins University, promises us gratings not only exceeding Rutherford's both in dimensions and accuracy of ruling, but ruled upon curved surfaces, so as to dispense with the use of telescopes and avoid all variations in focussing the different orders of spectra. His instruments, if they come up to the promise he holds out, will enable us to solve many questions which are difficult to answer with our present appliances.

But to return to the chemical elements: the spectroscope has in the last few years revealed to us several new metals. I will not venture to say how many, for when several new metals more or less closely allied are discovered at the same time, the process of sifting out their differences is necessarily a slow one. We cannot tell yet whether any of them are to fill gaps in Mendelejeff's table, and so add strength to the conviction that there is a natural relation between the atomic weights and the chemical characters of our elementary substances, or whether they will add to the embarrassment in which we already find ourselves with regard to the relations of the cerium group of metals; whether we may welcome them as the supporters of order or deprecate their coming as authors of confusion. Granting that the chemical characters of an element are connected with its atomic weight, we have, however, no right to assume them to be dependent on that factor alone. Why may there not be elements which, while they differ as little in atomic weight as do nickel and cobalt, are, on the other hand, so similar to one another in all characters that their chemical separation is a matter of the greatest difficulty, and their difference only distinguishable by the spectroscope? The spectra may be thought to suggest so much, and how shall we decide the question? At any rate the complications of the spectroscopic problem can only be unravelled by the united efforts of the chemists and physicists, and by the exercise of extreme caution.

I cannot dismiss the subject of chemical dynamics without alluding to the ingenious theory by which the President of the Association has proposed to account for the conservation of solar energy. He supposes planetary space to be pervaded by an atmosphere which, except where it is condensed by the attraction of the sun and planets, is in a highly attenuated state. The sun and planets communicate some of their own motion of rotation to the atmosphere condensed about them, and he supposes that in this way an action like that of a blowing fan is set up, by which the equatorial part of the sun's atmosphere acquires such a velocity as to stream out to distances beyond the earth's orbit, while an equal quantity of gas is drawn in at the poles to maintain equilibrium. The gases thus driven to a distance in planetary space will, of course, be enormously expanded and highly attenuated, and in this state Dr. Siemens thinks that such of them as are compound may be decomposed by absorbing the solar radiation, and thus the kinetic energy of the sun's rays be converted into the potential energy of chemical separation. The separated elements, or partial compounds, will in the circulation produced by the fanlike action of the solar rotation be carried back to the polar regions of the sun as fuel to maintain his temperature by condensation and recombination. I will not discuss the mechanical part of this theory further than to remark that the fanlike action can only be carried on at the expense of the energy of the sun's rotation, which must, in consequence, be continually diminishing, and must in time become too slow to produce any sensible projection of the atmosphere into distant regions of planetary space. As to the chemical side of the theory, Dr. Siemens supposes the gases which pervade the planetary space to be not only of the same kind as the components of our own atmosphere, which on the kinetic theory of gases must diffuse through that space, but also such gases as are not found in our air, but are found occluded in meteorites which may be supposed to have acquired them in their previous wanderings. Amongst these he specially mentions hydrocarbons which form the self-luminous part of most comets. It is to these gases, together with aqueous vapour and carbonic acid, that he ascribes the principal part in the conservation of solar energy. That compound gases at the extremely low pressure of the planetary space are decomposed by solar radiation is not inconsistent with the laws of dissociation, for it is quite possible that some compounds may be decomposed at ordinary temperatures by mere reduction of pressure, and the radiation absorbed will be the more effective because it will directly affect the vibratory motion within the molecule, and may well produce chemical decomposition before it can, when the free path of the molecules is so much increased by the attenuation of the gas, assume the form of an increased temperature. Dr. Siemens, moreover, adduces a remarkable experiment in confirmation of this supposition. We know, too, the power which our atmosphere, and especially the water vapour in it, has of absorbing the infra-red rays, and that amongst the Fraunhofer lines some of the strongest groups are due to aqueous vapour; and the capital observation made by the spectroscopic observers at the last total eclipse, that the group of lines known as "B," which is one of those produced by aqueous vapour, is greatly strengthened when the sun's light passes by the edge of the moon and so through the lunar atmosphere, may be taken as a confirmation of the theory that gases like our atmosphere are diffused through space and concentrated about the planets. But if it be true that the compounds are decomposed by absorbing the sun's rays, we ought to find in our atmosphere the products of decomposition; we ought to find in it free hydrogen, carbonic oxide, and acetylene or some other hydrocarbons. The hydrogen, from its small specific gravity, would not be concentrated in the lower regions of our atmosphere in the same proportions as the denser gases, but carbonic oxide and hydrocarbons could not fail to be detected in the air if they formed any sensible proportion of the gases in the planetary space. That a large portion of solar radiation is intercepted before it reaches the earth is no doubt true, for there are not only the dark bands which are increased by our atmosphere and may reasonably be attributed to the action of like gases pervading planetary space, but there is a continuous absorption of the ultraviolet spectrum beyond the line U, and Cornu has found that this absorption is not sensibly affected by our atmosphere so that the substance, whatever it be that produces it, may be an agent in the process imagined by Dr. Siemens, but cannot be the means of restoring to the sun any portion of his radiant energy which reaches our distance from him.

Dr. Siemens explains the self-luminous character of comets by the theory that the streams of meteoric stones of which they are supposed to consist bring from stellar space hydrocarbon and other gases occluded within them, and that in consequence of the rise of temperature due to the frictional resistance of such a divided mass moving with enormous velocity, aided by attractive condensation, the occluded gases will be driven out and burnt, the flame giving rise to the original light emitted by the nucleus. Now the spectrum of most comets shows only the principal bands of a Bunsen burner, and is therefore adequately explained by the flame of gas containing hydrocarbons such as have been found in meteorites; but Dr. Huggins has observed in the spectrum of more than one comet, not only hydrocarbon, but cyanogen bands; and, although carbon and nitrogen combine readily in the electric arc, a coal-gas flame in air shows no trace of the spectrum of cyanogen, and it would certainly put some strain on our credulity if it were asserted that cyanogen was one of the gases brought ready-formed by meteorites from stellar space. Dewar and I have, however, recently shown that if nitrogen already in combination, as, for instance, ammonia, be brought into a hydrocarbon flame, cyanogen is produced in sufficient amount to give in a photograph (though not so as to be directly visible) the characteristic spectrum of cyanogen as it appears in the comet. It is therefore no longer necessary to make any other supposition to account for the cyanogen bands in the spectra of comets, than that ammonia, or some such compound of nitrogen, is present as well as hydrocarbons in a state of ignition.

Quite recently Dr. Huggins has observed that the principal comet of this year has a spectrum of an entirely different character, but he is not yet able to say to what elements or compounds it is probably due. The notion that comets may bring us news of distant parts of stellar space, towards which our system is driving, where the atmosphere is not like ours—oxygen and nitrogen—but hydrogen and hydrocarbons, may fascinate the fancy, but the laws of occlusion oblige us to think that the meteorites have not merely wandered through an attenuated atmosphere of hydrogen and hydrocarbons, but have cooled in a much denser atmosphere of those substances, which we can only conceive as concentrated by the presence of a star or some large aggregation of matter. They may, perchance, have come from some nebulous mass, for Draper and Huggins tell us that in the great nebula in Orion hydrogen is dense enough and hot enough to show some of its characteristic lines, besides the F line which is seen in other nebulæ, and is the last to disappear by reduction of density, No comet on visiting our system a second time can repeat the exclusion of its occluded gases unless its store has been replenished in the interval, and it will be interesting to see, when Halley's comet next returns, whether it shines only by reflected light or gives us, like so many others, the banded spectrum of hydrocarbons.

Parliamentary and Law Proceedings.

Poisoning by Laudanum.

An inquest was held by Mr. Barstow, at the Prince of Wales Hotel, Halifax, on John Bates, aged fifty-six, who died on Sunday noon from an overdose of laudanum, It appeared the man had suffered much from sleeplessness, and on Saturday he went to Mr. Bancroft, chemist. Barum Top, and asked for two ounces of laudanum. Mr. Bancroft questioned him why he wanted so large a quantity, and he replied that it was to mix with some other things for a cough. Mr. Bancroft cautioned him about the use of it, telling him what was the dose for a cough. The man retired to bed early, and, his family being unaware that he had bought the laudanum, let him lie in bed until well into Sunday forenoon before going to see him. He was then found unconscious and breathing heavily. Mr. Gascoigne, surgeon, was fetched, and he, suspecting narcotic poisoning, searched the room, and found a bottle containing about half an ounce of laudanum wrapped in a newspaper and hid among some dresses in a drawer.

A verdict was returned of "Death from an overdose of laudanum, but whether taken to procure sleep or to destroy life there was no evidence to show."—*Leeds Mercury.*

Alleged Death from Lead Poisoning.

An inquest was held on August 29, at the Keighley Cottage Hospital, before Mr. T. P. Brown, touching the death of William Wilson Riley, forty-two, who, it was alleged, had died from lead poisoning. Mr. George Burr, Clerk to the Local Board, watched the case on behalf of that body. There were several members of the board also present.

Sarah Riley, the widow, deposed that her husband died on Saturday, the 26th inst., after being confined to his bed for a short time. He had had pretty good health, except being troubled with sick headache. He was in the Kildwich railway accident, about seven years ago, which made him rather nervous, and he had never seemed to recover from it. Her husband suffered from lead poisoning about two years ago, and she herself had had an attack of it.

Dr. William Dobie deposed to having twice seen deceased during his late illness, and found him to be suffering from symptoms of lead poisoning. He had made a *post-mortem* examination, in the presence of Dr. Eddison, Leeds, Dr. Jack and Messrs. Chaffers, Holman and Roberts, of Keighley. There were no marks of external injury, and the body showed the usual marks apparent after death. There was no dropsy. The body was wasted, but not extremely so. The left wrist presented an appearance of what is known as a "dropped" wrist. The brain was a little paler than usual, but otherwise healthy. The lungs were quite healthy, though there was an old standing of pleura covering them. The bag of the heart was quite natural; the heart somewhat enlarged. The stomach was natural. The appearances of death were not inconsistent with death from lead poisoning. The "dropped" wrist and the constricted condition of the large bowel especially pointed in that direction, but he would not dogmatically like to say that that was the cause of death. The proof would not be complete until a chemical analysis was made of the viscera.

In reply to the Foreman, witness said he did not find sufficient disease to cause death except from lead poisoning. Deceased visited him about two years ago, and then he was suffering for lead poisoning, At that time he advised him to discontinue using the water.

A Juror asked if he had come across many cases of lead poisoning.

Witness said he had reported sixty-four cases to the Local Board twelve months ago

By Mr. Burr: Those cases extended over several years.

By the Foreman: The lead was dissolved from the pipes by the action of the water. It was his opinion but for lead poisoning the deceased would have lived an average life.

By Mr. Burr: If the deceased's symptoms had not been known to him he should have inferred after he had made the *post-mortem* examination that lead poisoning had been the cause of death. He was not aware that deceased had been in the Kildwick railway accident.

The Coroner: We want three things before this inquest can be concluded. The viscera will have to be analysed, and samples of water must be taken from the tap in deceased's house and another out of the main before it entered the service-pipe to his house.

The inquest was adjourned for a month to allow the Coroner's instructions to be carried out.—*Leeds Mercury.*

Obituary.

ROBERT HOWDEN.

We have to announce with deep regret the death of this well-known pharmacist. He expired at 78, Gracechurch Street, City, just before midnight, on Thursday, August 31. Up to the commencement of his illness, only a week before, he was engaged in the full activities of business, when he was seized with an acute form of inflammation, from which he never rallied.

Mr. Howden was born in the City of London, January 18, 1822, and left school when fourteen years old, from which time, as far as general education was concerned, he was self-taught. His first regular employment was in some chemical works connected with a gas company, and the ability he there displayed led to the idea of his entering upon the medical profession, as a surgeon. Surgery, however, was abandoned for pharmacy, and about the age of nineteen he went to Mr. Henry Lamplough, then at Islington, since more widely known as the inventor of the Pyretic Saline. It was to improve his practical knowledge, rather than to pass through an apprenticeship, that the duties of the place were undertaken.

Subsequently he became an assistant to Mr. William Hooper, of Russell Street, Covent Garden. From thence he went to Mr. Winstanley (now Messrs. Corbyn), in the Poultry; learned practical chemistry in the laboratory, and in his lesiure hours became an adept in water-colour painting. Afterwards he became an assistant to Mr. Bartlett Hooper, of London Bridge. Thus he acquired a thorough insight into business details and was prepared to commence upon his own account with every prospect of success which personal experience could bestow.

In the spring of 1859 Mr. Howden established himself in Gracechurch Street, having chosen a centre of operation which was particularly adapted to his characteristic energy. It was an old establishment, in a decayed condition whether regarded as premises or connection. Mr. Howden boldly ventured on a somewhat hazardous undertaking; for the existing state of things was neither promising, nor free from grave anxiety. The business was at a low ebb: and the rent out of proportion to the receipts. From the first year affairs began to brighten, and at the expiration of five years the returns were doubled. These details are mentioned because they may interest others engaged in similar pursuits, and may prove an encouragement to those who are exposed to the struggles incident to commercial life.

As soon as Mr. Howden had gained an assured position he devoted himself with ardour to parochial and educational interests. He became overseer of the parish, and churchwarden of All Hallows, Lombard Street, and busied himself with church improvements and Christmas decorations.

Nothing could exceed the interest he took in the prosperity and internal organization of the Bishopsgate Ward Schools. He was one of the examining board, and ably seconded the efforts of the Rev. William Rogers, in whose parish the schools were situated. It was in a great measure owing to his personal energy and active interference that these schools were placed upon their present satisfactory basis.

Charitable institutions, connected with education, had for him a special attraction, and thus his voluntary labours were increased by his constant attention to the concerns of the Merchant Seamen's Orphan Asylum, at Snaresbrook, Essex. For the sake of the children, he arranged and conducted holiday excursions, and was one of their frequent lecturers. Amongst these discourses, which were illustrated by enlarged drawings executed by himself, those on Bread, Milk and its Preparations, Flashing Signals, as used in Military Service, and Paper, were keenly appreciated by his young audience.

To the literature of pharmacy Mr. Howden's chief contributions were two papers, one on "Cod Liver Oil," descriptive of its preparation at Lofoden, with commercial details; and a second on the "Pharmacy of the United States." His second communication to the members of our Society was a *résumé* of his own observations in America. To his not abundant literary work must be added a letter in the *Times* paper, commenting on the state of the pollution of the Thames. In this notice he attributed the loss of many of the ill-fated passengers in the *Princess Alice* to death by asphyxia, rather than to death by drowning.

Mr. Howden took no prominent part in the politics of the Pharmaceutical Society, and he steadily refused to aspire to a seat in council. In 1844 he obtained first class certificates in chemistry and botany; and became a member and pharmaceutical chemist in 1859. His reason for not accepting office was, that he held no one should enjoy the honour who was not prepared to give full time to the duties consequent on the position.

It will be conceded that he left himself scanty leisure, and that little was absorbed by a formidable array of responsibilities as executor and trustee, undertaken on behalf of friends who had implicit confidence in his financial skill.

Mr. Howden cultivated as an art the gift of conversation, and made it bear as much on business as on domestic intercourse. This, while it rendered him delightful as a companion, distinctly contributed to his advantage in business.

He died aged sixty, leaving a large circle to lament his loss. It would be difficult to find a more active man; a kinder or more unselfish one, would be impossible.

Correspondence.

Genealogical.

Sir,—The "Friends" are a long-suffering class, who do not need defence, but in justice to Mr. Hart's "Historic Quaker" it may be noted that he did not originate the principles which Mr. Hart most justly censures. As schoolboys we all made the acquaintance of his progenitors in Horace's first epistle—

"O cives, cives, quærenda pecunia primum est;
Virtus post nummos."

And again,—

"Rem,
Si possis recte, si non quocunque modo rem."

The curious may trace their genealogy still further back. Would that they could only be found in the "hoary chronicles" of the past.

Ryde. Henry H. Pollard.

Communications, Letters, etc., have been received from Messrs. Brown, Crompton, Woodland, Powell, Attfield, Hooper, Branson, Rowell, Schmidt, Robinson, Shenstone, Baker, Ignoramus, Ariovistus, Antiseptic, Jacque, Ferri, T. E. R., H.

THE INTERNATIONAL ELECTRIC EXHIBITION.

(*Continued from page* 143.)

The last economic application of electricity for obtaining light it is intended to notice in these articles is the "secondary or storage battery." The introduction of this electrical apparatus into the electric lighting industry will, without doubt, be found sooner or later of the utmost consequence in providing a steady flow of electricity in the electrical mains that are to be laid in a short time in the streets of the metropolis and in those of numerous provincial towns. The discovery of the phenomena utilized in the storage battery appears to have been made in 1801, by Gautherot, who observed that the platinum wire electrodes that had been used in the electrolysis of salt water were capable of yielding a transient electrical current after being detached completely from the battery. This discovery, made a year after Nicholson and Carlisle's fruitful announcement of the electrolytic decomposition of water, is the foundation of the modern storage battery or accumulator. It clearly explained the cause of the diminishing electromotive force of a voltaic battery when working on short circuit, as it was recognized almost at once that this momentary secondary current was opposite in direction to the primary current. In the first voltaic cells made, this opposing electromotive force was found to be an evil of such magnitude as to reduce the electromotive force of the battery, after a few minutes' continuous working, by one-half the original sum. This opposing electromotive force was denominated polarization of the plates, and constant attempts were made to make up a cell which should be free from this grave inconvenience. Apparently the first to design a practically perfect "constant" battery was Professor Daniel, of King's College, whose world-renowned combination has never been surpassed for producing constant electromotive force on short circuit.

This evil of former times has of late given promise of being of almost as much importance to electricians as the generator of the primary current itself. Without dwelling further upon the historical part of this subject it may be assumed that all the recent experimenters are working on the lines laid down in the first instance by M. Gaston Planté in 1869. To that experimenter more than to any other is due the progress that has been made in this direction. M. Planté devoted some twenty years to the elucidation of polarization, employing different metals as electrodes and different liquids as electrolytes. As a result of his continued researches he ascertained "that the greatest effective polarization was produced when dilute sulphuric acid was electrolysed between electrodes of lead." The form of cell preferred by Planté is circular and contains two spirally rolled sheets of lead rendered mechanically discontinuous by interposed strips of guttapercha; the two plates are covered with dilute sulphuric acid. The method of forming the cell by the passage of a current through it must be conducted in a peculiar way, minutely detailed by Planté; and the process unfortunately requires a considerable time before the cell gets in the best possible condition. The process is given in full in Gordon's 'Treatise on Electricity and Magnetism,' and also by Mr. J. W. Swan in a lecture which will be found in vol. v., p. 122, of the *Transactions of the Newcastle-upon-Tyne Chemical Society*.

On passing a current through the dilute sulphuric acid and lead plates of the Planté cell the plate by which the current enters becomes coated with peroxide of lead and the plate by which the current leaves the cell becomes covered with spongy metallic lead occluding large quantities of hydrogen gas. When these plates are united by a wire a secondary current starts from the peroxide plate and passes through the wire to the plate covered with spongy lead. It is almost sufficiently accurate to regard the cell as a voltameter with oxidizable electrodes, or as a voltameter in which the products of the electrolysis of dilute sulphuric acid are collected in the solid form; hydrogen being occluded by spongy lead, and oxygen combined with lead as peroxide. On discharging the cell the hydrogen and oxygen recombine to form water, or in other words the peroxide of lead disappears and the cell practically again becomes two simple lead plates in dilute acid.

As the elements recombine electricity is produced, the amount of current yielded being mainly dependent on the amount of peroxide of lead reduced. Hence it follows that a secondary battery does not store electricity in the same manner that the Leyden jar stores a charge of static electricity, or as a gas-holder stores gas; the storage or secondary battery stores electrical energy in a somewhat analogous manner to that in which coal stores heat energy, that is to say, certain substances are present in suitable conditions for producing electricity in one case and heat in the other.

The electromotive force of a Planté cell is as much as 2·38 or 2·7 volts when fully formed, and "as the large area and close proximity of the plates diminishes the resistance of the liquid to a very small quantity, such cells are capable of furnishing a very powerful current for a few minutes, and their calorific power is considerable. M. Planté shows that there is a loss of 11 or 12 per cent. between charging and discharging, and that of the whole current absorbed by the cell 88 to 89 per cent. is given back by the cell. According to M. Géraldy, a Planté cell containing 1·445 kilogramme of lead can store 4·983 kilogrammetres of energy, being at the rate of 3·45 kilogrammetres per kilogramme, or 11·329 foot pounds per pound."

Messrs. Gladstone and Tribe have contributed some valuable papers to *Nature* (vol. xxv., pp. 221 and 461, also in vol. xxvi., p. 251), on the "Chemistry of the Planté and Faure Accumulators," which form the best addition to our knowledge of the matter that has been written. The authors took up the inquiry in the first instance in order to ascertain if any resemblance existed between the "copper-zinc couple" discovered by them and the negative plate of the Planté and Faure accumulators. The copper-zinc couple owes its activity to what is well known to electricians as "local action," this name being given to the chemical action resulting in the development of electricity which occurs when a circuit of two mechanically adherent different metals is placed in a solution having a chemical action on the one and less or none on the other. In the copper-zinc couple of Gladstone and Tribe sheet zinc receives a coating of finely divided metallic copper by immersion in a weak solution of sulphate of copper. On placing this couple in water, bubbles of hydrogen gas are given off, and oxide of zinc is formed and remains in the liquid as such. This method of obtaining nascent hydrogen in a neutral liquid has been found of great service in analytical chemistry, and in the hands of its discoverers has been very effective in the formation of certain difficultly prepared organic compounds. From these results with the copper-zinc couple it appeared nearly certain to Messrs. Gladstone and Tribe that the formed negative plate of the Planté accumulator, consisting of metallic lead and very closely adherent peroxide of lead immersed in dilute sulphuric acid, must give a large amount of local action, especially as the electromotive force of lead and peroxide of lead in dilute sulphuric acid is three times as much as it is with zinc and copper in the same liquid. As expected, a continual local action was found to take place, resulting in the attached peroxide of lead being completely converted into white sulphate of lead. This apparently wasteful action was found to be absolutely necessary for future practical storage purposes in this way: the sulphate of lead formed all suffers decomposition when the cell is charged next time into finely divided metallic lead; this finely divided lead becomes ultimately converted into peroxide of lead, and thus the storage capacity of the cell increases with each recharging. The authors found quantitatively that the amount of peroxide of lead formed increased at every charge up to at least the fifth time of recharging, beyond which the experiment does not appear to have been carried. Messrs. Gladstone and Tribe think it is more in accordance with the observed facts to regard the electrolysis in the cell as being the electrolysis of sulphuric acid rather than that of water rendered conducting by admixture of acid. They state that if water alone is used in the cell the hydrated protoxide of lead is formed instead of the peroxide, even if twenty-four Grove's cells are employed to charge one Planté cell; but the addition of a single drop of sulphuric acid to the water causes the immediate production of the puce-coloured peroxide to be made manifest. The authors give some ingenious and probable chemical equations for representing the chemistry of the charging of the cell. The first of the equations shows the formation of peroxide of lead by the electrolytic decomposition of sulphuric acid; the second equation takes account of the formation of peroxide of lead from the decomposition of previously formed sulphate of lead. These distinguished investigators think that it is not improbable that both these reactions may take place according to the varying density, or other circumstances of the current. They also say that the coating of peroxide interposes a great difficulty in the way of the further oxidation of the metallic lead, and that hence Planté needs the successive periods of repose, to admit by local action of the formation of lead sulphate, and the oxidation of the increasing amounts of finely divided lead. To save this waste of power and time Faure covers both plates with red lead, and converts this into spongy peroxide and spongy lead respectively by the current. When minium is placed in dilute sulphuric acid it suffers decomposition in the following manner:—

$$Pb_3O_4 + 2H_2SO_4 = PbO_2 + 2PbSO_4 + 2H_2O.$$

It was found that 18·1 per cent. of the red lead was converted into lead sulphate after one hundred and twenty minutes. The authors, in commenting on this, show how all the sulphuric acid might be taken up if this point were neglected, leaving in such an event water only in the cells. Serious injury might be done to cells if this should take place, as a phenomenon might occur like that noticed by the authors when studying the phenomena accompanying the electrolysis of water with oxidizable electrodes. In this investigation oxide of lead was found to form, which eventually became converted into grey metallic lead, and this, after twenty-two hours, stretched across from plate to plate, "forming a metallic connection," which was so much heated by the passage of the voltaic current that the liquid became warm. It is stated that this modified "lead tree" has sometimes been found in Faure's cells. It is shown that there is probably no advantage in continuing the charging after the oxygen has ceased to be absorbed freely.

Messrs. Gladstone and Tribe conclude on very satisfactory grounds that the chemical action of the discharge is essentially what is expressed by the following theoretical formula:—

$$PbO_2\ H_2SO_4\ H_2SO_4\ Pb = PbO\ H_2O\ H_2SO_4,$$

which becomes—

$$PbSO_4\ H_2O\ H_2O\ PbSO_4.$$

This reaction is, however, sometimes complicated by the formation of a small amount of peroxide of lead on the positive plate, which is believed to be due to the oxidation of sulphate.

Messrs. Gladstone and Tribe conclude from their researches that unless the peroxide of lead unacted upon is allowed to be very considerable the quantity of lead compound on the two sides ought to approach equality; also that care should be taken that sulphuric acid is in sufficient excess to allow of some of it in still remaining solution after all the available lead has been converted into sulphate. If it is removed and only water is present, an oxide or hydrate will be produced with probably some serious consequences to the cell.

(*To be continued.*)

A BISMUTHIC HAIR-DYE.*

BY A. NAQUET.

The author states that he was induced by a knowledge of the injurious properties of the many hair-dyes that are put forward as perfectly harmless to make the attempt to produce one that should be fairly entitled to that description. Whilst working upon the subject he protected the different steps by patents, in order to secure priority, but having attained what he considers to be a satisfactory result he has now abandoned his rights for the public benefit.

M. Naquet's experiments were made in the direction of compounding a metallic tincture that should have an innocuous metal for a basis instead of lead, and for this purpose he selected bismuth. The preparation which was the subject of his first patent consisted of two solutions that were mixed immediately before being used, and he describes the method of making it as follows.

It has long been known that a solution of bismuth is obtained in treating bismuthic hydrate with a solution of bitartrate of sodium; but it is not very easy to prepare and not more than a very small proportion of the bismuthic hydrate employed is ever dissolved. M. Naquet therefore sought an easy method of preparing the double tartrate of potassium (or sodium) and bismuthyl ($C_4H_4NaBiOO_6$). The bismuth is dissolved in the smallest possible quantity of nitric acid and to this is added

* Abstract from communication to the *Moniteur Scientifique*, [3], xii., 880.

an aqueous solution of tartaric acid (3 parts of acid to 5 of bismuth) and a large quantity of water; the whole is then thrown on a filter and the precipitate washed. The wash water contains some bismuth, which can be removed by precipitating with a sulphide, then redissolved in nitric acid and used in a subsequent operation. The well washed precipitate, whilst still moist, is dissolved in a boiling solution of sodic bitartrate (12 to 15 parts of bitartrate to 5 of bismuth), then filtered, diluted with water, alcohol and glycerine, and again filtered. Each litre should contain 150 c.c. of glycerine, 150 c.c. of alcohol and 600 c.c. of water. The proportion of bismuth present should be 2 grams of metal per 1000, and if the liquor contains more or less it should be brought to that strength. The paper through which this liquid is filtered will retain some bismuth, precipitated by the alcohol; this can be redissolved in nitric acid and again used.

The bismuthic solution alone does not dye, but mixed with sodium hyposulphite it soon deposits sulphide of bismuth which dyes the beard and hair. But as this mixture is quickly decomposed it must not be made until just as it is going to be used. This form of bismuthic hair-dye, therefore, requires to be sent out in two bottles, one containing the bismuthic solution, the other the solution of sodium hyposulphite (1 part of solution saturated in the cold diluted with 5 parts of water). When required for use these are mixed together in equal proportions.

The bismuthic product precipitated by tartaric acid and water can be dissolved by means of carbonate of potash, or by any of the caustic or carbonated alkalies, including ammonia, the liquid being after neutralized by a current of carbonic acid gas and filtered. But unfortunately this neutral product, or even one slightly alkaline, does not act as a dye when mixed with either hyposulphite of soda or flowers of sulphur. It can only be used by moistening the hair first with the bismuthic liquid, and then, after it has dried, with a solution of sulphydric acid or a sulphide.

This dye is said to have a progressive action, and to produce all the shades from a light flaxen to a deep chestnut colour, according to the number of applications made.

The second patent was taken out for a preparation that could be sent out in one bottle, M. Naquet while pursing his investigation having found that an ammoniacal solution of the tartrobismuthic product will keep indefinitely when mixed with solution of hyposulphite of soda, if the containing bottle be kept well closed. Such a mixture is said to make an admirable hair-dye, it decomposing and depositing sulphide of bismuth in proportion as it loses ammonia and is acted upon by carbonic acid in the atmosphere, The degree of concentration of the liquid is not of great importance, nor the quantity of ammonia. The following is the working formula given by M. Naquet:—

Dissolve 100 parts of bismuth in the smallest possible quantity of ordinary nitric acid (about 280 parts). To this liquor add a solution of 75 parts of tartaric acid in water and then a rather considerable quantity of water to ensure complete precipitation. The whole is then thrown upon a filter and the residue washed with water until the washings are no longer acid. The magma left on the filter is then put into a dish and solution of ammonia gradually stirred in until all is dissolved. The magma derived from 1½ kilograms of bismuth will require 0·8 or 0·9 litre of ammonia. To this liquor is added 75 parts of hyposulphite of soda in powder, and when the salt is dissolved the product is filtered and put into bottles. In this state it is ready for sending into commerce, but it is of advantage to add 1 or 2 per cent. of glycerine; no addition of alcohol is necessary. The liquid so prepared would contain about 5 per cent. of bismuth. It may be further diluted with water if desired.

The hair or beard when saturated with this liquid acquires after five or six hours a deep chestnut colour. Upon washing the hair this colour disappears, giving place to a delicate flaxen colour. By repeating the operation daily a stage is arrived at when, after passing through all the intermediate shades, the deep chestnut colour remains persistent.

CHINESE CAMPHOR.*

In China camphor is grossly adulterated with a glue obtained by boiling a rattan creeper, locally called T'êngtsai. This weed, growing luxuriantly in the interior of Formosa, from whence, as everyone is aware, all Chinese camphor is derived, is full of a glutinous matter which boiling water converts into a colourless glue. Mixing this with the pure camphor and a small percentage of water prevents evaporation, though naturally destroying the high quality of the article itself. Camphor so adulterated will keep, it is said, for a couple of months without loss; indeed, will bear the journey to Europe without suffering appreciable diminution. Experiments recently made have demonstrated the existence of two parts of glue to three of camphor in certain samples offered in the Tamsui market, rendering the article absolutely useless. Happily fire will readily detect the foreign body. Mr. Walter Lay, to whose admirable report upon the camphor trade in 1880 we are indebted for this information, adds:—"I have obtained a sample of the plant from which the glue is obtained, but cannot find out what its botanical name is; indeed, I have not succeeded even in obtaining the correct Chinese characters for it. It is called locally T'êngtsai, but it doubtless has a more distinctive appellation than that. It is not given in the 'Topography of Tamsui.' Mention is made in the Wahu Report for 1878 of a plant which yields a glutinous substance on being boiled in water, and which is used in the manufacture of paper. The name given to it at Wahu is Yang Kout'êng, and this possibly may be the name of the creeper used here for the adulteration of camphor."

Before the ruthless axe of the Chinese woodcutter the beautiful inland forests still adorned by the graceful *Laurus camphora* are fast disappearing. The aborigines inhabiting the interior fight desperately for the possession of their woods, but each year sees a fresh tract surrendered to their indomitable enemies. To illustrate the difficulty attending the collection of the prized wood, it may be mentioned, on the authority of the above-named gentleman, that between five and six hundred Chinese were killed two years ago in the petty warfare which prevailed with the savages. Sooner or later there must be a dearth of camphor. With their customary want of common prudence the conquering race are recklessly clearing the ground for tea cultivation, burning up the camphor wood in tea-firing operations, for which purpose it can seemingly be used with perfect safety, despite the pungent fumes given forth.

Very little of the camphor manufactured in Formosa is consumed by the Celestials, nearly all being shipped to foreign countries. On the other hand, they continue importing for their own use the more precious natural article secreted by the *Dryobalanops camphora* of Sumatra and Borneo. For these concrete masses, commonly known as Camphor Baroos, fancy prices are still paid,—31*s.* a pound was the import price at Ningpo last year. Of this fine camphor, it may be added, but a small quantity finds its way to Europe; the relative cheapness of the manufactured article driving it quite out of our markets, although it is well known the native manufacturers in Formosa place no special reliance on their own product, which, they say, possesses little or no virtue—very little nowadays, one may opine, if adulteration is carried on to the extent asserted.

* From a paper on the Chinese Materia Medica, by F. Newcome, in the *Medical Press and Circular*, August 2.

IMPURITIES IN GLYCERINE.*

M. Ferdinand Jean has studied and described in a very competent manner the adulterations and imperfections in the manufacture of glycerine. He states that oxide of lead, lime and butyric acid are the impurities most frequently met with in commercial glycerine, and that they accrue from bad manufacture or incomplete purification. Perfumers test glycerine with nitrate of silver, no sensible coloration resulting at the end of twenty-four hours if it be pure.

The chloroform test consists of mixing equal parts of chloroform and glycerine, stirring, and then leaving the mixture to settle. The mixture separates into two distinct layers, the upper one consisting of pure glycerine, the lower of chloroform and the glycerine impurities. If the glycerine is pure, the chloroform remains clear; if not, a greyish belt is observed at the point of separation.

If to glycerine, diluted with its own volume of distilled water, first a few drops of dilute sulphuric acid, and then a little alcohol be added, a white precipitate may be observed if the glycerine is impure. This will be due to the presence of lime or lead, the latter being indicated if the precipitate is blackened by sulphuretted hydrogen.

The presence of butyric acid is detected by mixing strong alcohol and sulphuric acid with the glycerine, and heating slightly, when the agreeable odour of butyric ether becomes manifest.

Formic and oxalic acids have also been found in glycerine; their detection is very important, especially in glycerine destined for pharmaceutical preparations. This may be effected by mixing equal parts of the impure glycerine and sulphuric acid, sp. gr. 1·83, when carbonic acid gas is given off.

To ascertain if both the above acids, or, if only one, which is present in the glycerine, M. Jean uses the following tests:—1. To a part of the glycerine alcohol of 40° is added, and a drop of sulphuric acid, and slight heat applied; the odour of formic ethyl (peach-flower smell) indicates the presence of formic acid. 2. To equal quantities of glycerine and water add 2 drops of a solution of chloride of calcium containing a little ammonia (free from carbonate); if oxalic acid be present a white precipitate of oxalate of lime will be formed.

Sugar, glucose, gum and dextrine are easily discovered by the following tests:—150 or 200 drops of distilled water are poured on the glycerine to be tested in a porcelain cup; 3 or 4 centigrammes of molybdate of ammonia and a drop of pure nitric acid are added, and the whole is then boiled for half a minute. If the glycerine contains sugar or dextrine a blue coloration is produced. If glycerine adulterated with cane-sugar be boiled with a few drops of strong sulphuric acid a black colour is produced, due to the carbonization of the sugar. Adulteration with glucose is detected by means of caustic soda, the mixture having a brown colour when boiled. To ascertain the quantity of sugar, dextrine or glucose in glycerine the following process may be employed:—5 grams of the impure glycerine are boiled in a small glass beaker with 5 c.c. of distilled water and a slight excess of alkaline solution of tartrate of potash and copper; the precipitate of protoxide of copper is redissolved by adding some hydrochloric acid. The solution is then made strongly ammoniacal, and poured into a solution of nitrate of silver. Metallic silver is immediately precipitated, which is separated by filtration. After washing it with warm ammoniacal water, it is calcined at a red heat, and the weight of the silver taken. As 100 of glucose = 509·6 of metallic silver, the weight of the glucose can be easily calculated. If cane-sugar or dextrine be present it is necessary previously to boil the glycerine for half an hour with acidulated water, in order to convert these matters into glucose.

The quantity of water contained in impure glycerine can be determined, when the density is known, by means of Vogel's formula.

ARROWROOT MANUFACTURE IN QUEENSLAND.*

The machinery used for the manufacture of arrowroot is simple in the extreme, and is chiefly manufactured on the place, the shafts, pulleys and engine work being, of course, foundry made. The first process shown was the roots being tipped by two boys into a long trough, through the length of which a shaft slowly revolved, and by means of wooden projecting pegs the dirty roots were stirred up and so cleaned, there being a constant stream of water running through the trough. These revolving pegs have a screw pitch, so that the roots are gradually moved towards the far end of the trough, where they are caught up by a sort of bucket pump which elevates them some 12 feet and drops them regularly into a hopper. As they fall to the bottom of this they meet the grater, which is a drum of perforated galvanized iron driven at great velocity. A small stream of water pours into this all the time, and the roots are quickly grated up into a brown coloured pulp. This mass of fibre and pulp falls into a cylinder of perforated iron, about 9 feet long and 2 feet in diameter; through the length of this runs an axle on which are two beaters like the drum of a threshing machine; these smash up the fibrous pulp, exposing it to the action of the water, so as to enable all the starch and fine pulp to be washed out and squeezed through the perforations of the cylinder, while from the one end is discharged a constant stream of the dirty looking fibrous refuse. A stranger looking at the process at this stage would think it utterly impossible that the white arrowroot of commerce could be the result of such an unpromising material; however, water works wonders, and an abundance of pure, soft water is essential for the successful manufacture of arrowroot. The finer pulp, as squeezed through the perforations of this cylinder, is received in a precisely similar one below; here again the mass, now only pulp, is beat up; but the perforations around this second drum being very small, only the starch and dirty looking water passes through, the pulp being again discharged from the cloaca at the end. The stream of water and starch pouring from these cylinders is received in troughing, extending for 100 feet around the shed, and, as it runs along, the starch, being heavier than the water, all sinks to the bottom and the water runs away. So far the work goes on automatically, no one but the two boys throwing in the roots troubling themselves about it. But towards the end of the day the stream of water is stopped, and the arrowroot starch scraped up out of the trough, where it has accumulated in a layer some inches in thickness, and is placed in large vats or tubs, all ranged in regular rows. Before being put into these tubs it is passed through fine muslin sieves, and at the same time another stream of water is turned on. These fine sieves effectually clear it of any foreign matter, and it settles by the morning at the bottom of the vats, clean and white as snow. The water is drained from it, and the starch put into a centrifugal machine exactly similar to what is used for sugar; this soon forces out the surplus water, but perfect dryness is essential to its keeping qualities, so it is now carried to the drying room, which is some 60 feet long by 12 feet wide. Round the whole length of this runs a flue heated by a special furnace, and over this are shelves of galvanized wire netting; on this netting is placed calico, and on this is spread out the starch. In this hothouse the moisture is quickly evaporated, and the arrowroot becomes crisp and grain-like. On fine days it is spread out in the sun on similar wire stages. All operations are now finished, and the flour is stowed away in bins in the storehouse, and there made up into the packets usually seen in the shops. For this work-women are employed, and smart hands can earn as much at this employment as their husbands are doing at the rougher work of the mill.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 16, 1882.

OPIUM PRODUCTION IN CHINA.

In a volume of commercial reports by Her Majesty's Consuls in China, just issued, there is an unusual amount of space devoted to the subject of opium. As might be expected, the commercial and political aspects of the question occupy the most prominent positions in these reports, but intermixed there is some information upon the cultivation and consumption in China of native-grown opium which appears to be worth culling for these columns. Especially is this the case with the report of Mr. Consul Spence, who has recently spent four months in the province of Szechuan.

It appears that, notwithstanding the pretended opposition of the Chinese Government, the cultivation of the poppy is now carried on in every district of the province of Szechuan, in the south-west of China, except those on the west frontier, but most extensively in the districts of Chungking Fu and Kweichow Fu. Opium is a winter crop, and some of the districts are said to appear at that time of the year like vast poppy fields. For this reason the crop is becoming a great favourite with the farmers, as it does not interfere with rice, the staple food of the people, for when it is planted in paddy lands, as is often the case, it is gathered in time to allow rice or some other crop to follow. Moreover, the conditions under which the tenant farmers hold their land have also hitherto had a similar tendency, as the rent usually consists of a proportion of the summer crop. Landowners are now, however, becoming alive to the importance of the winter crop of opium and are commencing to stipulate for the payment of a proportion of it also. There seems to be some difference of opinion as to the remunerativeness of opium cultivation. Baron Richthofen, writing ten years ago, estimated the yield of opium at 200 ounces per acre; but Mr. Baber, a subsequent observer, has estimated it at double that quantity. Mr. Consul Spence's figures approximate more closely to the latter, he giving an average of 350 ounces per acre. Probably the difference is attributable to the fact that the cultivation is now more carefully carried on and the land well manured. Every part of the poppy plant has a market value: the capsules are sold for use in medicine; oil is expressed from the seeds; the oil cake and leaves are used for manure; and the stalks are burnt for potash. Taking all these sources of revenue into account, opium, as compared with wheat, is estimated to yield a crop of double the value.

A few years since in Szechuan the poppy was grown only on hill slopes of an inferior soil; but now it is cultivated everywhere, and the country people are agreed that it is most profitably cultivated on good ground with liberal manuring. This agrees with experience in India, where it is found to be best grown on rich soil near villages where manure can be easily obtained. According to Mr. Consul Spence the method of cultivation now followed in Szechuan is extremely simple. As soon as the summer crop is reaped the land is ploughed and cleaned, roots and weeds are piled in heaps and burned and the ashes strewed over the ground, and the land is liberally treated to dressings of night soil. The seeds are sown in December in drills $1\frac{1}{2}$ foot apart, the white poppy being by far the most commonly cultivated in the low grounds, though the red and purple varieties are also grown. In the following month, when the plants are a few inches high, the rows are thinned and earthed up so as to leave a passage between each, after which the plants are left to themselves, with the exception that the earth is occasionally stirred and is kept clear of weeds. In March or April, according to the situation, the poppy blooms, and as the capsules form and fill fresh dressings of liquid manure are made. In April and May the capsules are slit and the juice extracted. The total amount of opium produced annually in South-west China, chiefly in the provinces of Szechuan and Yunnan, is estimated at upwards of thirteen thousand tons, or more than twice the whole Indian import into China.

The principal part of the opium exported from the province of Szechuan is carried along mountain paths, on the backs of coolies, to Shashih, and passes from thence into the regular trade channels over the east and south of China; the more convenient mode of transit along the Yang-tsze river is avoided because of the heavy dues. The opium thus becomes available to the poorer classes who cannot afford the high-priced Indian drug. But its cheapness is alleged to be in some degree due to adulteration with oil, glue and other substances, although when pure it is said to be almost as good as Indian opium.

Some statements by Mr. Consul Spence as to the extent to which opium smoking is practised in Western China, and the consequent effects, are sufficiently astonishing. He says that the impression one gets in a Szechuan city or village is that everyone smokes; there it is no question of fractions of 1 per cent., but of 30, 40, or even 60 per cent. of the whole male adult population, besides a large number of women. In the city of Chungking, for instance, where there is a population of 130,000, there are 1230 opium shops, with a daily consumption of 12,000 ounces of opium. In country hamlets and villages, also, almost every second house in the main streets is an opium shop. In some rural districts the people smear the lips of their idols with the drug and at funerals burn paper imitations of pipes of opium, so that the dead may enjoy in the next world the solace they loved in this. Sometimes as many as five "drawings" are smoked from the same opium. The leavings of the rich smoker are mixed with the opium sold to the poor; the refuse of the poor is re-smoked by some more destitute; and even the unsmokable dregs are drunk in tea by labourers, sailors and others who have not time to knock off work for a smoke. But notwithstanding this abandonment to opium-smoking, and the fact that extreme excess in this as in other cases brings its punishment, the Szechuan people are described as being stout and able-bodied, and their general health and well-being remarkable, as well as their capacity for work and endurance of hardship. Mr. Spence sums up by saying that were Indian opium the fatal scourge it is sometimes asserted to be, there ought to be found in the west of China, where ten times more opium is smoked that elsewhere, a debased, debilitated and impoverished population. But he holds that the reverse is the case, and that the people are both in body and estate amongst the most prosperous in China, and he considers that unless it can be proved that Indian opium contains some noxious principle which does not exist in the Szechuan drug the hypothesis as to the poisonous effects of opium-smoking is open to grave doubt. But it is worthy of remark that Indian opium is almost unknown throughout this vast district.

THE MANUFACTURE OF CHEMICALS IN GREAT BRITAIN.

If Lord Beaconsfield's dictum be correct, that the prosperity of the trade in chemicals is correlative with the prosperity of the country, there exist signs in the north of England that might be construed as indicative of the decadence of Great Britain. In a special note which appeared in the *Times* a few days since, attention is called to the depression which has now for several years existed in the chemical industries carried on in the Tyne district. The importance of this condition of things will be manifest when it is stated that even now it is estimated that over eight thousand men are directly employed in the chemical works of the Tyne district alone, whilst the value of the total annual production of the chemical trades in the north of England has varied in recent years from two to four million pounds sterling, of which the value of the soda crystals has exceeded three hundred thousand pounds. The depression and consequent enhanced competition have resulted in a remarkable fall in prices, so that it is asserted that for some years past the cost of production of such articles as soda crystals and bleaching powder has been in excess of the selling prices, and serious losses have been incurred. This state of things is attributable to more than one cause, but no doubt began with the reaction from the enormous overproduction that some few years ago was fostered in the district. Another cause no doubt has been the introduction of new processes, especially in the manufacture of soda, which have been found more conveniently applicable in other localities than in the Tyne district. Thus Mr. Allhusen pointed out in a subsequent letter to the *Times* that Solvay's process can be employed to greatest advantage where brine is attainable, as in Cheshire and South Durham, and that under such conditions soda can be profitably produced by this process even at the present low prices. But there is undoubtedly another cause at work which is not noticed in either of these communications. A few years since Great Britain practically manufactured alkali for the world. But in recent years an ever-increasing number of manufactories have been brought into operation in other countries, especially in Germany and Austria, which successfully compete with this country, at least for the home manufacture. It is satisfactory to learn, however, that there are indications of improvement in the trade even in the Tyne district, as prices are tending upwards, although it may be some time before the prices of chemicals may allow of the manufacture being carried on there profitably. In the event of the salt deposit discovered recently in South Durham becoming available for working in the Tyne district it would probably accelerate the improvement.

EXEMPTION FROM JURY SERVICE.

In accordance with the provisions of the Juries Act lists of persons qualified and liable to serve on juries in England and Wales are now being exhibited on the doors of all places of religious worship in the various parishes, and will remain until Sunday next, the 17th inst. We would, therefore, remind those of our readers who are entitled to exemption under the statute as "pharmaceutical chemists" that if they wish to ensure that exemption it is desirable that they examine the lists relating to their respective parishes to see whether their names have been improperly included. In the event of a pharmaceutical chemist finding that his name has been inserted n the list he may claim to have it expunged on the day of appeal, and to support his application may obtain a certificate of registration from the Registrar. But if he fail to make the claim at that time, he will not be entitled to exemption as long as his name remains on the jury list.

AUTOGRAPH PRESCRIPTIONS.

We have great pleasure in calling attention to the letter of Mr. W. N. Allen, on p. 239, in which he asks for assistance in making a collection of autograph prescriptions for the use of the Irish Board of Examiners. The collection is being prepared under the auspices of the Council of the Pharmaceutical Society of Ireland, and we shall be glad to learn that the request for prescriptions is responded to so liberally that there is not only enough for the purposes of the examiners, but some left that may be made available for the use of students, as, thanks to the exertions of Mr. Joseph Ince, is the case in this country.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, September 6, in the College of Physicians, Kildare Street, Dublin, at 3 o'clock.

The Vice-President, Dr. Aquilla Smith, presided.

The other members of the Council present were:—Messrs. Allen, Brunker, Dr. Collins, Messrs. Doran, Grindley, Hodgson, Holmes, Sir George Owens, Messrs. Simpson, Wells, and Dr. Montgomery.

Mr. Hugh Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

The Registrar read a letter from Mr. James Carse, of Belfast, complaining of the decision which the Council had arrived at with respect to his case and stating that he would take an action against them unless they complied with certain requests which he made in his letter.

The Chairman: His request is limited to a very small thing, namely, allowing him one year.

Mr. Hodgson: I think the simple way would be to refer the letter to the Law Committee and let them deal with it as they think best.

Mr. Holmes: Is there not a threat in the letter against a member of the Council?

The Chairman: It does not appear to be a case for the Law Committee. It is a case for the Council to decide on. He says he has taken advice and will bring an action.

Mr. Allen: I think we should take no notice whatever of his threats.

Mr. Brunker: I move that the letter be marked "read." The Council have spent two whole meetings on his case and a majority have declared their opinion; I do not see any ground for re-opening the matter.

Mr. Holmes seconded the motion of Mr. Brunker, which was put and carried.

The Registrar was directed to inform Mr. Carse of the decision arrived at.

A letter was received from Mr. Thomas R. Lester, of Cork, presenting some prescriptions for the use of the Examiner in Pharmacy.

On the motion of Dr. Collins, seconded by Mr. Doran, a vote of thanks was passed to Mr. Lester.

The Registrar read a correspondence arising out of a letter written by Mr. Alexander Chapman, L.P.S.I., of Belfast, in reference to the acceptance of certificates for compounding by the Royal University of Ireland. Mr. Chapman wrote to the Secretaries of the Royal University, Drs. Meredith and Dunne, on the subject and received from them a letter, dated July 21, 1882, stating that "A certificate signed by a licensed apothecary, attached to a recognized hospital, would be accepted by the University." The Registrar wrote to Mr. Chapman asking for an explanation of the word "certificate," and received from him a reply, dated July 31, stating that "The Royal University required a certificate of having compounded for three months."

The Chairman: We are not to interpret what are the powers of the Royal University. If Mr. Chapman's question were, "Will the certificate of a licentiate of the Pharmaceutical Society be received by the Royal University," we should try to answer it; but having regard to the way in which the questions are put in the letters it appears to be a matter between Mr. Chapman and the Royal University.

Mr. Brunker: But is it not of importance to secure the interests of our licentiates?

Sir George Owens: You can raise the question by asking the Royal University whether they will accept the certificates of our licentiates.

Mr. Brunker: Would it not be advisable for us to place ourselves in communication with the Secretaries of the Royal University in order to ascertain if the certificates of our licentiates will be accepted, the Royal University having adopted the course of requiring from all licentiates in medicine a certificate in practical pharmacy?

Sir George Owens: I think the chances are that they will accept it.

Dr. Collins: All the bodies, the College of Physicians and the College of Surgeons included, require certificates in pharmacy.

Mr. Brunker: The Royal University have gone further, I believe, than any other body. They require a more extended knowledge and experience of pharmacy than other licensing bodies.

Dr. Collins: Should we recommend Mr. Chapman to write to the Secretaries of the Royal University asking if his certificate will be accepted, and in the event of the reply being that it would not, to communicate with us?

Mr. Grindley: Why should we not write to the Secretaries of the Royal University on the subject?

Mr. Brunker moved:—

> "That the Registrar be directed to address to the Secretaries of the Royal University of Ireland a query relative to the nature of the certificates in practical pharmacy required by the Council of that body, and to request that certificates signed by duly qualified licentiates of the Pharmaceutical Society of Ireland should be accepted by them."

Mr. Grindley seconded the resolution, which was unanimously agreed to.

A letter was received from Dr. Kaye, Q.C., Assistant Under-Secretary to the Lord Lieutenant, conveying his Excellency's approval of the election of Mr. Charles Evans as Examiner in Pharmacy.

The next subject on the paper was the recommendations of the Pharmacy Act Amendment Committee.

Mr. Allen said at the last meeting the consideration of those recommendations was postponed, on the understanding that they would not be taken up at the present meeting, the Belfast members of the Council having stated that they would not be able to attend it. In justice to those gentlemen it would not be fair to take up the consideration of those recommendations now. He (Mr. Allen) had called on the President and consulted him about the matter, and by his directions he had written to Mr. Pring, Mr. Payne, and Dr. Whittaker to say that the recommendations would not be considered that day.

Mr. Grindley said he could bear out what Mr. Allen had stated, as to the understanding with the Belfast members on the subject.

Mr. Holmes suggested that the recommendations should be taken into consideration at the annual meeting of the Society, which would be held on the 2nd of October.

Mr. Hodgson was of a similar opinion. He observed that there was an attempt in the recommendations to reintroduce the word "apprentice," to which he had a strong objection. He had understood that the principle of apprenticeship was exploded, as far as the Pharmaceutical Society was concerned. It was enough to require two years' practical pharmacy from a man without tying him down by the word "apprentice," whether he were forty years of age or only sixteen. These were considerations that ought to be brought before a meeting of the Society at large.

The Chairman: Then it would be necessary to send out copies of the recommendations beforehand to all the members.

Dr. Montgomery: I do not think it would be possible to enter into these questions at the annual meeting.

Mr. Wells: Can they be brought before the general meeting without having been first brought before the Council?

The Chairman: I should say not, until the Council have first voted on them.

Mr. Wells: These matters have not been voted upon by the Council yet.

Dr. Montgomery said he did not see what the general meeting had to do with these questions. It was the Council who were entrusted with the duty of deciding on them. Propositions might be made from the general meeting, which the Council could not accept, and then they would be in collision with the Society generally. The consideration of the recommendations ought to be adjourned until the next meeting of the Council.

The Chairman: I do not think any inconvenience can arise from adjourning the consideration of these recommendations until the next meeting of the Council. When a Pharmacy Bill is introduced it will be time enough for the members of the Society generally to express their opinions.

Dr. Montgomery: Is it essential that the general body should approve of the action of the Council?

The Chairman: No.

Dr. Montgomery: Or can we make laws without their approval?

Mr. Brunker: It is not a proposal to make laws. These are only recommendations for the amendment of the law. I take it that the Society in general by voting for members of the Council have delegated their authority to the Council, and except in the way of being consulted on important matters have no weight all.

The Chairman: The Council would have power to make suggestions on the occasion of the introduction of a bill, without going to a general meeting.

Mr. Brunker: As public affairs are going at present I do not think there is much chance of our getting amendments in the Pharmacy Act until next year.

Mr. Allen moved—

"That the consideration of the recommendations of the Pharmacy Act Amendment Committee be postponed to the meeting of the Council on October 4, next.

Dr. Montgomery seconded the motion, which was unanimously agreed to.

Some financial business having been disposed of, the Council adjourned.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 215.)

Wednesday, August 23.

The President took the chair at half-past ten, and the first paper read was—

On Some Reactions of Arsenic.

BY W. A. H. NAYLOR AND J. O. BRAITHWAITE.

Three years ago one of us devoted some attention to the action of certain reducing agents on arsenic acid and as a result devised and published a method for the volumetric estimation of this body based upon its reduction by hydriodic acid. First in order among the substances tentatively employed at that time was oxalic acid, which was thought not to have been previously studied in this connection. The result of the experimental inquiry was so far disappointing as to induce the belief that it could not readily be applied to the purpose of reducing arsenic compounds. Subsequently the discovery was made that not only had oxalic acid been tried in this capacity, but that in the hands of the experimenter it had proved a complete success. An account of this interesting observation is given by the author, M. Patrouillard, in the *Répert. de Pharmacie*, iii., 582, an abstract of which may be found in the *Pharmaceutical Journal* for November 27, 1875. His preference for oxalic acid over the reducing agents commonly employed, as sulphurous acid and alkaline hyposulphites, is founded on its solubility and the comparative ease with which it can be obtained in a state of purity. This discovery of Patrouillard received additional importance and credible acceptance when a place was assigned it in a standard text-book of chemistry. In regard to it, the manual referred to has the following statement:—"Arsenic acid is easily reduced to arsenious by the action of reducing agents such as sulphurous or oxalic acid

$(H_3AsO_4 + H_2C_2O_4 = H_3AsO_3 + H_2O + 2\,CO_2)$."

These latter opinions contrasted too strongly with the one first quoted to encourage the hope that on mature reflection some ground of agreement would be found. It was therefore resolved when opportunity offered to repeat the old experiments, extend them if necessary, and perform others on the lines laid down by Patrouillard. This we have done conjointly and have pleasure in now submitting the results. Here we would remark that while the author in his communication supplies but little data regarding the mode of testing his reduced compound, he is commendably explicit in his narration of the process intended to effect the desired reduction.

His instructions may be usefully reproduced:—

"10 à 15 grammes du sel à essayer sont dissous dans l'eau distillée, 50 grammes environ; on y ajoute 50 centigrammes d'acide oxalique crystallisé et l'on entretient la dissolution pendant à peu près cinq minutes à la température de l'ebullition; on filtre si cela est nécessaire et lorsque la liqueur est un peu refroidie on l'acidifie assez fortment par l'acide sulfurique. Dans cette liqueur acidulée on fait passer un courant de gaz hydrogène sulphuré. . . . Si le sel essayé contient au moins 2 pour 100 d'arséniate de potasse, par exemple, le précipité jaune floconneux de trisulfure d'arsenic se formera immédiatement."

The following experiments may be cited in illustration of our mode of working:—

Experiment 1.—·25 gram of arsenic oxide dissolved in 50 c.c. of water was boiled for half an hour with ·5 gram of oxalic acid.

Experiment 2 was identical with No. 1, except that the proportion of oxalic acid to arsenic oxide was doubled, and the boiling continued for two hours.

Experiment 3.—Fifteen grams of sodium nitrate containing 2 per cent. of added arsenic oxide were dissolved in 50 c.c. of water. ·5 gram of oxalic acid was introduced and the solution boiled for half an hour. On examining the respective solutions for traces of arsenious acid, negative results were alone obtained. The tests applied in searching for evidences of reduction may be briefly described. The solution was carefully neutralized with ammonia, barium nitrate added to complete precipitation, and filtered. The filtrate was boiled with sufficient sodium carbonate to convert the barium arsenite into a soluble salt, and withdraw from solution the excess of barium reagent. It was then filtered, the filtrate evaporated to a low bulk and divided into three portions. To one was added a little caustic soda, followed by the cautious addition of a weak solution of mercuric chloride. The first drop coloured the liquid permanently yellow. The nature of this reaction will be dealt with presently; for the moment it may be regarded as indicative of the absence of any arsenite. To another portion was applied the copper test in a modified form. In what this modification consists will be described shortly; suffice it to say that no cuprous oxide was formed and therefore inferentially no reduction of the arsenic oxide had taken place. To the third portion, after acidifying with sulphuric acid, a weak solution of potassium permanganate was added. A pink tint was at once imparted to the liquid, which did not become discharged on shaking. Advantage was also taken of the extreme delicacy of iodine as a test for arsenious acid, it being only necessary to substitute the corresponding bicarbonate for the monocarbonate of the alkali employed in effecting the decomposition of the barium arsenite. By its use, too, no appreciable reduction was obtained. As a demonstration that these tests are adequate to the detection of small quantities of arsenious acid, in respect of the conditions under which they were applied, it may be stated that satisfactory indications of the presence of this substance were afforded by each, when to one of the experimental solutions not more than 4 milligrams of arsenious oxide were added.

Failing to procure any evidence of a reduction, the original experiments were repeated, and another class of reagents applied. These afforded abundant proof of the existence of arsenate. Having removed the oxalic radical and obtained the arsenic compound in the form of an alkaline salt the respective solutions were separately examined. When neutralized they gave a chocolate coloured precipitate with nitrate of silver. With excess of ammonia and magnesium mixture a cloud was instantly produced, followed by a copious crystalline deposit on standing. And when acidified with hydrochloric acid, iodine was rapidly liberated on the addition of a 20 per cent. solution of hydriodic acid.

Experiment 4.—This differed from the preceding ones in that the boiling was conducted in sealed tubes, ebullition being maintained for from five to ten minutes. One tube was opened beneath the surface of clear baryta water, but no tangible proof of its containing carbon dioxide was obtained. Nor did the enclosed liquid respond to the before mentioned tests for arsenious acid.

Experiment 5.—One gram of oxalic acid and ·2 gram of arsenic oxide were dissolved in 50 c.c. of water, and introduced into a small flask carrying a delivery tube depressed beneath the surface of mercury. Having replaced the small volume of air in the flask with hydrogen, a tube containing baryta water and mercury was drawn over the end of the exit tube. The contents of the flask were then vigorously boiled. At the end of ten minutes the baryta water was distinctly opalescent, which was proved to be due to a little oxalate carried over with the steam. No barium carbonate was produced.

Experiment 6.—This consisted in dissolving ·200 gram of arsenic oxide and ·500 gram of oxalic acid in 50 c.c. of water and boiling for half an hour. The oxalic acid was then determined gravimetrically, when it gave the equivalent of ·624 gram of calcium sulphate. A second experiment conducted simultaneously and in precisely the same manner, but omitting the arsenic oxide, gave the equivalent of ·622 gram of calcium sulphate. We conclude, therefore, that under these conditions the oxalic acid suffers no decomposition.

Experiment 7.—Fifty c.c. of a 2 per cent solution of oxalic acid containing ·2 gram of arsenic oxide was boiled for half an hour, and, when cool, strongly acidified with sulphuric acid. Through the solution was transmitted sulphuretted hydrogen. No yellow sulphide made its appearance for the first five minutes, in ten minutes a distinct precipitate had fallen, and it was not until the gas had passed through continuously for four hours that decomposition could be declared complete. The sulphide was collected, dried, digested repeatedly in carbon bisulphide and filtered. The filtrate left, on evaporation, ·006 gram of sulphur.

The pure sulphide was examined in regard to its degree of sulphuration, and was found to exist mainly in the penta-condition. Hence we infer the absence of any indirect action between the sulphuretted hydrogen and the acids by which the arsenic might become reduced. It was now thought that we had arrived at that stage of our inquiry when we might legitimately discontinue our experiments and accept the conclusion to which they unmistakably pointed. We therefore express the opinion that oxalic acid exerts no reducing action under the conditions described by Patrouillard and ourselves.

Passing from this subject we proceed to give an account of our method of employing the copper test. It is based upon the fact of the solubility of cupric arsenate in the double tartrate of potassium and sodium. It is indeed a modified Fehling solution. The copper solution, as ordinarily prepared, cannot be substituted for it on account of the large quantity of double tartrate present which seriously interferes with its delicacy as a test. It should contain but little more double tartrate and caustic soda than would enable it to withstand boiling when diluted with twice its volume of water. Our formula for such a solution has the following proportions:—

Cupric sulphate recrystallized. . .	·200 gram
Water to measure	50 c.c.

Dissolve:—

Tartarated soda, crystallized . . .	·500 gram
Caustic soda	5·00 grams
Water to measure	50 c.c.

Dissolve.

The two solutions are kept separate, and mixed in equal proportions when required for use. The convenience of this mode of employing the copper test is best realized when search has to be made for traces of arsenite accompanied by much arsenate. By this simple modification the arsenate is held in solution, and the inconvenience of filtering a strongly alkaline liquid, or patiently waiting until the insoluble copper compound has subsided, is obviated. Moreover, in our hands it has conduced to accuracy, from the readiness with which the amount of copper desired to be taken may be apportioned. As affording some idea of its capability it may be mentioned that with 1 milligram of arsenious mixed with 2 decigrams of arsenic acid it will give on boiling a decided reduction. Its delicacy is, however, materially impaired by the presence of certain organic acids, as oxalic, citric, acetic, and tartaric. Sulphates and nitrates do not interfere, nor do chlorides, unless present in quantities proportionately large.

As a matter of scientific interest several attempts were made to apply the test volumetrically, but in every case a point was reached at which the copper solution refused to be reduced by the arsenic. Solutions containing various strengths of copper were employed, but not one could be made to yield, in a series of experiments, accordant results. At present, therefore, we are not able to offer an opinion upon its applicability to this purpose.

We now return to consider more fully a reaction which has received from us only a passing notice. We refer to the decomposition which takes place between arsenious acid and mercuric salts. In manuals of chemistry we are informed that when the action takes place between mercuric nitrate and an alkaline arsenite, mercuric arsenite is formed, and that this compound in contact with caustic alkali gives reduced metal. If to these facts be added the two observations of the solubility of this compound in excess of alkaline arsenite and in nitric acid, the most has been said that appears to be known about it. The fact that we have taken advantage of this decomposition by employing it qualitatively as a test for arsenious acid has already been referred to, the only difference being our substitution of the chloride for the nitrate. Here it may be permitted us to offer some remarks on the test itself. When mercuric chloride is added to a solution of arsenious acid only moderately alkaline, the solution remains clear, and upon standing becomes opalescent to a degree dependant on the amount of arsenic present. If, however, the solution be rendered strongly alkaline with caustic soda or potash and then a weak solution of mercuric chloride be added, the mercuric oxide at first produced quickly disappears, leaving as before a clear solution, which rapidly becomes cloudy and if set aside gives a greyish deposit of metallic mercury. Again, if the solution be not only strongly alkaline, but boiling, the liquid will assume a dark colour the instant the mercuric chloride is added. Assuming, for the moment, that the arsenic exists entirely in the higher state of oxidation, the mercuric oxide produced by the first drop of mercuric chloride will colour the solution permanently yellow. Before endeavouring to extend the usefulness of this test by attempts at making it quantitative it was necessary to satisfy ourselves on two points. These were the nature of the steel grey deposit and the condition in which the arsenic existed at the end of the reaction. That the deposit of reduced metal was free from corresponding oxides was verified by its insolubility on prolonged digestion in a 5 per cent. solution of hydrocyanic acid. That as a result of the action of the mercuric chloride, the arsenious had been wholly converted into arsenic acid, was indirectly proved by its failing to afford any evidence of an arsenite, and directly by the marked manner in which it responded to the tests for arsenates. From a knowledge of these facts we were enabled successfully to apply our test to the volumetric estimation of arsenious acid. For this purpose standard solutions of mercuric chloride and alkaline arsenite were prepared of strengths corresponding respectively to 13·55 grams of mercuric chloride and 4·95 grams of arsenic trioxide per litre. The mode of application consisted in delivering the mercuric solution from a burette into a measured volume of the arsenic solution previously heated to the boiling point, and rendered strongly alkaline with caustic soda. When the mercuric oxide ceased to disappear and from its presence imparted a permanently yellow tint to the liquid, the reading of the burette was taken. Operating in this way we learnt that the reaction took place between 1 molecule of arsenic trioxide and 2 molecules of mercuric chloride. After a little reflection the following equation in two stages was constructed to account for the facts thus far acquired:—

$$As_2O_3 + 2HgCl_2 + 4KHO = 2Hg''HAsO_3 + 4KCl + H_2O.$$

representing first stage of the reaction.

$$2Hg.HAs.O_3 + 6KHO = Hg_2 + 2K_3AsO_4 + 4H_2.O$$

representing final reaction.

Or as one equation

$$As_2O_3 + 2HgCl_2 + 10KHO = Hg_2 + 4KCl + 2K_3AsO_4 + 5H_2O.$$

Confirmatory evidence of the correctness of this equation was supplied by weighing the reduced mercury, and by determining the amount of arsenic acid produced in the reaction. Taking ·015 gram of arsenious acid, the mean of two experiments gave ·097 gram of metallic mercury, theory requiring ·098 gram. From the same weight of arsenious acid was obtained as the mean of two results a quantity of the double magnesium and ammonium arsenate equivalent to ·059 of arsenic pentoxide, theory requiring ·057 gram. Although so far as is known to us no molecular formula has been assigned to mercuric arsenite we consider that in representing it as $HgHAsO_3$ we are acting in harmony with the results of our experiments. The isolation of this body in a state of purity is a task requiring the observance of certain conditions with which at present we confess ourselves but imperfectly acquainted. For instance, if mercuric nitrate be employed as the precipitant, the product is invariably contaminated with mercuric oxynitrate. If in place of the nitrate the chloride be used, followed by the addition of alcohol, a precipitate falls consisting solely of calomel.

We conclude this paper by giving a series of experiments intended to afford an idea of the degree of accuracy of which our volumetric method is capable.

As_2O_3 taken.	As_2O_3 found.
·051 gram.	·052 grams.

·061 „	·062 „
·071 „	·070 „
·092 „	·093 „
·076 „	·077 „
·086 „	·087 „
·097 „	·098 „

Equally good results may be obtained in presence of much chloride, sulphate, carbonate, or bicarbonate, but phosphates prohibit its use.

The PRESIDENT proposed a vote of thanks to the authors of the paper, which was carried unanimously. He said this was a paper of considerable importance, and perhaps the most important point was the investigation into the conditions under which arsenic acid and other arsenates were reduced to arsenious acid and other arsenites, for no analyst examining the contents of a stomach, or a piece of wall paper, or anything else, would dare to say that arsenicum was absent until he had not only examined it in the ordinary way by the usual tests for arsenicum but had taken the precaution of adding some reducing agent, in order that arsenates might be reduced to arsenites, and so the possibility of missing arsenic be removed. Probably most who had employed these tests had used sulphurous acid for reducing the arsenates, but M. Patrouillard had stated so distinctly that oxalic acid would do as well, that, inasmuch as oxalic acid was always at hand, whereas sulphurous acid had usually to be prepared, it was not astonishing that many experimenters had gladly accepted the statement, perhaps a little hastily, and used oxalic instead of sulphurous acid. Having a great respect for the French investigator he confessed he had accepted his statement and recommended his students to use oxalic acid, but the denial by Messrs. Naylor and Braithwaite of this reaction was as distinct as M. Patrouillard's assertion, and, therefore, attempted reduction by oxalic acid should perhaps be discontinued until the matter was further investigated. He hoped M. Patrouillard would take notice of this paper, and clear the matter up. He said that after heating with oxalic acid, adding sulphuric acid, and passing sulphuretted hydrogen through the fluid there was an immediate precipitation of dry sulphide of arsenicum, and it would be remarked that he used the word "immediate." The authors of this paper, having done exactly what M. Patrouillard directed, got no precipitate for five minutes, then a cloudiness, and so on, and the precipitation was not complete for several hours. This was not only questioning an inference, it was denying a stated fact, and he hoped M. Patrouillard would make further experiments in order that this important question might be definitively set at rest.

Mr. MARTINDALE said there was a pharmaceutical preparation indirectly connected with the subject of the paper, which he should like to mention, because it had not given him much satisfaction. It was liquor sodæ arseniatis. The preparation, according to the Pharmacopœia, was never satisfactory, and he should be glad to know if Mr. Naylor had ever volumetrically estimated it by any of the reducing agents, such as he had suggested. He had tried to estimate it by means of the volumetric solution of nitrate of silver, without getting good results: it threw down chocolate-coloured arseniate of silver, but it was difficult to estimate when the decomposition was complete, and he had hoped from Mr. Naylor's previous paper that something might be done by the use of the volumetric solution of iodine. The formula in the Pharmacopœia which directed the arseniate of soda to be dried up to a certain degree never gave him very satisfactory results, and he understood from some medical practitioners that they obtained very varying results from the medicine as dispensed by different chemists. If some volumetric test could be given for it, it would be a great help to its being prepared of one uniform strength.

Mr. KINGZETT asked if the authors had used oxalic and sulphuric acids in conjunction, which he understood was the process of the French chemist. If sulphuretted hydrogen were used at the same time it would afford an increased facility for reduction taking place, because there would then be something which would combine with the arsenic at the moment of reduction.

Mr. BRANSON said he found the volumetric method with uranium nitrate or acetate very convenient for the estimation of arsenates, using potassium ferrocyanide as an indicator.

Mr. NAYLOR said he had never found any difficulty in preparing the liquor sodæ arseniatis, unless the temperature had been allowed to rise a little too high, when there was a danger of the arsenate becoming reduced to arsenite; of course if a very high temperature were used it would become reduced very considerably. As to Mr. Martindale's further question, it had been partly answered by Mr. Branson. If a volumetric method were desired uranium acetate might be employed, or the method suggested some time ago by hydriodic acid, provided sufficient hydrochloric acid were used at the same time, otherwise there would not be an equivalent quantity of iodine liberated. With regard to Mr. Kingzett's question, he could only say that they followed M. Patrouillard's directions exactly. The arsenic acid was boiled, and when slightly cooled the sulphuric acid was added.

The next paper read was on—

Some Results of the Action of the Digestive Ferments upon Drugs.

BY GEORGE BROWNEN, F.C.S.

I purpose in this paper to call the attention of this Conference to some of the results of the action of solutions of the digestive ferments upon medicinal substances.

Preparations containing the gastric and pancreatic ferments have recently become famous as dietetic auxiliaries; I need not therefore, occupy time with references to peptonized foods or drinks or even give a detailed account of their discovery and development.

In 1836, Schwann applied the term pepsin to an albumen-dissolving product obtained from the gastric juice, and subsequent investigations seem to show that the gastric juice contains more than one distinct ferment, or that this ferment may be modified by the process of extraction, so as to assume new or lose some of its original properties.

This is also true of the ferment or ferments of the pancreas. Bourchardat, in 1845, and Claude Bernard, a few years later, discovered or described some of the properties of the pancreatic secretion. In 1862, Danilewsky asserted the existence of three special ferments in the pancreatic juice, and since that time von Wittich, Kuhne and others have extracted and examined the ferments and applied them to dietetic purposes.

But there is a field of research outside the range of the peptonized foods, which merits the attention of the pharmacist and the physiologist. It is this, What are the possible modifications which drugs may undergo in contact with the digestive secretions, and will an examination of such results be of service in the preparation, combination or preservation of crude material so as to secure the best physiological results?

Solutions of the gastric ferment were obtained from the stomach of the pig, by means of dilute glycerine and also with acidulated water and alcohol. Pancreatic solutions were also obtained from the pancreas of the pig, by means of glycerine and a feebly alkaline, as well as an acidulated dilute alcohol. The first series of experiments were made with these solutions and crude drugs; the second with definite principles.

An infusion of rhubarb, ½ ounce to the pint of water, was prepared and as soon as the infusion had cooled to 50° C., some of the acid solution of pepsin was added and the temperature maintained by means of the incubator for two hours; 47 per cent. of the rhubarb was thus rendered soluble. The mixture was then neutralized by sodium carbonate, the alkaline solution of pancreatin added, and the temperature sustained for two hours longer. The insoluble portion was then found to consist of cellulose and earthy salts, retaining a small quantity of colouring matter. The 240 grains of rhubarb left an insoluble residue of 96 grains.

Infusion of calumba prepared with boiling water and passed through the same processes of digestion, gave somewhat similar results. The spongy cellulose was associated with a trace of berberia; 500 grains of calumba left an insoluble residue of 172 grains.

Cinchona and opium, upon the other hand, behaved somewhat differently; the gummy and extractive matters were dissolved and retained in solution, but a considerable portion of the alkaloids was left in the insoluble marc. Cinchona was about half soluble (48 per cent.) and opium about two-thirds, or 68 per cent. Quinine and morphia could be detected in the respective solutions and were also readily found and extracted from the insoluble residues. The cinchona tannin was destroyed in the digestive process and failed to precipitate gelatine, but this peculiarity will be noticed when we come to the action upon definite substances.

The possibility of the digestive ferments attacking gum acacia was deemed of some importance, in consequence of gum being used in a test demonstrating the acidification of fat by the emulsive ferment of the pancreas. Strong solutions of white gum arabic were therefore prepared and submitted in the incubator to the action of the gastric and pancreatic solutions. The feebly acid solution containing the gastric ferment remained clear even after several hours' digestion. A slight change, however, had occurred in the mixture, as a portion removed, neutralized with soda and boiled with Fehling's sugar test, showed a slight reduction to cuprous oxide, whereas a portion of the original solution undigested, but kept at the same temperature and under similar conditions, was not affected by the glucose test.

The mucilage digested with the alkaline pancreatin solution soon became cloudy, and ultimately a white precipitate was formed. The mixture seemed less viscid than that containing the gastric ferment, and a portion of the solution gave the violet reaction of peptone. The precipitate was found to consist of calcium carbonate, with a considerable quantity of the diastastic ferment carried down by the precipitated chalk. This precipitate, carefully washed, was found to possess strong amylolytic but no proteolytic or emulsifactive power.

I should, therefore, think that the arabin of gum acacia remained unaffected by the processes, and that the peptonizing change was wrought upon some slight impurity of gum, possibly containing nitrogen; this point, however, is reserved for further investigation.

Closely allied in physical character to gum, and holding an intermediate place between foods and medicines, are the mucilages obtained from Irish and Iceland moss. On Irish moss the alkaline extract of the pancreas seemed to exert very little action. The proteolytic ferment of the pancreas extracted with acids soon destroyed the viscidity of the mucilage, and divided the jelly into soluble and insoluble portions. These results were also obtained by the digestion of chondrus jelly with solution of pepsin; the products resembled and perhaps were identical with parapectin and pectic acid.

Cetraria, or Iceland moss, behaved somewhat differently. A jelly of this substance retained its colour, but became flocculent when acted upon by the gastric ferment. On the other hand, the pancreatized jelly retained more of its viscidity, became deeper coloured, and gave a deposit of yellowish-white flakes. These flakes under the microscope were found to consist of non-crystalline masses (pectic acid?).

The digestives were found to produce or accelerate the pectic fermentation by some experiments upon the pectin of the turnip.

I must now leave the consideration of this part of my subject and call your attention to the action of the ferments upon more definite substances. The acidulated extract of the gastric juice decomposed a watery solution of salicin very slowly and imperfectly; saliretin was formed, but it was associated with undecomposed salicin. On the other hand, the pancreatic ferment split up the salicin into saligenin and glucose, and the saligenin separated by solution in ether and subsequent crystallization was obtained in the form of white laminæ or scales.

A well-washed sample of jalapin remained intact after digestion with the pepsin solution, but pancreatic digestion withdrew a copper-reducing substance from the jalapin.

Santonin was unaffected by gastric and pancreatic solutions.

A solution of tannin treated with the acid pepsin solution became turbid, but the turbidity disappeared when a little more hydrochloric acid was added to the mixture. The results of several hours' digestion were, however, negative, but the pancreatic ferment, upon the other hand, rendered the tannic acid incapable of precipitating gelatine or isinglass, because of the transformation into gallic acid.

These are a few of the results obtained by digesting drugs with extracts from the digestive organs; they throw open a wide field for the pharmacist, and one deeply interesting to the physiologist.

The digestive process seems to consist of the hydration or splitting up of insolubles, and, as far as my observation has gone, the microzymous or bacteroidal fermentation need not occur until the primary digestion is in an advanced stage. For instance, in the digestion of the proteids, albumen and fibrin, I have noticed occasionally a point when the solution or hydration of these substances by the acidulated pancreatic secretion passes into the formation of leucin and tyrosin. I refer to the acidulated pancreatic solution, as the researches of Dr. Roberts and others upon the amylolytic power of a neutral or feebly alkaline pancreatic extract have seemed to throw into the shade the proteolytic power of acidified pancreatic juice, which, although incapable of transforming starch paste into sugar and dextrine, yet still possesses the power of dissolving fibrine or albumen, and ultimately splitting them up into leucin, tyrosin, and an organic acid. This is not the result of the putrid fermentation of albuminous bodies, as in this latter case the formation of ammonia renders the reaction alkaline instead of acidulous.

The emulsive ferment as well as the proteolytic in action produces acidity, although in the emulsification of fat the acidity is generally very slight and insufficient by itself to account for the minute subdivision of large proportions of fat. In the digestion of proteids the acidulous body is glutamic acid, and I think it may also occur in the emulsification of fats, as I have often sought for fatty acid and glycerine as separate bodies in emulsified fats; but I have always failed in my attempts to obtain any proportionate quantity which would justify me in ascribing emulsification of fat to their formation and presence.

The PRESIDENT proposed a vote of thanks to Mr. Brownen, which was carried unanimously. He said the results which Mr. Brownen had described were extremely important, and they must all hope that he would continue to work on this very large field of investigation. Ferments or septics, on the one hand, and antiferments or antiseptics, on the other, were now largely administered to human beings, while very little indeed was known of their action or the extent to which they retarded action when thus introduced into the system.

Mr. BENGER said the members of the Conference were much indebted to Mr. Brownen for having initiated this very original line of investigation on the action of the digestive ferments. His results were sufficiently interesting to warrant them in hoping that they would get something still more definite in future. The paper would, however, have possessed additional value had it given a few comparative results. Taking, for instance an infusion of rhubarb. Mr. Brownen said that, after digesting rhubarb with an acidulated pepsine solution and then with an alkalized pancreatic solution, there was nothing left but 96 grains of cellulose and earthy salts out of 240. It would be interesting to know if, had the rhubarb been digested with water only, or with acidulated water and then with an alkaline solution in succession, any different result would have been obtained. If he had tried that experiment perhaps he would state the result. The same with reference to the calumba: of course there would in this case be an action of the pancreatic ferments on the starchy matter, as Mr. Brownen prepared the infusion with hot water instead of cold as the Pharmacopœia directed. Another statement he should like to make a remark on, was:—That an acidulated pancreatic solution had no amylolytic action, but only proteolytic. That was quite contrary to his experience. He had always found a slightly acid solution both amylolytic and proteolytic, quite as much so as a neutral or alkaline solution. In Dr. Roberts's process for the peptonization of milk, carbonate of soda was ordered to be added, not with a view of increasing the action of the pancreatic ferments, but to prevent the precipitation of metacaseine, should the patient boil up the milk before the completion of the digestive process, which he was generally directed to do. If it were rendered alkaline no precipitation took place.

Mr. KINGZETT said the same thing had occurred to him, in listening to this interesting paper, as had been mentioned by Mr. Benger. For instance, taking salicin: if it were boiled with a dilute acidulated solution the compounds mentioned by Mr. Brownen would be obtained, viz., glucose and saligenin. It would be important to know how far the action observed was due to the ferments themselves, as distinguished from the alkali or acid severally employed. So far as regarded the splitting up of albuminous substances, the results mentioned were in agreement with those formerly worked out by Schützenberger, who had proved conclusively that albumen, when subjected to the action of hydration by ferments, or hydrolysis by baryta water or dilute sulphuric acid and so on, was split up into the two lesser molecules, hemiprotein and hemialbumen, one soluble and the other insoluble, though the insoluble part becomes soluble on further hydrolysis. On continuing the process these subsidiary molecules are further split up, yielding more ultimate products, including some of those mentioned by Mr. Brownen, viz., glutamic acid, aspartic acid, tyrosin and leucin, etc., which substances were always formed as ultimate products of the hydrolysis of albuminoids induced by chemical agencies or bacteroidal life.

Mr. PLOWMAN said everyone must feel that in experiments of this kind the exact condition of things could never be obtained artificially in the laboratory, such as occurred in the human body, in which a mysterious factor, "vital action" or "vital force," exerted its influence. He maintained, however, that as far as possible they ought to imitate the conditions which existed in the human body. As an instance of the importance of this, he remembered a most interesting paper being read by Professor Redwood at an evening meeting of the Society, in which he showed that when so-called "dialysed iron" was poured into ordinary water the iron was entirely precipitated, and that when that precipitate was dissolved in hydrochloric acid a solution was obtained which would not dialyse. If the idea were entertained that absorption of medicines was simply, or even mainly, owing to diffusion, this experiment seemed to show that dialysed iron would be worthless as a medicine; but it had been proved by medical men by actual observation that anæmic patients taking dialysed iron had had their condition considerably improved. As to the conditions which Mr. Brownen observed, the first thing that attracted his attention was that he performed these experiments at a temperature of 50° C., which of course was never reached in the human frame. At such a temperature as that any dilute acid solution would have a tendency to break up such bodies as salicin, independently of fermentative action. Another thing to be remembered in experimenting with pancreatic juice was this: the biliary secretion and the pancreatic secretion were discharged into the intestinal canal at a common orifice, and it was by no means determined what were the exact functions which the biliary secretion and the pancreatic secretion respectively fulfilled in the process of digestion. He should be glad to see some experiments performed in which the biliary was mixed with the pancreatic secretion, so as to ascertain the actual effect of the two secretions together. Mr. Brownen prepared an alkaline solution of the pancreatic secretion and also a dilute alcoholic solution, but he did not say which he used in these experiments; he should be glad to know which was used, or if both, if similar results were obtained. With regard to the violet reaction of peptone mentioned by Mr. Brownen, Mr. Plowman said there was a special product obtained by the action of the pancreatic secretion on proteids, which gave a violet reaction with chlorine; and there was the common reaction of peptones, which was obtained by adding cupric sulphate and an excess of caustic potash. When a very small quantity of sulphate of copper was added, a red coloration was produced, but with an excess of the sulphate a violet colour was produced. He should be glad to know which reaction Mr. Brownen referred to. Because he got this violet reaction, Mr. Brownen supposed that there was some nitrogenous impurity in the gum which produced it, but as a matter of fact pancreatic juice contained albumen in some considerable quantity and an intrinsic digestion of itself went on immediately after it was secreted, by which peptones were produced, so that the pancreatic juice of any age would itself give the peptone reaction. With regard to the action of the acidified solution, he would remark that as a matter of fact large quantities of undigested starch pass from the stomach into the duodenum, not being converted into glucose or dextrine by the saliva. There was no doubt further, that the contents of the stomach were not immediately neutralized by the biliary and pancreatic secretion, and, therefore, it would be useful and economical for the ferments in the pancreas to be capable of acting on starch, while the contents of the intestinal canal were still slightly acid. Further, it was proved that the actual body existing in the perfectly fresh and still warm pancreas had very little proteolytic action, and to that hypothetical body existing in the pancreas the term zymogen had been given. On keeping the pancreas for some time that zymogen was split up into the proteolytic ferments and that change was also brought about very readily by dilute acids.

The President said there was one point mentioned by Mr. Plowman which it would be out of order for the Conference to discuss, and that was the question of vital force. On any other portion of this interesting subject he should be glad to hear further discussion.

Mr. Groves suggested that when Mr. Brownen continued his experiments, he should try the action of these ferments on each other. It was often the practice to give the pancreatic ferment and the peptic at the same time, but he thought it not unlikely that they might digest and so destroy each other. As Mr. Plowman had remarked, in the economy of nature they were added successively, first ths saliva, then the gastric juice, then the pancreatine and then the bile.

Mr. Atkins said that, bearing in mind the President's caution, he had only one remark to make and that had no reference to the moral question or the one which was open to discussion. It was simply this, that in all these experiments it must not be forgotten that there was a vital force, though they could not go into the question of its origin or nature.

The President said they must not even have any discussion whether there was or was not such a force.

Mr. Atkins said he remembered that some years ago in America, some very interesting experiments illustrative of the processes and results of digestion were made on an Indian who had had a portion of his chest shot away; those experiments were conducted in the stomach and outside it, by the same agents, and wonderfully different results were obtained. Another familiar illustration of the same thing was, that if you wanted to make sea water, you might ascertain by analysis the ingredients of sea water and add them to fresh water, but you did not get the same result. In nature's laboratory there was something or other which made all the difference between artifical sea water and natural. One very interesting point in connection with this paper was as to the development of bacteroidal life. He understood that if the result of the processes of digestion were acid rather than alkaline, that development did not take place. This was an extraordinary fact, which was one rather for medical men than pharmacists to consider, but it was very interesting, and if it at all lay in the direction of Mr. Brownen's future experiments, he hoped he would pay some attention to it. If in the process of digestion there was an acid result, it was followed by an immediate extinction of that form of life which otherwise, perhaps in a few minutes, would be very largely developed.

Dr. Symes said he had made a note to ask the same question as Mr. Benger had put, because it struck him that the amount of residue was such as might be expected if the infusion had remained without the addition of the ferments. He should like to say, too, that this was rather a difficult investigation, inasmuch as, leaving out the vital force, these things were given, not to people in health, but to those who were sick, and consequently the results were not the same if one were experimenting on a healthy person. It was desirable, also, to follow as closely as possible the mechanical conditions which surrounded the use of these medicines. He remembered the case of the dialysed iron referred to by Mr. Plowman; on that occasion Professor Redwood had mixed the dialysed iron with peptone and had allowed it to digest for two hours in a glass bottle before attempting to dialyse it, and he pointed out then that he was not following the process of nature, under which a person began to digest the dialysed iron immediately it was mixed with the ferment, and the surrounding tissue was not a glass bottle, but the stomach, from which a certain amount of diffusion took place. All these points required consideration in prosecuting this study; he thought, too, that more satisfactory results might be obtained if the investigation were carried on, using diastase, than the animal ferments.

Mr. Kingzett said the discussion ought not to close without reminding Mr. Atkins that the biliary secretion was not acid but alkaline.

Mr. Symons asked if Mr. Brownen had tried the action of these ferments on starchy matters.

Mr. Brownen, in reply to the question put by Mr. Benger, said that at the same time that the experiments were made in the incubator they were also conducted on both acid and alkaline solutions of rhubarb, so as to control the tests. This would also apply to the remarks of Mr. Kingzett, because although he found that at the end of the time there was a small quantity of salicin split up by a temperature not exceeding 50° C., yet the greater portion of the salicin remained unaltered; he therefore presumed that the secretions had to do with the change which had occurred in the solutions he was then testing. A feeble acid solution was unquestionably amylolytic, but the amylolytic ferment acted more powerfully in an alkaline or neutral solution than the feebly acid solution; and if the acidity exceeded 2 per cent. it was almost completely neutralized or destroyed. Whether it could be reproduced again remained to be decided by further experiment. The temperature of 50° C. was adopted because it was the one at which he found the gastric and pancreatic ferments acted most rapidly without decomposition, though it ran very near that point. He therefore adopted that temperature, and never exceeded it, but many of his experiments were made at a much lower temperature, that of the human body, about 98° F. He used the higher temperature in order to obtain the maximum result of salicin, which he found was slowly decomposed even by the gastric ferment as well as by the pancreatic, and he wanted to get, within a reasonable time, the maximum amount of work from those ferments. The solutions used were a mixture of alcohol and water rendered slightly alkaline in one instance for pancreatine, and then rendered distinctly acid in the other case, so as to obtain an acidulated solution; the amount of alcohol and water being the same in each case. The glycerine experiment was made in order to see what the action would be without either alkali or acid. He used also, working in the laboratory of Messrs. Savory and Moore, their acid elixir and the neutral essence, testing them side by side with these other solutions, but he had not mentioned this in the paper, as he wished to avoid all trade reference. The violet reaction he obtained was with the copper solution, and not with chlorine. He tested the solution of gum, because in the lectures which Dr. Gamgee gave at the Royal Institution, he laid great stress on an emulsion of almond oil perfectly sweet, and the action upon it of a feebly alkaline pancreatic extract, which in a very short time became distinctly acid. He wanted to find out whether that acid was derived from the gum or from the oil, and he found that it was not derived from the gum, but from a small portion of the oil going into the acidulous state; but there was this other substance which he supposed was a constituent of gum, not perhaps an impurity, but an invariable constituent of the best white gum, acted upon, although the arabin was not acted upon by these secretions. Although these ferments seemed to act, one in an acidulous condition, and the other best on starch in an alkaline condition, yet they seemed as they passed the duodenum to become rather alkaline than acid. Some extracts of food he had obtained in different degrees of digestion, and also in some experiments in which he had tried to simulate the digestive processes (*minus* the vital force, which was objected to), had led him to the conclusion that the bacteroidal fermentation need not occur in any of the conditions necessary for digestion. In fact, there seemed to be a point in the digestion of the proteids analogous to the transformation of alcohol into acetic acid. These bacteroidal forms set up putrid fermentation which would invariably tend towards alkalinity rather than acidity. On raw starches he found very little action; that was why he boiled the infusion of calumba, contrary to the ordinary Pharmacopœia directions. He supposed the compilers of the Pharmacopœia wished to get rid of the starch, but in his experiment he wished to obtain the maximum action on cooked substances.

Remarks on the Root of Aconitum Napellus and other Species.

BY E. M. HOLMES, F.L.S.

Although aconite has been used in medicine for at least a hundred years and is recognized as one of the most powerful of medicinal agents, its internal use is not quite so general in this country as its properties might lead us to expect. Perhaps this is owing to variation in strength of the official preparations and to the known danger of using too large a dose. How far this variability is due to a non-recognition in the Pharmacopœia of well-known facts, may be open to question, but it appears certain that the requirements of that book might be complied with, and yet that preparations very variable in strength might be the result. That such is the case is proved by the statements made by Mr. Cleaver concerning extract of aconite (*Pharmaceutical Journal*, [3], xii., 722) and by the recent experiments made with the alkaloid, which have shown that one commercial sample may be seventy times stronger than another.

The Pharmacopœia describes aconite root thus:—

The dried root of *Aconitum Napellus*, L. (*Pharmaceutical Journal*, [1], xv., 449). The root may be "imported from Germany or cultivated in Britain and collected in the winter or early spring, before the leaves have appeared."

In the first place the figure of the root referred to is totally inadequate to distinguish the root of *A. Napellus* from that of other less poisonous species, the variation in form being very great, according to the age and position of the root. In the second place the root imported from Germany is collected by peasants who, as a rule, are not possessed of botanical knowledge, and is sold without any guarantee that it is collected in winter or early spring; indeed it is difficult to understand how the root of *A. Napellus* could be found before, or distinguished after, the leaves have appeared. Thirdly, the root is not cultivated as a crop in this country, because it could not compete in price with the German drug.

Under these circumstances it is easy to understand why the alkaloid of commerce varies in strength and why the preparations are also liable to a similar fault. It is also obvious that even the most careful chemical investigations of the commercial root must be founded on an unreliable basis, and that the results obtained by chemical analysis must in consequence be to a certain extent devoid of scientific value.

It becomes extremely important, therefore, that so powerful an agent should receive at the hand of the pharmacist far more attention than has hitherto been accorded to it, and that every means should be used to provide the medical profession with preparations of aconite as nearly as possible of uniform strength and perfectly reliable. This is the more desirable since aconite is now being used in the treatment of inflammation of the lungs, in puerperal and other fevers, and in acute cases in which prompt and reliable action is of the utmost consequence. The chief difficulty in making such a preparation is in obtaining the typical variety of the right species. De Candolle describes twenty-nine varieties of the official species, *Aconitum Napellus*, but whether all these forms, which possess the same specific botanical characters in common, have the same chemical constituents, and whether, like isomorphic crystals and isomeric bodies in general, they have a different physiological action, is very difficult to ascertain, seeing that it is by no means easy to identify them for the following reasons:—First, because a complete series of the members of the genus is hardly to be found for reference in any botanical garden or museum; secondly, because the varieties sold by florists are not always carefully named; and thirdly, because they cannot be procured in sufficient quantity for purposes of chemical investigation.

Moreover, botanists are not agreed as to the forms which should be placed under each species. Steudel enumerates about eighty which have been grouped under *A. Napellus* by different botanists. The aconites are so closely allied, and the varieties run so much into one another, like the willows, brambles, roses, mints, and cinchonas, that even De Candolle has placed the same plant under two varieties. Professor Maximowicz, who has paid considerable attention to the species occurring in Japan, remarks in a recent letter,—"The genus *Aconitum* is, botanically speaking, a most difficult one, not one characteristic holding its own from species to species. It is a matter of personal opinion, whether you accept a dozen species in all, while another thinks to separate thrice the number. I have observed them in Mandshuria and Japan very assiduously and have despaired of finding well defined species, for there will arise intermediate forms between such as in most cases are thoroughly different. One would think these were numerous hybrids, but they are as freely seed-bearing as the various hybrid aquilegias used to be."

Although it is almost impossible to define accurately in botanical terms the different aconites, it seemed to me worthy of inquiry whether those available for pharmaceutical purposes might not be characterized sufficiently for all practical purposes. It is well known that the Japanese peppermint plant, although botanically it offers no character to separate it from *Mentha sativa*, is readily distinguishable by taste, and it is, therefore, natural to suppose that the different forms of aconite might be distinguished to a certain extent in the same way. Experimenting in this direction I found that the roots of several species of aconite did not cause a tingling sensation when chewed, and that this was the case not merely with the Asiatic species, *Aconitum uncinatum*, *heterophyllum* and *palmatum*, but that also several plants which present the specific characters of *A. Napellus*, although easily distinguishable from it by habit, present the same peculiarity. Of these I may mention that forms which were supplied to me under the names of *A. Napellus*, var. *pyramidale* and *paniculatum*, etc., did not cause tingling when chewed, while others, such as *Stoerckeanum* and *albiflorum*, produced a slight, and others again, such as *A. autumnale*, a very powerful tingling sensation. Here a difficulty is met with in the fact that the plants are not always correctly named, either in botanical gardens or in the collections of florists, from labels becoming displaced. But all of the aconites in which this variation occurs, so far as I have observed, flower later than the typical *A. Napellus*, so that if the Pharmacopœia added to its description "the root obtained from plants flowering in May and June," and erased the words "imported from Germany," one cause of the unequal quality of the root would be removed. This is all the more important, since I have determined by direct inquiry that some florists would supply to a grower the plant flowering in May and June, and others would supply any variety of *A. Napellus* that happened to be in stock, no difference in the properties of the varieties being known to them. The only way to secure aconite of good and uniform quality appears to be to limit the official drug to home-grown aconite flowering in May and June and gathered when the plant is in flower. In this way there can be no mistake about the species, and the leaves collected at the same time could be used for making extract. Even if the root were thus not gathered in its most active condition, it would at all events have the advantage of uniformity of strength, which is of much more importance.

The aconite has the property of developing roots instead of leafbuds in the axils of the lower leaves, provided that these are covered with soil. Whether this property has been conferred on the plant with the view of enabling it to approach nearer to the surface when, as must often happen in its native mountains, the plant becomes almost buried by the fall of *débris*, or the earth washed away from the root by floods, or to propagate the species when not under favourable conditions for producing seed, it could at all events be turned to account in cultivation, since by earthing up the stems a larger yield of roots would probably be ensured.

In testing aconite root by taste it must be remembered that the tingling sensation is often not developed for ten minutes and lasts for two or three hours, so that half a day must be allowed to elapse before tasting a second sample, to prevent the chance of confounding the effect of one root with that of the next.

In conclusion, aconite is very easy of cultivation, and considering the small quantity used there is no reason why any chemist who has a small piece of garden should not grow his own aconite root.

The President, in proposing a vote of thanks to Mr. Holmes, which was carried unanimously, said his suggestions with regard to drugs were always acceptable, and these now given would doubtless have full consideration.

The next paper read was on—

Ammoniated Extract of Ergot and a Process for its Preparation.

BY A. W. GERRARD, F.C.S.

For ten years or more I have known a preparation bearing the above name; how long before this it had been in use or to whom it owes its origin, I can give no information.

My earliest practical acquaintance with this extract dates some five years back, about which time I was asked by one of the then obstetric assistants to University College Hospital to prepare some for him, as he wished to try it, having seen it used successfully in a general practice. In the absence of any published or private formula to guide me it was left to my discretion to follow such a process as I thought best suited for the object in view.

I premised at starting my experiments, that the preparation to have any good right to the name it bears should have ammonia employed in some form or other as the solvent of the extractive matters of the ergot, and not that the ammonia be merely added after an aqueous extract had been made. For this purpose the solvents that appeared most available and worthy of trial were aromatic spirit of ammonia, and solution of ammonia.

From a first consideration of the requirements of the case it seemed easy to frame a process that ought to give a satisfactory result, but practice proved the contrary. No difficulty was experienced in producing an active therapeutic agent, but a good deal of trouble had to be taken before an elegant or presentable pharmaceutical preparation resulted.

Experiments with Aromatic Spirit of Ammonia as the Solvent.

First experiment.—Ten ounces of well-crushed ergot was moistened quickly with the spirit and packed in an air-tight percolator, more of the spirit was added till 10 ounces was reached. Percolation proceeded very slowly, in twenty-four hours less than 1 ounce of percolate had passed; displacement was now resorted to by means of water, but the process went on so slowly that after four days only 5 ounces of percolate was obtained, meantime the displacing column of water had become strongly alkaline from the diffusion into it of the ammonia. The experiment was stopped.

Second experiment.—The same quantity of ergot was employed, but it was packed looser in the percolator, and 20 ounces of the aromatic spirit poured over it in several portions; percolation was still slow, but more rapid than in the first experiment; 9 ounces of percolate was obtained, very high coloured and rich in extractive; on attempting to displace the remainder of the spirit the same difficulty arose as in experiment No. 1.

If the second experiment had been successful I intended to have followed a process of repercolation, but the difficulty of displacement, and consequent waste of material, made it evident that the process would not answer. Therefore no further experiments were undertaken with this solvent.

Experiments with Ammonia Water as the Solvent.

First experiment.—Ten ounces of crushed ergot was treated with 50 ounces of water to which 1 per cent. of strong solution of ammonia had been added; on contact of the ergot and ammonia a marked deepening of colour to a purple was observable, this being the usual reaction of alkalies upon the colouring matter of ergot; at the same time an almost immediate softening of the drug is apparent, it being evident that water in the presence of the alkali rapidly penetrates its tissues. This action as compared with that of water alone is very marked, and although it produces a rapid removal of the extractive, it exercises an influence detrimental to percolation; the ergot swelling and softening so much as to assume a half colloid state, unsuited for the filtration of the solvent. Under these conditions the exhaustion of the ergot was so slow as to make it evident that the ammonia was present in excess and a weaker solution should be tried.

Second experiment.—The same process was repeated as in the last experiment, using a $\frac{1}{2}$ per cent. solution of strong liquor ammoniæ. Here the action was similar to that described in the last experiment, but much less in degree, and not enough to prevent percolation proceeding in a satisfactory manner. Thus the exhaustion of the ergot by means of an ammoniacal solvent was accomplished, and after a few further experiments the following formula was formed:—

Formula for Ammoniacal Extract of Ergot.

Take 10 parts of crushed ergot, macerate it for eight or ten hours with frequent stirring in 50 parts of cold water, containing ½ per cent. of strong solution of ammonia; then throw it upon a flannel strainer, and allow it to filter. Wash the ergot from time to time with more ammoniacal water, till sufficiently exhausted. The filtrate, which is somewhat turbid, is evaporated to 5 parts, any scum or fat rising to the surface being carefully removed. The extract when cool is treated with an equal volume of aromatic spirit of ammonia, and the product set aside until subsidence is complete; the clear portion is then decanted and the residue filtered through felt or flannel, washing the deposit with a little more spirit, so as to bring the volume of the extract to 10, 1 part fluid thus containing the soluble matter of 1 part solid of ergot.

In appearance this extract is much darker in colour than the ordinary form, the odour is mainly ammoniacal, and the average specific gravity 1000.

A sample I have kept for nearly a year does not appear to have undergone any change. The dose is the same as the ordinary liquid extract.

In studying the above process it may strike some observers as somewhat curious to use ammonia as a solvent, and then to dissipate it by evaporation, but it must be remembered that the ammonia is not eliminated until its work has been accomplished, and what therapeutic action it might have exerted is compensated for by the addition of the aromatic spirit.

In the process of manufacture, whilst evaporation is proceeding, it will be noticed that not only albumen and colouring matter separate but a considerable quantity of oil. The presence of this oil is accounted for by the formation of a soap between the ammonia and ergot fat during maceration, the soap remaining in solution whilst cold, but being decomposed by heat.

This extract, as regards its therapeutic value, has had a thorough trial in the obstetric department of University College Hospital, and has given general satisfaction, Dr. John Williams, one of the obstetric physicians, having requested it to be substituted for the ordinary extract in such mixtures as contain ergot.

To enter into a discussion as to why ammonia improves or increases the action of this drug is scarcely within the domain of pharmacy, and published therapeutic memoranda on this point are wanting. From inquiries I have made, it appears, as the result of numerous observations, that the ammonia developes a rapid action of the drug by acting as a nervine stimulant, which action is very useful during that period when the patient has to undergo that painful and trying ordeal for which ergot is so extensively employed. To this must be added the great solvent power of the ammonia, which ensures a most complete exhaustion of the active principles of the drug.

The President proposed a vote of thanks to Mr. Gerrard, which was carried. He said he was glad to find that Mr. Gerrard had had the courage to publish his failures as well as his successes, as such a course rendered a paper far more useful to future investigators. Their knowledge of the shoals of the sea of pharmacy, as well as of its depths, could not be too thorough.

Mr. Stuart asked whether it was not possible, with so small an amount of ammonia, that the whole of it might form a soap with the oil, and hence be neutralized, and whether an equally good result would not be obtained from a simple aqueous extract. He understood this was a superior preparation to that of the British Pharmacopœia, and he believed that in many quarters amongst medical men the British Pharmacopœia formula had for obstetric purposes fallen into discredit. If this ammonia process were a good one it would be a distinct gain to pharmacy and to the medical profession. In the United States Pharmacopœia since 1860 an acid extract of ergot had been used. Dr. Squibb was one of the originators of the process which included the maceration of the ergot with dilute alcohol in which there was a little acetic acid. He noticed in the report which the President read as to the proof sheets of the new Pharmacopœia that that acid was now exchanged for hydrochloric acid, but the Committee still adhered to the acid preparation, and in his experience, having made from the original formula large quantities of the preparation of ergot, that was immensely superior to the British Pharmacopœia process. It was a curious thing that apparently both an alkaline and an acid preparation should produce good results, but the chemistry of ergot was, notwithstanding all the investigation which had taken place, still in an undecided state.

The President remarked that in the formula of the United States Pharmacopœia now being issued, not only was hydrochloric acid substituted for acetic acid, but the glycerine formerly used was omitted.

Mr. Stuart thought from his experience that that would be an improvement.

Dr. Symes said all these investigations tended to show that water was really capable of extracting the active principle of ergot. He thought it had scarcely ever been questioned that the formula of the British Pharmacopœia really worked admirably. He did not understand Mr. Gerrard to claim that this was a superior preparation, but what he found was that certain ammoniated preparations were put forward by certain houses as being the original, the only genuine, and all that kind of thing; that they varied considerably in appearance from very pale sherry to a dark blackish colour; that he with many others had been rather surprised that all should be the original and the best, and had, therefore, investigated the subject. They were much indebted to him for so doing. He certainly thought in using the small quantity of ammonia that he did it was quite possible that a soap was formd, but that would only have the effect of removing a certain amount of oil from the ergot, and enable the water to act more freely than it otherwise would do; he would probably have alkaline soap acting on the ergot.

Mr. Martindale said he had been asked to make an ammoniated preparation of ergot for a medical practitioner, who told him that he had some which was much more active than he had ever been supplied with according to the British Pharmacopœia. That was eight or nine years ago, and since that he had continued to make a very satisfactory preparation. He could quite corroborate what Mr. Gerrard said that ammonia either in an aqueous or somewhat mixed aqueous and alcoholic solution had a powerful action in abstracting the active properties of ergot, making a strong dark brown solution immediately, but he thought Mr. Gerrard's process was a little too complicated. He did not adopt anything like so complicated a process; he used about equal parts of spirit and water mixed with one-eighth of solution of ammonia, which he percolated through the ergot in fine powder. The first product was set aside, the latter product evaporated to a certain small bulk, and then mixed with the other. He thought it was better to use an ammoniacal preparation of this kind rather than the one made with sal volatile as given in the new London Hospital Pharmacopœia. There the ergot was treated first with sal volatile, and after percolation to a certain extent the first product was set aside and the marc treated with so much water heated up to 160° F., so that it proceeded somewhat on the lines of the British Pharmacopœia process; this second product on evaporation was added to the percolated portion. There was no question that ammonia was a very powerful solvent, much greater than simple water, of the active properties of ergot. He had made a preparation according to the American Pharmacopœia, and the acetic acid solution there had undoubtedly a similar action to the ammonia in the process now described. He certainly did not think the British Pharmacopœia process was a good one; it never yielded really good results in his hands.

Mr. PARKER thought that in the present state of knowledge of the chemistry of ergot they were working somewhat in the dark in devising formulæ for its preparations. It was not known upon what exact constituent the activity of ergot depended, and therefore, they could not work out a process based on their knowledge of its chemistry. That being the case, before drawing any conclusions as to whether simply an aqueous, an acid, or an alkaline extract was best, they should start with a certainty as to the quality of the drug operated upon. Many drugs, ergot and cantharides especially, varied very much in quality according to the manner in which they were collected and stored. A good sample of ergot after being kept some time, unless very carefully kept, might be entirely deteriorated; therefore, the first thing to do would be to prove the activity of a sample of ergot; then from the same sample prepare an aqueous, an acid and an alkaline extract, and have them submitted to a comparative therapeutical examination.

Mr. GREENISH said he felt very much indebted to Mr. Gerrard for bringing this subject before the Conference, and if the amended preparation of ergot was not medicinally more active, which he was disposed to question, at least, the paper possessed considerable interest from the fact that this had hitherto been regarded as a secret preparation. He was not at all prepared to accept the statement that this preparation was better than that of the British Pharmacopœia. He recollected that Blumberg, who had paid great attention to ergot, had stated distinctly that water was quite sufficient to extract the active principles. Now, if a man like that, who had paid perhaps greater attention than anyone else to ergot and to the isolation of its active principles, had arrived at that conclusion, he thought they were justified in adopting it. Professor Dragendorff, who had also paid great attention to the subject, found that water was quite sufficient to extract the active principles. He should like to have heard from Mr. Gerrard the results of some more comparative trials by medical men of the two preparations, and he suggested that in experimenting upon ergot he should extract the fat from it previous to applying any menstruum.

Mr. HAMPSON said they were all much obliged to Mr. Gerrard for the formula he had given, because they wanted one to satisfy the demands of their medical friends, but he very much doubted if it were really any improvement on the former preparations. He could speak from direct knowledge of the efficacy of the British Pharmacopœia preparation in an institution with which he was acquainted, where that preparation, well prepared, was used and was always satisfactory.

Mr. MARTINDALE said no doubt water in itself was a good solvent, but the disadvantage was so much of it was required; the amended preparation could be prepared with very much less bulk and without having to evaporate it down for such a length of time.

Mr. PLOWMAN said there was one more point in connection with ergot which must be borne in mind; in the British Pharmacopœia process the oil was extracted with ether and rejected. Now, it was not proved by any means that that oil was inert, and so late as 1881 a paper was published in which amongst other things it was said to "constringe the blood vessels," and it was possible that a hydrochloric solution might extract the principle which was by the British Pharmacopœia process taken out by the ether and rejected. In Mr. Gerrard's process, in which a scum was formed which was skimmed off, some of the active principles might be withdrawn. He should like to know whether that had been rejected definitely without any experiment being tried to ascertain if it possessed any activity.

Mr. SCHACHT thought this question had been answered very elaborately within the last few years by a French authority. Two memoirs of considerable detail had been published by two different medical authorities about the various properties and powers of the different principles of ergot. In the one he remembered perfectly well that very considerable remedial power was attributed to this oily constituent of ergot, whilst a later writer on the subject contradicted almost word for word the opinions expressed by the previous chemist on that point. He thought Mr. Parker was right in his caution about elaborating processes too carefully until they had more knowledge about the chemistry of ergot and the therapeutical value of the particular ingredients capable of being separated from it. He might also venture to remind the meeting how carefully the late Mr. Stoddart had at one time worked, not only on this subject, but on the ergots of grasses generally, and then he found that even such principles as he was able to detect generally in them varied according to the time at which they were gathered. Many other points of interest had still to be cleared up before they could attach too much value to any particular suggestion with regard to these preparations.

Professor QUINLAN said it was a constant habit with medical men, particularly in obstetric practice, when using ergot to add to it a small quantity of ammonia. It was a well-known fact, which anyone could prove for himself, that ergot had the power of diminishing the tension in the capillary blood vessels, whilst ammonia had the contrary effect; therefore, a little quantity of ammonia was found to have a useful corrective effect in the exhibition of large doses of ergot.

Mr. GERRARD said it would be an answer to many inquirers if he stated at once that he did not claim for this preparation any activity beyond that of the liquid extract of the British Pharmacopœia. But the addition of ammonia appeared in some way to assist the activity or improve the action of the ergot. Those who used it gave it the preference, and every observation went to confirm this fact. Professor Quinlan had also corroborated that the addition of ammonia to a preparation of ergot, whether prepared first by simple aqueous extraction, or by ammoniacal extraction, did improve its action, probably by the fact that it was simply an adjunct and a stimulant. Mr. Stuart had referred to the use of acidulated water as a solvent for ergot preparations. He had no doubt that acidulated water was as good a solvent as water itself, or ammoniacal water, but it was a much slower solvent; by adding acid to water containing any albuminous principles, the passage of the water through the tissue was retarded. But the addition of alkali, on the contrary, caused a rapid penetration of those tissues, and that was just what took place here. It might be, too, that ammonia acted in some way to eliminate them and make them more soluble. It might be that it formed a combination with what had been called the active principle of ergot, sclerotic acid, although he did not himself look upon that as a definite substance. Mr. Martindale's process was similar to the one he had tried of using aromatic spirits of ammonia as a solvent, but practically he found that exceedingly difficult to work; he could not obtain a good process, there was considerable waste. The process of displacement was not practicable; there would take place a diffusion of the ammonia into the water used for displacement, and thus there was a loss, not only of ammonia but of the solvent and some of the ergot principles. There was this to be said, that if it could be carried out successfully in such a preparation there would be present not only the soluble extractive matter of the ergot, but also the ergot fats in the form of ammoniacal soap, and if those ergot fats did play any part in the action of the drug it would be an advantage, though according to the experiments mentioned by Mr. Schacht that appeared to be doubtful.

The next paper read was on—

TUMEFACTION AS AN AID IN THE IDENTIFICATION OF THE VARIETIES OF MARANTA AND OTHER STARCHES.

BY W. H. SYMONS, F.R.M.S., F.C.S.

It has been shown by different investigators that Bermuda, Natal and St. Vincent arrowroots require for their tumefaction water of varying temperature.

Since these starches are probably identical in chemical composition, it follows that this behaviour must be due to some physical cause, most likely the greater or lesser density of the integuments. Seeing this, I was led to infer that any reagent which affects starch in the same way as hot water ought also to yield comparatively the same results.

Several reagents were accordingly tried. The caustic alkalies being found the most powerful and uniform in their action were chosen for further experiments. Solutions varying from 0·5 to 1·5 per cent. of chemically pure caustic soda were prepared, and 1 c.c. of each strength solution placed in a small vessel; to every vessel was added ·1 gram of the starch to be examined. The mixtures were well stirred at intervals for ten minutes, after which they were examined under the microscope.

The following precautions were observed. The starches compared were examined side by side. The alkaline solutions were of known strength, freshly prepared, exposed as little as possible to the air, and on no account allowed to evaporate when mixed with the starch. A constant proportion of starch and solution was used, it having been ascertained that if a small quantity of the solution burst any of the granules a larger quantity would burst all.

From these numerous precautions it may be thought that this process is much more tedious than merely placing starch in water of a known temperature; but in practice it is not so, quite as much care being necessary in the latter case as in the former, and a larger quantity of starch is required.

The results are tabulated to show the strength of the solutions, which respectively tumefied, 1st, a few granules; 2nd, the majority of the granules; and 3rd, all the granules. The numerals in the left-hand columns show the order which the starches would take, if arranged according to size. A table showing tumefaction by heat is also given.

Tumefaction by Caustic Soda.

Order of size.	Starch.	A few swollen.	Majority swollen.	All swollen.
2	Potato	·6	·7	·8
8	Oat	·6	·8	1·0
4	Natal	·7	·8	1·0
1	Tous-les-mois	·7	·9	1·0
5	Wheat	·7	·9	1·0
4	Bermuda	·8	9·	1·1
3	Sago	·8	·9	1·1
6	Maize	·8	1·0	1·1
7	Cassava	·8	1·0	1·1
4	St. Vincent	·9	1·0	1·2
9	Rice	1·0	1·1	1·3
		Per cent. solution.	Per cent. solution.	Percent. solution.

Tumefaction by Heat.

Order of size.	Starch.	A few swollen.	Majority swollen.	All swollen.
2	Potato	55° C.	60° C.	65° C.
7	Cassava	58° C.	63° C.	68° C.
4	Natal	58° C.	65° C.	70° C.
5	Wheat	60° C.	65° C.	70° C.
1	Tous-les-mois	65° C.	68° C.	72° C.
4	Bermuda	62° C.	69° C.	73° C.
3	Sago	64° C.	68° C.	74° C.
6	Maize	65° C.	70° C.	77° C.
8	Oat	65° C.	70° C.	77° C.
4	St. Vincent	66° C.	73° C.	77° C.
9	Rice	70° C.	75° C.	80° C.

With the exception of the oat and cassava starches, the starches in both lists will be seen to be arranged in nearly the same order. The oat starch under the microscope appears clean, but with the caustic soda it forms a yellow paste, indicative of gluten, which does not interfere with the action of the alkali, but does with that of hot water.

In a paper published in the first number of the present volume of the *Pharmaceutical Journal*, I pointed out the striking relation which exists between the temperatures under which the starch grew and its tumefying point. "The higher that temperature, the higher the point of tumefaction," but I said "cassava and oat starch are exceptions." However, using the alkaline method of tumefaction these starches are also seen to bear this relation. The reason why oat starch does this has been given above, but why cassava starch should behave differently to hot water and the alkali I do not know; it was tried repeatedly with both reagents and always with the same result.

Instances are on record of analysts having certified pure maranta and other starches as adulterated, where, subsequently, more competent microscopists have proved the starches assailed to be genuine, although not until the accused retailer had suffered considerable annoyance and been put to great expense to defend his case. This, I think, proves that, in some instances, it needs more time to practise the microscopical identification of the starches than the analyst is able to devote to that branch of his studies. Therefore any chemical test which comes to the aid of the microscope in such cases must prove useful. The tumefaction of starch by the above process needs no special practice, yet affords additional data, and hence may, I trust, fulfil the condition mentioned above.

The PRESIDENT, in proposing a vote of thanks to Mr. Symons, said he had put a new method into the hands of workers in pure science and applied science, and one by which they might confirm the results obtained by other methods. He was sure, for this last addition to his work on the starches, the Conference would accord him a vote of thanks.

Mr. GREENISH could not allow this paper to pass without one or two observations. They were much indebted to Mr. Symons for giving them any assistance in determining the kind of starch they were examining, in addition to the microscope. Starch was almost universally diffused in nature, but in using the microscope for determining its presence, they found it very often where they did not expect to find it, and where really it had no business to be, whilst in other cases, when a particular kind of starch ought to be present, some other was detected. Starches being so widely distributed, any means by which they could be determined should be welcomed by pharmacists. Mr. Symons had confirmed some investigations of his own with regard to Bermuda, St. Vincent, and Natal arrowroot. Several years ago some maranta grown in Natal was pronounced by many public analysts to be potato starch, and it presented a considerable resemblance to it, but a good microscopist could determine the difference. There was, however, a great difference between maranta grown in Natal, and that in Bermuda or St. Vincent. The reason of this he could not explain, but such was the case. He was not sure that this method would be of very much service without the microscope, on which he should prefer to rely, and in the examination of starch he thought it was desirable to use one particular power, and adhere to that power for all starches. The relative sizes of the starch grains were of great importance, and these could best be determined by an educated eye, using one particular power. He also found that if the medium in which the starch is examined be coloured, it assisted the observer, and in addition to the microscope, the polarizer might be used to advantage.

Mr. SYMONS said he did not put forward this method as superseding the microscope, but by this means it was quite possible to distinguish between Natal arrowroot and potato starch. If Natal arrowroot were mixed with ten times its weight of ·8 solution of caustic soda, it would only be partially tumefied; if it were potato starch, it would tumefy completely. It took a 1 per cent. solution to tumefy Natal arrowroot to the same extent.

(*To be continued.*)

Review.

THE PHARMACOPŒIA OF THE LONDON HOSPITAL. Compiled under the Directions of a Committee appointed by the London Hospital Medical Council. London: J. and A. Churchill. 1882.

From the preface of a volume bearing the above title recently put into our hands by Messrs. Churchill and Co., we learn that the previous edition of the Pharmacopœia of the London Hospital has become exhausted, and that the present work is intended not only to keep abreast of the times, but also to form a useful guide to students in the art of prescribing.

The objects of a pharmacopœia are, first, to define the materia medica, and, secondly, to give formulæ for the various preparations from that materia medica. In this book the first of these objects has scarcely been fulfilled, for with the exception of certain chemicals from the British Pharmacopœia, to which "B.P." is attached, as a general rule no definition whatever is given of the various drugs. Rhubarb is described as rhei rad. simply—any rhubarb, English or foreign, may be used. For pepsine no mode of preparation is given, even the animal from which it is to be procured is not identified. Ergotine is mentioned, but it is particularized no further, although the mode of preparation has a great influence upon the strength of the product. We are glad to see that many new and recently introduced preparations of undoubted merit, such as sclerotic and hydrobromic acids, curare, gelsemium, thymol, homatropine, chrysophanic acid, pancreatin, etc., are included; but we miss an old and well-tried friend like cinchona calisaya, which is conspicuous by its absence, and even a liquid of such general utility as aq. dest. finds no place here. Although a form for ext. quebracho liq. is given, quebracho does not appear in the materia medica.

The formulæ are, however, as important, perhaps more important, than crude drugs, and here there is much to praise and a good deal to condemn. Hydrobromic acid is made by Fothergill's process, not the best either for purity of product or economy of preparation. The strength would be better stated in HBr rather than in Br. The formula for hypodermic injections, iodized cotton, extract of malt, etc., are good and well devised. The syrups are more properly glyceroles, and we can find no mode of preparing the "freshly precipitated" hypophosphites therein required.

The propriety of making all emulsions with tincture of quillaia is open to question, as is also the process for making ammoniated extract of ergot. The latter is anything but economical. The detection too of oil of theobroma with olive oil in a suppository basis is unnecessary.

The formulæ for children call for no special remark. The appendix contains directions for estimating urea and sugar in urine, for making staining solution, and a very complete list of poisons with their antidotes. The Latin abbreviations, the list of which includes many antiquated and obsolete forms, might have been left to 'Selecta e Prescriptis.' The work is completed by a list of metric weights and equivalents and a table of doses.

Although making a distinct advance on previous pharmacopœias, we cannot but wish that more care had been bestowed on the materia medica, and that the formulæ had been more fully revised. In a future edition we hope that this will be carried out.

Notes and Queries.

[733]. COLOURED CARBOYS.—In reply to J. R. Hill, I have been informed that coloured carboys were first introduced by the old alchemists, as a symbol that they were employed in the transmutation of the baser metals into gold.

The hieroglyphics were the same as those employed by the ancient astrologers to represent the planets. For instance:—

Gold (Sol) was represented by a circle ☉, indicating perfection and density.

Silver (Luna) by a semicircle ☾, because thought to be half gold.

Mercury represented by ☿, thought to consist of gold, silver and acrimony.

Copper, ♀, gold with acridity.

Iron, ♂, gold with acridity, dedicated to Mars the god of war.

Tin (Jupiter) ♃, half silver, half acridity.

Lead (Saturn) ♄, considered the oldest metal known, capable of destroying all others, resembling the father of the gods, Saturn, said to have devoured his own children.

FREDERICK DAVIS.

[737]. EXT. CINCHONÆ LIQUIDUM.—In reply to "737," the "divergent results" obtained by your correspondent with different samples of the above doubtless arise from each manufacturer using different samples of bark. The supply of yellow bark described in the B.P. as that of *Cinchona Calisaya* (Weddell), collected in Bolivia and Southern Peru, has certainly not met the demand for years, and therefore, in the absence of any official B.P. addenda, manufacturers may fairly lay claim to use their own judgment in making ext. cinchonæ liq., B.P., from bark of any hybrid or variety of *Cinchona Calisaya* which may happen to contain 2 per cent. of quinia. Some varieties of Indian bark contain more than the above percentage and yield at the same time more extractive matter to percolation. By using equal parts of Bolivian and Indian bark a very good sample of ext. cinchon. liq. may be produced, having a slightly higher specific gravity than that described in the B.P. At present dispensers are to a great extent in the hands of manufacturers for a supply of good liquid extract, but there are respectable wholesale drug houses who can be relied on to supply it.

SPECIFIC GRAVITY.

[738]. LINIMENTUM AMMONIÆ.—It is well known that the linimentum ammoniæ, B.P., becomes thick and lumpy after being kept for a short time. It may be of interest to your readers to know that this may be prevented by the addition of a small quantity (about 1 drachm to ℥iv) of spirits of wine. A. H. DOBSON.

Correspondence.

AUTOGRAPH PRESCRIPTIONS FOR IRELAND.

Sir,—The Council of the Pharmaceutical Society of Ireland having recently passed a resolution, proposed by me, authorizing a collection of autograph prescriptions to be formed for the use of the examiner in pharmacy, I am desirous to have the collection, as varied as possible, placed in books similar to those in use at the Bloomsbury Square examinations.

With this view, if any of your readers should be willing to contribute towards the above object, by sending original prescriptions to the undersigned, the favour will be alike esteemed and gratefully acknowledged by

48, *Henry Street, Dublin.* WILLIAM N. ALLEN.

LEECHES.

Sir,—A reference to pages 8 and 64 of the General Index to the Journal will show your correspondents that the subject of the "keeping of leeches" has received a fair share of attention. As, however, the Journals may not be at hand I may repeat the result of my experience, which has now extended over several years.

The best form of aquarium, at any rate the most economical, is the ordinary inverted bell or propagating glass, on a stand and with any suitable covering. At the bottom there should be a layer of mud 3 or 4 inches deep, procured from the bottom of a clear pond or ditch. Over this should be some well washed gravel. By far the most satisfactory plant to grow is the *Vallisneria spiralis*, as, if well rooted and not exposed to too much light, it thrives well, propagates, and keeps the water perpetually sweet. Otherwise the ordinary weeds from any pond will answer the purpose, only as they will not stand the "*forcing*" incidental to their changed circumstances they will require to be occasionally renewed.

Adopting this plan, we have kept from 20 to 30 leeches at a time, with rarely any loss. The water at present in the aquarium has not been changed for eighteen months, and before that it was not changed for six years, a quart or so only being now and again added to replace loss by evaporation.

The green on the side of the glass is a low form (conferva) of vegetable growth, which, though sometimes unsightly, aids in preserving the water. It may be prevented by putting the aquarium in a more shaded place. It should be remembered that submerged water plants do not require much light.

To those who care to see it, there is in a pond in a brickfield off Platt's Lane, Hampstead, the most luxuriant growth of *Anacharis* I have ever seen. The bottom is covered with plants from 12 to 18 inches high.

Has Mr. Hart any water snails in his aquarium? If so, the ova deposited on the side are more likely to be those of *Planorbis* or *Limnea*.

Slack's 'Marvels of Pond Life' is a book that will greatly aid the study of the microscopic forms of aquatic life, both animal and vegetable.

33, *Norfolk Terrace, W.* A. P. BAKER.

Sir,—In reply to "Aquam" I beg to state that the water in my aquarium was changed on June 30 last, and is now perfectly clear and free from smell, the evaporation of water having been reduced to a little over ½ inch from usual height in aquarium. The vegetation is very trifling, and I might state scarcely perceptible, neither have I noticed it much at any time.

Devonport. J. A. LAMBLE.

THE "NEW" STYPTIC.

Sir,—The paper read at the meeting of the British Pharmaceutical Conference, relating to the virtues of the plaintain, will undoubtedly be interesting to a great many. Why, however, it should be termed a "new" styptic I am rather at a loss to understand. Individually I have used it for many years as a hæmostatic in alveolar hæmorrhage, and consider it analogous to arnica and hamamelis in its action, though perhaps no better, if as good as the latter. In cases of odontalgia there is perhaps no better remedy. Applied after the Swiss method, *i.e.*, by tearing the fibres from the leaves and inserting into the ear of side aching, in cases benefited the fibres become black; if no relief is obtained they remain green. The ratio of cure is about seven-tenths of the whole number of cases. Its therapeutical value in erysipelatous inflammations, dysenteric discharges, lacerated and incised wounds, sphacelus, and as an antidote for ivy poisoning, it is decidedly of the first order. In point of fact it is one of the good old remedies, despised perhaps on account of its simplicity and discarded. The "new" sedative "pulsatilla" will likewise prove of much therapeutic value when more generally exhibited. It is very amusing to hear of these so-called "new remedies," lately discovered, and when we attempt to find out their "pedigree" to discover that Pliny, Hippocrates, and even Hahnemann prescribed them.

Exeter. JOSEPH ABBOTT.

MR. CYRUS BUOTT.

"The world is wide, these things are small,
They may be nothing, but they are all."

Sir,—Will you permit me to acknowledge the donations I have received since January last in aid of poor old Mr. Buott? It is with sincere regret I have to state that the fund is quite exhausted. I have not, however, withheld the weekly sum which for some time I have been enabled to give Mr. Buott and his daughter, who so devotedly attends on him, for I have hoped that I might continue to receive adequate additions to the fund.

In one sense I most reluctantly repeat my appeal, yet I am persuaded there are many who knew Mr. Buott when he was not an unimportant factor in pharmaceutical politics, who will not allow him to end his days in a state of unrelieved poverty. With this assurance I again make known his wants, and plead on his behalf. He is very old and feeble, but the care and kindness we may give will help to bring rays of brightness and comfort into his sick chamber.

THE INTERNATIONAL ELECTRIC EXHIBITION.

(*Concluded from page 222.*)

Among the modifications of Planté's important discovery that have been made there is probably none of them so well known as regards the name as the modification by Camille Faure, of Paris. As will be gathered from preceding statements, the Faure cell consists of two lead plates covered in the first instance by red lead. This coating being in a very loosely attached condition it is necessary to support it by wrappings of felt, and thus constituted it will be seen that M. Faure's modifications of Planté's great work are of a very simple character. It must, however, be admitted that Faure's combination possesses merit. According to M. Géraldy the Faure cell can store 3·28 kilogrammètres per kilogram, or 10·79 foot pounds per pound of lead. The most comprehensive comparison of the two accumulators that has yet appeared is due to Professor Silvanus Thompson, of University College, Bristol, who, in a paper read before the Society of Arts, has presented such a complete *résumé* of the whole subject of "Storage of Electricity" as to make that paper of the utmost value to anyone seeking definite information on this interesting and important subject. The comparison of the Planté and Faure accumulators is so compact, and yet comprehensive, that it is advisable to quote it direct:—

"No very reliable comparisons between the accumulators of Planté and those of Faure, or of De Méritens, have yet been made. Seeing that in each of these, when completely formed, the materials are the same—namely, lead and peroxide of lead immersed in dilute sulphuric acid—the maximum electromotive force must be eventually the same in each. The resistance of a cell is simply a question of size and shape. The relative strength of current actually furnished by these cells should therefore merely vary with their dimensions. The presence, however, of the felt, and its coatings of red lead, introduces resistance into the Faure cell, and as some recent determinations of M. Achard show, a Planté cell will heat a greater length of platinum wire, and do its work three times as quickly as a Faure cell, whose surface is of the same amount. One would also expect *à priori* that the layers of peroxide, formed upon the electrode by the working of the current itself, should be more regular, and yield currents with greater regularity, than the artificial and more rapidly-formed layers made by painting red lead upon the surface. On the other hand, M. Faure points out that taking cells of equal size, a larger proportion of the weight in his cell consists of the working substance, the weight of red lead placed in his cells being, for equal amounts of surface, about twenty-six times as much as the weight of peroxide produced by a "formation" during two years on the plates of a Planté cell of equal size. If this be so, it would imply that, though its resistance might be greater, and its rate of working slower than the Planté cell, the Faure cell would accumulate twenty-six times as much energy in an equal space. These figures require yet to be confirmed, and they are hardly borne out by the statistics of M. Regnier. Still less do they justify the extravagant pretensions that have been ignorantly set up on behalf of the enormous powers of the Faure cell—pretensions which have been angrily combated, though it is well to note that neither M. Planté nor M. Faure have taken part in this unpleasant recrimination. The Faure cell will do what the Planté cell will not, take in a greater charge, because it has a greater thickness of the working material, and it gives up its charge less rapidly. The Planté cell will do what the Faure cell of equal weight or surface cannot do, namely, produce rapid discharges in currents of greater volume; a property invaluable for the purpose of some of the applications already named."

The applications that had been previously mentioned were the application of the Planté cell for the operation of cautery, M. Trouve's surgical appliances including very small incandescent lamps to illuminate the cavities of the body—operation upon the larynx is given as an example—and dentists' appliances for destroying the nerves in hollow teeth; also, M. Achard's brake for railway trains, and M. Trouve's application of accumulators for propelling a tricycle up to a speed of 10 miles an hour are fully detailed. Amongst other applications especially deserving of notice are those describing the possibility of obtaining a powerful arc light for a few minutes from twenty cells, which time would be sufficient for some class experiments and for private spectroscopic work, also for photographic work, thus obviating the labour and expense of setting up fifty Grove cells. Further applications of accumulators appeared in *Nature* on June 2, 1881, in an article on "Electric Storage," by Professor Silvanus Thompson in the following words:—

"The uses for such secondary batteries may be of three kinds:—1. They may serve as portable supplies of electricity to be left and called for to recharge when exhausted. 2. They may serve to accumulate supplies of electricity from dynamo-electric machines, and store them until required for furnishing electric light or motive power on a small scale. 3. They may serve as equalizers of electric currents in a system in which the supply is liable to fluctuations. Suppose, for example, a dynamo-electric machine is employed to produce electric light. Any least thing which alters the speed of the machine, even for an instant, makes the light flicker and change in intensity; while the breakage of the engine-strap would at once cause total darkness. But if a secondary battery of suitable dimensions and power were inserted across the circuit between the dynamo-machine and the lamp, the inequalities of the current would be greatly modified. When the light was not in use, the battery would store up the current. If the engine failed, the battery would at once put forth its power. It is probably in this direction that the secondary battery will find no unimportant field of usefulness."

Other forms of accumulator have been devised by M. De Meritens, Swan, Sutton, Sellon and Volckmar, and some few others.

The De Meritens accumulator is a modification of Planté's form. The lead plates are made to overlap each other after the manner of venetian blind laths, the whole being secured to a stout outer framework of lead. This arrangement gives a greater effective surface in the space. The plates require forming as in Planté's cells.

The Swan accumulator is a modification of the Planté cell also. In this design, the surface of the lead plates is increased by forming lead foil into frillings, the interstices being filled with electolytically deposited lead.

The Sutton cell is a departure from all the preceding forms; it was fully described in this Journal, in the "Month" ([3] xii., 625). A great wonder connected with this form of accumulator is that it is entirely untrammelled by patent rights, a sufficiently astounding thing in these days. The cell appears to have given satisfaction to several amateurs who have constructed it.

No authorized description of the Sellon-Volckmar accumulator has yet been published, but from what little has been in print it would appear to be a decided improvement on the Faure cell, following closely in principle on that of Swan, whose patents have indeed been purchased by Mr. Sellon in order to save any future complications in the matter.

It may be mentioned here, that Mr. W. Symons, F.C.S., a well-known member of the pharmaceutical body, has published, in the pages of the *English Mechanic*, a description of an accumulator which would seem to be a useful and tolerably simple cell to construct. The acting materials are lead plates prepared by covering (on one side apparently) with red lead, the plates being immersed in an acidulated solution of sulphate of copper. If this article should induce any readers to attempt the construction of these fascinating and instructive electolytic apparatus, perhaps a few practical remarks on charging may be useful. As the electromotive force of a Planté, or Faure, or almost any other form of accumulator, may be taken as over two volts, it follows that the charging current must have an electromotive force greater than this, otherwise, the cell cannot be charged to its full power. This will necessitate the employment of two Grove's or Bunsen's cells or three Daniel's to one accumulator. If more than one accumulator is to be charged, the two or three primary cells can still be used if the secondary cells or accumulators are connected in multiple arc during the charging. As to when the charging is finished, this might be told by a galvanometer in circuit, or, perhaps, just as well by watching for escape of free oxygen at the peroxide plate. Too great an electromotive force should be avoided in charging the cells, as, although the charging is quicker, a great waste of current takes place in the form of local heat.

An important point is to have sufficient current density in charging, as the maximum polarization will not be attained unless there is sufficient current at every point of the area of the plates. According to Professor Silvanus Thompson it should not be less than 50 milliampères per square centimetre of surface in the cell. This would be found by ascertaining the current in the circuit in ampères, and dividing the total area of the plates in centimetres by the current found in the circuit.

According to the same authority there is a decided gain in forming a Planté cell by scratching the leaden surfaces.

This article forms the conclusion of this series of papers. At the commencement it was intended to describe the principal contents of the Crystal Palace Exhibition. It, however, appeared desirable to give a much more detailed description of the chief dynamo machines and lamps than would have been possible if the Exhibition had been noticed in the usual manner, which can only be done with advantage when readers are expert in the subject-matter of the descriptions; in this instance it was thought that the articles would be of greater utility if the reverse was assumed.

SOLUTION OF ACETATE OF ALUMINIUM.

The preparation of this valuable antiseptic, which is much used in continental hospitals, has heretofore often given annoyance by its tendency to deposit insoluble sediments, or by its readiness to gelatinize. It is owing to the labours of Professor Poleck, of Breslau, that the cause of this trouble has been ascertained and a process been devised which removes the drawback.

Professor Poleck confirms the previous statement of Walter Crum, that, on bringing together acetate of lead and sulphate of aluminium, there will be obtained as products, sulphate of lead, basic aluminium acetate, and free acetic acid. This latter was found to effect the change of the basic acetate into the insoluble modification, and it was therefore necessary to remove or neutralize it. This was accomplished by the following process, in which the sulphate of aluminium is assumed to contain 95 per cent. of the true salt, the remainder being the usual impurities found in the commercial article.

300 parts of sulphate of aluminium are dissolved in 800 parts of water, and the solution mixed with 360 parts of diluted (Germ. Pharm.) acetic acid (spec. grav. 1·041).

130 parts of precipitated carbonate of calcium are mixed with 200 parts of water, and the mixture gradually added, under stirring, to the former. The whole is allowed to stand for twenty-four hours at the ordinary temperature, being stirred occasionally; afterwards it is strained, the precipitate pressed without washing, the liquid allowed to settle, and finally filtered.

The filtered liquid has the specific gravity 1·0457. It will amount to about 1275 parts. It is clear, colourless, and has only a faintly acetous odour. On the addition of 2 per cent. of sulphate of potassium, and heating on the water-bath, it becomes gelatinous; on slow cooling, it becomes clear and liquid again after a short time.

The products of two different preparations by the above method had the following composition, showing that it is quite uniform:—

	I.	II.
Acetate of aluminium $Al_2(C_2H_3O_2)_4.H_2O$ . . .	7·76 per cent.	7·69 per cent.
Alumina, Al_2O_3	0·47 „	0·23 „
Calcium sulphate, $CaSO_4$	0·41 „	0·33 „
Spec. grav.	1·0457	1·0455

Dr. Vulpius, of Heidelberg, communicates his experience in following the above process. He states that it offers no difficulty at all, provided very capacious and shallow vessels are used, since the introduction even of small quantities of carbonate of calcium causes an energetic effervescence, particularly when working on the large scale. After the reaction is completed, the product appears to consist of an enormous quantity of precipitated sulphate of calcium with a very small amount of supernatant liquid, and, at first sight, it would seem as if the process were defective, since it might be supposed to be difficult to separate any useful quantity of liquid from the precipitate. This is a deceptive appearance, however; for, although but a small quantity of liquid runs off, at first, from the strainer, it is only necessary to slightly press the latter in order to effect a rapid disengagement of the liquid and a contraction in bulk of the precipitate. If the strainer is subjected to the action of a moderate press, the precipitate dwindles down to an insignificant amount. Dr. Vulpius proposes, in preparing large quantities of the solution, to use centrifugal machines for the separation of the precipitate from the liquid.

After the liquid has been allowed to stand for a short time, it filters clear and rapidly, and does not become turbid on standing.

Three kilograms of sulphate of aluminium, 3·6 kilos. of dil. acetic acid (spec. grav. 1·041) and 1·3 kilos. of carbonate of calcium, with the prescribed quantity of water, yield, in a round figure, 13 kilos. of solution of acetate of aluminium, containing 7½ to 8 per cent. of two-third basic acetate of aluminium [$Al_2(C_2H_3O_2)_4.H_2O$].—*New Remedies*. THE CHINESE DRUGGIST IN NEW YORK.*

BY FRED. HOHENTHAL.

The Chinese drug store here, the only one this side of San Francisco, was established by "Kwong Lung Jin," in 1878, and he is doing a flourishing business among his

* From the Eleventh Annual Report of the Alumni Association of the College of Pharmacy of the City of New York, 1882.

people now. The proprietor is a stout Chinaman, about thirty-five to forty-five years of age, very intelligent, revered by his countrymen, but not so well versed in English as his assistant, who is about ten years younger. I experienced much trouble on my first visit in assuring him that I was not a customs officer ferreting out his opium trade, but on seeing my readiness to buy little trifles, he immediately installed me in his good graces, and invited me to dine with him.

The store is a small apartment, about 20 by 30 feet, with sleeping rooms, kitchen, parlour, etc., in the rear. There were shelves all around covered with bottles and jars, and the top shelf mounted by many paper packages, cabalistically marked, and containing roots and herbs in great variety. In a small case behind the counter were the few mineral drugs, and a good many little trifles not belonging strictly to pharmacy, such as porcelain jars, pencils, scallops, beads, rings, etc. There were also some animal drugs, of which I will speak of later on.

Pendent from the ceiling were bunches of herbs and dried meat. On the floor, under the shelves, were articles of food, such as barrels of rice, flour, dried fish, etc. There were also about forty drawers behind the counter for the most used drugs, those in packages being very seldom used. Large jars were filled with different pleasant-tasting fruits, not used as medicines, and smaller glass jars with the various medicinal fruits, of which there was a large number, the chief uses of which seemed to be in the cure of consumption, a disease the Mongols seemed to be peculiarly liable to, judging from the fact that about 10 per cent. of their medicines are for its cure.

They have no liquid medicines whatever; they simply sell the drugs, extolling their virtues, and the purchaser or patient prepares them with boiling water in the form of infusion or decoction and sometimes extract, unless he has not the conveniences therefor at home, when the apothecary will do it for him. As an accommodation for his customers, the doctor keeps a pot of hot tea on the counter; anyone wishing to drink takes a cup from a basin of water near by, fills it, drinks, and replaces the cup without saying a word. A peculiarly constructed tobacco pipe, on the principle of the Turkish narghileh, is also on the counter, but only for the use of intimate friends. The tobacco they use is very fine and of peculiar flavour. Their tobacco pipes, the common kind, are made of a rod of bamboo strung with the kernels of a peculiar scented nut, and furnished with a bowl of metal about $\frac{1}{2}$ inch in diameter and $\frac{1}{2}$ inch deep, and an ivory mouth-piece. The pipe is perfectly straight and 2 feet long; they vary in price, from 2 dollars 50 cents to 7 dollars, according to age; those which have been already smoked for some time sell for more money than new ones.

Their balances are on the plan of the steelyard, the small ones with a bar of ivory, from which is suspended a brass pan and a moveable brass weight; one in my possession is 12 inches long and has over 125 marks for telling the weight, which ranges from 2 ounces downwards to 2 or 3 grains, very accurately. They have these balances of all sizes, and use them with great dexterity.

Their camels' hair pencils are about 10 inches long, of bamboo, into one end of which the brush is inserted, and it is fitted with a cover also of bamboo, the whole stem being curiously carved with their strange devices, and these cuts filled out with blue colouring.

Their writing materials are the pencil above described, an iron or porcelain plate, 6 by 8 inches, with a receptacle for water. They dip a piece of Indian ink in the water, rub it on the plate, and rub the pencil in this mixture and write from above downwards.

They have some very pleasant fruits: one of these, the "gua," is about the size of a walnut, and consists of a kernel as large as a hazel-nut, surrounded by edible fleshy pulp, and the whole enveloped in a hard, brown, brittle shell.

Among the familiar drugs I found Spanish saffron, safflower, musk, litharge, metallic mercury, ginger, ginseng, oil of peppermint.

I found also Russian castor and American castor, and what was claimed to be from the bear.

Also, fine Chinese isinglass, in one piece just the size and shape of an ordinary flounder, and which he wanted to sell me for two dollars. He called it by a name that resembled "Guiteau."

I found also several narcotic herbs resembling belladonna, hyoscyamus, stramonium, also a root resembling glycyrrhiza, only much larger in diameter than that is usually found. It is called "Gum Cho" and is used for chewing on account of its sweet taste.

Among the most notable goods was a substance in small lumps of yellow colour, and called "Nau Wau." It occurs, in lumps about the size of a walnut, in the stomachs of cows. The doctor said that it is found only in one cow in a hundred. It is used to apply to a sore foot in the form of paste, and is used only by the aristocracy.

There was a peculiar bark called "Os Chong," remarkable for the silky fibres it shows on breaking it in any direction; it is used in the form of a decoction for weakness of the heart. The price is ten dollars a pound. There were also dried lizards, which are to be boiled and eaten. There were disinfecting fumigators, strips of bamboo about one foot long, and as thick as a hair-pin, which were covered on the upper half with a fragrant mass, which glowed for two hours when once lit, perfuming the rooms very pleasantly. They were called "Sau Hong."

STUDIES ON THE ALKALOIDS.

BY DR. W. KOENIGS.*

ANNOTATED BY M. DE BECHI.

(*Continued from page* 128.)

Part II.—Chinoline and Lepidine.

Chinoline was discovered by Gerhardt in 1842.† By treating quinine with caustic potash and a little water, he obtained, with evolution of hydrogen, an oxygenated base $C_{18}H_{22}N_2O_2$, which he named quinoleine. By treating cinchonine‡ in the same manner, he found that the quinoleine obtained contained no oxygen. It is now known, through the researches of Butlerow and Wischnegradsky,§ that quinine gives an oxygenated base, $C_{10}H_9NO$, quinolidine, whilst cinchonine gives chinoline, C_9H_7N. The actual formula of chinoline has been settled by Laurent,|| from some recent analyses of Gerhardt.

In his researches on the bases of coal-tar, Hofmann¶ studied, besides kyanol or aniline, the leucol of Runge, and proved its identity with the chinoline of Gerhardt; these two bases giving with chromic acid the same characteristic yellow precipitate. According to Hofmann, the oil of coal-tar, which he used in his researches contained $\frac{2}{3}$ per cent. of leucol and $\frac{1}{3}$ per cent. of aniline. Later, the identity of leucol with chinoline was called into question by Gr. Williams** who, in studying the decomposition of cinchonine by potash, discovered two superior homologues of chinoline, lepidine, $C_{10}H_9N$, and cryptidine, $C_{11}H_{11}N$;

he also recognized the tertiary nature of chinoline. According to Liebig and Woehler,* by the action of cyanic acid upon aldehyde, trigenic acid, $C_4H_7N_3O_3$, was obtained, which, when heated, became charred and gave off chinoline together with cyanuric acid.

Thialdine, $C_6H_{13}N_2$, obtained by the action of sulphuretted hydrogen upon ammonic aldehyde, to which a little ammonia had been added, yielded, when heated to redness with lime, some chinoline, which was recognized by its characteristic odour and its double platinic salt. Nevertheless, it is very probable that the base thus obtained by Liebig and Woehler was collidine, which presents properties analogous to chinoline and which is formed, according to Baeyer and Ador† by distillation of ammonic aldehyde.

Lubavin‡ studied in Baeyer's laboratory, in 1869, the chinoline accruing from cinchonine and obtained from it two well crystallized substitution products, a sulphoconjugated acid and a tribromated derivative. Such was the state of our knowledge of chinoline when the author undertook, three years ago, some researches on chinoline and cinchonine.

Koerner's theory concerning the constitution of chinoline, has already been mentioned. If it be correct it ought to be possible to obtain chinoline from allylaniline, as naphthaline is produced from phenylbutylene or its bromide (Aronheim).§

$$\underset{\text{Phenylbutylene.}}{C_6H_5.CH_2.CH_2.CH : CH_2} - 4H = \underset{\text{Naphthalene.}}{C_6H_4\begin{cases} CH=CH \\ \quad | \\ CH=CH \end{cases}}$$

$$\underset{\text{Allylaniline.}}{C_6H_5.NH.CH_2.CH : CH_2} - 4H = \underset{\text{Chinoline.}}{C_6H_4\begin{cases} N=CH \\ \quad | \\ CH=CH \end{cases}}$$

Perkin had already tried to oxidize allyltoluidine in the hope of obtaining quinine. Instead of quinine, he obtained, by mixing the substituted base with a bichromate solution, a dirty-brown precipitate. It is known, how, in studying the oxidation of a simpler base, aniline, he was led to the discovery of the violet which bears his name and which was the first artificial colouring matter obtained from aniline.

If the vapour of allylaniline be passed over oxide of lead, heated to dull redness, a liquid with a benzonitrile odour is obtained. The product is purified with sulphuric acid; the precipitate of sulphate of aniline is filtered and the liquid shaken with ether; the acid solution is boiled with solution of potassium bichromate, until a filtered test is no longer altered by the oxidizing mixture. The liquid is then made alkaline and distilled with steam; when some oily drops pass over, having the odour of chinoline, the double platinum salt of which corresponds to the formula:—

$$(C_9H_7N.HCl)_2 . PtCl_4$$

The formation of chinoline from allylaniline answers to the synthesis of indol effected by Baeyer and Caro by means of ethylaniline:—

$$C_6H_5NH - CH_2 - CH_3 - 4H = C_6H_4\begin{cases} NH \\ CH \end{cases}\!\!\!\!\gg CH$$

and it may be admitted that in the formation of chinoline, the side chain is condensed in the ortho position, as takes place with indol and naphthaline, by means of phenylbutylene.

From this the formula of Koerner became very probable and it was clearly demonstrated by the beautiful synthesis of chinoline effected by Baeyer with hydrocarbostyrile. By reduction of orthonitrophenylacetic acid, Baeyer* obtained oxindol which, treated with phosphorus pentachloride, gives chloride of oxindol; this last, treated with hydriodic acid in acetic solution, gives retinindol, C_8H_8NO or C_8H_9NO, which yields indol by dry distillation.

If, instead of oxindol, its homologue, hydrocarbostyrile or orthoamidohydrocinnamic anhydride be operated upon, bichlorochinoline, $C_9H_5Cl_2N$, is first formed, a feebly basic body, which, treated with hydriodic acid in acetic solution at 240° C., gives chinoline.†

In successively nitrating and reducing the phenylangelic acid obtained by Perkin by means of essence of bitter almonds and normal butyric acid, Baeyer and Jackson obtained a homologue of hydrocarbostyrile, ethylhydrocarbostyrile, which separates in the form of a neutral anhydride from the acid mixture of isomeric amide acids. This body treated like hydrocarbostyrile, gives ethylchinoline and intermediary products.‡

The chloride of phosphorus does not here effect a substitution, for the second place (starting from the nitrogen) is taken by ethyl. Ethylchinoline has some properties analogous to chinoline; the small quantity at disposal did not allow it to be ascertained whether it is identical with cryptidine, and whether it gives cinchonic acid or an isomeric product by oxidation.

The researches of Baeyer and Jackson have shown that homologues of hydrocarbostyrile can be prepared, whenever the corresponding coumarine exists. The existence of homologues of chinoline with more than 5 atoms of carbon in the side chain is improbable, for, according to Baeyer and Jackson, corresponding hydrocarbostyriles do not seem to be formed, as, for example, by the nitration and reduction of normal phenylvaleric acid.

$$C_6H_5.CH_2.CH_2.CH_2.CH_2.CO_2H.$$

Baeyer and Jackson infer from these facts that the amido group, in the ortho position, combines readily with the second or third atom of carbon in the lateral chain, but not with atoms more remote. A chinolic body is also directly formed, when the third atom of carbon does not exist in the state of carboxyl, but in that of carbonyl (CO), as in phenylethylmethylacetone, and there are great probabilities that, in every case in which the second or third atom of carbon exists in the condition of an aldehydic, acetonic or alcoholic group, anhydrides belonging to the indol or chinoline§ group are formed. To prove this theory, Baeyer and Jackson prepared by means of phenylacetone, an isomer of scatol, the intramoleculary anhydride of orthoamidophenylacetone:—

$$C_6H_4\begin{cases} CH_2 \\ N= \end{cases}\!\!\!\!\gg C-CH_3$$

which they named methylketol; it is a homologue of the unknown ketol:—

$$C_6H_4\begin{cases} CH_2 \\ N= \end{cases}\!\!\!\!\gg CH$$

which should be isomeric with indol. Methylketol behaves in a manner entirely analogous to indol. As has been seen, indol is closely related to chinoline, a fact which could hardly have been expected, since these two bodies present entirely different properties. Whilst chinoline is an energetic tertiary base, which distils without decomposition, and is remarkable for its stability, indol is only a very weak base, of which the salts are decomposed even by boiling with water; it is partially decomposed by distillation and is generally very unstable: it contains an imide group, for it gives an acetyl compound.|| In pyridine, C_5H_5N, and pyrrol,

C_4H_5N, the same analogies occur as in chinoline and indol.

Pyrrol therefore constitutes the nitrogenated ring of indol, as pyridine does that of chinoline; this latter theory is proved by the oxidation of chinoline to the state of pyridino-dicarbonic acid.

By the conversion of hydrocarbostyrile into chinoline, the constitution of this base has been established with certainty. The author was compelled, however, to seek some more convenient methods of preparation than those accomplished by means of hydrocarbostyrile or allylaniline.

By dry distillation of acroleine-aniline, 70 per cent. of chinoline is obtained, which is analogous to the production of picoline with acroleine-ammonia by Baeyer.* Acroleine-aniline, prepared by Schiff's method† is distilled in small retorts in portions of 25 grams. An abundant charred residue remains; the distillate is purified by the method mentioned by Baeyer for picoline, which consists of treating the base with an oxidizing mixture of potassium bichromate and sulphuric acid. The liquid is made alkaline, distilled with steam, and the chinoline afterwards extracted with ether.

Acroleine-aniline, which, according to Schiff, has the formula $C_{18}H_{18}N_2$, should give two molecules of chinoline with a loss of 4H. The yield is, however, very weak. A base, boiling at a higher temperature than chinoline, appears to be formed at the same time as that substance. If oxidized directly, acroleine-aniline gives no trace of chinoline.

A still more simple method of preparing chinoline was indicated in the work of Graebe upon alizarine blue.‡ Graebe obtained, by reduction of the blue by means of zinc powder, an energetic, non-oxygenated, tertiary base, which he named anthrachinoline. He considers that anthrachinoline is to anthracene what chinoline is to benzine.§ It was natural, therefore, to have recourse to the action of sulphuric acid and glycerine upon nitrobenzol for the preparation of chinoline. Nevertheless, only a few traces of chinoline were obtained thus. The action of aniline (1 part upon a mixture of $1\frac{1}{2}$ to 2 parts of sulphuric acid and 1 part of glycerine at 180–190° C.) gave the desired result; acroleine-aniline is probably formed at first, and this, whilst in the nascent state, is oxidized by the sulphuric acid into chinoline, with an abundant evolution of sulphurous acid.

These two methods have been also indicated by Skraup at the meeting of the Vienna Academy of Sciences, April 8, 1880. Skraup also gave a much superior method to the preceding, since it gave him 70 per cent. of chinoline from the mixture employed; this method consists in replacing the aniline by a mixture of aniline and nitrobenzol. Here also acroleine-aniline is probably formed at first and is oxidized by the oxygen of the nitrobenzol to form chinoline, whilst the remaining C_6H_5N of the nitrobenzol, uniting with the acroleine, gives another molecule of chinoline with elimination of water.

[*Preparation of Chinoline.*

The following is the process for the artificial preparation of chinoline, as given by Skraup:||—

Twenty-four grams of nitrobenzol, 38 grams of aniline, 120 grams of glycerine and 100 grams of concentrated sulphuric acid are placed in a vessel having a capacity of 2 litres, and the mixture, which becomes hot, is agitated until the aniline sulphate formed is completed dissolved; it is then connected with a return condenser and heated upon a sand-bath. After five or ten minutes an energetic reaction sets up when the flame must be immediately removed. At first only a small quantity of vapour is given off, but after a few moments the ebullition becomes tumultuous. The reaction ceases after a few minutes, but after a short interval recommences and this takes place several times. Finally the reaction is brought to an end by heating during two or three hours, until the nitrobenzol has completely disappeared. The reactions are represented as follows:

$$\underset{\text{Nitrobenzol.}}{C_6H_5NO_2} + \underset{\text{Glycerine.}}{C_3H_8O_3} = \underset{\text{Chinoline.}}{C_9H_7N} + 3\,H_2O + O_2$$

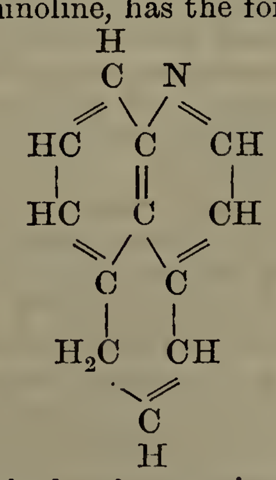
$$\underset{\text{Aniline.}}{C_6H_5NH_2} + \underset{\text{Glycerine.}}{C_3H_8O_3} = \underset{\text{Chinoline.}}{C_9H_7N} + 3\,H_2O + H_2$$

$$\underset{\text{Aniline.}}{2\,C_6H_7N} + \underset{\text{Nitrobenzol.}}{C_6H_5NO_2} + \underset{\text{Glycerine.}}{3\,C_3H_8O_3} = \underset{\text{Chinoline.}}{3\,C_9H_7N} + 11\,H_2O$$

The base is separated either by adding caustic soda in excess and distilling in a current of steam or extracting it by means of ether from the solution rendered alkaline. The former method is preferable as giving a purer product. The crude chinoline is dried and distilled over potash; in the first distillation it passes over between 225° and 230° C., but after twice repeating the operation it passes over between 227° and 228°. The alteration of crude chinoline in the light is due to the presence of a small quantity of non-basic resin, which is difficult to eliminate by simple distillation. To obtain the base quite pure it may be boiled in sulphuric solution with potassium bichromate, or dissolved in six parts of alcohol and the theoretic quantity of strong sulphuric acid added to the alcoholic solution. After cooling, it is filtered, and the residue washed with alcohol; the acid sulphate thus obtained, which is snow white, is then decomposed by caustic potash. Pure chinoline is completely colourless and may be preserved for a long time, especially if sheltered from light.]

The ideas of Graebe upon the constitution of alizarine blue have received a brilliant confirmation by the synthesis of chinoline by Skraup, who has generalized the reaction, by employing, instead of nitrating derivatives, the different amide derivatives, which, according to a communication by Skraup, react very easily upon the mixture of glycerine and sulphuric acid.

Another method of forming chinoline, which, without being synthetical, presents a certain amount of interest, has been discovered by Graebe and Caro.* By oxidizing acridine, which is found in great quantities in coal tar, by means of a dilute solution of permanganate, these chemists obtained acridic acid, a bicarbonated acid of chinoline, $C_9H_5N(CO_2H)_2$, which, distilled with calcic hydrate, gives chinoline. Acridine, which is a tertiary base as stable as chinoline, has the formula—



Of all these methods of preparing quinoline, there is no doubt that Skraup's mode is the best on account of the cheapness of the material employed, the facility of preparation, and above all the purity of the product obtained.

Subsequent researches on the action of reducing agents upon chinoline show that it is very difficult to obtain by the old process of preparing chinoline by means of cinchonine, a product entirely free from

lepidine, which is very troublesome in that it sometimes modifies the analytical results and the melting points of the different derivatives.

(*To be continued.*)

CAFFEIC ACID FROM CUPREA BARK.*

BY G. KÖRNER.

The raw material upon which the author experimented was supplied to him by the Lombardy Manufactory of Chemical Products, and was distinguished from other qualities of cinchona bark by giving a reddish-violet colour when a solution of potassic hydrate was added to its aqueous extract. The most important fact discovered by the author while pursuing his researches was that during the manufacture of sulphate of quinine from this bark there is formed a notable quantity of caffeic acid, which is evidently produced by the breaking up of a complex substance existing in the bark in company with the alkaloid. The caffeic acid is found in the mother-liquors as caffeate of quinine. This salt is obtained by repeated evaporation and fractional crystallization in slightly coloured mammilar crystals, which on being treated with dilute sulphuric acid and exhausted with ether sometimes give caffeic acid, but at others an acid which is obtained in such small quantities that it has not yet been studied. The mother-liquors turn brown when in contact with the air and deposit on the sides of the vessel containing them a dark powder, resembling in this respect solutions of caffeic acid and protocatechuic aldehyde. They also often give off an odour closely resembling that of vanilla.

The process adopted by the author for preparing the acid from the bark is as follows, the yield being about 0·5 per cent:—

The powdered bark is extracted with ether and then treated with boiling alcohol until nothing more is dissolved out. The alcoholic solution is then evaporated to dryness and the residue is treated with two and a half times its weight of boiling water, its own weight of caustic potash is added, and the whole is kept boiling for three hours. The liquid is then superaturated with dilute sulphuric acid, filtered while hot and shaken up with an excess of ether. The ethereal solution is then concentrated until crystals, accompanied by a syrupy liquid, are formed, the latter being separated by repeated washings with very small quantities of ether. The crystals are recrystallized from a boiling solution which has been previously submitted to the action of animal charcoal and filtered while hot. These crystals are in the form of somewhat brilliant and hard tables of a yellowish colour and containing 4·8 per cent. of water of crystallization. The solution does not reduce Fehling's solution; it takes a dark green colour with ferric salts, and a tint that turns to a cherry red on the addition of sodic carbonate. The neutral and basic acetates of lead give a bright yellow precipitate, and nitrate of silver a whitish precipitate, which darkens and becomes reduced on being heated. It has a strong acid reaction and is coloured deep yellow by concentrated alkalies, the tint changing to brown in the air. The acid may be obtained fairly well crystallized from its solution in boiling acetic acid in the form of crusts consisting of opaque warts. It does not seem to possess a fixed fusing point, but towards 414° F. it decomposes, giving off gaseous products. Submitted to dry distillation it yields an oil that becomes crystalline on cooling. These crystals give the reactions of catechine, especially the characteristic green colour with caustic potash.

The above are the characteristics of caffeic acid as described by Hlasiwetz in Liebig's 'Annalen,' vol. cxlii. Hlasiwetz obtained his acid by splitting up caffeotannic acid. Analyses of both compounds are similar to each other within ordinary limits. The formula determined from the analytical results, as interpreted by Hlasiwetz, is—$C_9H_8O_4 + \frac{1}{2}H_2O$.

In order to avoid any doubt on the matter the author prepared from the cuprea bark acid some bimethylcaffeic acid and its methylic ether, which both gave precisely the same characteristics as the corresponding compounds prepared from the caffeic acid of Hlasiwetz.

The fact of having produced caffeic acid from the *Cinchona cuprea* as a product of the splitting up of a complex substance contained in it, that acid only having hitherto been obtained by a similar splitting up of caffeotannic acid from coffee, furnishes an additional proof of the relationship which exists between the coffee and cinchonaceous plants, Zwenger having already obtained quinic acid from the former. With several extracts of other species of cinchona bark the author could not succeed in obtaining this acid.

AMMONIACAL CITRATES.*

BY E. LANDRIN.

It is well known that many metallic oxides and citrates, insoluble in water, are soluble in the alkaline citrates, even in the presence of reagents, which under ordinary conditions precipitate these oxides. This phenomenon has been made the basis of a quantitative method for the determination of phosphoric acid. Some years ago, Spiller (*Pharm. Journ.*, 1858) carried on a series of investigations, in order to study the influence of citric acid in preventing the precipitation of the metallic oxides, and arrived at the general result that the neutral citrates possess the property of combining with other salts to form a class of compounds of the general formula $M'_3C_6H_5O_7 + 3M'_2SO_4$, in which sulphuric acid may be replaced by carbonic, chromic, or boracic acids. For instance, solutions of these compounds are not precipitated by barium nitrate until a slight excess of sodium sulphate is present. Lebaigue (1864), however, considers that these phenomena are due to an interchange between the acids and bases, which is stable only so long as the citrate liberated in the nascent state is soluble, and thus the peculiar characteristics of the acids and bases present become apparent when the nascent citrate has saturated the alkaline citrate, viz., when the precipitant is in excess of the alkaline citrate. Further, the insoluble citrates are dissolved in the alkaline citrate in definite proportions, and citric acid being tribasic can saturate not only three equivalents of the same, but also of different bases to form soluble salts.

In order to decide between these views, the author has taken up the question, and has arrived at results in accordance with those of Lebaigue, *i.e.*, citrates insoluble in water dissolve in alkaline citrates, with formation of double salts of the composition $M_2M'C_6H_6O_7$, in which M is an alkali-metal, and M′ a metal belonging to some other class.

This result receives support from the following experiments:—If barium carbonate is gradually added to citric acid saturated with ammonia until one equivalent of acid and baryta are present, a clear solution is obtained, from which, on cooling, normal barium citrate separates out. The supernatant liquid contains in solution a double ammonium barium citrate. Analogous phenomena were observed with the oxides of calcium, strontium, lead and cadmium. Again, if aluminium hydroxide be dissolved in ammonium citrate, and the solution evaporated over sulphuric acid, white crystals of a double ammonium aluminium citrate, $3C_6H_5O_7(NH_4)_2H + [C_6H_5O_7(NH_4)_2]_3Al_2 + 6H_2O$, will separate out. A similar iron salt was obtained, a solution of which gives no precipitate with succinic and benzoic acids, no coloration with potassium thiocyanate, and no precipitate but only a green coloration with potassium ferrocyanide. The author also prepared and analysed analogous double citrates of ammonium and magnesium, manganese, nickel, cobalt, zinc, copper and mercury, but was unable to obtain salts of antimony, bismuth, tin or silver.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 23, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE "LANCET" ON DRUG ADULTERATION.

THE address delivered by Professor ATTFIELD before the British Pharmaceutical Conference at Southampton has furnished topics for editorial comments in most of our medical contemporaries. We doubt whether in all cases Professor ATTFIELD would be prepared to accept the construction put by the writers upon particular parts of his address, and certainly we think he must have been surprised to find himself ostentatiously thanked in the last number of the *Lancet* for giving the opportunity of writing one of the wildest productions upon the subject of adulterated medicines that has yet appeared in a journal claiming to speak with authority on medical subjects. The determining cause of the publication of such an article as that to which we refer is simply enigmatical to the uninitiated, but the consequences necessarily following such a course are such as to make it much to be deprecated. Amongst the good work done by the *Lancet* in the past that which is perhaps best known and remembered by the general public is the agitation it carried on against adulteration, which paved the way first for the Adulteration Acts of 1860 and 1872 and then for the existing Sale of Food and Drugs Act. Any statements made by our contemporary upon the subject of sophistication or substitution, especially in regard to medicines, with which it might be supposed to have special facilities for becoming acquainted, may well, therefore, be received as authoritative by a large portion of the community, though we are glad to believe that in this case they will not be so accepted by the members of the medical profession generally. The *Lancet* is, moreover, not entitled to the excuse—if it be one—that might be allowed to the *Saturday Review*, where the topic was started, that it was writing about an unfamiliar subject, since it deliberately joined in the discussion with the assumption that that journal was less perfectly acquainted with the facts.

The charge made by the *Lancet* is that death is often attributed to the virulence of disease, or perhaps to want of skill on the part of the doctor, when in reality it is attributable to the use of worthless medicines. "The doctor," it says, "ordered the "appropriate remedy, and if actually administered "it would probably have checked the course of "the disease. But what was actually administered "was not the remedy at all, but a counter-"feit of it, and though the patient did not "detect the difference, the disease did, and the "patient died." If language means anything this must be construed as applying to the conduct of pharmacists in the dispensing of the prescriptions of medical practitioners, and as involving a terrible allegation against the integrity of a class of men in whom, we believe rightly, the medical profession and the public at present repose considerable confidence. And with the exception of one piece of personal experience—the substitution of powdered sugar flavoured with quinine for salicin, which looks very much like an old story told backwards—the only evidence referred to in support of the charge is a report on the deteriorations, adulterations and substitutions of drugs presented to some public body in the United States.

The fact is that the whole article would be too grotesque for serious consideration were it not that a continued repetition of even irresponsible statements cannot fail to produce uneasiness and doubt where only confidence ought to exist. The time is past when men should be placed in a literary pillory without undergoing even the form of a trial. If there be offenders among British pharmacists, such as those described by the *Lancet*, a means has now been provided by Parliament for bringing them to punishment, and the evidence that ought to be considered indispensable before publishing such gross imputations would be sufficient for their convictions. But the absence of such convictions, although the law has now been in operation seven years, during which time the officers acting under its provisions have certainly shown no lack of attention to drugs and medicines, is sufficient to show how little justification there is for the statement above quoted. That drugs of inferior quality and adulterated drugs are still to be met with is not to be denied, but between them and the patient stands the skilled pharmacist who has been specially trained to detect and eliminate such disturbing influences in the battle against disease, and we do not believe the dispensing of the pharmacists of this country is fairly open to reproach. It may be that picked cotton is sometimes introduced into bottles of quinine to increase the bulk, as indeed the *Lancet* says it is; but we presume that our contemporary is hardly prepared to contend that such quinine, cotton and all, finds its way into mixtures upon which the lives of patients depend, or even into less critical preparations.

THE INTERNATIONAL PHARMACOPŒIA.

THE opportunity afforded by the recent meeting of the German Pharmaceutical Association was utilized by the President of the International Pharmacopœia Commission, Herr VON WALDHEIM, to present a statement as to the progress made in carrying out the work confided to that body by the International Pharmaceutical Congress held last year in London. Herr von Waldheim said that the Commission now consists of thirty-two members, two of which represent the United States and the remainder European countries. Only one European state, Spain, remains unrepresented, repeated applications, both oral and by letter, having been made to the Madrid Pharmaceutical Society to elect representatives, without effect. The first step taken by the President of the Commission was to send to each member a list of medicinal substances and preparations occurring in the European and American pharmacopœias, with the request that the recipient would strike out all those articles which he did not think suitable to be included in the International Pharmacopœia, and also add to the list any omitted articles that he thought should be included. From nearly all the members the revised lists have been received, Norway, Italy, and, of course, Spain, being the only defaulters in this respect, the lists being accompanied in many cases with the revisors' reasons for the course taken and as a rule presenting evidence of the most careful consideration. The list sent for revision contained 233 of the most used more or less powerful medicinal substances and preparations, and about 350 other drugs and preparations were recommended by the different members as suitable to be included in an International Pharmacopœia, the French representatives making in addition the general declaration that they were in favour of the largest possible list.

Although at the first glance it would seem difficult to determine among so large a number as 583 articles what were suitable for insertion and what were not, the problem was made considerably easier by, on the one hand, keeping in view the resolutions passed by the Congresses of Paris, Vienna, and especially of London, and on the other, the consideration that the fitness of any particular medicament, however powerful it might be, for a place in the International Pharmacopœia must be dependent upon the extent to which it is known and used. As a result it would appear that altogether 120 or at the most 150 articles should be included in the work, since most of the representatives were in favour of only the most powerful medicines being included, striking out the less active, whilst scarcely any of the 350 articles proposed in addition were recommended by more than one member.

The next step taken by the Executive will be to draw up a list of articles proposed to be included, based upon the revised lists and recommendations, together with formulæ for the preparations, and send a copy to each of the members of the Commission for consideration. The plan proposed to be followed in respect to the formulæ is to compare the recipes for each preparation occurring in the different pharmacopœias, and to recommend those for acceptance which are found in the majority of the pharmacopœias of the larger states, giving especial weight to those in the more recent works; consequently, there can be little doubt that the new edition of the German Pharmacopœia will exercise an important influence in this respect. Among the most difficult points to settle appear to be the materials for and the manner of preparation of extracts and the relative proportions of the original drug to many tinctures and preparations, concerning which the greatest divergence exists in the pharmacopœias of different countries. Herr von Waldheim is of opinion that in the case of countries where existing formulæ differ very widely from the new ones that may be adopted in the International Pharmacopœia, consideration should be shown for what will frequently be a very old custom, and that this could be best done by such old formulæ being retained in the respective countries under names quite different from those adopted in that work, and then indicating such preparations when intended by mentioning the pharmacopœias of their respective countries. With respect to simple substances it is proposed to give only the most important characters and to avoid as much as possible giving tests for chemicals, leaving these definitions to be supplied in the pharmacopœias of the different countries.

MENTAL MIST.

Our United States contemporary, the *Therapeutic Gazette*, assuming that a paper on "Secret Remedies," which appeared in the *Pharmaceutical Journal* for December 17 last (p. 502), was an expression of our editorial opinion, is pleased to express its approval of our aim, but is fearful that there is a mist in front of our mental vision that needs clearing up before we shall be able to see the difference between scientific pharmacy and the unscientific pharmacy of some specialties; to this friendly task, therefore, it devotes the greater part of two columns. Our contemporary is well qualified to speak with authority upon the subject of specialties, but it appears to be labouring under a mistake, which, as its remarks have been quoted by the *Pharmacist* and possibly by other journals, it will be as well to correct. We would therefore disclaim any right to the limited praise or any necessity for the volunteered coaching with respect to the article in question, since the only mist which has interposed has been that which came between our contemporary's own vision and the statement contained in the opening sentences, that the article was a quotation from a German journal.

At the recent meeting of the German Pharmaceutical Association in Berlin, it was announced that during the past year 114 names had been removed from the roll of members and 135 added, being a net increase of 21. The gross total of members of the Association is now 2755, which includes 17 extraordinary and 18 honorary members.

According to a recent Government return, the crop of cinchona bark derived from the Government plantations in the island of Java amounted in 1881 to 165,000 Amsterdam pounds (nearly 180,000 lbs. avoirdupois) against 100,000 pounds in the previous year.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 238.)

A paper was then read on—

THE PURITY OF COMMERCIAL CHLORIDE OF GOLD.

BY F. W. BRANSON.

In the Blue List issued annually to members of the British Pharmaceutical Conference, "The Purity of Commercial Salts of Gold" has, for several years past, appeared as a desirable subject for investigation; the contribution of the results of a series of recent analyses of chloride of gold may therefore prove of interest, especially as most pharmacists have at least occasional transactions in this article of commerce.

A standard of strength and the maintenance of this standard is by no means a matter of indifference, considering the large quantity used by photographers in the process of toning. As most of the salt met with in commerce is found in 15-grain tubes, ten of these from five distinct sources were taken for analysis, low results being obtained from Nos. 9 and 10; two other tubes from the same source were taken to prove whether the deficiency was an average one or due to careless weighing or loss in filling.

In the above series, owing to the distinctive appearance of the various samples, labels, etc., the products of four manufacturers could be recognized, series *A, B, C* and *D*.

After several experiments the following methods for the estimation of the weight of contents of tube and the contained gold were found to be convenient, rapid (if the time required for precipitation, thirty-six hours, be excepted) and accurate, the precipitated gold being nearly chemically pure.

The vol. process with oxalic acid and permanganate, as described by Sutton, was not tried, the direct method being considered preferable.

The actual weight of the contents of each tube was estimated as follows:—After removal of label by soaking in water the tube was filed round the centre to facilitate breakage; the weight of tube with contents was next taken, the salt shaken to one end of the tube and fracture made at filed portion; the two portions of tube with contents were now transferred to a beaker, and treated with successive quantities of distilled water; the resulting solution, after transference to a conical flask having a file mark at 5-oz. capacity (which measure the solution should occupy) was precipitated with oxalic acid.

The weight of fractured tube after drying was deducted from the weight of tube with contents, the difference being chloride of gold.

The annexed series shows the weight found in each tube, the average of each manufacturer is also given—

Sources.		
A	14·781 14·180 14·875 15·995	average 14·957.
B	15·620 14·673	average 15·146.
C	14·627 15·470	average 15·058.
D	13·547 13·948 13·825 13·677	average 13·749.

The best precipitant was found to be pure oxalic acid, several advantages being apparent; for, as the precipitation proceeds at a much slower rate than with either sulphurous acid or ferrous sulphate, should platinum or other metals be present they are less likely to be carried down with the gold; the metal is also thrown out of solution in a more coherent form, thus facilitating the subsequent operations. The non-introduction of a metallic salt is also obviously an advantage if the separation of metals is found requisite.

Experiments proved the time required for complete precipitation to be not less than thirty-six hours at a temperature of about 70° F., and twelve hours' exposure to light.

The quantity of oxalic acid found to give good results was 25 c.c. of the standard solution (63 in 1000) for the contents of each tube; this quantity was therefore measured by means of a pipette into the gold solution, the flask set aside under conditions as above described, and the contents finally raised to boiling point; after subsidence the colourless solution was found in a trial experiment to be not darkened by H_2S, and on evaporation no further reduction of metal occurred, the residue, oxalic acid, being quite white.

After precipitation the greater part of the fluid was poured on a filter, the flask was then shaken in a circular manner so as to cause the particles of gold to sweep off any film adherent to the sides of flask, which should now appear by reflected light to be quite free from metallic coating, the precipitated metal collected on the filter, washed, dried, incinerated and weighed, the following results being obtained:—

A	7·267 6·974 7·313 7·792	average 7·286.
B	7·349 7·082	average 7·215.
C	7·097 7·537	average 7·317.
D	6·595 6·773 6·661 6·588	average 6·654.

Sufficient time not being at my disposal for the complete examination of the residues from the evaporation and incineration of the oxalic acid solution from which the gold had been precipitated, they were placed aside for subsequent analysis. I will now, therefore, merely give in round numbers the weights yielded by series *A*, *B*, *C* and *D*.

A and *B* more than 10 per cent.
C and *D* less than 1 „

Metals precipitated by H_2S or AmHS were practically absent from all the above samples, which were obtained from firms most likely to supply the requirements of pharmacists, foreign samples being purposely excluded.

A small variation *plus* or *minus* within reasonable limits in the quantity of salt or metal contained by any given tube is, of course, allowable, and is to be expected, but the marked deficiency of tubes Nos. 9 to 12, inclusive, obtained from a firm possessing the confidence of the trade demands notice, for a deficiency of 8 per cent. in weight of contents or 5 per cent. in the proportion of metal that should be present demands notice, and it should be mentioned that neither trade mark, seller's name nor guarantee label was attached to either of these numbers; but tubes Nos. 1 to 8 all had attached one or other of these distinctive marks, and from sources *A* and *B* 7 grains of gold was guaranteed, which quantity was fully present, as proved by analysis.

In a paper by my friend, Mr. Richard Reynolds (*vide Pharm. Journ.*, [2], vol ii.), greater discrepancies than the above were detailed, and the proposal was then made that the commercial value of the article should be governed by the equivalent of gold present; now, as then, this desirable practice would, if generally followed, certainly tend in favour of the interest of the consumer, and probably for this very reason is not adopted by some manufacturers.

———

The PRESIDENT proposed a vote of thanks to Mr. Branson, which was carried.

Mr. HAMPSON asked if it would be any advantage to have the solution sold by measure.

Mr. BRANSON said there was the question of convenience of transport involved, as the tubes were frequently sent by post, but there was no reason why a strong solution of definite strength should not be sent out in capsules.

This was followed by a paper on—

THE IODIDES OF BISMUTH.

BY F. W. FLETCHER, F.C.S., AND H. P. COOPER, F.C.S.

The iodides of bismuth described in the text-books are two, viz., a black tri iodide (BiI_3) and a red oxy-iodide ($BiOI$).

To obtain the former, one equivalent of tri-sulphide of bismuth is directed to be heated with three equivalents of iodine in a capacious loosely-covered glass globe. The iodine turns out the sulphur, and the new compound is deposited on the sides of the vessel in the form of brilliant plates. This is Schneider's process. Another method, suggested by Weber, consists in throwing iodine into melted bismuth, and distilling the mixture out of contact with air.

The red oxysalt ($BiOI$) is said to be formed on heating the tri-iodide for some time in a crucible, when it collects below the surface of the crystallized iodide in a mass of copper-coloured rhombic laminæ.

Both of these compounds, however, may be much more conveniently obtained by the decomposition, under certain conditions, of a solution of a bismuth salt by means of a soluble iodide.

Mr. Pattison Muir, to whom, with his coadjutors, chemists are immensely indebted for researches upon bismuth compounds, has recently described a very striking method of exhibiting the formation of the two iodides by pouring a solution of the tri-iodide of bismuth in hydriodic acid into varying quantities of water at different temperatures. On adding the hydriodic acid solution of BiI_3 to a little cold water, the black tri-iodide is thrown down; whilst if a large bulk of hot water is employed, red crystalline $BiOI$ is produced.

We have lately met with a yellow iodide of bismuth, which, partly on account of its novelty, and largely on account of its bearing upon one of the Pharmacopœia tests for the purity of bismuth salts, we considered would be of sufficient interest to bring before the Conference.

In the course of testing a number of samples of metallic bismuth for lead, by the addition of dilute sulphuric acid to the solution of the metal in nitric acid, we observed in one instance that a very considerable deposit was formed after standing for about twenty-four hours. As this appeared to indicate the presence of a very much larger proportion of lead than we had previously met with, the precipitate was collected upon a filter, washed, and treated with solution of ammonium acetate, in which it dissolved. Upon the addition of potassium iodide to the liquid, a bright yellow precipitate was thrown down, having all the appearance of lead iodide.

A duplicate experiment being made, we found to our surprise that no precipitate was in this instance formed, when the solution of bismuth was treated with sulphuric acid; and the subsequent application of Chapuis and Lennoissier's potassium chromate test* conclusively proved the absence of lead in the sample of bismuth.

It occurred to us, on reflection, that the precipitate produced by sulphuric acid was probably a very basic sulphate of bismuth, produced owing to the bismuth solution being too concentrated. Experiment verified this assumption, and it may not be out of place here to mention that we find that if subnitrate or carbonate of bismuth,—free from lead,—be dissolved to saturation in nitric acid, diluted with half its volume of distilled water, as directed in the Pharmacopœia, and an equal bulk of dilute sulphuric acid then added, a precipitate of basic sulphate of bismuth is formed on standing, which, so far as the Pharmacopœia test goes, might reasonably be mistaken for sulphate of lead.

The solubility of freshly precipitated basic, or rather sesquibasic, sulphate of bismuth in ammonium acetate solution, has not, we believe, been previously noted, and it was therefore quite accidentally that we discovered the yellow iodide, which is the occasion of the present paper.

It naturally occurred to us that the yellow precipitate might not be an iodide of bismuth only, but a double iodide of bismuth and potassium. To ascertain this, a portion was treated with nitric acid and excess of ammonia. The filtered liquid evaporated to dryness left no residue on ignition.

The absence of potassium was therefore demonstrated.

We were now anxious to ascertain by what other methods the new compound could be obtained.

Being aware that Drs. Woodman and Tidy had some years since, in the *British Medical Journal*,* described the formation of a red precipitate in a mixture containing iodide of potassium and subnitrate of bismuth, and also that M. Jaillet had prepared various yellow compounds under somewhat similar conditions,† we proceeded to treat various samples of subnitrate of bismuth with iodide of potassium, and found that the products obtained varied in colour from a pale lemon-yellow to a deep orange-red. Knowing that subnitrate of bismuth varies considerably in its percentage of nitric acid, we inferred that in the absence of the latter the yellow salt would be alone produced. The samples of subnitrate were therefore first shaken with solution of ammonium or sodium acetate, in order that acetic might take the place of any free nitric acid that might be developed. The addition of KI to these mixtures formed the yellow iodide only, as we anticipated.

We found also that the iodide could be readily prepared by pouring a very dilute solution of nitrate of bismuth into mixed solutions of potassium iodide and sodium acetate. Liq. bismuthi, B.P., whether neutral or acid, gives no precipitate with potassium iodide, but an orange solution is formed. This, in fact, is the method recommended by Thresh, for preparing Dragendorff's reagent. If, however, scales of citrate of bismuth and ammonia are dissolved in water and the solution acidified with acetic acid a copious orange-yellow precipitate is formed on the addition of potassium iodide.

Yellow iodide of bismuth is sparingly soluble in acetic, and freely in hydrochloric acid. Sulphuric and nitric acids liberate iodine. Digested with zinc and dilute sulphuric acid, the bismuth is deposited as metal, and the iodine passes into solution as iodide of zinc.

It is not decomposed by water, even at a boiling temperature. Ignited in a porcelain crucible it first blackens, and then evolves iodine, leaving a residue of bismuthous oxide, which, however, obstinately retains traces of iodine, which are only expelled after prolonged heating.

We have made a large number of analyses of different samples prepared by various methods, and we find that the relative proportions of bismuth and iodine vary with the colour of the compound, those which are yellow containing more bismuth and less iodine than those which are orange or orange-red.

Analyses of several specimens of a fine lemon-yellow colour, prepared by treating equal weights of subnitrate of bismuth with similar quantities of sodium acetate and potassium iodide, gave concordant results. The bismuth was estimated by the two following methods and the results given represent the mean of several experiments.

1. By ignition, the precaution being taken to moisten the residue with nitric acid, and again ignite before weighing. Bi_2O_3 found = 86·6 per cent.

2. By solution in dilute nitric acid and precipitation with ammonia. The precipitate washed until free from

* *Journ. Chem. Soc.*, xxxvi., 80.

* See *Pharm. Journ.*, [3], i., 464.

† *Pharm. Journ.*, [3], vol. xi., 1063.

any trace of iodide, yielded on ignition 86·8 per cent. Bi_2O_3.

The iodine was also estimated by two methods:—

1. The compound was heated with solution of pure sodium hydrate, the precipitated bismuth hydrate thoroughly washed, the filtrate and washings acidified by nitric acid, and the iodine precipitated as a silver salt. The amount found was 11·35 per cent. A trace of iodine was, however, discoverable in the precipitated bismuth, even after prolonged washing.

2. Known weights of bismuth subnitrate and potassium iodide were agitated with water in the presence of sodium acetate, and the yellow iodide obtained filtered off, washed, dried and weighed. The filtrate and washings were then diluted to a certain volume and the iodine estimated by volumetric solution of silver nitrate. It was found that 12·8 per cent. had been absorbed in the formation of the yellow compound.

An attempt was made to separate the iodine in the form of HI by decomposing the iodide by a current of H_2S, but this was not successful, the resulting black precipitate being found to contain iodine in abundance.

The results obtained tend to show that the yellow compound is a very basic iodide of bismuth, represented by the formula—

$$BiI_3, 5B_2O_3 \text{ or } 3BiOI, 4B_2O_3.$$

This formula requires 12·9 per cent. of iodine and 87·7 per cent. of B_2O_3. The amount of the latter found by experiment was 86·7 per cent., and the iodine (calculated by difference) 12·8 per cent.

The formula of the tri-iodide of bismuth being BiI_3 and that of the oxy-iodide or bismuthyl iodide (BiOI), the latter may be regarded as formed from 1 molecule of BiI_3 and 1 molecule B_2O_3, thus—

$$BiI_3 + B_2O_3 = 3BiOI.$$

Between the latter and the yellow salt which we have described, it is probable that there may be many intermediate compounds, a supposition confirmed by the fact that iodides of various shades of colour, from pale yellow to deep orange-red, are easily obtainable by altering the relative proportions of the iodine and bismuth. A striking experiment illustrating the tendency of the tri-iodide to form oxygen compounds may be shown by dropping a few grains of BiI_3, or a few drops of the solution of the latter in hydriodic acid, into a large bulk of water, the latter at the same time being vigorously shaken. The brownish-black colour of the tri-iodide is seen to give place to a white turbitity, and on the careful addition of a little more of the powder or solution the formation of the yellow iodide is at once apparent.

The PRESIDENT, in proposing a vote of thanks to the authors of the paper, said it was one of considerable theoretical as well as practical value.

Professor TICHBORNE asked if Mr. Fletcher found the temperature at which the salt was precipitated affected its composition, as temperature was known to have a great influence on basic salts generally.

Mr. FLETCHER said the temperature seemed to have no action at all. The salt was not soluble in either cold or boiling water; this would instantly distinguish it from iodide of lead.

Mr. PLOWMAN then read the following:—

NOTE ON MICROSCOPIC ORGANISMS IN CERTAIN ORGANIC SOLUTIONS.

BY C. H. BOTHAMLEY, F.C.S.,

Assistant Lecturer on Chemistry at the Yorkshire College.

The growth of algæ and fungi in solutions of organic substances, as for example, in solutions of tartaric acid or potassium acetate, is a matter of common observation. A number of such forms were described and figured by Pereira many years ago (*Pharm. Journ.*, vii., pp. 337, 370, 426, 1847–48). Not only do they grow in purely organic solutions, but also in organic solutions containing a considerable proportion of metallic salts. Kützing observed the formation of such growths in solutions of "polychrome" (æsculin) mixed respectively with ferric chloride, cupric sulphate, tartar emetic, gold chloride and stannous chloride. Several of the forms which grow under these conditions are described by Pereira (*loc. cit.*), who also states that he had himself observed the growth of a filamentous plant in a solution which was used for the preservation of animal substances, and which contained mercuric chloride. The exact nature of the growth depends on the particular metallic salt present, each salt being favourable to the development of a particular species. In the same paper, Pereira states that he had observed the formation of similar growths in a solution of phosphoric acid prepared by oxidizing phosphorus with nitric acid, and also in a solution of arsenious acid! It is well known, too, that a very singular fungus grows in the cells of Daniell's battery, if allowed to remain unused and at rest for a long time. With these exceptions, however, the formation of such growths in inorganic solutions appears to be comparatively rare.

In the College laboratory we are troubled with the continual formation of a green vegetable growth in bottles containing respectively solutions of ordinary sodium phosphate, magnesium sulphate, and calcium sulphate, though no such growths are formed in solutions of ammonium salts, barium chloride, and other reagents standing on the same shelves. It was natural to suppose that the germs of these organisms are derived from the air, but their appearance only in the three reagents mentioned, and not in any of the others, although some of the latter seemed to constitute more favourable media, led to the supposition that the germs were possibly mixed with the particular salts. Experiments were therefore made to determine this point.

Ten per cent. solutions of magnesium sulphate and sodium phosphate respectively were prepared by dissolving the salt in cold recently distilled water, and portions of these solutions were placed in small flasks, as follows:—

A. Original solution, left exposed to air.

B. Solution boiled five minutes, then left exposed.

C. Solution boiled five minutes and flask plugged with cotton-wool.

D. Solution heated at 55°–60° C. for two hours, then plugged.

E. Solution heated at 70°–75° C. for two hours, then plugged.

For some time no growths made their appearance in any of the flasks, but soon after the air of the balance room in which the flasks were placed had been rendered dusty, in consequence of sweeping, the vegetable growth began to form in the exposed flasks *A* and *B*, and gradually increased. In one of the *B* flasks, containing magnesium sulphate, there was also a greyish flocculent growth. No growth appeared in any of the plugged flasks, even after fifteen months. It is evident, therefore, that the germs of this vegetable organism are derived from the air.

When examined with a good sixth or eighth inch objective the green growth is seen to consist of approximately spherical bodies of very simple structure. They consist of a cell-well, enclosing a green fluid, in which are a few patches of minute reddish granules. In general appearance they resemble *protococcus*, but are much smaller, and belong to that somewhat indeterminate group of bodies which are classed together as *crococcus*. My own observations in this respect are confirmed by those of several biological friends. A small quantity of the growth formed in sodium phosphate, when transferred to a clear solution of magnesium sulphate, multiplies and flourishes just as vigorously as in the original liquid, and *vice versâ*.

Both solutions no doubt contained small quantities of ammonia, and the sodium phosphate contained some sulphate. The amount of phosphoric acid in the magnesium sulphate solution was, however, not sufficient to give a reaction with ammonium molybdate. The magnesium sulphate is, however, prepared from dolomite, which almost invariably contains small quantities of phosphoric acid, hence it is probable that we have here further proof that the formation of these green vegetable growths constitutes a most delicate test for phosphoric acid.

A vote of thanks was accorded to Mr. Bothamley.

The PRESIDENT, in putting it, said he gathered from the concluding paragraphs of the paper that Mr. Bothamley was going on with the subject, and if so he would no doubt tell them in due time what would happen if they put phosphoric acid or a phosphate of potassium, etc., into the solutions in which he had not yet observed any growth.

Mr. PRESTON said he should like to know whether Mr. Bothamley had had under consideration Fehling's solution, which was so very difficult to keep. Very often, when it would act while freshly made, after being kept a little time it would become of little or no value. Perhaps the cause of that might be traced to the presence of these vegetable organisms. He had found when in preparing that solution great care is taken to scald out the vessels, and to use other necessary precautions, the solution kept almost an indefinite period.

Mr. PARKER asked if it were not possible that the growth of fungi might be due to the absorption of ammoniacal salts from the air, such being frequently present in the atmosphere of a pharmacy or laboratory.

Mr. GREENISH said the Conference was indebted to Mr. Bothamley for bringing this subject forward; the changes which took place in pharmaceutical preparations had not received as much attention as they deserved. It was found, for instance in vin. ipecac., that a change was constantly going on in the bottle, and if they examined it by the microscope they found fermentation active, cells being distinctly visible. Again, if they took orange flower water they found a yellow deposit, and on examining it under the microscope it would be found full of bacterian life. It was also of great importance to pharmacists that these fungoid growths which appeared in solutions, even made according to the Pharmacopœia, should be studied; but it was found by many dispensing chemists very desirable and almost necessary to keep solutions of a great many salts, and he found that in nearly every one of them there would be more or less of fungoid growth, which caused great annoyance. It was not confined to any one solution, but he scarcely knew of one in which it did not apppear. He had himself cultivated a fungus grown in a solution of arsenic, a very interesting fungus; and he had cultivated another in a solution of strychnine, which was also very interesting. But it was well known to fungologists that the particular fungus could not be determined from the vegetative process or the mycelium; it must proceed to fructification. Now the fructification of a fungus in a solution would not take place so long as there was any portion of the material which afforded the fungus nourishment in the solution, and what made this matter of great importance was that if the fungus was allowed to continue to vegetate and increase its mycelium in a solution which might contain a certain amount of strychnia, or anything else, a portion or the entire of the active principle or medicinal property would disappear; therefore, it was highly desirable that this matter should be thoroughly investigated, and he sincerely hoped that Mr. Bothamley would continue these inquiries, and in continuing them that he would not be satisfied in examining merely the mycelium which was found in the solution, but would take out the fungus, place it in distilled water, wash it, remove the nutriment on which it fed, and then endeavour if possible to promote its fructification. That could only take place on the surface if it were a fungus; if it were an alga it would of course take place under the solution. As these things appear in almost every aqueous solution used by dispensing chemists it was imperative that attention should be paid to them.

Dr. SYMES said he did not think that the presence of fungoid growth was in itself evidence of the presence of phosphoric acid, but he thought Mr. Parker's suggestion of ammonia assisting in its development would hardly hold good, because the flasks were simply plugged with cotton wool, placed side by side with those not plugged, the contraction and expansion of the air going on freely, and he assumed the ammonia would enter the flasks, and if ammonia had anything to do with the development, the growth would be found in them all.

Mr. PARKER remarked that although ammonia might get into vessels which were plugged by cotton wool the germs would be kept out.

Mr. EKIN said he might mention one instance where neither ammonia nor phosphoric acid had anything to do with a growth of this sort. It occurred in an experiment with one of the azo-colours in which the principal ingredients were amidoazobenzol and β-naphthol. The precipitated colour became a solid gelatinous mass from fungoid growth in the space of twenty-four hours. It certainly startled him, and he had never been able to get any explanation of it.

Mr. GREENISH said Mr. Bothamley spoke of the germs being in the atmosphere and of the fungi appearing in some solutions and not in others. Now the fungi were different in the solutions of arsenic and in the solutions of strychnia. Fungi would grow where there was a nidus suitable for them, one in one material and a different one in another.

The Conference then adjourned for luncheon.

The next paper read was on—

THE SOLUBILITY OF MORPHIA SALTS.

BY D. B. DOTT, F.R.S.E.

Early last year I read a short paper on the solubility of some of the salts of morphia, a report of which was printed in the *Pharmaceutical Journal* of January 29, 1881. Since that time two communications on the above subject have appeared in the same Journal, both originally proceeding from the other side of the Atlantic. The first is a paper* by Professor Frederick Power on "The Solubility of Sulphate of Morphine," and the second is by Mr. J. U. Lloyd on the "Solubility of the Officinal Morphia Salts in Water and Alcohol."† Neither of these experimenters has thought fit to take any notice of my paper, nor would I of theirs, if they merely confirmed or superseded mine. As, however, I consider both of them to be very much open to criticism, I should like to take this opportunity of pointing out what I believe to be their errors.

No exception can be taken to the method employed by Professor Power in determining the solubility of the sulphate, although it is not a process applicable to all salts. It consists simply in estimating the sulphuric acid as sulphate of barium and from that calculating the corresponding amount of sulphate of morphia. Professor Power also determined the solubility by evaporating to dryness a weighed portion of the saturated solution. The ratio given by the two methods, which ought to have yielded identical results, presents a difference of about 2·5 per cent.—a somewhat serious discrepancy. The former method is the one relied on, and Dr. Power concludes that "1 part of sulphate of morphia requires in round numbers 24 parts of water at 15° C. (59° F.) for solution." This result, however, is arrived at by dividing the *weight of the solution* by the weight of the salt dissolved therein. Now it is manifest that in order to ascertain the amount of water holding a salt in solution we must deduct the weight of the salt from the weight of the solution. The solubility is then obtained by dividing

* *Pharm. Journ.*, [3], 798.
† *Ibid.*, 1036.

the weight of the solvent by the weight of the salt. Thus treated Professor Power's numbers give for the solubility of morphia sulphate in water at 15° C. 1 in 22·99, by the precipitation method, and 1 in 20·44 by the evaporation method. The Professor speaks of "disregarding the slight increase of volume produced by solution;" yet I cannot see what increase of volume has to do with the matter.

Turning to Mr. Lloyd's paper I find that his method of determining the solubility of salts in the cold is by evaporating a weighed portion of the saturated solution, which is the plan I have always adopted. Mr. Lloyd allows the solution to evaporate spontaneously, weighing the residue with its water of crystallization. This, of course, is of no consequence if care be taken that the crystals have not effloresced. Referring to the residue remaining from an alcoholic solution, Mr. Lloyd remarks: "The alcohol may abstract more or less water of crystallization, and fail to take its place in like amount, if at all, thus leading us into a slight error." I am not aware of a single instance of alcohol combining with an alkaloidal salt, and all the well-known morphia salts separate from 85 per cent. alcohol with the same proportion of water of crystallization as when crystallized from water. I regard Mr. Lloyd's system of boiling a known weight of water in a retort and gradually introducing the salt through the tubulure as an elaborately erroneous method of ascertaining the solubility of the salt in the boiling menstruum. For ordinary determinations the flask containing the boiling solution may be tilted so as to pour some of the liquid into a capsule, which is immediately covered, and weighed when cool; while for more accurate estimations a small vessel fitted with a cover may be let down into the boiling solution. The solubilities given for the hydrochloride and sulphate are evidently nearly correct, but that of the acetate is certainly wrong. I am quite aware that there is some difficulty in ascertaining exactly the solubility of the acetate. This arises from the readiness with which that salt loses its acid, and also from the fact that a proportion of the free morphia is dissolved when the basic salt is brought in contact with water. Mr. Lloyd's ratio of 1 part acetate to 11·7 parts water is far wide of the mark, as the true solubility is not far removed from 1 in 2, which are the numbers given in my paper formerly referred to. When a saturated solution of morphia acetate is boiled, decomposition takes place and a certain amount of morphia is deposited. No doubt if a sufficient quantity of acetic acid be then added a clear solution is obtained, but it would hardly be safe to take the result of such an experiment as indicating the true solubility of acetate of morphia in boiling water; yet this is Mr. Lloyd's process. All the morphia salts, so far as I am aware, are less soluble in alcohol than in water, but the statement that "acetate of morphine is not so soluble in alcohol as the alkaloid morphine" is quite erroneous, the converse being correct.

I intended to have ready for this Conference a carefully compiled table of the solubility of morphia salts, but various circumstances have conspired to prevent me, especially the warm weather, as I wished to make all the determinations at 60° F. I trust, however, that what I have written will help to clear the ground for future work. Meanwhile the table which I formerly gave, and which is printed in the 'Year-Book of Pharmacy' for 1881, will be found "sufficiently correct for practical purposes."

The President, in proposing a vote of thanks to Mr. Dott, regretted that he was not present, and also Professor Power. Considering the difficulty of getting at the solubility of any salt or substance in fluids, and indeed the general indefiniteness and haziness of the matter altogether, he was not sure but that Professor Power was right in disregarding the slight increase of volume which was produced when a salt was added to water; at all events, in the cases mentioned. At the same time investigators were not quite so accurate as they might be in describing what they meant by solubility. It was common to see the solubility of a given salt stated to be 1 in 10, but one did not know whether that was 1 part by weight in 10 volumes, or that 1 part had been put into 10 parts of the fluid, or whether 10 parts by weight of the fluid contained 1 part of the solid.

Mr. Parker said he had been looking forward with considerable pleasure to this paper, and was very disappointed at Mr. Dott's absence. The subject of solubility was somewhat unsatisfactory; he would suggest that there should be standard conditions for the taking of solubilities, recognized through all countries. It was a disputed point as to its variability, but as far as his own work went he was satisfied that solubility might vary very much with the conditions under which it was observed. The solubility of a body of definite chemical constitution which was not altered in composition by the action of heat might be very well taken by the method of evaporation, but there were many bodies, volatile at a moderate dry heat, which could not be taken in that way; the solubility of the substance which he had the honour of bringing before the Conference on the previous day illustrated this fact. The chief point he had noticed was that when the substance was added to the cold menstruum, and the "point of saturation" observed, the result differed from that obtained by making a stronger solution with the aid of heat, and noting the "point of crystallization." In the case of terpin hydrate the solubility in cold alcohol was 1 in 13, whereas, taken in the hot way, it would be 1 in 11, so that either statement would be altogether useless unless the conditions under which the solubility was observed were mentioned. It would be very valuable to have throughout the whole range of chemical solubilities one standard by which they should be taken. Of course there would be some cases in which it might be taken more satisfactorily by another method, but these should be mentioned as exceptions to the general rule. The point of cold saturation appeared of most value to the pharmacist.

Mr. Williams thought this question of solubility had really a wider bearing than had perhaps been indicated either by the author of the paper or by the last speaker. The solubility of bodies seemed to be very intimately connected with their power of crystallization, and with that which arrested crystallization. He might remind the Conference of a paper which appeared in the *Pharmaceutical Journal* a few weeks before, by M. Tanret, in which he proved that caffein, which was extremely insoluble, was rendered soluble by salicylate, benzoate, or cinnamate of sodium. He had made some of the salicylic and some of the benzoic compounds, and they certainly were not chemical compounds, for chloroform dissolved the caffein from them; therefore, the caffein was merely held in them in a chemical form, or in a solution, but they could be converted into dry substances. These bodies, however, caused caffein to be perfectly soluble. This would upset, therefore, any attempted standard of solubility in a most important manner, and he believed caffein was not the only substance in which the same thing was illustrated. He would refer to salicylic acid and many of the alkaloids, which were really uncrystallizable until they got rid of the impurity, often in a very minute quantity, which entirely prevented their crystallization. That was very often represented by what was called solubility. He was very much of opinion that solubility should be taken rather as the measure of the want of power of crystallization than as simply the power of solution. Sulphate of lead, for instance, was a very insoluble body, absolutely insoluble probably in pure water, but it was known how terribly soluble it was in some solutions, such as sugar, acetate of sodium and some other bodies. For these reasons it seemed almost impossible to make a standard.

Mr. SHENSTONE said that already there was one practice which predominated in the statement of solubilities. He had lately been engaged a great deal on this question, and in looking through other people's work he found a large number of the old investigators gave their solubilities as the amount of salt dissolved by 100 parts of water, and those who made experiments of this kind would save a great deal of trouble by adopting that as their standard. If it became the practice of everybody working in this line to adopt that method it would simplify matters for the future, for if all adopted different standards it was very inconvenient. With regard to Mr. Williams's remarks, he did not think the case he alluded to, *i.e.*, the solubility of caffein in salicylate of sodium, was necessarily not a case of chemical action, because of the possibility of extracting the caffein from that solution by chloroform. It was possible that when caffein came into the presence of the sodium salicylate chemical action took place, a certain amount of salicylate of caffein being formed, and a certain amount of sodium hydrate set free in the solution. If the solution were now treated with chloroform, the result would be that the free caffein which remained there would be removed, and then the equilibrium being upset a reverse action would take place, some of the caffein being set free, which the chloroform would then remove, and this would be repeated, so that practically it might all be got out again.

Mr. P. W. SQUIRE said the value of solubilities depended very much on the object in view. For example, if a person wanted to dissolve a salt in water and had no notion about how much it would dissolve, the information he required was how much salt would dissolve in a given quantity of water. If, on the other hand, a manufacturer had a liquor which he wished to crystallize out, he viewed it from the point of how low it ought to go before the substance ought to crystallize out, and therefore he looked at the question from a totally different point of view from the other man. The salt would not crystallize out until it was supersaturated. It occurred to him, therefore, it was something like the case of 32° F. being looked upon as either the freezing point of water or the melting point of ice. It was rather the melting point of ice. He should call solubility the amount which would be dissolved in water, and the other point when it would crystallize after evaporation the point of crystallization rather than solubility.

A paper was then read entitled—

NOTES ON THE PHARMACY OF CINCHONA.

BY R. W. GILES.

It may be taken for granted that the members of the Pharmaceutical Conference are perfectly well aware of the contradictory and unsatisfactory state of the pharmacy of cinchona, for there has scarcely been a meeting at which it has not been pressed upon their notice, so that they may possibly ask "What is the use of this wearisome iteration?" The answer is that the grievance remains, and custom and prejudice are so inveterate that it is necessary to attack it again and again, even with the same weapons, before amendment can be hoped for. In this way alone pharmacists are able to exercise some influence upon their own Pharmacopœia.

All practical pharmacists must be aware that it is next to impossible to obtain officially recognized cinchona bark of the official alkaloidal standard; while there is no lack of barks of superior alkaloidal value and equally well adapted to pharmaceutical purposes which are not officially recognized. These evident truths have been asserted amongst others by Trousseau et Pidoux (*Traité de Thérapeutique*), Professor Flückiger (*Pharmaceutische Zeitung*), and by Messrs. Umney, Holmes, and Dr. Paul, at meetings of this Conference.

The only dissentient that I know of is Mr. de Neufville, who asserted in a paper read at the last Conference (*Pharm. Journ.*, vol. xii., p. 369), that the *supply* of *flat* calisaya during the past few years had been abundant, and the *quality* of *quill* calisaya had been good; but I cannot put that and that together so as to amount to a statement that in his opinion there had been an abundant supply of good calisaya bark; and even then I should be obliged to conclude that the preponderance of evidence was against him.

Thus far the cinchona difficulty appears to be geographical; good barks, far exceeding the modest pharmacopœial standard, being excluded because they do not grow west of Greenwich and do not bear the name of calisaya. These do not appear to be distinctions of sufficient importance to place in opposition to scientific tests. Dr. Paul put the case clearly and conclusively when he said that an alteration was necessary in the range of selection o. pharmaceutical barks; that South American barks should not be excluded, but that Indian barks should be admitted. In other words, let alkaloidal standard be the sole test.

In consequence of the "fearful deterioration of calisaya bark,"* and the unsatisfactory state of its pharmaceutical preparations, cinchona has fallen more and more into disuse, to the prejudice of pharmacy and of medical practice, its place having been usurped by quinine, contrary to the opinion of the best authorities upon the relative value of the two medicines. It is the province of pharmacists to rectify this miscarriage amongst their wares, and to restore one of the most valuable articles of the materia medica to its proper place and functions. It is not suggested that they should substitute even good Indian bark for inferior calisaya, when the latter or its preparations are prescribed, however unadvisedly; but that they should take care to have in stock bark of sufficient alkaloidal value (independent of the B.P. standard, which is too low) and that they should *educate* the medical profession to the use of it.

Although therapeutics are a forbidden subject, it may be permitted to quote the opinions of orthodox authorities upon the therapeutical qualities of cinchona and its alkaloids as an indication of the direction which pharmaceutical research ought to take, the more so as those opinions show that the chemistry of cinchona has hitherto moved in the wrong direction.

It has been well established by the Medical Commission appointed by the Government of India to investigate the febrifuge properties of the cinchona alkaloids,† and their conclusions are supported by the testimony of English and more especially of continental observers,‡ that the febrifuge and antiperiodic action of cinchona is common to *all* its alkaloids, and it follows that the exclusive employment of quinine, as it has long prevailed, is a wasteful mistake. But more than this, the best writers upon therapeutics assert that *cinchona* possesses medicinal properties superior to those of any or all of its alkaloids, which Dr. Pereira attributed in part to the astringent properties of the cinchotannic acid, and in part to the aromatic quality of the bark causing the alkaloids to sit more easily upon the stomach.§ From this it may be inferred that pharmaceutical preparations of cinchona would be free from the objection sometimes charged against the mixed alkaloids employed in India under the name of cinchona febrifuge, that they excite nausea. In Neligan's 'Medicines,' similar opinions are expressed, viz. (p. 737): "Most practitioners are of opinion that none of the alkaloids possess the same medicinal properties as cinchona bark, *more especially in the treatment of intermittent diseases*. . . . and . . . I must, however, confess that every day's increased experience induces me to prefer the preparations of bark to those of any of its alkaloids when a *tonic* effect is sought for."

Why then should "*most practitioners*" have so far changed their opinions, or at any rate so altered their

* See *Pharmaceutical Journal*, vol. ix., p. 213.

§ Pereira, vol. ii., pt. ii., p. 137.

practice, as to substitute quinine for cinchona almost universally, and particularly in those periodic diseases for which it is so emphatically asserted that none of its alkaloids possess equivalent virtues? Is it not, at least partly, because, in the words of Mr. Umney already quoted, "Calisaya bark has deteriorated to a fearful extent of late," and, as Dr. Paul told the Conference last year, "it now really contains nothing more than a little cinchonine."

It may be very loyal to the Pharmacopœia to continue the unquestioning supply of calisaya bark which was described upon the same occasion as "almost invariably worthless;" but how about the welfare of fever-stricken patients, and the credit of pharmacy? It must not be forgotten that the Pharmacopœia never initiates anything; it is a codex of remedies which have already been approved and which it has become desirable to place under control.

The reputation of cinchona has once before suffered, at a very early period after its introduction into Europe, from a similar deterioration in the importations of South American bark. The early supplies brought over from Peru by the Count and Countess of Chinchon (1640) proved so effectual in the cure of fevers and agues that more orders were sent out than the Peruvian merchants could execute properly, and they sent back consignments of inferior barks, which proved worthless and brought the new remedy into temporary disfavour. This deception is as good a reason as any other for the name of Jesuits' bark which was conferred upon it at about this period.

There was no quinine in those days or probably the parallel with our present experience would have been complete; but having no substitute the common sense of the 17th century set an example to the science of the 19th. It discarded the worthless barks and supplied itself with others of suitable alkaloidal standard assayed by the fever test. In these days of practical science brokers sell and quinine-makers buy cinchona bark on the basis of its alkaloidal percentage, ascertained by exact analysis. The pharmacist alone buys hap-hazard the "showy barks," often very poor in alkaloids, and hence known as "druggists' barks," which the quinine makers are only too happy to leave for him and the dealers only too pleased to get rid of, though for pharmaceutical purposes percentage of alkaloids is more than a relative test of value,—it is an absolute test of fitness.

The very reverse ought to prevail; the pharmacist should secure the first choice by being willing to give a better price than the quinine makers, who can only give the alkaloidal value, which is literally the intrinsic value of a part of its constituents. Under this system the pharmacist would get much better value for his money than he does now by buying a "showy bark destitute of alkaloids." I have heard of a time-honoured establishment, which I must not further particularize, buying several serons of calisaya bark at 3*s.* 6*d.* lb., which proved to contain not a particle of quinine and only a very small amount of cinchonine. Its assay value certainly would not have exceeded 6*d.* This is a sort of bark which should be left for the stores, whom it would exactly suit, and where no questions are asked.

The question then is "What standard should be adopted for the cinchona of pharmacy?"

First, it should be an alkaloidal standard, not a quinine standard.

Secondly, it should be a mean and not an extreme standard.

And, thirdly, it should be catholic, admitting barks from all sources without arbitrary geographical distinctions, which, originally intended as definitions, have now become irrational limitations.

At the Conference of 1878, Mr. Umney spoke of East India bark containing 5 or 6 per cent. of quinia as the future source of fine fluid extract, and, if of fluid extract, of other pharmaceutical preparations. Assuming him to have meant 5 or 6 per cent. of mixed alkaloids, that would be a reasonable standard to insist upon,—say a minimum of 5 per cent., which holds a mean place between the extremes. I have computed the actual average of ninety-three lots offered on sale by the Dutch Government last year, and find that it is exactly 4·7 per cent. The highest quality reached 9·8 per cent., the lowest touched 1·2 per cent., giving a mean of 5·5 per cent. The mean of the two results is therefore 5·1 per cent.

It remains to be considered how this standard should be secured, for it is to be feared that pharmacists generally do not submit their purchases of cinchona to the pharmacopœial test, and it is as well to acknowledge that refined tests are not practicable in the pressure of daily business. Mr. Holmes, probably having this difficulty in view, suggested that the wholesale druggists should be required to state the percentage of alkaloids in the samples they offer, but this is scarcely sufficient for the protection or for the credit of the pharmacist.

The same difficulty seems to have presented itself to Messrs. Squibb, of New York, who have endeavoured to meet it by publishing what they consider a simple, easy process of assay suited to the wants and the skill of well-trained pharmacists who are not expert quinologists. Whether the process possesses the desired qualities of simplicity and facility may be judged by perusal of the description at p. 77 of the third number of Messrs. Squibb's 'Ephemeris.'

In pursuit of a similar object I have been led to prefer the more simple hydrochloric acid process, which I tried on the recommendation of Dr. De Vry, in his laboratory at the Hague and with the advantage of his assistance. The *modus operandi* finally adopted is as follows:—

Take 25 grams finely powdered cinchona bark, mix with 2·5 c.c. strong hydrochloric acid (=2·6 c.c. B.P. strength) in 30 c.c. distilled water, or just so much as suffices to moisten the bark; set by for two hours, add 100 c.c. distilled water and let stand for twelve hours or more, stirring occasionally, until all foam disappears from the surface. Pour into cylindrical glass percolator, the mouth of which has been stopped by a pinch of charpi loosely drooped into it and moistened with a little water, and recover the clear percolate. Pour on more water until the percolate ceases to be precipitated by caustic soda. In this way about 300 c.c. are recovered. Precipitate with caustic soda in considerable excess. Set the mixture by for twelve hours, when it will be found that the alkaloids have settled in a compact coherent stratum from which nearly the whole of the supernatant may be decanted. The decantate must be reserved. The precipitate is then poured upon a filter and washed with a little weak solution of soda to remove traces of cinchona red; finally it is washed with a little distilled water, the whole of the washings being added to the decantate and the measure noted. When the precipitate has drained it is to be carefully transferred to a tared porcelain dish, dried over water-bath and weighed. The weight should not be less than 1·25 grams, corresponding to 5 per cent. mixed alkaloids. But this will not be an exact indication of the alkaloids contained in the bark, as an appreciable quantity remains dissolved in the mother-liquor. Practically this may be estimated as 0·05 grams in 100 c.c., which should be added to the ascertained weight of the precipitate, and the sum multiplied by 4 gives a very close approximation to the true percentage, quite near enough for pharmaceutical purposes. When greater accuracy is desired the mother-liquor is treated with benzol and the alkaloids are recovered by operations which it is not necessary to describe as they need not be employed in pharmaceutical assays.

The merit of the above process is its simplicity and facility of manipulation; the several stages may be set going as opportunity offers and they proceed automatically without withdrawing the operator from other duties. Secondly, the results correspond with the amount of alkaloids which can be extracted in practical operations.

If it were not for the title of this paper there would be no reason for saying anything about the pharmaceutical preparations of cinchona. As it is, a very few words will suffice. It is notorious that they do not meet the demands of modern medical practice. Cinchona won its reputation by administration in the form of powder, it has lost it by the substitution of inferior preparations of inferior bark. The tincture, decoction and infusion of former generations have had their day and are becoming obsolete, never again to find favour with prescribers, pharmacists or patients. They are all too feeble in alkaloids for administration when the specific effects of cinchona are in question. Their qualities and their condemnation will be found in a paper by Mr. Ekin, in *Pharm. Journ.*, vol. ix., p. 213. Nor can it be necessary to pour more obloquy upon the much abused fluid extract, which has never yet found a single defender. Its poverty and its wastefulness have been often told. The best that can be said for it is that when carefully prepared from barks of suitable quality (which does not mean barks rich in alkaloids) it possesses agreeable astringent properties associated with an unimportant amount of alkaloids which render it acceptable as a vegetable tonic, but it leaves the major part of the valuable and characteristic cinchona principles in the imperfectly exhausted bark.

Fluid extracts are the pharmaceutical preparations of the day. Their convenience commends them equally to the medical practitioner, to his patient and to the dispenser, and the demand for them is not likely to be diverted; but a fluid extract of cinchona, worthy of its name, is still a desideratum in pharmacy.

The PRESIDENT proposed a vote of thanks to Mr. Giles. He feared the present was not the proper occasion for going into any question as to what principles the cinchona bark owed its therapeutical properties to; their time would not suffice to discuss that, even if they had sufficient medical knowledge to do so; but several important pharmaceutical questions had been brought forward in the course of the paper, and those might very profitably be discussed.

Mr. WELLCOME said the subject of supplying chemists with bark of definite alkaloidal strength for dispensing and manufacturing purposes had been much discussed before, and he believed that some houses did offer to chemists with their bark an assay giving the definite alkaloidal strength. That was the custom of some houses in regard to opium, and he believed Dr. Squibb and others supplied the trade in America with barks with which he furnished assays. It appeared to him that that was one of the most important safeguards, and, while he thought it desirable that every chemist should be able to assay for himself the alkaloidal strength and to determine the amount of the respective alkaloids, it was hardly practicable that he should depend entirely on his own assays, and after all the guarantee of a respectable house would be the best general safeguard. As to the question of the strength that should be accepted as a standard for pharmaceutical preparations. Some members of the Conference might remember that he strongly urged last year that the quinine strength should not alone be accepted, but that a definite alkaloidal strength of the various alkaloids should be the only standard. A bark which yielded two per cent. of quinine ought to be satisfactory for manufacturing pharmaceutical preparations, providing it contained a proper amount of cinchonidine, quinidine and cinchonine, say to make 5 per cent. total alkaloidal strength. Quinoidine was also very active, and some of the preparations most sold in the Tropics for checking fever and ague consisted almost entirely of that resin, which was by many considered a modified or uncrystallizable quinine.

Mr. SOUTHALL said he could quite confirm the difficulty which had been mentioned in regard to getting a reliable calisaya bark for pharmaceutical purposes. There was still a good run on the preparations of bark other than the extract and tincture. The decoction was very much ordered by medical men in his part of the country, and was more relied upon than either the fluid extract or tincture.

Mr. HAMPSON thought they would be more likely to reach the point the author aimed at of having an accepted standard quality of bark, or bark yielding a certain proportion of alkaloids, if there were a standing committee of pharmacists, and not a pharmaceutical committee formed by the Medical Council entirely. The Pharmaceutical Society ought to be legally recognized in all these matters, and if practical pharmacists held their proper position with respect to the National Pharmacopœia these important changes or improvements would be sooner brought about. As it was these changes came about in an indirect and slow manner, and improvements did not take place as fast as they should.

Mr. EKIN said he feared the medical men in Birmingham had made rather an unhappy selection, according to Mr. Southall's statement, for in the experiments he had made, which were referred to by Mr. Giles, he found the decoction was by far the weakest in alkaloidal value of all the officinal preparations.

Dr. SYMES confirmed Mr. Southall's statement that the decoction was very largely used and very much relied upon by medical men; it was not peculiar to Birmingham.

The PRESIDENT said it would be seen from the remarks which had been made that they greatly needed increased activity in the promotion of therapeutical research, and it would be well if there were a society for this purpose formed by medical men having competent chemical and physical knowledge.

Mr. GILES, in reply, said he could not claim that what he had brought forward was new, but still it sometimes did good to repeat what was already known. With regard to the alkaloidal standard, Dr. Pereira pointed out that cinchona made its reputation as a febrifuge by the use of a species of cinchona which was not rich in quinine, but in which cinchonine largely prevailed, and this seemed to show that they had made a mistake in pinning their faith so much to the alkaloid which happened to be first discovered. Although recent investigations appeared to show that it was necessary to give cinchonine or quinidine or cinchonidine in larger doses than quinine to produce the same effect, there appeared to be no difference in the effects produced and, therefore, it seemed to be a great waste to throw away that which might be recovered simultaneously with the quinine. At all events it seemed to him that it was rather their business to support the pharmaceutical manipulation of things than the chemical. He had often been disposed to think that chemistry had been ridden a little to death, and that isolation of active principles had been carried too far.

The following three papers were read succesively before a discussion was taken upon them:—

NOTE UPON THE ACTION OF GLYCERINE ON SOME SALTS OF IRON.

BY G. F. SCHACHT.

About two months ago our friend and fellow member Mr. Shenstone brought me the remains of a mixture that had been dispensed for him and which appeared to have undergone during the interval a somewhat interesting change. The prescription runs as follows:—

℞	Tr. Ferri Perchlor.	ʒiss.
	Glycerini	ʒvj.
	Aquæ	ad ℥vj.
M.		

The mixture when first prepared was of a pale sherry colour, and possessed an astringent metallic taste. When brought to me, however, by Mr. Shenstone the colour had almost disappeared and the taste was sweet and metallic but not astringent. It appeared, in fact, as though the iron had become reduced from the ferric to the ferrous condition.

The application of ferricyanide of potassium and of sulphocyanide of potassium showed us that this change had really taken place to a very considerable extent, but not quite to the complete reduction of the perchloride.

Mr. Shenstone kindly left the matter in my hands and I deem it of sufficient interest to bring before the Conference.

My first experiment naturally started with a repetition of the original prescription and an examination of the results at the moment of mixture, and though somewhat prepared for the fact by previous observation, I found it necessary to record as the first memorandum that the *tincture* of perchloride of iron taken from the ordinary dispensing bottle was no longer what it was when originally mixed, for it gave an emphatic bright green colour with ferricyanide of potassium.

It was clear, therefore, a change in the condition of the iron in the *tincture made with ordinary alcohol* had commenced to take place, similar to that suspected to have been developed under the influence of glycerine.

The mixture, however, still exhibited the usual deep red reaction with sulphocyanide of potassium, indicative of a plenteous proportion of unreduced ferric chloride. It was loosely corked and placed in a fairly light position in the laboratory, but not in direct sunshine.

After a fortnight's interval it was examined. It still in part retained its pale sherry colour, it produced a deep blue with ferricyanide and a much less deep red with the sulphocyanide of potassium.

It has been kept since that time (about three weeks) under similar conditions and I do not observe much further change.

A similar mixture was prepared and placed where it could *receive the direct rays of the sun.* After two days it was found to be colourless, to show abundant evidence of ferrous iron, but not to have entirely lost its property of reddening with sulphocyanide, nor has further exposure to the sun and the addition of more glycerine to the mixture entirely deprived it of this property.

Sunlight was also found to produce a similarly accelerating effect when the ferric chloride was subjected to the reducing action of ordinary alcohol.

It being clear, then, that glycerine possessed in a marked degree the power of reducing iron from the ferric to the ferrous condition, it was thought probable that it might be employed to prevent the converse change of ferrous into ferric salts which is sometimes so inconvenient.

A mixture was therefore prepared consisting of—

Ferrous sulphate	gr. x.
Dilute sulphuric acid	ℳxv.
Glycerine	ʒvj.
Water	to ℥vj.

and was kept in the diffused light of the laboratory. When first mixed it resisted all the fascinations of the sulphocyanide and bestowed upon it not the slightest blush, but after a few days the usual demoralization had commenced and the salt showed distinct signs of peroxidation. The amount of this action, however, appeared to have a limit, the proportion of ferric salt produced being very similar to that left unreduced in the former experiment.

Exposure to sunlight did not appear to influence this mixture in any special manner.

In connection with the probable further chemical changes that accompany these phenomena, I may mention the results of two further sets of experiments that were made, though I need not recite their details. They showed that both glycerine and ordinary alcohol reduce permanganate of potash rapidly.

I find that the behaviour of glycerine under treatment with permanganate has been already studied and that according to Kasmann (*Bull. Soc. Chim.*, [2], xxvii, 246) the change consists in the conversion of 2 molecules of glycerine *plus* 1 molecule of oxygen derived from the permanganate into 1 molecule of glucose and 2 molecules of water thus:—

$$2(C_3H_8O_3) + O_2 = C_6H_{12}O_6 + 2(H_2O).$$

Whether the changes brought about by the persalts of iron are similar to the above throughout I am not at present prepared to assert, but that such should be the case appears to me very probable. The question is very interesting and will I hope one day be answered.

In the meantime, pharmacists and medical men may with advantage remember that ethyl alcohol and glycerine (and probably other alcohols) reduce persalts of iron and tend to prevent the oxidation of protosalts, and that this influence appears to be stronger when the mixture is exposed to sunlight than when it is left in the shade.

Note on a Reaction of Glycerin and other Polyhydric Alcohols.

BY WYNDHAM R. DUNSTAN, F.C.S.,

Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

The reaction which forms the subject of this note is one which has been observed during the course of an investigation upon the action of some polyhydric alcohols upon sodium biborate. The fact that when certain of these alcohols are added to a solution of borax an acid reaction results, was first noticed by Klein (*Compt. Rend.*, lxxxvi., 826). In the case of glycerin, this reaction has been further studied by Senier and Lowe (*Pharm. Journ*, [3], viii., 819), who have also proposed a test for glycerin based upon it (*Journ. Chem. Soc.*, xxxiii., 438). In this reaction glycerin appears to resemble an acid in its action. If, however, the acid solution obtained by the addition of glycerin to an aqueous solution of sodium biborate be heated, the liquid becomes alkaline. The first published observation of this fact was made by Donath and Mayrhofer (*Zeits. f. anal. Chem.*, xx., 379), who considered this reaction characteristic of glycerin and propose to employ it as a test for this substance, using litmus as an indicator of the reaction. No test experiments, however, are detailed by these observers. In the present note the results of some experiments are given which, although not originally instituted for this purpose, indicate the delicacy of the reaction and also its invalidity when considered as specially characteristic of glycerin.

A number of experiments were first made to determine the delicacy of the reaction. The results led to the employment of a dilute solution of sodium biborate and to the abandonment of litmus as an indicator of the reaction. Even when a dilute solution of borax was employed the colour-changes of the litmus were ill defined. Other indicators were then experimented with and, finally, satisfactory results were obtained by the use of phenol phthalein. When an alcoholic solution of this substance, which is faintly yellow, is added to a solution of borax a rose-red colour is produced owing to the alkalinity of this salt. Upon the addition of glycerin to this solution the red colour at once disappears, the solution being acid and colourless. Upon heating the liquid the rose-red colour is again developed, reaching the maximum tint near the boiling point of the solution. As the liquid cools, the colour gradually fades away, until finally the solution is again colourless. The colour-changes are sharp and well defined. Experiments have been made with solutions of borax of various strengths; the best results were obtained with a half per cent. solution. A convenient method of applying the test is to take two cubic centimetres of a half per cent. solution of borax and add sufficient of an alcoholic solution of phenol phthalein to impart a decided rose-red colour. To this liquid gradually add the solution of glycerin made neutral or faintly alkaline, until the colour is discharged. Heat the solution to the boiling point, the red colour is restored, and after cooling the liquid is again colourless. Excess of glycerin is to be avoided, otherwise the alkalinity of the solution is only partially restored by boiling. The delicacy of the reaction is dependent not only upon the excess of sodium biborate which might be present, but also upon the amount of water. If the colourless solution obtained in the above manner be largely diluted with water the red colour is partially restored. After a great many experiments it was found that using a half per cent. solution of borax the limit of the test is practically reached at a two per cent. solution of glycerin. Using two cubic centimetres of borax solution, about five cubic centimetres of a two per cent. solution of glycerin were necessary to discharge the colour. When a stronger solution of glycerin is used the amount required will of course be less than that of a two per cent. solution, but not proportionately less, for the more dilute the solution of glycerin the greater is the action of the water, which tends to reproduce the alkalinity of the solution. Hence the quantity of a stronger solution of glycerin required will be less than the proportional amount calculated from a more dilute solution. The test is not satisfactory with solutions of glycerin of greater dilution than two per cent., as the changes of colour become indefinite, owing to the action of the water. Neither can a more dilute solution of borax than a half per cent. solution be used for the same reason. I have made a series of experiments upon the utilization of this reaction as a basis for the quantitative estimation of glycerin, but so far the results have not been altogether satisfactory. The reaction is far from characteristic of glycerin, but is more so of the polyhydric alcohols in general. I find that it is also given by mannite, erythrite, dextrose, levulose, lactose and mycose. Sucrose (cane sugar) does not behave in the same way. In the case of mannite the reaction is extremely delicate, more so than with glycerin, and the solution is not so amenable to the influence of water as is the solution of the latter substance. Guaiacol, pyrogallol and saligenin also give the reaction. Orcin and resorcin, when added in large quantity, partially destroy the red colour, but it is not restored by boiling.

Ammonium salts, which are known to liberate boracic acid from solutions of borax (Woodcock, *Journ. Chem. Soc.*, xxiv., 785), discharge the red colour of the test solution, but it is not restored upon heating. In testing liquids for glycerin by this method ammonium salts should be removed by ebullition with sodium carbonate, and the solution either made nearly neutral or evaporated and extracted with a mixture of ether and alcohol before applying the test.

It appears from the above experiments that this reaction is not only given by glycerin but also by many other polyhydric alcohols, both of the paraffin and benzene series, and by certain sugars. Therefore in testing for glycerin by this method the absence of these substances must be ensured. I hope in a future paper to show precisely the nature of the reaction which occurs between certain of these polyhydric alcohols and sodium biborate.

The Solubility of Boric Acid in Glycerine.

BY DAVID HOOPER,

Pharmaceutical Chemist.

The extended application that has recently been made of boric acid combined with glycerine has created a demand for these two antiseptics in many forms. The most prominent among them is a preparation introduced by Professor F. Barff, M.A., and named by him "Boroglyceride" (*Journal of the Society of Arts*, xxx., 516), and still later the glycerborate of calcium and the glycerborate of sodium fully described by M. Le Bon (*Comptes Rendus*, xcv., 145). But it appears, on reference, that a more simple preparation, the mere solution of the one substance in the other, has been little investigated, or at any rate determined, and therefore some experiments were instituted to elucidate this point, and after determining the strength of a saturated solution at the mean temperature of our latitude, observations were continued in order to discover the relationship this result bore to its solubility at other temperatures.

As only two chemical bodies were to be employed in the following determinations, special attention was directed to their purity. The boric acid (B_2O_3,3 H_2O) was free from compounds of ammonium and magnesium, and from other salts and acids likely to be met with in its natural state or in its preparation from borax. Its specific gravity was taken and found to be 1·485. It was used in fine powder and kept under a bell jar over sulphuric acid to prevent absorption of moisture or gases. The glycerine was a very pure sample, it had a gravity of 1·260 at 15·5° C. and was always measured as near this temperature as possible.

The viscid nature of the glycerine, its slower dissolving capacity, and the alteration of boric acid when subjected to heat, make it tedious to estimate their solubility by any of the few ready methods employed when water is the solvent. It eventually occurred to the author that in a case like this some physical formula involving a knowledge of density and volume might well be utilized. As a datum, therefore, a solution was thus prepared. An excess of boric acid was added to some glycerine half filling a pint bottle, the mixture was kept with frequent agitation in an apartment where the temperature ranged from 18° C. to over 20° C., after three days the solution was poured off and transferred in another bottle to a cellar where it was kept for a similar period at 16° C. A slight crystalline deposit had formed in the mixture, due to the reduction of temperature. The specific gravity of the resulting saturated solution was then carefully taken. The weight of a certain volume and the gravities of its constituents being known, the following formula was used to obtain their proportions:—

$$V = V_1 + V_2$$
$$VS = V_1S_1 + V_2S_2$$

when V, V_1, V_2 represent the volumes of the mixture, the glycerine and the boric acid respectively, and S, S_1, S_2, their relative gravities.

The working of this formula may be illustrated by calculating from an actual experiment. The weight of a saturated solution when taken in a 1000 grain bottle was found to be 1290 grains. Substituting this with the other data the formula becomes

$$1000 = V_1 + V_2$$
$$1290 = V_1 . 1{\cdot}260 + V_2 . 1{\cdot}485$$

these two equations worked out simultaneously will give for glycerine, 866·6 and boric acid, 133·3 grain volumes per thousand; the volume of the last-named substance has, however, to be converted into weight. Then by proportion, it is shown that 4·37 parts by volume of glycerine dissolve 1 part by weight of boric acid at 16° C.

Some experiments were also made by mixing different quantities of glycerine with the same amount of boric acid and agitating them occasionally for several days, when it was again determined that 4·4 c.c. or practically 4½ c.c. of glycerine were sufficient to dissolve 1 gram of boric acid.

The methods used for determining the saturation point at higher temperatures were according to the following description:—The apparatus employed was, a long test tube furnished with a rubber stopper and graduated from the bottom in cubic centimetres accurately corresponding with those marked on a burette containing the glycerine, and a water-bath consisting of two beakers containing water, the one immersed in the other of larger size, and placed at such a distance over the source of heat so that the temperature might be regulated to any desired degree. A weighed quantity of boric acid and a measured quantity of glycerine were run into the tube, the acid being in excess, glycerine was cautiously dropped in until, after remaining in the water-bath for about half an hour, perfect solution was obtained. The temperature was then lowered and the degree at which the mixture began to be turbid was noted, and this was used as a check on the particular determination. After numerous experiments in this manner a line of solubility was formed extending to the boiling point of water. Some of these higher saturation points were tested by keeping the mixtures in stoppered bottles in an air oven with regulated temperature, but I consider the determinations as detailed in the above description would be performed with more expedition if not with more accuracy. It now remained to take the solubility at zero; this was found by diluting a saturated solution with glycerine until the acid ceased to crystallize out when immersed for half an hour in a tube in melting ice.

In the following table the results are exhibited as parts by weight dissolved in 100 parts by volume of the solvent; such a representation is found in the lines of solubility shown in Fownes's 'Inorganic Chemistry' (p. 144):—

Solubility of Boric Acid in 100 parts of Glycerine from 0° to 100° on the Centigrade Scale.

20	parts at	0°
24	"	10°
28	"	20°
33	"	30°
38	"	40°
44	"	50°
50	"	60°
56	"	70°
61	"	80°
67	"	90°
72	"	100°

The solubility of boric acid in water has been determined by Brandes and Firnhaber (Watt's 'Dictionary of Chemistry,' i., p. 639), the results were calculated so as to make a line comparable with the table just represented. The line formed is not absolutely straight, and although it occurs much lower down on the scale, it is not parallel; a slender convergence takes place in the direction of zero. I propose, if opportunity is afforded, to make fuller comparisons of these two lines and find what relation exists between them when lines of solubility are formed by dissolving the boric acid in glycerine diluted to various strengths with water.

Votes of thanks having been passed to the authors of the above papers,

The President said Mr. Schacht's note was very acceptable, and was a model in many respects. It belonged to a class which was always welcome, being the result of observations in the course of dispensing. With regard to the reaction itself, it had long been known that perchloride of iron was reduced to a ferrous condition by alcohol, and indeed there was in a former North German Pharmacopœia a preparation called ethereal spirit of chloride of iron, made by dissolving the perchloride of iron in alcohol and exposing it to light until the green colour was produced, and a tincture of a very pleasant flavour was obtained. Apparently the reaction was more rapid with glycerine. There might be a reaction such as Mr. Schacht had described, and probably there was a reaction with the glycerine, that substance being, indeed, an alcohol, a polyhydric alcohol as Mr. Dunstan had remarked. Mr. Dunstan's paper had considerable interest, inasmuch as it would throw light on the constitution, not only of glycerine, but of boric acid, and borax; all which substances being used in pharmacy, any further knowledge respecting their constitution would be interesting to pharmacists. Mr. Hooper's paper seemed rather to bear on the action of antiseptics. Not only were chemists and druggists interested in the preparation and sale of antiseptics, but advice respecting their employment might be very properly given by pharmacists. It was very gratifying to see that Mr. Hooper had produced a paper of this kind involving a large amount of skill and knowledge, just the paper that should be produced by a chemist who was also a druggist.

Mr. Kingzett said there was no reason to suppose that the antiseptic property of boroglyceride was any greater or more definite than that of boracic acid on the one hand, or glycerine on the other, or a mixture of the two substances into which the compound is resolved again by the agency of water, or even of the tissues in which water is always present. He therefore failed to see on what grounds this substance was put forward as a new or improved antiseptic. Boroglyceride might be regarded for all practical purposes as a mixture of glycerine and boracic acid, and there was no evidence on record pointing to the superiority of the compound as an antiseptic.

Mr. Gerrard was very much pleased with Mr. Schacht's communication, because it explained what took place in a perchloride of iron mixture which was very largely used in his hospital. It always contained some glycerine, and he found, after standing a week or so, the last portion was much clearer in colour than when first made, consequently a mixture made with this residual portion differed in colour from that first made, and it was often a question asked of dispensers why the mixture sometimes appeared dark and at others light. The explanation now given seemed very satisfactory.

Mr. Schacht, in reply, said he had nothing further to add except this, that he must acknowledge he did not remember, perhaps he never knew of the German preparation that had been referred to, but he was aware that there had been plenty of observations bearing upon this point by other men, and he should not have troubled the Conference with it, but at the time he first made his notes he thought it was just possible that he should be able to add something to what was known of the processes that went on during the change. The difficulties of the case, however, had been a little too much for him, and he had not been able as yet to determine what exact changes did take place.

(*To be continued.*)

Parliamentary and Law Proceedings.

Excise Prosecution.

At the Hull Police Court, on Tuesday, September 12, 1882, before Mr. E. C. Twiss, Stipendiary Magistrate, Robert Banks, chemist and druggist, Porter Street, was summoned by the Excise authorities "for unlawfully selling a certain article, capable of being used internally as a medicine, viz., paregoric, in the preparation of which methylated spirits and derivatives of methylated spirits had been used."

Mr. Claxton, Inspector of Inland Revenue, stated that, from complaints that had been made, two samples of paregoric were purchased at the defendant's shop, which were analysed, and both found to contain methylated spirit instead of ordinary alcohol, but in different quantities in each, which must have been taken from two different sources.

The defendant admitted the offence, and could only account for it by supposing that the paregoric had been taken out of the wrong jug, as he had one containing methylated spirit and the other ordinary spirit. He was not certain whether he or his assistant served it.

His Worship said defendant had made himself liable to a penalty of £100. He would be fined £10, including costs.—*Eastern Morning News.*

Suicide by Hydrocyanic Acid.

On September 14, Mr. Malcolm, coroner for Leeds, held an adjourned inquest touching the death of Mr. Wm. Hornby, a gentleman, aged 71 years, and who had formerly held the office of an alderman of the borough. The deceased was found dead in bed, and a *post-mortem* examination and chemical analysis made by Mr. Scattergood revealed the presence of hydrocyanic acid. A bottle which had contained the poison was found in the bedroom. From the evidence, it appeared that the deceased applied at the shop of a chemist where he was well known for an ounce of hydrocyanic acid, stating that he wished to kill a dog. From a letter addressed to his son by the deceased a deliberate intention of self-destruction was manifest, the cause being pecuniary difficulties originating in railway speculations some time since. The jury found that deceased died from poisoning, and that he was of sufficiently sound mind to know what he was doing.

Poisoning by Laburnum Seed.

At Richmond, Yorkshire, on Monday week, three young boys were poisoned by eating the seed which had fallen from a laburnum tree near the infant school in Dundas Street. Whilst at school during the afternoon the children vomited a good deal. Medical aid was afterwards obtained, and although the usual restoratives were applied, the boys continued in a very bad state until midnight, when they took a turn for the better, and they are now making favourable progress. There have been several similar cases in the town lately, but none of them have proved fatal.—*Leeds Mercury.*

Poisoning by Aconite.

A peculiar case of poisoning by aconite has come under the notice of Mr. Frederick G. Baker, one of the house surgeons at the Poplar Hospital, and from which no less than five persons are suffering. From what the surgeon has learned, it appears that one of the persons poisoned (a young man) saw something drop from one of Messrs. Pickford's vans, and on picking it up thought it to be a piece of horseradish. He tasted it, and on finding the root palatable he ate some and gave a piece each to three other young men, one of whom gave a portion to his sister. Alarming symptoms of poisoning soon began to show themselves, and the sufferers were taken to the Poplar Hospital, where Mr. Baker managed to keep up artificial respiration for about four hours, when the effects of the aconite began to be exhausted. The symptoms exhibited by the poisoned persons were paralysis of the legs and arms and a burning sensation on the tongue. A piece of the supposed root was examined by Mr. Baker, who at once found that it was aconite. All the persons are now nearly recovered.—*Leeds Mercury.*

Obituary.

Notice has been received of the death of the following:—

On the 15th of July, Mr. Henry James Henderson, Chemist and Druggist, Shieldfield, Newcastle-on-Tyne. Aged 62 years.

On the 7th of August, Mr. John Woods, Chemist and Druggist, North Street, Chichester. Aged 66 years.

On the 8th of August, Mr. Joseph Frederick Malins, Chemist and Druggist, The Dispensary, Reading. Aged 54 years.

On the 19th of August, Mr. James Sinclair, Chemist and Druggist, Llandudno. Aged 66 years. Mr. Sinclair had been a Member of the Pharmaceutical Society since 1877.

On the 23rd of August, Mr. William Graham Carr, Pharmaceutical Chemist, Berwick-upon-Tweed. Aged 78 years. Mr. Carr had been a Member of the Pharmaceutical Society since 1841.

On the 26th of August, at Scarborough. Mr. Edward Cass Coverley, Chemist and Druggist. Aged 51 years.

On the 1st of September, Mr. Henry Brearley, Chemist and Druggist, Swine Market, Halifax. Aged 41 years.

On the 2nd of September, Mr. George Frederick Kent, Chemist and Druggist, Shirehampton, near Bristol. Aged 44 years.

On the 4th of September, Mr. James Watmore, Pharmaceutical Chemist, Peach Street, Wokingham. Aged 31 years.

On the 5th of September, Mr. Hamilton Murray, Chemist and Druggist, Lancaster Street, Newcastle-on-Tyne. Aged 50 years.

On the 9th of September, Mr. Samuel Johnson, Pharmaceutical Chemist, Church Street, Liverpool. Aged 70 years. Mr. Johnson had been a Member of the Pharmaceutical Society since 1841.

On the 14th of September, Mr. Andrew Brunton, Chemist and Druggist, Partick, N.B.

Correspondence.

The Decomposition of Salicin.

Sir,—Permit me to remark upon certain of the points raised in the discussion which followed Mr. Brownen's paper at the late Conference meeting, as reported in your issue of last week.

With the general tenour of Mr. Kingzett's remarks I perfectly agree, but they contain one statement which I believe to be an error, and one which is so widely repeated that I venture to point it out a second time. The statement I refer to is that if salicin "were boiled with a dilute acidulated solution, the compounds mentioned by Mr. Brownen would be obtained, viz., glucose and saligenin." In a paper published in this Journal ([3], ix., 865) I showed that saligenin cannot be obtained by the action of boiling dilute acid upon salicin in quantity sufficient to give the blue colour with a ferric salt, much less to give the crystalline scales mentioned by Mr. Brownen. The fact is that though perhaps saligenin is formed in an intermediate reaction, the action cannot be stopped at that point, and the result is invariably glucose and saliretin. In the paper referred to I quoted the original investigator of the reaction in support of my results, and against the statements of most works on chemistry. If, however, anyone can show how different results may be obtained I shall readily admit that I am wrong.

Another point I wish to refer to is mentioned by Mr. Groves, and is certainly important. Have the digestive ferments any action upon each other which modifies their activity in any important respect? Some experiments of mine, published in the *Pharmaceutical Journal* ([3], ix., 751), though fragmentary, bear directly on this. They prove that in the case of a starch-converting ferment, such as that of malt, its activity is not affected by the presence of pepsin (itself not starch-converting) nor by a very weak acid, but that it is destroyed by a certain degree of acidulation.

Professor Attfield showed his usual tact in his veto of a discussion upon the "mysterious factor" or "vital force," but at the same time, as Dr. Symes pointed out, it is practically impossible in the chemical laboratory to imitate the conditions which obtain in the living alimentary canal. While, therefore, it must be admitted that the value of such an investigation as Mr. Brownen has commenced is immensely reduced by this fact, still its importance as a check upon purely biological evidence is quite enough to induce a hope that the subject will be thoroughly studied.

"THE MONTH."

Autumn is undoubtedly the best time to study the structure of fruits, more being then available for the purpose than at any other period of the year. The scarlet berries of the bryony, dulcamara and mezereon, and the still more specious fruits of the yew, as well as the cherry-like fruit of the deadly nightshade (*Atropa Belladonna*), are just such as would tempt the eye, and it is scarcely a matter of surprise that they should be picked and eaten by young children. In the *British Medical Journal* (p. 521) a case of poisoning by mezereon fruits is recorded, the patient being a little girl, two and a half years old, living at Maidstone, who seems to have eaten about fifty of them. After the administration of emetics and castor oil (the former of which did not cause the ejection of the seeds), the application of mustard to the chest, and the use of ammonia and brandy internally, she evacuated the seeds and recovered next day. The case possesses some interest as six to twelve berries have been considered a fatal dose, and the narcotic symptoms which formed a marked feature in this case have been disputed. A somewhat similar case of poisoning lately occurred at Plumstead in the same county, a little boy two years old having eaten some berries supposed to have been collected in the next garden. The medical man who saw the child found him suffering from inflammation of the stomach and intestines, "due to some irritant mineral poison." After a *post-mortem* examination death was attributed by the same medical man to the deceased having eaten some of the berries. These were said by the coroner to be belladonna berries; but the *British Medical Journal* doubts whether this plant is likely to have been found in a garden and suggests the *Solanum nigrum* or *S. Dulcamara.* It seems strange that the medical man should not know belladonna when he saw it, yet it can scarcely be called an irritant poison. The frequent mistakes which occur concerning this plant and the hemlock water dropwort seem to suggest that a practical knowledge of our indigenous poisonous plants, as well as of the commoner garden species, does not form so prominent a feature in botanical lectures as it should do.

At this time of the year orchids with green or white flowers seem to be the predominant species. The musk orchis, *Herminium monorchis*, the *Spiranthes autumnalis* (both with greenish-white flowers and fragrant towards the evening), and the *Habenaria viridis* are not unfrequent in pastures, but probably often overlooked. Another species, also with green flowers, *Malaxis paludosa*, probably often escapes notice from occurring in spongy bogs where it is dangerous to tread, but when found the curious gemmæ on the leaves are worthy of notice. The *Spiranthes* has, for the size of the plant, remarkably large tubers, which would probably make as good salep as the Indian kind.

At the Botanical Gardens at Regent's Park, one or two interesting economic plants may be seen in fruit. That of the star-anise, in which the carpels are erect in the centre of the flower when in blossom, may now be seen extended with the follicles occupying a horizontal position. The smooth fruits of *Croton Tiglium*, in the Economic House, present a marked contrast to the prickly fruits of the castor oil plant, which more resemble externally the thorny "apple" of the *Stramonium*. *Adenanthera pavonina* is also in fruit, and will afford an opportunity of watching the change of the seeds from green to the brilliant red colour which characterizes them. The sensitive plant, *Mimosa pudica*, is now decked with heads of flowers of a delicate lilac hue, and the jaborandi (*Pilocarpus pennatifolius*) is putting forth fresh flowering spikes.

At Kew the Economic Beds still present a number of medicinal plants in blossom, among which are conspicuous the pinky-white flowers of the scammony plant, while the violet-blue ones of the alkanet and the sky-blue of the borage are in close contrast; peppermint, lavender, horehound, chicory, safflower, hemp, and many others, also continue in flower. The barren terminal bracts of *Salvia Horminum* seem to concentrate in themselves all the colouring matter of the plants, and if colour serves to attract insects it is difficult to understand why they should present so conspicuous a purple, while the small, almost white, flowers might easily be overlooked.

In the country the colchicum should be in full blossom, enlivening the damp pastures, to which it is partial, by its brightness of colour. The camomile is abundant on damp grassy commons and the hop hangs its graceful festoons on the hedgerow. The catmint, too, with an odour which has been likened to that of some of the cages at the Zoological Gardens, is now in blossom on chalky banks.

Of roses the name is legion, and it requires some little courage to attempt the feat of mastering the distinctive features of even the British species. A new variety of a species of this intricate genus has recently been discovered by Mr. George Nicholson, Assistant Curator of Kew Gardens, at St. Cyrus, Kincardineshire. It has been named by M. Crepin, in compliment to the discoverer, var. *Nicholsoni* of *Rosa subauda* (*Gardeners' Chronicle*, p. 272).

The new British umbellifer, *Selinum carvifolium*, mentioned as having been discovered in Lincolnshire, has now been met with in great quantity, and undoubtedly wild, in Cambridgeshire, by a young botanist named Cross (*Gardeners' Chronicle*, p. 276). It is satisfactory to know that the plant may therefore be accepted as a native of Britain; probably a species so easily overlooked may yet be found in some of the other eastern counties of England.

Another new British plant has recently been discovered, viz., *Lycopodium complanatum*. This plant, which had previously been found as near this country as Belgium, was met with in heathy ground in Gloucestershire. Except in its compressed frond and procumbent habit, it bears considerable resemblance to *L. alpinum*, for which it might perhaps be overlooked. A figure and full account of the plant are to appear, it is said, in the forthcoming number of the *Journal of Botany.* Several other interesting discoveries have also been made recently, *e.g.*, the occurrence of *Eriophurum gravile* in the New Forest, and also *Isnardia palustris*, in tolerable abundance.

In *Nature* (p. 477), Dr. Schaarschmidt Gyula corrects a statement of Professor Pringsheim concerning the occurrence of hypochlorin in the *Bacillariaceæ* and *Cyanophyceæ*. Dr. Gyula says that he has with the use of hydrochloric acid found hypochlorin in all the *Bacillariaceæ* and *Cyanophyceæ* investigated, the experiment having succeeded best with *Calothrix scopulorum*. As this species is not uncommon all round the British coast, forming a dark green skin on the rocks, the accuracy of Dr. Gyula's remarks can easily be tested.

The investigations of Pringsheim on the nature and mode of formation of chlorophyll have been gone over by A. B. Frank (*Journ. Micr. Soc.*, p. 528), and among other interesting results arrived at he concludes that the change of colour of leaves in autumn is due to the disappearance of the protoplasm of the cells, in consequence of which the chlorophyll grains come in contact with the acid cell sap, the result being the change of the green colour into yellowish green or yellow, followed by the separation of oily drops of hypochlorin. The same change takes place in fruits and also in leaves which become yellow from want of light. Wiesner regards the protection of chlorophyll from injury as one of the functions of vegetable protoplasm.

In *Comptes Rendus* (xcv., 487), a note by Mr. E. Mer is published which throws some light on the curious dimorphic leaves of aquatic Ranunculi. He considers that as the petioles of submerged leaves elongate, while the contrary is the case with the floating leaves, it is probable that the petiole absorbs the nutritive matter to the detriment of the limb, the submerged leaves not producing starch and not being capable of transpiration. This does not apply to sessile leaves, since in them there is no disturbance of the nutritive balance, the dimensions only of the leaf being lessened.

Some interesting results have been obtained by A. J. Kunkel (*Journ. Micr. Soc.*, p. 532) concerning the various electric phenomena observed in plants. He found that the leaf veins are generally positive towards the rest of the leaf, but the direction of the current is reversed if the spot on the leaf where the electrode is placed is wetted before the other electrode is placed on the vein. A spot long moistened is positive towards one freshly wetted. When a plant is bent or wounded the electrode near the bend or wound is negative to the other. Dr. J. Burdon Sanderson has noticed somewhat similar phenomena in the leaf of the Venus's fly trap (*Dionæa muscipula*), the under surface of the sensitive lobe of the leaf being electro-negative to the upper at the moment that the leaf is irritated; after about half a second the upper surface becomes electro-negative and remains so for some time.

Baron F. Mueller, the well-known botanist, Director of the Botanical Gardens at Melbourne, defends, in the *Gardeners' Chronicle*, p. 278, his use of the words "algs" and "fungs" instead of "fungi" and "algæ," on the ground of conformity with the terms mosses and lichens. In the same way he uses the word "eucalypts" instead of "eucalypti," just as we say 'elms" instead of "ulmuses." His use of the diminutive termination "let" in "stalklet," "fruitlet," etc., and other alterations proposed by him, are, it may be hoped, the commencement of a change of foreign botanical terms into more easily understood English ones, a change which would certainly render the study more easy and pleasant than it is at present, and tend to remove the reproach that botany is a science of hard names.

In the report by Dr. Cobbold (*Nature*, p. 492) to the British Association, on the injurious parasites of Egypt, he points out that the little fluke parasite (*Bilharzia hæmatobia*) which causes endemic hæmaturia, although it is a genuine fluke parasite of the class which requires a change of hosts for its development, can still produce the disease if swallowed in the form of the free swimming *Cercania*, and that therefore the canal water in which these occur should not be drunk in the unfiltered state. In another paper, on the brown coloration of the Southampton water, by Dr. A. Angell, the colour is attributed to a brown organism (*Pendinum fuscum*), from which both brown and green solutions can be obtained giving the spectroscopic appearances characteristic of chlorophyll. The author considers it probable that the organism is of a vegetable nature.

In some experiments as to the conditions conducive to the action of pepsine, made by Herr A. Mayer (*Zeits. f. Biol.*, xvi., 351; *Mon. Scient.*, [3]., xii., 842) it was found that the action was favoured by elevation of temperature; the limit is, however, reached at 55° C., for between 55° and 60° the ferment is killed. Hydrochloric acid of a strength corresponding to 2 parts of acid in 1000 was found best to promote the action. Other acids were tried and gave results corresponding with the following order:—nitric, oxalic, sulphuric, lactic, tartaric, formic, succinic, acetic, butyric, salicylic. The last two had no action. Coagulated albumen was the substance operated upon and the pepsine used was prepared by macerating the mucus from a pig's stomach with glycerine and precipitating with alcohol. The presence of bacteria did not in any way retard the action of the pepsine.

In a recent communication to the Société de Biologie, M. de Korab described some results following the use of "helenin" in pulmonary diseases. The same observer now reports (*Comptes Rend.*, xcv., 441) some experiments made as to the action of that substance upon the bacilli of tuberculosis. He states that when the organisms were suspended in sterilized serum and placed in tubes, into some of which helenin was also introduced, the bacilli multiplied in the liquor containing no helenin, but that in which it was present showed no signs of their development. Further, whilst the former liquid when injected into animals produced the tuberculous condition the latter appeared to be inert in this respect. Some other experiments appeared to show that helenin administered in the food or injected subcutaneously acted as a preventive to tuberculous infection by inoculation, or in cases where the disease already existed modified it favourably. As the publication of this communication may possibly lead to some inquiries respecting helenin, it may be useful to recall the fact that it is a crystalline substance occurring in small quantity in elecampane root (*Inula Helenium*), and is represented by the formula C_6H_8O. According to the authors of 'Pharmacographia' the crystals have a slightly (?) bitterish taste, but no odour, and melt at 110° C.

A chemical investigation of the white and the yellow water lilies (*Nymphæa alba* and *Nuphar luteum*) has been carried out by Herr Grüning, in the laboratory of the University of Dorpat. He reports (*Archiv*, xx., 589) that he has separated an alkaloid from the rhizomes of each of these plants. The alkaloid from *Nuphar luteum*, which he has named "nupharine," is soluble in alcohol, chloroform, ether, amyl alcohol, acetone and dilute acids, but is almost insoluble in petroleum spirit. No crystalline salts have yet been obtained, and of the alkaloid only small greenish crystals have been obtained with difficulty. Nupharine is precipitated by the usual alkaloidal reagents. Upon analysis results were obtained corresponding with the formula $C_{18}H_{24}N_2O_2$, which is the composition attributed by Pelletier and Couerbe to menispermine and paramenispermine, with neither of which is it, however, identical. The alkaloid from *Nymphæa alba*, which had previously been observed by Dragendorff, resembles nupharine in its physical characters and its behaviour towards solvents and alkaloid reagents, but differs entirely in a series of colour reactions. No alkaloid was obtained from the seeds of *Nuphar luteum* or from the seeds or flowers of *Nymphæa alba*.

The conditions under which ammonia in contact with copper becomes oxidized have been studied by Dr. S. Kappel (*Archiv*, xvii., 567). He finds that in contact with copper, and with access of atmospheric air, ammonia is converted into nitric and nitrous acids even in the cold, but that the conversion is accelerated by heat; in both cases, however, all the ammonia is eventually oxidized. An acceleration of the oxidation takes place also in the cold if the operation be conducted in a current of carbonic acid gas, due to the formation of carbonate. If access of atmospheric air be entirely excluded, the oxidation of ammonia in contact with copper can no longer be recognized with certainty. Zinc and iron in contact with ammonia and with access of atmospheric air are capable of producing nitrites, but their action is weaker than that of copper, which Dr. Kappel thinks is possibly due to the hydrogen liberated in the nascent state exercising a reducing action upon the nitric and nitrous acid already formed.

According to M. Debray (*Comptes Rend.*, xciv., 1222) the reaction by which mercuric chloride in aqueous solution is converted into calomel in the presence of sulphurous acid no longer takes place under ordinary conditions if the solution contains a considerable quantity of sodium chloride, even if the solution be boiled and the sulphurous acid be continually renewed. But the reaction does take place slowly if the mixtures of chloride and dissolved sulphurous acid be heated in sealed tubes to a temperature of about 120° C. M. Debray also states that when mercuric chloride is precipitated with potash or soda in the presence of a considerable excess of sodium chloride the formation of intermediate oxychlorides does not take place, but after a short time there is produced a crystalline precipitate of oxide, which is more dense than the oxide ordinarily obtained by precipitation; this precipitate is yellow when formed in a cold liquid, but if the liquid be boiling it is of a red colour near to that of the oxide obtained by calcination of the nitrate. Like this latter, the red crystalline precipitated oxide is not attacked by dry chlorine; but the yellow crystalline oxide is slightly attacked, though much more slowly than the ordinary amorphous oxide.

In a paper on the hydrocarbons of the formula $(C_5H_8)n$, read before the Chemical Section of the British Association at its recent meeting (*Chem. News*, Sept. 15), Dr. Tilden mentions an experience that may eventually become of some practical importance. It related to isoprene (C_5H_8), a very volatile liquid discovered by Mr. Greville Williams among the products of the destructive distillation of india rubber, which has the property of being reconverted into india rubber by treatment with strong aqueous hydrochloric acid or nitrosyl chloride. As isoprene, when heated to about 280° for some hours, polymerizes into a terpene, which appears to be identical with terpilene, the optically inactive hydrocarbon obtained from turpentine, and when subjected to the action of sulphuric acid behaves precisely in the same manner as turpentine oil, Dr. Tilden was induced to try whether turpentine could be partially depolymerized into isoprene, and the synthetical production of india rubber be accomplished in this way. Upon passing turpentine through a red-hot tube and fractionally distilling the product a small quantity of liquid was actually obtained having the same composition and some of the properties of isoprene, and which by the action of hydrochloric acid yielded a tough substance closely resembling caoutchouc. But sufficient of this liquid has not at present been obtained to enable Dr. Tilden to say positively that it is isoprene.

It is known that the presence of organic matters in saline solutions will in some cases prevent the formation of precipitates, and a communication from Messrs. Lefort and Thibault (*Jour. de Pharm.*, [5], vi., 169) appears to show that a substance commonly used in dispensing, gum arabic, is capable of affecting the formation of precipitates to an unexpected extent. In operating under certain conditions these chemists have found that in the presence of gum precipitates of metallic sulphides are not formed in dilute solutions (one-tenth of an equivalent per litre). Metallic oxides behave similarly in more concentrated solutions, corresponding with their greater solubility in water. The same result was observed with mixtures of neutral phosphate of ammonia and chloride of calcium, nitrate of uranium and ferrocyanide of potassium, and perchloride of iron in dilute solution and ammonia. But what is perhaps of even more importance is the influence of gum arabic in the case of alkaloids, solutions of 1 in 1000 of quinine, cinchonine, morphia, strychnia, brucia, and veratria not giving in the presence of gum a precipitate with phosphomolybdate of ammonia, the double iodide of mercury and potassium, or tannin. On the other hand, iodide of lead, iodide of mercury, sulphate of barium and carbonate of lead are precipitated from solutions containing gum, as completely, though more slowly, than from distilled water. This action of gum may be profitably taken into consideration by a respected correspondent of this Journal who, a short since, criticised the recommendation to use gum mucilage in dispensing.

According to Payen, as much as 50 per cent. of crystallizable sugar remains in molasses, being prevented from crystallizing by other bodies present with it. Several methods have been suggested for avoiding the consequent loss; amongst others treatment with baryta or lime, so as to form insoluble compounds with the sugar. Strontia has also been recommended for the same purpose, and appears recently to have found practical application at Dessau. According to Dr. Bittman, in a lecture delivered at Magdeburg, caustic strontia is added in excess of the sugar to the heated molasses and the mixture is raised to boiling, when a separation takes place of an almost insoluble saccharate of strontium. This compound after separation is mixed with water, and allowed to decompose spontaneously, when a portion of the caustic strontia crystallizes out; the remainder is precipitated as carbonate by carbonic anhydride. The residual solution of sugar is then treated as refinery syrup. It is estimated that 38 per cent. of crystallizable sugar can be recovered from molasses by this process. At first some difficulty was experienced as to a sufficient supply of caustic strontia, which was obtained by roasting strontianite, but this has been overcome by the discovery of fresh mines of the mineral and the use of celestine. The strontium carbonate formed in the process is regenerated by making it with sawdust into bricks, and burning these in a gas furnace.

In an interesting account of the chemical industries of Italy (*Chemiker Zeitung*), the surprising fact is pointed out that although lemon juice is made in many places in Sicily, when it represented in 1881 a value of nearly three millions of francs, the whole being exported, chiefly to England and France, yet in Italy no one appears at present to be engaged in the manufacture of citric acid. Up to 1880 one factory existed at Messina, but when that town was made a free port it had to stop operations.

The *Weekly Drug News* (Sept. 1, p. 3) contains an article on sponge fishery in the Bahamas, from which it would appear that the Governor of those islands has approved a law passed in a special session of the Legislature to prevent the use of dredges, which have for some time past been used with considerable success instead of the pole and hooks. The penalty for violation of the law is a fine of 100 dollars and confiscation of the vessel on which a dredge is found. The law seems to have been passed under pressure of popular clamour, and in forgetfulness of the fact that there are many sponges to be obtained at a depth where the use of the pole and hooks is impracticable, and that the use of the dredge would have increased the trade without affecting vested interests had its use been confined to fishing at such a depth. How far this law will affect the price of sponges remains to be seen.

About twelve months since some cases were reported (*Pharm. Journ.*, [3], xii., 81, 176) in which symptoms simulating an attack of erysipelas followed the use of a scent sold as a preparation of heliotrope, and the explanation was suggested that the preparation might have been an artificial coal tar product. However this may be, it would appear that heliotrope is not without beneficent physiological properties. A medical correspondent of the *Medical Press and Circular* (Sept. 13, p. 230) states that while suffering from a long illness of gastric fever, instead of using the ordinary opiates, he had a small bunch of heliotrope placed in his bedroom at night, and to the odour of the flowers he attributes the refreshing sleep he obtained.

The effect of prescribing disagreeable medicines for some classes of patients, and especially the roving class which is often met with in hospital practice, is well known. Sometimes an artifice in the shape of a pleasant medicine is useful in securing the return of a patient whom it is desired to see again. The following form for a "lemonade iron" prescribed in a case of this kind was recently mentioned in a clinical lecture by Professor Goodell, of Pennsylvania University (*Practitioner*, Sept., p. 223):—

℞ Tinct. Ferri Chloridi	. . . . . .	ʒij.
Acidi Phosphorici dil.	. . . . . .	ʒvj.
Spiritus Limonis	. . . .	ʒij.
Syrup.	. . . . ad	℥vj.

M. Sig. A dessertspoonful, in water, after meals.

The spiritus limonis, U.S.P., is prepared by dissolving two fluid ounces of oil of lemon in two pints of stronger alcohol (sp. gr. 0·817), adding a troy ounce of freshly grated lemon peel, macerating for twenty-four hours and filtering through paper. It is used in this case with simple syrup as not being so sour as syr. limonis.

The value of jalap root is often roughly estimated by its weight, some pieces being much heavier than others and containing less resin. The powder likewise varies much in percentage of resin, twelve American samples recently assayed by Mr. V. Coblentz (*Amer. Journ. Pharmacy*, [4], xii., 385) being found to vary in yield of resin from 3·8 to 16·2 per cent. In the *Pharmaceutische Centralhalle* (iii., 307), Dr. H. Hager remarks that specimens of the root which have a specific gravity below 1·40 should be rejected. He considers that unless ninety out of a hundred specimens of a sample of the root sink in a solution of salt of the above specific gravity, the drug cannot be considered of good quality. He founds this opinion upon the fact that the resin of jalap is heavier than water, its sp. gr. being 1·15 to 1·16, while that of the sugar is 1·5 to 1·6. From these figures, however, it is obvious that the weight may be affected by the proportion of sugar and cannot necessarily be considered a criterion of the resinous contents of the root. Indeed some specimens selected from the stores of the Museum of the Pharmaceutical Society a year or two ago and separated into light and heavy portions were examined with the result that more resin was obtained from the light than from the heavy pieces. Dr. Hager, however, asks other experimenters to confirm, or otherwise, the results he has obtained.

From samples of belladonna root which have reached this country from New York, it is evident that the Japanese belladonna root has been sold for the genuine root in the United States and that the roots have not been distinguished.

Dr. Denis Dumont recently communicated to the Paris Academy a report of a case of hydrophobia in the Caen Hospital, which he had cured by hypodermic injection of nitrate of pilocarpine three times a day (*Practitioner*, p. 213). One so frequently hears of cases of cure of hydrophobia, that any cases in which confirmation of previous reports is given are worth recording. Unfortunately, however, as yet no remedy seems to have been successful in different hands.

Dr. Dumonprez (*Bull. Gen. Therap.*, p. 89) considers worm seed superior to santonin for killing as well as expelling round worms. He states that santonin does not kill the worms outright, but excites them to livelier movements which may reflexly stimulate the intestine to expel them. If this be true, it is important to know whether the fatal action of the drug on the worms is due to essential oil, and also whether the Barbary or Levant or other worm seed was used in Dr. Dumonprez's experiments, since the Barbary kind is not known to contain santonin, but is to be met with in commerce.

The mango fruit (*Mangifera indica*) it may be presumed in an unripe state, is being tried in the United States in medicine. Dr. Linguist, who has introduced it, states (*Practitioner*, p. 220) that it is an astringent with a special tonic action on the mucous membrane, and that in the treatment of hæmorrhage and muco-purulent discharges he knows of no equal to it.

In the *Boston Medical and Surgical Journal* (p. 221), Dr. A. P. Mason, gives an account of experiments made on himself with coca. He has arrived at the conclusion that coca had a good effect upon him both mentally and physically; that it almost always produced exhilaration and without exception prevented fatigue. This he believes to be due to stimulation of the nervous system and retardation in some way of the process of metamorphosis, so that work is done with less expenditure of force with than without coca. The experiments were made with the fluid extract. Coca leaves are so very variable in quality that experiments made with them cannot be said to be so satisfactory as if made with either the crystalline alkaloid, cocaine, or the volatile oil, hygrine.

Dr. E. W. Barton, in the *Lancet* (p. 333), recommends sulphide of calcium in the treatment of cancer. In two cases which appear to have been well authenticated, one of them being cancer of the breast, the remedy was given with the result of the disappearance of the disease. The sulphide was administered in the dose of 1 grain, increased to 3 grains, during the day and continued for three months.

Dr. J. H. Whelan, in the *Lancet* (p. 348), in describing some medical uses of the alkaloid atropine points out that it is valuable in preventing "death from shock" or nervous fright, and that it is valuable on that account for giving before operations. He calls attention also to the statement made by Dr. Gentilhomme, of Reims, to the effect that $\frac{1}{100}$ gram of the alkaloid relieves coryza or severe cold in the head in a most remarkable manner. In one case in which the drug was administered in fifteen minutes afterwards all sneezing ceased, the secretion stopped and respiration became normal.

A singular account is given in the *Lancet* (p. 311) of the deleterious effect of powerful electric light on the eye. Two workmen engaged in adjusting the carbon points of a lamp of 3000 candle power omitted to use coloured glasses while performing the operation. On ordinary occasions the brilliancy of the spark causes more or less paralysis of the retina, so that it is rarely possible to perceive the people walking on the footpath when descending the ladder from adjusting; but on this occasion one of the men experienced a severe attack of inflammation of the conjunctiva, the ball of the eye becoming of a brilliant scarlet; the other workman was similarly affected, but to a less extent. It does not appear whether the symptoms were caused by the brilliancy or radiant heat.

Pharmacists who have to handle metallic nickel for electro-plating will be probably glad to know of an easy, expeditious method of testing it. Mr. Thomas T. P. Bruce Warren, while trying the magnetic properties of some nickel cubes, found that only a portion of the sample was attracted by the magnet. On analysis the cubes remaining unattracted were found to contain over 33 per cent. of copper; the attracted cubes contained over 96 per cent. of pure nickel and less than a tenth of a per cent. of copper (*Electrician*, ix., p. 367). From this observation it will be seen that examination of samples of nickel by a magnet may occasionally give some useful information.

During the past month, a section of New York has been lit by the Edison incandescent lamp, being the first practical application on a large scale of electricity as a domestic lighting agent. The area lit includes no less than one square mile of the busiest part of New York, and fourteen miles of street mains are already laid. There are nine hundred and forty-six subscribers whose premises are already wired, the number of lamps supplied amounting to nearly fourteen thousand five hundred; at present some five thousand lamps are at work, but some ten or twenty buildings are being added daily to the number lighted. The subscribers pay "electricity rent" for the new light equivalent to the ordinary "gas rent," for the same amount of light. Thus the incandescent lamp, for the first time in its existence, enters into actual commercial competition with its powerful rival, gas, and, whatever may be the result, the community will certainly be gainers by the competition. The accounts published of the quality of the light are extremely flattering, and are all that its most sanguine supporters could possibly wish for. It now only remains to be seen what its financial future will be. The dynamo machines are of a somewhat larger type than the Holborn machines, which were described in this Journal (*Pharm. Jour.*, [3], xii., p. 925), otherwise they do not apparently differ in their essential details. Each machine is said to be capable of working 1800 lamps, at 16 candles, but it is only proposed to work them up to 1200. An extremely ingenious and original device is used to enabled unskilled labour to be utilized in regulating the current. It is an indicator consisting of two incandescent lamps, one of which has a blue glass globe, the other lamp having its globe of red glass. Neither of these lamps incandesce while the current is of normal strength. If from any cause the current in the circuit should increase in volume, the blue lamp lights up; the attendant then increases the resistance of the shunt circuits of the field magnets by means of a wheel switch which brings into the circuit one resistance coil after another, and this is done until the blue lamp goes out. If the reverse of these conditions should obtain (*i.e.*, too little current in the circuit), the red lamp becomes illuminated; in this event the attendant reduces the resistance of the shunt circuit by means of the wheel switch until the red lamp goes out. There are at present six of the large dynamo machines at work and these send their current into the two great main leads. Should it be suspected that one of the machines is working improperly it can be switched out of circuit without interfering with the others. The current of the suspected machine is then sent into a test battery of 1000 lamps; if these are found to have the proper amount of incandescence the dynamo is pronounced to be in proper order and is reinstated in the great circuit. All the details of the installation are very interesting reading and are exceedingly creditable to the great inventive genius of Edison, its originator.

It is a question whether the time has yet come when meteorology is entitled to be considered a science, for the conditions affecting weather phenomena are still so imperfectly understood that "forecasts" often include a considerable amount of speculation. In a letter, dated 4th September, that appeared in the *Scotsman* on the following day, attention was directed to the value of the spectroscope as an aid in this direction, and the writer, on the strength of the absence of the "rain band" on the morning of writing,—it having been for some time previously very strong,—ventured to predict the setting in of fine weather. This prediction appears to have been strikingly verified, as the 4th and the following four days were very fine in that part of Scotland, not a drop of rain falling, although the forecasts of the Meteorological Office for four of the five days predicted more or less wet. Confirmatory evidence as to the value of the spectroscope as a weather indicator appeared in a letter in the *Times* for the 14th inst., from Mr. Cory, who states among other things that if the amount of "rain band" is under 20 per cent. fine weather is certain for six hours, but that if, when the spectroscope is directed to the zenith, 80 per cent. of the dark band is shown, there will be a downpour of rain before long, although the barometer may be high and steady.

THE LACQUER INDUSTRY OF JAPAN.

BY JOHN J. QUIN,

Her Majesty's Acting Consul at Hakodate.

The following particulars are taken from a report intended chiefly as a description of the articles of various kinds illustrative of the lacquer industry of Japan, collected for the use of the Museum of Economic Botany at Kew, under instructions from Her Majesty's Chargé d'Affaires at Tôkiô.

Great difficulty has been experienced in obtaining thoroughly reliable information, as not only are the artificers, for the most part, uneducated, but they are entirely ignorant of what takes place in any other department except that to which they have been brought up. A well-known and most intelligent manufacturer, who has been over twenty years himself a worker in gold lacquer, was quite unaware of the mode of tapping and treating the trees, and had never even seen a cut specimen of the wood. He states that his head workman, a highly-skilled artizan over fifty years of age, hardly knows the name of a single article that he uses.

The *Rhus vernicifera*, the well-known lacquer tree of Japan, is met with all over the main island, and also in smaller quantities in Kiushiu and Shikoku, but it is from Tôkiô northwards that it principally flourishes, growing freely on mountains as well as in the plains, thus indicating that a moderate climate suits the tree better than a very warm one. Since early days the cultivation of the tree has been encouraged by the Government, and as the lacquer industry increased plantations were made in every province and district. The lacquer tree can be propagated by seed sown at the end of January or the beginning of February. The first year the seedlings reach a height of from 10 inches to 1 foot. The following spring the young trees are transplanted about 6 feet apart, and in ten years an average tree should be 10 feet high, the diameter of its trunk $2\frac{1}{2}$ to 3 inches, and its yield of lacquer sufficient to fill a 3-ounce bottle.

A more speedy method is, however, generally adopted. The roots of a vigorous young tree are taken, and pieces 6 inches long and the thickness of a finger are planted out in a slanting direction a few inches apart, 1 inch being left exposed above the ground. This takes place in the end of February and through March, according to the climate of the locality. These cuttings throw a strong shoot of from 18 to 20 inches the first year, and are likewise planted out the following spring. Under equally favourable circumstances these trees would in ten years be nearly 25 per cent. larger in girth, some 2 or 3 feet higher, and would yield nearly half as much more sap than the trees raised from seed.

It has not hitherto been the custom to bestow any special care on the trees after planting them out, but in cases where leaf or other manure has been applied they are much finer. Of late years hill sides and waste grounds alone have been used for lacquer plantations, as, owing to the rise in the price of cereals and farm produce generally, it does not pay the farmers to have their land cumbered with trees. Those that have been hitherto planted along the borders of the fields are being rapidly used and uprooted, and, where practicable, mulberry trees are planted instead, with a view to rearing silkworms. Nevertheless, as a good workman is expected during the season to tap an average of 1000 trees ten years old, and as the Province of Yechizen alone sends out about 1500 "tappers" yearly to the various lacquer districts, it will be seen that an immense production annually takes place, stimulated, doubtless, by the demand for cheap lacquered articles abroad. To remedy the possible exhaustion of the supply, and in view of the great rise which has taken place in the price of lacquer, several companies are being projected to plant waste lands with the trees. A ten-year-old tree, which some five years ago only cost from 1 to 2 sen, now costs 10 sen, which, allowing even for the depreciation in the value of the paper currency, shows a rise of about 500 per cent.

The best transparent lacquer comes from the districts of Tsugaru, Nambu, Akita, and Aidzu. It is largely used by the workers of Kioto, Osaka, and the southern provinces, but though also used in Tôkiô is not so much appreciated there as the lacquer produced from the neighbourhood of Chichibu in the Province of Mus-ashi, from Nikko in Shimotsuke, and that produced in the Provinces of Kōdzuke and Sagami, which hardens more rapidly, and is best for black lacquer.

There are some districts the lacquer obtained from which is best for certain kinds of work, but is not so well adapted for others. The kind which is used for transparent lacquer is mixed in large tubs, to insure a uniform quality, and being allowed to stand for some time (say, a week or ten days), the best portion, which is ordinarily 70 per cent. of the whole, is skimmed off. This is used for *Nashiji* and *Shu* lacquer, while the remainder is used for making inferior mixtures, such as *Jōhana*, etc., all described elsewhere. Almost all the various classes of lacquer are similarly dealt with to insure uniformity, as some qualities dry much quicker and are better than others, and the slow drying qualities would otherwise remain unsold.

The whole country produces at present on an average from 30,000 to 35,000 tubs per annum, each tub being of about 4 gallons capacity. Some 70 to 80 per cent. of this total amount is produced from Tôkiô northwards. Nearly one-half of the lacquer produced is sent to the Osaka market, where it is prepared as required and resold all over the western and southern provinces, the remaining portion being used up locally and in Tôkiô.

The usual age at which a tree is tapped is ten years, but in some few cases a tree is tapped when only three or four years old. The best lacquer for transparent varnish is obtained from trees from one to two hundred years old, as their sap has more body, and is more glutinous. The tools used in obtaining the lacquer are as follows:—

Kawa-muki (bark parer), a curved knife with which the workman smooths all inequalities of the bark before tapping the tree.

Yeda-gama (branch sickle), an instrument with a gouge on one side and a knife on the other, fitted with a piece of bamboo to give the hand a good hold when tapping branches.

Kaki-gama (scraping sickle), a similar instrument, without the piece of bamboo used for tapping trees generally.

Yeguri (a gouge), used in autumn to scrape the bark smooth before giving the final cut with the *kaki-gama*.

Natsu-bera (summer spatula), used for scraping the sap out of the incisions into the receptacle named *gō*.

Hōcho (knife), used for cutting the bark of branches in obtaining *seshime* or branch lacquer.

Seshime-bera (seshime spatula), used for collecting the sap which exudes from the incisions in the bark of the branches.

Gō, the bamboo or wooden pot, in which the sap is put as it is collected.

Gō-guri (pot gouge), a long straight knife for scraping the lacquer out of the pot into the tub.

Te-bukuro (glove), worn by the tapper to protect his hand from contact with the sap.

The first tapping takes place about the beginning of June. The standard number of trees allotted to a tapper for the season is 1000—presuming them to be about ten years old (the size of the small specimen), about 800 of the size of the large specimen, and so on, less and less according to the size of the trees. Having cleared away the grass from the roots, the workman makes the round of his allotted trees, marking each with small notches about $\frac{1}{2}$ inch long. The first of these notches is made about 6 inches from the bottom of the tree on the right hand side; and next, one "hand stretch" higher up on the left hand side; the next, one "hand stretch" higher on the right, and so on, alternately as far as the workman can reach. These preliminary markings, which are to determine all the places for subsequent tapping, take fully four days, being at the rate of 250 trees a-day. The tapper then goes round, provided with the bark scraper, the ordinary scraping sickle, the summer spatula, and the pot to held the lacquer, and first smoothing the bark where required gives one cut above and one cut below the two lower marks, and one cut above the remainder of the other marks, the cut being in each case about 1½ inch long. After giving the cut the instrument is reversed, and the knife is run along the incision to insure the bark being entirely cut through. This process is repeated every four days, each incision being made a little longer than the preceding one, up to the fifth tapping, inclusive, after which the remaining incisions are made of the same length. At each round, when all the requisite incisions have been made on the tree, the workman gathers the sap which has exuded with the spatula, beginning with the two lowest incisions, and so on to the uppermost cut. Twenty-five is considered the normal number of cuts, which, at the rate of one incision at each place every four days, occupy one hundred working days, and allowing for some twenty days of rain during which the sap cannot be drawn, the season is brought to a close by the end of September. If the workman has any large trees to tap, the whole of which he cannot reach when making his ordinary rounds, he taps all he can reach, and when his round is concluded he returns with a ladder, and mounting each tree taps the remainder of the trunk and the leading limbs in the same manner as above described, previous to making a fresh round.

When the full number of incisions has been given, the workman gives an extra long cut underneath all the initial notches on each tree to obtain the sap which has collected there, and another above the uppermost cut of each set. These incisions are called *Ura-me* (back marks). The workman also makes a number of cuts, each about a foot apart, in all the branches whose diameter exceeds 1 inch. This operation requires about sixteen days to get through the whole number of trees. The next operation is called the *Tomé* (the finish). This consists in a number of incisions completely encircling the tree wherever the workman perceives a likely place. The next process consists in cutting off all the branches: the larger ones are once more tapped after being cut off to extract any sap that may still remain in them, and the small branches which have not yet been tapped are tied in bundles and steeped in water for about ten days. When taken out and dried the bark is cut with a knife, and the sap which exudes is collected with the branch spatula, and is called *Seshime* lacquer. This word seems to be derived from *Sehi*, the name of a machine, and *shimeru* (to press), from a practice which obtained in olden days of pressing the branches in such a machine to optain the sap. It is also known as *Yeda urushi*, or branch lacquer, which latter more explicit term is, for the sake of convenience, used throughout this report.

The sap obtained from the first five cuts above each notch is poor, containing, as it does, a large proportion of water; the middle fifteen cuts produce the best sap, and the sap obtained from the last five incisions is poor, and lacks consistency. Again, the sap obtained from the *Ura-me* (back marks) and *Tomé* (finishing) cuts is very good, and dries quickly.

The sap from the first twenty-five cuts is mixed and sold together, but the *Ura-me* and *Tomé* sap is almost always mixed and sold separately. The operations above described kill the tree in one season, but frequently the tree is made to last two years or more, by giving only half the number of incisions, and reserving the *Ura-me* and *Tomé* cuts for the final year. The sap obtained the second and following years is, however, of an inferior quality, and this method is only resorted to by private individuals, who tap their own trees during the intervals of farming. Ordinarily, a wholesale dealer in lacquer buys so many thousand trees from the owner, and, as a matter of course, extracts the sap with as little delay as possible, making a contract for the purpose with professional tappers. A first-rate workman will receive over 100 yen (equal, at the present low rate of exchange, to nearly £13 sterling) for the season, and can collect four and a-half tubs (equivalent to 18 gallons), but the average receive 75 yen, and collect proportionately less. The present price per tub of lacquer ranges from 90 to 100 yen.

After the sap has been taken the exhausted tree, which remains the property of the seller, is cut down by him, and is used for firewood, for building purposes, or for making boxes. The roots of the young trees throw from three to five shoots the following spring, and these can be used in six or seven years. Of these five sprouts three are commonly much stronger than the other two. In such cases, the strong ones only are tapped and cut down, the weaker ones being allowed a year or two longer to grow, when, receiving the whole of the nutriment, they shoot up in one year as much as an ordinary tree would in three. After tapping and cutting down, fresh shoots to the number of five are again allowed to sprout, and so on, the root not seeming to become exhausted by the process; but when a very old tree is cut down the root will not give out new shoots. In the northern provinces very old and large trees are met with in considerable quantities. These were kept for the sake of their berries, from which the wax used for the Japanese candles was obtained. This was the more profitable use to which to put the tree, as a good tree, from eighty to one hundred years old, yielded yearly, on an average, equal to 6*s.*, while the price of a ten-year-old tree to be used for extracting the sap was under ½*d.* Previous to the revolution of 1868 every tree reserved for making wax was officially registered, and the owner was not allowed to mutilate it in any way. Even if a tree died, he had to get official permission before removing the stump. The Shōgun's Government and also the local magnates had large plantations of the lacquer tree reserved for wax, but since the opening of the country to foreign trade, and the introduction from abroad of kerosene oil, the wax industry has greatly declined, and there are now no restrictions on the free sale of the tree for tapping, and, consequently, all the fine old trees (which will sell for from 5 to 6 yen each) are fast disappearing.

To show the relative value of the berries and the trees a few years ago the following may be cited:—A wholesale lacquer merchant informed me that five or six years ago he went as usual to purchase trees in the district of Aidzu, and among others bought one tree for a yen (then equal to 4*s.*), the owner reserving the berries that might be got as his own property. He does not consider the bargain was a cheap one, but the owner realized the sum of 80 sen (equal to 3*s.* 2*d.*) from that year's yield of the berries alone before cutting down the tree.

It should be mentioned that the above description of the method pursued in tapping the lacquer tree is that which is recognized as the proper one; but, as even the specimens of the lacquer tree forwarded will show, the rule is not rigidly observed, the style and size of the tree, and the caprice of the workman, combining to cause variations in the number of incisions given in each series.

Various Woods used in making Lacquer Ware.

The woods chosen for lacquering on are naturally selected according to the use to which the lacquered article is to be put. For shelves, cabinets, and boxes of all kinds, the following are principally used, and are set down in the order of their excellence:—

Hinoki (*Chamæcyparis obtusa*).—This is by far the best wood for making boxes, as it does not warp.

Kiri (*Paulownia imperialis*).—A light wood, used for clothes boxes, which are only lacquered on the outside. It is also used for making teacaddies, as the wood has no smell.

Hōno-ki (*Magnolia hypolema*).—All sword sheaths have hitherto been made of this wood.

Sawara (*Chamæcyparis pisifera*).—This is a wood of a coarser grain than *Hinoki* (*Ch. obtusa*).

Hime-ko-matsu.—This wood is used for carved figures of men, animals, etc. It is not liable to split and crack.

Tsuga (*Abies tsuga*).

Hiba (*Thujopsis dolabrata*).—Used for making cheap articles.

Akamatsu (*Pinus densiflora*).

Sugi (*Cryptomeria japonica*).—This wood is only used in making the cheapest and most inferior goods.

The following woods are mostly used in the manufacture of such articles as are turned in a lathe, as bowls, rice cups, round trays, etc.:—

Keyaki (*Planera japonica*), the best being obtained from the province of Hiuga.

Shoji.

Sakura (*Prunus pseudo-Cerasus*).

Katsura (*Cercidiphyllum japonicum*).

Tchō (*Ginko biloba*).

I-go.—Grown in large quantities in the neighbourhood of Hakone. It is principally used in the manufacture of toys and cheap articles.

Buna.—Principally used in the district of Aidzu for the same kind of utensils as *Keyaki* and *Sakura*, but being a brittle wood, it cannot be turned in a lathe to make such fine articles; those made of this wood are coarser and heavier. For raising gold lacquering over the unvarnished surface, the following hard ornamental woods are often used:—

Shitan.

Tagayasan.

Karin (quince).

Kuwa (mulberry).

Keyaki (*Planera japonica*).—Ornamental grain.

(*To be continued.*)

ACETATE OF LIME AND ALLIED SUBJECTS.*

From an interesting paper on this subject, by Messrs. Stillwell and Gladding, read before the American Chemical Society, we abstract the following:—

METHODS OF ANALYSIS.

1. *Based on the Amount of Soluble Lime Salts present.*—The value of an acetate of lime depends entirely on the amount of glacial acetic acid present. Two methods of analysis are in use at the present time; one determines the amount of lime salts soluble in water, and by calculation the amount of lime so found is converted into acetate of lime, or glacial acid, as the case may be. This method is based on the supposition that all the soluble lime salts present are acetates; but this is not so. Acetates of lime almost invariably contain caustic lime in slight amount, and if the lime has been overheated, it is present in still greater quantity. Again, organic salts of lime are always present. With improved methods of manufacture, the amount of these has diminished of late years, and the difference between the amounts of acetate of lime found by distillation of the acetic acid and that found from the amount of soluble lime is much less than formerly. The better the sample of acetate, the less is the difference between the results given by the two methods.

In the year 1872 (see *American Chemist*, vol. ii., p. 324, and vol. iii., p. 8), this question of methods of analysis came up. It is necessary to state here the objection raised by certain English chemists against the process of distillation, which was advocated by some American chemists, since the objectors to a distillatory process had no good foundation upon which to rest. But as the general custom of the trade was at that time based upon the method of analysis by means of the soluble lime salts present, we have before and since that date used the term "*English Commercial Test*," to designate analyses made in this manner, and so state the results on our reports of analysis. Whenever an analysis is made by distillation it is so stated.

2. *Based on the Distillation of the Acetic Acid.*—Three acids may be used in the process of distillation—hydrochloric, sulphuric, or phosphoric.

a.—When *hydrochloric acid* is used, a part of it is carried over with the acetic acid and must be estimated and a correction made. It possesses these two advantages; that it does not act upon the organic matter present, and that the solution of chloride of calcium will permit of the distillation being carried to a low point without danger of error. The distillation is made in a retort connected with a condenser, and the total acids present in the condensed liquid are estimated, and the proper correction applied for the amount of hydrochloric acid found to be present.

b.—The use of *sulphuric acid* has three disadvantages.

First.—As it becomes concentrated in the retort during the process of distillation, it acts upon the organic matter present, forming sulphurous acid, which is carried over with the acetic acid and included in the estimation of the total acid power of the distillate. Thus the amount present would be calculated as acetic acid, and the result thereby increased unduly. To prevent such action, recourse is had to distillation in a current of steam. (See *American Chemist*, vol. vi., p. 294.)

Second.—The sulphate of lime formed by the addition of sulphuric acid to the solution of the acetate of lime, is troublesome on account of the bumping which takes place during the distillation. This is partly prevented by the use of a current of steam.

Third.—When a sample of acetate of lime contains *chloride of calcium* or *chloride of sodium*, the chlorine is carried over in the form of hydrochloric acid and neutralizes its equivalent amount of the standard soda, used to receive the acid distillate. The amount thus distilled must be estimated and the correction made. To prevent this, the chlorine present is precipitated by the addition of sulphate of silver to the solution of acetate before distillation begins.

c.—*Phosphoric acid* is the best acid for use in the process of estimating acetic acid by distillation. It has three advantages.

First.—It does not act on the organic matter.

Second.—During the distillation, the liquid in the retort is not suffered to fall below 15 c.c. in bulk. Under such circumstances, phosphoric acid does not decompose any chlorides of calcium or sodium which may be present in the acetate, thus requiring no addition of sulphate of silver. Only the merest trace of chlorine is carried over, as shown by experiments with a sample of acetate containing nearly 5 per cent. of chloride of sodium and also by trial on a known amount of pure chloride of sodium. This unexpected result merits attention, since in this respect phosphoric acid differs so decidedly from sulphuric acid.

Third.—It forms a perfectly clear solution with the acetate of lime. By the use of a large amount of glacial phosphoric acid, at least five times the weight of acetate of lime taken for analysis, the phosphate of lime first formed is redissolved to a clear solution. The distillation proceeds quietly and uniformly without bumping, and the liquid in the retort is easily kept at any desired point. The use of a current of steam is necessary, both for ease of manipulation and accuracy of results.

After a thorough trial of hydrochloric and sulphuric acids we discarded both in favour of phosphoric acid, and for some years past have used it to our full satisfaction. It is important that the phosphoric acid used should contain no nitric or other volatile acids which would increase

* *Journ. of the Amer. Chem. Soc.*, iv., 104. Reprinted from *New Remedies*, September, 1882.

the results obtained above the truth. Each new lot of phosphoric acid should be examined for such impurities before use. If it be suspected that any phosphoric acid has been carried over during the distillation it is easily detected in the distillate by the use of molybdate of ammonia.*

The process of distillation, if carefully and intelligently done, is very accurate. Duplicates made by this method agree with each other fully as closely as do those made by the estimation of the soluble lime. For example, in January last a sample of grey acetate was analysed by distillation in our laboratory with a result of 78·22 per cent. acetate of lime. Three months later the same sample was re-analysed by another man in our laboratory, using fresh standard solutions, and 78·20 per cent. of acetate was obtained. This sample contained 3·16 per cent. of common salt, shell-lime having been used in its manufacture. With care and experience in this method of analysis by distillation it is not difficult to obtain duplicates which agree to two-tenths of one per cent. of acetate of lime; usually the difference is less than that. A sample of grey acetate analysed recently was distilled with sulphuric acid, and a duplicate with phosphoric acid. The results agreed exactly; the latter distillation, however, requiring less attention than the former, for reasons given above under processes of distillation.

The indicator used for titration is a few drops of a solution of phenol-phthalein, one gram in 250 c.c. of a mixture of equal parts of water and alcohol. We have found this indicator far preferable to either litmus or cochineal; of course, whichever indicator is used the same must be used both for the standardizing and the actual analysis.

To show the need of some uniform and accurate method of analysis we refer to a note in Allen's 'Commercial Organic Analysis,' vol. i., p. 205. He finds from experiments made in his own laboratory on the *same sample* of acetate of lime that results were obtained varying from 47·4 per cent. to 57·6 per cent. of acetic acid. In our own practice for many years previous to the publication of the present, we found differences fully as great between results by distillation and by the various commercial processes; but, as we said before, at the present time the differences are not nearly so great as formerly.

In conclusion, we wish to lay strong emphasis upon the facts that, inasmuch as the process of distillation is the only one which gives the real amount of glacial acid present, and inasmuch as it is an imitation of the actual manufacturing process for obtaining acetic acid from its acetates, it is the most reliable and should be adopted. This position we have maintained for many years, and we notice that, especially in the case of grey acetate, buyers are more and more insisting on the test by distillation. The price should be based on the unit of glacial acid, just as, in fertilizing materials, the prices are based upon the units of phosphoric acid, nitrogen, and potash.

In the course of discussion on the preceding paper, Dr. Grothe asked if the authors had noticed the presence of acetone in the products of the decomposition of acetate of lime by heat.

Mr. Stillwell said he had not noticed it particularly, since his attention had been confined simply to the loss of acetic acid.

Regarding the production of acetic acid from wood Dr. Squibb remarked that it was not necessary to carbonize the wood, but that all the acetic acid could be obtained at a much lower temperature (about 160° to 200° C.), and the products then contain no acetone. For the analysis of sodium acetate he uses a glass retort covered with copper gauze, and heats it on one side to prevent frothing and bumping. He uses 10 grains of the acetate with 20 c.c. of water, and 10 c.c. sulphuric acid; after distilling off 10 to 15 c.c. of the liquid the distillation is interrupted—about 20 c.c. of water are added to the retort, and 10 to 15 c.c. of liquid again distilled over. This is repeated a third time, when all the acetic acid will have come over, without trouble from frothing or bumping during distillation.

Dr. Squibb further remarked that he used in his factory retorts 20 feet long, 2 feet wide, and 10 feet deep, holding 2½ cords of wood, and heats them in a hot air bath. During the first twelve hours, only water is given off. In about twenty-four hours the acetic acid begins to distil over, the process being completed in six to seven days for each retort. Seasoned oak is preferred, and any admixture of softer woods diminishes the yield of acetic acid. Chestnut is notable in this respect. Throughout the active heating, but more copiously toward the end, a gas, colourless and odourless (and so far as tested, uninflammable), comes over, having anæsthetic properties. This gas adheres to the wood after the charge is cooled and drawn, and seems to be a reason why small vermin will not remain near it. If the charge is heated too long, smoke appears at the exit pipe, and carbonization of the wood begins at the centre of the top of the charge, extending in V-shape toward the bottom. When once started, this carbonization proceeds spontaneously without further application of heat. Indeed, it is sometimes found difficult to check it, even by the liberal application of cold water to the outside of the retort. In the course of the operation, when properly managed, the charge shrinks to one-third of its volume. 4000 lbs. of wood yielded about 2800 lbs. of residue. The residue retains all the appearances of the wood before distillation, only that it becomes walnut-coloured, and it has the same elementary composition as that of kiln-dried wood. It is brittle and not well adapted to construction, but forms a most excellent fuel for many purposes, especially for kindling anthracite coal. The distillate is neutralized with soda-ash and distilled to about one-fortieth its volume. The first product is crude wood spirit. This is redistilled, and gives rectified wood spirit, and lastly wood oils, which contain large quantities of furfurol and no acetone. The wood oils are separated by passing the last portions of distillate into water. The rectified wood spirit contains about 80 per cent. of methyl acetate, and when saponified gives a very pure methyl alcohol. One cord of well-seasoned wood will afford 1200 to 1400 lbs. of liquid products. A cord of oak yields 60 or 70 lbs. of glacial acetic acid.

Dr. Squibb further remarked that there was no process commercially practical for obtaining pure acetic acid from pyroligneous acid or acetate of lime, but only from acetate of soda.

Mr. Parker remarked that he had tried a process for making acetic acid by heating wood fibre with steam, under a pressure of 60 lbs. at 275° C., and confirmed Dr. Squibb's observations on the deterioration of the woody fibre, and also the impracticability of making pure acetic acid from pyroligneous acid.

* The objection raised against this method by Dr. Waller, namely, that the presence of acetic acid interferes decidedly with the precipitation of phosphoric acid by the molybdate solution, was answered by Mr. Stillwell to the effect that he overcame the difficulty by using large quantities of ammonium nitrate.

IRRITATING EFFECTS OF STINGS IN THE ANIMAL AND VEGETABLE KINGDOMS.*

BY PROFESSOR AUGUST VOGEL.

It is well known that the effect of a stinging nettle on the skin agrees very closely with the sensation produced by the sting of a bee or wasp. But the great similarity is not limited to the feelings it causes, but, what may not be so well known, the cause of the irritation produced on the skin is essentially the same. It may be considered as definitely settled that formic acid is present

* From the *Scientific American*, September 9, 1882.

in the poison sac of the bee sting, in the so-called bee poison. The same corrosive acid also occurs in the sting of the nettle. Some species of caterpillars have formic acid in some of their hairs, which they seem to be able to shake off at will, and when a person touches such a caterpillar the poison penetrates the skin wherever it is moist and causes burning, itching, and inflammation. These poisonous members preserve their irritating powers even after the death of the worm. This accounts for reliable statements that visitors to collections of caterpillars have suffered from exanthematous eruptions on the neck. "Many hairy caterpillars cause itching and burning of the skin when touched, and sometimes it gives rise to swelling and redness. This depends on the fine hairs, which produce the same effect when they float around in the air. Many ladies who visited the caterpillar room of the naturalist Reaumur had a breaking out on the neck."

In the sting of the bee, wasp, hornet, etc., a minute drop of a transparent liquid may be observed on the sting, and is called "bee poison" (formic acid). It penetrates into the wound produced by the sting, and causes the well-known effects. It would, hewever, be a great mistake to assume that the only object of this is to increase the effect of the sting, that is, that it serves only to injure. It has a far more important purpose, namely, to prevent fermentation and decay. The celebrated bee cultivator, Holz, reports that in his long experience with honey that which came from what are called "rancorous swarms" (boshaft) had peculiar properties. It always had a bitter, harsh taste, and its smell was sharp too. How can the character of the swarm affect the smell and taste of the honey they gather? We know that bees, when they are disturbed, run out their stings, on the end of which may be seen a tiny drop. This little drop, as we have already said, is bee poison, or formic acid. When the disturbance is at an end they draw in their stings again, but the little drop of liquid does not go back with it, being wiped off on the comb, and sooner or later getting mixed up with the honey. This explains how honey from such excited bees must taste and smell sharper than from peaceable bees. Excitable bees will rub off this little drop of formic acid more frequently than other bees; perhaps a larger drop is formed by nervous bees than by those that are not nervous, and hence the honey is richer in formic acid. This acid is never absent from genuine honey, but the amount differs. This contamination is not only uninjurious but very useful, in fact, necessary, for it keeps the honey from spoiling; we know, indeed, that purified honey, from which the formic acid has been removed, very soon ferments, while unpurified honey will keep unchanged for years. Nature furnishes the bees with this knowledge instinctively, and therefore they do not carry this drop of formic acid away out of the hive. Bee connoisseurs assure me that the bees add it to the nectar which they collect that is free from it so as to make it keep, and they do this in places where they are not disturbed too.

Bee stings are often spoken of in agricultural and popular papers as a remedy for rheumatic affections, and numerous cures are adduced to prove it. If the formic acid that accompanies the sting can be looked upon as the principal agent in the cure, it would be worth while to try the experiment of rubbing the spot with this acid or injecting it under the skin, so as to avoid the somewhat inconvenient method of applying live bees.

Two hundred years ago formic acid was made from the brown wood ants, by triturating them with water and distilling it. The acid liquid was used to irritate the skin. The reddening of the skin, by using baths of pine leaves, is also due to the action of the formic acid. The anti-fermentative action of formic acid has also long been recognized.

As regards the irritative action of stinging nettles and other similar vegetables, it depends, as already stated, on formic acid. The point of the nettles is brittle as glass, and by the lightest touch penetrates the skin and breaks off, pouring out its acid and causing the burning sensation.

ANIMAL PRODUCTS IN THE CHINESE MATERIA MEDICA.*

BY F. NEWCOME, F.S.S.

Of animal products, musk probably stands highest in repute among Chinese doctors, but owing to prohibitive prices, the use of it is confined exclusively to the wealthier classes. For the pure unadulterated article obtained from the male *moschiferus*, or Thibet musk, from 20*s.* to 40*s.* an ounce is the common price to pay, and although the dose given is small—seldom more than ½ a drachm to a drachm at a time—it is impossible that the poor can afford such a luxury. Even high prices are frequently paid *wholesale* by Chinese merchants for home consumption, and this fact, viewed in connection with the average value of the musk exported to this country (during last year it was less than a guinea an ounce all round), leaves but one conclusion in our minds, namely, that the supply for this market is adulterated to a greater or less extent, despite London druggists charging for it gold price or higher. Last year (1881) the total exportation from China amounted to 1877 catties, or say 2503 lbs., valued at 149,780 taels, or about £41,501; in other words, the average was something like a guinea an ounce, whereas true musk always fetches from 30*s.* to 60*s.* an ounce at Shanghai or Tientsin. Here, again, it is just possible that some of the unfavourable results attributed to musk, and its bad repute among Europeans, may have been owing to adulteration, which, as everyone knows, was, and still is, largely carried on.

Bezoar stones are equally in repute, almost fabulous sums being given for the genuine article. For *Bezoar bovine,* classified in the Returns of Trade as "Cow Bezoar," the export price varies from 400 to 500 taels the catty; that is to say, from £6 to £7 10*s.* per ounce. Probably, however, several kinds of bezoar, including stones derived from animals of the goat tribe, are included under the generic term; but upon this point our knowledge is deficient. When such an astounding price is paid for the Chinese article by native dealers, there is little wonder if the samples that formerly reached Europe were spurious as alleged. Whether there is any great medical virtue in bezoar, or whether there is none, is a question that will probably be decided in time; but to settle the point it is necessary to examine and test the true Chinese article, which evidently cannot be sold under double its weight in gold.

The Chinese also import a considerable quantity of Indian Cow Bezoar. This, after transport to China, is only worth about 8*s.* to 9*s.* an ounce, or barely one-twentieth that of the genuine native article, which we have no hesitation in asserting to be one of the dearest drugs in existence. Beargall is another expensive animal product, being commercially worth some 16*s.* an ounce in Shanghai; but for what medical purposes it is used we are unable to state. All we know is that it forms a part of the Chinese *materia medica*, the same as do the ordinary vegetable nutgalls, with which the country-side everywhere abounds.

Beeswax plays a by no means unimportant *rôle* in Chinese medicine, forming the base of most ointments and plasters, in the manufacture of which an enormous quantity is annually consumed. So vast, indeed, is the consumption of beeswax for this purpose that one is inclined to join the good Dominie in crying "Prodigious!" That the Chinese should elect to use beeswax as the base for their ointments is somewhat curious, seeing how many other equally suitable substances are to be found within the borders of the empire.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 30, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELLIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE FUNGI SEASON.

AT this season of the year one is forcibly reminded of the truth of the old saying, "A little knowledge is a dangerous thing." Owing partly to the fashion for fungus forays and partly to the publicity given by newspapers to the fact that other species of fungi besides the common mushroom are edible, the impression has gone abroad among those who cultivate a superficial knowledge of science, that many species of fungi can be eaten with impunity, while the fact is ignored that poisonous species often so closely resemble the edible ones that they can only be distinguished by those who have seen both. Persons reading that the champignon (*Marasmius oreades*) grows in open pastures straightway draw the conclusion that all fungi growing in pastures are wholesome, collect and eat *Agaricus semilanceatus*, or perhaps a dangerous *Hebeloma*, and pay the penalty of their rashness. Unfortunately the penalty is often severe, as in the recent case of an English clergyman in France, whose lamentable death from eating a poisonous species comes as a timely warning at a time of year when fungi are most abundant.

Perhaps no nation eats so few fungi as the British; certainly none is more careless in ascertaining the characters by which edible species may be distinguished from poisonous ones. But forewarned is forearmed, and the simplest way to prevent these constantly recurring accidents would probably be to teach in schools the means of distinguishing the edible and poisonous species and the danger of experimenting with all others. The number of edible fungi occurring in our woods is estimated, by Dr. BADHAM, at thirty species, and the number being so limited, it would be just as easy to teach the young how to discriminate the wholesome from the dangerous as it is to teach them how to distinguish the different chemical compounds in common use. At all events there are probably more deaths caused every year by poisonous plants than by poisonous drugs accidentally administered, and if the latter deserve the attention of Government the former ought not to be altogether ignored.

In other countries legislation has been enacted to prevent the frequent occurrence of poisoning by fungi. Thus, in Rome, as long ago as 1837, an Inspector of Fungi was appointed by Government to examine every morning all the fungi offered for sale. This official had powers to direct that all stale fungi left from the preceding day, as well as all that were mouldy, maggoty, or dangerous, including any specimen of the common mushroom, should be sent under escort and thrown into the Tiber; also to fine or imprison anyone not complying with the Government regulations. In a country where a city of 154,000 inhabitants consumed yearly between 60,000 and 80,000 pounds weight of fungi, such regulations were indeed requisite. But the very fact of such an enormous consumption of these plants shows that the want in England of a practical knowledge of this class of plants deprives the poor of a considerable amount of cheap, and, if properly inspected, wholesome food, no country being richer than our own in esculent fungi.

Practical instruction also in the characters of the more dangerous poisonous plants cultivated in gardens or growing wild in this country might well replace a great deal of the botanical knowledge of much less real value at present taught and required in science and other schools. Mezereon and yew would then be not so likely to tempt children with their bright-coloured berries, nor would aconite be mistaken for horseradish; neither would some of our leading daily papers make the mistake of including species not yet recorded as British (*e.g.*, *Agaricus Cæsareus*) among the edible fungi of this country.

On the Continent and in China and Japan dried fungi are largely used, and doubtless there is less risk in eating these than in eating fresh fungi, the poisonous principle probably undergoing decomposition. In some cases the kitchen fire will render fungi which are acrid when raw, innocuous when cooked; this is the case with some of the species yielding a milky juice. In others the poison is extracted by immersing the fungus, before dressing it, in vinegar or brine, the liquid then containing the poison which was originally in the plant. This was known to the Greeks, who said, "Prepare your funguses with vinegar, salt or honey, for thus you will rob them of their poison." The practice is still continued in Russia, where many species reputed to be poisonous are eaten with impunity after having been soaked in vinegar before being cooked. We know, however, very little concerning the influence of climate in developing poisonous principles in this class of plants. Aconite is said to be eaten without danger in some parts of northern Europe, and it is a recognized fact that many plants are less poisonous in the north than in the south of Britain. And the mushroom, which is wholesome in this country, is reckoned poisonous in Italy.

It is very easy to mistake the poisonous *Amanita phalloides* for the edible *A. rubescens*, or the orange-coloured false chantarelle (*C. aurantiacus*) for the delicious *C. cibarius*, especially if a cold in the head prevents the delicate apricot odour of the last from being perceived. The downy margin and white milk of the very poisonous *Lactarius torminosus*, also, are not likely to be noticed by anyone unacquainted with this plant, which bears a strong resemblance to the esculent *L. deliciosus*. No one, therefore, even though he may know the edible species well, should attempt to experiment on those differing from them in even the most trifling particulars. The pleasure to be derived is not worth the risk.

Those who wish to enjoy eating fungi with safety should follow the practice of the Italians, and cultivate known species. *Agaricus caudicinus* is thus grown with but little expense or trouble. The pollard head of the black poplar tree is brought home, watered freely for the first month, and in a short time becomes covered with abundant specimens of the above species, and the block continues to yield for twelve to fourteen years. *Polyporus avellanus*, an excellent species to eat, is grown on stumps of the cobnut tree, which are singed over a little burning straw and then watered plentifully. In about a month the perfectly white fungi, each about 2 to 3 inches in diameter, appear so profusely as almost to hide the wood from which they spring. It is said that *Boletus edulis* can be grown by watering the ground in suitable places with an infusion of the spores. It should not be forgotten that fungi, especially fleshy ones, decay very rapidly, and that a species which may be good eating at noon may undergo such changes in a few hours as to be anything but good eating at night.

Good service might be done to science, and possibly many a valuable life might be saved, were the poisonous principles of the different groups, such as *Russula, Lactarius, Boletus*, etc., isolated and examined by chemists, and their physiological action investigated by medical men. Unfortunately, even the antagonistic action of belladonna to muscarine, and possibly to the poisonous group to which *Amanita muscaria* belongs, appears to be so little known that it is hardly ever tried as an antidote, whilst our knowledge of other poisonous principles of fungi is almost *nil*.

PROSECUTION FOR COUNTER PRESCRIBING IN CANADA.

A CASE of prosecution for counter prescribing is reported from Ottawa, which is of a somewhat unusual character. It appears that the defendant, a Mr. MORTIMER, who is described as "an old and respected druggist," had a physician's prescription presented to him to dispense, but instead of doing so, he informed the patient that he could give him something better, and on the strength of that statement sold to the patient a preparation of his own. This led to his being summoned to appear before a police magistrate on a charge of giving advice without being a licentiate of any medical college. In defence Mr. MORTIMER pleaded that what he had sold was a specialty, and that he had given his advice gratis, which he claimed anyone had a right to do; further he alleged that he had acted similarly for thirty-five years previously and that it was only what every druggist in the Dominion was in the habit of doing. The magistrate, however, held that the law had been broken, and fined the defendant twenty dollars and costs. With rather mistaken zeal a local newspaper took up the case of the druggist, and in "spread eagle" diction championed the right of the public to free trade in medicine. But the *Canadian Pharmaceutical Journal* very properly remarks that the magistrate's decision was alike in accordance with law, justice and common sense, since Mr. MORTIMER decidedly overstepped his position as a druggist and had no right whatever to substitute any preparation for that named in the prescription. Moreover our contemporary expresses the opinion that every druggist in the province will repudiate the assertion that he is in the habit of doing as Mr. MORTIMER has done.

THE OPENING OF A NEW SESSION.

THE first week in October is in London always noticeable for the opening of schools and the delivery of "introductories." First among them in point of interest to pharmacists stand the proceedings in connection with the School of Pharmacy in Bloomsbury Square. The new session commences, as will be seen by the official advertisement, on Monday, October 2, with the lectures on Chemistry and Pharmacy by Professor REDWOOD and the instruction in Practical Chemistry under the supervision of Professor ATTFIELD; whilst on Thursday, the 5th, Professor BENTLEY will commence his lectures on Botany and Materia Medica. It is to be hoped that a good number of pharmaceutical students will avail themselves of the opportunity thus afforded them for obtaining instruction in the science of their calling. But the meeting on Wednesday evening will appeal to a larger number, since on that occasion the successful students of a past session are to be rewarded and the new comers are to be welcomed. An invitation to this meeting is extended by the Council to all students and friends, both ladies and gentlemen, and we do not doubt that, as in former years, the theatre will be well filled. After the Professors have made their reports, the prizes will be presented by the President, and then an address to the students will be delivered by Mr. JOSEPH INCE, which we do not doubt will be worthy of the occasion.

LIVERPOOL CHEMISTS' PRICE LIST.

RECENTLY we had the opportunity of calling attention to a new edition of the Price List issued by the Manchester Association, and we now have the pleasure of referring to the fifth edition of the Dispensing and Retail Price List recommended by the Committee of the Registered Chemists' Trade Association of Liverpool. The acceptability of this little work is proved by the fact that four editions have been exhausted in less than seven years, and additions and improvements have been made in the present edition which it is hoped will make it even more useful. We presume that copies may be obtained from Mr. J. HOCKEN, the Honorary Secretary to the Association.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page* 259.)

The following papers were then read—

Note on Methyl Orange as an Indicator of Free Acid.

BY B. S. PROCTOR.

Dr. Lunge, in an article in the *Chemical News*, December 16, 1881, advocates the use of methyl orange (sulpho-benzene-azo-dimethylamine), as an indicator in alkalimetry. I have found it useful also as an indicator of the presence or absence of free acids in salts, which in their normal condition have an acid reaction with litmus.

One grain of the dye in a pound of water makes an orange-yellow test liquor, two or three drops of which added to 1 ounce of water give it a yellow tint, which is changed to pink by a very small trace of free mineral acid.

It is not so sensitive to oxalic acid, still less so to acetic and not at all affected by carbonic.

Ferrous Sulphate.—The yellow liquor is not coloured pink by a solution of pure ferrous sulphate though the change is at once effected by a trace of free sulphuric acid in the presence of the sulphate.

With Perchloride of Iron the indications are not so satisfactory; the colour is deepened but the reaction is not clearly marked when neutrality is disturbed by additions of hydrochloric acid or ammonia.

Alum.—Pure or commercial alums do not change the colour of the orange, though they strongly affect litmus; a trace of free sulphuric acid added in the presence of the alum at once changes the orange to pink. Ammonia being added to this pink liquor promptly rendered it yellow and turbid; dilute sulphuric acid being then added drop by drop with an interval, and constant stirring, each drop produced an instantaneous tint of pink, which gradually changed back to yellow, as the acid was neutralized by the alumina in suspension; when the successive additions of acid had dissolved nearly all the alumina, the restoration of the yellow colour became very slow, finally the pink colour appeared permanent before the last traces of the alumina had dissolved.

Sulphate of Zinc.—1 ounce of water, 1 grain of sluphate of zinc, 4 drops of test liquor, remained faint yellow and changed to pink on the addition of $\frac{1}{4}$ of a drop of dilute sulphuric acid. On adding ammonia and acid the reactions were similar to those obtained with alum.

Repeating the test with sulphate of zinc to ascertain its delicacy, 1 ounce of water with 1 drachm of sulphate of zinc, and 4 drops of the test liquor, remained faint yellow, but changed at once on the addition of 0·08 of dilute sulphuric acid.

Organic Acids.—The action of organic acids though not so sharp as that of the mineral acids, is as clear as with most of the indicators in use.

With 1 ounce of water and 5 drops of test liquor, a small fraction of a grain of tartaric or citric acid sufficed to develope the pink colour. One drop of B.P. acetic acid produced the change, but 1 drop of vinegar strength did not produce a pink colour, though there was a change in that direction. In the liquor thus tinted by acetic acid, $\frac{1}{100}$ of a grain of sulphuric acid at once developed the pure pink colour.

Bicarbonate of Lime.—Water tinted pink in this way is very sensitive to ordinary hard water, and might probably give a fair approximation to the degree of temporary hardness in a water free from alkalies.

Chloride of Zinc produces no change of colour.

Corrosive sublimate causes a tinting towards pink, which is removed by the addition of chloride of ammonium.

Boracic Acid causes no change.

Cream of Tartar gives a tinting towards pink which is not much altered by small additions of caustic potass, or by tartaric acid, nor even by small additions of hydrochloric acid, until the addition probably left some free hydrochloric acid in the solution.

Hydrocyanic Acid produces no change even when present in nearly full pharmacopœia percentage, but the addition of a fraction of a drop of dilute hydrochloric acid developed the pink colour in a solution containing more than a drachm of the B.P. hydrocyanic acid.

Arsenious Acid has no action on the colour even on boiling for some minutes with the reagent.

Sulphurous Acid in small quantity produces the red coloration and does not bleach it when added in large excess.

Superphosphate of Lime does not cause reddening unless there is more phosphoric acid present than is requisite for retaining the lime in solution.

Note on a Commercial Sample of Liquor of Iodide of Iron.

BY B. S. PROCTOR.

If I had had a vote in establishing the laws of nature, I should probably have arranged that ferrous iodide should not have a propensity to absorb oxygen, liberate iodine, or behave in any other unsightly way on our shelves, and so I should have earned the thanks of all good pharmacists.

There has been evinced in our body a chronic desire to circumvent the nature of iodide of iron; and every now and then we have been promised by some maker, or someone who has devised a new formula, that we should at last be relieved of the hitherto troublesome changeability of iodide of iron or its syrup.

To my mind it does not appear probable that the *same* material should possess different properties when made by different processes, and if it were possible to obtain the same material endowed with different properties by deviating from the B.P. process, I should say that deviation ceased to be legitimate.

Holding these views I have not been very prone to accept the unchangeable iodides, but in a weak moment I was tempted to buy a little "Liq. Fer. Iodidi," which I was assured by the maker was not prone to darken, and could be made into a syrup of full Pharmacopœia strength by mixing with simple syrup as wanted; and which I was also assured I might examine as I liked and would find nothing but the legitimate iodide of iron and water.

I noted his words and concluded that it contained some preservative which he felt safe to promise me I should not find; perhaps he counted on my not carrying out my suggestion to examine it.

The first thing I noted was that it was freely acid, it not only reddened litmus more than solution of iodide of of iron made by the B.P. process, but it also reddened methyl orange (sulpho-benzene-azo-dimethylamine) which is not acted upon by pure iodide of iron.

Sulphuretted hydrogen, when passed through the liquor, caused no change except the slow precipitation of white sulphur, which would result from the presence of a small quantity of a ferric salt, or a little sulphurous acid. The same reagent produced a small black precipitate, with the pure neutral solution of iodide of iron. The commercial liquor was free from odour of sulphurous acid and from appearance of oxidation. The reaction suggested that oxidation might have been masked rather than prevented. It also suggested that the ferric salt, if present, might be the oxalate, which is green and of such a pale tint as not to be visible in the blue-green of the iodide.

As a check to this surmise a little ferric oxalate was added to a portion of liquor of iodide of iron and it developed a little yellowness which again disappeared on heating with a little free oxalic acid, the original blue-green colour being restored.

I do not find, however, that oxalic acid has any specially protective power.

The presence of a little sulphurous acid, too small in quantity to be readily detected either by odour or reagents, would probably account for all the unchangeableness noticed, but would not account for the acidity of the liquor.

Phosphoric acid, having a reputation of preserving the presentable appearance of the liquor, was also sought for, and its presence proved by separation as ferric phosphate, and confirmed by precipitation as ammonio-magnesium phosphate.

After most of the experiments had been tried I noticed a small precipitate at the bottom of the bottle, which had previously escaped my notice from the dark blue colour of the glass.

This precipitate, removed and washed, proved to be ferrous oxalate, as its lemon-yellow colour at first suggested.

Half a fluid drachm of the liquor, precipitated with nitrate of silver, indicated gravimetrically 13·47 grains iodide of iron, instead of 17·2, which was required to make a full strength syrup when the liquor was used according to the directions accompanying it.

A trace of sulphuric acid was found, but only such as might represent a little hard water, or the product of the oxidation of sulphurous acid. A trace of hydrochloric acid also, but too small to have any significance.

I do not profess that this is an exhaustive examination of the sample; my object was gained when I ascertained that its permanence was not the result of purity, not attained without a sacrifice of purity. I do not suggest the propriety of adding any foreign matter as a preservative. I have not even suggested the impropriety of such a course; but I do suggest that if any pharmacist feels himself impelled to any other expedient than that of keeping his solution in contact with an iron wire, he had better at least know what he is doing. Add the adulterations yourself rather than buy the liquor ready adulterated and not know what it contains.

The President, in proposing a vote of thanks to Mr. Proctor, said there had been so much said and written on the subject of solutions of iodide of iron that he need not say anything to stimulate discussion upon it. This last note on methyl orange as an indicator seemed particularly useful and it would be well if they had a similar series of experiments made with phenol-phthalein. Litmus really seemed to have too much its own way in this matter of acid and alkaline reaction; they had been using the terms acidity and alkalinity for so many years that they had got into the way of thinking that those were definite properties of a substance, whereas really all they were doing was speaking of the qualities of that substance in terms of litmus. He did not see why they should not speak of them in terms of phenol-phthalein or of methyl orange. If they did so they might even get nearer to truth repecting acidity, alkalinity, and neutrality.

Mr. Ekin said the use of these bodies as indicators was first brought into notice in this country by Dr. Witt some years ago. He advocated the use of what was known as Tropœoline O.O., which had very much the same chemical composition as methyl orange, the methyl being replaced by the phenyl group and it was more stable. Professor Lunge, in the article in the *Chemical News* referred to, had claimed that methyl orange was more delicate as an indicator, which was doubtful, and one of his statements that it was not affected by acetic acid, as Mr. Proctor had shown and he could confirm, was decidedly erroneous. He had sent Mr. Proctor a sample of Tropœoline O.O. to try against the methyl orange, and he had heard from him that he had not had time to try it properly, but he fancied it gave a purer red with acid and purer yellow with alkali, but was not quite so delicate.

Mr. Fletcher said no meeting of the Conference could be considered complete without the question of iodide of iron coming up, and when he saw Mr. Proctor's paper on the list, he had the curiosity to turn up some old volumes of the *Pharmaceutical Journal*, and in ten minutes he counted no less than forty-two papers on the syrup and liquor of iodide of iron. Dr. Thompson, in 1834, first suggested iodide of iron as a medicine, and, rather curiously, it was introduced first as a liquor. It was made official in the old Edinburgh Pharmacopœia, the strength being that of the present syrup, viz. 4·3 grains of ferrous iodide to the fluid drachm. In 1836, Mr. Squire, for even then this solution did not seem to have been quite immaculate, suggested that when dispensed it should be sent out with a coil of iron wire traversing the whole length of the solution. In 1842, Dr. Thompson read a paper at an evening meeting of the Society, when Mr. Savory was in the chair, and he seemed to have thrown cold water on the suggestion, for he said that having prescribed the solution of iodide of iron for a lady patient, she gravely wrote to ask him whether the iron screw which the bottle contained was to be swallowed whole, or taken in parts after each dose of the mixture. Dr. Thompson then recommended the syrup of iodide of iron, and suggested the very formula which has remained without alteration to the present time. He (Mr. Fletcher) had noticed that whenever this question came up, some gentleman always rose and said he was surprised that there should be any bother about making syrup of iodide of iron; that he was always able to make it perfectly colourless and keep it. The very fact that such a number of papers had appeared in the Journal upon it, was pretty good evidence that the majority did not find it satisfactory. He felt a little delicacy in offering any remarks on Mr. Proctor's paper, partly because that gentleman was a much more experienced pharmacist than he was, and he also feared that as a manufacturer of iodide of iron his remarks might be misinterpreted; still he should like to say a word upon it purely from a chemical point of view. If there was one thing about making iodide of iron, which he had hoped had been thoroughly settled, it was that when iodine and iron were brought together in the presence of water hydriodic acid was developed. That had been proved to demonstration over and over again, and if the solution were distilled very large quantities of hydriodic acid might be got from it. If iodine and iron were boiled together in water and the solution afterwards boiled up with more iron there would be very brisk effervescence, which showed that there was free acid in the solution. That could be proved by distilling and precipitating the hydriodic acid as a silver salt. Mr. Proctor took exception in the first place to the solution because it was very acid; but he was open to challenge Mr. Proctor, or any other pharmacist, to make any solution of iodide of iron which should not be very acid when tested; at all events he would challenge him to make one which would not contain hydriodic acid. Then Mr. Proctor said he found ferrous oxalate. The wholesale druggists and manufacturing chemists had not had a very good time of it at this Conference, but he really thought that no manufacturing chemist or wholesale druggist would have the hardihood to introduce such a poisonous substance as oxalic acid into a medicinal solution, if he had any reputation he cared to lose. With regard to sulphurous acid, he would only say that if anyone wanted to try and keep a solution of iodide of iron by sulphurous acid, he had better try it; it would give a thick muddy deposit and do all sorts of other disagreeable things. The suggestion of preserving the solution by phosphoric acid was due to an ex-President of the Conference, Mr. Groves, some years ago, and at the Swansea meeting, he recollected an admirable little paper, by Mr. Groves also, in which he suggested that if coloured syrup of iodide of iron were treated with a few drops of liquor potassæ, the colour would disappear, and if a little phosphoric acid were then added it would keep very well; and he concluded with the very sensible remark that of two evils he preferred to choose the lesser. He could not help regretting that Mr. Proctor was not present to answer any questions. He did not make any mention of the specific gravity of the liquor, which was in itself an indication of its strength. Further than that, he said that he separated phosphoric acid as ferric phosphate; but if phosphoric acid were really there, and he had a ferric salt there, he should imagine the ferric phosphate would already have come down. Mr. Proctor maintained, in the early part of the paper, that it was illegitimate to add anything whatever to a pharmaceutical preparation, whether it was faulty or perfect; but he recollected, at the London meeting of the Conference, Mr. Proctor read a paper on hydrocyanic acid, wherein he recommended the addition of some mineral acid to preserve it, and at another meeting, Mr. Williams recommended the addition of glycerine. The question for pharmacists was whether they should send out syrup of iodide of iron of all sorts of colours, or whether they should modify the process, as it was evident the Pharmacopœia never intended to have hydriodic acid present, and send out a preparation, which was always perfectly white and good and which no one could complain of.

Mr. Williams said his recommendation was not that glycerine should be added to hydrocyanic acid by chemists without authority, but that it might be added as a preservative by the authorities of the Pharmacopœia. He never presumed to say that a chemist should add glycerine on his own responsibility.

Mr. Fletcher said in the course of the paper he referred to, he believed Mr. Williams said that no chemist, whoever he was, would be able to make hydrocyanic acid to keep without the addition of some trace of mineral acid, and in the place of mineral acid he recommended glycerine.

Dr. Symes said Mr. Fletcher had rather sat on those chemists who had said that syrup of iodide of iron by the Pharmacopœia process could be made to keep without some preservative being added to it; he happened to be an individual who, on more than one occasion, had said that. He did not believe even in Mr. Proctor's suggestion of adding iron wire. The syrup properly made and put in small, well-filled, stoppered bottles, exposed to a strong light, kept well. A liquor which kept well under almost any conditions was an undoubted convenience to many chemists and deserved to be appreciated, but the syrup prepared from it and that by the Pharmacopœia process should not differ.

Mr. Parker wished to say one word in support of Dr. Symes. He had in his possession a specimen of syrup of iodide of iron, prepared according to the British Pharmacopœia, which had remained unaltered for two years and a half. The only precaution he took was to fill the bottle so as to entirely exclude air. To his mind the use of a "liquor" was, in many cases, very convenient, but he doubted whether it would be so in the case of this syrup, where the difficulty in dispensing small quantities, say a drachm, or ½ a drachm, would be very much increased if one-eighth the quantity had to be measured. The only excuse he could see for a pharmacist using liq. ferri iodid. for the preparation of the syrup was from his being unable or finding it very inconvenient to prepare and store the syrup properly.

Professor Tichborne quite agreed with the remarks made by the last speaker. In giving a history of the syrup of ferro-iodide Mr. Fletcher was not quite correct in some respects. As far as he recollected the history of syrup of ferro-iodide, the first improvement suggested was the use of iron wire, which he (the speaker) strongly objected to as he did not think the wire preserved it at all. The next improvement was suggested by himself many years ago, in a paper read at Bloomsbury Square. In that paper it was pointed out that up to that day the proportion of sugar was not sufficient; by the formulæ used up to that date a very thin syrup was produced, and one of the essential points of his (the speaker's) paper was to propose that the ferro-iodide should be run into a supersaturated syrup. Such a syrup, according to his experience, kept perfectly well. Hydriodic acid was formed in making iodide of iron in the first instance, but the amount formed would depend a great deal on the boiling, and the error which was implanted in the student's mind by the direction of the Pharmacopœia was that he did not boil the iodide of iron enough. The direction was that when the yellow froth became decolorized the iodide of iron was supposed to be formed. That, however, was not a measure of the completion in the operation, and there was no doubt at that stage a considerable amount of free hydriodic acid present. If the boiling were continued for a considerable time the hydriodic acid would be brought down to a minimum, and that was one of the secrets which made the difference between a well prepared and a badly prepared syrup.

The next paper read was—

Report on the Strength of Commercial Samples of Tincture and Liquid Extract of Opium.

BY JOHN WOODLAND, F.L.S., F.C.S., ETC.

Having, during the past year, made several determinations of the strength of different samples of these two preparations of opium, I submit a compilation of the results of these and other estimations in the form of a paper to the members of this Conference.

From the variation in strength of the samples of opium used in pharmaceutical operations, a divergence in the results was anticipated and experienced, and in the present state of pharmaceutical progress such variation ought not to exist, and might be remedied.

Regarding morphia as the chief of the active ingredients of opium, and the assaying of this alkaloid an operation attended with no very great difficulty, I do not see why the samples, as they are wanted for use, should not be estimated, and having an official standard of say 8 or 10 per cent. (one or the other) of morphia, a mixture of the various samples made, which would bring the whole to this standard.

Many samples of best Smyrna opium contain 12 or even a greater percentage of this alkaloid; in such a case allowance could be made for the excess over the standard; for instance, a sample of opium is found to contain 12 per cent. of morphia, and a gallon of tincture is required; if the standard be 8 per cent. and the proportions of drug and spirit the same as now exist in the Pharmacopœial formula, 12 ounces will be necessary, but in the present case 12 per cent. being contained, either a gallon and a half can be made with 12 ounces of this opium, or 8 ounces can be used to prepare a gallon.

It may be urged that the other principles contained in opium are of physiological value in the administration of the tincture, and therefore they ought to be estimated as well; but whilst their number is so great, and isolation tedious, I do not see that it would be practicable, the estimation of morphia only being sufficient for all practical purposes. The following is a table of the percentages of solid residue and morphia obtained from fourteen samples of tinct. opii procured from both London and provincial chemists:—

No. of sample.	Character of residue.	Percentage of residue.	Percentage of morphia.
1.	Resinous	4·35	·62
2.	Resinous	3·21	·41
3.	Resinous	3·93	·45
4.	Oleaginous	4·81	·38
5.	Resinous	4·22	·61
6.	Resinous	4·51	·59
7.	Resinous	5·01	·68
8.	Resinous	3·56	·32

No. of sample.	Character of residue.	Percentage of residue.	Percentage of morphia.
9.	Resinous	3·41	·45
10.	Resinous	4·67	·70
11.	Resinous	3·82	·51
12.	Oleaginous	5·11	·41
13.	Resinous	4·28	·65
14.	Resinous	4·54	·69

The samples were evaporated at a temperature of 70° C. in an air-bath, and when perfectly dry treated by a modification of Prollius's method for the estimation of morphia as follows. The solid residue was taken up with ten times its weight of equal parts of rectified spirit (60 over proof) and water, to this solution enough liquid ammonia was added to render it strongly alkaline, and then an equal bulk of ether was introduced, and having well shaken the mixture it was set aside for twenty-four hours, after which the crystalline morphia was collected, washed with ether, dried and weighed.

One or two blank experiments were made with a known quantity of morphia in solution by which the accuracy of this method was demonstrated, the difference between the quantities introduced and estimated being extremely slight.

Allowing that the opium from which the tincture is made contains the maximum percentage of morphia mentioned in the Pharmacopœia, viz., 8, the percentage of this alkaloid in the tincture will be about ·6, hence in six of the samples examined an over percentage was found, whilst in eight a deficiency existed, the lowest being No. 8.

Ten samples of liquid extract of opium were treated in a similar manner to those of the tincture, viz., evaporation to dryness, and the subsequent estimation of morphia in the residue. The following table indicates the results:—

No. of sample.	Percentage of residue.	Percentage of morphia.
1.	4·47	·37
2.	3·39	·21
3.	4·45	·30
4.	4·71	·36
5.	3·11	·19
6.	3·40	·23
7.	4·92	·37
8.	4·21	·31
9.	3·85	·21
10.	3·02	·22

On calculation it will be found that if a sample of opium contains 8 per cent. of morphia, the liquid extract made from this sample should contain ·38 per cent. of this alkaloid, but in each of the above instances the percentage was too low, especially in the cases of Nos. 2, 5 and 9.

The PRESIDENT, in proposing a vote of thanks to Mr. Woodland, said this paper opened up the question of drug standards, which was rather a large subject. The percentage of morphia, indicated in the Pharmacopœia, which should be contained in opium was not 8 per cent., but from 6 to 8 per cent., but even assuming it was 8, it was rather curious that these samples of tincture should yield on the average apparently within 10 per cent. of that quantity, while the liquid extracts did not yield enough morphia by 25 per cent. It would seem as if the opium were very poorly extracted in the case of the solutions.

Mr. PLOWMAN said it would be useful to know on what data Mr. Woodland proceeded when he said, on calculation, it would be found, if crude opium contained 8 per cent., the liquid extract ought to contain ·38 per cent. of morphia. It could not be the same in every case.

The last paper read was—

REPORT ON THE PURITY OF COMMERCIAL SAMPLES OF SILVER SALTS.

BY JOHN WOODLAND, F.L.S., F.C.S., ETC.

I was led to make the following analyses partly by seeing on the green paper issued by the Conference Committee that such a report was wanted, and partly on account of curiosity, awakened by seeing various sized caustic points sold for the same price, and after obtaining a large caustic point for a small piece of money, came to the conclusion that the maker, fearing that the caustic point might prove too strong, with due regard to the tender feelings of the public modified its action by the aid of a diluent. The diluents found in the two forms of nitrate of silver, viz., caustic points and crystals, were the nitrates of potash and soda, those of potash being chiefly present, as the following table will show:—

Caustic Points.

No. of Sample.	Percentage of $AgNO_3$.	Name of Diluent.	Percentage of Diluent.
1	63	Potassium nitrate	36
2	71	Sodium ,,	26
3	64	Potassium ,,	35
4	75	Potassium ,,	25

Crystals of Silver Nitrate.

No. of Sample.	Percentage of $AgNO_3$.	Name of Diluent.	Percentage of Diluent.
1	89	Potassium nitrate	10
2	99	None	—
3	92	Potassium ,,	8
4	84	Sodium ,,	14
5	80	Potassium ,,	19
6	100	None	—

In the estimation the points and crystals were reduced to powder and dissolved in recently boiled distilled water, to which a standardized solution of pure cyanide of potassium (prepared from an alcoholic solution of KHO) was added until the precipitated cyanide of silver at first formed was exactly dissolved, the data being derived from this equation—

$$2KCN + AgNO_3 = AgCN,KCN + KNO_3$$

It may be noticed that the above figures do not in every case aggregately come to 100, the deficiency in number being due to a slight amount of moisture present. Crystals of nitrate of silver when pure are transparent, and an impurity can usually be told by its giving a translucent appearance, and so causing them to somewhat resemble the crystals of chlorate of potash. The impurities in the above samples were estimated by precipitating the silver as chloride with hydrochloric acid, filtering, and evaporating the filtrate and weighing the residue.

The other salt of silver estimated was the oxide, most samples of which had been in stock for some time. Six samples furnished the following table:—

No.	Percentage of Silver.	Corresponding Percentage of Oxide.	Impurities.	Percentage of Impurities.
1	76	81	Carbonate and chloride of silver	19
2	70	75	Siliceous matter	25
3	81	87	Carbonate and chloride of silver	13
4	72	77	Carbonate and chloride of silver	24
5	78	83	Carbonate and chloride of silver	17
6	69	74	Carbonate and chloride of silver	26

The samples of oxide were estimated by dissolving in nitric acid, precipitating with hydrochloric acid, washing, fusing, and weighing the residue. The presence of carbonate and chloride with the oxide of silver seems to indicate that either solution of potash or soda is used in its preparation, instead of lime water as officially ordered, as carbonate and chloride are to be found in both of these solutions. The siliceous matter is undoubtedly an intentional adulteration.

The PRESIDENT, in proposing a vote of thanks, remarked that caustic points did contain nitrate of potassium, because nitrate of silver was too brittle to be used alone in the small cases. He believed that all makers put in some nitrate of potassium. Crystals of nitrate of silver certainly should not contain potassium or sodium nitrate or chlorate of potassium either. As for the oxide there could be no doubt that if precipitated with the common soda it might contain carbonate, but not if precipitated with pure soda.

Professor QUINLAN said the addition of potassium nitrate to pencils of nitrate of silver was perfectly recognized and necessary. Nitrate of silver of itself was too brittle, particularly when applied to the throat and parts where it would be liable to drop down. It was a great advantage to the practice of surgery to have these neat little points, compared to the trouble of grinding away with a wet cloth at a stick of nitrate of silver, which the surgeon used to have to do before the points were brought into the market. He need not say that nothing would justify the addition of extraneous matters to silver nitrate crystals.

Mr. MASON said he did not know whether Mr. Woodland stated the source from which he obtained some of these samples, but he did not think it possible that such nitrate crystals came into the hands of chemists and druggists. Photographers were in the habit of buying up waste from which they recovered nitrate of silver, and probably some dealers in photographic chemicals might be tempted to adulterate it in this way. Respecting the oxide of silver, he believed as a matter of fact it was not sold pure, for being in want of some absolutely pure some months ago, he wrote to a large manufacturer for it who replied that he should have to make it for him. He ultimately received a small quantity in a moist state, and was told that he could not be supplied with it dry.

Professor TICHBORNE said oxide of silver was a pharmaceutical preparation and there should be no difficulty in procuring it at any house, retail or wholesale.

Mr. WILLIAMS said the tough nitrate of silver, made specially for surgical purposes in points, contained as a rule nitrate of lead, not nitrate of potash, as the former toughened it much more than the latter. It was not put in as an adulteration and was allowed for in the price charged for the article. It was a special thing, known as toughened nitrate of silver, at least so he understood, for he did not make it himself. He was certainly very much astonished to hear of the impurities found in the crystallized nitrate of silver. He had had a great deal of experience in this article for many years and knew it was not always pure, and the commercial article was not as pure as it might be; but it could be purified, and was all the better for being recrystallized and purified again and again. Still he did not imagine that the impurity was above $1\frac{1}{2}$ or 2 per cent. at the most, and he did not believe any photographer would purchase an impure nitrate of silver; photographers knew perfectly well what nitrate of silver should be and would not purchase it twice if it were impure.

Mr. NAYLOR said he had examined commercial nitrate of silver by means of a standard solution of chloride of sodium on various occasions, but had not found it to contain more than $1\frac{1}{2}$ to 2 per cent. of impurity.

Mr. ANDREWS said that after the remark made about oxide of silver, which, to the dispenser, was of even greater importance than the nitrate, he was in hopes that some of the practical manufacturing chemists would say whether there was such an amount of impurity as was stated. It was a powerful remedy when used in small doses, and if adulterated to such an extent it would be a very serious matter. Mr. Williams said the oxide of silver in commerce generally contained a certain quantity of chloride. It was perfectly certain that pure caustic soda, absolutely free from chloride, was never used in practice for precipitating the oxide, and, therefore, as the caustic soda would contain a percentage, not very large, of chloride, so the oxide of silver would probably contain a little chloride too. That would explain why Mr. Mason could not obtain chemically pure oxide of silver except by special order. The idea of throwing it down by lime water, which was suggested in the paper, was one which was not recommended in any works on the subject, although of course it would be very effective. The difficulty was that the lime water held so small a quantity that it would take a large bulk of water to effect the object.

Professor TICHBORNE said the lime water was the Pharmacopœia process.

Mr. GROVES said on one occasion the presence of carbonate in oxide of silver was manifested to him by the swelling and effervescence of some pills that he was making. The oxide of silver became reduced to the metallic state, carbonic anhydride was given off and the pills became very large. On examining the specimen of the oxide he found it contained a large proportion of carbonate.

PLACE OF MEETING IN 1883.

The PRESIDENT said the next business before the Conference was to appoint a place of meeting for the year 1883. Usually the Committee had been able to announce that the British Association would meet in such and such a town, and it had been the practice for the Conference to meet in the same place. On this occasion, however, this could not be done, because Oxford, which was the place chosen by the British Association for 1883, had sent word to that body that owing to some unforeseen circumstances it would not be able to entertain the British Association next year, and it was not at that moment decided where the British Association would meet. A question might arise whether the Conference should necessarily meet in the actual town in which the British Association met, but unless it really was important to go into that question, he hoped it would not be raised. It was quite a distinct question, the Committee decided it a year or two ago, and for the present, at all events, it was undesirable to alter the rule of meeting where the British Association met. That practice had been carried out with one single exception, which was perfectly justifiable, ever since the Conference was formed. He held in his hand an invitation from the Oxford chemists which was everything the Committee could wish, but he would suggest that the members should leave it to the Committee to decide at an early meeting where the Conference should meet in 1883.

Mr. GROSE (Swansea) then moved that the place of meeting for 1883 and the selection of local officers be left to the Executive Committee.

The motion was seconded by Mr. DEAN and carried unanimously.

OFFICERS FOR 1882–83.

The Conference then proceeded to elect the officers for the ensuing year, Messrs. Robinson and Clark (York) being appointed scrutineers of the ballot papers.

The following officers were unanimously elected:—

President.—Prof. Attfield, Ph.D., F.R.S., F.I.C., F.C.S.

Vice-Presidents.—M. Carteighe, F.I.C., F.C.S., London; J. R. Young, Edinburgh; C. Umney, F.I.C., F.C.S.

Treasurer.—C. Ekin, F.C.S., Hounslow.

General Secretaries.—F. Baden Benger, F.C.S., Manchester; S. Plowman, F.I.C., London.

Other Members of Executive Committee. — Alexander Kinninmont, F.C.S., Glasgow; J. C. C. Payne, Belfast; W. A. H. Naylor, F.C.S., London; R. Chipperfield, Southampton; P. W. Squire, F.L.S., F.C.S., London; G. S. Taylor, F.C.S., London; J. C. Thresh, D.Sc., F.C.S., Buxton; F. W. Fletcher, F.C.S., London.

Auditor.—James Spearing, Southampton.

VOTES OF THANKS.

Mr. WILLIAMS said it was with great pleasure he rose to propose a resolution, which he was sure all present would cordially agree with. It was one proposed every year, and it would be almost impossible to find fresh language proper to such an occasion; but fortunately it was not necessary that much should be said. He was quite sure the gentlemen on whose behalf he was going to move the resolution would take his words as expressing the very cordial feeling which the meeting had towards them. It was—

"That the cordial thanks of the non-resident members of the British Pharmaceutical Conference be given to the Local Committee, and especially to Messrs. Randall, Chipperfield and Dawson, for the very successful manner in which the various arrangements connected with the Southampton visit had been carried out."

He would not add one single word, except to say that he considered the meeting had been an exceedingly good and successful one.

Mr. Giles seconded the motion with very great heartiness. He said the pleasure they had all felt in receiving the hospitality and attention of the local members had been greatly enhanced by the courteous personal attention they had received at the hands of those gentlemen who had been named. He and many others met an old friend in Mr. Randall, whom he was glad to see as Chairman of the Local Committee. He had had great pleasure in meeting Mr. Chipperfield and making his acquaintance, and he could not help saying, as a good many others felt, that he regretted that it should be necessary on these occasions to have a Treasurer at all, whose duties must be somewhat severe. They could not help feeling while they were receiving such friendly attention they were also imposing considerable liabilities on their friends, who so kindly and cordially entertained them; but these things could not be helped, and he only trusted that those gentlemen received some satisfaction from them, as they were told, on the highest authority, that it was more blessed to give than to receive.

The motion was carried unanimously.

Mr. Randall, in reply, said it was very common to say that one felt more difficulty in speaking on such an occasion than on almost any other, and it was perfectly true, but he might be allowed to say that the members of the Local Committee were greatly obliged to all the members of the Conference for the kind way in which they had received all their efforts and overlooked their shortcomings. When a thing of that sort had to be done just for once, no one could do it so well as if it had to be done frequently. Southampton could not say, as York said through its representative standing in the position he now occupied, that it was essentially a city of the past; it could not aspire to be a city at all and it would not wish to look back; if it could it would rather be an aspirant to future progress. Southampton burst its stone-bonds, of which they saw the relics in the gates and some of the walls, about the seventeenth century and went out into the open and had been going on increasing ever since. It was only that year that Southampton burst what they considered a very serious iron bond and was now looking forward to the north to help them by coming down more readily, as it would have two ways instead of one of doing so, and assisting by its enterprise and commerce and science too. He believed science nowaday did more to help commerce and enterprise than it ever did before. The pharmacists of Southampton, of course, hoped that they would participate in the general improvement in commerce, which they looked for as these things went on, and he heartily thanked the Conference for giving them some hints at least towards improving pharmacy as an art, and especially as a science. If, therefore, the visiting members had received a little hospitality in that which was material, they in the district had gotten a great deal more in that which was far better, which he hoped they would make use of in the future. In the name of the Local Committee he begged to express their high appreciation of the way in which their endeavours to promote the comfort of the visitors had been received.

Mr. Chipperfield said he was no orator or else perhaps he might express himself in such a manner as would startle the meeting. He was a bad hand at whistling and was especially disinclined to attempt whistling before he was through the wood, and they had still to look forward to the morrow. He was happy to believe that they were satisfied that the local chemists had been doing what Nelson told his sailors England expected them to do,—they had striven to do their duty. *A propos* of what Mr. Randall had said, he might add that he had felt very strongly indeed during the last twelve months the truth of the poet's lines which he learnt in his youth,—he had not read much of that author's poetry in his maturer years,—that—

"A man must serve his time to every trade,
Save censure; critics all are ready made."

His share of this work had been done during his apprenticeship, and the same with his *confrères*, and the shortcomings which no doubt had been noticed and would still be witnessed must be placed to that account. He felt that by the next night he should have thoroughly served his time at this business, and that if they could only persuade the Conference to come again next year they should then be able to do the work well; at any rate he believed he should do his part then perfectly. At present he could only say he had done it to the best of his ability.

Mr. Dawson also thanked the Conference for the acknowledgment which had been given for the slight trouble he had taken and the services he had been able to render to the gentlemen attending the Conference. When the matter was first mooted it was with considerable fear and trembling that he took the office of Local Secretary, but since then he had scrupulously attended to all the minor details he possibly could with the view of rendering their visit as pleasant and comfortable as possible. He hoped the gentlemen attending the Conference would carry away with them as pleasant reminiscences as the pharmacists of Southampton would retain of the visit of the Conference.

Mr. Chipperfield asked leave of the President to add a word or two which a sense of duty compelled him to utter. He hoped no one would go away and fancy that the hospitality they had received, and would still receive, came exclusively from Southampton. They had to thank almost every town in the county for its kind assistance, and also several gentlemen residing in other places, such as Salisbury, London, Redhill, Cheltenham, Shepton Mallet, and elsewhere. He mentioned this so that any town which perhaps might be as poor as Southampton and might, therefore, not be able to entertain the Conference, might follow the example of Southampton, and gain that extraneous aid which would enable them to do the same as had been done for seventeen or eighteen years.

Professor Tichborne said they would all feel that this was what might be termed in the annals of the Pharmaceutical Conference, a red letter meeting, and, individually, he should take this opportunity of thanking the local gentlemen for the reception they had given him as a stranger amongst them. The success of that meeting so far had been perfect, and although they felt deeply indebted to the local men for that success, they knew also that it was almost impossible, even for local men, to make these meetings successful, unless they had support from the authorities and other general assistance. Everybody who had been at the Ordnance Survey Office must have felt that it was a great treat; in fact, it was an unique exhibition. He was informed that the zinco-lithography, which was now so universally used, to which they owed cheap music and many other things, was chiefly due to the Ordnance Survey Office of that town, that it was invented and perfected there. It therefore possessed a peculiar interest, and very properly the people of Southampton were very proud of it. It would be wrong, therefore, if they separated without passing such a resolution as he was about to move, namely—

"That the best thanks of this Conference be given to Major-General Cooke, the Inspector-General of the Ordnance Survey Department, for his kindness in affording the members facilities of visiting the Ordnance Survey Office."

Dr. SYMES seconded the motion. He said every one who had visited the office and seen the processes employed would be impressed with the thoroughness of the work which was done there and the science which was brought to bear in carrying it out.

The motion was put and carried unanimously.

Mr. ATKINS then moved—

"That the hearty thanks of the members are due and are hereby tendered to the President for the courteous and very able manner in which he had conducted the business."

He said there was a danger that he might weaken the force of these well selected words by any ill selected words of his own, but he could not allow the resolution to pass without expressing his own personal feeling with regard to it. He had been most solicitous, coming from a neighbouring city which could hardly venture to hope to have the honour of a visit from the British Association or the Pharmaceutical Conference, that this Southampton meeting should be a great success and that desire had been amply met. He did not know that there had been the slightest thing to mar their enjoyment excepting a little wet weather; the room in which they had met, the admirably representative gathering of those assembled, and the character of the papers would all render the meeting memorable. It was an important thing to have a good President, and though he wished to make no comparisons he ventured to say they had never had a better. Professor Attfield had this disadvantage that he had a great reputation and a man who had a great reputation had to work up to it, as a beautiful woman had alway to keep up to the report of her beauty. Professor Attfield had excited great expectations and he had realized them. He had given an address of which he ventured to say yesterday that the highest compliment he could pay to it would be that it would excite attention and possibly criticism. Besides that there fell upon him in his office as President the duty of seizing the salient points of all the papers and presenting them in clear, accurate language to the meeting, and he need hardly say to do that required many gifts, large reading and much knowledge. In addition to the address and in addition to presenting the points of the paper he had, with all the courtesy and consideration possible (barring that one matter of the vital force), allowed the widest latitude to discussion. They would all look back with pleasure to this Southampton meeting, no small part of the success of which was due to the fact that Professor Attfield had been President.

Mr. STEPHENSON had much pleasure in seconding the motion. As a delegate, with Mr. Borland, from the northern division of the United Kingdom, he could only say that as far as he was concerned he had felt it was his part to listen rather than to speak.

Professor QUINLAN said it would not be fitting if no voice from Ireland were raised to support this resolution on an occasion when the Conference was presided over by a gentleman whose work on chemistry was the standard book in the Irish medical schools. This would be always regarded as a red letter meeting of the Conference, partly from the admirable way in which Professor Attfield had presided, and partly from the kind and generous hospitality received from the Southampton members, which none would ever forget.

The motion was put by Mr. SCHACHT, and carried by acclamation.

The PRESIDENT, in responding, thanked the members for the kind way in which they had shown their appreciation of his humble endeavours to fulfil the duties of President. The secret of his apparent success, and he must admit it had been a success, after what had been said, was chiefly that he had profited by the example of his predecessors, and not only his predecessors in that chair, but, Mr. Stephenson and Mr. Atkins would allow him to say, of other Presidents and other Vice-Presidents also, connected with the Conference and with the Pharmaceutical Society. He thanked his colleagues, the previous Presidents, for their kind support during this meeting, and he thanked all the other officers too, and he was sure the officers generally would excuse him if he especially thanked the Secretaries for their labours in carrying on the business of the sittings. He must also thank the authors of the numerous papers; they had seldom had a larger number of more practical papers. He must recognize, too, the kindness of so many gentlemen who had contributed to the discussion of the papers, and it was particularly gratifying to him to find amongst the authors of papers and the speakers so many of his old pupils. He was particularly pleased to have met them, and he thanked them for coming. He had been glad to meet at Southampton members whom he had not met before. He was particularly glad to have met so many of the friends he had made at the meetings of the Conference, during nineteen years, and including Newcastle, twenty consecutive years. He thanked the members very much for the kind way in which they had passed this resolution and, in conclusion, could assure them that he would do his best to promote the interests of the Conference during the coming year.

Reviews.

DICTIONARY OF ECONOMIC PLANTS. By JOHN SMITH. London: Macmillan and Co., 1882.*

Visitors to the Kew Gardens or to other botanical gardens, who notice in the economic houses the names of plants, of the uses of many of which they are entirely ignorant, would probably be glad of a handbook to which they could refer and in which they might find a short and popular account of the uses and native countries of the different plants. To help the inquiring mind seeking such information few are perhaps more competent than Mr. J. Smith, seeing that he was officially connected with the Royal Gardens at Kew for over forty years and that the economic collections which now fill the three museum buildings there were formed during the time that he filled the post of curator to the gardens. His son, who was the first curator of the museums at Kew, worked most industriously, until his death in 1865, with the view of writing a work on economic and commercial botany. From his arranged notes, which occupied no less than thirty octavo volumes, the materials for the present work have been selected by his father. To give some idea of the number of subjects treated of in the book, it is stated in the preface that 1600 are mentioned belonging to 1163 different genera.

The selection of material seems to have been carefully made with a view to throw light upon the names and nature of such economic objects as might be met with in commerce, in agriculture, in general reading, in gardens, and in museums. The character of the book may be compared with that of the 'Treasury of Botany,' but it is written in a more popular style, and as it forms one volume only it is more convenient for carrying and for reference. It also has the advantage that while the vernacular or commercial names are arranged throughout the work in alphabetical order, there is in addition an index of scientific or botanical names at the end.

Looked at from a pharmaceutical point of view, a large number of interesting products are mentioned, and the omissions are but few. Among the latter we observe that Goa powder does not receive any notice, although better known in this country than pituri, to

* Demy 8vo; pp. i.–ix.; 1–457. 14s.

which a paragraph is devoted, and although *Jacaranda* is mentioned no notice is taken of the medicinal value of the leaves. Ceylon and Bengal cardamoms, which are not unfrequently imported, are not described or noticed under the head of "Cardamoms."

The omissions, however, are evidently very few, and in another edition will doubtless be rectified, should it be revised by Mr. J. R. Jackson, the present able curator of the Kew Museums, to whom the author expresses his indebtedness in furnishing many new subjects and in correcting proof sheets.

Mr. Smith's complaint against popular names for plants, such as Adam's needle, Job's tears, Jacob's ladder, as being vulgar and undignified, may be almost regarded as a protest against the exercise of the imagination, a faculty too little exercised, probably, in this practical age. Certainly the term crane's bill instead of geranium and stork's bill instead of pelargonium can scarcely be more vulgar than the scientific names derived, as Mr. Smith informs us, from the Greek words *geranos*, a crane, and *pelargos*, a stork.

The difficulty in compiling a work like the present must have been in reducing the materials at hand into the small space of an octavo volume and to weigh the relative importance to the public generally of the kind of information to be given concerning each subject. Mr. Smith may be congratulated on having produced a work which will be found useful alike in the household library, in the day school, as a handbook of economic botany to the student visiting economic museums, and to the merchant who wishes to find out the value and uses of imported vegetable products.

New Commercial Plants and Drugs. No. 6. By Thos. Christy, F.L.S. London: Christy and Co. 1882.*

Most persons who are interested in materia medica are congnizant of the valuable services rendered during recent years by Mr. Thomas Christy, whose commercial instincts have led him in a direction where it is to be hoped he has secured personal advantages for himself as it has certainly enabled him to confer benefits upon the community. For directly a new drug from any part of the globe has been mentioned, or a plant that promised to be of economic value, Mr. Christy's energy has been exerted to place it with the least possible delay within the reach of those who wished to test it; indeed he has frequently done his best to create a demand for it by placing at the disposal of those likely to be interested the best available information upon the subject. Although this may be a form of advertising, it is of a very superior character, and is serviceable to more than the advertiser. To these efforts are due the publication of a series of reports on new commercial plants and drugs, the sixth of which is the subject of this notice.

The greater portion of the present number is taken up with a treatise on fibres, their botanical sources, the methods of examining them under the microscope, and their treatment by the Ekman process. The treatise is illustrated by six coloured plates, containing figures and sections of various fibres drawn by M. Vétillart, the French authority on the subject, who has assisted Mr. Christy with his experience, and it contains a large quantity of valuable practical information, although not as a rule put before the reader in the most elegant style. Whilst the work was being prepared, Mr. Christy became acquainted with Ekman's process for the separation of vegetable fibres, which seems likely to exercise an important influence upon the future at least of paper-making. It consists in boiling the substance containing the fibre under pressure in water containing sufficient magnesium or other soluble alkaline sulphite to prevent oxidation of the organic matter. The treatment completely dissolves the incrusted substances and the cellulose is said to be thus separated in a practically pure condition, retaining its fibrous form and uninjured in strength, whilst the dissolved incrusting substances form a by-product that should possess some value. The success of the process in the preparation of wood pulp for paper-making renders it useless, in Mr. Christy's opinion, to search for vegetable fibres to compete with it for that purpose. The reader has, however, an opportunity of forming an independent judgment, as the different sheets of the number are printed on varieties of paper made entirely from wood prepared by this process.

The latter portion of the number is devoted to notes on new plants and drugs and their uses.

Leeches.

Sir,—I am pleased to find that Mr. Hart and "Observer" coincide somewhat with my views, and I wish to relate my experience of leech keeping during my first year of apprenticeship, which is now eighteen years ago.

We had tried several methods of keeping them in a bell-shaped aquarium, various plants having been supplied by leech importers; we had to change the water every other day, sometimes oftener; the water would get quite a green tinge and very foul, the shingle at the bottom would have to be well washed to free it from smell. The loss of leeches was very great.

At my suggestion, we adopted a plan which succeeded fairly well, necessitating the water to be changed once only in two or three months. It consisted of a piece of perforated zinc, in the form of a half circle with a rim of the same, to the depth of 1 inch, which was filled with earth, and small ferns placed in the same with moss packed between to hide the earth and zinc. In the bottom of the aquarium was a layer of shingle and on this three stones about 5 or 6 inches in length, placed in such a position to support the zinc and its contents. Water was then poured in to just reach the zinc by a ¼ of an inch. In a few days the rootlets of the ferns found their way through the perforated zinc, and touched the water; I imagined that this kept the water good for the time mentioned. At this time I had little or no knowledge of leech breeding, and on going to the aquarium one day and on examining some of the ferns I was surprised to see something like a piece of wet sponge. I took it out and cut it open and found that it contained either four or six young leeches (I cannot quite recollect the exact number). We discovered several after this. I would also state that I have frequently noticed little insects darting about in the water, and at such times have found the leeches very healthy.

Devonport. J. A. Lamble.

Junior.—Certainly you did wrong. Liq. hydrarg. perchlor. is not a simple solution of hydrarg. perchlor.

Nectandra.—Use the ordinary tests for distinguishing between potash and ammonia.

A. B.—We cannot undertake to recommend particular houses of business.

F. J.—You are recommended to consult some technical work on the subject.

W. H. B.—Wild cherry bark, bruised, 2 ounces; proof spirit, 20 ounces: digest for fourteen days, express, and filter. Or the tincture may be prepared by percolation. See also a paper on *Prunus Virginianæ*, by Professor Bentley, in *Pharm. Journ.*, [2], v. 105.

Chemicus.—(1) The tincture prepared according to the formula given by Dr. Fleming in his treatise on *Aconitum Napellus* is nearly six times stronger than the official tincture. (2) "Dialysed iron" is ferric oxide in a soluble form.

Communications, Letters, etc., have been received from Messrs. A. H. Mason, J. G. Fowler, P. MacEwan, P. Davidson, W. Robertson, The Leeds Chemists' Association and the Chemists and Druggists' Trade Association.

INTRODUCTORY SESSIONAL ADDRESS

DELIVERED AT THE COMMENCEMENT OF THE FORTY-FIRST SESSION OF THE SCHOOL OF PHARMACY, *October* 4, 1882.

BY JOSEPH INCE, F.L.S., F.C.S., ETC.

Fifteen years ago the Annual Sessional Address to the students of the School of Pharmacy was inaugurated. The Council by whom the arrangement was made, and by whose immediate sanction it was carried out, met under the happiest circumstances.

It was not too late in the history of pharmacy to see gathered round the table as our representatives, men whose names have become household words, and whose memories will be for ever held in honour; nor was it too soon to recognize at the board, men of of a younger generation whose presence there was the best proof of the success of our educational system. Mr. George Webb Sandford was the President; and in view of actual and impending legislation he was chosen yet another year as Dictator; Mr. Daniel Bell Hanbury had just retired not without bequeathing to the Society a distinguished son, whose manner of work and conduct raised the dignity of our calling; there was Mr. Henry Deane of Clapham who taught by precept, and by example, that the one thing to be ashamed of doing, was a dishonourable action; the watchful intelligence of Mr. John Mackay removed all fear that the interests of Scotland might possibly be neglected; and specially is a speaker standing within these walls, bound to mention the name of Mr. Thomas Morson, to whose personal devotion so much of the prosperity of our Society is due.

Many of these foremost promoters of the cause of British Pharmacy have passed away, but of those who were on the Council during the historical year of the Act of 1868, two still remain; Mr. Peter Squire who last year renewed his youth, and held his own, at the deliberations of the London International Congress; and Mr. Thomas Hyde Hills who has contracted a habit of liberality from which he seems by no means anxious to be set free.

As regards the select band of councillors who were less advanced in years, they are now of age, and consequently can speak for themselves: if they had not as much experience, they had more of the spirit of the initiative than their seniors, and to them in the first place must be attributed the proposal which issued in the establishment of these pleasant anniversary rejoicings, the latest of which takes place to-night. The then President of the Council gracefully waived his indisputable right to address the students of that school of which he was the official head; and our elders did not feel themselves compromised by acceding to a project which though dictated by a generous impulse, was an innovation.

The time had long since passed when Pharmaceutical Education was in its infancy: the assistant who knew something of the contents of a book was no longer an object of suspicion to his master, or a source of anxiety to his friends: the teaching of the school was beginning to be a felt influence, and the idea was spreading amongst the most practical of business men that the best way to ensure the welfare of their children was to let them have a sound knowledge of those principles on which much of their trade, and the whole of its developments depended.

A fair number of students had exchanged the laboratory and the class-room for the activities of daily life; and, carrying with them the prestige of rewarded scholarship into new circles, became the centres of fresh educational endeavour.

It was thought therefore, and the assumption was not unreasonable, that a period had been reached when a more formal recognition of the re-opening of a session would be acceptable, and that no time could be more appropriate, than when legislation was about to change the framework of British Pharmacy. He would however be an incorrect chronicler of events who gave this as the sole motive for the creation of a sessional address.

Frequent representations had been made that London not only had the lion's share of executive administration, but the chief talk at the evening meetings, and generally floated at the surface of affairs. The country was left comparatively in the shade, and its interests were said to suffer in consequence.

Certain councillors held the opinion that geographical hindrances were not solely to blame for this inequality, and that if good men and true were invited from the provinces to address a London audience on some state occasion, it would be an excellent arrangement. At least one signal opportunity would be afforded for the country to be honourably represented.

So originated this ceremonial, and never shall I forget the eventful evening of October 7th, 1868. Would the thing prove a failure? It was to be a gala night: successful candidates were to receive their prizes: fathers and mothers were to rejoice over their sons' success: ladies were no longer to be excluded ftom the circle, but by sharing were to increase immeasurably the students' happiness. But would the fair sex fail to come and thus precipitate a collapse? or, would the lecture fall upon irresponsive ears? Everything went off brightly as sunshine, and the lecturer was quite himself—no higher praise can be imagined.

With occasional exceptions from that time forth, the address has fulfilled its double purpose. Mr. Brady led the way, and was followed by Mr. Deane of Clapham. To him succeeded a master of polite literature, Mr. Schacht, and next the regretted Mr. John Mackay. Then rose the western circuit to the occasion, bent on showing that its romantic neighbourhood was not to be confused with Nazareth:

many good things, particularly pharmacists, reached us from there, and the students listened with pleasure to Mr. Stoddart of Bristol; Mr. Giles of Clifton, and Mr. Ekin of Bath.

This would have been too much, had not a London man, Mr. George Webb Sandford, intervened in 1873 and equalized the pressure.

He was chosen because it was the unanimous opinion of his fellows that he could never be out of place.

Later on the list came Mr. Barnard Proctor, with his quaint originality and characteristic thought.

Mr. Southall passed in review the discoveries of modern science; while the reputation of Norwich was sustained by Mr. Corder.

The lot now fell, as it was fitting, upon two former distinguished students, Dr. Tilden and Dr. Langdon Down, and the discourse of Dr. Symes of Liverpool is still within your recollection.

I feel it no small honour to have been asked to follow men like these; and I thank those who hold the direction of our affairs, that I am permitted to say words of encouragement and advice to some who have gained distinction in this, the parent School of Pharmacy; and to such others as may desire to emulate their example.

In the name of the President and Council before whom I stand; in that of the Professors who will guide your studies, and in my own, we bid you hearty welcome.

You have come to London, that true metro-polis, the central city round which so many smaller towns have gathered, and by which they have been absorbed.
