A. E. Welch.—It is not legal for any unregistered person to sell by retail poisons included in the schedule to the Pharmacy Act.

"*Health.*"—(1) We are unable to identify the recipe referred to. (2) Rubini's preparation is said to be a solution of camphor in its own weight of 60 o.p. spirit.

A.P.S.—There is no recognized preparation, though a liquid extract and a tincture have been used, and sometimes the drug has been administered in powder. See *Pharm. Journ.*, vol. x. (1880), pp. 521, 541.

Omega.—(1) The coloration of the solution of acetate of morphia referred to is the result of some decomposition, though this has been stated not to affect the medicinal properties of the salt until the colour becomes intensely yellow. (2) The preparation should certainly not be substituted for the B.P. tincture. (3) Submit the questions to the Inland Revenue authorities. (4) A wine licence is necessary—see *Pharm. Journ.*, June 24, 1882, p. 1060. (5) The subject is not dealt with in the Draft Pharmacy Acts Amendment Bill. As to this and the following question see the Bill printed before, p. 644.

Communications, Letters, etc., have been received from Messrs. Symes, Buchanan, Winter, Paris, Cock, J. W., Associate.

THE PREPARATION AND COMPOSITION OF UNGUENTUM HYDRARGYRI NITRATIS.*

BY THOMAS MABEN,

Pharmaceutical Chemist.

In the course of an investigation in connection with olive oil and its adulterations, several reactions which I have noted seem to throw some light on the causes of the variability in the properties of citrine ointment, as prepared by the official process. These reactions occur in subjecting the oil to the action of a solution of mercuric nitrate in excess of nitric acid, in the presence of heat, and without anticipating what I may, at some future time, submit to you regarding the subject for which the experiments were initiated, I may cite the following results as furnishing some explanation of the causes of the variability referred to.

Effect of Acid Solution of Mercuric Nitrate on Olive Oil at Different Temperatures.

1. When pure olive oil is heated with the mercury solution to 180° F., moderate chemical action takes place, the mixture frothing up to a small extent only, and solidifying on cooling.
2. When the mixture is heated to 212° F. the chemical action is much more decided, the result in general appearance being similar to that in the former case, but with this difference, that a small quantity of a yellow semi-crystalline substance is precipitated.
3. The mixture heated to 300° F. gives very energetic action, the solidified cooled mass presenting much the same appearance as before, but with an increase in the quantity of yellow precipitate.
4. When olive oil adulterated with any of the common seed oils is heated with the reagent, the mixture at 180° F. assumes a reddish colour, due to the action of the nitric acid on the foreign oil; at 212° F., a slate-coloured precipitate, which seems to vary in quantity according to the extent of the adulteration, is thrown down, together with a quantity of the yellow precipitate already mentioned; at 300° F., the quantity of slate-coloured precipitate is increased, but no further change is noticeable.
5. The yellow precipitate is insoluble in ether and alcohol, but is slightly soluble in water, and gives mercurous reactions; it is evidently mercurous nitrate. The slate-coloured precipitate is unaffected by these solvents, but is dissolved by nitric acid, and is apparently mercurous oxide thrown down by the reduction of the mercurial salts in the presence of the foreign oils.
6. A portion of No. 1 treated with ether is found to be entirely soluble; portions of Nos. 2, 3 and 4, similarly treated, are found to be partially soluble only, the precipitates being insoluble.

In view of these reactions, there would be no difficulty in our assuming that substantially the same results would follow in the case of citrine ointment, but for the introduction of the new ingredient, lard. Actual experiment has shown, however, that the analogy is all but complete, as we shall find if we compare the *data* already given with the results obtained when the ointment is prepared at different temperatures, results which explain several phenomena that have not, so far as I am aware, been elucidated, while they tend to reconcile the conflicting statements which have been made regarding this preparation.

Effect of Different Temperatures in the Preparation of Ungt. Hydr. Nitrat.

A. When citrine ointment is prepared at 180° F. we have a beautiful, somewhat transparent, lemon-coloured ointment, of a soft consistence, and soluble in ether.

B. Prepared at 212° F., the ointment is rather less transparent, not quite so soft, and only partially soluble in ether, a small quantity of yellow precipitate being insoluble.

C. Prepared at 300° F., the colour is the same, but the ointment has a denser appearance, and is much harder. The yellow precipitate is, as in the last instance, insoluble in ether.

D. When the olive oil has been adulterated even to the extent of only 5 per cent., the appearance of the ointment is quite changed. Instead of a lemon colour, it has now acquired a distinct greenish hue, while with a larger percentage of foreign oil, this is still further intensified. The red colour visible in the case of the adulterated olive oil is not now so apparent, it being disguised on the one hand by the lard, and on the other by the mercurous oxide.

Coming now to the consideration of these facts, there are three points to which I desire to direct your attention, viz., the composition of the ointment, its colour and consistency, and its liability to deteriorate, regarding all of which there is no little difference of opinion.

I. *Composition.*—Pereira states that "by the action of the fatty bodies on nitrate of mercury, the latter is transformed into a yellow subnitrate of the protoxide of mercury, a small portion of elaïdate of mercury being also formed."*

Christison says the ointment "is believed to be a mixture of oleic and stearic acids, elaïdic acid and nitrate of binoxide of mercury."† Mr. Schacht, in an account of several experiments, says:—"A portion of best ointment treated with a large quantity of ether dissolved entirely. Samples possessing inferior external properties deposited a yellow powder perfectly insoluble in ether, which proved to be nitrate of mercury;"‡ his conclusion, therefore, evidently being that *good* citrine ointment contains *no* nitrate of mercury. Mr. Martindale, adopting, with most other authorities, Pereira's view, states that the ointment "contains a complex mixture of basic nitrate of mercury, elaïdin, fatty acids in combination with mercury, etc."§ These are only a few of the different opinions that might be cited, and the question seems to turn on this point, viz., Does the mercury in citrine ointment really exist in any quantity as nitrate, as the B.P. name implies, or is it entirely combined with the fatty acids? From the results that I have submitted to you it will be apparent that both views may be regarded as being correct. The B.P. directs no definite temperature to be observed, and till it does so pharmacists are left to their own judgment. If one ointment

§ *Pharm. Journ.*, [3], vol. xi., p. 912.

is prepared at 180° F., and another at 212° F., both may be citrine ointment, and excellent preparations, but both cannot strictly be said to be *unguentum hydrargyri nitratis.*

The theory which commends itself to my mind, as accounting for this double result, is that a reaction takes place somewhat after the following manner: The effect of the nitric acid is to resolve the fats into their proximate constituents, viz., glycerine, stearic acid and oleic acid, the latter, according to most authorities, being transformed into elaïdic acid. In the presence of these acids mercuric nitrate is, at a low temperature, split up, the mercury uniting with the elaïdic acid to form elaïdate of mercury. On the temperature being raised this salt is partly decomposed, but the excess of nitric acid being at the same time driven off, there remains only sufficient to combine with the liberated mercury to form mercurous nitrate, which is, as we have already seen, precipitated. Oleate of mercury is practically insoluble in ether, and it is highly probable that the palmitate and stearate will be of a similar nature in this respect, and this has led me to the conclusion that the mercury exists as elaïdate, until that salt is decomposed or partially decomposed by the higher temperature.

Perhaps it is too much to expect that this theory will meet all the difficulties of the case, but I submit it to you, as a probable explanation of the reaction that takes place.

If the ointment is prepared at a low temperature the excess of nitric acid will not be driven off. Most of you, if not all, will have observed an acid liquid at the bottom of the shop jar, or even sweating out of the ointment itself. This is certain to be present if the temperature does not exceed 180° F., and even at 212° F. the excess of acid is occasionally not all driven off. Mr. Donovan* complains of this excess in the B.P. preparation from a therapeutical point of view, and we can easily understand that needless irritation will be caused to a tender surface by its presence.

It is thus possible to have two distinct citrine ointments, the one containing fatty acids, elaïdate of mercury and mercurous nitrate, the other composed of fatty acids, elaïdate of mercury and excess of nitric acid. If we wish to follow Mr. Schacht's idea of a good ointment, we are certain to displease Mr. Donovan by excess of acid; on the other hand, if we eliminate the acid by increasing the temperature we at the same time cause the formation of mercurous nitrate. Further, if it is admitted that the B.P. means the ointment to contain nitrate of mercury in some form it is clear that it ought so to be prepared that it will really be what it professes to be. For these reasons, therefore, it is perfectly evident that the B.P. ought to state the temperature definitely, as until this is done the composition of the ointment is liable to vary, it being quite as likely to be *ungt. hydr. elaïdatis* as *ungt. hydr. nitratis.*

II. *Colour and Consistency.*—I have already anticipated, to a certain extent, the remarks that naturally fall under this head, and would simply repeat that at whatever temperature the ointment is prepared, the lemon colour is the same, provided pure oil is used. The only visible difference is that the lower the temperature the more transparent does the ointment appear to be. If the oil is impure, the colour is darker and of a greenish hue, owing to the action that has been already explained. Ointment prepared at a high temperature, say 300° F., is considerably harder than that prepared at 212° F., or 180° F., though there is little difference between the two latter.

III. *Deterioration.*—If citrine ointment becomes discoloured early, say within a few months, the presumption is that the oil was not pure, always granting, of course, that due precautions had been taken in its manufacture and preservation. This is more especially likely to be the case when the discoloration is homogeneous or regular and the ointment preserves its consistency. We have seen that the mercury is reduced by the action of the foreign oil. This reduction takes places rapidly at a high temperature, but we may justly infer that the same action goes on more slowly at normal temperatures. As an illustration of this, here are two specimens adulterated with equal quantities of the same oil,—10 per cent. rape. The one has been prepared at 180° F., and the other at 212° F., and while the former is of a bright yellow, the latter has the characteristic green hue. An ointment may therefore be satisfactory as regards appearance when it is newly prepared; but this is no guarantee that it will not deteriorate, as I venture to assert this yellow specimen will do ere long. This contingency (of impurity) has been very much overlooked in connection with the ointment, and it is quite possible that to it, rather than to unskilful methods of preparation, is referable in many cases its liability to deteriorate. Mr. Schacht's theory was that the reduction of the mercury was due to the evaporation, in course of time, of the nitric acid; and he proved it so far, by adding acid to a discoloured sample and restoring the ointment to its original appearance. This is correct enough, as far as it goes, because, by adding more acid you merely redissolve the mercurous oxide, and practically re-prepare the ointment; but it does not afford sufficient grounds for the general inference drawn from it. The difficulty lies in the fact that when those adulterated ointments are heated to 212° F., discoloration takes place, while this pure ointment retains its colour though heated to over 300° F. If, in the former case, all the acid has evaporated, much more must this be true in the latter, yet no discoloration is visible; on the contrary, it is, so far as appearance goes, the best specimen on the table.

In concluding this paper, let me say that there should be no difficulty in turning out an elegant and durable preparation by the B.P. process, and I am strongly of opinion that an ointment carefully made with pure oil and good lard, according to the directions there given (interpreting "hot" as at least the boiling point of water), will keep for a very long period indeed, without deteriorating in the slightest. With the exception of this indefiniteness as to temperature, the B.P. formula, which is practically that devised by the late Mr. Duncan, is as near perfection as it possibly can be.

In view of a new edition I would suggest that it be made complete in this respect, and that the temperature fixed ought not to be less than 212° F.—it might with advantage be even more—so that there may be uniformity, not only in the appearance of the ointment, but, what is of more importance, in its composition.

NAPHTHALIN AS A WOUND-DRESSING.*

BY G. R. FOWLER, M.D.

The most recent, as well as the most promising, addition to our means of combating sepsis in all its varied forms in wound treatment is that which has been brought forward by Lücke, of Strasburg. The agent proposed by Lücke is naphthalin, a product of the distillation of coal-tar, and it is to the claims of this article as an antiseptic in the treatment of wounds that attention is now invited.

Naphthalin, in a pure state, is a white substance, occurring in laminated crystals; its formula is given in works upon chemistry as $C_{10}H_8$. It forms wherever organic bodies, especially those containing an abundance of water, are burned. Coal-tar contains it in large quantities, and it is obtained by subjecting this substance to distillation. It passes over after the coal-oils, and it is produced by passing the vapour of coal-tar through red-hot tubes. It is derived from the residue of gas manufactories, and not unfrequently clogs up our gas pipes. In its crude state it is a brownish-yellow, sand-like substance, containing an indefinite quantity of the phenols. It may be purified by sublimation with charcoal, and, as before stated, when in a pure state is a white crystalline body. It has an odour decidedly like that of coal-tar, and a slightly aromatic taste; its specific gravity is 1·05; it is volatile at any temperature, but melts at about 176° F., and crystallizes upon cooling; it boils at 420° F. It is inflammable, and burns with a lurid, smoky flame. It is but sparingly soluble in water and in the secretions of wounds, but its gaseous vapour is given off readily at the temperature of the body, and especially when in contact with moist surfaces; it is likewise insoluble in alkaline and acid fluids; it is readily dissolved by ether, hot alcohol, hot concentrated sulphuric acid, and the different ethereal and fatty oils. It is deposited from its alcoholic solution in white lamellar iridescent crystals. In the sulphuric acid solution a sulpho-naphthalic acid is formed. Naphthalin combines with chlorine, producing two chlorides; these latter, upon further investigation, may prove serviceable and available as germicides. When exposed to a temperature of 300° F., naphthalin sublimes quite rapidly in thin scales, and the atmosphere of a room can be thoroughly saturated with it in a gaseous state by simply adding some of the crystals to water and heating it. If the latter be continued for some time, naphthalin will be precipitated upon the walls of the apartment. If crystals of naphthalin are simply strewn upon the floor, the same result will take place, only more slowly. Nearly all of the samples obtainable contain more or less of the phenols as an impurity. The following test for pure naphthalin has been suggested by Dr. Schulte, of Strasburg: Dissolve a small quantity of naphthalin in a weak solution of chloride of sodium; heat to a boiling point—cool, and filter. If the filtrate is made slightly acid and a watery solution of bromine is added, phenol being present in small quantities, a milky condition of the fluid appears; if present in larger quantities, a more dense white precipitate, the bromide of phenol, is formed.

Naphthalin produces no poisonous effects upon man and the higher animals when given internally or applied to large absorbing surfaces, but it is most efficiently destructive of low vegetable and animal organisms, such as fungi, spores, small insects, etc. The preservation of meats, after exposure to smoke, is partially due to the influence of this body. It, therefore, belongs to the class of germicides, and bids fair to prove of value as an aseptic and antiseptic in the treatment of wounds.

In my own experience with naphthalin I have noticed that when it is used in an aseptic manner, that is to say, when it is brought in contact with fresh wounds that have never been in a septic condition, they continue in an asceptic, and consequently in a healthy state; and that septic and unhealthy wounds, indolent ulcers, ulcerating cancers, growths, phagedenic chancres, etc., rapidly assume a healthy appearance when its antiseptic action is brought to bear upon them. This is due, without doubt, in the first place to an efficient protection of the wound from septic influences, and in the latter instances to a complete and thorough disinfection of the wound. Its application does not interfere with free drainage from wound surfaces; in a powdered state it may be applied directly to the cavity, or over the parts, after suturing the edges. Serum and blood will percolate through it precisely as they would through sand. As an additional advantage, it does not unite with wound secretions to form crusts or scabs.

I have found, as a simple and convenient method of employing naphthalin, that of using it in substance, finely powdered. After thoroughly disinfecting the wound—if it is not already aseptic—and surrounding parts with a solution of carbolic acid or chloride of zinc, suturing and making proper provision for drainage, I cover the parts to be dressed with a narrow strip of oil-silk previously dipped in a one to forty solution of carbolic acid, and having a perforation here and there to facilitate the egress of whatever secretions may accumulate beneath it, as well as to permit the vapour of the naphthalin to penetrate to the wound itself. This also serves the purpose of preventing the dressings from adhering upon removal. I then make a roll of absorbent cotton about ½ an inch in diameter, and in length sufficient to enclose the wound and an inch or more of the contiguous parts ; this is wrung out of the solution of carbolic acid or chloride of zinc, and disposed as a ring encircling the wound and adjacent surface. Within the space tuhs isolated, I sprinkle the naphthalin in a powdered state to the depth of a quarter of an inch or more, place a dressing of absorbent cotton over it, and apply a muslin roller over all. This dressing is not disturbed until the wound secretions make their appearance through and soil the bandages, or some other indications exist for their removal. In a recent case of Hueter's operation for resection of the head of the first metatarsel bone for hallux valgus, the dressings were first removed at the end of eight days. The parts were in a typically aseptic condition, and only the odour of naphthalin gas pervaded the dressings. In the case of cavities left after operations for the removal of suppurating buboes, necrosed bone, etc., simply packing the cavity in all of its recesses, after thorough disinfection, and applying a dressing of absorbent cotton is found to be sufficient. After operations within the vagina and other natural cavities having outlets, absorbent cotton, in the meshes of which naphthalin has been incorporated, either by saturating it with its ethereal solution and subsequently drying, or simply by rubbing in the powder, may be used. Dressing materials, gauze, etc., may be especially prepared in the same manner as like dressings are prepared containing carbolic acid and iodoform. The method above described possesses the merit of simplicity, however; as to its efficiency, I can bear testimony with great positiveness.

As to the possibility of any dangerous symptoms arising from its free use, I can only say that Lücke and Fischer, of Strasburg, have used it largely, and no disturbances of any kind whatsoever have followed its use. In my clinic at the Bushwick and East Brooklyn Dispensary I have now employed it in a large number of cases, in both young and old, feeble and strong ; filling large cavities and applying it unsparingly, I have always met with the best results following its use, and never with a single untoward sequence. I have found it convenient of employment ; its odour is not more objectionable than that of carbolic acid, and certainly not as disagreeable to the average nostril, nor as difficult to get rid of as that of iodoform.

* From a report read before the Kings Co. Medical Society. From the 'Proceedings.'

DEODORIZED TINCTURE OF OPIUM.*

BY R. ROTHER.

The most important active ingredients contained within a plant are frequently, if not generally, chemically allied, and are either derivatives of one another or of some common source. The odorous constituents, although generally characterized by extreme potency, become most usually dissipated by reason of their volatility, or if not evaporated, are changed by oxidation into less fugitive, less odorous, and also less active resinous bodies. Therefore, many plants when used in the fresh condition have different degrees of activity and quality than when consumed in a dried or in a prepared state. Modern pharmacy has isolated many of these special agents, and in some instances modified or attempted to modify the raw material in such a manner as to cancel or wholly abolish certain objectionable features.

It was found that opium contained a perturbing body, at one time supposed to be alkaloidal, but now presumed to be of a resinous nature. In order to avoid this substance in certain of its preparations, opium or its aqueous extraction was treated with ether, having in view the removal of this noxious impediment. Such a preparation is the so-called deodorized tincture of opium. The fact has been, however, ascertained that aqueous treatment alone, by excluding the resinous matter, yields a deodorized and otherwise analogous product, showing that the washing of the watery extract with ether is superfluous and wasteful. In order to prevent the possible solution of the resinous matter during the extraction of the opium and incidentally avoid the unnecessary ethereal treatment, but especially circumvent the decidedly objectionable and untimely application of heat needed in the extensive evaporation, the writer changed the operation accordingly. Most volatile oils, resins and semi-resins are soluble in fixed oily menstrua, aside from their various special solvents. Hence, the writer concluded that should there be a tendency in any of the opium resins or odorous principles to pass into aqueous solution, the presence of a fixed oily substance would be likely to prevent it. Vaselin was added to the heated mixture of opium and water, but since the vaselin did not promptly solidify in the cooling mixture, spermaceti was further incorporated with desirable effect. So thorough was the extraction of the activity and exclusion of the malodorous matter, and so admirably were the dregs gathered up by the solidifying fat, that the solution permitted of ready removal by simple decantation. The mixed decantates filtered clear and rapidly, and as no evaporation was necessary the tincture could be completed at once by the admixture of the requisite measure of alcohol. This magnificent result, in connection with the speed and facility of the operation and comparative cheapness of the product, encourages the suggestion to abandon the ordinary tincture of opium altogether. Should it be advisable to retain the narcotine remaining in the dregs, a small proportion of dilute sulphuric acid might be used to secure it in the tincture as soluble narcotium sulphate. From these results the following formula for a deodorized tincture of opium is deduced:

Take of

Opium dried and powdered	$2\frac{1}{2}$ troy ounces.
Vaselin, Spermaceti, of each	1 troy ounce.
Alcohol	7 fluid ounces.
Water sufficient.	

Upon the opium contained in a suitable capsule pour 12 to 14 fluid ounces of water and boil the mixture ten to fifteen minutes; then add the spermaceti and vaselin, stir them well together, let the mixture cool, and decant the liquid from the dregs. Upon the residue pour 8 fluid ounces of water, again heat the mixture, stir it well, and, after cooling, decant as before. Repeat this operation once more with 8 fluid ounces of water or sufficient to make the mixed decantates measure 25 fluid ounces. Mix the three decantates, let the mixture become cold, filter, and finally add the alcohol.

* From the *American Journal of Pharmacy*, February, 1883.

SCHIZOMYCETIC FERMENTATION.*

BY G. MARPMANN.

In this paper the author has collected all the facts known concerning the various kinds of fermentation. Specific bacteria fermentation is that in which, by reason of the growth of bacteria, reduction products are formed, whilst oxidation processes by means of the same agents, such as nitrification, are not fermentation. Nencki explains the reducing action of bacteria by their power of decomposing water, one hydrogen-atom of which reduces, whilst the hydroxyl-group is assimilated by the bacteria.

Glycerol.—Fitz describes three glycerol fermentations: (*a*) in the ethyl alcohol fermentation produced by a slender bacillus, probably identical with *B. subtilis*, in which neither butyric nor succinic acid, nor butyl alcohol is formed; neither can this bacillus decompose calcium lactate; (*b*) butyl alcohol alone is produced by a bacillus 0·005–6 mm. long by 0·002 mm. broad; (*c*) succinic acid is never formed by bacilli from glycerol, but Fitz found in blue pus a small micrococcus, which did act in this way. Schulze has found other bacteria, which besides forming ethyl and butyl alcohols, butyric and caproic acids, also produce a phorone of the composition $C_9H_{14}O$.

Tartaric Acid.—According to Gautier, Mediterranean wines under certain conditions rapidly become thick when exposed to the air; the red colour changes to a blue-violet, and a brown deposit is formed, as also acetic and lactic acids; the cause of this is a bacillus of varying length, but 0·0012 mm. broad. König found succinic acid amongst the products of the fermentation of tartaric acid: hydrogen ammonium tartrate yields butyric acid and ethyl butyrate, under the influence of *Ascococcus Billrothii*.

Sugar.—The mass resembling frog spawn, into which beet-sugar juice is frequently converted, is due, according to Cienkowski and v. Tieghem, to *Ascococcus mesenteroïdes* (0·0018–0·002 mm. thick), whereby sugar is converted into cellulose. The lactic ferment of sugar consists of a thin scum, built up of cells 0·001–3 mm. broad, and nearly double as long. These cells are active only as long as oxygen is present: consequently the conversion is indirect. This ferment, described by Boutroux, does not produce succinic acid, but the acid is formed from grape-sugar by *Bacillus amylobacter*, fully described by v. Tieghem. *B. amylobacter* exists in the cells of all milky-juiced plants; a butyric fermentation of albumin is caused by *B. subtilis*.

Nitrogenous Matter.—Normal urine is decomposed by *Micrococcus ureæ* (0·00125–0·002 mm. broad) with formation of ammonium carbonate; pathological urine is affected by other bacteria. The most important fermentation of albuminous matter is occasioned by *Bacterium Termo* (0·0015–0·002 mm. long), and it is this bacterium which induces the decay of all organic matter, and to which, as preserving the balance between animal and vegetable matter, our thanks are due. All the other schizomycetes are in some way or another harmful to us.

Ptomaines are produced by bacteria as yet undescribed, and the same bacteria also produce phenol, which is remarkable, as phenol is detrimental to their existence; also in decaying matter phenylpropionic and phenylactic acids, indol, cresol and scatol, etc., have been found. Reference is made to various fermentations, and to *Dispora caucasica*, which forms "kephir."

THE PHARMACY ACTS AMENDMENT BILL.

In addition to the various expressions of general approval of the draft Pharmacy Bill that have already been agreed to by local associations, it will be seen from the reports published in this week's Journal that the Manchester Chemists and Druggists' Association and Chemists' Assistants' Association have signified their concurrence with the decision already arrived at in other local centres, with some few suggestions as to particular details. The meeting of the Manchester Association on the occasion referred to does not, indeed, appear to have been very numerously attended, if we may judge from the remark of the chairman, Mr. W. WILKINSON, that he had hoped to have seen a larger attendance in response to the invitation which had been issued to every chemist whose name appears in the Manchester Directory, and to the assistants and apprentices engaged in the trade. This circumstance might be construed as indicating an absence of any desire to object to the suggested provisions of the Bill, and as justifying the inference that they are regarded favourably; but even in that case it would have been desirable that an expression of opinion at so influential a centre as Manchester should have been supported by a greater number of those directly interested in the proposed legislation. There is, however, some reason to fear that a spirit of indifference was the real cause of the small attendance at the meeting, and that on this occasion as well as a former meeting, the men whose business it is to have regard for the interests of pharmacy were "not equal to the occasion," as Mr. WOOLLEY remarked at a late meeting of Council when speaking of the meagre response to the call for a meeting in Manchester, to consider the Pharmacy Bill. We can but express our regret that such should be the case at a time when united and consistent efforts on the part of members of the trade are so much needed.

Passing on to the actual proceedings of the Manchester meeting, the first point referred to is the proposed schedule of "poisonous articles," and though this part of the Bill was not definitely objected to, regret was expressed that it had been thought necessary "to introduce the principle of allowing unregistered persons to sell 'poisonous' articles." These words, quoted from the report of the meeting, put a construction upon the provisions of the second clause of the Bill which is somewhat erroneous and decidedly inconsistent with the fact that unregistered persons being now entitled, as they always have been, to sell the articles in question, no permission is needed for their continuing to do so. It would, indeed, be difficult, from a pharmaceutical point of view, to find any reason for attempting to interfere with established usage in that respect, and as a matter of political economy we should certainly not expect any such reason to be discovered at Manchester.

The real purport of the second clause of the Bill is not to grant permission to sell certain articles, but to regulate the sale of them out of regard for public safety, that being the only consideration upon which such a step can be submitted to the notice of the Legislature. The regret expressed at the Manchester meeting is therefore based upon a misconception of the true nature of the clause in question, no less than upon the erroneous assumption that the particular articles to which the clause would apply are part of the materia medica which appertain exclusively to the practice of the arts of pharmacy and medicine. The unfortunately mixed nature of the business carried on by chemists and druggists is no doubt, to some extent, an explanation of the erroneous opinion conveyed by the above expression of regret at the meeting in Manchester, but it is to be hoped that on reflection it will become evident that it is not by regretting or objecting to a provision for the public good that the trade interests of pharmacy are to be promoted.

Among the other suggestions put forward at the Manchester meeting, three relate to matters of detail, which could well be dealt with satisfactorily in Committee, if the Bill should ever arrive at that stage of maturity, and we therefore refrain from any comment on them. The last suggestion as to the title of Fellow of the Pharmaceutical Society being granted to pharmaceutical chemists who have passed or may pass the Major examination prior to January, 1886, and to those who may after that time pass a higher examination than that provided for in clause 16 of the Bill, is in accord with an opinion that appears to have prevailed at the meeting of the Chemists' Assistants' Association, and is one that merits careful consideration; for while we would deprecate any step tending to increase the present confusion of titles and signs of qualification, and would gladly see the title of "pharmaceutical chemist" made the qualifying title, it must be admitted that there is reason for giving all possible recognition to the voluntary action by which that title has hitherto been acquired.

The papers of Messrs. FRAZER and GILES, dealing with the subject from two diametrically opposite points of view, are in themselves so copious as to render any comment upon them superfluous.

SOLAR PHYSICS.

Eight years have now elapsed since the Royal Commission on Scientific Instruction and the Advancement of Science recommended the establishment by the State of an observatory for solar physics, which led, four years afterwards, to the appointment of a "Solar Physics Committee" and to the first grant of public money being made to be spent in this direction. During this time a growing interest has been manifested in investigations as to the constitution of the sun, and especially those dealing with the phenomena of sun spots and their possible influence upon this planet, concerning which speculation has sometimes run rather wild. A Report just issued shows that the Committee on Solar Physics is now vigorously grappling with the subject, and although the work done by it up to the present time has consisted principally in organization with a view to securing future results, the programme set forth covers a wide area and deals with more subjects than can even be mentioned here. There are, however, one or two passages in the Report to which reference may be made, and especially some "conclusions" of the Committee respecting solar phenomena—based upon the evidence furnished by series of sun pictures—which are, to a great extent, confirmatory of opinions previously expressed.

It appears probable that the varying phenomena of the sun's disc represent the play of a huge system of convection currents, the darker patches, or "spots," being the manifestation of gigantic down currents of comparatively cold matter from above, whilst "faculæ" and "red flames" may denote the corresponding up rush of hot matter from beneath. These convection currents would seem to be always present on the sun's surface, though the scale of the phenomena and the rapidity of the motion are on occasions greatly increased, giving rise then to the complex appearance which is associated with the outbreak of sun-spots. It is thought that it is in virtue of this convection system that a sufficiency of intensely heated matter is brought to the surface of the sun to supply the enormous quantity of radiant energy which it gives out continuously. It would therefore seem to follow that the amount of radiation from the sun's disc would be affected by the relative vigour of this convection system. All observations tend to the demonstration that greater agitation of the sun's atmosphere is coincident with epochs of maximum sun-spot frequency, and the results of some spectroscopic investigations by Mr. Norman Lockyer allow of the conclusion that at such times certain definite levels of the solar atmosphere are heated to a peculiarly high temperature. Further spectroscopic observations are required to clear up this point, but the evidence presented by the sun itself appears on the whole to be in favour of the above inference, and shows that our luminary is really most energetic in its radiation at periods of maximum sun-spot frequency. But it does not follow that this increased radiant energy of the sun always results in an increase of the temperature of the earth; for there are indications that it is also coincident with an increase in the number of great terrestrial atmospheric disturbances, and in some localities with an excessive rainfall, which would tend to lower the temperature. It is evident, however, that should this inequality of the sun's power prove to exercise any definite influence upon the meteorology of the earth, it would become of great importance to be able by the analysis of a sufficiently extensive series of sun-spot records to arrive at a true knowledge of the law of the sun's variability, so as to allow of the state of the sun in any future year being approximately foretold. The collection and collation of such records will therefore form an important branch of the future work of the Committee.

It is well known that Mr. Norman Lockyer has put forward views concerning the nature of the solar atmosphere, based upon his spectroscopic work, which are not in accord with those held by previous observers. Briefly, the ordinary theory is that the atmosphere of the sun is formed by a series of concentric layers of different elementary bodies, passing inwards from hydrogen, through a number of other elements common to the earth, to the "reversing layer" in which are present a large number of metals, and that the spectrum, which in the outer reaches is of extreme simplicity, gradually becomes more complex, because as fresh layers are encountered the outer ones do not die out, but are continued down to the photosphere. Mr. Lockyer, on the other hand, supposes that at the temperature of the sun the chemical elements with which we are acquainted are broken up into finer groups of matter, and that the terrestrial elements, if they exist at all in the sun, only exist in the outer, and therefore colder parts of the sun's atmosphere, from whence the vertical currents of the sun bring down the formed material to be dissociated in the lower reaches, after which, by virtue of its consequent reduced density, it reascends to again become formed material at the appropriate heat level. If the atmosphere were quite tranquil, and the spectrum of a section of it could be examined, Mr. Lockyer believes it would be seen to be divided into an almost innumerable number of layers, each with its appropriate spectrum, not extending very far above or below its normal position, as held in the previous theory, but confined to one heat level, whilst the spectrum would appear simpler as the photosphere was approached from without. The metallic elements, instead of existing as such in a so-called "reversing layer", resting on the photosphere, undergo, as previously stated, entire dissociation there; whilst their germs, becoming distributed throughout the atmosphere, cause the molecular grouping to grow more complex as the distance from the region of greatest heat increases. The appearance, under these conditions, in the spectrum of the sun, of FRAUNHOFER lines which are recognized as being characteristic of any particular terestrial element, Mr. LOCKYER explains by supposing that such a spectrum does not result from the vibration of the molecules of the particular element existing as such at any given height in the sun's atmosphere, but results from an integration of the vibration of the "germs" of that element existing, perhaps distributed, from the top of the atmosphere to the bottom. Professor STEWART suggests that if solar phenomena are correctly represented by this hypothesis, the alternate association at high, and dissociation at low levels of solar elementary matter would be expected greatly to increase the intensity of the solar convection currents, and thus the enormously strong currents which observation reveals might find a ready explanation.

With respect to the influence of the state of the sun upon the magnetism of the earth, there can be no doubt that the diurnal range of the earth's magnetism is greatest when there are most sun spots, and that there are at such times an unusually large number of magnetic storms with their accompaniments in the form of earth currents and auroral displays. From the fact, however, that the fluctuations in diurnal ranges, as a rule, lag in point of time behind the solar influences which produce them, it is inferred that they are not produced directly by solar magnetic influences, but indirectly by solar radiation. At present we can only mention that this may find an explanation in a new theory which Professor STOKES has propounded as to the connection between solar activity and auroræ, magnetic disturbances and earth currents, according to which auroral discharges are the immediate excitants of earth currents and magnetic disturbances.

Allusion was recently made in this Journal to the ludicrous position created by the circulation of volunteered reports on the water supplied to the metropolis. The subject was on Monday evening brought before the House of Commons in a question put by Mr. Firth to the President of the Local Government Board, as to whether his attention had been called to the fact that every month reports of London analysts on the character of London water, purporting to be addressed to him, were widely circulated, although not authorized or paid for by his department, but by the water companies, and whether as such a form of report was calculated to mislead the public and to give an appearance of official authenticity not consistent with fact he would either decline to receive any more of such reports or require their form to be altered. Sir Charles Dilke, in reply, said he agreed in thinking that such reports, purporting to be addressed to the President of the Local Government Board, are misleading, and that he should expect that after this expression of opinion they would be discontinued.

In order to grapple with the difficulty experienced in establishing a uniform system of pharmaceutical education in the Australasian colonies, so that the certificates granted by the different local pharmacy boards may become interchangeable, Mr. C. R. Blackett has suggested the holding of a conference in which the pharmacists of these colonies shall be represented. There appears to be considerable probability that the suggestion will be carried out.

* * *

At the date of the latest advices new Bills for the regulation of the practice of pharmacy were before the Parliaments of Queensland and New South Wales, whilst in New Zealand the Pharmacy Board was contemplating attempting some amendment of the Act at present in force in that colony.

* * *

At the recent "commencement" services of the Philadelphia College of Pharmacy, as the result of the examination held at the end of the term 1882–83, the degree of "graduate in pharmacy" was conferred upon 153 persons, including one lady. This was said to represent the largest proportion of passes of the largest graduating class, numbering 160, in the experience of the institution, which has now sent out upwards of two thousand graduates.

* * *

Although not on quite so large a scale, the operations of the New York College of Pharmacy are by no means insignificant, the last session having furnished 63 successful candidates for the degree of "graduate."

* * *

A new edition of the well-known 'Dispensatory of the United States' (Wood and Bache) has just been issued by J. B. Lippincott and Co., of Philadelphia. The work has been revised and to a great extent rewritten, to bring it into accord with the new edition of the United States Pharmacopœia, by Dr. H. C. Wood, Professor J. P. Remington and Professor S. P. Sadtler, and it speaks well for the energy of these gentlemen that although some new rivals have been announced they have been able to bring this standard work of about two thousand pages first into the field. We hope to have an opportunity on a future occasion of noticing the work more in detail.

* * *

Her Majesty has been pleased to confer the honour of knighthood upon Professor F. A. Abel, F.R.S., Dr. Lyon Playfair, F.R.S., and Dr. C. W. Siemens, F.R.S.

* * *

On Monday evening next, Professor Osborne Reynolds, F.R.S., will deliver before the Society of Arts the first of three lectures on "The Transmission of Energy." The lectures will constitute the fourth course of Cantor Lectures for the present session.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, April 26, at 8 p.m., when a communication will be read on "The Synthesis of Uric Acid," by Mr. T. S. Dymond. Mr. Cripps will read a note on "The United States Pharmacopœia Process for the Estimation of Hydrocyanic Acid," and a "Report upon Pharmacology" will be made by Mr. H. G. Greenish.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The last meeting of this session was held in the Society's rooms, 119A, George Street, Edinburgh, on the evening of Wednesday, April 11, at 9 o'clock.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The following donations to the Library were then announced:—

Register and Report of the Pharmacy Board of Victoria, 1883.
From the SECRETARY AND REGISTRAR.

Elementa Chemiæ, Hermani Boerhaave. 2 volumes. London, 1732.
From Mr. FRED STEPHENSON, Edinburgh.

Morphology and Physiology of the Cell, recent contributions to our knowledge of. By Patrick Geddes, F.R.S.E. 2 copies. From the AUTHOR.

On the motion of the President a cordial vote of thanks was accorded to the donors.

Mr. Thomas Maben then read a paper on—

THE PREPARATION AND COMPOSITION OF UNGUENTUM HYDRARGYRI NITRATIS.

The paper is printed on p. 857 and gave rise to the following discussion:—

The President, in moving a vote thanks to the author, said that the ointment had always been a troublesome one, but from what had been said by Mr. Maben it appeared possible to prepare an ointment of unvarying composition, provided that certain precautions were taken. He hoped that the members would freely express their opinions on the subject.

Dr. Inglis Clark said that the paper was one of great practical value, the subject having been wrought out in a way which had not been previously done, at least so far as the influence effected by the impurities was concerned. Referring to the impurities, he mentioned that this matter had already been drawn attention to in this Journal, and showed how imperative it is to ensure purity of the oil. Regarding the question as to whether discoloration is due to deficiency or excess of nitric acid, he pointed out that any advantage due to excess of acid and high temperature could also be had by using less acid with a lower temperature, and suggested that in addition to designating the temperature at which the action should take place, the B.P. should also reduce the quantity of acid to about 9½ ounces. The way in which Mr. Maben had explained the formation of mercurous nitrate was exceedingly interesting; it was evident from the insolubility of mercurous salts in ether, that the nitrate was not present in the ointment prepared at a low temperature. Altogether the paper was an able contribution to the literature of the subject, while it commended itself for its thoroughly practical nature.

Mr. Stephenson said that he was struck with the three specimens of ointment prepared from pure oil at different temperatures. That prepared at 300° appeared to be the best. It should not be forgotten, he said, that the Pharmacopœia did practically recognize a temperature in ordering the liquids to be mixed while hot, and if frothing did not take place to apply heat until the mixture did so. Speaking from his own experience he could say that the frothing took place at different temperatures, but the particular frothing which accompanied a well-made article took place, he was sure, at a higher temperature than 212°; probably 300° was nearer the mark. But independent of all this care the ointment did deteriorate, not on the surface, but through the lower layers, so to speak. Regarding the use of oils other than olive oil, he said that he had experimented with fine palm oil, which gave a beautiful ointment, and with trotter and neatsfoot oil, from the former of which he got a good result. The remarks regarding the existence of elaidate of mercury in this ointment were very interesting, and he hoped that it would be determined whether the mercury should be in combination with elaidic acid or nitric acid, or with both.

Mr. Gilmour said that the paper was interesting apart from its relation to citrine ointment; it contained some valuable reference to the effect of an acid solution of mercuric nitrate on oils, and he hoped that the author would continue this portion of his work on the drying as well as the non-drying oils. He had noticed in several experiments in oil-testing that when the oil was at a lower temperature than the acid solution, there was a material difference between the result so got, and that obtained when the temperatures were equal and high. On this point he would like to hear the opinion of the author of the paper.

Dr. Clark, in asking Mr. Maben if he had any experience of the use of vaseline in the preparation of the ointment, said that of late several medical men had prescribed such an ointment, and as it had been stated that it is very satisfactory and permanent, pharmacists had to do their best to produce a good-looking article. It had already been pointed out that an ointment made with vaseline could not have a similar composition (so far as mercury salts were concerned) to the Pharmacopœial preparation, but he might say that the ingredients did not even form a homogeneous mixture, also having the objectionable property of great acidity. Again referring to the question of temperature, he remarked that it was only necessary to melt the lard in the oil by means of a water-bath, and using 9½ ozs. of nitric acid to add the mercury solution cold, when abundant frothing took place during five or six minutes, the result being a very satisfactory ointment.

Mr. Stephenson said that he could speak of the use of vaseline from experience. He got a nice smooth, though high coloured ointment by using it, but on standing a few weeks he was surprised on going to it one day to find that its bulk had increased very much, the lid of the pot being forced up. He had no hesitation whatever in saying that the proposal was thoroughly unworkable.

Dr. Stevenson Macadam, on the invitation of the President, said that he was afraid he could not throw much light on the subject, having come in late and lost the more important points of the paper; but he wished to express his gratification at finding an old pupil continuing his studies in so practical a manner.

Mr. Maben, in thanking the meeting for the manner in which his communication had been received, said that he had seen the letter to which Dr. Clark had referred, the writer of which expected an ointment made with adulterated oil to be of an orange colour; this was a natural assumption, but experiment showed that the colour would be blue or green, according to the extent of the adulteration. Regarding the excess of acid, he would only repeat his opinion, that an excess was required to decompose olein into elaidin, and further that a high temperature is better than a lower for effecting the whole series of decompositions taking place in a well-made ointment. In reply to Mr. Gilmour, he said that he maintained the temperature until all action ceased. He had experimented with all the known adulterations of olive oil, and being still engaged in the work he would take advantage of the hint thrown out. Mr. Stephenson's experience of the use of vaseline so well refuted the statements of its suitability that he required to add nothing to what he had said. The suggestion was quite an unscientific one.

Mr. Patrick Geddes, F.R.S.E., then delivered a lecture on the "History and Present State of the Cell Theory," and the President of the Branch closed the session by a few valedictory remarks. The lecture and other business will be reported next week.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

THE PROPOSED CHANGES IN THE PHARMACY ACT OF 1868, AND IN THE EDUCATIONAL SYSTEM OF THE PHARMACEUTICAL SOCIETY, TOGETHER WITH SOME REMARKS ON THE PRESENT POSITION OF PHARMACY.

BY DANIEL FRAZER.

(*Concluded from page* 850.)

Having thus gone over the contents of the Bill, as well as noticed the omissions just discussed, I would like, with your permission, before proceeding to sum up and give my judgment on the case before you, to make some remarks on the present educational proposals of the London Council.

The report of the Committee on the Relation between Pharmaceutical Education and the Pharmaceutical Examinations was discussed and generally adopted by the Council exactly a year ago (see Journal of April 15, 1882). The report then carried was remitted to the original Committee to put into a practical form. The resulting report was laid before our Council on March 7, last, and adopted, after considerable discussion. I will now notice some of the more important innovations or novelties embraced in these reports, and leave you very much to form your own conclusions as to their practicability.

The most important of these is the sought-for establishment of a curriculum. This is to consist of sixty lectures in Chemistry and twenty on Physics relating to it—eighty in all, forty-eight lectures on Botany and forty lectures on Materia Medica; each of these lectures must occupy at least one hour in delivery. In addition to the lectures there is to be a three months' attendance at Practical Chemistry of not less than five hours a day. Some of the things embraced in this curriculum are such as these:—The Laws of Gravitation—Cohesion—Adhesion—Elasticity—Molecular Attraction — Comparative Hardness of Bodies—Physical Condition of Gases—Mariotte's Law—Light: its Nature—Polarized Light—The Spectroscope and its Uses—the Making of Barometers and Thermometers, etc. The time over which the curriculum is to extend—

Ten months	Two hours daily.
Five months	Three hours daily.
or	
Three months	Five hours daily.

All the recommendations embraced in both reports are, when finally adopted, to be "incorporated into the bye-laws, according to existing regulations, and to come into force on and after December 31, 1887."

In addition to the innovation of the curriculum itself there is the one already referred to in the first part of this lecture—the one rendering it necessary that the student attend in open shop for three years *after* registration before he can go up for the *first portion* of the qualifying examination. There is also this further innovation—*one year* at least must elapse between the passing of the *first part* of the qualifying examination and the date at which the candidate can enter for the second part of it.

All that I will add here is that in both the discussions that took place in the Council when these reports were submitted to it Messrs. Williams and Hampson maintained that the powers sought in respect to the age of the candidate, and to the breaking up of the examination into two parts, are illegal, and beyond the powers of the Council. On this point Mr. Williams is reported to have said:—"Probably certain clauses had been put into the new draft Bill which had been submitted for the approval of the Council at their last meeting with the view of enabling the Council to alter the examinations in the way indicated, but at present he was quite clear the Council had no legal power to do so; and so on that ground alone he should feel bound to vote against these recommendations."*

Mr. Hampson is reported to have said that "he believed the Act of Parliament had been unduly stretched already in imposing the condition that a candidate should be twenty-one, which was distinctly illegal, in his opinion;† and the division of the examination into two parts, as now proposed, he believed was utterly beyond the powers the Society now possessed."

I will not insult you by offering a single argument in vindication of my own, and, I hope, your condemnation of the curriculum and all its belongings.‡ But I do add this, my intense regret that Messrs. Hampson and Williams, in their opposition to even a portion of the recommendations—that of dividing the examinations into two portions—had not the support of our much respected representatives, Messrs. Young and Borland.

In connection with the proposed changes in our educational arrangements, I here seek your indulgence for a very few minutes while I attempt to give a brief summary of proposals on the subject, emanating from a gentleman outside the Council and even of the Society itself, but who is of much, and most deserved, influence with most, if not all, its members. These proposals reached the members of Council in the form of a printed letter in the autumn of 1881—after the withdrawal of the proposed Pharmacy Bill of that year. This letter has not been published, and may, so far as my knowledge is concerned, have since then been withdrawn or been superseded by a later and a quite different one.

The following are some of the recommendations contained in the letter:—

Preliminary Examination.—"This examination should be increased in scope and stringency. The following should be added to the present subjects of examination:—Algebra, Euclid, and French or German."

Minor Examination.—This is to qualify for "assistants" only, and the *Minor* shall not be permitted to be registered as a chemist and druggist as heretofore, nor to "commence business on his own account."

* Mr. Williams, in the debate on the educational proposals in April last year, is reported to have said that he "need not say that the examinations to be carried out under the scheme proposed would be of a totally different character to that ever contemplated by Parliament when the Pharmacy Act was passed. Mr. Schacht might say it was only one examination, but he contended it was distinctly three, and he could not mould three into one. He was quite sure it was never contemplated by Parliament when the Pharmacy Act was passed. They had already stretched the Act a long way when they made the original alteration of introducing the Preliminary examination and insisting that there should be three years between that and the Minor."

† Better late than never. When this restriction on the age of the candidate was proposed, my own hand was the only one held up against it. Mr. Mackay offered to second my motion if I would have accepted twenty years as the age, instead of putting no restrictions at all, as I wished. I have no access at present to a report of this meeting, but feel sure that the facts are as stated. If wrong I will be most happy to be put right.

‡ The Home Secretary and the Postmaster General are lecturers or professors in Cambridge. Does anybody know how many students attend their lectures, or, for that matter, anybody else's lectures there? There are lectures in the Middle Temple. How many who pass their examinations and become full-fledged barristers attend a single lecture there or elsewhere? Is it not the fact, that in the great majority of cases in Cambridge the whole work is done by a series of examinations? Is it not the case, that a man may, and sometimes does, pass all the examinations of the Temple, not only without attending any law lectures anywhere, but without being necessarily once in a law office or court? If it be so in these cases, how can the necessity of a curriculum for the pharmacist be vindicated before the Privy Council?

Major Examination.—Some knowledge of microscopy to be added to it.

Fees.

	£	s.	d.
Preliminary	3	3	0
Minor, as above	6	6	0
Major	6	6	0
Total Examination Fees . .	15	15	0
Life Membership Ticket .	5	5	0
(Or Annual Subscription, £1 1s.)			
	21	0	0

"'Assistants'—that is persons who have only passed the Minor examinations—should not be permitted to carry on business on their own account or to manage a branch business, or the business of a deceased registered person for executors, etc."*

The close of the paragraph from which I have just quoted is as follows:—"The names of 'pharmaceutical chemists only' should therefore be published in the official register of persons entitled to carry on business, except those chemists and druggists already on the register."

The writer of the letter further suggested as a possibility, but does not recommend it, that in case the existing Minors might complain of the proposed change, "they might be permitted to qualify as pharmaceutical chemists by passing a somewhat modified examination, provided that was passed within a certain time—say one year."

As I think I can safely leave you to form your own conclusions as to the recommendations just quoted, I do not add what mine are, but leave them to be guessed at; and I do so with full confidence that all here at least will guess aright.

I wonder whether some of you are thinking of Cowlairs and Queen Street Stations, and of the rope that unites the two? It cannot surprise me though you were so thinking, for my yarn on the Pharmacy Acts Amendment Bill has been so spun out that even I, myself, had begun to think that it might turn out to be as endless as that often-circling but never-ending rope. But the longest lane has always a turning, and my story will have an ending. The only difficulty I now feel is, which of the many strands of my wearisome yarn should first be dealt with. As "the safety of the public" is the ground on which the present demand for further legislation in pharmaceutical matters is demanded, it had better come first in our review.

On this point, then, I demur to the assertion that the "public safety" calls for such further legislation as our Council is now seeking. I do not think it does, and I ask what evidence can be produced that it does? Have the public demanded it? Has the press advocated it? Certainly not. The Veterinary College at Lincoln, an ill-informed coroner here and there at long intervals, and an excitable doctor whose patients ventured to doctor themselves rather than trust him with their case, neither singly or unitedly, form "the public" for whom laws are passed by Parliament. Is there a particle of evidence to prove that the "safety of the public" has been jeopardized through the defective education of the existing pharmacists of the country? I unhesitatingly say no. And if this be so with us—thirteen or fourteen pharmacists of all ranks—how is it with the non-pharmacists who have invaded our territory? Has our most able law-adviser, Mr. Flux, has the indomitable Mr. Barclay, with all the lynx-eyedness of himself and of Mr. Haydon, been able to bring before the country any evidence of the abuse of the trust awarded by law to the stores for the selling of "poisons" and the dispensing of "medical prescriptions?" I answer:—I believe that no such evidence is producible. We may, therefore, dismiss the plea of the "safety of the public" as calling for this Bill.

"Protection of Trade" may probably be thought by many of you a fitting theme to be here dealt with. There is no theme so popular with the letter-writers in the Journal of the Society. When anything goes wrong—when the inevitable corn is trod upon, or when the pharmaceutic shoe pinches anywhere, up goes a letter to the Journal or to the *Chemist and Druggist* asking why the Council takes no steps to protect the interests of the afflicted letter-writers.

For a very simple reason. The Council are helpless in most of the cases for which their support is invoked. The Council can only step into the breach when the law has been invaded. So it is with Parliament. Parliament will only step in in the interest of the public, and not in that of the pharmacist. If there is any conflict at any time between these two interests, that of the pharmacist will undoubtedly go to the wall and that of the public will be cared for.

What led to the enactment of the Irish Act of 1875? Let it speak for itself:—"And whereas, a great deficiency exists throughout Ireland of establishments and shops for the sale of medicines and compounding of prescriptions, and great inconvenience thereby arises to the public in many parts of the country," etc.

How did this deficiency in the supply of shops and establishments for the supply of medicines and the making-up of prescriptions arise? Through the over-education and the over-protection of Irish apothecaries. The education to qualify for passing was so high and so expensive that few entered the ranks, and there were whole districts and villages without apothecaries. Coupled with this was the strict protection to the apothecaries in the compounding of "medical prescriptions." There were druggists in abundance everywhere, but none of them had this privilege; and hence the "great inconvenience" to which the public were subjected, and which led to the passing of the Irish Act.

"Like causes produce like results."

It is to a like restriction in this country that the present policy of our Council is directly tending. I strongly oppose the increasing of the stringency of the present examinations and the increased cost of them, on two grounds. First. Because I believe they are high enough already. I again insist upon it that no case has been made out for an increase in the character or the cost of the examinations. Second. I oppose the increase because of its inevitably thinning our ranks—that thinning that has begun to attract the attention of those of our number who ever give such matters even a passing thought. That this thinning process will go on as a sequence to the passing of the present Bill—if it ever be carried—is not denied by even our officials. The Vice-President of the Council, Mr. Atkins, at a late dinner of the London assistants, and where Mr. Carteighe presided, is reported to have said that "he was glad to address young men—the assistants of to-day but the pharmacists of to-morrow. He envied them their age. He thought that whatever might be the changes of the future there were fair days in store for them. Their numbers might be reduced, but there would be a more elevated few possessing a higher degree of culture."

Yes, the "upper ten" of our ranks perchance may become the "upper five." Such a policy may profit the wealthier houses, but it will assuredly injure their less fortunate brethern. I do not say that this is the aim of the promoters of the measure under discussion, but I most unhesitatingly affirm that this will be the result. The toilers and moilers—the rank and file of the Society—unable to procure apprentices or assistants to carry on their business, will be left out in "the race for riches;" and they going to the wall, the "upper ten" or the "upper five," as the case may be, will get one portion of their lost trade, and the store and the grocer will get the balance!

* The etcetera here means the widow and orphan children of the deceased!!

The Government, warned by the effect of the restrictive principle in operation in Ireland before the passing of their Pharmacy Act, will take care that no such restriction shall be allowed in this country.

The London *Times* (February 14, 1881), writing on the then proposed Medical Amendment Act, wrote:—

"The Bill of Mr. Hardcastle is one which no British Parliament could ever sanction. Under the disguise of providing for *medical education*, it is a measure of scarcely veiled trades unionism," etc.

Were our Amendment Bill to reach the stage which Mr. Hardcastle's did, could the *Times* more accurately or concisely describe it than by applying this very language towards it? Especially applicable would this description of it be were it applied in connection with the educational proposals of the Council. And if so applied to it, how long could you expect it to survive the castigation? Rather than run such a risk, better even yet, I say, withdraw the Bill; and instead of acting on the educational resolutions so lately adopted, pass one to reduce the Preliminary fee to £1 1*s*., and to make the Minor the only pass examination needed to qualify as "pharmaceutical chemists."

Soberly and seriously I mean all this, and had our Councillors but the faith to try the experiment, sure I am they would ere long see a more contented and better-to-do constituency than they can hope to see under the "spotless ideal" scheme of education that Mr. Schacht considers so "exactly correct."

Though last, not least, the stores must not be overlooked in my summing up. I have already so largely referred to them that what I add here need not detain us long. We cannot close them; we must rest content with their existing side by side with us. Is their existence an unmixed evil after all? I think not. The underlying principle on which they are conducted, and which has led to their success as trading companies, is the "ready cash" one; no credit given, no day-books kept. This may lead to a large measure of reform in this matter with others, and if so, we may share the common good derived by others through the operation of the principle of ready cash, small profits and quick returns. When an omnibus proprietor wishes to run an opponent's 'bus off the line he runs one of his own right in front of it and one behind. Well, you find that the stores are underselling you in proprietary and other articles. They are selling our specialties at rates that can yield them such bare returns for the capital invested, that I do not despair of their giving up very large portions of it. Meanwhile they are making rich by having remunerative prices for the staple articles of their trade. You add some of these to your business and undersell the stores in them. Do not attempt to compete with them in selling your own standard articles at prices under those of their own makers, because if you do you will gain nothing by it. On such a topic, the just remuneration of us pharmacists, ponder well the wise words of the old Glasgow citizen and professor, Adam Smith.*

* "Apothecaries' profit is become a bye-word, denoting something uncommonly extravagant. This great apparent profit, however, is frequently no more than the reasonable wages of labour. The skill of an apothecary is a much nicer and more delicate matter than that of any artificer whatever; and the trust which is reposed in him is of much greater importance. He is the physician of the poor in all cases, and of the rich when the distress or danger is not very great. His reward, therefore, ought to be suitable to his skill and his trust, and it arises generally from the price at which he sells his drugs. But the whole drugs which the best employed apothecary, in a large market town, will sell in a year, may not perhaps cost him about £30 or £40. Though he should sell them, therefore, for £300 or £400, or at a 1000 per cent. profit, this may frequently be no more than the reasonable wages of his labour charged, in the only way in which he can charge them, upon the price of his drugs. The greater part of the apparent profit is real wages disguised in the garb of profit."—'Wealth of Nations,' book 1, cap. 10.

Every dog has its day, and the stores are having their days of prosperity just now; but days of adversity are sure to come to them, as they do to all some time or other. Very many of the stores started under most favourable auspices have had to close their doors, and be sure, there are "more to follow." But do believe this—they will not be put down through any action of Parliament. So do not invoke its aid for such a purpose until you can prove that by shutting the stores and drug-dealing grocers up you will thereby be acting in the interests of the public, and not in your own merely. I have one more morsel of comfort to give you on this subject. Stores are not new—they have been born and they have died in the past, as they will doubtless do in the future. Here is the advertisement of one of these, exactly as it appeared in the columns of the *Glasgow Mercury*, of December 1, 1789:—

JOHN SWANSTON,

At his Shop a little West from the Candleriggs,

BEGS leave to acquaint his Friends and the Public, that he has just now imported, from the first markets in Britain, a complete Assortment of the following Articles, which he is selling, WHOLESALE and RETAIL, at very moderate prices, for ready money.

A parcel of fine Bohea, Congou, Souchong, Hyson, Gunpowder TEAS, in the original packages, from the Indiahouse.

Lemons, China Oranges, Wine Grapes, St. Katharine's Prunes, Turkey Figs, Jar and Muscatel Raisins, Currants, Almonds, Pistachia Nuts, Cashue Nuts, and Walnuts——Fine ENGLISH SUGARS, best Raw and Powder Sugars——Refined Liquorice in small boxes.——Patent Cocoa, Cocoa Shells, Churchman's Patent——Chocolate, Best Raw and Ground Coffee.—Red and White Port, Lisbon, and Sherry WINES—Florence Oil—Best French and English Vinegars—Pickled Mushrooms, Walnuts, Capers, Cucumbers, and French Beans; India Soy, Mushroom Ketchup, French Olives, Anchovies.—SPICERIES of all kinds.—Truffels and Morrels, Best Mustard, Hartshorn Shavings, Maccaronie, Vermicelli, Rice whole and ground, French Barley, Saloop, Sago, Millet, Isinglass, Basket Salt—Best French and Poland Starch, Blues of all kinds—Best Wax and Sparmaceti Candles, all sizes, Green and White Wax Tapers, Mogul Cards; Spanish Door Mats; Punch Ladles and Strainers.

Bailie's Patent Blacking Cakes, BING's and WALKER's Blacking Balls—A neat assortment of GLASSWARE—CONFECTIONERY of all kinds, Citron, Orange, and Lemon Peel, Red and Black Current Jellies, Marmalade, and Virgin Honey.—Oliphant's Powder and Pomatum, Lavender and Hungary Water, Essence of Peppermint, WARREN's Milk of Roses, STOUGHTON's Elixir, Pectoral Lozenges of Tolou, Hemmit and Ruspini's Tincture and Dentifrice, GREENHOUGH's Tincture for the Teeth and Toothache, Dragon Roots and Teeth Brushes, White Almond and Cream Wash Balls, Italian and Windsor Soap, Almond Powder, Essential Salt of Lemons, Best Swan-down Puffs, &c., &c.——Best New KENTISH HOPS.

A few GOLDEN PIPPINS and NONPAREIL APPLES.

From the frequency with which his advertisements, even in those early days, appeared, it must be supposed that John Swanston did a roaring trade in his day—but, alas! his name and his fame have long, long since disappeared from the roll of Glasgow citizens. Not so with another early, but only a rarely advertising firm—and one that, unlike our hero of the ancient store, did not proclaim themselves as "selling at very moderate prices for ready money only."

John Swanston and his successors, if he had any, are all unknown to fame now; not so with the other firm—the M'Aslan and Austin of 1789, are now flourishing more than ever, though under the more euphonious title of Austin and M'Aslan! Surely there is a moral not to be easily cast aside in this?

That Mr. Swanston was not the sole poacher on the supposed sacred territory of the chemist and druggist of his times, the following extracts from *The Glasgow Mercury* at the respective dates quoted, amply prove:—

(*From* "GLASGOW MERCURY" *of Wednesday, February* 13, 1788.)

J. WHITELAW,
HAIR-DRESSER AND PERFUMER,
At his shops, No. 36, opposite the Old Guard, Trongate, and No. 184, opposite Bell's Wynd, High Street,
GLASGOW;
Where the PUBLIC may be supplied, on the most reasonable terms, with the following articles, viz.

. . . . The Essential Salt of Lemons, for taking ink spots or iron-moulds out of linen, lawns, cambric, &c. Each box, 1 s.—Refined Liquorice, for Coughs and Colds.—Milk of Roses, Tooth Powders and Brushes.—The very best Blacking Balls and Cakes, for Boots, Shoes, &c. at 1 s. or 6 d. each.

(*From* "GLASGOW MERCURY" *of Tuesday, April* 28, 1789.)

MR SPILBURY'S DROPS.

. . . .

N. B. Mr Spilbury's Drops are vended in bottles of 5 s. and 1 l. 2 s. Also his Treatise on the Scurvy, Gout, Diet, &c., fourth edition, price 2 s. with a hundred cures relative to those disorders, and other irritating painful maladies arising from impurities of the blood, &c.—Sold by James Duncan, bookseller, Trongate, Glasgow: P. M'Arthur, bookseller, Paisley; William Muir, Kilmarnock; Mr. Boyd, Dumfries; and by the general vendors of medicines in Great Britain and Ireland.

(*From* "GLASGOW MERCURY" *of Tuesday, July* 8, 1794.)

Just received,
By Messrs. DUNCAN and CHAPMAN.*
Trongate, Glasgow.
A FRESH SUPPLY OF THE
CHEVALIER RUSPINI'S STYPTIC.

. . . .

The Chevalier has every week instances of its wonderful effects.

Where also may be had,

Ruspini's DENTIFRICE POWDER for keeping the Teeth and Gums in a state of beauty and purity, 6s. per box, duty included.

——— TINCTURE for do. 6s. per bottle, duty included.

——— ELIXIR for the cure of the Toothache, 6s. per bottle, duty included.

——— BALSAMIC STYPTIC for curing internal and external Bleedings, 8s. 6d. per bottle, duty included.

(*From* GLASGOW MERCURY" *of Tuesday, July* 8, 1794.)

A CERTAIN CURE FOR CORNS.
INFALLIBLE
GERMAN CORN PLAISTER.

. . . .

This is the celebrated Plaister that gained so much reputation in Germany; and has been sold in London upwards of 50 years with the greatest reputation.

Price 1s. $1\frac{1}{2}$d. the box, duty included.

Sold in London wholesale and retail by T. Axtell, Bookseller, No. 1, Finch-lane, near the Royal Exchange, Cornhill. Also, by appointment of the Proprietor, by Mr. Baxter, South Bridge, Edinburgh; and by ANGUS M'DONALD, jeweller, Glasgow.

You see by these extracts that proprietary articles were, in those olden times, sold by almost everybody but druggists; and so, after all, perhaps it is the corresponding traders of our day that have to complain of us invading their territory, and not we of them invading ours!

It may now very properly be asked what is to be the upshot of all this commotion, what the fruit of all these boilings up in the pharmaceutical caldron into which we have so long been looking to-night? For years the uneasy heads, that wear not crowns, of pharmacy, "troubled with thick-coming fancies" of dire disaster to our calling, through the competition of the stores with it on the one hand, and with dreams of crowds of entrants to our ranks through "cram" on the other, have at last entered the field of Parliamentary warfare with sword unsheathed and flag unfurled, to do battle with both their dreaded foes.

Through their Pharmacy Acts Amendment Bill the Council hope to deal a death-blow to the first, and to all such; and through their educational resolutions, they count upon obtaining an easy victory over the last. If they do succeed in getting all the powers they are now seeking, then the doom of the stores has come, and the days of "cram" are over, and a right merry dance of exulting professors, and of jubilant councillors, in the halls of 17, Bloomsbury Square would speedily ensue to gladden the heart, and cheer the spirits of the most worthy of all Secretaries and the most faithful of all Registrars.

But if they do not succeed—if Parliament should refuse to pass the Act, and the Privy Council withholds its sanction from the Resolutions—what then? It may be difficult even to surmise what Parliament may positively do, but I do not think that there can be any difficulty in settling beforehand two things, at least, that it will not do. It will not legislate for our interest, at the sacrifice of that of the public; and it will not give our Society powers to override those of the Privy Council itself.

Not till it pass an analogous Act regarding its own powers—the transference of its powers of administering existing laws and of enacting new ones, to the Cabinet, even with a Gladstone or a Salisbury at its head,—will Parliament grant our Council the powers sought in their Act and their Resolutions.

But what is very likely to happen is this: Our "glory" will be preserved or perhaps enhanced, but it will be done at the expense of our purse. All our existing titles, and more if we ask them, will be sacredly preserved to us, but our trade will be divided. None but entrants through the portals of Bloomsbury Square will be allowed to emblazon over their doorways any one of all our legally-sanctioned titles; but "licensed to sell poisons and poisonous articles" will most likely be seen written in more sombre colours over the humble doorway of the grocer and the general dealer. That is what I expect—the extension of the principle of clause 2, expanded to embrace all the poisons of schedules 1 and 2. Not only so, but I think it not improbable that the Chancellor of the Exchequer will seek to couple this new licence with the old one of patent medicines, and double the amount for the double privilege, thus at once "dishing" the existing monopoly in "poisons," the wished-for monopoly in patents containing poisons, and greatly enhancing the revenue of the country. My reasons for thus thinking that some such results as these may follow from our rushing into Parliament are abundantly simple.

1st. "The safety of the public." That has been so much cried about by our Council and the Trade Association, as well as by odd men here and there at intervals, that the Government imagine they must do something. That something need not be much. Possibly it may be thought by them that the "public safety" will be sufficiently conserved by their establishing over the country numbers of such licensed premises as I have named, and enforcing the labelling *as poisons*, or *as poisonous*, of all restricted articles. This would be sufficiently secured by the infliction of a heavy penalty for its infraction, or by liability to have the licence withdrawn for the second or third offence. Even less than this may be deemed adequate protection of the public. The labelling only, as provided for in clause 2 of the projected Act, may be all the security the Government shall deem necessary.

2nd. Warned by the evils that arose from the restriction of drug establishments where the public in Ireland could have their prescriptions dispensed, and which called for the passing of the Act of 1875 to remedy the evil, the Government will take care not to sanction such fresh legislation as would lead to a similar inconvenience and evil to the public of this country. That the convenience of the public as well as their safety will be most jealously guarded by Parliament may well be deemed certain, when we remember the action the Privy Council took when it refused, at the request of our Council, to add the mineral acids to either of the existing poison schedules. And that

* Printers and Publishers of *The Glasgow Mercury*, etc.

the sought for legislation and the accompanying changes in our educational system would tend directly to the reduction of the number of pharmacists and of "shops for the sale of medicines and compounding of prescriptions" throughout this country, as did similar legislation in Ireland, is not only asserted, as we have already seen, by the Government Inspector of Examinations, but is even allowed, as we have also seen, by the Vice-President of our own Council—Mr. Atkins.

And now with a word of warning I am done. If on consideration of the facts and arguments I have at such unpardonable length placed before you, you should come to think with me that the continued protection of our titles may be the only shred of protection left to us at the close of the struggle that our Council backed up by that of the Trade Association have entered upon with the stores, then "Be strong and quit yourselves like men," be up and doing, and on the twenty-third day of May next let your voice be heard in Bloomsbury Square—not for war, but for "peace, retrenchment, and reform"—that is, withdraw the Bill, cast out the resolutions, and rest and be thankful with such protection and privileges as ye now enjoy.

If you and others nearer the centre of influence do this, and you succeed, then I will not despair of seeing brighter days for the pharmacist than he has seen of late, and that too without loss to that ideal "pharmacy" for which not a few of our men of science and men of "culture," appear willing to sacrifice its bone and sinew.

The tide has of late been running against you—but patience, brother! and it will turn, as all tides have turned for willing and patient workers, and the waters will yet swell up to the brim, and the pharmacists of the future will float at least as prosperously on their breast as ever their predecessors did.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth general meeting of the above Association was held at the Royal Institution, on Thursday, March 29, 1883, the President, Mr. Councillor Woodcock, in the chair.

The minutes of the previous meeting were confirmed, and the following donations announced:—The *Pharmaceutical Journal*, from the Society, and the 'Annual Report of the Law Students' Association,' from the Association.

Mr. Michael Conroy, F.C.S., read a communication upon—

Insect Powder and Insect Flowers.

BY M. CONROY, F.C.S.

Probably most of the insect powder sold in this country is that ground here from closed Dalmatian flowers (*Pyrethrum cinerariæfolium*); but there is also a large quantity of the foreign ground powder imported, which, owing to its brighter yellow colour is preferred by many, and consequently finds a ready market. The imported flowers, are commercially known as "closed," "half open," and "open," the first consisting of unexpanded flowers, while the two latter kinds consist of the expanded flowers, many of which are deficient in, or have entirely lost the active florets, and are consequently of much less value than the closed flowers as an insecticide. There is still a further distinction caused by the popularity and increased demand for this powder, the result being that the flowers are now specially cultivated, so that now both wild and cultivated varieties are offered. The wild kind, however, is the most esteemed, and fetches a higher price owing to it being much more energetic in its action. The imported powder arrives here chiefly in kegs and tins, and most of it is of a bright yellow colour, such as English grinders find it impossible by any legitimate means to match. Some foreign dealers, more honest than others, euphemistically call this "dyed insect powder," while others term it "yellow closed," but as many prefer this article to the duller coloured English ground powder, it cannot be generally known that this bright coloured foreign powder is largely adulterated with yellow colouring substances. It has already been shown that it is frequently dyed or rather adulterated with chrome yellow, though personally I have never found it in any sample; but the samples on the table, which are of a very rich colour, are largely adulterated with fustic, and are being now offered at a price at least 10*s.* below what is now paid for the unground flowers. This fraud has been practised for some time past, and though a strong advocate of free trade principles, I would recommend dealers in this article to avoid the foreign powder until, at least, it is sent here in a genuine state.

Mr. Conroy then exhibited samples of the various kinds of flowers and powders as imported.

A vote of thanks was passed to Mr. Conroy for bringing this communication forward.

Mr. Charles Symes, Ph.D., then read a paper entitled "Some Facts concerning Filtration."

The paper will be printed in a future number.

A lengthy discussion, in which Messrs. Davies, Conroy, Mason, T. F. Abraham and A. C. Abraham took part, followed the reading of this paper, and a vote of thanks was passed to the author, who replied to some of the criticisms, and thanked the members present for their attention to his remarks.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

A meeting of members of the above Association and other registered chemists, was held at the Memorial Hall, Albert Square, on Friday evening, April 13. Mr. W. Wilkinson, Vice-President of the Association, occupied the chair, and in the course of some introductory remarks referred to the fact that at the last ordinary meeting of the Association the proposed Pharmacy Act Amendment Bill had been thoroughly discussed by the members present, but it was thought desirable to give every registered chemist in the city and suburbs an opportunity of expressing his views on the proposed enactment before forwarding resolutions to the Council of the Pharmaceutical Society. With this object in view every chemist whose name appeared in the 'Manchester Directory' had been invited on the present occasion, and, further, it had been intimated to each, that all engaged in the trade as assistants or apprentices would be cordially welcomed. Under these circumstances, he hoped to have seen a larger attendance.

The proposed Act was then read, clause by clause, and fully discussed, and the following resolution was proposed by the Chairman, seconded by Mr. Jackson, and carried unanimously:—

"That this meeting of members of the Manchester Chemists and Druggists' Association and other registered chemists and druggists of Manchester and district, having considered the Draft Pharmacy Act Amendment Bill, proposed by the Council of the Pharmaceutical Society, hereby expresses its approval of the same if amended in accordance with the following suggestions:—

"It regrets that it has been thought necessary to introduce the principle of allowing unregistered persons to sell poisonous articles.

"In clause 4 it should be more distinctly expressed that the bottle or other vessel containing the poison should itself, as well as the outer wrapper, bear the word 'poison' with the name and address of the seller.

"If in clause 5 it be a 'second offence' to sell a different patent medicine containing poison unlabelled, this clause requires amendment.

"In clause 6 the word 'and' should be substituted for 'or,' in line 4.

"Pharmaceutical chemists who have already or shall have passed the Major examination prior to January, 1886, to have the title of Fellow of the Pharmaceutical Society. This title to be also conferred upon all who shall subsequently pass a higher examination than that provided for in clause 16 of the Act."

The Secretary was requested to forward a copy of the above resolution and suggestions to the Council of the Pharmaceutical Society.

A paper by Mr. Alfred H. Jackson, B.Sc., on "The Educational Value of Pharmaceutical Studies," had been announced, but in consequence of the lateness of the hour the reading of this paper was postponed till a future meeting.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The eleventh meeting of the session was held on Wednesday, March 28, in the rooms of the North British Branch. Mr. P. Boa, President, in the chair.

The minutes of last meeting having been read and confirmed the Chairman called upon Mr. W. Aitken to read a paper on—

Photography—Dry Plate Process.

The author, in opening the subject, briefly referred to "light," with regard to photography generally, after which he explained what was meant by the "dry process" of to-day, as the coating of glass plates with an emulsion containing the sensitive salts in the form of the bromide, iodide and chloride of silver. He also considered the properties and peculiarities of gelatine, and noticed the photograptive properties of bromide of silver, drawing attention to the various conditions under which a slow or a rapid emulsion may be formed. He then explained the camera and the conditions necessary for making the exposure, and described the process of development by the pyrogallic and ferrous oxalate methods, giving the reactions which occurred, and afterwards briefly described the manner of procuring the prints. An interesting collection of pictures was exhibited, comprising a series of photos of the finish of the Derby, views of Niagara Falls, several transparencies, as well as some amateur work, apparatus, etc.

An interval of ten minutes after the reading of the paper gave the members an opportunity of examining the specimens, and thereafter, on the motion of Mr. McEwan, a hearty vote of thanks was awarded to Mr. Aitken.

The discussion which followed was taken part in by Messrs. Boa, Crowden, Henry and Turnbull, and a vote of thanks was accorded to Messrs. J. D. Robertson and McEwan for the loan of some fine specimens of photographic art. Some formal business having been disposed of and the Chairman having intimated that the Annual Business Meeting would be held on Thursday, April 12, the meeting was closed.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Pharmaceutical Politics.

BY R. W. GILES.

(*Concluded from page* 855.)

The conduct of the Bill through Parliament exercised all Mr. Bell's tact to reconcile the crotchets of critics of all shades of opinion, from the friendliness of English sympathizers to the direct opposition of Scotch doctors. I had the satisfaction of giving evidence in its favour, when I also had an opportunity of observing the dexterity with which Mr. Bell, as chairman of the Committee, managed the hostile witnesses. It showed me how poor the chances of the Bill would have been if the chairman had been less thoroughly conversant with the points of the case. *A Bill* was passed on June 30, 1852, but not *the Bill* which had been introduced a year previously. In fact it would be difficult to recognize any common principle in the two drafts. On the following day Parliament was dissolved and, Mr. Bell's constituents having been disfranchised for yielding to solicitations which Jupiter did not scorn to use and Danae could not resist, Mr. Bell never sat in another. It was "touch and go" with the first Pharmacy Bill!

As originally introduced by Mr. Bell, the Bill provided that it should be unlawful for any person to exercise the business or assume the name of pharmaceutical chemist unless he was upon the register of pharmaceutical chemists in the manner prescribed by the Bill. As it left the Committee and subsequently became law, it simply confirmed the Charter and constituted a sort of upper grade of "pharmaceutical chemists," who alone were privileged to use that title; but it left the practice of pharmacy as much open to unqualified persons as it had been before.

This was a lame and impotent, and it may be added an illogical conclusion; but in spite of its manifest shortcomings I shall class the passing of this Act as the third great epoch in the history of modern English pharmacy. Let us see how much it actually effected.

1st. It gave legislative sanction to the pharmaceutical profession, placing it upon common ground with the other medical corporations and practically securing it from ever being put under their domination. Thus it was a death-blow to future aggression from that quarter.

2nd. It recognized the fact that the public welfare demanded the enrolment of a qualified class of pharmaceutical chemists; it took measures for creating such a class; and it sanctioned a system of examinations for the purpose of testing their qualifications.

3rd. It entrusted the examination of pharmaceutical chemists (as sanctioned above) to members of their own profession, to be appointed by the Pharmaceutical Society.

4th. It adopted the principle of registration for pharmacists and commissioned the Society with the custody of the register, and generally constituted it the executant of its provisions.

Thus, though it fell far short of what had been asked for, it contained the germ of everything that could be desired.

It will be observed that in the preceding sentences I have (without design) twice applied the term "profession" to the business of a pharmaceutical chemist. It appears to me that the Act of 1852 impressed that character upon it, and that any other word would have been less appropriate. At the same time it must be acknowledged that a great deal of trafficking clings to the skirts of pharmacy, which cannot be distinguished from any other description of retail trading. Pharmacy is, therefore what the individual pharmacist makes it, and if the majority make it a trade, it is not to be expected that the public will look upon it as a profession.

Much fault was found with the Act of 1852, which was stigmatized as a miserable deception, and the blame of its inefficiency was cast upon the Society, Nothing could be more unreasonable. The Society were responsible for the Bill they introduced, but Parliament was responsible for the mutilated form in which it left their hands. "One man may lead a horse to water, but a dozen men cannot make him drink," and the same rule applies to Bills brought into Parliament. The objectors made the mistake of looking at the Act as if it had been final, in which case it would have deserved all their condemnation. Regarded as the first step in pharmaceutical legislation it was most encouraging, securing for the Society a *point d'appui* from which to operate upon a future occasion. Later Acts may confer greater powers, but no subsequent Act can effect such a radical change in the political status of the Society. The Act was accepted in this light by Mr. Bell and his colleagues, shrewd men whose calm judgment was not easily disturbed, and who managed the affairs of the Society in critical times without ever losing their heads or making a mistake. I wish I knew where to look for their equals now.

The years immediately succeeding were not eventful; the calm succeeded the storm. In 1853 the Council were harassed by a quibbling objection, raised in a cantankerous spirit by one of its own members, to the validity of a bye-law passed with the liberal intention of admitting into the Society, without examination, all chemists and druggists who had been in business before the Act, and who could produce certificates of fitness satisfactory to the Council. The contention was pertinaciously carried through the Courts from 1853 to 1855, when final judgment was given in favour of the Society, with costs against the appellant, in the Court of Exchequer Chamber. The only useful purpose served by this troublesome and costly litigation was to obtain an *obiter dictum* of the judge deciding the vexed question of pharmaseutical *v.* pharma*k*eutical in favour of "c" soft.

In 1856 Lord Campbell, in his place in the House of Lords, called attention to the prevalence of criminal poisoning and appealed to the Government for further legislation to regulate the sale of poisons. The subject was taken up by the press, and some Bills with that object were brought into Parliament by independent members, but nothing was accomplished in the way of legislation.

In the same year (1856) a Parliamentary Committee reported upon the adulteration of food and drugs.

These movements, though but inchoate, were symptomatic of the direction of popular and parliamentary feeling, and their effect upon the Pharmacy Bill, 1868, and their probable effect upon future Bills in Parliament, must not be overlooked.

The Medical Act, 1858, was the next event affecting, though indirectly, the development of pharmacy. The only provision bearing upon this point was one which assigned the duty of publishing the national Pharmacopœia to the "General Council of Medical Education and Registration," authorized by the Act. This change is greatly to be regretted, for if the publication of the Pharmacopœia had been suffered to remain for a few years longer in the hands of the College of Physicians it might reasonably have been expected that the Pharmaceutical Society would have established its claim to be officially associated with the work. But now it is to be feared that this special enactment, occurring so recently as 1858, may prove an obstacle to an early rectification of what I must characterize as an objectionable anomaly; for there can be no harm in saying in words what the General Medical Council have more emphatically expressed by their acts, viz.: that they are totally incapable of performing the duty that has been imposed upon them. The Pharmacopœia is essentially an official pharmaceutical laboratory book; and what could be more ridiculous than to entrust its compilation to a corporation which (in its corporate character) has never seen the inside of a pharmaceutical laboratory, and to withhold any share in it from those whose lives are spent either in the laboratory or in the after-manipulation of pharmaceutical preparations. Of course the Medical Act theory has utterly broken down in practice. We all know perfectly well, and the Medical Council have been constrained to acknowledge in the preface to the Pharmacopœia, that the work was actually done by our own Professor of Pharmacy, Dr. Redwood, than whom no man is more capable, or equally deserving of the respect of pharmacists for a long life devoted to useful pharmaceutical work. The present arrangement for publishing the Pharmacopœia is a perpetual reproach to English pharmacy, and a painful contrast to the practice in other countries. You may remember that in the year 1874 the Council sent two representatives to attend the International Pharmaceutical Conference at St. Petersburg. One of the questions proposed for discussion was, "Has not the time arrived for instituting an International Pharmacopœia?" Was there not something burlesque in the Society sending two grave and reverend pharmacists all the way to St. Petersburg to consult about a "Pharmacopœia Universalis" for all Europe, when they are not allowed to share in the production of their own? The making of Pharmacopœias is like charity, and should begin at home. This is a grievance that should never be lost sight of until it is remedied. And indeed the pharmacists have the remedy in their own hands. They have only to "strike," and say that they will not help clandestinely, and they must be consulted officially; for I venture to say the Medical Council would not dare to submit to general criticism a Pharmacopœia which had not previously been subjected to pharmaceutical revision. Some may wonder that this important question has not been dealt with by the Pharmacy Bill; but a little consideration will show that a Pharmacy Bill is not the proper place in which to introduce amendments to a General Medical Act. I understand that a new Medical Bill is now before Parliament, and I am strongly of opinion that the Council of the Pharmaceutical Society should seize the opportunity to press this question of the Pharmacopœia temperately, but firmly, in the proper quarter, so that it may now be put upon an honest footing. The present arrangement involves something very much like wearing other men's clothes, which is not a dignified guise for the Medical Council, to say nothing of the unseemly spectacle of pharmaceutical nakedness.

Passing over some minor legislation, which exercised the vigilance of the Society, but left no permanent mark upon pharmaceutical politics, we come to the year 1863, in which year the Medical Council proposed a new Medical Bill intended to amend the Act of 1858. The chief feature of this Bill which demands our consideration was a proposal to include pharmacy amongst the departments of medicine placed under the control of the Medical Council. It also contained a wholesale prohibition against the sale of secret remedies, which exhibited a very small acquaintance with the habits of the people or the temper of the Legislature on the part of those who made it. There is no reason to suppose that the proposal to bring pharmacy within the scope of the Medical Act was dictated by any hostile or aggressive spirit. On the contrary, the Bill marched, in many respects, on the same lines as the Pharmaceutical Society; but the time was not ripe for amalgamation. Nor has the time yet arrived when pharmacy can be incorporated with medicine upon reciprocal terms, and until that can be it is better that pharmacy should continue to walk alone. But I think the time will come, and probably some of you may live to see it, when such a union may take place with advantage to both. Upon the objection of the Society all the clauses affecting pharmacists were struck out of the Bill before it was presented to Parliament, and in lieu thereof the Medical Council adopted the following resolution, viz:—

"That a communication be addressed to the Secretary of State for the Home Department, drawing his attention to the present defective state of the law regarding the practice of pharmacy, under which any person, however ignorant, might undertake it, and expressing the opinion of the General Medical Council that some legislative enactment was urgently called for to ensure competency in persons keeping open shop for dispensing medicines and for the compounding of physicians' and surgeons' prescriptions."

Nothing could jump better with the purposes of the Pharmaceutical Society. The Resolution in effect said to Parliament, "You made a great mistake in not giving the Pharmaceutical Society the powers they asked for in 1852, and the sooner you repair your blunder the better." The Council of the Society were not slow in taking up the ball. In the following May, 1864, they submitted a draft Bill to the Annual Meeting, by which it was unanimously adopted. The United Society of Chemists and

Druggists, which had been formed in 1861 for protecting the trade interests of its members (which it imputed were neglected by the older Society), also promoted a Pharmacy Bill; and the two Bills coming into collision before a Parliamentary Committee, shared (as might have been expected) the fate of the Kilkenny Cats, except that there was not even a tail left between them. In plain English both were rejected, but it will point a moral to compare the leading features of the two Bills.

Bill (No. 1), promoted by the Pharmaceutical Society, proposed that after a certain date it should be unlawful for any person to practise pharmacy unless duly qualified as thereinafter provided.

Bill (No. 2), promoted by the United Society, proposed that all retailers and dispensers of "dangerous drugs" (as per schedule), and all persons keeping open shop for retailing drugs, should be examined by examiners appointed under the Act, and that certain specified regulations should be observed in the sale of active poisons.

Now I beg you to note who was responsible for the first suggestion of imposing regulations upon duly qualified pharmacists in the matter of the sale of poisons. It was not the Society, which had been accused of being the personification of high pharmacy (as though that were a crime), but the rival society which had set itself up as the poor druggist's friend, as the upholder of the trade interests of the struggling many, as distinguished from the advocate of the opinions of the favoured few. We shall have occasion to see presently how the popular feeling of the same "many" was appealed to in order to coerce the Council into breaking their engagements with Parliament in relation to this very question of compulsory poison regulations which the action of the United Society upon this occasion had helped to force upon them.

Mark also, as an important factor in the case, the action of the Parliamentary Committee to whom the consideration of the two Bills had been referred. The Committee reported—

1. "That no compulsory examination or registration under the Bills referred to the Committee should be required of persons now carrying on the trade of chemists and druggists.

2. "That the Bill do provide that no other person shall, after a day to be fixed by the Bill, sell dangerous drugs to be scheduled in the Bill, unless he be examined and registered.

3. "By the adoption of the second resolution as an amendment to a proposal that persons compounding medicines from the prescriptions of medical men should also be examined, your Committee decided against the principal provision contained in the Chemists' and Druggists' (No. 1) Bill, and they accordingly resolved to proceed with the Chemists' and Druggists' (No. 2) Bill."

Now legislation is a practical matter; and how can anyone blame the Society, after this experience, for yielding to the pressure on all sides for poison regulations? They do so because they take no trouble to inform themselves of the facts. It is so easy (and apparently so pleasant) to censure. As Byron said—

"A man must serve his time to every trade
Save Censure: Critics all are ready made!"

In further proof of the disinclination of the Council voluntarily to interfere with the discretion of pharmacists, listen to the following extract from a letter addressed officially by the President of the Pharmaceutical Society to the President of the United Society, on March 7, 1866, viz.:—"I think you will agree with me that a mere Poison Bill, fettering us with registration of sales and attendance of witnesses, prescribing a particular form of bottle in which poisons might be kept and sold, and a particular corner in our shops in which they should be placed, would be only an encumbrance to the statute book, inoperative as regards the public, and especially objectionable to men who, if they be properly qualified to deal in dangerous articles, will each, according to the special circumstances of his case, adopt precautions far more conducive to the public safety." The writer of this trenchant passage was Mr. Sandford, who is popularly credited with the desire to force poison regulations down the unwilling throats of his brother pharmacists. Let me take this opportunity of expressing my best wishes for Mr. Sandford (in which I am sure you will heartily join) on his recent retirement from business.

I cannot, however, agree with his vigorous denunciation. Let it be granted that every properly qualified man, who is also prudent, does use suitable precautions—the pharmaceutical millenium has not yet arrived, and all keepers of open shops for the sale, etc., of drugs are not properly qualified, and we may venture to doubt if they are all sufficiently prudent. At any rate, we have a reasonable suspicion that in hundreds of shops no precautions are taken at all. The "laudanum" bottle stands in friendly contiguity to "tinct. rhubarb." by reason of similarity of colour, and the "pulvis antimonialis" is alliteratively located next to the "pulvis antim. tart." If this arrangement does not obtain in the front shop, who shall guarantee that it does not prevail in the dark store at the back, where paper labels sometimes fall off and sometimes become illegible, and where what Captain Marryat called the "Rudimans" are relegated to the tender mercies of the apprentice and the porter? Before too much reliance is placed upon "men properly qualified to deal in dangerous articles" means must be devised for eliminating the disturbing element of "human fallibility" inseparable from the necessary institution of apprenticeship. I have said before, legislation is a practical matter, and it deals with what is, not with what ought to be. If all men did voluntarily what they ought to do, there would be no need for penal legislation of any kind, but I believe it to be a perfectly legitimate function of the Legislature to compel those who require compulsion. The most harrowing fatality by accidental poisoning that has occurred within my recollection would have been impossible if these regulations had been observed, and it occurred in a pharmacy second to none in the United Kingdom. In fact, I scarcely remember a case of fatal mistake in a pharmacy which would not have been prevented by the adoption of the poison regulations which were actually prepared by the Council. All this clamour about "compulsion" is rather childish. It would be as rational to feel aggrieved because "duly qualified pharmacists" are subject to the "compulsion" not to pick pockets. It looks very much like Falstaff's famous excuse—

"What upon compulsion! No—Were I at the strappardo, or all the racks in the world, I would not tell you on compulsion. Give you a reason on compulsion! If reasons were as plenty as blackberries, I would give no man a reason upon compulsion. I!"

The moral of the story is that Falstaff, of course, had not a reason to give.

Untimately, after much negotiation and some concessions, the United Society agreed to co-operate with the Pharmaceutical Society in support of an amended Bill prepared by the Council of the latter, which was submitted to Parliament on May 11, 1868, under the title of "A Bill to regulate the Sale of Poisons and alter and amend the Pharmacy Act, 1852." The poisons regulations had been inserted in deference to the requirements of the Government and as the condition of Government support. They were materially enlarged in Committee, and when the Act issued from the Legislature, its leading features were as follow, viz.:—

1. That it shall be unlawful for any person to retail, dispense or compound certain "poisons" as per schedule unless such person be a pharmaceutical chemist under the Act of 1852, or otherwise registered as a chemist and druggist under this Act.

[As these "poisons" included articles of every day use in medicine, *e.g.*, prussic acid, opium and all its preparations, etc., this provision practically, though not expressly rendered it unlawful for unqualified persons to practise pharmacy.]

2. From and after the passing of the Act all persons (not having been previously in business as chemists and druggists, or, etc.), shall pass an examination before being registered under the Act.

3. The Pharmaceutical Society was constituted executant of the Act.

4. For the purposes of the Act the Society was authorized, from time to time with consent of the Privy Council, to prescribe regulations as to the keeping, dispensing and selling of "poisons;" and all persons practising pharmacy under the Act were required to conform to the said regulations under a penalty of £5 for each offence.

Parliament contemplated the possibility of individuals offending against the last quoted provision, and therefore attached to it what jurists call a "sanction," in the shape of the penalty alluded to; but apparently Parliament did not contemplate the possibility of the Society itself failing to fulfil its obligations, and it unwisely, as the sequel showed, omitted to attach a "sanction" to that command. But no one has ever questioned the intention of the Legislature, which is plainly deducible from sec. 1 and sec. 15 of the Act. It was understood on all sides that the Society was charged with the duty of prescribing regulations. It was so understood by the Council of the Society, who shortly after the passing of the Act set about framing them—it was so understood by the Privy Council, who were pressing in their request for the regulations to be submitted to them for approval—it was so understood by the Government, who, as soon as they found the Society would not act, brought in a Bill to amend the Pharmacy Act, 1868, by taking the initiative in the matter of poison regulations out of the hands of the Society and placing it entirely under the control of the Privy Council. Thus in a moment the Society found itself at issue with all those powers whose goodwill it had conciliated by years of persistent well-doing; and it is to be feared that the ill impression remains as a black mark against the conduct of the Society and may rise up like Banquo's ghost to shame its next appearance in Parliament. I will not dwell upon the unpleasant topic, but this epitome of the history of pharmacy would be incomplete if I did not record that an angry organized opposition was stirred up against the "poison regulations," though their most furious opponents did not deny that similar precautions (and it was open to them to indicate what they should be) were indispensable; that the Council were weak-kneed and limp in the back and contrary to their convictions withdrew them as regulations to propose them as recommendations, in which form, being entirely emasculated of all potentiality they were accepted at the Annual Meeting, not without a vehement protest on the part of a large minority. You have seen what Mr. Sandford's opinions were, but he behaved on this occasion with a straightforwardness which was both characteristic and commendable. It was no longer a question of opinion, but of fulfilling an engagement, and Mr. Sandford was the only member of Council (if I am not mistaken) who never faltered in the determination to give effect to the Act in the sense in which the Society had accepted it. Mr. Sandford, like myself, is one of a past generation, and had probably read in an old-fashioned book of which a copy may be found in the Library at Bloomsbury—

"Blessed is he that sweareth unto his neighbour, and disappointeth him not; though it were to his own hindrance."

At all events, he acted upon that principle. By a happy chance the Government Bill was withdrawn for want of time at the annual "slaughter of the innocents" on July 17, 1871; and as no other penalty had been provided, the Society was able to congratulate itself that it had lost nothing—but honour.

We have now reached the fourth epoch marked by the Pharmacy Act, 1868, which, so far as legislation is concerned, brings us down to the present time, in which we stand with one foot upon the past and one advanced to the future. Let me now briefly summarize the powers conferred upon the Society by its several public instruments, viz.:—

1. The Charter (1843) granted incorporation to a voluntary Society and defined the conditions of membership, which in future was restricted to persons engaged in pharmacy who should have been duly examined.

2. The Pharmacy Act, 1852, confirmed the Charter. It also constituted a new class of "registered pharmaceutical chemists," which should in future be recruited solely from persons who should give evidence of qualification satisfactory to examiners appointed by the Society; but this Act conferred no substantial privileges upon this new class.

3. The Pharmacy Act, 1868, gave legal status to a second class of "registered chemists and druggists." The qualification of this class (after making provision for vested interests) was also to be ascertained by examiners appointed by the Society; but it was provided that the test examination should be less stringent than that in force under the Act of 1852 for testing the qualification of pharmaceutical chemists, that it should be what has been known as the "Minor" examination. The registered chemists and druggists are therefore a lower grade than the pharmaceutical chemists, but both are equally entitled to be registered under this Act. The privileges of pharmaceutical chemists and of chemists and druggists are therefore at the present time practically the same.

No person not registered under this Act may use any title conferred by this or the former Act, nor may such person deal in any retail manner with certain "poisons" scheduled to the Act. But there is nothing in the Act to prevent unqualified persons from setting up open shops for compounding prescriptions or practising pharmacy, provided they do not call themselves pharmaceutical chemists, or chemists and druggists, and do not meddle with the scheduled poisons.

We are now prepared to consider the merits of—

4. The Pharmacy Bill, 1883.—This Bill differs from former Acts in expressly prohibiting the practice of pharmacy by unqualified persons. The words used are (section 9) "It shall be unlawful to sell by retail or to keep open shop for retailing, dispensing or compounding medical prescriptions, or," etc., unless the seller shall have complied with the requirements of the Act.

The next important enactment is to be found in section 16, viz.: "Every person who, after December 31, 1886, shall obtain a certificate of competent skill and knowledge and qualification under section 6 of the Pharmacy Act, 1868, shall be entitled to be placed on the Register of pharmaceutical chemists and shall be eligible for election to membership of the Pharmaceutical Society of Great Britain according to the Bye-Laws thereof."

[Section 6 of the Pharmacy Act, 1868, prescribed the Minor examination which entitled the examinee to be registered as a chemist and druggist (not as a pharmaceutical chemist), and section 18 of the same Act declared registered chemists and druggists to be eligible as members of the Society. The Bill proposes to make the Minor examination the sole test of qualification, and attaches to it the rank and title of "Pharmaceutical Chemist," with option of membership of the Society as before. The title of chemist and druggist is therefore abolished for the future, and will cease when the present holders under the the Act of 1868 are extinct. But, inasmuch as the Act of 1868 is not repealed, it will not become possible for future interlopers, be they grocers, drysalters, or others, to assume the lapsed title of chemist and druggist, and by so doing to mislead the public as to the character of their business or the extent of their qualification. Beyond that the public must look after itself on the principle of "caveat emptor."]

Next in order of importance come sections 12, 13, 14, referring to examinations; authorizing the Society to make bye-laws which will enable it to prescribe a "curriculum," and to make other changes which experience has shown (or may hereafter show) to be desirable. Section 13 directs that the Preliminary examination shall be passed before apprenticeship, that is to say that the Preliminary examination shall be preliminary.

Section 3 places wholesale dealers in articles in part 1 of the schedule A. to the Pharmacy Act, 1868, under restrictions somewhat analogous to the regulations imposed by the same Act upon retailers.

Section 4 extends to patent medicines the provisions of the Act of 1868 as to the labelling of poisons.

Section 2 is an extension of the poisons regulations of the former Act to a new class of poisonous articles, but without restricting the sale of such "poisonous articles" to registered or examined persons.

Section 8 provides that the public shall have the same security in branch shops as is enforced in other cases.

The remaining enactments are subordinate and accessory.

You have now before you all that is necessary upon which to form an opinion of the merits of the Bill, and you can come to a conclusion as well as I. I shall deal with this part of the question briefly and broadly, leaving details to be threshed out in discussion as far as time permits. It appears to me that the pervading feature of the Bill is—symmetry. It gets rid of the confusion attending the present variety of titles, viz.: Pharmaceutical Chemist, Member of the Pharmaceutical Sciety and Registered Chemist and Druggist, the relative values of which have proved incomprehensible to the public, who therefore have not learnt to attach any particular value to either; and it substitutes the one title of "Pharmaceutical Chemist," which will depend for its future estimation upon the quality of those who hold it. In this respect the Bill marches upon the lines of the first Bill promoted by the Society in 1850. In respect to the poisons regulations it removes certain of the exceptions which existed under the older Act; and while there seems to be nothing to object to in the slight restraint imposed upon wholesale transactions, which has been called for by a recent *cause célèbre*, the assimilation of patent medicines to other wares is a resonable step. The provision relating to branch shops rests upon the same basis of symmetry, and I cannot understand that any objection can be made to it. The powers in relation to examinations possess the same characteristic, for they will enable the Pharmaceutical Society to regulate its examinations and the course of study incidental to them in harmony with the principles upon which almost all other examining bodies act. But the most distinguishing feature of the Bill is, that in an intelligible and symmetrical manner it connects its enactments with its preamble, thus:—"*Whereas* it is expedient that pharmacists should possess competent skill, *therefore* let no man presume to act as pharmacist who has not given proof of such skill." The preamble was the the same in former Acts, but the enactment was inconsequent, and ran thus:—"*Whereas* it is expedient that pharmacists should possess competent skill, *therefore* let us leave them in their ignorance and allow persons who give proof of such necessary skill to call themselves Pharmaceutical Chemists!" It is true that the later Act of 1868 was less absurd than this, but it was a halting and unsatisfactory measure, needing to be reconsidered and amended as soon as circumstances should permit.

Finally, Should the Bill of 1883 receive your support? That is the practical question. Well, if pharmacists know their own mind, there can be no doubt of the answer. For forty years they have been asking for this very thing. During those forty years no one has come forward to assert that any other object ought to be substituted; and the experience of forty years has but confirmed the policy expounded in 1841 in the general terms "to benefit the public and elevate the profession of Pharmacy, by furnishing the means of proper instruction." This Bill is the result of that forty years' experience, which has shown that "voluntaryism" is incompetent to bring "proper instruction" home to the general body of pharmacists. In one particular only has the Society seemingly deviated from the principles laid down by its Founders. Those worthy men, in a spirit of optimism justified by their own high principles, broke loose from the precepts of tradition, and decided to dispense with everything in the nature of a "curriculum" in the case of those who presented themselves for examination. It would have been impossible in those early days to have done otherwise without postponing indefinitely the work they had taken in hand; but later experience and the systematic development of "Cram" have forced first the examiners and through them the Council back into the time-honoured grooves, which change of opinion finds expression in section 12 of the new Bill. This is after all but an adaptation of means to altered circumstances and implies no abandonment of principle.

There are other topics upon which I should have wished to make some remarks, if it had not been for the absorbing interest now centred upon legislation. Especially I should have liked to say something upon prices, as an important element of pharmaceutical politics. I should have been glad of the opportunity to speak particularly upon the relation which prices of dispensed medicines ought to bear to retail sales, upon which I hold some decided opinions; but these topics sink into insignificance by the side of the momentous question of pharmaceutical legislation, added to which I have already trespassed most unconscionably upon your patience by the unlooked for length to which these observatious have extended.

At the close of the reading of the paper, the discussion was adjourned.

A meeting of the Association was held on Wednesday evening, April 18, when the adjourned discussion upon Mr. R. W. Giles's paper on "Pharmaceutical Politics," was continued.

Mt. R. Winfrey proposed, and Mr. Phillips seconded, the following resolution:—

"That this meeting of members of the Chemists' Assistants' Association, having considered the 'Draft Pharmacy Acts Amendment Bill,' does in the main approve of such proposed legislation, and trusts the Pharmaceutical Council will receive the necessary support from all sections of the trade to enable them to promote the passing of the Bill by Parliament."

After a long discussion, in which the President, Messrs. Parkinson, R. H. Parker, W. S. Cooper, jun., Wallis, Allcock, Kerr, Luff, Parke, Hartridge, Cracknell, Hadfield, Roper and Millhouse spoke in favour of the resolution, it was put to the meeting by the President, and carried unanimously.

The majority appeared evidently in favour of instituting an honorary examination in addition to the proposed qualifying one.

Parliamentary and Law Proceedings.

Alleged Death through a Cough Mixture.

The adjourned inquest on the body of the child, Arthur Long, whose death was alleged to have been caused by morphia contained in a cough mixture (see before, p. 856) was resumed at the Town Hall, Brighton, on Thursday, April 12.

The mother upon being recalled admitted that she had given the child a "Steedman's powder" shortly after the first dose of the mixture. She had given similar powders on many occasions, but had not noticed the direction accompanying the packet that no other medicine should be given whilst using these powders.

Dr. Ross being recalled said he inquired what had been given to the child directly he saw it, but could not say whether he heard anything about the powder. He did not think the point was of much importance. He believed that a "Steedman's powder" contained James's powder and calomel, but no morphia; if he had thought the powder contained morphia or opium he would have given more attention to it.

Dr. Stevenson, of Guy's Hospital, was next called, and said he had received a stoppered bottle which contained some human viscera, the stomach and its contents, and part of the intestines, and a second bottle, which contained other viscera, one kidney, a part of the liver, and the urinary bladder and its contents. There were no unusual appearances in this viscera. It was to all appearances healthy, there being no signs of disease. The stomach was empty of food. He had analysed this viscera. He found in the stomach and intestines in the first bottle distinct traces of antimony, and also a trace of morphia, but in an unweighable quantity. He also found a trace of some other matter, possibly mercury. The other bottle contained the liver, kidney and bladder, which showed distinct traces of antimony. He believed there was also a trace of morphia, but the quantity was so small he could only obtain one reaction, and he would not swear to it. A third bottle contained some medicine, in which was present morphia and antimony. The whole bottle, when full up to the neck, would hold $2\frac{1}{4}$ fluid ounces. The quantity which it actually contained was a little over 1 ounce. The quantity of morphia in the whole bottle if it had been full would be very nearly $\frac{1}{6}$ of a grain of acetate of morphia. One drachm, or one medical spoon, would contain $\frac{1}{110}$ part of a grain of the hydrochlorate of morphia. There was also present a small quantity of antimony, equivalent to about 10 minims of antimonial wine of the British Pharmacopœia in each fluid drachm. He thought that four medicinal teaspoonfuls of the medicine administered in two doses would be sufficient to kill a child of that age. He could not say positively. Asked as to the contents of a Steedman's powder, he said there were two kinds, Steedman's and Stedman's. He had analysed both, but could not charge his mind as to which was which. There were two active ingredients in each, calomel and a preparation of mercury, and one contained morphia and the other a proportion of opium. His analysis had been disputed, and he had examined them again and was sure he was correct in stating this. They both contained morphia as active ingredients, and each contained as much as $\frac{1}{120}$ part of a grain of morphia.

After some further evidence had been given,

The Jury returned a verdict, "That the child died from an overdose of morphia and antimony, through the injudicious administration of various medicines," and added that they were of opinion that chemists in dispensing patent drugs should give more detailed and clear instructions as to their use.—*From the Sussex Daily News.*

Pharmacy Acts Amendment Bill.

Sir,—Readers of the Journal had last week an opportunity of reading the opinions of two gentlemen concerning pharmacy and the new Bill. Mr. Frazer's opinions will not, I believe, be shared by the majority of chemists. Free trade is undoubtedly the great bulwark of England, but I cannot see that free trade in pharmacy is at all desirable,—no more, in fact, than is that of dynamite. A little has been obtained with each appeal to the Legislature and no doubt we shall get a little more if this Bill is progressed with, if not perhaps all we ask for. If we have to qualify ourselves we have a perfect right to some amount of protection. There will be sure to be opposition to the clause which will touch the legality of stores carrying on a chemist's business; but I do not think that the whole Bill will be endangered because we ask that a loophole in the 1868 Act should be stopped. In fact the different courts of law were undecided whether it was intended by the last Act or not.

The dispensing by stores is more of a vital interest to the chemists of London and a few more large towns; it is not a heart-burning question to the majority of country chemists.

There is far too much reticence observed in asking for extended privileges; we ought to assert them. I maintain they are really for the benefit of the public. Thousands of people place themselves in the hands of chemists; and it is well shown that the trust is not misplaced, by the scarcity of mistakes which occur.

I hope that the new Bill will be well supported by all chemists, and pressure should be brought to bear on it by writing to their representatives in Parliament.

With the new Bill in view and the likelihood of one qualification only being recognized in the future, the severity of the Major examination should be reduced for present Minor men, and not increased, by introducing estimations of solutions for total alkaloids and then for the quinine and such like, in a limited space of time. The present Minor is more difficult than the Major was a few years back, which gives the title of "pharmaceutical chemist" to so many of our present Major men.

Pharmaceutical chemists are a most heterogeneous crowd, with qualifications of all kinds, the worth of which can only be decided by the date of the diploma, whilst there are some who have no qualification, *i.e.*, by examination, at all. The sooner we have one bold front the better.

Darlington. An Associate.

The Registration of Sales of Poison.

Sir,—It would seem sometimes as if, with all our vaunted educational advances and our compulsory examinations, there are still a great many who cannot read, or reading cannot understand, the English of our Poisons Act, in so far as it concerns that portion of the 17th clause which reads, "and on every sale of any such article the seller shall . . . make . . . an entry in a book . . . to which entry the signature of the purchaser . . . shall be affixed."

One would scarcely think it possible for this to be misunderstood, so plainly is it worded. Yet, when entering a sale, I am so often told that "Mr. A—— never requires my signature because he knows me;" or, as is very frequently the case with photographers, that "Mr. B—— never made me sign for cyanide after the first time," that I determined to get official opinion on the legality of such sales. Accordingly, I wrote to the Secretary of the Pharmaceutical Society, and I give below his reply, just received, that those who have hitherto unwittingly broken the law may have no excuse for its further violation.

Extract.—" . . . 'and on every sale' can have no other meaning than that the process (registration) should be gone through every time any of the articles are sold."

Manchester. H. Kemp.

ACETIC ETHER.

Sir,—As Dr. Clark assumed, I did notice the discrepancy between Professor Redwood's figures and my own.

I think Dr. Clark will at once see the cause (if, indeed, he has not already done so) if he looks at his figures as published in the Journal. He will find that the quantity of rectified spirit given is 10 ounces, not 10 fluid ounces, which it should have been.

I did not, at the time of writing, observe that the same number of c.c. was given as the equivalent of 10 ounces of spirit and 10 fluid ounces of sulphuric acid. I have not yet had time to estimate the amount of acetic ether in the sample I have now on hand, but am quite prepared to find that it contains alcohol, and, indeed, have done so. I may say that I have not made any of the preparation in question for some years. Indeed, having made it and finding its gravity to agree almost exactly with the authority which I consulted, I assumed, not, perhaps, unnaturally, that I had got a pure article, and when I found a house which supplied an article free from acid and of the same gravity, I was satisfied to buy from them, and have done so since.

Liverpool. ALFRED C. ABRAHAM.

PARRISH'S SYRUP AND POTASSIUM CHLORATE.

Sir,—A few days ago, after a mixture consisting of 1 drachm of chlorate of potassium with 4 ounces of Parrish's chemical food had been dispensed some little time, the red colour of the syrup was noticed to have entirely disappeared.

The physician who prescribed the mixture was not aware that such would be the result, for upon seeing the bleached syrup when next visiting his patient he brought it, together with the prescription, back again to the pharmacy for an explanation. He (and his patient too) expected a red mixture, and evidently thought that the chemist was at fault, and not that the chemicals had been at work. Upon finding that the former was not to blame, but that it was the potassic chlorate among the latter which caused so much havoc to be made with the colouring matter, he discarded it, and ordered the simple (?) compound syrup.

Upon making another quantity in the same proportions the red colour gradually disappeared, and in a few hours had passed to that of a pale straw. A portion of the chlorate of potassium remained undissolved.

A cursory examination being made, it was thought that the free phosphoric acid acting upon the chloric radical, eventually reducing it to hydrochloric acid and liberating nascent oxygen, might probably be the cause of the bleaching effect, free hydrochloric being found in the bleached syrup. The original red syrup, however, was found to contain hydrochloric acid. It would appear likely that the cause might be traced to the decomposition of some secondary chlorine compounds, as there is a strong smell of chlorine upon uncorking the bottle containing the mixture even now, the chlorate of potassium being entirely dissolved or rather assimilated.

As there may be some who, not having noticed the above fact, might in such a case be misjudged of having used syr. ferri phosph. instead of syr. ferri phosph. co., they being now forewarned will be forearmed.

I hope that this letter will be the means of again opening up the instructive, interesting and useful dispensing column which lately has been closed, to the regret of many of the apprentices, associates and members of your Society, and that it will lead to further investigation of the subject.

13, *Baker Street, W.* T. H. PROSSER.

PHARMACEUTICAL ASSISTANTS IN INDIA.

Sir,—As an advertisement has recently appeared in the *Pharmaceutical Journal* inviting applications from chemists' assistants for a situation in India, may I be allowed to insert a few remarks upon the general subject, as I have very good reason for believing that considerable misapprehension exists as to the true value of the rupee, and also the cost of living in India.

There are many reasons why a chemist's assistant should be well paid on coming out to India, *e.g.*, the climate is unhealthy and an unnatural one to a European, so much so that instead of a man getting acclimatized through living out here a few years, it is just the reverse; he finds the climate tells upon him the longer he remains. Expenses, taken all round, are 100 per cent. heavier than in England. An assistant is expected to do more than he is in a similar position at home; in addition to long hours, he has night and Sunday duty recurring much more frequently than at home, because often he is single handed, and the so-called chemist, his employer, is not always in truth a chemist. Again, he may have three or four servants to keep, and must do it in unfurnished quarters.

The rupee, nominally two shillings English, is really one shilling and sevenpence (a fraction more or less is neither here nor there), so that to remit £10 home, if he is so inclined, means to put aside 127 rupees,—a rather heavy premium, twenty-seven rupees on a hundred.

He would be a clever man who could manage to save the cost of his passage home in a year on 150 rupees a month. What reward then does he expect for his three years' exile on 100, 125 and 150 per mensem? 100 or 125 rupees a month is mere beggary for a European in this country, a statement which will be re-echoed by every assistant in the land. I am only astonished that any respectable firm should offer such. No man should dream of coming out here on less than 150 per mensem the first year. He ought to get 200 rupees. An assistant cannot throw up his berth just as he likes here; he is practically the slave of his employer, and whether he likes or dislikes his duties or situation, must finish his term, and it behoves him, therefore, to secure for himself the best terms he can. A master may easily find an excuse to act without an incompetent (?) or unsuitable assistant; the latter cannot so easily slip the noose! MINOR.

PHARMACOGRAPHIA.

Sir,—In a paper by Professor Henry E. Armstrong, Ph.D., F.R.S., on "Turpentine; its Nature and Adulterations," published in your issue of January 20, 1883, occurs a passage, which I have only just now observed, but which I desire to amend, as it might be misinterpreted. Professor Armstrong has occasion to refer to me, and assigns to me the title "American Editor of the 'Pharmacographia.'" This title, which was probably not meant in a literal sense by Professor Armstrong, does not belong to me. There have only been two editions, in English, of the 'Pharmacographia,' both published by Macmillan and Co., of London, the editors of the first edition being Professor Flückiger and Mr. Daniel Hanbury, and of the second edition, Professor Flückiger alone. No reprint or edition has ever been published in the United States.

The notes which I have been enabled to place at the disposition of Professor Flückiger, as a contribution towards the second edition, were too insignificant both in nature and extent to deserve editorial honours.

New York. CHARLES RICE.

Errata.—In the paragraph in the "Month," on p. 797, col. ii., respecting the use of stillingia, Dr. Sims's formula should have been given as follows:—

Fl. ext. of Smilax sarsaparilla,
" " Lappa minor,
" " Phytolacca decandra,
" " Stillingia sylvatica, āā ℥ij.
Tinct. of Xanthxylon Carolinianum, ℥j. M.

On p. 838, col. ii., line 2 (in some copies), *for* "Bailey," read "Baily."

On p. 839, col. ii., line 5 (in some copies), *for* "10 per cent.," read "6½ per cent."

S. and D. McKinney.—The kola nut is the fruit of *Sterculia acuminata*, and its seeds are known to contain a considerable quantity of theine. We are not aware that any formula for a pharmaceutical preparation has been published. An analysis of the nut will be found in a paper on the "Food Value of the Kola Nut," by Professor Attfield (*Pharm. Journal*, [2], vi., 457).

Minor Associate in Business.—The subject of the first part of your letter is dealt with in the Bill in the sense that you wish; the subject of the second would probably be arranged by bye-law.

D. Buchanan.—We are unable to identify the leaves sent.

Herbalist.—(1) *Lamium purpureum.* (2) *Anemone nemorosa.* (3) *Cardamine sylvatica.* (4) *Fegatella conica.* (5) *Ranunculus Ficaria.*

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Samuel, Boa, Willing, Sell, Davenport, Hocken.

"THE MONTH."

The proverbial April showers have this year been conspicuous by their absence, and in spite of the warm sun and the fact that the time of the singing of birds is come, the floral harbingers of spring have not yet assumed their wonted beauty. The cold nights and keen north-east winds have in many places nipped the young buds, and probably by lessening the supply of sap have prevented the proper development of the flowers. At the Botanical Gardens, Regent's Park, the almond trees and mezereon can hardly be said to have blossomed, so few and short lived have been the flowers. In the Economic House, however, the cassia and cinnamon plants have presented a very pretty appearance, the graceful panicles of small white flowers and the young leaves tinged of a brilliant crimson forming quite a picture. At Mr. Ware's nursery, Tottenham, several interesting medicinal plants were observed in blossom. Among these were *Adonis vernalis*, only recently introduced into medicine, *Anemone Pulsatilla*, *Mandragora officinalis* and *Sanguinaria canadensis*.

In sheltered nooks in the South some early flowers may be met with, but even in the Isle of Wight a correspondent could only find this month one hundred and twenty-three species as against one hundred and fifty-eight at the same date last year. Among those noticed by him were *Genista tinctoria*, *Helianthemum vulgare*, *Sanicula europœa* and *Pedicularis sylvatica*. *Smyrnium Olusatrum*, a plant which was formerly used in medicine, under the name of Alexanders, may now be found in sunny places by the seaside in the South of England, just opening into blossom, and the pinkish flowers of the butterbur, *Petasites vulgaris*, may be met with by the sides of streams and in damp places, where later on its leaves will form a far more conspicuous object.

In the Winter Garden, at Kew, *Smilax China* is now in flower. The flowers are small and green, but the red tints of the young shoots, the leaf-stalk and peduncles, as well as the bronze shades of the bright shining foliage, render the plant a pretty object. The woody tuberous root forms the China root of commerce, an article now rarely imported.

In the open ground at Kew several medicinal plants are in bloom. The purplish blossoms of the asarabacca (*Asarum europœum*) and the American wild ginger (*Asarum canadense*) are so hidden underneath the leaves that they might easily pass unobserved. The anthers in these flowers, sessile on the style and terminating in pointed appendages, are worth notice. The former species is sometimes found in botanical gardens, labelled *A. canadense*, but the latter is easily distinguished when the two grow together by its larger hairy leaves and larger flowers with reflexed sepals. The broad leaves of the colchicum now form a conspicuous object and are in the best condition for the herbarium. *Podophyllum peltatum* is opening its leaves after the fashion of a miniature umbrella and the white flower buds are just peeping forth. Several rare British plants may also be looked for in blossom this month. *Doronicum Pardalianches*, *Leucojum vernum*, *Myrrhis odorata*, *Corydalis solida* and *C. lutea*, *Fritillaria Meleagris*, *Muscari racemosum*, *Allium triquetrum*, *Ornithogalum nutans*, *Geum rivale* and *Claytonia perfoliata* are all now in blossom at Kew and should be looked for in the localities where they grow wild. The horsetails, too, are now sending up their fertile stems, so different in appearance from the barren ones produced in the early summer as to be scarcely recognized by the tyro in botany. *Equisetum arvense*, in clayey fields and by roadsides, and *E. maximum*, near ponds and in damp places, are the most noticeable species at this time of year; the latter is distinguishable at sight by its much larger size, the heads bearing the sporangia being often 2 inches long and more than ½ inch in diameter. The curious elaters borne by the spores are best seen by examining them in the dry state with a hand-lens or microscope, as when wetted they curl round the spores and are much less noticeable.

Adenandra fragrans, the leaves of which were offered as buchu in the London market a short time ago, is now in flower at Kew. The curious glandular bodies at the apex of the stamens, which give the name to the genus, are curved back between the petals when the anthers open, while at the base of each petal there is an erect cylindrical staminode or abortive stamen tinged with pink. Whether or no these appendages are useful for attracting insects does not appear to be known.

The yellow root, *Xanthorrhiza Apiifolia*, a North American tonic bitter, containing berberine, official in the U.S.P. of 1870, but now expunged, is also at present flowering freely at Kew, forming a fine mass in the dell near the flagstaff, where the cool damp soil suits it perfectly. It is a small bush with yellow creeping underground stems, which send up abundance of suckers and thus form a large clump. The leaves are irregularly pinnate and the minute flowers are borne in rather large branching spikes of a dark purple colour.

From Mr. Lynch, the Curator of the Botanical Gardens at Cambridge, we learn that the mastic tree is now in flower there, a somewhat rare occurrence. *Anemone Pulsatilla* and *Cochlearia officinalis* are in full bloom and the sumbul plants are pushing up strongly, quite uninjured by the bitterly cold winds. Among many other rare British plants, *Selinum carvifolium* is now being cultivated successfully at these gardens.

At a recent meeting of the Linnean Society, the leaves of *Arum italicum* were exhibited, obtained from a new British locality. Swanage, Torquay and Folkestone Warren have already been added to the list of localities where the plant occurs in Britain, and doubtless it will be found in many other places on the South Coast by those who will take the trouble to look for it. The leaves are of a shiny glossy green, quite different from the dull green hue of *A. maculatum*; the spadix is yellow and the spathe much more membranous, and the plant flowers in May and June.

At a recent meeting of the Hertfordshire Natural History Society, Professor Attfield communicated some observations on the sap of the birch tree, in addition to those already published in this Journal. A suggestion having been made to him that the sugar contained in the sap was probably the result of the action of some schizomycetous fungus or other ferment, a specimen of sap was re-examined by Mr. Dunstan, at the request of Professor Attfield, and the presence of a ferment capable of transforming starch into sugar was recognized. When estimated by Messrs. Dunstan and Dimmock's process (*Pharm. Journ.*, [3], ix., 733), it was found that the quantity of this ferment contained in one gallon of the sap was capable of converting into sugar 21 grains of dry starch. It appears probable that like other ferments this one may become active on reaching a certain temperature and become inactive below it. An investigation in this direction might reveal some interesting results. Some experiments made about ten years ago by Mr. W. S. Clark, the President of the Agricultural College of Massachusetts, showed that the composition of sap differed remarkably according to the date of its flow, and also in the time at which it began to flow, and in the rate of pressure exerted. The temperature of the soil and of the atmosphere also gave rise to variation in amount. The relation which the structure of the wood in different trees and the time of flowering bear to the flow of the sap are other points worthy of investigation.

Probably most botanists have observed the central purplish flower in the umbel of the carrot, but may not have noticed whether it was sterile or fertile. In the *American Journal of Pharmacy* (1882, p. 585), Professor Maisch remarked that the central flower was usually barren in the United States as in Germany. In the same Journal (1883, p. 163) it is now stated that the flower is usually represented as fertile in Europe and sterile in the United States. Mr. Thomas Meehan, however, points out in the *Proc. Acad. Nat. Science*, Philad. (1882, p. 221), that while in the first umbel expanded the purple flower is fertile, this is not the case with those in the umbels from lateral shoots.

In Hanbury's 'Science Papers' (p. 238, fig. 5), a seed named *Te-tsaou-tow*, is figured, and doubtfully referred to "*Dialium ? Leguminosæ*," of which at that time the plant was unknown. In the last number of Hooker's 'Icones Plantarum,' the plant yielding these seeds is figured and described, having been previously named by Dr. Baillon. It belongs to the genus *Gymnocladus* and is named *G. Chinensis*, Baillon. Specimens of the pods have been sent to Kew from Fokien, by Mr. F. S. A. Bourne, of Her Majesty's Consular Service. These pods are 3 to 4 inches long and hard and horny in the dried state, but capable of swelling up greatly in water. In China they are used for washing purposes, the outer shell being steeped for two days in water and the liquid resulting from it used as soft soap or dried into hard soap (*Gard. Chron.*, April 21, p. 499). The use of the seed is not stated.

The cultivation of drug-yielding plants seems to form an important feature in the Botanical Gardens at Saharunpur (*Nature*, April 19, p. 588). During the past year *Fraxinus ornus*, *Guaiacum officinale* and *Rheum palmatum*, var. *Tanguticum*, one of the supposed sources of Chinese rhubarb, have been added to the gardens. Dr. Duthie proposes to cultivate either on the hills or at Saharunpur, aconite, aloes, buchu, calumba root, colchicum, digitalis, gentian, jalap, liquorice, scammony, colocynth and others. This will be done with the view of supplying drugs for the use of the medical department, for which extracts of henbane and taraxacum have already been made from plants cultivated in India. It seems that the cost of maintaining these gardens has hitherto much exceeded the income derived from them; it may be hoped, therefore, that this new departure will bring about a different state of things.

Attention has recently been drawn in the United States to the medicinal properties of *Polygonum hydropiperoides*, a plant which Dr. Eberle in his work on 'Materia Medica and Therapeutics speaks of as the most active and certain of emmenagogues. It was also held in estimation by Professor M. B. Wright, of Cincinnati, who prescribed it with considerable success. The form of administration most in favour appears to be the fluid extract, which is given in doses of 5 to 30 minims three or four times a day mixed with wine or glycerine. The activity of the drug is supposed to be due to the same active principle as previously isolated from *P. Hydropiper*, L., by Dr. C. J. Rademacher, in 1871 (*Pharm. Journ.*, [3], ii., 426). *Polygonum hydropiperoides* is said to have a decided stimulant, even vesicant property, when rubbed into the skin, whence its common name of smartweed. The *American Journal of Pharmacy* gives Michaux as the authority for the species, but according to Gray's 'New Manual of Botany,' that species is not acrid. The plant intended, therefore, is probably *P. hydropiperoides*, Pursh., which is described by Asa Gray under the name of *P. acre*, H.B.K., and differs from the English species, *P. Hydropiper*, in having larger leaves, erect flower spikes, whitish flowers and smooth, shining, sharply triangular achenes.

The results of an examination of the Californian "manroot" (*Megarrhiza Californica*), used by the Indians as a drastic purge in dropsy, was reported recently by Mr. W. M. Young to the Californian College of Pharmacy (*Proceedings*, p. 52). He confirms the presence of very bitter glucosidal principle, called by Heaney (*Pharm. Journ.*, [3], vii., 393) "megarrhizin" and said by him to closely resemble colocynthin, which was found to be purgative in doses of a quarter of a grain. Mr. Young also found another glucoside, resembling saponin, and possessing the power of dilating the pupil; this he has named "megarrhin."

A fluid extract of the flower heads of red clover (*Trifolium pratense*) having been introduced in the United States as a remedy for whooping cough and scrofula, and an infusion as a wash for ill-conditioned ulcers, Mr. Grazer, submitted some flower-heads to analysis. He found two resins (one soluble in alcohol and with a yellow colour in caustic potash solution; the other soluble in ether and with a green colour in caustic ammonia) as well as a peculiar acid principle; but he does not appear to think that there is any principle present to which a special therapeutic action could be attributed.

A singular effect of corrosive sublimate, first observed by Salkowski, has recently been confirmed by Prévost and Trutiger, of Geneva (*Lancet*, April 14, p. 640). They have found that it causes the lime to be removed from the bones to the extent of 2 to 4 or sometimes 8 to 10 per cent. and to be deposited in the cortical substance of the kidneys, so that the kidneys appear almost as if petrified, while the bones, at least in the case of rabbits, become so altered that the epiphyses of the long bones are at length movable on the shaft. This decalcification takes place to the greatest extent when the doses of the poison are such as to cause death in three or four days, but are too small to kill in twenty-four hours.

The alkaloid pelletierine, which has recently been introduced into medical practice as a tænifuge, appears to require caution in its use. A case is mentioned in the *Medical Press and Circular* (April 11, p. 316), in which a dose of 8 grains is said to have caused alarming symptoms. The patient had vomiting and diarrhœa, and the body became cold and exsanguine, and only recovered from the state of collapse after medical treatment for a hour. It is not stated whether the pure alkaloid or the tannate was used, but it is singular that similar cases have not been reported before, if the symptoms were not due to idiosyncrasy.

In the new volume of the *St. Bartholomew's Hospital Reports*, there is an interesting paper by Dr. Lauder Brunton and Dr. T. Cash, on the influence of various alkaloids and alkaloidal salts in arresting the process of oxidation set up by the vegetable protoplasm of the potato and by blood, as indicated by the degree of coloration produced when tincture of guaiacum was brought into contact with potato infusion or diluted blood to which one of the chemicals had been added. The authors state that in comparative experiments it was observed that oxidation in a potato infusion was diminished most powerfully by strychnine; then by quinine and conine; next almost equally by morphine, codeine, cinchonine and atropine; next by nicotine, and then by veratrine. Aconitine did not seem to affect the oxidation. On the other hand, caffeine, picrotoxin and digitalin appeared to hasten the oxidation. When blood was used cinchonine showed the greatest power of retarding oxidation, then came veratrine, morphine, quinine, codeine and atropine, whilst strychnia appeared to have much less power than in the case of potato infusion. Of the salts of morphia, the acetate and bimeconate had almost no action, whilst the hydrochlorate and iodide appeared to accelerate oxidation.

Dr. R. Külz has been engaged upon an investigation of laserpitin, the bitter principle found in the root of *Laserpitium latifolium*, popularly known in Germany as "white gentian root," with the object of determining its composition and also whether it is allied to such bitter principles as peucedanin, athamanthin, and ostruthin, occurring in other umbelliferous plants (*Archiv*, xxi., 161). The laserpitin was obtained in large colourless prisms by exhaustion of the finely sliced root with light petroleum spirit, distilling off the greater part of the solvent, and leaving the coloured residual liquid to evaporate spontaneously. The crystals were insoluble in dilute solutions of caustic alkalies and acids, freely soluble in chloroform, ether, benzol, and carbon bisulphide and much less soluble in alcohol; they melted at 118° C., and the mean of a number of analyses corresponded closely with the formula $C_{15}H_{22}O_4$. Laserpitin forms a crystalline compound with acetic acid ($C_{15}H_{22}O_4 . C_2H_4O_2$), and acetyl, nitro, and brom derivatives were also obtained. Treated with strong sulphuric acid it is decomposed, with formation of methyl-crotonic acid, and with alcoholic hydrochloric acid the isomeric angelic acid is produced, whilst fusing with caustic potash gives the former, and boiling in a solution of it gives the latter, the other substance formed being a resinous body which has been named "laserol." None of the decomposition products obtained by the author corresponded with those obtained under similar conditions from peucedanin, ostruthin or athamanthin.

The seeds of *Nigella sativa* have again been subjected to a chemical examination, this time by Dr. Pellacani (*Archiv f. exp. Path. und Pharm.*, xvi., 441). The author reports the isolation of two alkaloids, nigelline and connigelline, which resemble the active principles of jaborandi in their physiological action. To the presence of these two alkaloids the therapeutic effects of the seeds, as observed by Dr. Canolle, are to be attributed.

The leaves of four species of cinchona, grown in California, have been submitted to an examination by Mr. Haffenberger, who reports (*Proc. Cal. Coll. Pharm.*, p. 53) that he has obtained an average of 2 per cent. of alkaloid from the leaves of *C. Calisaya*, 1·8 per cent. from those of *C. succirubra*, and 0·66 and 0·70 per cent. from those of *C. officinalis* and a hybrid respectively. In the calisaya leaf the bulk of the alkaloid, 4 per cent., was found in the midrib, and only 0·76 per cent. in the lamina. The alkaloids from this species consisted of quinine, quinidine, cinchonine and cinchonidine, the quinidine constituting about one-half of the whole. These results resemble those obtained in an analysis of cinchona leaves made some years ago by Mr. J. E. Howard (*Pharm. Journ.*, [2], v., 368).

During the past month *Andrographis paniculata* has been offered in the London market for chiretta. The demand for bitters, owing to the scarcity of hops, seems to have led to an increase in the number and quantity of such drugs imported, as many as 906 bags of calumba root having been offered at the last drug sale in London.

More than a ton of Calabar beans were also put up for sale and 41 bales of scammony root, a drug which has lately been scarce and dear and of which it was stated that the exportation had been stopped by the Turkish Government. From some specimens recently received it would appear that boldo is known in Chili as "boldu." This is a lauraceous plant, *Cryptocaryx Peumus*. The leaves are ovate and leathery, whitish below, with an odour resembling that of bay leaves.

For some months past an oil has appeared in the London markets under the name of Japanese cod liver oil. According to the *Oil, Paint and Drug Reporter* (Dec. 20, p. 1353), it is made from various species of fish, and is extracted during the process of treating fish scrap for fertilizing purposes. The reason of its introduction into this country is said to be that it was refined and used in Japan as an illuminating oil before the introduction of petroleum into that country, but that now another market has to be sought for it in consequence of the lower price of that oil. It resembles ordinary cod liver oil in colour and odour, but is said to be more affected by cold. It is put up in cans each containing 2 to 5 gallons.

Alicante saffron has already a bad name in commerce and it seems probable that the misplaced ingenuity of those who manufacture the drug will lead ultimately to the destruction of the trade in it. A new adulteration of this commercial variety of saffron has been described by Dr. J. Biel, in *Pharm. Zeitsch. f. Russland.* It consists of marigold florets (*Calendula officinalis*) coloured with dinitrocresylate of sodium, then impregnated with oil and rolled up lengthwise, and mixed with 4 to 30 per cent. of true saffron. The adulterated saffron colours water yellow and gives an amount of ash equal to that of the true drug. It is detected by imparting to petroleum spirit a lemon-yellow colour, the colouring matter of saffron not being soluble in that liquid. Dinitrocresylate of sodium, giving a colour like that of saffron, being cheap and apparently innocuous, has for some time past been used for colouring liquids.

Herr Hirschsohn has published a paper (*New Remedies*, April, p. 99) in which he speaks favourably of an antiseptic dressing consisting of an oakum made from old tarred ropes saturated with chloride of zinc. A dressing containing 15 per cent. of zinc chloride is prepared by boiling the thoroughly carded oakum for half an hour with ten or fifteen times its weight of a 10 per cent. solution of zinc chloride in a closed kettle; afterwards pressing it between two hinged boards, drying it in thin layers and carding it; or it may be preserved uncarded in waxed paper. If a 10 per cent. dressing be required, a 7 per cent. solution of the dry salt is used, and for a 5 per cent. dressing the strength of the solution is reduced to 3½ per cent. It is pointed out by the editor of *New Remedies* that as oakum would often contain too much tar, ordinary tow might be substituted with advantage.

A comparatively new line of investigation in pharmacy has been taken by Mr. W. E. Saunders, who gives in the *American Journal of Pharmacy* (April, p. 161) a description of insects injurious to drugs. Although an imperfect communication, inasmuch as the descriptions are not sufficient for the identification of the insects, it yet contains some valuable practical remarks. He states that the little brown beetle so common in the cummin seed and many other drugs, while they become uncomfortable, seem to thrive just as well with camphor as without it; the little beetle which feeds on cantharides, while it dislikes camphor, is not killed by it. The vapour of chloroform, however, rapidly kills them.

In the last number of the *Journal für praktische Chemie* (vol. xxvii., p. 231) Herr Heinrich Struve publishes some interesting results obtained in the dialysis of various animal and vegetable substances containing albumen, using an animal membrane that had been treated with ether as a septum and chloroform water or ether as the dialysing liquid. The antiseptic properties of the chloroform were found to be effectual in preventing decomposition, so that the operation could be prolonged during a considerable time without change taking place. Amongst other substances experimented upon was the milk of women and cows, and it was found that by the use of chloroform water in the dialysing operation the whole of the albuminoid substances dissolved in the milk could be separated from undissolved casein and butter. A portion of the undissolved casein constituted the enveloping material of the milk globules and this separated with the cream, whilst the other part remained in the "skim" milk. Herr Struve's observations and experiments have led him to the conclusion that the digestibility of any particular milk is in inverse relation to the quantity of this undissolved casein which is not taken up in the formation of the milk-globule envelope, and he, therefore, endorses the recommendation of Dr. Biedent that in the artificial nourishment of infants, at first, only the cream of cows' milk should be used.

In a paper read before the Applied Chemistry and Physics Section of the Society of Arts (*Journ. Soc. Arts*, April 20, p. 545), Professor R. W. Atkinson called attention to the subject of the formation of diastase from grain by the action of moulds, as illustrated in the production of the Japanese fermented drink, "saké." The first steps especially of the manufacture as described, which include the preparation of the diastatic material, appear full of interest to the pharmacist at a time when preparations containing diastase and other ferments are in such great demand. The preparation of *koji* diastase differs in a very marked manner from the malting process. In the case of malt the degradation of albuminoid matter in the barley grain, which results in the formation of diastase, is the effect of a vital process or germination, whilst in the case of *koji*, the first step is to destroy all vitality in the rice grain by removing the husk and embryo and then steaming it. The rice after this treatment is placed in contact with growing mould, the mycelium of which penetrates the substance of the grain and there acts upon the starch and nitrogenous matter, liberating carbonic acid and producing certain soluble nitrogenous bodies, which are capable of converting starch jelly into sugar and dextrin. After the rice has been mixed with the fungus spores it is spread out on trays, which are arranged in underground chambers, kept at a temperature between 79° and 84° F., the heat developed during the growth of the fungus being ample for this purpose. The action does not give rise to the evolution of any ammonia, possibly because the fructification of the mould is avoided except when a fresh supply of spores is required. In the freshly finished *koji*, the soft and swollen grains of rice appear bound together into lumps by fine white silky filaments. Water at a temperature of 113° F. almost entirely dissolves it, leaving only the cellulose skeleton of the grain and mycelium. Treated with cold water a considerable portion dissolves, forming when filtered a golden yellow solution possessing in a marked degree the property of converting starch into sugar. It is worthy of notice that the conversion does not, as in the case of malt, stop short at the production of maltose, but that hydration of the maltose readily takes place, with the formation of glucose. Professor Atkinson is unable to give any very definite information as to the nature of the mould employed. The powder sown is of a yellowish-green colour, and appears to be a mixture of spores, principally of species of *Penicillium* and *Mucor*; this is confirmed by the fact that it is used also in the production of yeast, and that it sometimes gives rise to the butyric fermentation.

In a recent valuable communication on the salts of caffeine (see before, p. 103) M. Tanret cast a doubt upon the existence of true saline compounds of caffeine with the organic acids, and especially disputed the formation of an acetate, valerianate, citrate or lactate. As this was contradictory of some published experience, Professor Schmidt, of Halle, requested Dr. H. Biedermann to work out the subject, and in the current number of the *Archiv der Pharmacie* there is a paper containing descriptions and analyses of a number of definite salts of caffeine, including the formate, acetate, butyrate, and valerianate, as well as the hydrochlorate, hydrobromate, nitrate, sulphate, aurochloride and platinochloride. According to Professor Schmidt the salts may, as a rule, be obtained by dissolving the caffeine, with a moderate amount of heat, in the respective concentrated acids; upon cooling the salts usually crystallize out, but if not, crystals of the salts may be obtained by keeping the solutions over chloride of calcium. It is admitted, however, that these salts are all very unstable, splitting up when brought into contact with water or alcohol, and that they are therefore quite unsuited for medicinal use.

The essential oil of angelica root has been the subject of an investigation by M. L. Naudin. He states (*Comptes Rendus*, xcvi., 1152) that when obtained by distillation in the vapour of water it is a mobile liquid, sp. gr. at 0°, 0·875, with an odour of angelica much less delicate than that possessed by oil from the seeds. When freshly distilled it is colourless, but it becomes yellow if exposed to the light. It absorbs oxygen and resinifies slowly. Experiments showed that the oil of angelica root is composed of a single terpenic carbide, boiling at 166° C., and with a density of 0·870, which M. Naudin calls "β-terebangelene," mixed in the commercial oil with various polymers, formed by the action of heat during the distillation and augmenting in quantity with the age of the oil. The essential oil of angelica seeds also consists of a single carbide, "terebangelene," boiling at 175° C., and much more alterable by heat than its isomer from the roots.

In the production of œnanthol from castor oil by distillation, Stanck found that a highly elastic sticky substance resembling caoutchouc remained behind in the retort. Professor A. R. Leeds (*Ber.*, xvi., 290) has made a further examination of this substance, which he obtained by distilling castor oil *in vacuo* until all the œnanthol had passed over. On washing with ether and alcohol the stickiness and elasticity disappeared, and on analysis the formula of the substance was found to be $C_{42}H_{68}O_5$, which agreed with that obtained by Stanck. The substance thus purified was saponified with potassium hydrate and the filtrate precipitated by hydrochloric acid, by which means a light brown oil was obtained, which was insoluble in water and only slightly soluble in alcohol and ether. When purified from ether its formula was found to be $C_{36}H_{68}O_7$. The solution from which this substance had been precipitated contained no glycerin. The oil was fractionally distilled, and the portions distilling at 120°, 180° and 220° C., collected. These oils formed no salts with either potassium or sodium. Thus the experiments of the author do not confirm the view of the constitution of the substance taken by Stanck, namely, that it was an acryloxy-compound which was capable of yielding pyroricinic acid ($C_{36}H_{60}O_3$) and acrolein.

The vapour density of sulphuryl chloride (SO_2Cl_2) has been studied by Messrs. Heumann and Köchlin (*Ber.*, xvi., 602) with extremely interesting results. These observers find that at the temperature of boiling aniline (184° C.) the vapour density is normal (4·5); but at the boiling point of sulphur (442° C.) the vapour density is only 2·36, that is to say, that at this temperature sulphuryl chloride is dissociated into sulphur dioxide and free chlorine, thus, $SO_2Cl_2 = SO_2 + Cl_2$. These gases were detected and separated by passing the mixture over lead peroxide, by which means the sulphur dioxide was retained as lead sulphate, and the chlorine which passed on was detected by the liberation of iodine from potassium iodide. The same observers have determined the vapour density of chlorosulphonic acid ($SO_2.OH.Cl$), a substance possessing interest from the fact that its discovery by Williamson led to the present view of the constitution of sulphuric acid as a compound of two hydroxyl groups with one molecule of sulphur dioxide. Williams (*Journ. Chem. Soc.*, vii., 304) had previously shown that the vapour density of this substance at 216° C. was rather more than half the normal calculated density, and he accounted for this by supposing that the compound was at this temperature dissociated into hydrochloric acid and sulphur trioxide, thus, $SO_2.OH.Cl = SO_3 + HCl$. Heumann and Köchlin have confirmed the correctness of the vapour density determination, but consider that the explanation is not in harmony with the general behaviour of chlorosulphonic acid. A determination of the vapour density at 442° C. gave 2·09 instead of the normal 4·04, which these observers explain by the following decomposition:—$2(SO_2.OH.Cl) = SO_2 + Cl_2 + SO_3 + H_2O$, and they further consider that at 216° C. this same decomposition occurs, but at that temperature it is only partial. This explanation appears to be in harmony with previous observations.

A new synthesis of anthracene has been made by Messrs. Anschütz and Eltzbacher (*Ber.*, xvi., 623) by the action of aluminium chloride upon a mixture of benzene and acetylene tetrabromide, thus, $2C_6H_6 + C_2H_2Br_4 = C_{14}H_{10} + 4HBr$. The reaction may be represented as the removal of four atoms of hydrogen from the benzene by four atoms of bromine in the acetylene tetrabromide, the two benzene residues, $2(C_6H_4)$, being then held together by $2(CH)$ constituting anthracene, $C_6H_4\begin{matrix} \diagup CH \diagdown \\ \diagdown CH \diagup \end{matrix}C_6H_4$.

A new and delicate test for aldehydes has been discovered by Messrs. Penzoldt and Fischer (*Ber.*, xvi., 657), which is based upon the fact than in presence of a caustic alkali, aldehydes give a violet-red colour with an alkaline solution of diazobenzenesulphonic acid. The reaction is more delicate if sodium amalgam be added. The authors recommend the following method of applying the test. One part of freshly prepared diazobenzenesulphonic acid is dissolved in 60 parts of cold water rendered alkaline with caustic soda. To this solution is added the substance to be tested for an aldehyde, previously mixed with dilute caustic soda solution. A small fragment of sodium amalgam is added, and the liquid allowed to stand for about twenty minutes. If an aldehyde is present an intense violet-red coloration is produced. This reaction is easily given by a solution containing 1 part of oil of bitter almonds (benzoic aldehyde) in 3000, and has been obtained by the authors with acetic, valeric, and œnanthylic aldehydes, also with furfurol and glyoxal. Chloral does not give the reaction. Acetone and acetic ether give a red colour, but without the characteristic violet tint which is yielded by an aldehyde. The reaction is not given by phenol, resorcin or pyrocatechin. It is somewhat remarkable to note that the reaction is given by grape sugar, which does not give the reaction for an aldehyde with other reagents for this substance, as sodium bisulphite or "fuchsin sulphite." The present test is said to be more delicate than this latter reagent, which is a solution of fuchsin decolorized by sulphurous acid. The authors consider that this reaction points to the fact that grape sugar is probably a ketone-alcohol, as has been suggested by other observers. The composition of the violet-red colouring matter is unknown.

It is well known that when pure zinc is mixed with sulphuric acid and water very little hydrogen is evolved, but upon the addition of a small quantity of platinum perchloride the action proceeds energetically. Ballo has shown that similarly the metal magnesium is incapable of decomposing pure water, but on the addition of a trace of platinum perchloride hydrogen is copiously given off and hydroxide of magnesia deposited. The observer of this reaction recommends (*Ber.*, xvi., 694) the use of platinized magnesium as a general reducing agent. A dilute alcoholic solution of nitrobenzene was treated with a drop of platinum perchloride and a small piece of metallic magnesium. Hydrogen was rapidly disengaged and hydroxide of magnesia precipitated. The solution after filtering gave the usual reaction for aniline, and the nitrobenzene was wholly reduced. This method of testing for nitrobenzol has this advantage over the ordinary method with an acid and zinc or iron, that the aniline is liberated in the free state and can at once be detected in the filtrate without the addition of potash and subsequent filtration as is necessary in the latter method.

In considering the analogies that exist in one or two instances between selective absorption of light and selective absorption of radiant heat, Professor Tyndall has been led to discover experimentally "a hitherto unobserved resemblance between carbonic acid and bisulphide of carbon" (*Chem. News*, April 13, p. 169). As is well known, when by means of an electric current a metal is volatilized and submitted to spectrum analysis, the "reversal" of the bright band of the incandescent vapour is commonly observed, this being due to the absorption of the rays emitted by the vapour by the partially cooled envelope of its own substance which surrounds it. The author finds that an analogous phenomenon is manifested in respect to radiant heat in the case of hot carbonic acid gas and cold carbon bisulphide. Carbon bisulphide is the most diathermous body known for all ordinary sources of radiant heat, a thin layer of it transmitting 90 per cent. of the radiation from hydrogen gas; but under the same conditions it transmits only 25 per cent. of the radiation from carbonic acid gas, the remaining 75 per cent. being absorbed. This result goes to confirm the accepted atomic structure of these bodies.

Rather more than five years since Messrs. Cailletet and Pictet, working independently, demonstrated the possibility of liquefying oxygen and nitrogen, but the conditions under which the experiments were performed precluded more than a momentary evidence of their success. It remained still to effect the liquefaction under conditions which would allow of the products being examined more minutely, and this is now reported to have been accomplished by Messrs. Wroblewski and Olszewski (*Comptes Rendus*, xcvi., 1140), who have availed themselves of the intense cold produced by the vaporization in a vacuum of liquid ethylene, which under the pressure of one atmosphere boils at a temperature of about $-105°$ C. The critical point of oxygen occurs, however, at a much lower temperature than this. In a series of experiments the gas was found to commence to liquefy at a temperature of $-131{\cdot}6°$ C. under a pressure of 26·5 atmospheres; at $-133{\cdot}4°$ C. under 24·8 atmospheres, and at $-135{\cdot}8°$ C. under 22·5 atmospheres. Liquid oxygen is described as being colourless and transparent like carbonic acid, very mobile, and forming a very distinct meniscus. Nitrogen is said also to form a colourless liquid, with a perceptible meniscus. The experimenters, in addition, succeeded in freezing bisulphide of carbon at a temperature of about $-116°$ C.; whilst alcohol became viscous at about $-129°$ C., and solidified at about $-130{\cdot}5°$ C., forming a white substance.

INDOPHENOL.*

BY ALBERT H. SAMUEL.

Indophenol is the name given by Mr. Horace Koechlin, of the Lörrach Print Works, Baden, to a new colouring matter, the formation of which he has discovered in the course of a series of experimental researches, in conjunction with Dr. Otto Witt, on the action of nitroso compounds on phenols.

Dr. Witt has published from time to time his researches on the combinations and variations that could be formed, resulting in the production of new blue and violet colouring matters, which are most interesting to those who desire to see the various steps which have led up to the discovery of these new substances.

Dr. Raphael Meldola, an accomplished English chemist, nearly three years ago published an account also of his own personal researches in a similar direction quite independently of Dr. Witt, resulting in forming new compounds of brilliant *violet* colouring matters, and he would seem to have been on the verge of eliminating indophenol, as he worked in pretty nearly the same direction as that which led to the successful discovery accidentally made subsequently by Mr. Horace Koechlin, and it is to the skill and perseverance of Mr. Koechlin that the full credit of this discovery is to be awarded, as well as the manner of practically applying same in printing and dyeing.

Mr. Horace Koechlin and Dr. Otto Witt were prosecuting their researches in the direction of endeavouring to produce a *violet* dye from the action of nitroso-dimethyl-aniline hydrochloride upon α-naphthol.

There are two isomeric modifications of naphthol known to chemists as α and β, and distinguished from each other by the fact that α-naphthol gives a violet coloration when chloride of lime is added to its aqueous solution and β-napthol gives no such coloration with chloride of lime.

Mr. Horace Koechlin's idea was to print a mixture of the ingredients on the fabric in the usual *acid* solution. By accident, on this occasion, however, the solution used, instead of being *acid*, happened to be an *alkaline* one, and Mr. Koechlin at once observed that instead of obtaining the expected violet colour, a *blue* colour was the result. This was so unexpected that he was induced to follow up this striking modification, and after making further experiments on other phenols, he found that this series of aromatic alcohols or phenols are all more or less capable of forming *blue* colouring matters when acted upon by nitroso compounds in an *alkaline* solution, and as it was thought by Mr. Koechlin that these substances might be used as substitutes for the natural production indigo, they received the generic name "indophenols," there being seemingly no other reason for the prefix indo, but this one.

Immediately following these interesting and important results, Mr. Horace Koechlin, in Lörrach (Baden), in conjunction with Dr. Otto Witt, of Mullhouse (Alsace), took out German letters patent for the manufacture of these new blue colouring matters, in which they describe two distinct methods of preparing the same, viz.:—

First Method.

By the action of tertiary aromatic nitrosamines on an alkaline or ammoniacal solution of one of the phenols. The reaction is a very slow one, but can be greatly accelerated by introducing into the mixture a reducing agent, such as zinc in powder, glucose, etc.

The nitroso compound selected by the patentees was nitroso-dimethyl-aniline.

As these names do not convey a clear idea of the process to those who are not conversant with these complex substitution products, it may be as well, perhaps, if I endeavour to explain what is the chemical nature of a tertiary aromatic nitrosamine.

An *amine* is a name given to a class of compounds de-

* Read before the Liverpool Chemists' Association.

rived from ammonia by substitution of alcohol radicals for one or more of the hydrogen atoms in same.

Thus ammonia is chemically known as—

$$NH_3 \text{ or } N\left\{\begin{array}{l}H\\H\\H\end{array}\right.$$

By substituting the alcohol radical *methyl* (CH_3) for one of the atoms of hydrogen we get—

$$N\left\{\begin{array}{l}CH_3\\H\\H\end{array}\right. \text{ or } CH_5N - \text{or methyl-}\textit{amine.}$$

if two atoms of the H are replaced by methyl (CH_3), we get—

$$N\left\{\begin{array}{l}CH_3\\CH_3\\H\end{array}\right. \text{ or } C_2H_7N - \text{dimethyl-}\textit{amine}$$

and if the whole three atoms of H are replaced—

$$N\left\{\begin{array}{l}CH_3\\CH_3\\CH_3\end{array}\right. \text{ or } C_3H_9N_3 - \text{or trimethyl-}\textit{amine}$$

Now aniline may also be considered as an *amine*, in which one of the H atoms is replaced by the alcohol radical phenyl (C_6H_5).

Thus:—

$$N\left\{\begin{array}{l}C_6H_5\\H\\H\end{array}\right. = C_6H_7N - \text{aniline}$$

as above explained *dimethyl-aniline* would then be—

$$N\left\{\begin{array}{l}C_6H_5\\CH_3\\CH_3\end{array}\right. \text{ or } C_8H_{11}N$$

and nitroso-dimethyl aniline—

$$N\left\{\begin{array}{l}C_6H_4NO\\CH_3\\CH_3\end{array}\right. = C_8H_{10}N,NO$$

nitroso-dimethyl aniline is therefore a *nitrosamine.*

Now I have stated that indophenol is prepared by the action of a tertiary aromatic nitrosamine on a phenol in an alkaline solution, and to those who are not acquainted with these phrases the words ' tertiary aromatic" may also need explanation.

The series of organic compounds in question is called by chemists *aromatic*, from the fact that many of its members occur in essential oils, balsams, gum resins, etc., all possessing an *aromatic odour.*

I have already shown the constitution of an amine. Now, if only *one* of the atoms is replaced by a radical, it is called a *primary* amine; if *two*, a *secondary* amine, and if all three atoms are replaced by radicals the compound resulting is called a *tertiary* amine.

You are, I hope, now acquainted with the chemical constitution of a tertiary aromatic nitrosamine. The chemical constitution of the phenols will not, I think, need any explanation, as they are, comparatively, compounds whose chemical formula are simple.

The phenols mentioned by Koechlin and Witt in their patents are ordinary phenol, resorcin, orcin, and the two naphthols already described.

The patentees wish it to be known that their new dyes, the indophenols, differ materially from those previously discovered by Dr. Meldola in his investigations, the latter being formed in *acidulated* solutions with *boiling*, whereas the *indophenols* are produced at the *ordinary* temperature and in *alkaline* solution.

The *second* method employed by the patentees to produce indophenol is as follows:—

First, to reduce the nitrosamine and then to oxidize it in an alkaline solution of the phenol.

For this purpose they dissolved acidulated nitroso-dimethyl-aniline in water and reduced it with zinc powder to the form of paramido-dimethyl-aniline by agitation at a temperature of from 45° to 50° C. The clear liquid is then separated from the surplus zinc and zinc compounds and mixed with a mixture of α-naphthol and oxidizing agents, such as bichromate potass and soda lye. When the contents are completely mixed a weak solution of acid is slowly added and the dye is formed immediately, and is completely precipitated.

With naphthol the dye obtained is *pure blue*, with phenol it is more of a greenish shade, and it varies according to the phenol employed.

Indophenol in powder, as met with in commerce, is formed of the sodium salts. It has both acid and basic properties. Its compounds with acids are light dirty coloured, and soluble in water. Its metallic salts, on the contrary, are bright blue coloured substances and insoluble in water. Indophenol dissolves in alcohol with a blue colour, but is insoluble in water. It is partially soluble in organic acids, and also in *dilute* inorganic acids, but *concentrated* inorganic acids destroy it. Reducing agents transform it into a comparatively colourless compound, called *leuco*-indophenol or white indophenol, a reaction which occurs in other colouring matters. The colour is immediately reproduced by an oxidizing agent and even by the oxygen of the atmosphere.

The *leuco*-indophenol is *indophenol* reduced by a salt of tin in an acid solution. This form of indophenol is a very important one to the calico printers, as it enables them to print with indophenol in combination with other colours (as is constantly necessary in printing fabrics) without the same becoming mixed, and the colours are reproduced subsequently by oxidation and steaming.

The formulæ for printing are given by Mr. Koechlin and were published in a recent number of the *Chemical News.* In conversing with those printers who are using indophenol, they state there are several difficulties yet to be overcome if the substance is to obtain any extensive use as a substitute for indigo and other *blues.* They complain of its being of too delicate a nature, for one thing, that is to say, the steaming must be dry and not exceed half an hour, which will not suit the other colours that are printed with it, and, consequently its use in combination with other colours is much limited on this account. Again, it is not a fast colour in comparison with indigo, and stands washing only moderately, although it has been reported as being unaffected by sunlight or washing.

As to its present practical application in England the information on these points I have been able to glean shows that its use at present is decidedly limited, that it is not applicable practically for dyeing purposes, and that where used in printing it can only be used with safety by itself and not in combination, which limits its application still further. I am informed, however, that it is largely used in the extensive printing establishments on the continent, namely, at Mulhouse, Alsace, and at Elberfeld, in Prussia. No doubt it would come into equally extensive use here, if our practical men were more intimately acquainted with it, as naturally our continental neighbours must have a great advantage in a knowledge of applying it, inasmuch as the patentees are on the spot and are no doubt interested in it, not only as their own discovery but also as a personal commercial success.

The patentees claim a third method of producing indophenol, namely by forming the dye itself on the material to be printed upon.

They describe *three* ways of effecting this:—

1st. They steep the material in a naphthol salt, and after drying, print with a concentrated solution of nitroso-dimethylaniline hydrochloride, in an alkaline solution in which are mixed some reducing agents, such as glucose, zinc, etc. The colour is developed after the usual steaming.

2nd. The material is first steeped in a solution of the reducing agent, and then printed with a concentrated solution of nitrosodimethylaniline and naphthol salt and steaming.

3rd. Bleached calicoes can be printed without previous preparation with a concentrated solution of amido-dimethylaniline and naphthol salt, steamed and then run through a solution of potass. bichromate and washed

The full development of the colour comes out in the bicromate bath.

The patentees claim that there are two special characteristics in which indophenol differs from the violet and other colours obtained by Dr. Meldola and others in prior researches, namely, that the latter are all more or less *fluorescent* and unchanged or dissolved by acids, whereas in the indophenol blues there is an entire absence of fluorescence and they are extremely sensitive to acids.

As already stated, these new dyes, indophenols, are soluble in weak acid solutions, but decompose after a short time, more quickly the higher the temperature is, and form brown substances, the chemical constitution of which is little known.

As regards the chemical constitution of indophenol the patentees state that at present they are only able to express their conjectures, supported by experimental evidence. They find, they say, unexpected difficulties in the way, and therefore their analytical data are incomplete.

They entertain, however, the following formula of indophenol as being probable:—

Indophenol produced by Action of a Tertiary Aromatic Nitrosamine on Phenol.

$$\left.\begin{matrix} CH_3 \\ NCH_3 \\ NO \end{matrix}\right\vdots C_6H_4 + C_6H_5OH$$

Nitrosodimethylaniline. + Phenol.

$$= C_{14}H_{14}N_2O + H_2O.$$

Indophenol (from phenol) Water.

If naphthol instead of phenol be used the formula must be altered accordingly.

Indophenol produced by Action of Oxidation of a Reduced Nitrosamine on Naphthol.

$$\vdots\begin{matrix} CH_3 \\ N\,CH_3 \\ NH_2 \end{matrix}\vdots C_6H_4 + C_{10}H_7OH + 2O$$

Dimethylparapheny-lendiamine (reduced nitrosamine). Naphthol. Oxygen.

$$= C_{18}H_{16}N_2O$$

Indophenol (from naphthol). + $2H_2O$ Water.

There seems to be an impression that this new dye indophenol, and the substance known as artificial indigo, are one and the same thing. This of course is not so.

Artificial indigo is the result of an elaborate series of researches commenced, I believed, by Adolph Baeyer more than twenty years ago. He prepared it from cinnamic acid, which he treated in the first place with nitric acid, forming ortho-nitro cinnamic acid. In second place he converted the latter into the dibromide, and third, he further treated the latter with caustic soda, forming ortho-nitrophenyl propiolic acid, and by a reducing agent, converted the latter into *indigotin*, which is the pure colouring matter of indigo.

The calico printers use this ortho-nitrophenyl propiolic acid in the form of a paste, of which I have also a specimen on the table, which is printed, I understand, on the cloth with an alkali and reducing agent such as grape sugar, and subsequently steaming the fabric to reproduce the colour.

With grape sugar, however, the process of reducing was found not to work well as it required *heat*, and there was the risk of the production changing to indigo *white*, and it was found difficult to stop this reaction at the right moment.

To obviate these difficulties, Dr. Caro, of Mannheim, proposed as the oxidizing agent, xanthate of soda, $NaC_2H_5COS_2$. Using this the reaction can be effected in the cold, and thus the risk of destroying the colour can be avoided.

My personal inquiries lead me to state that neither artificial indigo nor indophenol have as yet found much favour with our English printers, and for dyeing purposes they both seem at present to be *hors de combat* altogether.

Both substances, however, are capable of improved developments, and just as alizarine has now almost superseded the use of the natural product *madder*, so it may be quite possible in a not very distant future to see these new artificial blues becoming formidable competitors with the natural product indigo, and when we recollect that from statistics obtained by Dr. Roscoe about eighteen months ago, he showed that the saving effected by the use of alizarine instead of madder is over £4,000,000 per annum, we can appreciate the necessity of our scientific and practical chemists leaving no stone unturned in the further prosecution for improved results on these blues, with a view of ultimately having their labours crowned with a similar success.

Germany and France at present have considerable advantages over us, in the facilities and financial encouragement given to their chemists by their governments, in supporting their chemical researches, and until this state of things is remedied in England, and also our patent laws remodelled, we must expect to see ourselves constantly outstripped in the race of discovery of these new chemical developments, and reconcile ourselves to the *un*pleasant fact that although we supply the raw material, we are forced to be in the main simply consumers of these dyes, leaving the field of production, and the consequent commercial benefits derived therefrom, in the hands of our continental neighbours.

SALICYLIC ACID AS A REMEDY FOR CORNS.

Dr. Traill Green, writing to the *Medical and Surgical Reporter*, speaks highly of the results obtained in the treatment of hard and soft corns with salicylic acid. He has adopted a formula recommended by Mr. Gezou, which is as follows:—

"℞ Salicylic acid	30 parts.
Ext. cannabis indicæ	5 parts.
Collodion	240 parts.

Dr. Green says:—"The collodion fixes the acid on the diseased part, and gives speedy relief by protecting it from friction. The cannabis indica acts as an anodyne, and the acid reduces and loosens the corn, so that it comes off in four or five days, adhering to the collodion. The remedy is applied with a camel's hair pencil, and if the corn is not well cured, the application may be repeated. In four or five days the patient should use a warm foot-bath and rub off the collodion. If any portion of the corn remains the acid should be applied again, and the treatment continued until the whole of the corn has disappeared. The skin will be soft and smooth, as in the healthy state.

"The mixture dries immediately, and does not prevent for a moment the use of the stocking.

"I have used salicylic acid in the treatment of bunions with like good results.

"Collodion as found in the shops makes a good mixture, but I have found a flexible collodion preferable, as it makes, with the other ingredients of the remedy, a denser fluid. The extract of cannabis should be the solid extract.

"I am sure no remedy has ever been proposed which is so useful in those painful affections of the feet as salicylic acid."

OIL OF GAULTHERIA.*

W. P. Underhill, who has distilled this oil since 1874, gives the average yield as 10 pounds from a ton of the leaves, the highest yield being 14, and the lowest 9 pounds of oil. The larger yield is obtained when the season is dry. The cost of the leaves delivered at the mill is 1½ cents per pound, and it is very difficult to obtain leaves at that price. Since it will require about 200 pounds of leaves to make 1 pound of oil, the cost of the latter is 3.00 dollars for the leaves alone. The author does not believe that the large sleazy leaves of New Jersey yield more oil than the stiff, hard and brittle leaves of New Hampshire.

EXPLOSIVES AND MATERIALS FOR MAKING EXPLOSIVES.

THE opinion that we ventured to express a fortnight since, as to the far-reaching effect of the provisions of the new Explosives Act and the necessity for the exercise of caution by chemists and druggists in the supply of articles capable of being used as materials in the manufacture of explosives, has received confirmation in a letter which has been issued by the Home Office to local authorities, with an instruction to bring the subject matter of it under the notice of all pharmaceutical chemists, chemists and druggists, drysalters, oil and colourmen, and manufacturers of or dealers in chemicals within their districts. The object of this circular is to direct attention to the importance of exercising special and vigilant observation with a view to preventing the acquisition, by persons intending to use them for improper purposes, not only of explosives, but of materials from which, if possessed of a little technical knowledge, they would be able to manufacture explosives. In order to assist in the exercise of the desired observation, a memorandum, drawn up by Colonel MAJENDIE, is appended to the circular, in which it is pointed out that independently of the purchase of explosives specially adapted for blasting, and therefore, generally available for destructive purposes, by persons who may not be reasonably supposed to require them for industrial operations, suspicion should attach to the acquisition in notable quantities of any materials adapted for the making of explosives, if the person seeking to purchase the same is unknown to the seller, or is not known to require such materials for trade or other legitimate purposes. Many of the substances falling within this category are dealt with in the ordinary course of the chemist and druggist's business, as will be seen from the following list of those which are specially enumerated:—Nitric and sulphuric acids, especially in their more concentrated forms, glycerine, potassium and sodium nitrates, chlorates (especially potassium chlorate), picric acid and the picrates, phosphorus, orpiment, iodine, metallic mercury and nitrate of mercury, the last three even in comparatively small quantities. As a stimulant to sharpen the powers of observation it is announced that a reward of £100 will be given to any person (not belonging to the police force) who furnishes information that shall lead to the discovery and conviction of an offender who may be engaged in the illegal manufacture of explosives, provided that the case is one where the Secretary of State is satisfied that the illegal manufacture constituted a serious infraction of the law and was being carried on for an illegal purpose.

Almost simultaneously with the appearance of the circular above referred to, the *London Gazette* contained three Orders in Council, made in accordance with section 43 of the Explosives Act, 1875, which provides that Her Majesty may in this way prohibit the manufacture, *keeping*, importation, conveyance and *sale*, either absolutely or except in pursuance of a licence, or subject to restrictions, of any explosive which may be deemed of so dangerous a character as to require that the Order should be made in the interest of the public safety. The three Orders apply respectively to "stores licensed for mixed explosives," "premises registered for the keeping of mixed explosives" and the keeping of explosives for private use, and with the necessary variations of language they contain practically the same provisions, except that the last-mentioned includes fresh restrictions as to the quantity of explosives that may be kept for private use. The provision most likely to affect some of our readers, and which is common to all three Orders, is that henceforth it will be *unlawful to keep* in any licensed store or premises registered for mixed explosives "any explosive which is *not an authorized explosive* or "which *is an explosive of the fifth (fulminate)* "*class.*" The next provision is that "authorized explosives," other than those of the "fulminate class," with some exceptions in favour of cartridges made with gunpowder and fireworks kept for private use, may not be kept in licensed stores or registered premises or for private use, except in pursuance of a certificate, granted by the chief officer of police or some person authorized by him, that the person holding it is a fit person to keep, during the continuance of the certificate, such explosives as are specified in it.

For the purpose of obtaining a definition of the terms "authorized explosives" and "fifth (fulminate) class," as used in these Orders, it is necessary to refer to an earlier Order in Council, made on the 5th of August, 1875, soon after the passing of the Explosives Act of that year, and for the purpose of completing the information relating to the Act which has already appeared in this Journal and in the Society's Calendar, it may be useful to summarize it briefly. In this Order, for the purposes of the Act, explosives are divided into seven classes, named respectively, (1) "gunpowder," (2) "nitrate mixture," (3) "nitro compounds," (4) "chlorate mixture," (5) "fulminate," (6) "ammunition," and (7) "fireworks." In Class 1 the term "gunpowder" means exclusively the substance ordinarily so-called. The 2nd or "nitrate mixture class" includes any preparation, other than gunpowder, formed by the mechanical mixture of a nitrate with carbon or any carbonaceous substance not possessed of explosive properties, whether sulphur be added or not, and is represented by "pyrolithe," "pudrolithe" and "poudre saxifragine." Class 3, the "nitro compound class," includes chemical compounds possessed of explosive properties or capable of combining with metals to form an explosive compound, produced by the action of nitric acid, or of a nitrate mixed with sulphuric acid, upon carbonaceous substances. There are two divisions in this class, nitroglycerine being typical of the first, and gun cotton and the picrates of the second. Class 4, the "chlorate mixture class," includes any explosive containing a chlorate. In Class 6, the term "ammunition" means an explosive of any of the foregoing classes or of the "fulminate" class, when enclosed in any case or contrivance, or otherwise adapted or prepared so as to be used as a cartridge or charge for small arms, cannon or other weapon, or for blasting, or as a safety or other fuze, a fog signal, percussion cap, etc. Class 7, the "firework class," comprises firework composition and manufactured fireworks, including coloured fires.

The foregoing six classes constitute the "authorized explosives" which it will be lawful under the terms of the Orders just made to keep in "licensed stores," "registered premises," and for private use, to the extent specified in the permissive certificate. The 5th, or fulminate class, which, as well as unauthorized explosives, it will be *illegal to keep*, is thus defined. The term "fulminate" means any chemical compound or mechanical mixture, whether included in the other classes or not, which from its susceptibility to detonation is suitable for employment in percussion caps or other appliances for developing detonation, or which, from its extreme sensibility to explosion or its great instability, is especially dangerous. The class consists of two divisions, the first of which includes such compounds as the fulminates of silver and mercury, and preparations of them; any preparation consisting of a mixture of a chlorate with phosphorus, or certain descriptions of phosphorus compounds, with or without carbonaceous matter; and any preparation consisting of a mixture of a chlorate with sulphur, or with a sulphuret, with or without carbonaceous matter. The second division comprises such substances as the chloride and the iodide of nitrogen, fulminating gold and silver, diazobenzol and the nitrate of diazobenzol.

It only remains to add that under the Explosives Act the local authorities have considerable powers of search and seizure, section 73 giving power to search for ingredients of an explosive as well as the explosive itself. Further, section 23 imposes upon the occupiers of stores and registered premises the obligation of taking all due precautions for preventing unauthorized persons having access to the premises.

THE NORTH BRITISH BRANCH.

On another page will be found an account of the proceedings at the Annual Meeting of the North British Branch of the Pharmaceutical Society of Great Britain, which was held in Edinburgh, on Tuesday last. The Annual Report presented by the executive of the Branch on that occasion shows that under Mr. Alexander Napier's presidency the operations of the Pharmaceutical Society in the North have been carried on with vigour and efficiency, and with results that furnish good ground for congratulation. Especially has this been the case with respect to the Evening Meetings, the past session having been remarkable for the number of interesting and valuable papers brought forward. The Library and Museum have been augmented, and the figures quoted in the Report show that their value is becoming increasingly appreciated by students, upwards of fifteen hundred persons having visited the Museum during the year, and the Library having been well used. For several years past the executive of the North British Branch has endeavoured to meet one of the principal difficulties attending pharmaceutical education in the provinces in a practical way, by making arrangements for enabling students to attend regular courses of lectures on scientific subjects allied to pharmacy upon special terms. This privilege has again been secured during the past year, and the Report specially states that the students who availed themselves of it have shown, by the position they have taken in the classes that they are at least equal to the other students with whom they have been associated.

In one respect the proceedings on Tuesday last presented a novel feature, namely, in relation to the election of the Council which is to conduct the business of the North British Branch during the next twelve months. In previous years this body has consisted of fifteen members; but in accordance with the report of a committee, appointed to inquire into the rules and precedents which have hitherto regulated the election and proceedings of the Council, the voting papers issued this year contained an intimation that it had been decided to increase the number to twenty-one, of whom fourteen would retire annually. This step has been taken with the view of securing a fuller representation of the provinces, and it will be seen by a reference to the list of gentlemen elected that the object has been fairly well attained.

The unanimity with which the services of the retiring President and other officers were recognized was equally gratifying and well deserved. In its new President the Branch will have the advantage of the services of a gentleman well acquainted with the business, Mr. Nesbit having just served a term of office as Vice-President, whilst the gentleman who succeeds him in that position bears a name which is already honourably associated with the history of the Society.

BOTANICAL LECTURES AND PRACTICAL DEMONSTRATIONS AT THE GARDENS OF THE ROYAL BOTANIC SOCIETY.

It will be noticed by reference to the advertisement of the School of Pharmacy of Great Britain in the present number of this Journal, that Professor Bentley will commence his Course of Lectures and Demonstrations on Systematic and Practical Botany, at the Gardens of the Royal Botanic Society, in Regent's Park, on Saturday morning next, May 5, at 8 o'clock. The lectures will be continued on the succeeding Friday and Saturday mornings, at the same hour, till the end of July.

It may be useful to call the attention of Members and Associates of the Pharmaceutical Society who have not yet paid their subscriptions for the current year to the official notice that the Secretary is unable to receive subscriptions after Monday next.

* * *

On Tuesday evening, the Council of the North British Branch, and their friends, according to an annual custom, met at dinner in the Windsor Hotel, Edinburgh, the company numbering about forty. Mr. Nesbit presided, and Mr. Henry Bellyse Baildon acted as croupier, and the dinner appears to have been a decided success.

* * *

The statement that the fire by which the Parliament House of Quebec has been destroyed owed its origin to imperfect electric light fittings, has elicited a letter to the *National Zeitung*, from Dr. Werner Siemens, of Berlin, containing a timely warning as to electricity used for lighting purposes becoming a source of danger from fire. Passing by the fact that the steam or gas engines necessary for the production of the electric current may have been the cause of this fire, he points out that the special apparatus requisite for electric lighting is quite capable of originating a conflagration unless constructed with the greatest care and knowledge. If the calibre of the wires has been wrongly calculated for the current, they may become red hot; whilst the lamps themselves, if improperly fixed, may become a source of danger. Dr. Siemens alleges, what appears very probable, that numerous companies now engaged in the extension of electric lighting do not possess the necessary knowledge or experience, and, in aiming to make electric light as cheap as possible, are overstepping the limits of safety. But he is of opinion that when proper precautions are taken, electricity is much less dangerous than any other mode of illumination.

* * *

The Committee of the International Pharmaceutical Exhibition, to be held in Vienna in August next, has issued a notice that it has taken the necessary steps to secure for all foreign firms the admission into the country of goods to be exhibited free of duty, and their return carriage free of cost. In order also to meet the wishes of intending American exhibitors it has been decided to extend the time for applications from extra-European countries to May. As the forthcoming exhibition will be the first pharmaceutical exhibition of any kind that has been held in Austria, it is naturally exciting considerable attention. It seems, however, almost a pity, in view of the international character which it is desired to give to it, that the notices are sent out written in the German characters that are as a rule so unfamiliar and perplexing to natives of other countries.

* * *

A circular has been issued, signed by the President and Treasurer of the American Pharmaceutical Association and the Presidents of the Pharmaceutical Associations of twenty-two States, calling a meeting of the retail druggists of the United States for the purpose of organizing a national convention, having for its object "to discuss and take action upon the many and growing evils that affect the retail trade." It is not intended that this organization shall at all interfere with the functions of the American Pharmaceutical Association, but work in harmony with it, and it is proposed to hold the meeting in Washington, D.C., on the day previous to the meeting of that Association in September next.

* * *

At a recent meeting of the Société de Pharmacie, convened specially to consider a report which was intended to serve as a preliminary chapter to the forthcoming edition of the Codex, it was decided that instead of attempting to define a tablespoonful as a measure of weight or of volume, it would be preferable to propose to medical men to agree that when they prescribe a tablespoonful they are to be understood to order a quantity equal to fifteen grams of distilled water.

* * *

At the same meeting the size of the normal *compte-goutte* was defined that the diameter of the tube at the point from which the drop falls should measure three millimetres exactly. An opinion was also expressed that the practice of measuring certain very volatile liquids by drops should be abandoned.

* * *

According to a Parliamentary paper issued last week the number of births registered in England and Wales during the year 1882 was—males, 452,829; females, 436,111: total, 888,940. The number of deaths registered during the same time was—males, 266,034; females, 250,749: total, 516,783. The total population, estimated to the middle of 1882, was 26,406,820.

* * *

An inquest was held at Dulwich, on the 20th inst., on the body of Mr. William Leatham Andrews, Pharmaceutical Chemist, who had been found dead in his shop, having apparently just returned from a walk. The medical evidence attributed the death to rupture and diffusion of blood in the pericardium.

* * *

At the next meeting of the Chemical Society, on Thursday, May 3, papers will be read on "A New Oxide of Tellurium," "Tellurium Sulphoxide," and "A New Reaction of Tellurium Compounds," by Messrs. Edward Divers and M. Shimosé; "A Simple Modification of the Ordinary Method for Effecting the Combustion of Volatile Liquids by Glaser's Method with Open Tubes," by Mr. Watson Smith; and "On Acenapthene," by W. R. Hodgkinson, Ph.D.

* * *

The Annual General Meeting of the Chemists' Assistants' Association will be held on Wednesday evening, May 16th.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

Wednesday, April 11, 1883.

(*Continued from page* 846.)

After the discussion on Mr. Maben's paper, the President called upon Mr. Patrick Geddes, F.R.S.E., Demonstrator of Botany, Edinburgh University, to deliver a lecture on the "History and Present State of the Cell Theory." In the course of the lecture the labours of Grew, Malpighi, Bichat, Brown, Schleiden, Schwann and recent investigators were reviewed. By means of a series of elaborate diagrams and other illustrations, the lecturer showed the identity of the animal and the vegetable cell, and gave an interesting account of recent investigations and theories. A *résumé* of the lecture will be given shortly.

Dr. Inglis Clark, in moving a vote of thanks to Mr. Geddes, said that everyone would be struck by the manner in which a very intricate subject had been made interesting. He had listened to the lecture with great pleasure, because it contained many points which were matters for reflection, and considering that a great deal of the subject matter was the result of research on the part of the lecturer, he was sure that the audience would join him in thanking Mr. Geddes for the manner in which he had brought the subject before them.

Mr. Stephenson seconded the motion, and Mr. Baildon, in supporting it, remarked that the lecture had been a very fascinating one. Beginners on the subject felt something very "dreech" about the bare details and long names, but when the beautiful history of the progress of discovery was told, the whole matter took shape and became thrilling with interest.

The motion was very heartily responded to by a large audience.

The President of the Branch then made the following remarks:—

"Gentlemen,—Our twenty-ninth session this evening comes to a close, and it may not be out of place to review it very briefly in its scientific, educational and trade aspects. At the first meeting on November 8 the business of the session was as usual commenced with a few opening remarks from the chair, after which a paper by Mr. D. B. Dott, F.R.S.E., on 'The Solubility of Morphia Salts,' was read. This included a valuable contribution to what is already known on the obscure subject of solubility generally, and particularly in reference to morphia salts. At our second meeting we had an interesting paper by Mr. Robert Aitken, on 'The Pharmacopœial Extracts of Aloes and their Preparation,' and also one giving details of a method for preparing syrup of phosphate of iron, by which the acidulous rather than the basilous radicle is precipitated; this was contributed by Mr. D. Gorrie. At our third meeting, Mr. Gilmour gave us an insight into the new edition of the United States Pharmacopœia, which raised an entertaining discussion, and Mr. Peter MacEwan read a note on 'Pungent Liniment of Iodine.' On the same evening, Mr. H. B. Baildon presented a fine bust of his father to the Society. This bust is a fitting memorial of one who was highly esteemed by those connected with this Branch, and who by the dignity of his personal and professional life did much for the elevation of pharmacy. The fourth meeting took place in February, when we had the pleasure of listening to a lecture by Dr. Matthew Hay, on 'The Methods for the Separation of Alkaloids.' This paper was principally devoted to the methods employed in original research, but independent of its purely scientific worth it contained much matter applicable to the everyday work of the pharmacist. At our fifth meeting, Mr. Maben showed a hot-air chamber which he has had in use in his own laboratory, and on the same evening Dr. Inglis Clark made a valuable communication on 'Acetic Ether;' the most valuable portion of this paper is that in which Dr. Clark proposes a modification of the process of purification, and which Professor Redwood regards as 'a great improvement on that described in the Pharmacopœia.' I need not remark on the papers which we have had the pleasure of listening to this evening. I have to congratulate the members of the Branch that so many of the papers have emanated from themselves, and I have to urge on those who are able to devote a little of their limited leisure in the course of the summer to the preparation of papers for our next session. Our special thanks are due to those members of professions allied to our own for the highly appropriate subjects on which they have lectured to us; and further, I am sure that you will all join with me in thanking all the gentlemen who have addressed us during the session." The President then referred to the "Pharmacy Acts Amendment Bill," and the educational requirements which would be entailed by it. In this respect he likened the Bill to the "Scottish Universities Bill," and remarked that Scotland at the present time is ripe for an advance in education. Having glanced at the commercial aspects of pharmacy at the present time, he concluded by thanking the members for the courtesy accorded to him in his discharge of the duties of the chair.

Mr. Stephenson proposed a vote of thanks to the President for his conduct in the chair, which was cordially responded to by the audience.

In the course of the evening it was intimated by the Secretary of the Branch that a paper by Mr. Hugh Macullum, Hong Kong, with specimens illustrative of an investigation in a case of malicious fish poisoning, had been forwarded but had not come to hand.

ANNUAL MEETING.

The Annual Meeting of the Branch was held in the Society's rooms, Edinburgh, on Tuesday, April 24, at 12 o'clock noon.

Mr. Alexander Napier, President of the Branch, took the chair, and called upon the Secretary to read the—

Annual Report.

The Council of the North British Branch of the Pharmaceutical Society again have the pleasure of submitting their Annual Report.

The operations of the Branch continue to be carried on with efficiency as hitherto.

The library and museum have been considerably augmented during the past year; several valuable donations have been made to the chemical portion, which has been greatly enriched thereby. Your Council would specially refer to a fine bust of the late Mr. H. C. Baildon, which has been presented by his son, Mr. H. B. Baildon, and which will prove a pleasing memorial of the valuable services which their late respected friend rendered to the cause of pharmacy, especially as represented by this Branch. The museum continues to be largely taken advantage of by students; the total number of visits during the past year being 1565, made up of 953 day visits and 612 evening visits. From the library, nearly three hundred volumes have been lent out, while a large number of volumes have been used for reference. These facts are a satisfactory indication that the educational facilities afforded by the Society are fully appreciated by our students.

In connection with the issue of special tickets for lectures in subjects allied to pharmacy, your Council are pleased to note the honourable positions taken by several students. This circumstance affords an opportunity of comparing pharmaceutical with other students attending these clases, and it shows that our students. are not inferior to others.

There have been six evening meetings during the past year, the attendance being quite up to the average, and on several occasions exceptionally good; but it is to be regretted that members generally do not avail themselves of the advantages which are presented by such meetings.

The papers read during the session have been of a highly interesting and instructive nature, and your Council desire to record their appreciation thereof and their indebtedness to those pharmacists who have made the communications. They also wish to express their warmest thanks to Dr. Matthew Hay and Mr. Patrick Geddes for the able and interesting lectures which they delivered under the auspices of the Council.

The Board of Examiners for Scotland have had four meetings for examination (in all on nine days) during the past year. Minor candidates have numbered 99, of whom 53 passed. These numbers show an increase of 26 candidates over the previous year, and failures to the extent of 46·5 per cent. For the Major examination there have been 9 candidates, of whom 4 passed, and 1 Modified candidate, who passed. Your Council have pleasure in noting a great improvement in Scottish Preliminary candidates since the last report: 204 candidates have presented themselves at the various centres in Scotland, and of these 118 have passed, showing 42 per cent. of failures as compared with 60 per cent. in the preceding year.

The most important event in the proceedings of the Society during the past year has been the adoption by the London Council of the suggestion of Mr. Schacht's Committee, that in future candidates for examination be required to produce evidence of having undergone a curriculum of education in botany, chemistry (both theoretical and practical), and materia medica, and that the examinations be divided into two parts, the first *written* and the second *oral*, with an interval of at least twelve months. Without entering into the debatable aspects of this measure your Council feel satisfied that its adoption, which it is proposed to effect in 1887, will greatly modify the distressing results of the examinations as they exist at present.

At the February meeting of the Council of the Society a draft Pharmacy Acts Amendment Bill was unanimously adopted. This Bill had been prepared on the suggestion of the Privy Council, chiefly with the view of placing some restriction on the sale of poisons under the guise of patent medicines, and of regulating the sale of poisonous articles, which there was a difficulty in embracing within the Poisons Schedule of the 1868 Act. Besides provision for these purposes the Bill contains various clauses for obviating difficulties and hardships which have been experienced in the operations of the last Act, and appears to have been drawn with great skill and with a practical adaptation to the purposes to be effected.

Your Council had a meeting to discuss the Bill and, although there were one or two dissentients, the great majority of members were in favour of supporting the London Council in promoting the measure almost in its entirety; and this resolution is simply an echo of an almost unanimous expression of opinion throughout the pharmaceutical body.

The Council have to record with feelings of regret—which they feel assured will be shared by all who knew him—the death of Mr. George Blanshard, for many years a member of this Council. Mr. Blanshard was a constant attendant at the meetings of this Branch, whether for business or scientific purposes, and his genial and gentlemanly bearing, as well as the zeal and diligence he always displayed in the interests of the Society, will cause his name to be long held in honour and esteem.

In laying on the table the result of the voting for the new Council, tabulated as formerly, your Council take the opportunity of referring to the alteration in the number of members, which was intimated in the nomination papers. This alteration was suggested by a committee appointed by the Council to inquire into the rules and precedents which have hitherto regulated the election and proceedings of the Council. The suggestion was adopted. The number, twenty-one, being believed to be that which would best ensure provincial representation, while the retirement of only two-thirds annually will provide for the continuous carrying on of the work.

Mr. Laird, in moving the adoption of the report, said that he was glad to know that the affairs of the Branch were in so satisfactory a condition. Much of this, he was sure, was due to the office-bearers, and he had pleasure in moving that the report be adopted.

Mr. Rait (Partick) seconded the motion, and it was unanimously adopted.

The President of the Branch then made some remarks regarding the work of the Branch, and a discussion thereon ensued, but no resolution was come to in the matter.

The Secretary to the Branch then submitted the results of the voting for the new Council as follows:—

Voting papers issued	247
Voting papers returned	134
Voting papers informal	4

Leaving 130 voting papers to be recorded.

These having been scrutinized it was found that the following gentlemen had a majority of votes, and were accordingly elected as the

Council for 1883–84.

Ainslie, William, 58, George Street, Edinburgh.
Baildon, H. Bellyse, 73, Princes Street, Edinburgh.
Borland, John, Kilmarnock.
Clark, William Inglis, 26, South Canongate, Edinburgh.
Frazer, Daniel, 131, Buchanan Street, Glasgow.
Gilmour, William, 11, Elm Row, Edinburgh.
Kermath, Wm. Ramsay, 18, Market Street, St. Andrews.
Kinninmont, Alexander, 69, South Portland Street, Glasgow.
Laird, George Hardie, 40, Queensferry Street, Edinburgh.
Mackay, George Duncan, Canning Street, Edinburgh.
Mackenzie, James, 45, Forrest Road, Edinburgh.
MacRitchie, David, 30, High Street, Inverness.
Napier, Alexander, 69, South Clerk Street, Edinburgh.
Nesbit, John, 162, High Street, Portobello.
Pinkerton, William, 17, Greenside Place, Edinburgh.
Stephenson, John B., 48, Frederick Street, Edinburgh.
Storie, Robert, 94, High Street, Dalkeith.
Storrar, David, 228, High Street, Kirkcaldy.
Strachan, Alexander, 148, Richmond Street, Aberdeen.
Watt, James (Senior), Haddington.
Young, James R., 17, North Bridge, Edinburgh.

Mr. Gilmour, in proposing a vote of thanks to Mr. Napier, said that as a President of the Branch that gentleman had been anxious to conduct his duties faithfully, and in doing so had been quite alive to the interests of the Branch and the Society. He very heartily proposed the thanks of the meeting for his conduct in the chair at that time and during the year he had held office.

Mr. Young seconded the motion, remarking that Mr. Napier had been assiduous in his attention to the duties of his office, and had shown great ability in conducting the affairs.

Mr. Napier returned thanks, and moved a similar vote to Mr. Nesbit, Vice-President, which was cordially agreed to.

Mr. Watt (Haddington) then moved a vote of thanks to the Honorary Treasurer (Mr. Stephenson). In doing so he said that a remarkable amount of enthusiasm had been thrown into any work which Mr. Stephenson had undertaken. This, coupled with his knowledge of affairs, had tended greatly to carry on the work which had fallen to the share of the late Mr. Mackay.

Mr. Mackenzie seconded and Mr. Nesbit supported the motion.

Mr. Stephenson having replied, the meeting adjourned.

The new Council met after the Annual Meeting for the election of office-bearers for the ensuing year, with the following result:—

President of the Branch, Mr. John Nesbit; Vice-President, Mr. H. Bellyse Baildon; Auditors, Messrs. Mackenzie and Young.

EXAMINATIONS IN EDINBURGH.

April 18, 19 *and* 20, 1883.

Present on each day—Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kinninmont, Nesbit and Stephenson.

Professor Maclagan was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

18*th.—Four* candidates were examined. *Three* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Holmes, James Henry............Kendal.

MINOR EXAMINATION.

18*th.—Ten* candidates were examined. *Seven* failed. The undermentioned *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Anderson, George Watson ......Forres.
Barlow, George Robert ....Congleton.
Campion, Martin Hand ....Louth.

19*th.—Twelve* candidates were examined. *Five* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cooper, Albert ....Huntingdon.
Donald, Andrew ....Perth.
Douglas, William ....Woodside.
Dunbar, George ....Dumfries.
Duncan, Adam.......................Edinburgh.
Edwards, Rees William ....Brecon.
Hendry, Robert Love ....Edinburgh.

20*th.—Twelve* candidates were examined. *Eight* failed. The undermentioned *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Scott, Charles ....Fraserburgh.
Simpson, Charles ....Aberdeen.
Slater, James Morrieson ....Loftus in Cleveland.
Thresh, Arthur.......................Buxton.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held on Wednesday, April 25, 1883, the report of the College of Preceptors on the examination held on April 3rd was received.

Three hundred and sixty-six candidates had presented themselves for examination, of whom *one hundred and ninety-five* had failed. The following *one hundred and seventy-one* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

Adamson, John Robert ....Bishop Auckland.
Affleck, John.........................Fort William.
Affleck Theodore Sykes ....Swindon.
Aitken, Thomas ....Kilmarnock.
Alexander, William Maxwell...Dundee.
Allanson, James ....Wishaw.
Allez, Peter Arnold ....Guernsey.
Anderson, George H. ....Edinburgh.
Andrews, Edward Arther ......London.
Angel, Alfred ....Guernsey.
Arnold, John Julius................Brighton.
Aslin, William ....Sunderland.
Aspland, Wm. Harold G. ......Newark.
Bagshaw, George William ......Kenilworth.
Baker, William James............Bradford.
Bard, Cecil Harry ....Exeter.
Barker, Joseph ....Doncaster.
Bates, John ....Bicester.
Beynon Benjamin ....Swansea.
Botterill, Frederick William ...Otley.
Bradbury, Charles..................New Fletton.
Brassington, Herbert William...Rugeley.
Breese, Charles ....London.
Brent, Arthur Redding ....Ashford.
Briggs, Thomas.....................Halifax.
Broadley, John Wilfred ....Louth.
Bromwich, Thomas ....Dudley.
Bunting, Edmund Robert ......Hoylake.
Butterworth, Frederick ....Rochdale.
Carter, Thomas.......................Hereford.
Chaplin, Albert Edward ....Taunton.
Church, Edward Harry ....Cambridge.
Clark, Alexander John ....Grantown-on-Spey.
Cole, Harold ....Congleton.
Colenutt, Frederick Moreton ...Shanklin.
Cook, Thomas Marsden ....Hindley.
Cooper, Edwin ....Lincoln.
Cripps, George Thornton.........Devizes.
Cussons, John William ....Ossett.
Davies, Charles Gardiner ......London.
Davies, James Lloyd ....Talgarreg.
Davis, George David ....Malvern Link.
Davis, William Orton ....Malvern Link.
Dawson, William Thorndick ...Norwich.
Dickie, Thomas......................Glasgow.
Dixon, Richard.......................Newport, I. W.
Downing, Samuel...................Braintree.
Drayton, Ernest ....Tunbridge Wells.
Drysdale, Robert ....Dalmeny.
Edmondston, Francis E..........Edinburgh.
Evans, Alexander Rae............Ely.
Evans, Dewi Louis ....St. Clears.
Evans, John ....Neyland.
Feather, Arad ....Pontefract.
Field, Reeve Holyoake ....Birmingham.
Fitton, Robert ....Huddersfield.
Fisher, George William ....Holt.
Fletcher, Richard Bewley ......Sunderland.
Flint, Charles ....Stratford-on-Avon.
Flynn, William.......................Lockerbie.
Forrester, William ....Lochee.
Fowler, Harry ....Shrewsbury.
Fraser, Robert ....Macduff.
Galt, Thomas James ....Thornley.
Gardner, John ....Bolton le Sands.
Gass, George Muncaster ....Whitehaven.
Gee, Ernest ....Bath.
Golland, James Henry ....Sheffield.
Goodman, Frederick William...Newport Pagnell.
Grammer, Frank ....Newark.
Green, Walter ....Hendon.
Green, William Henry ....Gargrave.
Greenhill, James Donaldson ...Glasgow.
Grimes, Henry ....Chesterfield.
Harrison, William Arthur ......Louth.
Hayton, Thomas R.................Plymouth.
Herington, Horace Edward ...Leighton Buzzard.
Hobson, Edmund...................Cheadle.
Hollely, Thomas Lowe ....Ollerton.
Hopley, David ....Goole.
Hughes, Philip Henry Alban...Liverpool.
Jackson, Thomas ....Altrincham.
Jones, John ....Rhyl.
Joy, Thomas George ....Cardiff.
Keddell, Charles Frederick ...Epsom.
Keene, Bernard ....London.
Kingston, George Thomas ......Bath.
Kirk, James ....Edinburgh.
Lee, George ....Barnstaple.
Letheren, Samuel Kemp.........London.
Lock, James ....Edinburgh.
Lockyer, Cuthbert Hy. Jones...Bruton.
Loeffler, George Berthold ......London.
Long, Frederick C. ....Norwich.
Lonnen, Walter ....Sheerness.

Macaulay, Donald .... Inverness.
McGregor, James .... Aberdeen.
Macintosh, P. F. .... Dunfermline.
Mackridge, William............... Barnsley.
Makepeace, Alfred Joseph ...... Nuneaton.
Martin, Stanley .... Derby.
Masterman, Francis John ...... Driffield.
Matheson, Joseph Milne......... Andover.
Mennie, Robert............... Aberdeen.
Menzies, James Acworth ...... Inverkeithing.
Miles, William Henry............ Portishead.
Millard, Edgar James........... Derby.
Millard, Percy .... London.
Mitchell, Walter Stuart .... Gloucester.
Moffat, John Archibald .... Whitehaven.
Mollard, James Kingston ...... Penzance.
Morris, William John .... Pontypridd.
Mousley, William Joyce .... Redditch.
Munro, James Innes .... Perth.
Murdoch, Henry William ...... Macduff.
Murray, Allan Grierson .... Annan.
Muskett, Frederic James ...... Newport Pagnell.
Newton, Arthur .... Northwich.
Nicholson, Gilbert .... Tunbridge Wells.
Ogdon, William .... Derby.
Pate, Charles .... Lincoln.
Paternoster, George Sidney ... Cirencester.
Peach, Charles William .... London.
Pegg, Joseph Edmund Jones ... Birmingham.
Phillips, Henry Allan .... Tavistock.
Pilkington, George Ratcliffe ... Haslingden.
Plevin, John .... Birkenhead.
Pottage, Frank Ernest .... Edinburgh.
Price, Joseph .... Wrexham.
Robertson, Robert .... Leith.
Robinson, Richard Hardy ...... Wainfleet.
Roe, Edwin John .... Nottingham.
Rowlands, William Handcock... Cardigan.
Ryall, Frederick John............ Devonport.
Sanderson, John William ...... Leeds.
Sewell, William John .... Barton-on-Humber.
Shand, Alexander............... Dunfermline.
Skinner, Donald McDougall ... Oban.
Slinn, Frederick Harry .... Rhyl.
Standing, William .... Darwen.
Staniland, Edwin Marshall...... Tadcaster.
Stark, George Miller .... Gatehouse.
Stephen, David J............... Kilmarnock.
Stewart, Robert McAll .... Penryn.
Stirling, David Alexander ...... Dunoon.
Stone, Leopold Hawkin .... Holsworthy.
Thomas, David............... Brynaman.
Thomas, Isaac Jenkin .... Aberavon.
Thomson, John............... Dalbeattie.
Thomson, Marshall .... Banchory Ternan.
Thorne, Henry Courtenay ...... Taunton.
Thorpe, Arthur Winton .... Northampton.
Thursfield, Bevington .... Kettering.
Tilsley, James Henry .... Berriew.
Timmis, John .... Silverdale.
Turnbull, Henry John............ Darlington.
Turner, George Reuben .... Peterborough.
Vassalli, Bartholomew Joseph .. Leeds.
Wadsley, William............... Wisbeach.
Waitt, Walter .... Cheltenham.
Wall, Henry Watson .... Coleshill.
Walters, James Lewis............ Burry Port.
Watkins, William H. .... Pontypridd.
Weekes, Ambrose............... Rochester.
White, Thomas Henry............ Whitby.
Wilkinson, Sidney .... Birkenhead.
Wilkinson, William .... Bradford.
Williams, Arthur John Berry... Wolverhampton.
Willington, Joseph Arthur...... Sheffield.
Wilson, John Codner .... London.
Wood, Albert Edward............ Highbridge.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Aberdeen	8	5	3	Lancaster	9	1	8
Birmingham	18	10	8	Leeds	20	10	10
Brighton	5	2	3	Lincoln	9	7	2
Bristol	11	6	5	Liverpool	18	6	12
Cambridge	5	1	4	London	49	19	30
Canterbury	2	1	1	Manchester	22	8	14
Cardiff	7	5	2	Newcastle-on-T.	6	3	3
Carlisle	8	2	6	Northampton	7	4	3
Carmarthen	10	5	5	Norwich	9	3	6
Carnarvon	6	2	4	Nottingham	8	4	4
Cheltenham	6	4	2	Oxford	1	1	0
Darlington	5	3	2	Peterborough	3	3	0
Dundee	4	3	1	Sheffield	10	5	5
Edinburgh	28	13	15	Shrewsbury	6	3	3
Exeter	12	8	4	Southampton	5	2	3
Glasgow	17	9	8	Truro	4	2	2
Guernsey	3	2	1	Worcester	7	3	4
Hull	9	3	6	York	7	2	5
Inverness	2	1	1				

The questions set for examination were as follows:—

Time allowed: Three Hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Ipse de quarta vigilia eodem itinere *quo* hostes ierant ad eos contendit, equitatumque omnem ante se mittit. (ii.) *Diutius* quum sustinere nostrorum impetus non *possent*, alteri se ut coeperant in montem receperunt, alteri ad impedimenta et carros suos se contulerunt. (iii.) *Id* ea maxime ratione fecit, quod noluit eum *locum* unde Helvetii *discesserant* vacare, ne propter bonitatem agrorum Germani e suis finibus in Helvetiorum fines *transirent* et finitimi Galliæ provinciæ Allobrogibusque essent. (iv.) His *rebus cognitis* Cæsar Gallorum animos *verbis* confirmavit, pollicitusque est sibi eam rem curæ futuram; magnam se habere spem et beneficio suo et auctoritate adductum Ariovistum finem injuriis facturum.

2. Parse the words in italics in the above extracts.

3. Decline together *hoc verbum* and *ea res*; and give the principal parts of the verbs *mitto*, *facio*, *duco* and *venio*.

4. Translate into Latin:—

(i.) All the cavalry will be sent by the same route. (ii.) We will betake ourselves to the mountains. (iii.) The general sees that the soldiers cannot sustain the attacks of the enemy. (iv.) The horsemen having been sent accross the river, the Gauls suddenly attack the camp.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. How many yards of carpet, $\frac{3}{4}$ of a yard wide, will cover a room 16 feet wide and $27\frac{1}{2}$ feet long?

2. If 20 men can reap a field of 105 acres in 6 days of 12 hours each, how long will it take 16 men to reap 126 acres, working 16 hours a day?

3. Multiply the sum of $2\frac{1}{3}$ and $3\frac{1}{4}$ by the difference between $4\frac{3}{7}$ and $2\frac{1}{5}$.

4. Reduce $\frac{47}{32}$ and $\frac{7}{1250}$ to decimals; and reduce $\cdot 5\dot{7}\dot{3}$ to a vulgar fraction.

Multiply 1·525 by 80·08, and divide 31·5 by 126.

5. Give the ratio of a yard to a metre, and of a pint to a litre. Express 7 miles 7 furlongs in metres to four places of decimals.

III. ENGLISH.

1. Define *transitive verbs* and *intransitive verbs*, illustrating your definitions by examples. What difference is indicated by the terms *strong verbs* and *weak verbs*? Give the present tense of the verbs of which *sped, lit, cloven, shorn, gotten, flown* are respectively the past participles.

2. Show, by example, that *after, before*, and *since* may ae used—(i.) as adverbs, (ii.) as prepositions, (iii.) as conjunctions.

3. Parse each word in the following sentence:—"How wretched is that poor man that hangs on princes' favours!"

4. Correct the following sentences, giving your reason in each case:—(i.) Haste as well as waste are to be avoided. (ii.) Anybody may have this, I care not whom. (iii.) Paley's 'Evidences' are a well known book. (iv.) In memory of John Smith, born March 1, 1854, died July 2, 1876.

5. Write a short composition on one of the following subjects:—(i.) The Suez Canal; (ii.) Examinations; (iii.) Ventilation; or (iv.) give an account of some distinguished writer.

BOTANICAL PRIZE FOR 1884.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom, between the first day of May, 1883, and the first day of June, 1884; and should there be more than one collection possessing such an amount of merit as to entitle the cellector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Merit, will be given at the discretion of the Council. In the event of none of the collections possessing sufficient merit to justify the Council in awarding medals or certificates, none will be given.

Competitors must be Associates or Apprentices or Students of the Society, and under twenty-one years of age.

The collection must consist of phanerogamous plants and ferns, arranged according to the natural system of De Candolle, or any other natural method in common use, and be accompanied by lists, arranged according to the same method, with the species numbered.

The collector must follow some work on British botany (such as that of Babington or Hooker), and state the work he adopts. The name of each plant, its habitat, and the date of collection must be stated on the paper on which it is preserved.

Each collection must be accompanied by a note, containing a declaration signed by the collector, and certified by his employer, or a pharmaceutical chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1883, and the first day of June, 1884, and were named and arranged without any other assistance than that derived from books.

In estimating the merits of the collections, not only will the number of specimens be taken into account, but also their rarity or otherwise, and the manner in which they are preserved, and should a specimen be wrongly named, this will be erased from the list.

The collection must be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1884, indorsed "Herbarium for Competition for the Botanical Prize." After the Prize Distribution in October, collections will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collector, if required.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

A special meeting of the Council was held at the College of Physicians, Kildare Street, Dublin, on Monday, April 16, at three o'clock, p.m.

Present—Professor Tichborne, President; Dr. Collins, Messrs. Allen, Bennett, Brunker, Draper, Hayes, Simpson and Wells.

The meeting had been called with a view to consider the subject of the compilation of the Pharmacopœia and the advisability of attempting to secure the introduction into the new Medical Acts Amendment Bill (House of Lords) of a clause to provide for the formation of a standing committee of medical men and pharmacists for the purpose of compiling the Pharmacopœia.

After the subject had been discussed at some length with reference to what course should be adopted by the Council in the matter, it was proposed by Mr. Brunker, seconded by Mr. Draper, and resolved—

"That a memorial be drawn up and forwarded to Lord Carlingford, the member of the Government in charge of the Medical Bill in the House of Lords, praying that the pharmaceutical bodies in these Kingdoms shall be represented on the body to whom shall be committed the revision of the British Pharmacopœia."

Proposed by Mr. Brunker, seconded by Mr. Allen, and resolved—

"That a petition be drawn up to the House of Lords, conveying the same prayer, and that it be sent to the President of the Pharmaceutical Society of Great Britain, to be entrusted by him for presentation to such member of the House as he may think best."

The following memorial was then drawn up and agreed to:—

"To the Right Honourable Lord Carlingford,
"Lord President of the Council.

"The Memorial of the President and Council of the Pharmaceutical Society of Ireland—

"Humbly showeth, that this Council has had its attention called to the Medical Bill now before the House of Lords, and the clauses of same refering to the periodic revision of the British Pharmacopœia, and the absence of any provision by which the pharmaceutical bodies of these Kingdoms shall have a voice in such revision.

"They therefore pray that in any body appointed for this purpose due representation shall be accorded to pharmacists, as having special qualifications for aiding in an undertaking of such importance to the country.

"And your memorialists will ever pray.

"Signed on behalf of the Pharmaceutical Society of Ireland,

"Charles R. Tichborne, LL.D., Ph.D., *President.*
"Hugh James Fennell, *Registrar.*"

The Registrar was instructed to forward the memorial to Lord Carlingford, and to have the petition to the House of Lords engrossed on parchment, and forwarded as directed by the above resolution.

The Council then rose.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, April 19, Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—

C. Beringer, H. E. Harrison, C. Hulke, E. H. B. Stephenson, A. Smith.

During the evening a ballot was held and the following gentlemen were declared by the scrutators, Messrs.

Spiller and Groves, to be duly elected Fellows:—T. L. Briggs, J. A. Basker, J. B. Coleman, W. H. Cannon, E. C. Conrad, C. Gillett, E. C. Hemming, N. K. Humphreys, L. Levy, A. Ness, V. J. Schopoff, A. E. Wilson.

The President called on Dr. Percy Frankland to read a paper on—

The Gases Evolved during the Conversion of Grass into Hay. By P. F. Frankland and F. Jordan.—About 5 grams of finely cut grass were imprisoned in a small retort adapter, which was then filled with mercury, the small end of the adapter corked up, the cork protected by a mercury cup, and the whole allowed to remain over mercury during the observation. In atmospheric air at 15° C. 3 c.c. of gas were evolved in three days and 4 c.c. more in thirty days. The gas in the first case was composed of CO_2, 46·35 per cent., O, ·07 per cent., N, 53·58 per cent.; in the second case CO_2, 85·33, O, 0·00 per cent., N, 14·67 per cent. Other experiments were made in which the grass was surrounded by atmospheres of carbonic anhydride, of hydrogen and of oxygen, with almost similar results; the authors conclude that the atmosphere with which the grass is surrounded has but little influence either upon the volume or the composition of the gas evolved; the grass in every case undergoes a rapid process of oxidation in which it speedily removes all the oxygen from the atmosphere with which it is surrounded, and in the absence of any oxygen in the free state, with which to combine, much carbonic acid is produced at the expense of the combined oxygen present in the grass. When, however, free oxygen is present in the atmosphere surrounding the grass, the gas evolved contains a considerable proportion of nitrogen. At a temperature of 36° C. more gas is evolved than at 15°. In all cases, carbonic anhydride is the chief product of decomposition, whilst hydrogen and hydrocarbons appear in only very small quantities. The authors have made similar experiments as to the gases evolved by grass when kept under water. Large volumes of gas are evolved (about five times as much as in the previous experiments), which are characterized by the presence of a notable proportion of hydrogen, which is doubtless due to the lactic fermentation induced by bacteria; acetic, lactic and probably propionic acids with bacteria being found in the water. If the water contain phenol or mercuric chloride or if the grass be steamed, no gas is evolved.

Dr. Voelcker said the paper was peculiarly interesting, not only from a scientific point of view, but from its direct bearing on the making of hay in wet weather and on the preservation of grass as "ensilage." The changes observed when the grass was immersed in water were those which take place in the "silo." He had examined some "ensilage" from Boston and had found considerable quantities of propionic and acetic acids. These acids are the best preservers of green food; the grass is in fact pickled. Well-made ensilage can be exposed without becoming mouldy; it contains no sugar. It would be interesting to know to what extent, as indicated by loss of weight, the changes observed by the authors had taken place. He had made some observations at Rothamsted, on a stack of hay made in dry weather under the most favourable conditions, and the loss was only 5 per cent.; on the other hand a stack made in wet weather at Cirencester had become so hot that it had to be taken down, and the quantities of carbonic anhydride, aldehyd and acetic acid completely overpowered the men employed. In the lower part of this stack the grass was completely calcined and 5 or 6 pounds of ash were collected. Now it would be extremely interesting to determine quantitatively the loss which grass undergoes when improperly stacked and to study the effect of temperature on these changes.

The President asked if any experiments had been made as to the composition of the combustible gases evolved, whether any marsh gas was present.

Dr. Percy Frankland said he had not been able to weigh the grass after the experiments; and that most of the combustible gas was absorbed by strong sulphuric acid.

Dr. L. T. Thorne then read a—

Note on an Apparatus for Fractional Distillation under Reduced Pressure.—By means of this apparatus, which was exhibited by the author, the various fractions can be removed from time to time without impairing the vacuum and the distillation can therefore be continued from beginning to end without interruption. If the substance under distillation is affected by exposure to the air any inert gas can be introduced instead of air without disturbing the apparatus.

The President said that the apparatus had been in use in his laboratory for some time, it seemed to be very convenient and answered extremely well.

Mr. W. H. Deering then read a paper entitled—

Notes on the Condition in which Carbon exists in Steel. By Sir F. A. Abel, C.B., and W. H. Deering.—Two series of experiments were made; in the first series discs of steel 2·5 in. in diameter and 0·01 in. thick were employed; they were all cut from the same strip of metal, but some were "cold-rolled," some "annealed" and some "hardened." The total carbon was found to be —"cold-rolled," 1·108 per cent., hardened, 1·128 per cent., and annealed, 0·924 per cent. and 0·860 per cent. Some of the discs were submitted to the action of an oxidizing solution consisting of a cold saturated solution of potassium bichromate with 5 per cent. by volume of pure concentrated sulphuric acid. In all cases a blackish magnetic residue was left undissolved. These residues, calculated upon 100 parts of the discs employed had the following compositions:—"cold-rolled" carbon, 1·039 per cent., iron, 5·87 per cent., annealed, C, 0·83 per cent., Fe, 4·74 per cent., hardened, C, 0·178 per cent., F, 0·70 per cent.; so that by treatment with chromic acid in the cold, nearly the whole of the carbon remains undissolved with the cold-rolled and annealed discs, but only about one-sixth of the total carbon is left undissolved in the case of the hardened disc. The authors then give a *résumé* of previous work on the subject. In the second part they have investigated the action of bichromate solutions of various strengths on thin sheet steel about 0·008 in. thick, which was cold-rolled, and contained carbon, 1·144 per cent.; silica, 0·166 per cent.; manganese, 0·104 per cent. Four solutions were used; the first contained about 10 per cent. of bichromate and 9 per cent. of H_2SO_4 by weight, the second was eight-tenths as strong, the third about half as strong, the fourth about one and a half times as strong. In all cases the amount of solution employed was considerably in excess of the amount required to dissolve the steel used. A residue was obtained as before. With solution 1 the residue contained C, 1·021; solution 2, C, 0·969; solution 3, C, 1·049 (the atomic ratio of iron to carbon was $Fe_{2\cdot694}C_1$, $Fe_{2\cdot65}C_1$, $Fe_{2\cdot867}C_1$); solution 4, C, 0·266 per 100 of steel. The authors conclude that the carbon in cold-rolled steel exists, not simply diffused mechanically through the mass of steel, but in the form of an iron carbide, Fe_3C, a definite product capable of resisting the action of an oxidizing solution (if the latter is not too strong), which exerts a rapid solvent action upon the iron through which the carbide is distributed.

Mr. Spiller said that there was, perhaps, a possibility of decomposing the carbide of iron, if all the iron present were deposited, and suggested that it would be preferable to leave a little iron undissolved to prevent this risk.

Mr. Deering said that it seemed to him the only natural stopping point was to dissolve as much as possible with a given solution and examine the residue.

On the Spectrum of Beryllium, with Observations relative to the Position of that Metal among the Elements. By W. N. Hartley.—Owing principally to the difficulty of obtaining beryllium pure, it is still questionable whether beryllium is a triad with atomic weight 13·8 and oxide Be_2O_3, or a dyad with atomic weight 9·2 and oxide BeO. The author has photographed the spark spectrum from a saturated solution of the chloride, prepared from pure oxide presented to him by Dr. Emerson Reynolds, and concludes that beryllium is the first member of a dyad series of elements of which, in all probability, calcium, strontium and barium are homologues.

The Society then adjourned to May 3.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of this Association held on Wednesday, April 11, a paper was read by W. Ralph Dodd, entitled "A Few Hints on Germs in Disease." He stated if there was one subject more than another about which there was so many conflicting opinions, it was the question of germs. He pointed out that bacteria were known as early as 1675, but were looked upon as mere microscopic and scientific curiosities, and that it is only of recent date that their life history has been made out, and they have been relegated to their proper position in the organic world. He stated that they belonged to the order Schizomycetes, the simplest organism of the vegetable world, thriving best in liquids that contain decomposing or decomposable organic matter. They were all semi-cellular and as yet are seen only to reproduce themselves by cell division. Diagrams were shown illustrating the various species of the order: *Bacterium Termo*, associated with ordinary putrefactive change, *B. Limola*, the germ which produces the lactic fermentation of milk, and also other species, with their functions, were described. The incredulity that existed with reference to spontaneous germination was alluded to, and it was mentioned that at one time creatures as high up in the scale as frogs were supposed to be without parental origin, and that caterpillars were thought to be evolved from the leaves upon which they fed. The important part which these organisms play in putrefaction was pointed out, and that in their absence the process was a very slow one indeed. Some experiments of Pasteur, Koch and others on sheep, cattle, silkworms, etc., were cited as showing what relation these organisms bear to the various diseases in the human species, and it was pointed out that no less than thirty zymotic diseases were attributed to the so-called germs. On the other hand some were of opinion that they are not the actual cause of the disease, but rather that they are associated with it, since they do undoubtedly coexist with the disease. Various processes of staining were detailed for the detection of these germs in the tissues of the body for their isolation and cultivation outside of the animal body.

Some interesting microscopic specimens were shown of *Bacillus tuberculosis*, *B. Anthrax*, in lung and liver, from cases of splenic fever, and others, putrefactive bacteria, woolsorter's diseases, etc., etc.

Parliamentary and Law Proceedings.

Poisoning by a Narcotic.

An inquest was held by the Birmingham Borough Coroner (Mr. H. Hawkes), on Saturday, April 21, on the body of Edward Kiernan, 22, manufacturer's clerk, who had been found lying in bed dead. There was a small medicine bottle on the side table empty, and under a book on the table was found a letter addressed to the coroner, in which deceased expressed his intention to commit suicide.

Joseph Lucas, chemist, Colmore Row, stated that on Monday evening deceased called on him, and asked for a mixture of chloral so that he might get some sleep. Witness strongly advised deceased to try and do without narcotics, but deceased said if he did not get something to make him sleep he should have to take a dose of another kind. Finding deceased was determined to have sleeping draughts, witness let him have the bottle produced containing 2 drachms of chloral and 2 drachms of bromide of potassium, 2 drachms of spirit chloroform, and 2 drachms of syrup. This was made up to an ounce and a half, and the direction was that a twelfth of the whole was a dose. If deceased had taken the whole at once it was sufficient to poison him.

A verdict of "Suicide whilst in a state of temporary insanity" was returned.

Obituary.

CHARLES HERBERT HUTCHINSON.

The death is announced, at the early age of 24, of Mr. Charles Herbert Hutchinson. Mr. Hutchinson was a student from 1874 to 1877 in the laboratories of the Pharmaceutical Society, and afterwards studied at Wiesbaden with Professor Fresenius. Upon his return to England he occupied the position of Assistant-Curator of the Pharmaceutical Society's Museum, and then became Assistant to Professor Armstrong, at the London Institution and at the City and Guilds of London Institute in Cowper Street. In 1879 he was elected a Fellow of the Chemical Society, and in the year following began to interest himself in brewing. With this object he studied at Burton-on-Trent, and also at Strassburg, finally becoming proprietor of a brewery in Essex. Mr. Hutchinson was a prominent member of the School of Pharmacy Students' Association. In 1877 and again in 1878 he was elected Vice-President, and for four years fulfilled the duties of Reporter upon Inorganic Chemistry. Many of his Reports have been published in this Journal, and are noteworthy for the concise way in which papers containing the details of scientific work have been brought together and condensed so as to form summaries containing the essential points of long and intricate yet interesting and important researches. The following are the most important of Mr. Hutchinson's contributions:—"The Chemical Constituents of Ivy Berries" (with Mr. R. H. Davies), *Pharm. Journ.*, [3], vii., 275; "Myrtus Chekan," *Pharm. Journ.*, [3], ix., 653; "The Formulæ of some Inorganic Substances," [3], x., 841, and xi., 141; "Berthelot and Ditte's Researches upon the Hydrochlorides of the Metallic Chlorides," [3], xi., 1053; "Soxhlet's Researches upon the Quantitative Estimation of the Sugars," [3], xi., 720, 757; "Quantitative Electrolytic Analysis," [3], xii., 715.

Those who knew Mr. Hutchinson, and there are not a few in pharmacy, will regret the loss of one who stood high in the estimation of all as an able and conscientious worker of great promise, while his familiar friends will sadly miss the exhilarating effect of his amiable fellowship.

Notice has also been received of the death of the following:—

On the 21st of March, Mr. John Watkins, Chemist and Druggist, High Street, Abergavenny. Aged 53 years.

On the 24th of March, Mr. John Anderton, Chemist and Druggist, Northgate, Halifax. Aged 60 years.

On the 2nd of April, Mr. John Reay, Chemist and Druggist, St. Bees, Cumberland. Aged 54 years.

On the 6th of April, Mr. John Allan Paige, Chemist and Druggist, South Street, South Molton. Aged 79 years.

On the 7th of April, Mr. George Walter Brock, Chemist and Druggist, Chelmondiston, Suffolk. Aged 43 years.

On the 7th of April, Mr.

and Druggist, Charles Street, St. John's Wood, London. Aged 55 years.

On the 8th of April, Mr. George Wilson, Chemist and Druggist, Cathcart Street, Greenock. Aged 53 years.

On the 8th of April, Mr. William Howell, Chemist and Druggist, King's Lynn. Aged 29 years.

On the 10th of April, Mr. Frederick Robertson Martin, Pharmaceutical Chemist, Clevedon. Aged 40 years.

On the 12th of April, Mr. George Samuel Drury, Chemist and Druggist, Parrock Street, Milton. Aged 50 years. Mr. Drury had been a Member of the Pharmaceutical Society since 1875.

On the 13th of April, Mr. John Becket Hurst, Pharmaceutical Chemist, Market Place, Louth. Aged 36 years. Mr. Hurst had been a Member of the Pharmaceutical Society since 1870.

On the 21st of April, Mr. Thomas Baker, Chemist and Druggist, Islip Street, Kentish Town, London. Aged 41 years.

Notes and Queries.

[746]. Horse Hair.—Can any of the readers of the *Pharmaceutical Journal* inform me of a process for destroying the yellow pigment in horse hair? That at the root is quite white, becoming yellow or auburn towards the tip. Under 50 diameters the pigment appears crystalline. Of course this must be got rid of without destroying the hair. "Norsk."

Pharmacy Acts Amendment Bill.

Sir,—The expression of opinion respecting clause 2, which was appended to the resolution carried at the recent meeting in Manchester, might, with advantage, have been more clearly worded, but it was not based upon any misconception or erroneous assumption, as conjectured by you in your leader of last week.

The feeling of the meeting was one of regret that the Council had relinquished the claim, so recently made by them, to include, in the interests of the public, these same "poisonous" articles in the list of scheduled "poisons." In other words, that it had been thought necessary to admit the principle of allowing unregistered persons to sell poisonous articles, *i.e.*, poisons, when the main object of the poison clauses of the Pharmacy Act of 1868 was to limit, as well as regulate, the sale of them. We can hardly be blamed for supporting a view so clearly expressed in the earlier clauses of that Act, and so often and so ably enlarged upon by you on former occasions.

If Parliament will not accept the suggestion that these be added to the list of scheduled poisons, is it necessary to make such a compromising proposition as the one objected to by us?

If it be desirable in the interests of the public to limit, as well as regulate, the sale of poisons, surely it is inconsistent to approve the unrestricted sale of these so-called "poisonous" articles, no whit less deadly than those included in the Poisons Schedule of the 1868 Act. The fact that they have not yet been included is no argument that they ought not to be; the former action of the Council points, indeed, in quite the opposite direction. It was both logical and consistent for us, therefore, to object to the introduction of a clause approving of the sale of these articles by unregistered persons.

I fail to see that there is anything erroneous in our assumption that the particular articles referred to are not less a "part of the materia medica which appertain exclusively to the practice of the arts of pharmacy and medicine," than oxalic acid, corrosive sublimate, cyanide of potassium, vermin killers, etc., which were, with one accord, included in the poisons schedule.

F. Baden Benger,
Hon. Sec. Manchester Chemists and Druggists' Association

Sir,—As you have devoted two columns to our meeting at Manchester, I may venture to ask room for an explanation of the paragraph in the resolution which relates to clause 2. It is perhaps rather unfortunately worded and does not exactly express what was intended by the meeting, but not expecting a whole page of criticism and half a column of editorial lecturing we did not choose our words so carefully as we otherwise might have done. The real intention of the resolution was to express regret that "a legal sanction for the sale of poisonous articles by unregistered persons had been proposed for the first time in a Bill promoted by the Pharmaceutical Society," not that they were to be allowed to sell them. We are not quite so ignorant as not to know that unregistered persons are, and always have been, entitled to sell the articles in question, and, therefore, need no permission for continuing to do so, nor did we wish to interfere with established usage in that respect; but the opinion was very strongly expressed that the great objection to the clause is this,—that legislative sanction having once been given to the sale of poisonous articles by unregistered persons, there was no certainty that it would not, and no reason why it should not, be given to the sale of other poisons, *e.g.*, oxalic acid and some others, and so gradually extended to the whole Poisons Schedule.*

We are quite aware of the real purport of the second clause of the Bill and think we do not need much information about the real purport of any of the others, but did not think it either necessary or desirable to publish our opinions to all the world.

I should have thought that we, in this part of the country, who are accustomed to see them by hundreds of gallons, would hardly be supposed to labour under the "erroneous assumption that the particular articles to which the clause would apply are part of the materia medica which appertain exclusively to the arts of pharmacy and medicine." We do know a little more about them than to entertain such an idea, and though the business carried on by some of us is, unfortunately, of a mixed nature (very mixed), and we should probably be plucked for the Minor, or even the Modified, we do know that oil of vitriol, spirit of salt, aqua fortis and carbolic acid are not used exclusively in the practice of medicine and pharmacy, but are at least sometimes used in manufacturing processes.

I quite agree that it would have been desirable that an expression of opinion from this district "should have been supported by a greater number of those interested in the proposed legislation;" but people have to be thankful for small mercies sometimes, and it is just possible that a larger attendance might not have arrived at the same conclusion, for I have good reason to believe that many of those who stayed away are not merely "indifferent," but a good deal like the old apothecary spoken of by Mr. Giles, and have the same feeling towards the Pharmaceutical Society and all its acts as he had towards the College of Physicians; and, perhaps, do not quite see how a Bill, of which it is said, "that regard for the public safety is the only consideration upon which it can be submitted to the Legislature," should be considered necessary in the interests of pharmacy.

Manchester. W. Wilkinson.

[*** Our correspondent is over modest in being surprised that we should call attention to the proceedings of the Manchester Association, and he is uncharitable in forgetting that, editorially, we also have often to be thankful for small mercies. As regards the point upon which we appear to have incurred the displeasure of our Manchester friends, we do not, however, perceive any reason for altering our opinion as to their misconception, but of course we do not mean to insinuate that it is intentional.—Ed. Ph. Journ.]

* Mr. Frazer's remarks on this subject at page 868 deserve the very serious attention of every one interested in pharmacy.

Parrish's Syrup and Potassium Chlorate.

Sir,—Concerning Mr. Prosser's letter regarding the decolorizing effect of potassium chlorate on compound syrup of phosphate of iron, I beg to state that having made the experiment suggested in his paper I can only agree with his remarks to a certain extent.

I find if Squire's syrup be used no visible alteration takes place during a lapse of six hours, beyond the destruction of the characteristic bright appearance; if, however, the mixture be boiled for twenty minutes it assumes a dark flesh colour. Apparently this is due to the chloric acid, liberated by the free acid present, oxidizing the colouring matter of the cochineal, it behaving in a similar manner towards indigo and other pigments.

7, Poultry, E.C. William Thomas Deeks.

Sir,—The letter of Mr. T. H. Prosser, in the current number of the Journal, is an interesting comment upon the prevailing practice of preparing Parrish's syrup with hydrochloric acid. The fact that the *syrupus phosphatum compositus* being extremely liable, when manufactured on a large scale, to deposit considerably, has furnished the pretext, recommended originally, I believe, by Professor Parrish himself, for the production of a more elegant elixir by substituting for a portion of the free phosphoric acid, a more or less large proportion of HCl.

It is to the presence of this latter body that the decomposition, ascribed by Mr. Prosser to phosphoric acid, is due. Potassic chlorate and hydrochloric acid, dissolved in a large quantity of water, constitutes the well-known *mistura chlorinii acida,* which, besides its medicinal qualities, possesses in an eminent degree the powerful bleaching properties of chlorine.

On the other hand, dilute H_3PO_4 exercises no such undesirable action upon the chlorate; and if, in the case he has described, Mr. Prosser had employed a syrup prepared with this acid, and without the addition of HCl, he would have been spared the unpleasant *rencontre* with the prescriber to which he was subjected. Such a syrup, containing no hydrochloric acid and upon which $KClO_3$ exercises no inconvenient decolorizing powers, was fully described by Mr. S. Daniel, in a paper read at the London meeting of the British Pharmaceutical Conference, and which may be found in the published transactions of that body ('Year-Book of Pharmacy,' 1874, p. 596; and *Pharm. Journal* [3], v., 213).

I would like, ere concluding, to add that I heartily agree with the sentiment expressed in the last paragraph of Mr. Prosser's letter. I have, personally, always assumed that the reason Mr. Baldock's views had finally prevailed, and the 'Dispensing Memoranda' ceased to exist, was that recipes of a sufficiently difficult character had not been forwarded by correspondents to your office for elucidation.

Rock Ferry, Cheshire. J. E. Saul.

Assistants in India.

By the courtesy of Mr. Turner, of Great Russell Street, we are enabled to publish the following extracts from a private letter recently received, which throw further light upon the position of chemists' assistants in India:—

"With regard to myself I have no reason to regret coming out here; I am doing fairly well, with prospects of doing better, and am enjoying my usual good health.

"I had a liberal increase in my salary before I had been out six months.

"I have now got accustomed to the life in Bombay, and made a few friends, so that I am never at a loss to know how to spend an evening.

"When I came out I was put in charge of the laboratory and soda water factory, the former has been transferred to the opposite side of the "compound" to more convenient premises, and I have now got it nearly finished with all the latest improvements for carrying on laboratory work. The soda water factory also is a great item in the business. We have received lately one of Hayward and Tyler's largest and most improved soda water machines which works splendidly. I have over thirty men and boys to look after in my two departments.

"We have just finished another large warehouse specially built for drugs, druggists' sundries and patent medicines, and there is every probability of another one being erected, for the business goes on increasing wonderfully, so much so that five men have been brought out from home during the last twelve months.

"The assistants here are all on a very different footing to those at home; here you are practically your own master in your own department, and of course held responsible as such.

"I should not care to return to the life of an assistant at home again.

"We commence business at 8 o'clock; breakfast at 9 o'clock, and read the daily papers with all the latest intelligence; tiffin at 1 o'clock, to which we take one hour; at 4 o'clock we have a cup of tea and some toast; at 6 o'clock business is finished for the day. On Saturdays we close at 4, dinner at 8 o'clock.

"I joined the volunteers soon after I came out and find the Saturday afternoon parades great fun."

G. A. Paterson.—The subject of concentrated infusions was fully discussed in the earlier volumes of this Journal: see especially vol. xiv. of the first series. The varying results you speak of would appear to have been due to some irregularity in the mode of operating.

S. Griffith.—*Equisetum arvense.*

C. T.—*Ornithogalum nutans.*

Cerium.—No apparent decomposition takes place in this mixture; neither does it on standing show any tendency towards the disengagement of gas. Cold water should be used in dispensing mixtures with pulv. tragac. co.; the probable use of the starch is to separate the particles of gum and so facilitate the formation of the mucilage.

J. W. Aplin.—There should be no cloudiness or precipitation when liq. bismuthi is mixed with liq. magnesiæ, if both preparations used are according to the B.P.

Gulielmus.—When liquor bismuthi is ordered in a prescription the liquor bismuthi B.P., should be used. As the difficulty referred to does not occur with the B.P. preparation it needs no further remark. It is sometimes very difficult to determine the nature of the decomposition which takes place when a private preparation is used.

An Assistant (Leeds).—The prescriber has in this instance ordered for one pill the amount of ol. carui usually ordered for a dozen, and the dispenser must act accordingly.

U. A. Coates.—When tinct. quin. ammon. is mixed with plain or medicated water a separation of quinine takes place. If a little mucilage be previously added to the water the quinine will remain suspended in a finely divided condition, and there will be no aggregation of particles as a flocculent separation or as a precipitate.

P. H. and Novice.—A very suitable excipient for these pills is glycerine of tragacanth, made by mixing 1 part of powdered tragacanth with 6 parts of glycerine, allowing the mixture to gelatinize before it is used.

A. J. Rayson.—The disrespectful tone that pervades your letter throughout would render it unsuitable for publication, even if your complaints had a better foundation than they appear to have.

Pyrotechnist.—A recipe for making "Cheltier's Copper" will be found in vol. viii. of the present series of this Journal, p. 619.

F. C. S.—We are not acquainted with any such list.

H. Lambie.—Several communications on the preparation of koumiss have appeared in this Journal. See i., 865; iii., 544; iv., 692; v., 323. A recipe for making an imitation koumiss from cow's milk will be found in vol. ix., 1022.

Botanist.—The announcement for the Botanical Prize for 1884 will be found on p. 892 of this number of the Journal.

Blind.—It has not been published yet, but we hope to insert it in an early number.

Communications, Letters, etc., have been received from Messrs. Moon, Howie, Forrest, Saul, Colonial.

RESULTS OF THE ANALYSIS OF SAMPLES OF CINCHONA BARK GROWN IN JAMAICA.

BY DR. B. H. PAUL.

It having been considered desirable that analyses should be made of the samples of Jamaica cinchona bark, presented to the Museum of the Pharmaceutical Society by the Colonial Office, portions of these samples were placed in my hands for that purpose, and the following table gives the results arrived at.

It will be seen that there is some considerable difference between these results and those referred to by Mr. D. Morris in his notes,* as having been obtained by Mr. John Eliot Howard, and to some extent this is to be accounted for by the fact that the samples analysed by Mr. Howard two years ago were specially selected samples of the richest part of the lower trunk, while those recently presented to the Museum are a fairer average representation of the bark product for sale in Jamaica. This is especially the case as regards the sample of "officinalis," as I have had opportunity of ascertaining by a comparison of my results with those obtained by the analyses of a parcel lately sent over from Jamaica.

	Variety of Plant.	Kind of Bark	Quinine.	Quinidine.	Cinchonidine	Cinchonine.	Amorphous.	Total.
1	*Cinchona officinalis*	Trunk	3·74	0·04	1·77	0·23	0·30	6·08
		Twig	1·08	trace	·37	·60	·20	2·25
		Root	2·90	1·01	·67	4·60	·58	9·76
2	*Cinchona succirubra*	Trunk	2·04	·13	2·58	2·45	·50	7·70
		Twig	·78	—	·47	·23	·29	1·77
		Root	1·76	·34	1·39	4·40	·90	8·79
3	Hybrid?	Trunk	2·47	—	2·24	·90	·52	6·13
		Twig	1·00	—	·87	·40	·36	2·63
		Root	2·45	·57	2·02	3·54	·56	9·14
4	*Cinchona Calisaya*	Trunk	·34	·23	·82	·82	1·80	4·01
		Twig	—	—	—	—	—	1·30
		Root	trace	4·07	·45	1·80	·65	6·97
6	*Cinchona micrantha*	Trunk	1·13	·30	·67	3·24	·68	6·02
		Twig	·43	—	·28	·60	·50	1·81

The data in the foregoing table are also interesting in some other respects: thus, for instance, the large proportion of quinidine in the root bark of the "calisaya" sample is quite exceptional, and taken together with the small amount of quinine may perhaps be evidence of unhealthy growth or of the influence of unfavourable conditions of soil or climate. This small amount of quinine may, however, be due to the circumstance, referred to by Mr. John Eliot Howard at the Linnean Society last Thursday evening, that the plants sent to Jamaica as "calisaya" were really plants of *C. micrantha*, var. *Calisayoides*, instead of the true *Ledgeriana*, characterized by the large amount of quinine contained in the bark. Again, the amount of quinine in the "succirubra" sample shows that there is a very good type of this cinchona being cultivated in Jamaica.

While referring to these analyses it may perhaps be useful to publish some analyses made by me in 1878 of some of the first samples brought from Jamaica by Mr. R. Thomson. These samples were all very thin and green, probably having been taken from very young trees. The results furnished by the dried bark are as follow.

A comparison of these results with those furnished by the samples of bark presented to the Society's Museum shows such differences as may be taken to justify the inference that with further growth there has been in most instances an improvement in the quality of the bark. In the "succirubra" samples there is on the average more than twice the amount of quinine, and in the "officinalis" samples there is a considerable increase. In the case of the samples represented as "calisaya," however, the reverse is the case and this may be due to the bark having been derived from different varieties of that species.

	Quinine alkaloid. Per cent.	Cinchonine alkaloid. Per cent.	Cinchonidine alkaloid. Per cent.	Moisture. Per cent. in bark as received.
1 *Species uncertain*	0·95	0·20	1·39	34·7
2 *Succirubra*— From bridge at old foundation	0·98	1·30	2·92	10·0
3 *Succirubra*— From Latimore River	1·23	4·24	1·88	10·25
4 *Calisaya*— Facing William "Puv" (*sic*)	2·52	Traces.	4·04	11·25
5 *Officinalis*— Latimore River	2·27	0·20	5·46	8·50
6 *Officinalis*— From Monkey Hill	2·77	Traces.	0·58	13·0

EXPLOSIVES AND MATERIALS FOR EXPLOSIVES.

A copy of the following Circular, addressed to local authorities under the Explosives Act, has been forwarded from the Home Office, by direction of Sir William Harcourt, Secretary of State for that department, with a request that it might be published in the *Pharmaceutical Journal*:—

"Home Office,
"18*th April*, 1883.

"Sir,—I am directed by the Secretary of State to inform you that it appears to him desirable that the attention of the local authorities and of the police should be directed to the importance of exercising special and vigilant observation with a view to preventing the acquisition by persons for unlawful objects not only of explosives adapted for such purposes, but of the materials with which, if possessed of a little technical knowledge, they would be able to manufacture explosives.

"With a view to assisting you in exercising such observation, I beg to enclose a memorandum which has been drawn up by H.M. Chief Inspector of Explosives, and which enumerates the more important of the materials which are capable of being more or less readily applied to the production of explosive.

"It would be desirable that you should take immediate steps to bring this circular under the notice of all pharmaceutical chemists, chemists and druggists, drysalters, oil and colourmen, and manufacturers of or dealers in chemicals within your jurisdiction, and otherwise obtain for it such publicity as may be practicable in order that any suspicious cases of purchase or possession may be promptly brought under the notice of the police.

"I am at the same time to call your attention to certain provisions of the Explosives Act, 1875, *e.g.*, section 69, which directs that 'It shall be the duty of every local authority to carry into effect the powers vested in them under this Act,' and to the powers of appointing officers (sections 69 and 75), and the considerable powers of search and seizure conferred by sections 73, 74, and 75. You will not fail to observe that section 73 gives a power to search for ingredients of an explosive as well as for the explosive itself, while the Explosive Substances Act, 1883, which incorporates the same powers, extends them to the search for and seizure of any apparatus for firing explosives.

"Section 23 of the Explosives Act, 1875, imposes upon the occupiers of factories, magazines, stores, and registered premises the obligation of taking all due precautions for preventing unauthorized persons having access to the factory, magazine, or store, or to the explosive therein or in the registered premises, and attention should be at once called to any case in which it may appear to the local authority that this obligation is imperfectly discharged. The local authorities should also require their officers to direct the particular attention of the occupiers of all stores and registered premises within their jurisdiction to this obligation.

"I am also to insist upon the importance of the local authority availing themselves of the powers which the Explosives Act of 1875 confers upon them of appointing competent officers to carry out the Act within their jurisdiction; and these officers should be enjoined to direct their particular attention to the prevention by every means in their power of the illegal manufacture and possession of explosive.

"I am to add that a reward of £100 will be given to any person (other than a person belonging to a police force in the United Kingdom) who furnishes information which may lead to the discovery and conviction of any person who may be engaged in the illegal manufacture of explosive, in any case in which it is shown to the satisfaction of the Secretary of State that such illegal manufacture constituted a serious infraction of the law, and was being carried on for a criminal purpose.

"I am, Sir,
"Your obedient servant,
"A. O. F. Liddell."

"*Memo.*

"Independently of the purchase of explosives (such as dynamite, blasting gelatine, guncotton, tonite, potentite, and detonators) specially adapted for blasting, and therefore generally available for destructive purposes, by persons who may not be reasonably supposed to require the same for industrial objects, suspicion should attach to the acquisition in notable quantities of all or any of the materials adapted for the making of explosives when the person seeking to purchase the same is unknown to the seller, or is not known to require such materials for trade purposes or other legitimate use.

"Among the substances which fall within this category may be specially enumerated the following:—

Nitric acid } especially in their more concen-
Sulphuric acid } trated forms.
Glycerine.
Saltpetre.
Chili saltpetre (nitrate of sodium).
Chlorates (especially chlorate of potash).
Picrates.
Picric acid.
Phosphorus.
Iodine }
Metallic mercury } Even in comparatively small quantities.
Nitrate of mercury }
Orpiment.

"V. D. Majendie, *Colonel*,
"*H.M. Chief Inspector of Explosives.*"

DEODORIZED COD LIVER OIL WITH IRON.*

BY W. A. HENRY.

Take of—

Cod liver oil	1 pint.
Sulphate of iron, dried	64 grains.
Castile soap, powdered	128 grains.
Charcoal, powdered	1 ounce.
Coffee, ground	½ „
Or,	
Chocolate, powdered	¼ „
Hot water	q.s.

Dissolve the sulphate of iron and Castile soap, each separately in a sufficient quantity of hot water, mix the two solutions, and after washing the resulting precipitate (oleate of iron) with water, triturate the oleate in a mortar with the cod liver oil (previously heated in a water-bath) gradually added; then the remaining ingredients, subject the whole to a water-bath for an hour, and filter, while hot, through paper or flannel.

The oleate of iron, which each tablespoonful of this preparation contains, is equivalent to nearly 1 grain of the sulphate of iron. To increase the quantity of iron in the above formula, twice the amount of the sulphate and soap may be used; the preparation would then contain oleate of iron equivalent to nearly 8 grains of sulphate of iron to the fluid ounce, or 1 grain to a teaspoonful, the latter modification being adapted to the administration of small doses of the oil.

The preparation has a dark brown, almost transparent appearance, the oleate of iron combining readily with the warm oil. It retains only a faint odour of cod liver oil, the charcoal assisting as a deodorizing agent, and the chocolate or coffee adding flavour to the same. It has the advantage of being acceptable to persons who would reject the oil in its unmodified form.

The Pharmaceutical Journal.

SATURDAY, MAY 5, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEDICAL COUNCIL AND PHARMACOPŒIA REVISION.

WE learn from the medical journals that the British Pharmacopœia is again to be placed upon the stocks, for repair of such dilapidations as in the lapse of time naturally result from the progress of knowledge rather than any other cause. The sixteen years that have passed since the work was last in hand have been so fertile in additions to our chemical science, to our materia medica, and in applications of science for the purposes of medicine and surgery, that it is full time the standard authority in accordance with which pharmacists are bound to regulate the execution of their duties should be brought to the level of the time.

The responsibility of carrying out this work from time to time is by law entrusted to the General Medical Council, and although that body as at present constituted has probably but a brief existence to look forward to, it has been deemed expedient in the face of that prospect to provide for the preparation of a new edition of the Pharmacopœia. The Committee appointed last July for this purpose consisted of Drs. QUAIN, AQUILLA SMITH, PITMAN and HALDANE, and Messrs. COLLINS, BRADFORD and MACNAMARA. At its first meeting a Sub-Committee was empowered to take such steps as were thought necessary towards preparing the new edition and to report thereon. At the late meeting of the Medical Council the Pharmacopœia Committee presented a report, showing that the Sub-Committee had communicated with Professors REDWOOD, BENTLEY and ATTFIELD, as to undertaking the duty of preparing a new edition of the Pharmacopœia under the direction of the Committee; that these gentlemen had submitted a report which, subject to certain modifications recommended by the Sub-Committee, had been approved of, and that an arrangement had been made to pay them a sum of £800 as their remuneration for the work of carrying out any experiments required, correcting the press, and preparing an index to the satisfaction of the Committee.

From the report of the Professors it appears that the negotiations relating to this arrangement have been in progress since last November, and that some time prior to the date of the report, the Pharmacopœia Committee had given instructions for the work of revision to be proceeded with. The Professors then go on to explain such changes as they think requisite, and assuming the general arrangement of the matter in the Pharmacopœia to be satisfactory they direct attention mainly to chemical nomenclature and notation, and to the mode of representing quantities of ingredients in preparing medicine. The recommendations in regard to the former subject embody the views propounded some years ago by Professor ATTFIELD and subsequently adopted in the United States. It is also proposed to discontinue the use of symbolic notation according to the old system, and to indicate that chemical formulæ have a somewhat qualified meaning in regard to the commercial forms of such articles as cream of tartar. This will, perhaps, be of benefit to public analysts afflicted with a mania for impossible purity, and it may be useful in preventing them from troubling without reason.

In regard to the subject of proportional weights reference is made to the comments upon it in the preface to the Pharmacopœia, and the reasons there given for not adopting the metric system as being in their general bearing applicable now with almost as much force as when they were written; but with the view of facilitating and promoting the more general use of metric weights and measures it is suggested that proportional parts should be substituted for specific weights and measures wherever it be applicable in the description of processes. It is not recommended that this change should be carried so far as to adopt parts by weight for liquids as well as solids, as has long been the case in Germany and is now in the United States, but it is thought that, with few exceptions, parts might be substituted for specified weights and measures with advantage, the term "parts" being used to represent parts by weight, and the term "fluid parts" to indicate the volume of the specified number of parts of the same value of water. This method of representation will be adopted side by side with the present method in the new edition of the Pharmacopœia, and it will thus be seen that in describing or interpreting a process by the new method, all the proportional numbers applied to the process must refer to one and the same denomination of weight or measure. It is pointed out that in the great majority of cases the quantitative relation of ingredients in the processes is simple, and the application of the new method would be obvious and easy; but some processes would require to be reconstructed and, in a few instances, it will be necessary to make a slight alteration in the proportions of the ingredients. The only cases in which the method is inapplicable are those of the enemas and inhalations, and the formulæ of these will be left as exceptions to the general practice.

The advantages anticipated from the adoption of this method are—that the use of proportional numbers will tend to the simplification of proportions in compounded medicines; that the proportions given being equally applicable to either of the two systems of weights and measures, a way will be opened to the more general use of the metric system; that the processes of the B.P. will be more intelligible to medical men and pharmacists abroad who are accustomed to use the metric system exclusively; and that thus provision will be made for the assimilation of medicines bearing the same names in different Pharmacopœias.

So far as relates to the introduction of new drugs or preparations, and the elimination of any that have proved to be unnecessary, the report of the professors witholds any opinion as to specific articles until opportunity has been offered for investigation and consultation with the Pharmacopœia Committee and with such medical and pharmaceutical authorities as it may think should be consulted. A more decided view is expressed on the alteration of processes, as well as of descriptions and definitions of substances, and it is justly stated that in this direction there is room for improvement involving much experimental work. The same will also be needed in connection with the chemical processes generally, and for extending and rendering more complete the application of chemical tests.

The satisfaction with which pharmacists might be expected to regard the prospect of a speedy revision of the British Pharmacopœia may, however, be very considerably modified, if the reports given in the medical journals as to the arrangements that have been made for the execution of the work convey a complete account of those arrangements. It is true that the Committee makes mention of an intended application to the Pharmaceutical and Chemical Societies, as well as to the several medical authorities and such persons as may be likely to furnish useful information for making the Pharmacopœia as complete as possible; but this is a proceeding that would not travel beyond the necessities of the case so far as the Committee is concerned, and it does not seem, so far as we can gather from the published reports, to comprise any consideration for the views respecting the representation of pharmacy that have of late years been put forward and supported by forcible arguments derived from the nature of the work to be done as well from the usage of other civilized countries.

Whether the want of information on this point is due to deficiency in the reports or not, it is certainly matter for surprise that the revision of the Pharmacopœia should now appear to have been for many months under consideration by the Medical Council without any communication on the subject having been made to the Council of the Pharmaceutical Society. Is it to be inferred that some malign influence hostile to the Society dominates the proceedings of the Pharmacopæia Committee, or is that body unmindful of the necessity for recourse to practical pharmacists for assistance in the preparation of a Pharmacopœia? It would, we think, have been easy on the part of the Pharmacopœia Committee of the Medical Council to place this matter in a position satisfactory to pharmacists and calculated to ensure the attainment of the objects which that Committee has in view, by communicating to the Council of the Pharmaceutical Society the plan contemplated for the revision of the Pharmacopœia and asking the advice and support of the Society in carrying it out. Certainly, the absence of any such communication with the body which represents pharmacy bears the appearance of a slight, whether it be intentional or not, and we cannot refrain from expressing our great surprise that without such a step the arrangements for the revision of the Pharmacopœia should have been carried so far as they appear to have been. Nor is our surprise lessened by the circumstances that the Pharmacopœia Committee has entered into arrangements for engaging experts to carry out the work of revision in regard to chemistry, materia medica and practical pharmacy, and that the experts requested and willing to undertake the duty of preparing a new edition of the Pharmacopœia, without any official recognition of the Pharmaceutical body, are the Society's Professors.

NOMINATION OF LOCAL SECRETARIES.

Probably before the publication of another number of this Journal the Members and Associates in Business of the Pharmaceutical Society will be in receipt of the voting papers for the forthcoming election of Members of Council and Local Secretaries. This will, therefore, be a timely opportunity for calling attention to a form of abstention from voting which it is especially important shall not obtain to any extent this year: we refer to the omission of a large number of provincial voters to fill in the papers relating to the office of Local Secretary. The extent of this default may be estimated from the statement made last year by the Secretary, that whilst the number of towns entitled to appoint a Local Secretary was three hundred and three, nominations for the office had been received from only one hundred and ninety-two. Such a condition of affairs, if existing at certain conjunctures, might deprive the Society of one-third of its political strength. It will be seen, for instance, from the report of the proceedings of the Council on Wednesday, that it may become desirable at an early date to support the action of the Council in respect to Pharmacopœia revision by the presentation of petitions from every district, and in other ways to bring local influence to bear upon members of Parliament; but it must be evident that it will be difficult to do this effectually in places where the pharmacists have neglected to provide the most elementary means for securing prompt intercommunication and co-operation. Nor is this the only subject upon which it may become necessary for the trade to make its influence felt during the present or the next session of Parliament, and it is, therefore, to be hoped that each voter will make a point of nominating as Local Secretary the man whom he may deem most competent to serve the Society in this direction.

At the meeting of the Linnean Society last Thursday, a paper was read by Mr. John Eliot Howard bearing on some important questions in reference to the cultivation of cinchonas as a source of quinine-yielding bark. Want of space prevents our referring more at length to this paper in the present number, but we hope to have an early opportunity of giving a *résumé* of Mr. Howard's views.

* * *

On Friday, the 27th ult., the Medical Acts Amendment Bill was read a third time in the House of Lords and passed, and on Wednesday it was read a first time in the House of Commons, Mr. Mundella's name being on the back of the Bill. As a last finishing touch, before parting with the Bill, their Lordships eliminated the Apothecaries' Society of London from the list of bodies that would be entitled under its provisions to send representatives to the "Medical Board" entrusted with the carrying out of the "final examinations in England for the admission of candidates to registration as medical practitioners." The Society does not seem to have mustered a single defender, and even the Lord President admitted that its claims to representation were of the slightest. So that, as the Earl of Camperdown put it, the Society of Apothecaries will, if the Bill passes in this form, lose its power of granting licences to medical candidates, and it may, therefore be expected that its degree and diploma will not be sought after with so much avidity in the future. The Bill is set down for second reading on Thursday next.

* * *

An attempt made by the chemists and druggists' assistants of Walsall to obtain from their employers the boon involved in closing their establishments on Monday and the three following evenings in each week at eight o'clock has been fairly successful, ten out of thirteen employers having promised to conform to the rule.

* * *

We regret to have to record that on Thursday, April 26, another annuitant, Mr. William J. Froom, passed away at the age of eighty-one, the immediate cause of death being cerebral hæmorrhage. Mr. Froom was formerly in business at Exeter, and was one of the Founders of the Pharmaceutical Society. He was elected at the second election of Annuitants, in the year 1866.

* * *

Some little amusement has been caused by a paragraph that has gone the round of the press to the effect that an experiment consisting in the explosion of a thimbleful of dynamite under water, made by Mr. Allen, of Sheffield, to illustrate a lecture he was delivering in Firth College on the "Chemistry of Explosives," resulted in the destruction of the containing bucket and the scattering of the water over a portion of his audience. In an explanatory letter that appeared subsequently Mr. Allen deprecates exaggeration, and states that the explosion occurred exactly as arranged, and that the scattering of the water and the tearing open of the bucket were effects fully anticipated. It is not surprising, however, that some of the audience who did not share Mr. Allen's expectations should have come to a different conclusion and made a hasty retreat from his demonstrations.

* * *

In a paper published in the *Chemical News* (April 13, p. 169) Professor Bloxam states that removal of the nitro radicle from nitro-glycerine can be safely effected by treatment with potassium or ammonium sulphide, or the solution produced by boiling flowers of sulphur and slaked lime together in water. This last, though somewhat more slow in its action and requiring most agitation, would furnish the cheapest method of decomposing nitro-glycerine, unless it were found that the "calcium sulphide" from the tank waste of alkali works could be substituted for it. The nitro-glycerine is poured into the sulphide liquor, and after a few minutes' stirring the reduction appears to be complete, free sulphur being deposited.

* * *

The *Pharmaceutical Record* tells a strange narrative of a recent occurrence in the Insane Asylum at Staunton, Va., in which institution it is the custom to dispense the medicines for the patients in single doses in mugs. It is supposed that whilst three trays full of these mugs containing medicines were waiting for the nurses to take them into the respective wards some person tampered with the contents, for immediately after the administration of the medicines, which were supposed to be limited to iron and quinine tonics and an anodyne mixture containing fluid extract of hyoscyamus, some of the patients complained of the effects, and within ten minutes several had died, whilst two others died after two hours, and another after two days. *Post mortem* examinations disclosed the presence of aconitine, as much as four-fifths of a grain being recovered from one stomach, some of it in a crystalline condition. That the results were attributable to tincture or fluid extract of aconite is thought impossible, and, moreover, the dispensary stock of these two preparations was found undisturbed. To add to the mystery, no aconitine was known to be in the asylum, and it was not kept in stock by any chemists in the town.

* * *

It is reported to be the intention of the French Government to lay before the Legislative Assembly a Bill having for its object to increase the annual pension to M. Pasteur, voted some time since, from 12,000 to 25,000 francs, with reversion to his wife and children.

* * *

It has been decided to adopt for the new Codex, in respect to degrees Baumé, the experimental results of Messrs. Coulier, Berthelot and d'Almeida, as embodied in a report which was printed in this Journal in the year 1873 (vol. iv., p. 470).

* * *

According to the *Pharmaceutical Record* the police authorities of Washington, D.C., have issued warrants for the arrest of fourteen druggists for violation of the local Pharmacy Act, in the employment of "clerks" that were not registered pharmacists or assistants.

* * *

At a meeting of the School of Pharmacy Students' Association to be held on Thursday next, May 10, at 8 p.m., a paper on "Acetic Acid and its Derivatives" will be read by Mr. H. S. Elworthy, and a Report on Pharmacy will be made by Mr. R. A. Cripps, consisting of "Notes on the United States Pharmacopœias."

* * *

A meeting of the London Section of the Society of Chemical Industry will be held on Tuesday next, the 8th inst, when a paper on "Secondary Batteries," by Mr. C. T. Kingzett, will be read.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 2, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Austin, Alfred.
Holmes, James Henry.
Levett, Herbert.
Marsh, Edward.
Pidgeon, Joshua David.
Ransom, Francis.
Smith, William Thomas.
Spencer, George.
Stephenson, Stephen.
Townsend, Henry Holden.
Tyson, Thomas Balmforth.
Worsley, Albert George.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Burton, Walter......Geneva.
Deeks, William Thomas......London.
Fisher, Harry......Bristol.
Fletcher, James Edward......London.
Foggitt, John Blackett......Thirsk.
Holmes, James Henry......Kendal.
Levett, Herbert......Bodiam.
Marsh, Edward......Luton.
Parker, William Henry......London.
Ransom, Francis......London.
Shephard, William Arthur......Gt. Malvern.
Smith, William Thomas......Bridgnorth.
Spencer, George......Hitchin.
Stephenson, Stephen......Llyn y mawn.
Townsend, Henry Holden......Bristol.
Tyson, Thomas Balmforth......London.
Worsley, Albert George......Folkestone.
Wright, Robert......Buxton.
Yeatman, Frederick James......London.

Chemist and Druggist.

The following registered chemist and druggist, who was in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society:—

Pullan, John Richard......Harrogate.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Anderson, James......Dundee.
Bates, Frederic William......Manchester.
Baxter, William Smith......Bradford.
Beacock, Joseph Henry......Leeds.
Birkbeck, John Thomas......Lincoln.
Boon, Nathaniel......Kirton Lindsey.
Burroughs, George Henry......Oxton.
Bush, Robert......Norwich.
Chambers, Herbert......Brighton.
Chapman, Walter......London.
Clare, John......Scarborough.
Coslett, Thomas Watts......Brierley Hill.
Dickinson, John George......Lancaster.
Duncalf, Thomas Henry......Macclesfield.
Elliott, Henry......Kimberley.
Fraser, Alexander......Liverpool.
Harwood, George Rosamond......Forest Hill.
Jackson, Henry Lawson......London.
Jenkins, Evan......New Southgate.
Jones, Charles William......Ashby-de-la-Zouch.
Jones, Thomas Glynne......South Stockton.
Lloyd, Walter......Carmarthen.
McGregor, Donald......Leith.
Michie, Charles Coutts......London.
Morgan, William John......Great Bridge.
Need, John......Gt. Malvern.
Newton, George Harry......Ashton-under-Lyne.
Phethean, James......Bolton.
Russell, John William......Dundee.
Saunders, Thomas Samuel......London.
Skinner, Robert......London.
Taylor, Henry......Marple.
Thomas, Thomas Rees......Burry Port.
Thorpe, Thomas Frederick......Northampton.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

RESTORATIONS TO THE REGISTER.

The following persons having severally made the required declarations and paid a fine of one guinea, their names were restored to the Register of Chemists and Druggists:—

Edwin John Frith, 50, Westminster Bridge Road, London, S.E.

Nathan Moore Green, 34, Fox Street, Liverpool.

George Francis Hart, 53, Albert Row, Southwick, Sunderland.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was read and adopted, and various accounts ordered to be paid. The Committee also recommended that £3000 on the General Fund be placed on deposit at the London and Westminster Bank.

The Council went into committee to consider the question of re-investment in ground rents. After considerable discussion, the Council resumed, and it was resolved that Mr. Butt's name be added to the Committee entrusted with this matter.

The Council again went into committee and discussed for some time the regulation under which fines are imposed on members who have left the Society and desired to return.

It was decided to refer the whole subject to the consideration of the Library, Laboratory and Museum Committee, to report at the next meeting of the Council.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£20 to the widow and the daughter of an associate and member from 1841 to 1877, to assist the applicants in emigrating, providing a certain additional sum be raised by their friends.

£10 to a former associate and member, aged 65, who has had two previous grants.

£10 to assist in the education of two orphan children of a late associate.

£10 to a registered chemist and druggist, aged 76.

The report and recommendations of the Committee were received and adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Librarian's Report.

This report stated that the report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
March	Day	687	37	11	28
	Evening	189	17	3	10

Circulation of books.	No. of Entries. Town.	Country.	Total.
March	176	123	299

Carriage paid, £2 6*s.* 2*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Berichte d. deutschen chemischen Gesellschaft, 188?.
Journal of the Chemical Society, 1882.
From Mr. WALTER HILLS.
Foster (M.), Text-book of physiology, 4th ed., 1883.
From the AUTHOR.
Hoffmann (F.) and F. B. Power, Manual of Chemical Analysis, as applied to the examination of medicinal chemicals, 3rd ed., 1883. From the AUTHORS.

The Committee recommended the purchase of the undermentioned works for the Library:—

Ogilvie (J.), Imperial Dictionary of the English Language, new ed., by C. Annandale.
Sprague (J. T.), Electricity, 1875.

The Committee also recommended the purchase of the undermentioned works and periodicals for the Society's Library in Edinburgh:—

Dorvault's L'Officine.
Stillé and Maisch's National Dispensatory.
United States Pharmacopœia.
British Homœopathic Pharmacopœia.
Hager's Handbuch der pharmaceutischen Praxis.
Ringer's Handbook of Therapeutics.
Quain's Dictionary of Medicine.
Sachs' Text-book of Botany.
Lindley and Moore's Treasury of Botany.
Payen's Industrial Chemistry.
Roscoe and Schorlemmer's Treatise on Chemistry.
British Medical Journal.
Lancet.
Edinburgh Medical Journal.
Nature.
Chemical News.
New Remedies.
Journal of the Chemical Society of London.
Proceedings of the Royal Society of London.

Curator's Report.

The Curator had reported that the attendance in the Museum had been:—

	Total.	Highest.	Lowest.	Average.
Morning .	483	33	11	20
Evening .	105	11	0	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

A complete and valuable collection of the barks, and of Herbarium specimens of the Cinchona trees cultivated in Madras. Forwarded through HER MAJESTY'S SECRETARY OF STATE FOR INDIA.
Specimens of pure Aldehyde and Metaldehyde.
From Messrs. HOPKIN AND WILLIAMS.
Specimens of the leaves of Sethia acuminata, of Mollugo cerviana, of the resin of Semecarpus Gardneri and of the Fruits of Randia dumetorum.
From Dr. ONDAATJE, Ceylon.
Specimens of crude and refined Ozokerit; and of elastic Bitumen, from Castleton, in Derbyshire.
From Mr. L. FIELD.
Specimen of Wild Belladonna root.
From Mr. H. B. JOHNS, Southampton.
A basket of Elemi from Manilla, being an unusual form of package for the drug.
From Messrs. EVANS, LESCHER AND WEBB.
Fine pod of Bourbon Vanilla (*V. Pompona*).
From Mr. EMIL SELBERG.
Specimens of Madras and Bombay and Cochin Nux Vomica seed. From Mr. T. WHIFFEN.
Specimens of Cinchona barks not now met with in pharmacy. From Mr. E. N. BUTT.
A case of chemical specimens prepared some years ago in the Laboratory of the Society by Mr. FORD.

Professors Redwood and Bentley had attended and reported satisfactorily of their respective classes.

The President had reported the steps taken with respect to the laying down of wood pavement in Great Russell Street, he having taken the responsibility of guaranteeing that the amount required by the Board of Works in order to carry out this improvement should be forthcoming. The Committee recommended that the President's guarantee be confirmed.

The Committee had considered the alterations necessary in the regulations for written examinations consequent upon the extension of time to be introduced into the Preliminary examination, and recommended that on and after December 31, 1883, the resolution of January 7, 1874 (*Pharm. Journ.*, January 10, 1874, p. 563), be rescinded, and that the following regulations be adopted instead thereof:—

"*Regulations for Written Examinations.*

"That persons be especially appointed by the Council to superintend the written examinations; that they be called superintendents of examinations, and be paid fees for each examination; such superintendents not being necessarily members of the Board of Examiners.

"A deputy-superintendent shall be also appointed by the Council in each centre.

"A fee of one guinea for the first part and half-a-guinea for the second part of the examination shall be paid to the superintendent or deputy-superintendent on the occasion of each examination.

"The Local Secretary shall be, in the first instance, offered the appointment of superintendent.

"The Preliminary examinations shall be held in the months of January, April, July and October, on the second Tuesday of the month, from 11 a.m. to 4 p.m., with an interval of one hour from 2 to 3 p.m.

"No examinations shall take place in the house of the superintendent or deputy-superintendent. He shall be authorized to engage some apartment suitable for the purpose, and charge a sum not exceeding 15*s*. to the Society on account thereof.

"The examination for the Jacob Bell Memorial Scholarships shall be held annually on the second Tuesday in July, concurrently with the Preliminary examination.

"Notice shall be given in the *Pharmaceutical Journal* two months prior to the day of holding each Preliminary examination, that such examination will take place, and giving a list of the centres at which it will be held.

"Candidates for the Preliminary examination must pay the fee and give notice to the Registrar (on a printed form of application, to be obtained from him) of their intention to present themselves for examination, and shall also state the centre at which they desire to be examined. Such notice and the fee must in each case be in the hands of the Registrar not less than fourteen days prior to the day on which the examination is to be held.

"The examination papers shall be forwarded by the Registrar under seal, to the superintendents or deputy-superintendents, so as to be received by them not later than the morning of the day fixed for the examination. Special sheets for the candidates to write upon will also be sent by the Registrar.

"Writing materials for each candidate must be provided, and all arrangements for the accommodation of the candidates completed before the hour fixed for opening the packets of questions from the Registrar.

"The instructions to superintendents and deputy-superintendents of examinations shall be as follows:—

"*Instructions to Superintendents and Deputy-Superintendents of Examinations. To be read aloud to the Candidates before commencing their writing.*

"Candidates must be in their places at the time appointed, and after this time no candidate will be admitted.

"Candidates must be placed at a sufficient distance from each other to prevent copying, and they are not permitted to take either books, scribbling papers, or memoranda into the examination room.

"The examination papers must be opened by the superintendent or deputy-superintendent at the appointed time, in the presence of the candidates, and immediately distributed by him.

"He must see that each candidate signs his papers in the place indicated.

"The answers to the questions are to be written on one side of the paper only, the other side being intended for scribbling and calculations. No other scribbling paper is allowed to be used.

"No examination paper shall be taken from the room until the examination is complete.

"The superintendent or deputy-superintendent must carefully watch the whole examination, to see that the candidates do not use unfair means, either by assisting each other, or using books or notes. No person except the superintendent or deputy-superintendent, or a member of the Council, or of the Boards of Examiners, is permitted to be present, and on no consideration shall candidates be allowed to speak to each other after the papers are distributed.

"A candidate wishing to ask any questions must hold up his hand; the superintendent or deputy-superintendent will come to him, and satisfy any legitimate inquiry, but no explanation will be given on the subject-matter of the questions.

"At 11 a.m. the questions on Latin shall be handed to the candidates, who must deliver their written papers on that subject, with all memoranda and scribblings thereon, to the superintendent or deputy-superintendent at 12.30 p.m.

"At 12.30 p.m. the questions on Arithmetic shall be handed to the candidates, who must deliver their written papers on that subject, with all memoranda and scribblings thereon, to the superintendent or deputy-superintendent at 2 p.m.

"The superintendent or deputy-superintendent must then forthwith enclose all the written papers on Latin and Arithmetic in an envelope sent for that purpose by the Registrar, seal it with his seal, and forward it by first post thereafter to the Registrar, enclosing the accompanying declaration duly filled in and signed.

"At 3 p.m. the questions on English shall be handed to the candidates, who must deliver their written papers on that subject, with all memoranda and scribblings thereon, to the superintendent or deputy-superintendent at 4.30 p.m.

"The superintendent or deputy-superintendent must then forthwith enclose all the written papers on English in an envelope sent for that purpose by the Registrar, seal it with his seal, and forward it by first post thereafter to the Registrar, enclosing the accompanying declaration duly filled in and signed."

The resolution of the Council at its last meeting with reference to the Medical Acts Amendment Bill and Pharmacopœia revision had been considered, and it had been deemed desirable for the President to have an interview with the promoter of the Bill (the Lord President of the Council) previous to drafting any proposed amendment.

The regulations for the admission of visitors to the Museum had been considered, and it was recommended that the regulation on this subject, published in the Calendar, should be worded as follows:—"Persons not connected with the Society who are desirous of obtaining admission to the Museum, should make application to the Secretary."

An estimate had been obtained for further accommodation for specimens in the Museum, and it was recommended that an additional case be fixed in the examination room, for the reception of reference specimens, at a cost of £45.

At a second meeting of the Committee the President had reported that he had sent the following letter to the Clerk to the Privy Council. He had since had an interview with the Lord President of the Council, who was not disposed to agree to the principle of the proposed alteration of the Medical Bill.

"Pharmaceutical Society of Great Britain,
"17 Bloomsbury Square, London, W.C.
"*12th April*, 1883.

"C. Lennox Peel, Esq., C.B.

"Dear Sir,—I am requested by the Council of this Society to call the attention of the Lord President of the Council to the provisions of the 'Medical Acts Amendment Bill' in so far as they relate to the preparation and revision of the British Pharmacopœia.

"This volume is to be produced under the direction of the Medical Council, but there is no instruction as to what class of persons is to constitute the Committee which must necessarily be appointed for compiling and revising the Pharmacopœia *previous* to its publication.

"In this country, hitherto, that Committee has consisted solely of members of the medical profession, whereas in all other European countries the constitution of that Committee is fixed by law, and it includes, in every case, a considerable number of pharmaceutical chemists, and in the United States of America, pharmacists form a majority of the Committee of Revision.

"The decision as to what drugs or medicines shall be introduced into or expunged from the Pharmacopœia rests with the medical members of the Committee and the working out of the chemistry and pharmacy of the preparations and the manner in which they should be made rests with the pharmaceutical members.

"The Council of this Society considers that this or some such method should be followed in this country and laid down in the Bill now in the House of Lords. It is supported in this view by many members of the medical profession and by articles which have appeared from time to time in the medical press. Moreover, inasmuch as by the Pharmacy Act, 1868, and the Sale of Food and Drugs Acts, the Pharmacopœia is taken as the standard of purity and strength of such drugs and medicines as are contained therein, it seems desirable that the practical experience of pharmaceutical chemists should be made available on the Committee.

"I am desired by the Council to solicit the favour of a personal interview with the Lord President before the Bill is considered in Committee, to enable me to explain more fully its views and point out other considerations bearing on the subject.

"I am, dear Sir,
"Yours faithfully,
(Signed) "M. Carteighe.
"*President.*"

The Committee had resolved that the President be instructed to arrange for an interview between a deputation from the Committee and those members of the House of Commons who have charge of the Bill when it arrives in that House.

The draft Annual Report had been submitted, approved and ordered to be sent to each member of the Council.

Mr. Woolley asked if in future the admission of visitors to the Library and Museum would be in the discretion of the Secretary.

The President said the Secretary would be the person responsible.

Mr. Symes thought it would be very satisfactory to everyone to know that any person, within reasonable limits, might gain information from the Museum and Library. He hoped the discretionary power now placed in the hands of the Secretary would be exercised in a broad and liberal spirit.

Mr. Greenish feared that difficulties would constantly crop up in connection with this question. If it were possible—he did not know that it was—he should like to see some arrangement carried out in the Museum whereby those drawers which were really used by students qualifying for an examination should be removed to some room upstairs, all those specimens which were objects of scientific interest being left in the Museum. If this were done those visitors who came for scientific purposes would not be so liable to interfere with those who came for educational purposes.

The President thought the tendency of the Committee's work was in the direction indicated, and probably the difficulty would solve itself in a year or two.

Pharmacopœia Revision.

Mr. Greenish wished to direct the attention of the Council to a very important subject which arose in connection with the Report of the General Council of Medical Education and Registration, as published in the last number of the *British Medical Journal.* It included a report from the Pharmacopœia Committee of the Medical Council which had been ordered to be received and entered on the minutes. It was in the following words:—"The Pharmacopœia Committee, at their first meeting on July 8, 1882, appointed a Sub-Committee, with power to take such steps as they thought necessary towards preparing a new edition of the Pharmacopœia and to submit a report to a future meeting of the General Committee. The Sub-Committee have reported that they have held two meetings since their appointment, and that they have communicated with Professors Redwood, Bentley and Attfield as to undertaking the duty of preparing a new edition of the Pharmacopœia under the direction of the Committee. These gentlemen have submitted to the Pharmacopœia Committee a report, which with certain modifications recommended by the Sub-Committee has been approved of and, as so amended, is appended hereto." In their report the Professors said, "Having received your instructions to proceed with the revision of the British Pharmacopœia, we now, in accordance with the suggestions made in our joint letter of November 7, enter into a more detailed explanation than we previously gave of the changes that seem to be required." He must confess it was with a feeling of great humiliation that he saw there was to be a new edition of the Pharmacopœia brought out without any official reference to the Pharmaceutical Society at all; and it was to his great astonishment that he found the three Professors of the Society had been engaged more or less in this work since November 7, six months ago. Those gentlemen held chairs endowed by the Society, and it seemed to him that they were scarcely loyal to the Society, knowing as they did that this subject had been constantly under discussion, in not giving some official intimation that they were engaged on this work. It had been said that the darkest hour of the night was nearest the dawn, and he thought one inference at any rate might be drawn, viz., that the Medical Council, by employing these gentlemen, acknowledged that it was itself incapable of undertaking the revision of the Pharmacopœia. At the same time it was humiliating to find that the Society, which had been established upwards of forty years, and had done so much for pharmaceutical education and the general advancement of pharmacy, was not directly recognized. He had no doubt that other members would feel as he did on the matter, and he hoped that the fact that their existence had been ignored on the present occasion, and that this work had been going on for six months unknown to the Council, would not prevent the Council from pressing the claim of the Society in the first place on the promoters of the Medical Acts Amendment Bill, in the shape of such an amendment as had been shadowed forth in the President's letter, and if that were not effectual, he hoped that the House of Commons would be flooded with petitions asserting the just claims of pharmacists to direct influence in the preparation of any future edition of the national Pharmacopœia.

Mr. Hampson said he must express the same sense of surprise which had been stated by Mr. Greenish. But though he was much grieved at the action of the Society's own professors, considering the relation which had existed between them and the Council for so many years, it must not be forgotten that there was a practical purpose to be kept in view, viz.:—to press forward the claim of pharmacists with regard to the Pharmacopœia. It might possibly be that in consequence of this appointment their cause was damaged; he was disposed to think it might be; and it was a sad thing to think that it might be damaged by the Society's own professors. Those gentlemen seemed to be interested in keeping things as they were. If they had had the interest of the Society at heart, they would no doubt have conferred with the Council on the subject, and he was sure the Council would not have desired to stand in the way of their obtaining any emolument which was offered them. He did fear that the position of the Society in respect to this question had been jeopardized from this unfortunate circumstance. Still he would rather pass over this matter and return to the more important question before the Council, how to obtain official recognition with regard to the national Pharmacopœia. He hoped the Council would strengthen the hands of the Committee and urge the necessity of leaving nothing undone, and that all legitimate and constitutional means should be employed to obtain that recognition.

Mr. Williams suggested that it would be well if the President were now to give any information he was in a position to do, as to what passed with the Lord President of the Council.

Mr. Young asked if it was known to any member of the Council at the last meeting that the professors had been in communication with the Pharmacopœia Committee of the Medical Council.

Mr. Butt thought it would facilitate matters if the President stated the results of his interview with the Lord President.

The President said he was quite ready to do so, but nothing was said on the occasion with regard to the appointment of the professors.

Mr. Symes supported the view put forward by Mr. Greenish, and was very much surprised and grieved to hear of the position of affairs. Much as they all wanted a new Pharmacopœia, he was sorry to hear that a new one was being prepared under the conditions which had been explained. The assistance wanted in preparing a new Pharmacopœia was that of practical pharmacists, rather than professors of pharmacy, botany, materia medica and chemistry. Some of the greatest difficulties which occurred in pharmacopœias arose from the men who prepared them being men of theory and not of practice; a great deal might be correct in theory, which failed in practice. He was very pleased to observe in the *British Medical Journal* that all medical men did not ignore the position of pharmacists, for he noticed that Dr. George Johnson in speaking of a test for diabetic urine said he "hoped and believed that our friends and fellow workers, the pharmaceutical chemists, will prepare the standard solutions." He should support Mr. Greenish in proposing to go any reasonable length in opposing the Medical Acts Amendment Bill, unless it contained a clause which would provide for pharmacists assisting in what was their legitimate work.

Mr. Schacht thought it desirable that the Council should, before going further, hear anything the President had to communicate, if necessary, in committee.

The President said he thought there was no necessity for going into committee. The Lord President had, of course his letter before him, and also a memorial from the Council of the Pharmaceutical Society of Ireland, which had met specially to consider the subject. The Lord President listened patiently to all he had to say on the subject, and asked him two or three questions, and then he said, the broad question was whether the Pharmacopœia as a public document was a bad book. Of course his reply was that the Society did not bring a charge against the Pharmacopœia of being a bad book, but that it might at any time become a bad book if it were not properly compiled. As a result the Lord President said he did not feel inclined to move in the question on public grounds, especially as the Bill did not make any change in this respect in the existing law. He did not wish to be weighted with too many amendments, and he did not think a sufficiently strong case had been made out to induce him to move in the question. He also asked if the editor of the Pharmacopœia was not a pharmaceutical chemist; to which, of course, he replied that though a pharmaceutical chemist he was also a professor of chemistry and pharmacy. The Lord President gave it as his opinion that in some cases the best results were obtained by employing competent men to prepare works for the body having charge of a subject. He gathered from Lord Carlingford that he rather looked upon it as a question to be dealt with between the Society and the Medical Council.

The VICE-PRESIDENT said this question had now assumed great complexity, and something more must necessarily arise from it. He understood the President did not gather that the Lord President was at all conscious of the employment of professors on the Pharmacopœia at the present time.

The PRESIDENT said he did not think the Lord President knew anything about it. He simply referred to the existing volume, and raised the question whether, if you had good special officials who submitted a report to the public body you did not get a result which was sufficiently good for the purpose. Of course he, the President, dissented from that.

Mr. YOUNG did not think the Government could be blamed for the action it had taken. The painful thing to his mind was the position in which the Society's professors stood, and he could not understand how it was the professors should have been in communication with the Pharmacopœia Committee of the Medical Council for such a long period and the Council had heard nothing about it. It appeared to him that however well fitted they were to do everything necessary in the revision of a new Pharmacopœia, they would have been very much assisted by having two or three practical pharmacists associated with them, and it would have been perfectly easy on their part to make that suggestion to those with whom they were in communication. It was a very painful thing to find that gentlemen who had been long connected with the Society should have placed themselves in such a very invidious position. At the last meeting of the Council he expressed the opinion that it was an oversight on the part of the Government that the Society had not been consulted, but he had no doubt now that the Government had been of opinion all along that the Society had been consulted, as this conference was going on with the professors. He quite agreed with Mr. Hampson that the Council should do everything to help forward this new revision and to make its influence felt.

The PRESIDENT said he had no doubt that Professor Redwood's idea was that he was a servant of the Pharmacopœia Committee. Some time ago, in a report he made to the Committee of the Medical Council, he did refer to the importance of having a committee of pharmacists. The opinion of the Council had always been that the Committee should contain practical men who were capable of knowing that any professional men appointed were competent to do their work, added to which there was a question of representation. This book became the pharmacist's law, and it seemed an anomaly in a country where representation was looked upon as a *sine quâ non* for legislation that practically those who had to obey the law were not represented on the body which made it.

The VICE-PRESIDENT suggested the Council should leave the personal question and come to the important one of what was to be done. What was wanted was direct recognition and direct representation.

Mr. GREENISH apprehended the next step would be to bring under the notice of those who might have charge of the Bill in the House of Commons, the amendment which had been suggested, and if this were not accepted, there was only one course left, namely, to do, as had been done before very efficiently, to send up petitions on the subject.

Mr. SCHACHT took the same view. He said he felt so extremely angry about the personal matter that he would rather not say anything about it. It was only within the last hour or two that he had heard of it, and he felt so much annoyed that he refrained from saying a word about the position which the Medical Council had chosen to take in the matter and the behaviour of the professors. The result showed the utter futility of attempting to employ diplomacy against professed diplomatists. The only chance of doing any good for the Society and the public was to go straight for what was thought right before the whole world, not try to creep up any back stairs, or hang on by any man's coat tails. He hoped in future the policy adopted would be a bold straighforward appeal to the authorities in a public way, letting the whole world know what they thought right, and what they wanted, and their motives for aiming at it. Then, at any rate, if they were beaten they could go again on a future occasion on the lines they had been driven from.

The PRESIDENT said there had been no attempt at diplomacy. It was the usual course to go first to the promoters of a Bill before trying to amend it. He was requested by the Committee to ask a question of the promoter of the Bill, and this he had done.

Mr. HILLS asked if anything had been done which merited the terms Mr. Schacht had used.

The PRESIDENT said he understood Mr. Schacht was speaking generally.

Mr. SCHACHT said it was desirable now to go before the House of Commons and endeavour by some such petition as the Committee would be able to draw to influence that House. The letter which the President had addressed to the Clerk of the Privy Council appeared to him to be a masterpiece of letter writing, and if a memorial to those who had charge of the measure in the House of Commons were framed on the same lines it would, in his view, be perfectly satisfactory.

Mr. HAMPSON remarked that the Committee already had full power to take all necessary steps, excepting that it had not the power, nor had the President, without the sanction of the Council, to affix the seal of the Society to any petition. He would move a resolution, therefore, conferring that power upon the President. He believed if the Council was in earnest it would succeed. The case was plain and consistent, and by no means novel, for there were precedents all over the civilized world.

The PRESIDENT then read the following resolutions, which had been passed by the Council of the Pharmaceutical Society of Ireland and forwarded to him:—

"Resolved—

"That a Memorial* be drawn up and forwarded to Lord Carlingford, the Member of the Government in charge of the Medical Bill in the House of Lords, praying that the pharmaceutical bodies in these Kingdoms shall be represented on the body to whom shall be committed the revision of the British Pharmacopœia."

"Resolved—

"That a petition be drawn up to the House of Lords, conveying the same prayer, and that it be sent to the President of the Pharmaceutical Society of Great Britain, to be entrusted by him for presentation to such member of the House as he may think best."

---

* The Memorial drawn up in accordance with this resolution was printed on p. 892.

Mr. ANDREWS said he had only heard the news, which had just been communicated, on Monday last, and he had never heard anything in connection with the Society which he felt more acutely. It was very painful to think that the labours of the Society for more than forty years had been entirely set aside, but it was still more painful to think that the Society's professors should have acted as they had done. He trusted, however, there would be some answer to this part of the case. If there were not he should consider their conduct most ungrateful. On that point he would say no more, but he should like to hear any explanation which the professors had to offer. The practical issue was how the Council was to go on at present, and that had been pointed out by several speakers. It must go to the promoters of the Bill, and if it could do nothing with them it must get pharmacists throughout the country to petition for their just claims.

Mr. GOSTLING suggested that it would be only proper if the Council were to ask the professors for a copy of the letter addressed to them by the Medical Council in November last.

The PRESIDENT did not think it would be dignified for the Council to raise any question with the professors on the subject. He assumed most fully, that in their communications to the Committee of the Medical Council, at some time or another, they had expressed their sense of the importance of being associated with practical pharmacists.

The report and recommendations of the Committee were then received and adopted.

It was also resolved on the motion of Mr. GREENISH—

"That the Library, Museum, Laboratory and House Committee be empowered, at its discretion, to draw up and address to the House of Commons, in the name of the Council, a petition in reference to the question of Pharmacopœia revision, and that the seal of the Society be affixed thereto."

The Council then went into committee, and considered one or two clauses of the Medical Acts Amendment Bill.

The Annual Report.

The Annual Report, as drafted by the Library, Museum, Laboratory and House Committee, was also considered by the Council in committee.

On resuming, the Report was adopted and ordered to be issued with the voting papers for the Annual Meeting.

GENERAL PURPOSES.

The report of this Committee, which was read in committee, included the usual letter from the Solicitor, stating the progress of cases which had been placed in his hands.

Two cases of alleged infringement of the Pharmacy Act had been brought before the Committee, and after consideration, it was recommended that proceedings be taken against the offenders.

The report and recommendations of the Committee were unanimously adopted.

On the motion of the PRESIDENT, seconded by the VICE-PRESIDENT, it was resolved—

"That in pursuance of a resolution of Council at its last meeting, the name of John Keith, 28, Kirkgate, Leeds, be removed from the register of members of this Society."

REPORTS OF THE GOVERNMENT VISITORS ON THE EXAMINATIONS.

The following reports from Dr. Greenhow and Dr. Maclagan, having been forwarded from the Privy Council Office for the information of the Council, were ordered to be printed in the Society's Journal:—

REPORT BY DR. GREENHOW.

[*Copy.*]

"*Report on the Examinations held by the London Board of Examiners of the Pharmaceutical Society during the year* 1882.

"During the year 1882 the London Board of Examiners of the Pharmaceutical Society held twenty-six meetings for the examination of candidates for registration under the Pharmacy Act, 1868, at twelve of which I was present on behalf of the Privy Council. This is exclusive of the first or Preliminary examination in English, Latin and Arithmetic, which is held four times in the year, and continues to be conducted by the College of Preceptors, as it has been since 1875.

"*Preliminary Examination.*—During last year 1269 candidates presented themselves for this examination, of whom 629 passed, and 640, or 50·4 per cent. failed.

"This is a smaller portion of rejections than in the previous year, when 56·6 per cent. of the candidates were rejected; but it must not therefore be too hastily assumed that there has been any material improvement in the elementary education of the candidates. Indeed, no such sudden change can be looked for, though eventually the regulation requiring this examination to be passed previous to the commencement of apprenticeship or pupilage may, perhaps, diminish the proportion of rejections, by compelling the candidates to come up for the examination immediately after leaving school.

"Whether this should prove to be the case or not the regulation cannot fail to be most beneficial to the candidates in two respects: first, when young men, on presenting themselves at the age of 16 or 17 years for this examination, find themselves unable to pass it, by reason of defective education, they will still be able, without serious loss of time, to turn themselves to some other occupation; whereas, at present when a youth fails he commonly goes on studying under very disadvantageous circumstances, during his apprenticeship, with a view to presenting himself again at a future time in the hope of eventually getting through. The second advantage I have referred to is, that having already passed this educational test before the commencement of his apprenticeship the student will be able to devote his time and thoughts exclusively to learning the strictly technical part of his business.

"The proportion of rejections to passes last year was about the average of the preceding five years, including 1881, when, as I have just said, it was very large, namely 50·9 per cent.; but the variations from year to year have been considerable, having, exclusive of the exceptional year, 1881, ranged from 42·4 per cent. in 1876, to 52·4 in 1878.

"Two changes have been made in the mode of conducting this examination, which will, I understand, come into operation this year. The examination is a written one and hitherto one hour has been allowed for each of the three subjects. Henceforward this period is to be increased to one hour and a half with an interval of one hour between the second and third subjects; and, further, the candidates are to have the option of translating a passage from the first book of Virgil's 'Aeneid,' instead of being, as heretofore, limited to one from the first book of Cæsar's 'De Bello Gallico;' these changes are favourable to the candidates and will add to the efficiency of the examination without increasing its stringency.

"Of the rejected candidates, 15 who had obtained the minimum passing number of marks allotted to each subject failed because they had not gained half the aggregate number of marks required for passing the entire examination; 80 failed in all the subjects; 303 in arithmetic; 173 in two of the three subjects; 49 in English; and 20 in Latin.

"This latter number, however, by no means represents the actual number of failures in Latin, for if those who failed in all the subjects, or in two of them, whereof Latin was one, and those also who failed in the aggregate, be added together the rejections for Latin amount to 181: and, even of those candidates who pass the Preliminary examination, a considerable number, amounting last year to 60, fail at the Minor examination in translating prescriptions written in Latin.

"*Major Examination.*—During last year 94 candidates were examined for the Major examination, entitling such as pass it to be registered as pharmaceutical chemists, 36 of whom passed, and 58 or 61·7 per cent. failed. This is the largest proportion of failures that has ever occurred; the next largest having been in 1880 when 54·3 per cent. were found incompetent. The large number of rejections last year cannot be ascribed either to any change in the regulations for conducting the examination or to increased strictness on the part of the examiners.

"The examination must be regarded as an examination for honours, since candidates must previously to presenting themselves for it have passed the Minor examination, which confers all the business privileges necessary for keeping an open shop for retailing, dispensing or compounding of poisons. Looked at from this aspect I do not consider the examination as set at too high a standard. It is a good practical examination and candidates who cannot pass it are certainly not entitled to hold the higher grade of pharmaceutical chemist. Of the 58 rejected candidates 19 failed upon the examination as a whole; 29 in chemistry and practical work; and 18 in botany or botany and materia medica.

"*Minor Examination.*—During last year 572 candidates offered themselves for this examination, of whom 242 passed and 330 or 57·7 per cent. failed. This again is a very large proportion of rejections, the largest excepting in 1874, when the rejections amounted to 69·3 per cent. Since that year the proportion of rejections, exclusive of 1882, has varied from year to year, and has ranged from 48·1 to 54·6 per cent. in different years.

"Of the 330 rejected candidates last year, 75 failed in the examination as a whole, that is to say, although they had gained the minimum passing number of marks in each of the several subjects, they did not obtain half the aggregate number of marks upon the whole examination. A candidate may be so weak in one subject as only to obtain the passing number of marks in it, and this may be compensated for by greater excellence in the other subjects; but, when he is so weak in all the subjects as not to gain half the aggregate number of marks on the whole examination, even though he may have attained the lowest passing number in each subject, he is clearly not fit to pass and undertake the responsibility of keeping an open shop for dispensing and compounding prescriptions. As a rule, I have observed that candidates are seldom very weak in one subject only, but, on the contrary, that when a man is weak in one branch of the examination he fails more or less completely in the other subjects.

"I may here state that the examination for each subject is conducted by a different examiner, so that a candidate who fails in the aggregate must have been found incompetent by six different examiners who are rarely aware how he has acquitted himself in the other subjects. Of the remainder 81 failed in chemistry; 39 in reading Latin prescriptions; 30 in materia medica; 24 in practical dispensing; 19 in pharmacy; 16 in botany; and 46 in two of these subjects.

"As I said in my report for 1881 the large number of rejections at this examination has occupied the serious attention of the Board of Examiners and the Council of the Pharmaceutical Society. It has also been the subject of much discussion in the pages of the *Pharmaceutical Journal.*

"Some of the speakers and writers seem to have thought that the examinations are imperfect and unsatisfactory because so many candidates are rejected, whereas on the contrary, this circumstance ought rather to indicate that the examinations are carefully conducted. It might indeed be asserted on the other hand, that the requirements from candidates are too high; but, of this no one who has not carefully observed the examinations in progress can be competent to form an opinion.

"I have now for fourteen years very closely and impartially done so, and whilst I have never hesitated to suggest improvements, or to point out deficiencies in the regulations, or in the mode of conducting the examinations, whenever I have considered it necessary, I have yet been able invariably to express a favourable opinion of the efficiency of the examinations and of the tact and good sense with which they are conducted by the Board of Examiners. I should here perhaps add that the several recommendations which I have made from time to time, more especially during the earlier years after the Pharmacy Act was passed, have been courteously received, and I believe, after due consideration, always adopted.

"Unquestionably the several changes which have been introduced in the regulations, and the mode of conducting the examinations, more especially the practical part, have raised the standard; but this was inevitable and necessary if the intention expressed in the preamble of the Pharmacy Act was to be fulfilled.

"In commencing a system of compulsory examination it would have been manifestly inequitable to have passed at once from the laxity which, previous to the enactment of the Pharmacy Act, permitted persons to carry on the trade of a chemist and druggist without any recognized qualification, and to have exercised a degree of strictness which, however desirable in itself, would have made the examinations press hardly upon a large number of candidates whose education had commenced before the Act came into operation.

"At a later period it was quite proper to make the examinations more thorough and practical and to introduce such changes as experience might have shown to be desirable.

"It is indeed much to be regretted that so many candidates should be rejected, but I am quite sure that the present examination is a sufficient test of competency in those who pass. It may, indeed, possibly happen that a rather weak candidate occasionally passes, though I cannot recollect such an instance to have fallen under my observation; but, on the other hand, I believe that no really competent candidate is ever rejected. I am als satisfied that all those who pass are qualified to carry on the business of a chemist and druggist with safety to the public, which must be regarded as the essential purpose and requirement of the Pharmacy Act.

"In my last report I mentioned that the Pharmaceutical Society had adopted a scheme of education and examination prepared by a Committee and approved by the Council of the Society, and I said that I entirely agreed with two of the recommendations: viz., first, that the Preliminary examination should be passed prior to the commencement of the period of apprenticeship or pupilage; and second, that the candidates should be required to produce evidence of apprenticeship or pupilage of not less than three years with some duly registered chemist and druggist.

"It has always appeared to me that the absence of a clause rendering an apprenticeship compulsory was an oversight in the Pharmacy Act, and my experience of the examinations from year to year has but strengthened this opinion. Pharmacy is a skilled occupation, requiring those who exercise it to possess such a practical acquaintance with drugs and manipulative skill in compounding them as can only be acquired by long and constant practice, and this skill and knowledge can in no other mode be so advantageously acquired as during an apprenticeship in a chemist's shop. Yet it was not until several years had elapsed after the enactment of the Pharmacy Act, that a regulation was adopted requiring a candidate for the Minor examination to produce a certified declaration that he had been for three years registered and employed as an apprentice or student, or that he had been otherwise for three years practically engaged in the translation and dispensing of prescriptions. This regulation has not been found to afford a sufficient guarantee that the candidates actually have had the practical training that was intended, and the new regulation is intended to obviate this defect. An apprenticeship or pupilage, such as is now intended, should imply a certain share of responsibility on the part of the master for the pupil's progress, as well as on that of the student, and it may be hoped that henceforward the apprentice will receive a better training and have better opportunities for learning his business than seems to have hitherto been the case. I regret that, if the Society have the legal power, the period of apprenticeship has not been extended to five years. Under the new regulation a candidate who has had a fair education ought to be quite able to pass the Preliminary examination at the age of sixteen years, and the subsequent five years of his life could not be more advantageously spent than in qualifying himself by practical training in a druggist's shop for his future calling.

"When the apprenticeship is served in a small country pharmacy it might be arranged, with the concurrence of the master, that the two last years of the apprenticeship should be passed in a pharmacy in some large town, where better opportunities for learning might be found; or, the last year might, at the option of the apprentice, be occupied in attending a certain specified course of instruction in practical chemistry at a recognized school of pharmacy.

"To the fourth of the proposed regulations I can only express a qualified approval. It provides that the Minor or qualifying examination shall 'be divided into two parts, with an interval of not less than six months between the first and second portions.'

"'That the first portion be a written examination to be conducted in London, Edinburgh, and certain provincial centres, and shall consist of the translation of prescriptions from Latin into English and English into Latin, pharmacy and theoretical chemistry and botany.'

"In a further report drawn up by the same Committee and presented to the Council in March, 1883, it is proposed to omit botany from the written examination, and to extend the period between the date of passing the first portion of the examination and the second to not less than one year.

"To the proposal to divide the examination I see no objection, but I think it undesirable to hold it anywhere except in London and Edinburgh; neither do I think it desirable to insist upon an interval of not less than a year between passing the first and second portions. The candidate might, perhaps, have the choice of presenting himself for the first portion of the examination one year or six months before coming up for the second or final portion; but if in order to avoid the expense and trouble of attending twice in London or Edinburgh, he preferred passing both parts of the examination at the same time, the interval between them should not necessarily exceed a few days.

"The recommendation that the examination should be a written one is also, I think, objectionable as regards prescriptions, pharmacy and botany. The present examination in each of these subjects is thoroughly good and practical. In prescriptions the candidate is required to translate several, of different kinds, which have actually been dispensed in chemists' shops, in the presence of the examiner, who further tests the knowledge of the candidate by *vivâ voce* questions upon the doses and strength of the medicines prescribed. Next he is sent to a table by himself with a simple prescription written in English, and required to translate it into Latin, ample time being allowed him for this purpose. I consider this examination quite satisfactory as now conducted. The examiners are thoroughly competent, and whilst they do not pass incompetent candidates they allow a weak or nervous one every chance of passing if he be fit to do so. The importance of continuing this *vivâ voce* examination in translating Latin prescriptions is further shown by the fact that, notwithstanding they had all previously passed the Preliminary examination, which comprises a written examination in Latin, more than one-sixth of the candidates who were rejected at the Minor examination last year failed in reading Latin prescriptions.

"Pharmacy, as now conducted, is also a practical examination. The candidate is required to recognize the various pharmaceutical preparations of the British Pharmacopœia, submitted to him by the examiner without labels, and to describe the processes by which they are made; to explain the reasons of those processes, and to state the strength and ordinary doses of each preparation. Notwithstanding that botany is no longer recommended to be included in the written portion of the examination, I may observe that, as now conducted, the examination in it is thoroughly good and practical. It is conducted in a most efficient manner; the table in front of the examiner is covered with fresh specimens of plants upon which the candidate is required to show the various parts of the flower and the character of the leaves, stem, root, etc., the examiner putting such *vivâ voce* questions as may appear necessary in order to test the candidate's knowledge. At seasons when recent specimens of the indigenous medical plants cannot be procured, the examination is supplemented by submitting well-mounted, characteristic dried specimens to the candidate for recognition.

"I am of opinion that the proposed written examination would be an inadequate and unsatisfactory substitute for the present more practical one in each of the subjects I have mentioned; but, the case is otherwise as regards theoretical chemistry and a written examination in that subject might very beneficially be added to the present practical one, *provided* it was not allowed to stand in any respect as a substitute for it. It might be held on the same day as the examination in prescriptions, pharmacy and botany, a certain fixed time being allowed for writing the answers.

"There still remains one recommendation of the Committee to which it seems necessary that I should briefly refer. It is, that the candidate be required to produce evidence that he has, since passing the Preliminary examination, attended a course of lectures on materia medica, a course of lectures on chemistry, a course of lectures on botany, and a course of instruction in practical chemistry. This recommendation has been approved by the Council of the Pharmaceutical Society, but is not intended to come into operation until after December 31, 1887. I have already, in former reports, expressed my opinion that such a curriculum is not required for the purpose of the Pharmacy Act, and I see no reason for changing that opinion. As a matter of fact, a certain number of the candidates do not attend such lectures; and as I have already said a portion of the apprenticeship might, at the candidate's option, be passed in following such a curriculum. But whilst I would not discourage the candidates from attending the proposed course of instruction, if they pleased, I do not think it necessary to enforce such attendance. The preamble of the Pharmacy Act, 1868, states, 'that it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists should possess a competent practical knowledge of their business, and to that end . . . all persons not already engaged in such business, should, before commencing such business, be duly examined as to their practical knowledge.' I infer from this that no restriction beyond what is necessary for the safety of the public was intended to be imposed upon pharmacists, and I have been able, from year to year, to express my satisfaction with the results of the examination, and my opinion that, as at present conducted, it affords a sufficient guarantee for such safety; and further, that the candidates who pass it are fit persons to be registered under the Pharmacy Act as qualified to keep open shop as chemists and druggists. I think that, so long as this is the case, no additional burden of expense or examination should be imposed upon the candidate for the Minor or qualifying examination. I conclude that the Council of the Pharmaceutical Society have been advised that they have the legal power to enforce the regulation respecting a curriculum, but I cannot help expressing a hope that, having adopted the very sound and practical regulations as to the time of passing the Preliminary examination and the stricter apprenticeship, they will defer making any further change in their regulations for candidates until these have been fairly tried and found wanting in efficiency.

"As regards the Major and voluntary examination, I have more than once said that the standard might very properly be raised, from time to time, and I think that candidates for it might be required to attend such a curriculum, as has now been proposed for the Minor examination, after passing the latter before presenting themselves for this higher qualification.

[*Copy.*]

"REPORT BY DR. MACLAGAN ON PHARMACEUTICAL EXAMINATIONS IN EDINBURGH.

"My last report embraced a period of three years; the present report does the same, extending from February, 1880, to January, 1883, inclusive.

"The results of the examinations conducted during this period will appear from the following statement:—

	Candidates.	Passed.	Failed.	Percentage of failures.
Majors . . .	29	15	14	48·2
Minors . . .	292	166	126	43·15
Modified . .	6	2	4	66·6
	327			

"The total number is smaller than in the previous triennium, when it amounted to 368; but the number of candidates, and the length of the period by which these numbers are furnished, are sufficient to enable me to remark that the proportion of failures, instead of diminishing, is actually increasing. This will appear from a perusal of the percentage of failures during these two triennia:—

	1877-80.	1880-83.
Majors	37·5	48·2
Minors	37·8	43·15
Modified	50	67

"I am, by these figures, compelled to repeat the remark made by me in my last report, that there is a great, and I may add, deplorable ignorance on the part of candidates for admission to the profession of pharmacy, as to what is required of them in the way of preparation for their examinations. It may be supposed that as some changes have taken place during these three years in the *personnel* of the examining Board in Edinburgh, this may be due to greater strictness on the part of the new examiners. On this personal matter I have only to observe that whilst the new examiners leave nothing to be regretted in regard to the changes which have taken place, they do not discharge their duties with any more stringency than was done by their predecessors, and that to my mind the decisions given as to the appearances of candidates are now, as they have always been, well balanced between justice to the public interest and fairness to the candidates. I cannot, therefore, attribute the large proportion of failures to any other cause than the want of preparedness, and the ignorance of what constitutes preparedness, on the part of candidates.

"As regards the causes of failure, I have little to say on the subject of the Majors, except to explain that the reason why 11 out of the 14 failures are due to deficiency in practical chemistry is this, that the examination on this subject is always conducted on the day before that on which the full Board of Examiners meets, and that, therefore, those who fail in the practical work do not go on to the *vivâ voce* examination. We see from these numbers, however, how little idea candidates have of the necessity for extending, or even for keeping up, their chemical knowledge after they have passed the Minor examination.

"The Modified candidates give no room for any remarks. Their number is small and is diminishing, and in a short while this very undesirable class of candidates will become extinct. The failures were 67 per cent., chiefly due to general insufficiency.

"The Minors are those regarding whom I have to offer a few more detailed observations, and I can, I think, make these more intelligible by adverting to the appearance of candidates in respect to the several subjects of examination.

"It is to be borne in mind that this table does not tally with the number of rejected candidates, because sometimes two of the failures refer to the same individual, and many rejections were due to general insufficiency, *i.e.*, that though the candidates got the minimum number of marks entitling them to pass in each individual subject, they did not come up to the aggregate number of marks entitling them to get their certificate. The percentages, and what I may call "black marks," got in individual subjects, and exclusive of cases of general insufficiency during the three years from 1877 to 1880, and 1880 to 1883 respectively, are as follows:—

	1877-80.	1880-83.
Botany	32·12	20·80
Chemistry	23·08	17·44
Materia Medica . . .	6·41	·671
Prescription Reading . .	1·92	5·36
Dispensing	15·38	12·08
Pharmacy	23·08	12·08

"On these various causes of failure I beg to offer a few remarks, though they must, in great measure, be repetitions of those made on former occasions.

"*Botany.*—This still stands highest among the sources of failure, and although there is considerable improvement in the average appearances, it is quite clear that the greater number of the candidates have not studied the subject in any proper sense. Most of them can name herbarium specimens of medicinal plants fairly, but they are often deficient in vegetable organography, and still more so in vegetable physiology. This last may appear to be too purely a scientific matter to be of great importance; still it is of practical value if it were only to secure that the candidate has an intelligent appreciation of the reasons why medicinal plants should be gathered at one season more than another.

"*Chemistry.*—This, as usual, takes the second place in the subjects in which failures occur. I am bound to say that there is amelioration in the average appearances of candidates as regards chemistry, but there is still much room for improvement. I have actually seen one candidate present himself to whom the examiner very properly did not give a single mark for chemistry. He did not, for instance, know any way of distinguishing sulphate of zinc from sulphate of magnesia, except by the taste.

"With regard to these two subjects, botany and chemistry, I have to remark that the appearances of candidates, whether succeeding or failing, show how much they require a more methodical instruction than most of them have enjoyed. In my report of the previous three years I stated my opinion of the necessity for pharmaceutical students going through a regular curriculum of study. I am every year more and more impressed with the absolute necessity for this, but I do not need to insist upon this at length, because I think there is now a general consensus of opinion that a regular curriculum is necessary. Even in the case of candidates who get a sufficient number of marks to enable them to pass, the want of systematic instruction is observable. It is easy to observe, though impossible to define, the difference between a correct and an intelligent answer, between one which is the result of cram and one which is the outcome of a good instruction. But the difference can be seen better when the candidate has made a blunder. The intelligent and instructed man retrieves himself and shows that he knows more than at first sight appeared; the man who has crammed, in his struggles to correct his mistake only flounders more and more deeply into the mud. The remedy for this is true systematic instruction. It is not necessary that this should be given in London or Edinburgh, for in the case of one candidate in December, 1881, who made a most admirable appearance in chemistry, I asked the examiner after the examination was over to ascertain where this young man had been instructed, and I learned that he had had a course of chemistry by an excellent teacher in an English provincial town.

"*Materia Medica.*—The proportion of failures in this subject is comparatively small in the last three years as well as in the former three. The recognition of crude drugs is generally good, and shows that the candidates avail themselves of the museums and other collections for this purpose. Candidates are generally asked if the drugs presented to them are of good quality, but I would venture to observe that the samples shown to them are in general rather too good and typical, and that it would be well to show them also some bad samples and thus to ascertain that they can recognize those inferior or false drugs which, it is to be feared, are too common in commerce.

"*Prescription Reading.*—I was disappointed, in calculating out the averages, to find that there had been an increase of failure on this subject, because, probably accidentally, I had come upon several examples of young men whose translations of Latin prescriptions into English, and putting English prescriptions into Latin, were really very good. It is clear, however, from the average Latinity of candidates that there is room for improvement in the Preliminary examinations. It is, perhaps, not of much importance as regards practical use that a candidate should be well up in Latin quantities, provided he knows the grammar and can translate the words of a prescription, but it is desirable that some amendment should take place in this respect. It might be well if those who undertook the editing of a new Pharmacopœia would put the signs of quantity over the names of the drugs, and that we should not hear candidates who are reading prescriptions use such pronounciation as atrōpa, gentiana lutēa, conĭum, acĕtum, liquŏris. It must be said for candidates that they do not get much help in regard to Latinity from some of the things which they see in print. I have before me an advertisement from a well-known firm, in the advertising columns of the *British Medical Journal*, in which they give the designation of a special preparation, consisting of three words, two of which are hideous violations of two of the most elementary rules of Latin grammar.

"I wish here to make an observation on prescription reading in its relation to the examination in pharmacy. It is impossible in any system to avoid making one subject over-ride another to a certain extent, but this should as far as possible be avoided. In both the above-named subjects I have often observed that the very same questions as to the doses of drugs are put to the same candidate. It appears to me that these posological questions belong essentially to the examiner in pharmacy, and that in prescription reading all that need be ascertained is that the candidate shall not overlook the fact that the prescription, either through ignorance or inadvertence on the part of the prescriber, contains dangerous doses of potent drugs. It is obviously essential that the pharmacist should know the proper doses of the medicines which he dispenses. All I wish to point out is, that in examinations where the value of the candidate's replies are stated numerically, he should not, when he makes a blunder, have it counted against him twice, or that when his answers as to doses are correct he should have them twice put to his credit. It is to be distinctly understood that these remarks do not apply to the present examiner in prescription reading only, but apply equally to the examiners before his time.

"*Dispensing*: *Pharmacy.*—I take these two subjects together because the percentage of failures is the same in both, and because in the proportion of failures they come next to the two scientific subjects botany and chemistry. I have on former occasions pointed to these as showing that while there must be many creditable exceptions, there can be little doubt that, to a large extent, members of the pharmaceutical profession do not do their duty properly to their apprentices. If young men during their apprenticeship do not learn pharmacy and dispensing, it may come to be asked, and in a very practical form, what do they learn during the three years' apprenticeship the utility of which is so much insisted on? If the apprentice is merely to learn the routine duties which fall on any one standing behind a counter, six months would be enough and the three years' apprenticeship might be abolished with advantage. Pharmacists would have themselves to blame were this to come about, and would regret it if they found that instead of having apprentices to aid them in their business, they would need to secure the services of assistants, which cost money. I repeat what I have said before now, that it is an immoral thing in a pharmacist to take a young man as his apprentice and not to enable him to learn the very things which his master can teach him. Every discouragement should be given to the practice, I suspect too common, of purchasing galenical preparations, such as tinctures, from wholesale houses, instead of making the apprentice prepare them and seeing that he does so accurately. Perhaps some change in the terms of indentures, enforcing more decidedly the duty of the master to teach his apprentice practical dispensing and pharmacy, would be of use in saving time which is wasted behind the counter in retail dealing, and which might more profitably be used at a school of systematic instruction.

"As regards the final result of the examinations, I have to state my belief that the Minor examination affords ample security for the public safety at the hands of those who obtain their diplomas. I am equally bound, however, to say that the Major examination does not, to my mind, fulfil what ought to be its object,—the raising up of a class of scientific pharmacists in Britain. It is well known that it is proposed to abolish the distinction between these two examinations, and the difference between them is not so great as to lead me to make any objection to this proposal. I hope, however, that this will be done by raising the standard of the pass examination at least up to the level of the present Major, and that a strenuous attempt will be made by creating a higher class of members of the pharmaceutical profession to produce, more than at present exists, of a body of truly scientific British pharmacists.

(Signed) "DOUGLAS MACLAGAN."

THE INTERNATIONAL PHARMACEUTICAL EXHIBITION AT VIENNA.

The PRESIDENT said a communication had been received from the Imperial and Royal Austro-Hungarian Consul-General calling attention to the International Pharmaceutical Exhibition at Vienna, in August next, with a request that it should be brought under the notice of persons interested. It would be remembered that several notices respecting this exhibition had already appeared in the Journal, and he believed some members intended to contribute to it.

PHARMACY ACTS AMENDMENT BILL.

The PRESIDENT stated that communications had been received concerning the draft Bill from the Manchester Chemists and Druggists' Association, from King's Lynn, and from Mr. Vizer. These communications were referred to the Law and Parliamentary Committee.

The PRESIDENT also announced that the Secretary had received from Mr. Sandford the following notice of motion which he intended to bring forward at the Annual Meeting.

"That in the opinion of this meeting certain provisions set forth in the proposed Bill to regulate the sale of poisons and alter and amend the Pharmacy Acts require alteration, especially clauses 4 and 5, which render retail vendors of patent or proprietary medicines, who have not and cannot have any control over the required labelling of such medicines, liable to prosecution for insufficient labelling, for which offence the proprietors only should be and can be made responsible."

REPORT OF EXAMINATIONS.

April, 1883.

ENGLAND AND WALES.

PRELIMINARY EXAMINATION.

Candidates. Examined.	Passed.	Failed.
366	171	195

Sixteen certificates had been received in lieu of the Society's examination:—

5 College of Preceptors.
2 Society of Apothecaries.
5 University of Cambridge.
1 " London.
3 " Oxford.

EXAMINATIONS IN LONDON.

April 18, 19, 20, 25, 26 *and* 27, 1883.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Tanner, Taylor and Thresh.

Dr. Greenhow was present on the 26th, on behalf of the Privy Council.

MAJOR EXAMINATION.

18*th.*—*Seven* candidates were examined. *Six* failed. The undermentioned passed, and was declared to be duly qualified to be registered as a Pharmaceutical Chemist:—

Austin, Alfred ....Birmingham.

19*th.*—*Seven* candidates were examined. *Four* failed. The undermentioned *three* passed, and were declared to be duly qualified to be registered as Pharmaceutical Chemists:—

Levett, Herbert ....Maidstone.
Marsh, Edward.................. ...Luton.
Ransom, Francis ....Hitchin.

25*th.*—*Five* candidates were examined. All passed, and were declared to be duly qualified to be registered as Pharmaceutical Chemists:—

Pidgeon, Joshua David ....Brighton.
Smith, William Thomas ....Bath.
Spencer, George ....Hitchin.
Stephenson, Stephen ... .Congleton.
Townsend, Henry Holden ......London.

26*th.*—*Six* candidates were examined. *Four* failed. The undermentioned *two* passed, and were declared to be duly qualified to be registered as Pharmaceutical Chemists:—

Tyson, Thomas Balmforth ......London.
Worsley, Albert George ....Folkestone.

MINOR EXAMINATION.

18*th.*—*Twenty-three* candidates were examined. *Fourteen* failed. The undermentioned *nine* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Arnott, Daniel ....Pontypridd.
Badcock, Harry Digby ....Ottery St. Mary.
Baily, Edward ....Ramsgate.
Banbury, Richard..................Camelford.
Barnes, James Bunden ....Knightsbridge.
Beckett, Harry Rumbold ......London.
Bishop, Cecil... ....Brading.
Carter, William ....Penzance.
Roberts, Arthur Harry ....Barrow-in-Furness.

19*th.*—*Twenty-two* candidates were examined. *Twelve* failed. The undermentioned *ten* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Bayley, Cornelius..................Boston.
Chattaway, William...............Leicester.
Codling, Arthur John ....Norwich.
Corder, Walter Shewell ....Sunderland.
Cubey, Robert ....South Shields.
Cullwick, Geo. Hamar Jones ...Birmingham.
Cunningham, Oscar William ...Norwich.
Curnow, William Albert.........Swansea.
Dulley, David ....Wellingborough.
Dymond, Thomas Southall......Bristol.

20*th.*—*Twenty-six* candidates were examined. *Fourteen* failed. The undermentioned *twelve* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Crow, William Edward ....Louth.
Elstob, John ....Richmond.
George, Isaac ....Great Yarmouth.
Gill, William........................Nottingham.
Gradidge, James Henry ....Truro.

STATEMENT OF ATTENDANCE OF MEMBERS OF COUNCIL ON COMMITTEES FOR THE YEAR 1882-83.

	Committees held once a Month or Oftener.		Committees held Occasionally.		Special Committees.	Total Number of Attendances.
	Finance.	Library, Museum, Laboratory, and House.	Benevolent Fund.	General Purposes.		
Number of Committee Meetings held.	12	10	12	10

NUMBER OF ATTENDANCES OF MEMBERS OF COUNCIL AT COUNCIL MEETINGS FOR THE YEAR 1882-83.

Andrews, Frederick	10	Gostling, Thomas Preston	11	Savage, William Dawson	11
Atkins, Samuel Ralph	11	Greenish, Thomas	10	Schacht, George Frederick	11
Borland, John	10	Hampson, Robert	11	Squire, Peter Wyatt	8
Bottle, Alexander	11	Hills, Walter	11	Symes, Charles	11
Butt, Edward Northway	11	Radley, William Valentine	11	Williams, John	11
Carteighe, Michael	11	Richardson, John George Fredk.	10	Woolley, George Stephen	9
Churchill, Walter John	10	Robbins, John	10	Young, James Robertson	10

Number of Meetings during the year, 11.

Granger, Harold ....Nottingham.
Guest, George Robert ....Brentwood.
Harrison, James Hughes.........Sheffield.
Haynes, Joseph Alfred ....Fairford.
Hepple, Thomas ....North Shields.
Hill, John ....Alford.
Horne, Charles ....Stourbridge.

25*th.*—*Twenty-three* candidates were examined. *Thirteen* failed. The undermentioned *ten* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Jeans, Alfred ....Mansfield.
Johnson, Leonard ....Aiskew.
King, Arthur...........................Norwich.
Mallett, Thomas John.............Luton.
May, Samuel Augustus ....Jersey.
Micklem, Edwin ....London.
Midgley, Walter ....Keighley.
Nickolls, John Bate ....Bromsgrove.
Taylor, Ernest Sanderson ......Grantham.
Thomas, Llewelyn Lloyd ......Bala.

26*th.*—*Twenty-four* candidates were examined. *Sixteen* failed. The undermentioned *eight* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Low, David ....Hexham.
Painter, Frederick Hubert ....London.
Pearson, William Jackson ......Little Gowerby.
Phillips, Sidney......................Wolverhampton.
Presbury, Herbert Henry ......London.
Rawling, William John ....Devonport.
Thomas, Arthur William WynneBala.
Wood, Edward James............Brentford.

27*th.*—*Twenty-six* candidates were examined. *Fifteen* failed. The undermentioned *eleven* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Shepherd, Robert James.........Wisbech.
Stevens, Chas. Willm. Davis...Upper Norwood.
Talbot, William Widdowson ...Bulwell.
Thwaites, Frederick................Bishop Auckland.
Toplis, John Walter................St. John's Wood.
Walker, George John ....Revesby.
Wallis, Edwin ....Streatham.
Williams, William Lloyd.........Buckley.
Willis, William........................Chudlington.
Willoughby, Arthur John ....St. Leonards.
Wilson, Richard ....Kidderminster.

MODIFIED EXAMINATION.

18*th.*—*Two* candidates were examined. *Both* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

Crosby, John ....Lincoln.
Jones, William Shepherd ....Southport.

19*th.*—*Two* candidates were examined. *One* failed. The undermentioned passed, and was declared to be duly qualified to be registered as a Chemist and Druggist:—

Troake, Charles Francis ....Newbury.

PRELIMINARY EXAMINATION.

27*th.*—The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Bircham, Jesse ....Reepham.
Blomfield, Thomas Nevill ......London.
Heath, Walter George............Norwich.
Milbanke, William B. ....Sunderland.
Yates, Charles George............Brighton.

Certificates of the Society of Apothecaries.

Scott, Sack Noy ....St. Austell.
Stocker, George ....Exeter.

Certificates of the University of Cambridge.

Dawson, Theophilus Ernest ...Gateshead.
Gibbons, Alfred John ....London.
Hobbs, William Harry ....Uxbridge.
Islip, Charles Cater ....St. Leonards.
Poole, Weston ....Newcastle, Staffs.

Certificate of the University of London.

Stacey, Wilson ....London.

Certificates of the University of Oxford.

Carter, Benjamin...................Falmouth.
Fowle, Sydney ....London.
Seaton, Richard ....Stamford.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth general meeting of the above Association was held at the Royal Institution, on Thursday, April 12, 1883, Mr. A. H. Mason, F.C.S., Vice-President, in the chair.

The minutes of the last general meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal*, from the Society; the 'Annual Report and Journal of the Liverpool Polytechnic Society' for 1882, from the Society.

Mr. James Crawford Bredin was elected a member, and Mr. V. T. Cole an associate.

Dr. C. Symes, alluded to one of the new tests for albumen in urine, viz., picric acid, and pointed out that strongly acid urine might give no reaction with this reagent unless a considerable excess were used.

A few remarks were made upon this subject by Messrs. R. M. Sumner, E. Davies and Conroy.

The Chairman, Mr. A. H. Mason, read and commented upon an article in the *Times*, referring to an explosion stated to have occurred on the occasion of the destruction of the dynamite prepared from the nitro-glycerine recently seized in London.

Several gentlemen, including Messrs. Conroy, Symes, Davies, A. C. Abraham and A. H. Mason, discussed the question, Mr. E. Davies explaining it by supposing that a portion of the train might have become heated, not to a sufficient extent to cause combustion at the time, but sufficient to produce such a critical molecular condition as to explode when again lighted. In proof of the probability of this explanation, Mr. Davies cited an instance in which some ½ ounce of nitro-glycerine, when being dried in his laboratory, exploded with great violence. The assistant had, in fact, in the absence of instructions, been drying the preparation on a water-bath, and having neglected it until the water had all evaporated was about to add fresh water when the air-bath, into which it had been converted, caused the explosion. Mr. Davies did not think that the temperature could have exceeded 200° to 300° C.

Mr. Mason thought that Mr. Davies' explanation did not agree with the results of Professor Abel's experiments and his opinions founded upon them.

Mr. A. C. Abraham thought that Mr. Davies' explanation would not be found to be opposed to the results arrived at by Professor Abel. He pointed out that the only difference between explosion and ordinary combustion was in the rapidity with which decomposition took place, and thought that the experiments which had been carried out by the authorities conclusively showed that the nearer the temperature of dissociation of an explosive was approached the more rapid would the combustion be, and, therefore, the more would it approach in violence to an explosion caused by a detonator.

The Honorary Treasurer then took the chair and called upon Mr. A. H. Mason, F.C.S., to read a paper on "Odours, Perfumes, and Flavours," of which the following is an abstract:—The necessity of educating the sense of smell in our ordinary avocation was first referred to, and the action of the olfactory apparatus explained. The influence of the sense of smell, the classification of odours, the impregnation of odours, the origin and introduction of perfumery into this country, and the sources and uses of the materials derived from the animal and vegetable kingdom used in the manufacture, were fully entered into, the materials referred to being divided into ten series—animal, floral, herbal, citrine, spicey, ligneous, radical, seminal, balmy, and fruity. The various products of these materials taking the form of essential oils, ottos, pomades, essences, scented oils, alcoholic tinctures and waters. The processes actually employed for the extraction of the odorous principles from these substances were detailed—(1) by distillation with water; (2) by impregnation with fatty bodies; (3) by pressure and expression.

Mr. Mason next explained the method of procedure in the various attempts which have been made to extract these principles by more scientific and economical ways, but said these were not found of utility in actual practice. The production of artificial odorous principles by chemical artifice, such as cumarin, vanillin, and heliotropine was next explained, also the manufacture of artificial fruit essences or flavourings.

The paper was illustrated by diagrams and specimens of the various articles alluded to.

A vote of thanks was proposed by Dr. Symes, and seconded by Mr. Michael Conroy, who recommended no one to attempt to prepare artificial fruit essences from the published formulæ, as they would not thereby obtain a satisfactory product.

The discussion was continued by Messrs. E. Davies, Samuel, and the chairman, after which the vote of thanks was carried, and Mr. Mason having replied, the proceedings terminated.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of the Association was held at the Masonic Hall, on Wednesday evening, April 25, the President in the chair. There was a good attendance of members and associates.

The minutes of the last meeting having been read and confirmed, the President briefly introduced Mr. H. Major, B.A., who delivered a very interesting lecture on "Beverages." He stated that a beverage, or water in some form or other, was a necessity to the human body; in fact, the body itself contained 87 per cent. of water, muscle containing 75 per cent., which was the same as blood. The functions of the body could not be carried on without water to sustain life, its greatest use being the reduction of heat in the system. There was no definite standard as to the purity of water in the ordinary sense of the word. The lecturer next dealt with milk as a beverage; this was the next in importance, and in fact contained all the elements necessary to the sustenation of the life and work of the body, and he remarked that less milk was drunk in England than in any other country of Europe, the average being only ¼ pint per head per day. After speaking of the adulteration of milk, he directed the attention of his hearers to tea and coffee as beverages, stating that the former was more preferable for general use, it having the properties of exciting vital action and perspiration, and acting directly upon the cerebral portion of the brain; coffee did not induce perspiration, but rather suppressed it, and in this respect was less valuable than tea. In conclusion, the lecturer made some remarks upon alcohol, stating that whisky was the oldest form in which it was used as a beverage, but it was with great difficulty that either it or brandy or gin was obtained pure, the latter especially being "doctored" to a very large extent. Rum was the purest form of spirit obtainable in England. He then treated upon alcohol as a food and deprecated its use, remarking that it was a narcotic, and certainly could not be proved to be of any use in the human economy.

The lecture was listened to with great interest, and at its close a vote of thanks, proposed by Mr. Beverley, and seconded by Mr. Warriner, was accorded to Mr. Major. Mr. Major having responded, the meeting terminated.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Thursday, April 26, at 4 p.m. Present—Professor Attfield, F.R.S., etc., President, in the chair; Messrs. Brady, Carteighe, Ekin, Squire, Taylor; and Messrs. Benger and Plowman (Hon. Secretaries).

The minutes of the previous meeting were read and confirmed.

Letters of thanks for copies of the 'Year-Book of Pharmacy' were read from various societies.

A letter was read from Mr. O. R. Dawson, Secretary to the Local Committee of the last Conference meeting, expressing thanks, on behalf of the chemists of Southampton for the Bell and Hills gift of books.

In reference to a resolution passed at a previous meeting, that a circular inviting to membership be sent to all registered chemists in Great Britain and Ireland, not already connected with the Conference, it was resolved "That the mode of canvassing be adopted as on previous occasions, and that the Secretaries be instructed to carry out the details."

The question of the desirability of appointing Colonial Secretaries was discussed, and the Secretaries were instructed to obtain the names of suitable gentlemen in the colonies and India willing to undertake the duties, and submit them to a future meeting for further consideration.

The Honorary Secretaries reported that the arrangements for the Southport meeting were making satisfactory progress.

The names of a number of members whose subscriptions were in arrears were ordered to be removed from the list.

The following gentlemen were elected to membership:—Messrs. T. P. Garrett, Newport, Mon.; C. J. Holmes, London; A. C. J. Horrell, Dartford; A. E. Martin, Oldham; C. Paterson, Pollokshields; J. Righton, Southport; F. E. Rookledge, Easingwold; G. Tocher, Helensburgh; A. W. Gabriel, Queanbeyan, N.S.W.; T. M. Wilkinson, Dunedin, New Zealand.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

H. C. Dodson.—The point has not been lost sight of, as all persons passing the qualifying examination would be registered as "pharmaceutical chemists."

R. Prust.—All sales of preparations—except "patent medicines"—containing scheduled poisons are subject to the provisions of the Pharmacy Act.

G. R. Guest.—No, they are not exempt.

"*Inquirer.*"—(1) *Lychnis dioica.* (2) *Geranium molle.* Send geraniums with fruit in future. (3) *Ribes sanguinea*: not a British plant. (4) *Peltigera polydactyla* and *P. canina.* (5) *Rumex Acetosella.* (6) *Conium maculatum.*

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Baldock, Reynolds, Salmon, Hill, Greenish, Alcock, Modlen, Millhouse, Junior, W. J. W.

THE ETHER TEST OF QUININE SULPHATE.

BY A. J. COWNLEY.

It has already been shown by Dr. B. H. Paul (*Pharm. Journ.*, [3], vii., 653) that the use of ether as a means of judging of the purity of quinine sulphate cannot be relied on to give accurate results as hitherto practised, and that the ether test requires several important modifications to make it of any value for the purpose of detecting the presence of cinchonidine. The sulphate of this alkaloid being the most frequent impurity of commercial quinine sulphate and the one which is most of all likely to be met with, it is of no little importance to bear in mind that when using an undue proportion of ether, such as is prescribed in the British Pharmacopœia, the ether test will admit of quinine sulphate being passed as pure which contains nearly 30 per cent. of cinchonidine sulphate.

In the French Codex the proportion of ether to quinine sulphate prescribed for the application of this test is little more than one-half as much as is directed in the British Pharmacopœia, but it is still far too large for the detection of the presence of cinchonidine.

M. H. Byasson (*Jour. de Pharm.*, [5], vii., 291) has lately suggested a modification of the ether test for the detection of cinchonidine, quinidine and cinchonine in quinine sulphate, which consists in agitating 0·5 gram of the sample with 6 c.c. of ether and 2 c.c. of ·950 ammonia solution. On account of the proportion of ether used being less than that required by the Codex, he claims the possibility of detecting, by the separation of insoluble alkaloid, the presence of from 3 to 4 per cent. of sulphate of cinchonine, 4 to 5 per cent. of sulphate of quinidine, and from 5 to 6 per cent. of sulphate of cinchonidine.

As regards the detection of cinchonidine, however, this statement is not borne out by experiment. Applying M. Byasson's test to a mixture of pure quinine sulphate with the maximum proportion of cinchonidine sulphate said to be indicated by this test, viz., 6 per cent., it was found that no evidence of the presence of cinchonidine was given, and that even after some days' standing there was no recognizable separation of crystals of cinchonidine. Operating in the same way, with mixtures containing larger proportions of cinchonidine salt, it was found impossible by this test to detect the presence of even 20 per cent. of the admixture.

There is, indeed, no reason for being surprised at this result, since we know from the experiments described in the paper above referred to that even when using the smallest quantity of ether short of allowing the gelatinization of the alkaloid it is quite possible to fail to obtain evidence of the presence of 10 per cent. of cinchonidine by means of the ether test.

M. Byasson's results are no doubt to be attributed to the fact that the sulphate of quinine operated upon was not absolutly pure, as it is not of uncommon occurrence to meet with commercial sulphate of quinine containing up to 10 per cent. of cinchonidine sulphate (*Pharm. Journ.*, [3], vii. 672), an amount which would be passed over by the ether test.

So far as quinidine or cinchonine is concerned, the presence of salts of these alkaloids in quinine sulphate may be more easily ascertained, and the probability of their being present is so much less than that of cinchonidine sulphate that they may to a great extent be left out of consideration.

THE UNITED STATES PHARMACOPŒIA PROCESS FOR THE ESTIMATION OF HYDROCYANIC ACID.*

BY R. A. CRIPPS,

Assistant in the Laboratories, Bloomsbury Square.

The directions given in the United States Pharmacopœia for the estimation of hydrocyanic acid are as follows:—"13·5 grams of diluted hydrocyanic acid, diluted with 30 c.c. of water, and mixed with enough aqueous suspension of magnesia to make the mixture quite opaque, and afterwards with a few drops of solution of chromate of potassium, should require 50 c.c. of the volumetric solution of nitrate of silver, before the red colour, caused by the latter ceases to disappear on stirring (corresponding to the presence of 2 per cent. of absolute hydrocyanic acid)." On reading this I was struck by the small amount of solution of nitrate of silver required, and on calculating the amount theoretically required to precipitate the whole of the hydrocyanic acid as cyanide of silver found it to be 100 c.c. instead of 50 c.c. *Assuming* the formation of a double salt of cyanide of silver and cyanide of magnesium of the formula $MgCy_2(AgCy)_2$, and *assuming* also that chromate of silver will be precipitated as soon as the double salt is completely formed, then the figures given in the U.S. Pharmacopœia would be correct.

The object of the experiments shortly detailed in this note was to prove, first, whether or no the U.S. Pharmacopœia is correct in assuming that chromate of potassium will indicate the complete formation of double cyanide of magnesium and silver (if such exist), in the estimation of hydrocyanic acid, or whether it will only indicate the precipitation of the whole of the cyanogen as cyanide of silver; and second, whether a double cyanide of magnesium and silver really does exist, and if so, what is its composition?

To determine the first point—(1). 2·8402 grams of a sample of dilute hydrocyanic acid was estimated by the B.P. process (Dr. Senier's modification), and required 4·7 c.c. of the vol. solution of nitrate of silver, indicating nearly ·9 per cent. of absolute HCy. (2). 2·4446 grams of the same sample were then estimated by the U.S.P. method, and required 8·25 c.c., indicating 1·82 per cent. admitting the assumption before mentioned, or ·91 per cent. if (as is evident from the figures) the whole of the cyanogen is precipitated as AgCy, before any silver chromate is permanently formed, agreeing to about ·01 per cent. with the B.P. process.

The same experiment was repeated with the same result, proving conclusively that chromate of potassium will not serve as an indicator on the basis of the figures mentioned in the U.S. Pharmacopœia.

2. To prove the existence of a double cyanide of silver and magnesium, no mention being made of a double cyanide of magnesium and silver, either in Gmelin's 'Chemistry,' Watt's 'Dictionary,' or the leading English and American chemical journals, I made a few rough experiments to determine the existence of such a compound. (1). Calcined magnesia was shaken with hydrocyanic acid until alkaline to test-paper, filtered, a little chromate of potassium added, and solution of nitrate of silver run in in small quantities at a time; the precipitate at first formed was redissolved, showing that either a

* Read before the School of Pharmacy Students' Association.

double cyanide was formed or that cyanide of silver is soluble in solution of nitrate of magnesium, which latter was disproved by the addition of more nitrate of silver, when white cyanide of silver was precipitated, until the whole of the cyanogen was converted into silver cyanide, when red chromate of silver was formed. (2). Having thus proved the existence of a double salt I attempted to determine its composition by repeating the above experiment quantitatively, noting the number of c.c. of nitrate of silver solution required to give a cloudiness from the precipitation of silver cyanide, and also the number required to completely precipitate the cyanogen (indicated by the formation of red chromate of silver).

Quantity of hydrocyanic acid used .	2·5688 grams.
Quantity of st. sol. of $AgNO_3$ required to give cloudiness, from precipitation of AgCy	5·64 c.c.
Quantity of st. sol. of $AgNO_3$ required to *completely* precipitate the AgCy.	11·24 c.c.
corresponding to:—	
Real hydrocyanic acid	·030348 of a gram.
HCy required to form AgCy in double salt	·015217 of a gram.
HCy left in combination with Mg in double salt	·015131 of a gram.
Silver required to form double salt .	·0607 of a gram.

thus agreeing within the limit of experimental error with the formula $MgCy_2(AgCy)_2$.

The salt was prepared in filamentous crystals by filling an ordinary vial with hydrocyanic acid, adding excess of calcined magnesia, securely corking and heating in a water-bath for about twenty minutes, filtering and dissolving in the filtrate cyanide of silver until saturated, again filtering and evaporating over sulphuric acid.

From these experiments the following conclusions have been drawn:—

1st. That the United States Pharmacopœia is at fault in the directions given for the estimation of hydrocyanic acid, arising from a false assumption, viz.:—that chromate of potassium will indicate the complete formation of double cyanide of silver and magnesium.

2nd. That in order to use this method for the practical estimation of hydrocyanic acid, the clause "should require 50 c.c. of the volumetric solution of nitrate of silver" in the U.S.P. must be read, "should require 100 c.c. of the volumetric solution of nitrate of silver."

3rd. That the method is not so satisfactory as that in vogue in this country; for if it be carried on till the formation of red chromate of silver, double the amount of silver solution will be required, and if it be filtered before estimation, the length of time required for complete union of MgO with the HCy, and for filtration and washing, would generally exclude the method from use.

4th. That a double cyanide of magnesium and silver does exist, having the formula $MgCy_2(AgCy)_2$, analogous to that of silver and sodium NaCy,AgCy.

Since writing the above I find that the U.S. Pharmacopœia in another place states that 1 c.c. of solution of nitrate of silver is equivalent to ·0054 of a gram of HCy, which is also incorrect, being also based upon the assumption that chromate of potassium will indicate the complete formation of a double salt. The correct statement would be, that 1 c.c. of decinormal solution of nitrate of silver is equivalent to ·0027 of a gram of real HCy as shown by the following equations.

$$HCN + AgNO_3 = AgCN + HNO_3;$$

or with the addition of magnesia:—

$$2HCy + MgO = MgCy_2 + OH_2$$
$$MgCy_2 + 2AgNO_3 = 2AgCy + Mg(NO_3)_2$$

That is to say, 2·7 grams of hydrocyanic acid are equivalent to 1000 c.c. of decinormal solution of nitrate of silver, and therefore ·0027 of a gram equals 1 c.c.

ESSENTIAL OILS AND DISTILLED WATERS.

BY PERCY WELLS.

Now that the season is approaching for the distillation of essential oils and perfumed and other waters, I desire to call attention to a very simple and inexpensive plan for improving the odour and quality of oils, and preventing the decomposition of distilled waters. I have given the process a fair trial and can, therefore, speak confidently of its efficacy. The article I use is permanganate of potash, and it should be added to water before it is put into the still only in quantity enough to make it a *faint* pink.

If any chemist has rose, elder flower or orange flower waters, which are partly spoiled, let him add to them just enough of the salt to give the permanganate tinge, and then distil them, and he will find the products to have recovered their odour and not again change.

I have some waters which I treated in this way nearly two years ago, and they are perfect. I have also redistilled oils, adding to the water permanganate in the proportion of ½ to 1 grain per ounce of oil, and the result has been most satisfactory.

THE CULTIVATION OF THE POPPY IN EUROPEAN TURKEY.

The following is a translation of instructions as to the cultivation of the poppy and the method of extracting and preparing opium, which have been drawn up under the authority of the Turkish Government, and distributed throughout the agricultural districts of Macedonia, with a view to promote the development of the opium industry in that province:—

"If we take into consideration the fact that poppy seed is capable of yielding 6 okes [22½ lbs.]* of opium and 10 kilos of seed to every dunum [100 sq. metres] of land sown; that an oke of opium realizes 400 pias [£3 12*s.*], and a kilogram of poppy seed 40 pias, and therefore that altogether a dunum of land sown with poppy seed may be worth as much as 2640 pias [£23 15*s.*]; if at the same time we bear in mind that a dunum of land sown with wheat seed yields at most 10 kilos of wheat and 2000 okes of straw, and that with wheat realizing 25 pias the kilogram, and with straw being only worth 30 pias per 200 okes, the total possible value of a dunum of land sown with wheat is 280 pias [£2 10*s.*], we see at once that in comparison with wheat and other similar products the cultivation or the opium poppy is a most lucrative industry.

"Seeing then how productive of wealth the cultivation of the opium poppy has been to the agricultural population of the sandjak of Broussa the following is a short treatise supplying information on this point.

"*The Various Species of Poppy Seed and the Proper Season for Sowing.*—Poppy seed is also sometimes styled

* The figures between brackets are inserted as approximately correct.—ED. PH. J.

'Khashkash' seed. It is very small and it is of two kinds. One is white and the other is of a darker hue, both being contained within shells or pods, which are sometimes termed cocoons. These cocoons are globular in shape, and of the size of a Jerusalem artichoke, having on the upper side a roundish mark which is termed the 'comb.'

"The darker-hued seed is of two species. The outer shells or cocoons of the first species are small, and may be distinguished by a row of small holes, through which if great attention be not paid, as soon as the outer shells are fully matured and ready to receive the produce of the seed the latter drops and is lost. The flowers of this first species are generally of a red or purple hue. So also are the flowers of the second species, but the outer shells of the latter are larger and of an oval shape, and they have no holes in their combs.

"The white poppy seed is also of two kinds, of which though one is white the other is yellow. In other respects there is very little difference between these two kinds, both having large oval-shaped, outer shells with no holes under their combs, the flower, like the seed, being white. The opium extracted from this species of poppy is more abundant and of a superior quality to that which is the produce of the first-named species.

"Although in some localities the 'Khashkash' or poppy seed is sown, as a rule it is only utilized by yielding an oil which is extracted from it. From 100 okes (275 lbs.) of seed may be obtained a yield of 30 or 40 okes (82½ or 110 lbs.) of oil, which is of two kinds, of which one is obtained by first pounding the seed, then heating it and extracting the juice, while the seed is still hot. This oil is used in Europe in the composition of water-colour paint and oil paint, and is also burnt in lamps. It is also used in the manufacture of glass shades.

"The other kind of oil is obtained without heating the crushed seed, and having a pleasant taste is used in the preparation of food.

"Arkara-Hissar Sahib ('Afion Kara Hissar').—The seed is first heated before the oil is extracted, which is then universally used by the inhabitants in the preparation of food.

"The oil extracted from the yellow poppy seed, like the opium so extracted, is of a superior quality to the others. In localities where there is no hoar frost in spring and autumn, poppy seed is sown from the month of September up to March; but in places where there is hoar frost the seed must without fail be sown in the month of September and in the spring after the chilly weather is passed. However, seeing that in most places there is hoar frost both in spring and autumn, and that in spring, even in the month of April, there is usually some hoar frost, and that after the month of April seed time is already passed, in this country the seed should be sown in September, or at latest in the beginning of October; if the seed be sown at the season mentioned the yield both of opium and of poppy seed is more plentiful than if that operation be performed when the weather is chilly.

"*Description of the Kind of Soil most suitable to the Poppy.*—The poppy seed must be sown in light, rich, and yielding soils. If it be sown in cold clayey soil or in damp localities the yield will be small and the opium of an inferior quality.

"Ground which is to be sown with poppy seed, of whatever kind it be (*i.e.*, the seed), should be well manured, sheep's dung being of course preferable. Experience has proved that if a field which has just yielded a crop of opium be immediately sown with wheat, the crop resulting from this last sowing will be remarkably good.

"*The Method to be adopted in Sowing and the necessary subsequent Treatment.*—The soil of a field which is to be sown with poppy seed should be ploughed two or three times and well turned up. The seed should then be scattered about with the hand, just as flax seed is. After this the soil must be thoroughly stirred up and mixed by a rake or a row of bushes bound on to the back of a harrow.

"If 100 drachms (*i.e.*, Turkish drachms) of poppy seed be sown on every dunum of land, or on such an extent of land as will take a kilogram of wheat seed, it is sufficient. As soon as ever the young poppy plants begin to appear above the surface of the soil and to bear three or four leaves, in those places where they are too close together they must be taken up and planted again in such a manner as to leave a space of a span between each plant. In order to remove any weeds that may make their appearance in these spaces the soil must be hoed once or twice. This use of the hoe must never be omitted, for if there be many weeds in the field they stunt the proper and healthy growth of the plants, and cause a considerable diminution in the amount of the crop. Moreover, if the seeds of such weeds remain in the soil it becomes subsequently impossible to rid the field altogether of them.

The Course of Treatment to be observed at Harvest Time.—Opium being a substance which is extracted from the pods or outer shells described above, as soon as these pods become green in colour and have reached their full growth the green hue changes to yellow. A few days before this change of colour takes place there forms over the pods a very thin watery film of a light green hue, though somewhat indistinct in appearance. This film is called 'cougak.' If it be wiped away with the finger its place remains quite visible. If at about this time the pod be squeezed between the thumb and forefinger, it becomes so far strengthened that it cannot be easily crushed. It is then that the juice which forms the opium must be gathered.

"In order to gather the juice or paste, the first step is to take a knife made especially for this purpose, being small and as sharp-pointed as the end of a penknife, and with it to cut a semi-circular line in the pod beginning from the middle and going round the edges, at the same time leaving a space of about a finger's breadth. Immediately this is done there appears a white milk-like fluid of a bitter taste, and there forms. This fluid little by little increases in consistency, and its colour becomes darker and darker, until in twenty-four hours it becomes coffee-coloured, and as thick as paste. This is opium. This must be scraped off with the edge of a somewhat large and blunt knife and put into a poppy leaf, and so on until as much as 20 or 30 drachms of opium have been collected on one leaf, the edges of which must be turned in so as to prevent it being spilled. If, while the opium is being collected, the film above described be mixed with it, it has a beneficial effect.

"At Karahissar the work of cutting lines in the pods of the poppies is generally begun early in the afternoon and continued until nightfall. As the opium must be collected twenty-four hours after the above operation has been concluded, the following day also, soon after twelve o'clock, they begin on the one hand to collect the opium from the pods which were cut the day before, and also to cut lines in other pods, which work occupies them until the evening. But should they come across pods which are not quite ripe, they leave them alone, and five or six days afterwards they again visit them, and after cutting lines in them collect their juice.

"In order that the exact season for collecting the juice may not be missed, the whole work must be gone through and finished in five or ten days. Moreover, the proper time for marking the pods must be accurately ascertained, for if the pods be cut say ten days before or after they are quite ripe, there is no yield of opium. As an instance of this it may be mentioned that in the plain of Broussa the experiment was made. Although the plants had reached their full growth, the pods were marked or cut both before and after the exact time when the operation should have been performed, and consequently there was no yield of opium. Sometimes it happens that a dry wind begins to blow at the very time when the poppy pods should be cut, and the atmosphere becomes chilly in consequence. During such weather the yield of opium is very small. The pods also should not be cut when it is raining, for the rain washes away and destroys the juice as fast as it exudes from the seams that have been cut for it.

"After the opium crop has been gathered in, the pods change their previous hue of either green or yellow to rose colour; when this change takes place the poppy plants should be taken up by the roots one by one and collected into small bundles. Each bundle should then be bound by a young green withe, and then so placed upright in the ground that the roots of the plants be covered, in which position they should remain for a few days until the seed contained within the pods shall have become thoroughly matured and dry. Then the pods should be threshed with a stick until they break open, when the seed may be collected.

"Another method is to sever the stem of the plant at the knot which is to be found close up to the pod, with the finger and thumb, and after collecting the ends so severed to spread them out to dry in some open place, and then to break them open by threshing, or else to pull them to pieces, and, after sifting the seed until it is quite free from extraneous matter, to collect it.

"At Karahissar they purposely burn most of the pods and reduce them to ashes, a fluid extracted from which they use to bleach cotton, on the ground that it is more effective than the water strained off from ordinary ashes.

"After extracting the oil from the poppy seed, there remains a sediment technically called 'kyusebe,' on which buffalo, cows, and black kine generally are fed, on the ground that such diet increases the amount of milk and so of 'caimak' (cream)."

THE ACTIVE CONSTITUENTS OF THE OLEANDER.*

BY O. SCHMIEDEBERG.

It is known, especially through the investigation of Pelikan, that the oleander (*Nerium Oleander*, L.) contains a cardiac poison with an action similar to that of digitalin, which the different authors who have been engaged in ascertaining its characters, — Landerer, Latour, Lacornski, Lukomski, Pelikan, Girard and Betelli,—have generally agreed in describing as a yellow resinoid body, whilst their opinions as to its chemical nature have shown a wide divergence. In the following investigation, which had for its object, among other things, to discover the chemical relations between the active constituents of the oleander and the purple foxglove, the principal materials used were oleander leaves, which were brought back in considerable quantity from Tunis, by the late Professor Gustav Williams. These were packed in bales whilst quite fresh, were scarcely withered when they arrived and were then first carefully dried.

Even with these materials the active constituents could only be isolated and their characters, but not their elementary composition, investigated. In order to establish with certainty their empirical formulæ a quantity would be required which would only be yielded in a manufacturing operation.

Oleander leaves contain two chemically different non-nitrogenous substances, both of which, however, produce the known cardiac action in a similar manner. One of these appears to be identical with digitalein, occurring in *Digitalis purpurea;* but since this identity is not yet established with the necessary certainty the substance may be provisionally called "neriin." The other active substance, which, except as to basic properties, agrees essentially with the oleandrin of Lukomski and Betelli, forms an amorphous mass very slightly soluble in water, and very easily soluble in alcohol, ether and chloroform, for which the name "oleandrin" may be adopted.

In perfectly fresh oleander leaves, gathered in German gardens in spring-time, only these two constituents could be detected. The African leaves, on the contrary, contained, besides, other substances in considerable quantity, which may have originated from the decomposition of neriin or oleandrin. One of these presented in respect to its properties a certain resemblance to digitalin, but was almost inactive. It might be named "neriantin," since upon treating it with sulphuric acid and bromine it gave very readily the beautiful colour which is peculiar to the red flowers of the oleander. Oleander leaves also contain the derivatives of neriin and oleandrin corresponding to digitaliretin.

The method adopted in the preparation of the substances mentioned was as follows. An extract was prepared with 50 per cent. alcohol from the dried and powdered leaves, and this was treated with subacetate of lead and ammonia. The precipitate first produced was lemon-yellow, and consisted of a lead compound with a substance belonging to the class of tannins, which was not further examined. Further treatment yielded a pure white precipitate which consisted of a lead compound of neriin. The neriin is not, however, completely precipitated from the liquid in this way; a portion remains in solution probably in the form of a lead compound.

Upon concentration of the yellowish filtrate from which the lead has not been removed, the neriantin separates as the alcohol evaporates in bright light flocks, which are removed by filtration of the liquid before all the alcohol has been removed, and before the separation of other dark coloured substances which would contaminate the neriantin and be afterwards difficult to remove. Subsequently, when all the alcohol has been driven off, besides fresh quantities of neriantin, oleandrin separates as a resinous mass. The filtered liquid still contains considerable quantities of oleandrin and neriin, besides the decomposition product of the latter already referred to.

1. *Neriin, or Oleander Digitalein.*

The precipitation of neriin can be effected either by means of lead subacetate in the presence of ammonia, or by tannic acid. In the presence of much free mineral acid it is also precipitated by various so-called alkaloidal precipitants, especially by solution of iodide of bismuth and potassium. This behaviour of non-nitrogenous glucosides was first utilized by Marmé in the isolation of helleborein. The most convenient method of liberating the neriin from the almost resinous tannic acid compound is to dissolve this in alcohol and then heat it to dryness on a water-bath with zinc oxide. The liberated neriin is then extracted by means of absolute alcohol, from which it is precipitated upon the addition of an excess of ether. The further purification of the crude neriin is effected by fractional precipitations of alcoholic solutions with anhydrous ether.

For the precipitation of neriin by means of an alkaloidal reagent a solution of iodide of bismuth and potassium is used most advantageously. In order to obtain a precipitate a quantity of acid—sulphuric acid is the best—must be added to the liquid. The precipitate, which quickly adheres together, is well washed upon a filter, or by decantation, with dilute sulphuric acid and decomposed in the ordinary manner with barium hydrate. The solution freed from excess of the latter by means of carbonic acid contains neriin together with barium iodide. This is removed by silver sulphate, the filtrate treated with barium hydrate to throw down excess of silver, and then after again filtering the baryta and the last traces of silver are removed by passing through the liquid first carbonic acid gas and then a few bubbles of sulphuretted hydrogen.

The colourless or faintly yellow coloured liquid contains, besides neriin, a considerable quantity of oleandrin, which upon evaporating the solution in a vacuum over

* *Archiv fur experimentelle Pathologie und Pharmakologie*, vol. xvi., p. 149.

sulphuric acid gradually separates tolerably well as a glass-clear resinous mass and is completely removed by filtration. The neriin can be then further purified in the way already mentioned by fractional precipitation. In this way perfectly colourless preparations were obtained from German oleander leaves.

Neriin, when purified as much as possible, possesses all the properties of digitalin [? digitalein]. After drying it has a faint yellowish colour, dissolves perfectly clear in water and alcohol in all proportions, is insoluble in chloroform, ether and benzin, upon boiling with concentrated hydrochloric acid communicates to the liquid a yellow, or when a less pure preparation is used, a yellowish-green colour, and gives with sulphuric acid and bromine the red colour reaction before mentioned. Its behaviour towards precipitants is the same as that of digitalein, since the latter is also precipitated by tannic acid, by subacetate of lead in the presence of ammonia and different alkaloid reagents. Slight differences in external character and in the behaviour of the two substances towards concentrated hydrochloric acid, as well as sulphuric acid and bromine, diminish with increasing purity. After complete drying over sulphuric acid it forms, when freshly prepared, a friable mass; but when preserved some time in well-closed bottles it loses this property, becomes viscous and gum-like, and no longer dissolves clear in water.

Upon carefully boiling neriin with dilute mineral acids it splits up, without any notable change of colour, into glucose and a resinous body which perfectly agrees in its reactions and external characters, as well as in respect to its physiological action, with the corresponding decomposition product from digitalein.

Although the identity of neriin with digitalein cannot be affirmed with certainty in the absence of analytical data, for which the available material was insufficient, the above facts prove beyond doubt that the two substances at least stand in very near relation to one another.

2. *Oleandrin.*

This body is obtained, as before stated, in the evaporation of the oleander extract and as a bye-product in the precipitation of neriin by alkaloidal reagents, either colourless, or more or less yellowish, or even brownish, according to the degree of purity or freedom from colour of the original solutions. For its purification oleandrin is treated with large quantities of water, which takes up about 2 or 3 parts per 1000, and this is removed from the filtered, usually colourless, aqueous solution by shaking with chloroform. Upon evaporation of the filtered chloroform solution the oleandrin is left as a transparent colourless mass, or only perceptibly yellowish coloured when in very thick layers, very easily soluble in chloroform and alcohol, but not so soluble in ether and benzin; in contact with water it gradually becomes opaque and crumbly, and after drying forms a loose white or faintly yellowish coloured, easily pulverizable substance. When solutions in alcohol and water are very slowly evaporated oleandrin separates partially in the form of thin tables of irregular contour, showing no double refraction, and presenting no crystalline structure under the microscope. After being kept some time the colourless substance assumes a lemon colour, which is not entirely removed by treatment of the alcoholic solution with charcoal. Oleandrin is also soluble in tolerably strong acetic acid. By concentrated sulphuric acid it is dissolved with a brown colour, which upon the addition of potassium bromide passes into a rather bright red.

Upon boiling oleandrin with very dilute acids a substance is formed which reduces cupric oxide in alkaline solution, and is probably glucose, and a yellow resinous body, very slightly soluble in water, but freely soluble in alcohol, chloroform and ether, which gives the bromine and sulphuric acid reaction like digitaliretin, and like it and toxiretin produces convulsions in frogs, followed by muscular paralysis. The boiling of the oleandrin must not be suspended too soon, or a portion remains unaltered and cannot be separated from the resinous decomposition product. In such cases the action of oleandrin is produced in frogs as well as the action of digitaliretin (oleandretin). Upon boiling oleandrin more strongly with concentrated mineral acids there is found again, as in the case of digitalin, a yellow or yellowish-brown inactive resinous substance, which also gives the bromine and sulphuric acid reaction. Further, upon oleandrin being kept, besides change of colour it undergoes decomposition, oleandretin being formed and, apparently, neriantin. The relations of the latter to the mother substance can not, however, be stated.

Oleandrin possesses all the physiological properties characteristic of the group of digitalin poisons. To produce systolic pause in the heart of a frog the average dose required is 0·25 milligram.

3. *Neriantin.*

The crude neriantin obtained by the process described is most suitably purified by dissolving it in a little warm alcohol containing water, treating this solution with so much ether that a thin layer of aqueous liquid is separated at the bottom of the vessel, and removing from this the alcohol-ether solution by decantation. Upon treatment of the latter with a larger quantity of ether and a proportional quantity of water, so that a layer of aqueous liquid is again formed at the bottom, after standing the neriantin separates out from this layer as an almost perfectly white flocculent mass, which after decanting off the ether can be collected on a filter. The removed ether, if shaken with water, usually yields a further quantity of neriantin.

After being dried over sulphuric acid neriantin forms a hard mass, resembling in colour and condition commercial gum arabic. If this be dissolved in hot absolute alcohol and the solution be very strongly concentrated on a water-bath, it assumes a brownish colour, and after long standing, without evaporation, the neriantin separates at the bottom of the vessel in the form of semiglobular brownish granules, the size of a pin's head (sphærocrystals). If the alcoholic solution, without being strongly concentrated, be allowed to stand for a considerable time in a glass vessel, the opening of which is simply covered with paper, a white layer of neriantin is gradually formed upon the bottom and sides of the vessel, which under the microscope appears to consist of closely aggregated roundish disks. The substance is in this way obtained perfectly pure with the greatest certainty. After drying it forms a chalk-white crumbly mass.

From the solution in alcohol and water neriantin separates after a time as a white gelatinous substance, which under the microscope appears to be composed of extremely fine, but very long felt-like interlaced threads. With a larger proportion of water in the hot concentrated solution the entire mass often gelatinizes very rapidly, so that a removal of the separated neriantin from the liquid is not possible. In this behaviour neriantin differs very essentially from digitalin, which under similar conditions takes a granular form, whilst under a very slow evaporation, lasting over a month, it crystallizes in very thin rhombic tables, with which some granules are always mixed.

Prepared in this way neriantin does not show a distinctly crystalline structure. But it is soluble in small proportion in ether, and from this it separates upon gradual evaporation of the ether in long, fine, flexible needles. But this method cannot be adopted for the preparation of large quantities of crystallized neriantin.

In respect of solubility in alcohol, water, ether, chloroform and dilute acids, as far as can be stated without quantitative determinations, neriantin behaves like digitalin. It contains no nitrogen and gives when warmed with concentrated hydrochloric acid a greenish-yellow colour, and upon treatment with concentrated sulphuric acid and potassium bromide the beautiful red colour which is characteristic of digitalin. In this respect it might be referred to chemically pure digitalin.

On the other hand, neriantin differs from digitalin in the properties mentioned above and in its decomposition products. If a solution of neriantin in alcohol and water containing two or three drops of hydrochloric acid in 20 c.c. be boiled until the alcohol is driven off, a colourless pulverulent precipitate separates, which, examined under the microscope, appears to be composed of tolerably large four-sided pyramids, some more or less irregular and some well formed. The liquid filtered from the crystalline precipitate, after cooling, very strongly reduces cupric oxide in alkaline solution; so that neriantin must be looked upon as a glucoside, which under such treatment splits up into sugar and the crystalline body referred to. This, in analogy with "sapogenin" and "digitogenin," may be named "neriantogenin." Neriantogenin behaves towards concentrated hydrochloric acid and sulphuric acid and bromine like the unaltered neriantin, and like it is without any special action on the heart of a frog.

A more thorough investigation of neriantogenin could not be effected through want of material, but would be of especial importance to the chemical history of the peculiar active constituents of both the foxglove and the oleander. The peculiar reactions with hydrochloric acid and sulphuric acid, which distinguish almost all the oleander and digitalin constituents belonging to the digitalin pharmacological group, and reach their greatest purity and beauty in neriantogenin, indicate that in neriantogenin we have possibly to do with the nucleus which, in combination with other atom groups, especially the glucoses, gives rise to the active substances of those plants.

Neriantin, although a glucoside, does not produce the systolic pause in a frog's heart; at most it exercises a weak action, like saponin and digitonin. But it is not improbable that it originates from the very active oleandrin. Digitalein and digitalin give decomposition products which show the two reactions with hydrochloric acid and sulphuric acid and bromine most beautifully and are equally inactive, but have not hitherto been obtained crystallized. The fact appears to be, that the complete breaking up of these bodies results only from the action of stronger acids, which at the same time, as in the reaction with hydrochloric acid, gives rise to an alteration in the nucleus. The decomposition products are therefore almost all yellow or yellow-green.

From digitalin and digitalein there is formed first, upon heating with dilute acids, digitaliretin, and from this, through prolonged boiling with concentrated acids, the yellow-green inactive amorphous decomposition product. It might, however, be possible to effect by other means a splitting off, without a more fundamental decomposition, and thus to obtain a well-characterized crystallizable derivative.

Upon being kept digitalein, as before mentioned, gradually undergoes alteration, a colourless flocculent substance, insoluble in water, being formed, which gives the corresponding reactions with hydrochloric acid and sulphuric acid and bromine. This would appear to be the decomposition product corresponding to neriantin.

The difficulty in procuring these substances in large quantities makes it almost impossible to carry out an exhaustive chemical investigation of them. Digitalein is the most easily obtained, from the German commercial "digitalin." But the material alone for one kilogram of substance would cost five or six hundred pounds (10,000 to 12,000 marks). For the preparation of one kilogram of digitalin at least five or six thousand kilograms of dried digitalis leaves would be required.*

* An exhaustive list of the pharmacological literature of the oleander is appended to the original paper.

INSECTS INJURIOUS TO DRUGS.*

BY WILLIAM EDWIN SAUNDERS, PH.G.

In this paper is given simply what has been noted by the writer during a study of these insects extending over more than a year.

Sirodrepa panicea.—This is the elliptical, reddish-brown beetle, about one-eighth of an inch long, which is found in almost every edible drug, and in some, such as aconite root and capsicum, that would be pronounced far from edible. In addition to these two drugs I have found it in bitter almonds, sweet almonds, angelica, boneset, calumba, chamomile, chocolate, coriander, dandelion, elm bark, ergot, extract of licorice, German chamomile, orris root, prince's pine, rhubarb, squill, and sweet flag.

The larva is white with a brown head, is about twice as long as the beetle when full grown, although it is seldom or never seen stretched out at full length, always remaining curled up in a ball. It will in time fairly honeycomb a piece of root with small holes about one-twenty-fifth of an inch in diameter, at the end of which it is generally to be seen at home. Under the influence of camphor, these larvæ become uneasy, but being apparently unable to crawl away, resign themselves to their fate, and seem to thrive just as well with camphor as without it.

Calandra remotopunctata.—This is a small black beetle, about the size of the last, with what is popularly termed a "snout" projecting from the front of the head downwards. Under the microscope the back, thorax, and head are seen to be finely pitted, giving the insect a rough appearance. It was found in large numbers, the larva feeding on pearl barley, inside of which it lives, the egg being probably laid in the grain by the parent, and on hatching, the little insect makes its home there, eating all but the shel and sometimes attacking the grain from the outside.

Tenebrioides mauritanica, a species of "meal-worm," was found in pearl barley, and one specimen in calumba. It is a dark brown beetle, five-sixteenths of an inch long, the head and thorax forming nearly half the total length, and the mouth being fringed with hair. The back, which at first sight appears perfectly smooth, proves to be, when examined under the microscope, longitudinally corrugated. The larva is nearly half an inch long, white with a brown head, and between the jaws is a row of hair as in the perfect insect. The posterior end is furnished with a pair of jaws very similar, though, of course, for a different purpose.

Trebolium ferrugineum is a flat reddish-brown beetle, about one-eighth of an inch long, appearing smooth to the naked eye, though the microscope shows the back numerously pitted. These insects affect patent foods and similar substances, and the beetles are possessed of remarkable longevity, as proved by the fact that I have kept a few alive for two months in a small box with a little cerealina, which seems to be their favourite food. Whether the beetles themselves eat it or not I do not know, but they certainly have a liking for the dead bodies of other beetles.

Silvanus surinamensis is a narrow, brown beetle, almost one-eighth of an inch long, with a pitted and longitudinally corrugated back. One specimen only was found, on anthemis.

Anthrenus rarius.—This insect has been found only in cantharides, but I believe also attacks other animal drugs, such as castoreum. During the month of July there emerges from the egg a very active larva, densely covered on the tops of the segments with stiff brown hairs, which at the posterior end point towards the centre of the back, forming a ridge, and when the insect is annoyed, it has the power of dividing the ridge in the centre and throwing half down on each side in a fan-like position,

* From an Inaugural Essay presented to the Philadelphia College of Pharmacy. Reprinted from the *American Journal of Pharmacy*, April, 1883.

the object of which movement could not be determined. When the insect has been feeding on the whole cantharides, all these hairs on the back become rubbed off, those forming the ridge being generally last to go, because, being on the downward slope of the body they are not exposed to the same amount of friction. Underneath, however, the hairs are shorter and do not become rubbed off as on the back.

The larva consists of eleven segments, those at the ends being of a much deeper brown than those towards the middle, and the six legs being inserted on the three anterior segments, each furnished with a short, straight claw. The skins are shed quite often during the larval state, and are discarded by a slit nearly the length of the back, terminating indifferently at either end, and through which the insect emerges. The shed skins present a beautiful irridescent appearance under the microscope when viewed by reflected light.

These larvæ feed on the cantharides all winter, and, if in quantity, commit great havoc, leaving only the hard exterior portions untouched, such as the upper portion of the thorax, the green wing-cases and transparent wings. When their legitimate food gives out they have no compunction about first eating their dead parents, and then each other; but on this diet they do not seem to thrive so well.

The beetle emerges in May or June, and is about one-eighth of an inch long, oval, and black, the upper parts being marbled and streaked with whitish and rufous hairs, which are rubbed off after death if the insect is subjected to any rough usage.

Camphor does not kill these larvæ, and after keeping some for a day in a small box about a quarter full of camphor, the only thing worthy of remark in their actions was that they did not seem quite so lively as those kept without it. That they have a distaste for it, however, is proved by the fact that some which were put in a box with holes in it, left the box during the night. The Pharmacopœia direction to keep camphor with the cantharides is, therefore, not a *remedy*, but merely a preventive measure, and not a very good one either. The vapour of chloroform rapidly kills them, so that by putting a small quantity of chloroform in a gallipot on the top of the infested cantharides, the heavy vapour will sink through it and destroy them.

PHOSPHORUS AND A NEW METHOD OF EXHIBITING IT IN PILL-FORM.*

BY H. H. MILLHOUSE.

In choosing the above title as the subject of my dissertation, I would remind you that I am not the first who has been engaged in this field of inquiry. It is well known that many pharmacists have written much on this subject, and for that reason a new form of the administration of phosphorus is looked upon with suspicion, and often after a short time sinks into oblivion. My object is really to introduce to your notice an account of the experiments I have made and of what appears to me to be a new form of exhibiting this remedial agent in solid, *i.e.*, in pill form, which shall contain phosphorus in a free and unaltered state. I may preface my remarks by stating that the kind of phosphorus used was the one recognized in the British Pharmacopœia, viz., the ordinary or vitreous variety.

The medicinal value of uncombined phosphorus is dependent upon it being exhibited in a free, unoxidized and finely divided form, uniform in composition, easily and gradually assimilable, and mixed with ingredients, which do not cause decomposition, do not derange the stomach of the patient, nor counteract the action of the phosphorus.

On reference to several standard works on materia medica and various other sources we find that many medical men raise objections to the administration of phosphorus in solid form, each having different reasons for his assertions. Pereira says it should never be given in solid form, not even in pills. On the other hand Neligan remarks as follows:—

"It is generally stated that phosphorus should never be administered in solid form. If strictly interpreted this is perfectly correct, but it is not so if it be understood that phosphorus may not be administered in the form of pills, as in my opinion this is by far the best and safest way of exhibiting it."

Dr. Kirby in referring to the danger consequent upon the preparation of phosphorus pills, says:—"Bearing in mind the exceedingly poisonous properties of phosphorus and the great difficulties attending its pharmacy and its uncertain action when improperly prepared, I have refrained from publishing the details of my process, which it would be dangerous to undertake, without experience, preferring that its preparation should have proper personal supervision." In spite of this I venture to say that the average pharmacist of our own day is fully competent to undertake without risk the preparation of his own pilula phosphori when a suitable formula is presented to him.

I commenced my experiments by preparing pills from the official formula for pilula phosphori (for which I will refer you to the 'Additions to the British Pharmacopœia'). You will probably agree with me in saying that it is unsatisfactory. My reasons are briefly these. 1st. It is too hard and insoluble, for it has been known to pass through the body unchanged; 2nd. The quantity of phosphorus per cent. is too small, and consequently when other ingredients have to be added it makes the pills inconveniently large; 3rd. Being of light materials, 3 grain pills (usual dose of phosphorus $\frac{1}{30}$ of a grain) are when coated with an ethereal solution of such substances as tolu, sandarac, etc., sugar or chalk, too large. The recommendation to keep under water is both inconvenient and objectionable, the former because when a quantity is to be weighed out great care has to be taken to squeeze out all the adherent moisture, which when soap, spirit, or extracts are added causes the mass to become too soft, the latter because the amount of oxygen naturally taken up by water (4 per cent.) might cause some oxidation of the phosphorus, and thus weaken the preparation. This perhaps might be rendered less objectionable if the vessel containing the mass were filled to the brim with well-boiled and cold distilled water. No doubt other objections may be raised. The French Codex and also the recently published Pharmacopœa Germanica (1882) give no formula for phosphorus pills. I then made some from the formula of the last edition (1882) of the United States Pharmacopœia, which is as follows:—

Take of—

Phosphorus	1 grain.
Powdered althea	80 grains.
Acacia in fine powder	20 "
Glycerine	40 "
Water	20 "
Purified chloroform	50 "
Balsam of tolu.	
Stronger ether (94 per cent.)	q.s.

Dissolve the phosphorus in the chloroform, mix the powdered althea and acacia in a mortar, add the solution of phosphorus, then the glycerine and the water, make into a mass and divide into 100 pills. Coat with a solution of 1 part of balsam of tolu in 1 part of the stronger ether and keep in a stoppered bottle.

Among other suggestions that I have found are the following:—In a paper read at an Evening Meeting of the Pharmaceutical Society in 1873, A. W. Gerrard proposed the use of resin as a solvent. Tolu as a vehicle for pills was recommended by A. C. Abraham in 1874. W. H. Walling, in 1875, pointed out that cacao butter was a good solvent.

* Abstract of paper read before the Chemists' Assistants' Association, March 28, 1883.

Twenty-five grains of phosphorus were agitated with 300 grains of cocao butter until dissolved, and then 200 grains of powdered soap added and shaken until uniformly mixed, which gave a nice combination. W. B. Addington, in the same year, proposed incorporating a solution of phorphorus in carbon bisulphide with a suitable extract, continuing the trituration until the solvent had evaporated. Barnard Proctor recommended a similar formula in which the extract is replaced by soap, tragacanth, liquorice powder and confection of roses. E. Lilly, in 1876, suggested fusing phosphorus under syrup, shaking well so as to finely divide it, then mixing the phosphorus thus divided with flour. Mandl employed the following formula:—

Take of—

Phosphorus	5 centigrams.
Carbon bisulphide	20 drops.
Almond oil	18 grams.
Carbonate of magnesium .	q.s.

Make fifty pills and coat with gelatine.

Tavignot used a pill prepared from an oily solution alone, thus avoiding the objectionable ingredient unnecessarily employed in Mandl's formula.

Balsam of Peru, yellow and white wax, Canada balsam, silica, crumb of bread, borotartrate of sodium, resin, spermaceti, albumen, storax, suet, lard and phosphate of calcium, have also been from time to time recommended as excipients.

The objections which have at different times been raised against the numerous published formula are manifold and various; some of these are subjoined. Cacao butter melts too quickly in the stomach, causing unpleasant eructations and is too difficult to manipulate, and when mixed with tragacanth powder or other plastic ingredients neither of these objections is obviated. Mr. Gerrard's phosphoretted resin process has, in my opinion, as many objections as the British Pharmacopœia one; the complicated mode of preparation is alone sufficient to condemn its adoption, even by those pharmacists who are anxious to follow as far as practicable the advice meted out to them in an eloquent address by a respected professor of chemistry. Then, as Dr. Méhu has remarked, the process is very dangerous and during the operation a portion of the phosphorus passes into the amorphous or insoluble form, the resin being supersaturated with phosphorus. At a high temperature it would probably separate into solid fragments on cooling, and be very liable to oxidation during the pulverization of the resin. Lard and other readily oxidizable organic compounds become rancid and assist the oxidation of the phosphorus.

Personally my troubles with this preparation have been very great, especially when other things have to be added, and I imagined that a formula with a basis having qualities as above described would be a desideratum, so I began by looking up the literature of the subject with the foregoing result. I have tried a great many formulæ, most of which are given below, and they have been prepared both in mass and divided into pills coated with different coatings.

No. 1. Is the B.P. mass rolled out into 3-grain pills and varnished with a solution of sandarac in ether. For objections see above.

No. 2. Are 3-grain B.P. phosphorus pills, each containing in addition ½ of a grain of powdered hard soap. This addition has been recommended by medical men and others to prevent the pills passing through the body unacted upon; it, however, makes them more difficult to manipulate, since they have a tendency to split, and of course they are too large; less soap (⅛ or ¼ of a grain) would perhaps suffice.

No. 3. Consists of—

Phosphorus	5 grains.
Mutton suet	250 grains.
Powdered liquorice	145 grains.
Powdered mastich	50 grains.
	(1 part of phosphorus in 90).

Melt the suet, add the phosphorus, digest with agitation over a water-bath until dissolved; now pour the solution upon the powder previously well mixed, thoroughly dried, and placed in a stoppered bottle standing in hot water so that the melted suet is not chilled, but readily mixed by violent agitation with the powder. When divided into 3-grain pills each pill contains $\frac{1}{30}$ of a grain of phosphorus. They are large and in consequence of the basis being bulky, inconvenient to mix with other ingredients. Possibly they would be improved if a larger percentage of phosphorus were added.

No. 4. Contains—

Phosphorus	2 grains.
Powdered liquorice	120 grains.
Carbon bisulphide,	
Chloroform, of each a sufficiency.	
Glycerine of tragacanth	76 grains
	(1 part of phosphorus in 99).

It was prepared by carefully dissolving the phosphorus in 20 minims of carbon bisulphide, pouring the solution upon the liquorice powder contained in a mortar, mixing thoroughly and making into a mass with the glycerine and tragacanth paste, keeping the vapour of chloroform present during the entire process to prevent undue oxidation. $\frac{1}{33}$ of a grain of phosphorus will be contained in every 3 grains of the mass. This method is frequently resorted to when medical men order phosphorus in the form of pills without giving any basis or guide as to the way in which they wish it to be dispensed. This is the principle carried out in the United States Pharmacopœia. It is objectionable, as it retains the smell of the carbon bisulphide, and cannot safely be preserved in mass.

Carbon bisulphide, which is capable of dissolving phosphorus with greater rapidity and in larger proportion than any other solvent, has also been used in the manufacture of pills by Mandl, Proctor, and many others. M. Gubler has pointed out the fact of it possessing, in a notable degree, the power of counteracting the effect of free phosphorus. It imparts an offensive odour and taste to all preparations in which it has been used; probably even when, as in Mr. Proctor's process, the evaporation of it is calculated upon, the smell of the solvent is retained, and unless very dexterously made, some of the solvent itself.

No. 5. This is a sample which I have procured from one of the leading dispensing establishments in the West-End, and, if in the hands of a clever manipulator, may be rolled out into nice-looking pills, especially when coated with gelatine; but they, however, very quickly become sticky to the touch and unmanageable. The basis of this probably consists chiefly of cacao butter (the ordinary basis for suppositories) and tragacanth. I am informed that 1 part of phosphorus is contained in 60 parts of the mass, a 2-grain pill will therefore contain the usual dose of phosphorus, $\frac{1}{30}$ of a grain, but the ingredients being evidently light, this size pill is proportionately large.

No. 6. This was also obtained from a well-known firm, is similar in its appearance and behaviour to No. 5, and is probably of the same composition with a little soap added. These two preparations (No. 5 and 6) struck me as likely to produce those disagreeable eructations it is so essential to avoid, and my assumption was verified by actual experiment "in vili corpore," for within half an hour of taking a 2-grain pill, I experienced a slight yet disagreeable burning sensation in the stomach, and unpleasant feeling in the throat with the usual "*brimstone-like*" eructation.

No. 7. From a large City dispensing establishment. It is of much better consistence than the two preceding ones, and rolls out well. From its general behaviour I imagine it is slowly dissolved in the stomach and the phosphorus gradually absorbed. From the odour of the mass I should say carbon bisulphide has been used in its preparation, which, together with it being a private formula, is the only objection I can raise against it. I am given to understand that 1 part of phosphorus is contained in 50 parts of the mass; hence, each 2-grain pill contains $\frac{1}{25}$ of a grain of phosphorus, thus allowing of other ingredients being added without rendering the pills inconveniently large. By examination it seemed a probable mixture of liquorice, soap, mastich, phosphorus and moisture.

No. 8. Is an advertised English nostrum which I was unable to procure in mass, it being only sold in divided pills with a white coating; as we are told, it is necessary to have it divided into pills and coated directly it is made, or oxidation of the phosphorus would take place, a fact which of itself would prevent its adoption for general pharmaceutical purposes. The basis probably consists of an inert powder, with extract of gentian. I examined the coating and found it was easily detached when placed in warm water, and was composed of French chalk, sugar and gum.

No. 9. Was the following formula:—

Take of—

Phosphorus	8 grains.
Vaseline	196 grains.
Paraffin wax	36 grains.
Phosphate of calcium	240 grains.

(1 part of phosphorus in 60).

The wax and vaseline were melted together by the heat of a water-bath in a stoppered bottle, the phosphorus added while warm and shaken until dissolved, continuing the agitation until cold. It was then carefully mixed in a mortar with the phosphate of calcium. Here a peculiar phenomenon was noticed immediately after mixing, heat being developed and the mass assuming a semi-solid condition and remaining so in spite of the addition of more phosphate of calcium; when all what seemed to be chemical action had ceased, it gradually acquired a more solid form. This was not proceeded with but laid aside for future investigation, the cause of which peculiar action I hope to be able soon to explain.

No. 10. Consists of:—

Phosphorus	4 grains.
Powdered myrrh	46 grains.
Paraffin wax	30 grains.
Vaseline	70 grains.
Kaolin	90 grains.

(1 part of phosphorus in 60).

The paraffin wax and vaseline were melted together in a porcelain capsule by the heat of a water-bath and poured into a wide mouthed stoppered bottle previously thoroughly dried and warmed by standing in hot water; the phosphorus was now added and the whole briskly agitated until the phosphorus had dissolved and the mixture had finally solidified; when quite cold it was made into a mass with the kaolin and powdered myrrh, previously well mixed in a mortar. This mass is not difficult to manipulate, though it is rather soft in consistence and the pills do not varnish nicely. When divided into 2-grain pills, each pill contains $\frac{1}{30}$ of a grain of phosphorus.

No. 11. Is of the following composition:—

Phosphorus	4 grains.
Cacao butter	100 grains.
Prepared mutton suet	100 grains.
Powdered tragacanth	36 grains.

(1 part of phosphorus in 60).

The cacao butter and suet were melted as described in No. 10, and transferred to a similar stoppered bottle, the phosphorus added and shaken until dissolved and while the mixture was still liquid the powdered tragacanth was introduced and the whole violently agitated until uniformly mixed. The objections to Nos. 5 and 6 will apply to this.

No. 12. Is composed of:—

Phosphorus	4 grains.
Paraffin wax	130 grains.
Vaseline	70 grains.
Powdered tragacanth	36 grains.

(1 part of phosphorus in 60).

The paraffin wax and vaseline were melted by the heat of a water-bath, and the same mode of preparation adopted as in No. 11.

No. 13. Contains:—

Phosphide of zinc	4 grains.
Powdered althea	20 grains.
Resin ointment	24 grains.

Make a mass and divide into twenty-four pills.

This can scarcely be called a mode of exhibiting phosphorus in the free state, inasmuch as an acid must be present in the stomach, causing decomposition with production of nascent hydrogen, which combining with the phosphorus forms phosphoretted hydrogen, and is thus absorbed.

This has, however, of late years been largely prescribed by the medical profession and I find such a combination as the one above to give satisfactory results.

In concluding my list of formulæ, I would specially direct your attention to the following, the latter of which I am given to understand is quite a new method for giving a satisfactory basis for the administration of phosphorus.

No. 14. Consists of—

Phosphorus	5 grains.
Benzoated lard	250 grains.
Phosphate of calcium	205 grains.
Carbonate of calcium	20 grains.

Melt the lard by means of a water-bath, transfer to a strong stoppered and perfectly dry glass bottle made warm, add the phosphorus, shake until dissolved, then pour the solution upon the powders, previously well mixed and contained in a similar stoppered bottle, kept warm by standing in hot water, shaking briskly until the mass is thoroughly uniform in consistence. Each 3-grain pill contains $\frac{1}{32}$ of a grain of phosphorus in the free state.

No. 15. Consists of—

Phosphorus	4 grains.
Powdered mastich	30 grains.
Paraffin wax	50 grains.
Vaseline	66 grains.
Kaolin	90 grains.

Melt the wax and vaseline together in a porcelain capsule by the heat of a water-bath, place them in a strong glass stoppered bottle, previously warmed by allowing it to stand in an oven or other warm place, add the phosphorus (care being taken that the mixture is not too hot, a temperature of 140° F. being quite sufficient to fuse the phosphorus), and shake briskly until cool; when quite cold rub carefully in a mortar with the kaolin and powdered mastich, previously well mixed, until a uniform mass is obtained. It should be kept in a covered pot.

The vaseline used in the foregoing formulæ was kept in an evaporating dish at a temperature a little above its melting point for twelve hours, in order to dissipate all trace of moisture.

These two formulæ, Nos. 14 and 15, I feel confident in strongly recommending, presenting as they do to every pharmacist a practical method of dispensing phosphorus in the free state. Both are easily prepared, and if ordinary care is exerted, the danger of oxidation of the phosphorus is reduced to a minimum. The masses are of a good consistence and easily rolled into pills which possess the advantage of being small in size (in No. 15, more especially, the ordinary dose of phosphorus, $\frac{1}{30}$ of a grain, being contained in a 2-grain pill, which when coated with gelatine is considerably smaller than a 2-grain B.P. quinine pill), and thus convenient to mix with other ingredients, are readily but not too quickly disintegrated in the stomach; consequently the phosphorus is gradually absorbed into the system. Having taken several, I have experienced no unpleasant eructations, but a sensation (after a few hours have elapsed) of what the French would term *bien être*, thus leading me to believe that the active ingredients of the pills had been assimilated. I have used several different coatings (some specimens of the pills coated with them are upon the table), including sandarac varnish, gelatine, isinglass, French chalk, and a mixture of gelatine, sugar and gum acacia dissolved in water; but as pill coating might be made the subject of a very useful and valuable paper by some one of our members, I will merely content myself with according my preference to the latter for coating phosphorus pills, which is but a slight modification of a process recommended in a paper by Clay W. Holmes and published in the *Pharmaceutical Journal*, December 23, 1882. It, however, requires a certain amount of practice before the operator is able to employ it satisfactorily.

Several of my pills were coated by merely placing one on either end of a piece of fine wire bent in horse-shoe fashion, dipping them into the liquefied coating solution and hanging on nails until the coating had firmly set. This, though a tedious process, is nevertheless a very good one, and more easily managed than the pin process advocated by Mr. Holmes.

Before coating with French chalk (pearl coating), these pills should be varnished with an absolute alcoholic solution of sandarac, or other suitable alcoholic solution, ether partially dissolving the basis employed in their preparation.

I should recommend the mass to be kept in a covered pot, in boluses of about two drachms each, wrapped in wax paper to exclude the air and prevent any consequent liability of the phosphorus becoming oxidized. The different masses I have prepared (and placed on the table) have all been kept several months without this precautionary measure having been taken and no deleterious effects have ensued.

I have mixed No. 15 mass with various ingredients, including the following; in each case satisfactory results have been obtained.

No. 16. Contains in each pill—

No. 15 mass . . .	2 grains (equivalent to $\frac{1}{30}$ of a grain of phosphorus).
Sulphate of quinine	1 grain.

This requires no excipient and makes a very nice and workable pill.

No. 17—

No. 15 mass	2 grains.
Sulphate of quinine	1 grain.
Reduced iron	2 grains.

With the addition of a small quantity of glycerine of tragacanth and balsam of Peru these make good and convenient sized pills.

The following method was adopted for approximately estimating the comparative melting points and probable points of absorption of each in the stomach.

A beaker, having a capacity of 10 fluid ounces, was placed upon a tripod and two-thirds filled with cold water, and in this was placed a test tube (an inch in diameter and 5 inches in length), also two-thirds filled with cold distilled water previously boiled, in which was suspended a very sensitive mercury thermometer dipping nearly to the bottom of the test tube. 5 grains of the mass to be tested was placed in the test tube; heat was then applied by means of a Bunsen's burner to the beaker, in such a manner that the temperature rose exactly 1° Fahrenheit per minute, each degree rise being accurately noted. The temperature was taken down at which the mass altered in consistence or otherwise; and to the water contained in the test tube was added, after the experiment was completed, a weak solution of litmus to see if any acid of phosphorus was present. The subjoined are the results obtained:—

Number of pill.	Softens.	Very soft.	Disintegrates.	Remarks.
1 . .	104° F.	114° F.	122° F.	
2 . .	98°	108°	115°	
3 . .	79°	88°	105°	
4 . .	82°	89°	110°	
5 . .	82°	89°		This melts and floats on the top of the liquid at 89° F.
6 . .	77°	82°	86°	Melts at 86° F.
7 . .	79°	88°	105°	
8 . .	102°	114°	118°	Coating readily removable at 102° F., completely dissolved at 130° F.
9 . .				*Vide* remark under this head.
10 . .	90°	98°	102°	
11 . .	84°	90°		Melts and floats on the top of liquid at 90° F.
12 . .	85°	93°	94°	Melts at 94° F.
13 . .				Phosphide of zinc.
14 . .	86°	95°	104°	
15 . .	91°	100°	106°	

The waters in which Nos. 1 and 2 were separately digested, each gave an acid reaction on the addition of a weak solution of litmus. The different portions of water in which the other samples had been individually digested, remained neutral to the litmus solution.

LUMINOSITY OF FLAME.*

BY W. SIEMENS.

The luminosity of burning gases is a secondary phenomenon dependent on the separation and incandescence of solid particles suspended in the flame. Gases from which no such particles are separated burn with a feebly luminous flame, and this luminosity is attributed to the incandescence of the gases themselves. No experiments have hitherto been made to ascertain whether pure gases heated to a high temperature really emit light. In order to examine this point, the author's brother made a series of observations with a Siemens regenerative oven, of the form used in the hard glass manufacture, whereby a temperature of the melting point of steel, 1500–2000° C., could easily be attained. By a suitable contrivance the interior of the oven could be examined, and it was thus found that, provided the experimental room was kept perfectly still, the heated air in the oven emitted no light. The introduction of a luminous flame into the oven caused its interior to be only feebly illuminated. As a result of these experiments, it follows that the supposition that the luminosity of the flame is due to the incandescence of the gas is incorrect. In order to determine the temperature at which luminous flames become non-luminous, the author suggests a repetition of the above experiments with a more refined apparatus. The heat-rays emitted from hot gases are very small in number as compared with those emitted from equally hot solid bodies.

Observations on the behaviour of flames themselves prove equally that the luminosity of flames is not due to the incandescence of the products of combustion. If the gases to be burnt are more quickly mixed, the flame becomes shorter, since the process of combustion is accelerated, and hotter, since less cold air is mixed with the burning gas. The same phenomenon occurs if the gases are strongly heated before they are burnt; but since the ascending products of combustion are maintained for a short time only at the temperature of the flame, the above phenomenon would be reversed were the gases self-luminous. The luminous part of the flame is separated by a line of demarcation from the products of combustion, and is coincident with the termination of chemical action, which is probably the cause of the emitted light.

The Pharmaceutical Journal.

SATURDAY, MAY 12, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL REPORT.

Though the Anniversary Meeting of the Society will not be held this year until a week after the usual time, the Report of the Council upon the transactions of the past year is already in the hands of the Society's members, and as the hopes which have been entertained of a satisfactory amendment of the law relating to the practice of pharmacy are still deferred, attention will naturally be directed in the first place to that portion of the Report which deals with this subject. As regards the Pharmacy Acts Amendment Bill, which has been submitted to the Privy Council, the position of the Council is still only one of expectancy, and it is unable to do more than state that the draft Bill is engaging the attention of the Government. That the result of the deliberations on the Bill will be favourably influenced by the very general approval it has met with from the Society's members and from the trade at large may reasonably be anticipated; but it must be remembered that if the Bill should be eventually introduced into Parliament there will still be need of the hearty support and thoroughly united action of the entire pharmaceutical body in order that it or any Pharmacy Acts Amendment Bill shall become law. This necessity is forcibly expressed in the Report of the Council, and we trust its appreciation will be so general as to strengthen the hands of the Society's executive for its endeavour to promote the interests of pharmacy and enable it effectually to urge the claims of those engaged in that business.

As bearing upon this point, we may refer to the circumstance that the period has arrived for the members of the Society to manifest their interest in the constitution of the executive body by which they are represented, and in whose hands is placed the power of dealing with such matters as affect their interests. In former years it has afforded ground for regret that a large proportion of those entitled to vote have failed to send in their papers at all or in time to comply with the requirements for their acceptance. We feel sure that this disregard of the exercise of so important a function must be due to a want of proper appreciation of what is requisite from every one connected with the Society. If it be expected that the Council of the Society is to have any useful influence in regard to contemplated legislation, or otherwise as a representative of the pharmaceutical body, it must be evident that the extent to which such a power exists will depend upon the general hearty support the Council receives from all the members of that body. It is to be regretted that so many of them do not belong to the Society; but it is still more matter for regret that among its members there should be any who give reason for supposing that they are indifferent as to who are elected to represent them in the way we have referred to.

As a matter closely connected with special pharmaceutical legislation, the introduction of a Medical Acts Amendment Bill into Parliament is next referred to in the Council Report. As we have already pointed out in a former article, this Bill does not propose to interfere in any way with the legitimate exercise of the business of chemists and druggists; but in regard to one of the duties with which the proposed newly constituted Medical Council is to be charged, the Bill fails to do justice to the claims of pharmacists since it does not provide for any such representative recognition of pharmacy as obtains in all other countries in the production of a national Pharmacopœia. The Council of the Pharmaceutical Society has, on several occasions, had this subject under consideration, and has expressed its sense of the desirability of practical pharmacists being officially associated with medical men in carrying out the work of revising the Pharmacopœia. The Medical Bill, however, merely adopts the provisions of the existing law that the Medical Council shall from time to time cause to be published under its direction a British Pharmacopœia. According to the practice hitherto followed the work of revision would thus be done by a committee of the Medical Council consisting solely of medical men and assisted by such chemical, pharmaceutical and other experts, as it may deem desirable to engage, for the sake of making their special knowledge available.

This mode of carrying out the work of Pharmacopœia revision for Great Britain and Ireland is, however, one that does not accord to the possessors of pharmaceutical skill such a position as is consistent with the advance that has been made during late years in their educational and practical qualifications. The Council is therefore taking steps to obtain an amendment of the clauses of the Medical Bill, when it comes before the House of Commons in Committee, of such a nature as to provide for the adequate representation of practical pharmacists in the body charged with the preparation of a national Pharmacopœia.

In the effort to be made in this direction, the Council of the Pharmaceutical Society of Ireland has expressed its willingness to co-operate, and it is but natural that a desire should be entertained on the part of Irish pharmacists to have a voice in the preparation of a book which constitutes the law by which they are to be bound, no less than their English and Scotch colleagues.

The unexpected prominence that has been given to this matter by the recently disclosed proceedings of the present Medical Council, has led to some expression of dissatisfaction on the part of the President of the Pharmaceutical Society of Ireland, on the ground that the principle of centralization had been applied in such a way as to leave the Irish Society out in the cold; but however much we are disposed to acknowledge that Irish pharmacists have not been considered as they should be, we cannot admit the justice of the complaint so far as the Council of the Irish Society is concerned. On the contrary, it might be contended that there is some ground for charging the Council of the Irish Society with complicity in the arrangement entered into between the Pharmacopœia Committee of the Medical Council and the professors of this Society. At any rate the Pharmaceutical Society of Ireland is to some extent represented in that Committee by its Vice-President and another of its members. If therefore the Irish Society feels aggrieved by the revision of the Pharmacopœia being placed in the hands of three English professors, how much more reason is there for English and Scotch pharmacists to complain of those members of the Irish Council who have helped to prevent the general emancipation of British and Irish pharmacy that might have been promoted by them as members of the Pharmacopœia Committee of the Medical Council.

The present aspect of this matter is, we think, such as to render it one of especial importance to the pharmacists of all parts of the Kingdom, and it would seem to offer an excellent opportunity of urging upon the Government the reasonable claims of pharmacists to recognition. We believe that it is contemplated to submit to the Privy Council a memorial embodying the views of the Council and stating the general case on which action is to be taken. The substance of this memorial will be communicated to the Local Secretaries of the Society for their information and guidance in the endeavour to organize measures for supporting the Council. By this means it will be possible to bring influence to bear upon members of Parliament through their constituents in various parts of the country, with a view of ensuring their aid when the Bill comes before the House of Commons. Of course it will not be until after the Whitsuntide holidays that anything can be done in Parliament; but the interval that will elapse before the Bill is taken in Committee will furnish opportunity for doing the work required, and the coming anniversary gatherings will enable members of the Society to confer together as to the best mode of being severally useful in this important movement.

The financial statement is a very satisfactory feature of the Council Report, showing that the income for the past year exceeded the expenditure by more than one thousand pounds, and it is to be anticipated that this good result will be continued by the improved investment of the Society's capital as proposed for the future in freehold ground rents.

The Benevolent Fund has been considerably augmented, not only by several legacies, but also by the subscriptions sent in through the efforts of the Local Secretaries, who have so zealously given their services for the promotion of that object. It is to be hoped that the publication of local lists of subscriptions and donations, commenced last February in the *Pharmaceutical Journal*, will materially assist towards further advocating the claims of the Fund amongst those who have not hitherto contributed to it from not having had their attention called to the pressing claims for relief which the Council has made upon it constantly from all parts of the country.

The Evening Meetings held during the past session have been more than ordinarily well attended; the papers read have been numerous as well as important, and the participation of younger members in the discussions has afforded much satisfaction.

The Library has been augmented by the addition of five hundred books and pamphlets, and that its importance has received due attention we may infer from the fact that it has been visited by more than a thousand readers during the year.

The Museum has been enriched by several gifts from the Government of medicinal plants from the Botanic Gardens at Ceylon, and cinchona bark from Jamaica and Madras. Dr. Parker has also presented a number of interesting drugs from Madagascar.

During the past year the subjects of education and examination have received much consideration from the Council; but for the present we defer any further detailed reference to the changes that are contemplated in this direction, as the course to be taken in regard to them would depend much upon the future progress of the Bill which the Council has submitted to the Privy Council.

It is with pleasure we mention the Council's intention of recommending the members to pass a bye-law to allow of the election of corresponding members. It is so desirable that the interest which many eminent men take in pharmacy should be enhanced by some official recognition on the part of the Society, as the labours and services of British pharmacists in the same direction are recognized by Continental and American associations, that this mode of associating with the Society distinguished pharmacists and others residing permanently outside the United Kingdom has been thought to be especially adapted to further the interests of the Society and promote the objects which it has in common with those who might thus be attached to it in the character of corresponding members.

We are requested by the Secretary to mention that through an oversight the words "for the use of the Council only" were printed on the copies of the Report intended for the Members and Associates, and that in some instances these words were not erased.

* * *

Another Medical Bill has been introduced into the House of Lords by Lord O'Hagan, and read a second time on Thursday, but its sole object is to amend the Medical Act of 1858 and to confer upon the Royal University of Ireland the power to appoint a member of the Medical Council formerly exercised by the Queen's University in Ireland, now dissolved. If, however, the Government Bill should pass, the necessity for this second Bill would be superseded.

* * *

In reply to the application of the Committee of the Vienna International Exhibition the Imperial Minister of Finance has granted the privilege of introducing into Austria, duty free, such goods intended for the Exhibition as are not sold in the country. The State Railway Department has also decided to charge the usual tariff for conveying goods to the Exhibition, but to make no charge for the return carriage.

* * *

The New York correspondent of the *Standard* states that at a recent auction sale of quinine an aggregate amount of a ton and a half was sold. This is the largest peremptory sale of quinine that has yet taken place in America. It may be added that a few days since there was a sale of sixteen thousand ounces of quinine sulphate in London, and it is understood that a sale of a similar quantity is to take place shortly in Berlin.

* * *

In the *Journal de Pharmacie* for the present month there is an interesting note by Messrs. Regnauld and Villejean on an analysis of some bark from a plant of *Cinchona succirubra*, which had been grown in the open air in the botanical garden of the Faculté de Médecine, Paris. Notwithstanding the unfavourable conditions, climatic and otherwise, under which the plant was reared, the bark is said to have yielded 1·47 per cent. of quinine and 1·05 per cent. of cinchonine.

* * *

The last month has seen the completion of Messrs. Bentham and Hooker's great work, 'Genera Plantarum,' after a lapse of more than twenty-one years from the time when the first portion of the MS. was placed in the printers' hands. The complete work forms three large octavo volumes, written in Latin and printed in small type.

* * *

The *Journal of Botany* quotes the following estimate by Mr. Bentham of the number of phanerogamic plants at present known to science:—Polypetalæ: 82 orders, 2610 genera, 31,874 species. Gamopetalæ: 45 orders, 2619 genera, 34,556 species. Monochlamydeæ: 36 orders, 801 genera, 11,784 species. Gymnospermeæ: 3 orders, 44 genera, 415 species. Monocotyledons: 34 orders, 1495 genera, 18,576 species. Total: 200 orders, 7569 genera, 97,205 species.

* * *

By a recent Proclamation of the Governor of Victoria the schedule of poisons to the Sale of Poisons Act of that colony has been augmented by the addition of—Solutions or admixtures of arsenic, with some exceptions; all solutions or admixtures of strychnia and of other vegetable alkaloids and their salts; all preparations of corrosive sublimate; vermin killers, if preparations of poisons included in the first part of the schedule; solutions and preparations of chloral hydrate; red oxide of mercury; ammoniated mercury, and the tincture and all vesicating preparations of cantharides.

* * *

The *New York Tribune* reports a case in which damages to the amount of 100 dollars have been recovered against a druggist for injuries sustained by the plaintiff through negligence in dispensing a prescription. No more exact information is given as to the nature of the mistake than that a single dose caused the plaintiff to keep her bed for a month; but the defendant, while admitting that a mistake had been made, asserted that the compound ought not to have produced the ill effects complained of.

* * *

The authorities of the Californian College of Pharmacy appear to have invited a General Barnes to deliver an address on the occasion of their last graduating exercises, a compliment which he repaid with some very plain speaking upon the subject of the "patent medicine" trade. Singling out one preparation, "The Balm of a Thousand Flowers," he described it as follows:—"A mixture of oil, potash, alcohol and sugar, boiled together, and flavoured with musk; a bad liquid scented soap, capable perhaps of washing a dirty face and nothing more. Yet the advertisement alone of this fraud has cost over 100,000 dollars, which is said to have been profitably spent, and hundreds of thousands of bottles have been sold by reputable pharmacists, every one of whom knew it to be a fraud." The general's anger against the offending proprietor pursues him even beyond the tomb, and his wish as expressed was not exactly "*Requiescat in pace!*"

* * *

A little later, General Barnes's oratory took another flight. "Your patent medicine fiend swoops down upon humanity as soon as it is launched into the world, with soothing syrups that take the place of nature's healthy rest, and with artificial food better than the pure and healthy fountain which nature gives for its sustenance. It hangs over old age with the lying promise of the restoration of vitality, and squats at last upon its coffin, holding some embalming nostrum that shall make the corpse proof against the ravages of the worm." It is not surprising to learn that at the end of the "oration" one of the professors ventured to suggest that it was the public which most wanted educating in this direction, for as long as the public demanded patent medicines somebody would supply them, even if druggists did not.

* * *

If official reports are worth publishing at all, it is desirable that they should appear within a reasonable interval from the period to which they refer. This can hardly be said of the Eighteenth Annual Report by the Inspector under the Alkali Acts, which was issued a few days since. This report refers to proceedings in the year 1881, is supplemented by a short note dated August, 1882, and is presented to Parliament in May, 1883, after many of the conditions discussed in the report have been affected by fresh legislation.

Transactions of the Pharmaceutical Society.

Errata.—Page 902, col. 2, line 25 from bottom, *for* Barnes, James Burdon, *read* Barnes, James Burden.

Page 913, col. 2, line 28 from bottom, *for* Barnes, James Bunden, *read* Barnes, James Burden.

Our attention has also been called by Mr. Gostling to a misprint in the report of his remarks at the Council at its last meeting (before, p. 908), which evidently referred to the letter addressed by the Professors to the Medical Council on the 7th of November last.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, the 2nd inst., in the College of Physicians, Dublin, at three o'clock.

The chair was taken by Dr. Collins, and afterwards by the President, Professor Tichborne.

The other members of the Council present were:—Messrs. Allen, Brunker, Doran, Grindley, Hayes, Hodgson, Lester, Simpson, Wells and Dr. Montgomery.

Mr. Hugh Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

Mr. Fennell read a letter from Dr. Kaye, Q.C., Clerk to the Privy Council, stating that that Council had been advised that the amended resolution of the Society relative to the certificate to be required from candidates for the licence was not sufficiently explicit, and that the law officers of the Crown had drafted the following rule, which was forwarded for consideration and approval:—

"Resolution—

"Every candidate for the licence who has not previous to January 3, 1883, passed the Preliminary examination of this Society, or such examination as is accepted as equivalent thereto, shall be required to produce (*a*) A certificate signed by a pharmaceutical chemist or apothecary, keeping open shop, stating that such candidate has served a *bonâ fide* engagement for a term of four years, or for two or more lesser terms, amounting in all to four years, as apprentice or assistant, with and in the sole employment of such pharmaceutical chemist or apothecary, or of a firm of legally qualified pharmaceutical chemists or apothecaries, of which the aforesaid pharmaceutical chemist or apothecary is a member; or (*b*) In cases where such candidate has not served a four years' engagement as aforesaid, in the employment of one such pharmaceutical chemist or apothecary or firm as aforesaid, but has served two or more shorter engagements for terms amounting in all to four years as apprentice or assistant, with and in the sole employment for the time being of a succession of different pharmaceutical chemists or apothecaries or firms of legally qualified pharmaceutical chemists or apothecaries keeping open shop, then like certificates showing that the candidate has served for such shorter terms as aforesaid, each of which certificates is to be signed by the pharmaceutical chemist or apothecary in whose employment the term therein mentioned has been served, or in case of a firm, by a pharmaceutical chemist or apothecary, being a member of such firm at the time of the signing of such certificate. When by reason of the death of the pharmaceutical chemist or apothecary with whom any such term as aforesaid has been served, or where from any other cause it shall become impossible or inconvenient for the candidate to procure a certificate signed as aforesaid, it shall be lawful for the Society to accept in lieu thereof such evidence as it shall consider satisfactory, showing that the candidate has actually and *bonâ fide* served such term or terms as aforesaid."

Mr. Brunker: The resolution follows our view of the case, only that it is expressed in legal terms.

The President: If it embodies the spirit of our resolution we had better let them have it in their own phraseology.

Dr. Montgomery: I think it would be better to refer it to the Legal Committee to look over before we adopt it. There is no hurry about the matter. What is the object of having so many words in the resolution?

Mr. Brunker: To prevent candidates from wriggling through. The rule as we drafted it was too vague.

The President: I think the object is to tighten us down, to prevent our resolution from being used too much against the candidates. The Certificate Committee is the one to consider it.

On the motion of Dr. Montgomery, seconded by Mr. Allen, the draft resolution was referred to the Certificate Committee, with a request that they would consider and report on it.

A letter was received from Mr. Charles L. Peel, Clerk to the Privy Council of England, acknowledging the receipt of a memorial from the Council of the Society to Lord Carlingford, on the subject of the Medical Bill.

The letter was ordered to be marked "read."

The President brought under the notice of the Council a report of the Pharmacopœia Committee of the General Medical Council. That Committee appointed a Sub-Committee on the 1st of July, 1882; and that Sub-Committee had placed the task of preparing a new edition of the Pharmacopœia in the hands of Professors Redwood, Bentley and Attfield. These gentlemen were to receive a sum of £800, which was to include the cost of experiments, etc., and the work was to be carried through the press to the satisfaction of the General Medical Council. The Committee intended to apply to all medical authorities, pharmaceutical and chemical societies, and others that they thought were likely to furnish useful information, in order that the work might be made as complete as possible. This report was satisfactory in one sense, and unsatisfactory in another. It was satisfactory to know that the editing of the Pharmacopœia was to be in such excellent hands as those of the gentlemen named. Professor Redwood was a thoroughly practical man, Professor Attfield had been for many years associated with pharmaceutical education and he would endeavour to make the Pharmacopœia an educational work. As to Professor Bentley, from his position in the Pharmaceutical Society of England, he believed that he was an excellent man also. But the unsatisfactory part of the matter was that the work was exclusively in the hands of the officers of the Pharmaceutical Society of England and that the Irish Society was left out in the cold. Of course they could not help that. It was one of the fatalities of that Island. But it was one of those little things that made constitutional people think that there were grounds for the Home Rule cry. At any rate all those things appeared to tend towards a principle of centralization. They in Ireland had to physic the people according to the directions of their friends on the other side, who had the entire control of the matter.

Mr. Brunker: They propose three omissions from, and twenty-nine additions to, the Pharmacopœia.

The President: One objection to the matter being placed exclusively in their hands, is that they will make the Pharmacopœia according to the London practice. They will probably introduce a lot of footy things, because they are fashionable in London practice, and expunge important articles.

Dr. Montgomery: Are we in a position to make suggestions to them?

The President: We will have to wait until we are asked.

Dr. Montgomery: But even before we are asked?

The President: It would not be consistent with our dignity to do so after what has occurred. I know that Dr. Apjohn took a very prominent part in the preparation of the last Pharmacopœia, and spent an immensity of time upon it, and yet I think his services were hardly recognized.

Dr. Collins said he knew that the services of Dr. Apjohn in connection with the last Pharmacopœia were not sufficiently recognized.

The Registrar read a letter from Mr. T. S. Hance, dated from the "P. L. Surgery, Limerick," forwarding his subscription of £1 1*s.* to the Society, and asking whether the Society would consider his certificates of pharmacy in conformity with the requirements of the Act. The shop he kept was not a public place of business, but he had the sanction of the Local Government Board for taking apprentices, and his certificates were recognized by all the medical boards.

The President: Does he compound prescriptions for the public?

Mr. Wells: He does not. It is not a shop. He has merely the dispensary to the workhouse; and I know that he has taken pupils there for some years.

It was ordered that Mr. Hance should be informed that the regulations required that the certificate should be from a pharmaceutical chemist, or apothecary, *keeping open shop.* His certificate could not therefore be recognized.

A report of the Law Committee was adopted.

A report from the Examiner stated that 10 candidates had passed the Preliminary examination held on April 2.

The following candidates passed the examination for the licence, held on April 4 and 5, and were now registered as pharmaceutical chemists:—

John Robson, 26, Clare Street, Dublin.
John Starrett Shortt, 16, Strand Road, Derry.

Some financial business having been disposed of, the Council adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourteenth general meeting of the above Association (the last of the session) was held at the Royal Institution, on Thursday, April 26, 1883, the President, Mr. Councillor Woodcock, in the chair.

The minutes of the last meeting were read and, with some corrections, confirmed.

The following donations were announced:—The *Pharmaceutical Journal*, from the Society; the *Canadian Pharmaceutical Journal*, from the Editor; and 'Suggestions for Students' Classes,' by Mr. H. B. Bare.

At the request of a member, the Chairman submitted the following question to the meeting:—"How can a stannic salt be detected qualitatively in the presence of a stannous?"

To this Mr. Davies replied that he found that nitrate of ammonium admirably answered this purpose, as it precipitated the stannic but not the stannous salt.

Dr. Symes presented a specimen of green ginger, or rather undried ginger, to the Association and made some remarks respecting it.

A discussion upon this subject took place in which several gentlemen took part.

Mr. Mason asked whether Mr. Davies or any other member could give the Association any information as to whether the effects of an explosion were produced equally in all directions or whether the lines of destruction were somewhat erratic. The question was raised in his mind by the effect produced by exploding a match under the foot.

Mr. Davies thought that the gases, except when diverted from their original direction by intervening objects, followed a tolerably regular course, although he would not say that they exerted their influence quite equally in all directions from the centre.

Mr. E. Davies, F.C.S., F.I.C., then delivered a short lecture upon—

The Influence of Suspended Matter on the Indications of the Hydrometer.

In a discussion on milk analysis four years ago a distinguished professor said that floating matter in a liquid, whether heavier or lighter, did not affect the specific gravity of the liquid as shown by the hydrometer. The statement was promptly challenged and abandoned; but as I find that it is still commonly believed, I have made some experiments to see if it could be readily demonstrated that suspended matter has an influence, and if, in fact, the specific gravity, as shown by the specific gravity bottle and by the hydrometer, was the same under these circumstances.

I found that the latter subject was undertaken by Mr. Siebold, in a short communication to the *Analyst*, in 1879, and therefore the quantitative experiments need not be repeated. He showed that precisely the same specific gravity is shown by the hydrometer or by weighing when calcium carbonate or magnesia was suspended in gum water.

My intention to-night is simply to demonstrate that suspended matter exerts an appreciable influence.

At first sight it would appear that suspended matter should have no influence. It forms no part of the liquid and does not break the continuity of the liquid. If the suspended matter has the same specific gravity as the liquid it will not affect the hydrometer at all, and as most suspended matter has the same or nearly the same specific gravity as the liquid in which it floats, the question does not often arise. On consideration it will be seen that if suspended matter is diffused evenly an influence must be exerted, the greater as the difference between the specific gravity of the liquid and that of the suspended matter is greater. For the reason that a hydrometer floats at any given mark is, that the part of the hydrometer which is immersed exactly displaces a bulk of liquid equal in weight to that of the entire hydrometer. That is, each cubic inch immersed displaces a cubic inch of liquid, and that cubic inch of liquid of course included the solid matter floating in it, and the weight of that cubic inch of liquid was the weight of the fluid and solid matters in that cubic inch taken together. It would be so if the solid matter were dissolved; it is equally so when it is merely suspended.

This is true whether the floating matter is lighter or heavier than the liquid. Hence skim milk is denser than fresh, both by the hydrometer and specific gravity bottle. The fat globules displace an equal bulk of the heavier milk, so that a smaller weight being contained in a given bulk a greater bulk of the hydrometer must be immersed in new milk than in skim.

The illustrations were:—First. A hydrometer was floated in pure water. Calcium carbonate was then diffused in the water and the hydrometer now had its stem entirely out of the liquid. Second. A small figure of glass weighted so as just to remain at the bottom of a vessel of water, rose to the surface when powdered glass was sprinkled into the water. Third. Gum water, of density 1·025, was rubbed with a little oil to make an imperfect emulsion; it now showed a density of 1·012.

An experiment previously made with starch showed that $2\frac{1}{2}$ per cent. of starch in suspension in water raised the specific gravity to 1·010. An equal quantity of starch boiled with water and made to the same bulk gave precisely the same density.

This most interesting and valuable communication was illustrated by striking experiments, and was followed by a number of questions, to which Mr. Davies replied.

A hearty and unanimous vote of thanks was passed to Mr. Davies.

The President then read his—

VALEDICTORY ADDRESS.

It is an old and, like many such, a good custom for the person whom you have raised to the highest dignity attainable in our Association—the Presidential chair—to address, on the occasion of the last meeting of the season, some simple words of thanks for the ready and acceptable help he has received during the closing session; for the kind forbearance with which you have glossed over his many shortcomings; and, above all, for the valuable and instructive essays with which you have, often at great personal inconvenience, maintained the interest of the meetings, and the high character of this Association, during the winter that has gone.

It is especially difficult for myself adequately to express the deep sense of obligation, under which I rest, for the courteous and sympathizing kindness I have experienced from you during the period of severe illness that has, most unfortunately, interfered much with my fit performance of the duties appertaining to this high office. I am glad, however, that on all those occasions, during which I was unable to preside, you have secured for chairmen, former presidents who combine experience of the requirements of the position with a higher degree of efficiency than I could possibly lay claim to.

Since I had the honour, in my inaugural address in October last, of delivering a dissertation upon the pharmaceutical "events" of the year, the Council of the Society, which exercises jurisdiction in this country upon matters affecting the welfare of the profession, has drawn up and sent to Her Majesty's Privy Council, the draft of a Bill intended, by amending the faulty Act of 1868, to abolish some existing abuses, and make an onward stride in the direction of that pharmaceutical progress, which is now, as it was in the days of Jacob Bell—of glorious memory!—the keystone and watchword of British pharmacy.

The various provisions of the draft Bill have received full and ample discussion in other quarters, and it is unnecessary for me in this short valedictory address to criticize, or even describe, the character of its provisions. There is one of the clauses, however, of which, whilst willing for the general good to sink all petty differences of opinion, I must express my deep regret at seeing included. I allude to that second clause, which has received so much disapproving criticism from pharmacists in all parts of the country. The Editor of the *Pharmaceutical Journal*, writing last Saturday upon the subject, appears to imagine that misapprehension of the exact purport of the provision lies at the root of this hostile attitude; but I would venture, in all respect to assure him that chemists and druggists are not necessarily babes and sucklings. Dr. Paul asserts, in effect, that as unlicensed persons are at present permitted to retail certain poisons, which the clause in question is intended to affect, it would not be an injustice to pharmacists if some purely formal restrictions were placed upon their sale by persons possessing no knowledge of their properties; and again, that the articles in question are not such as should be entirely intrusted for retail distribution to chemists and druggists. Everybody knows, all pharmacists at any rate, that these poisons are not, and have never been, subjected to any regulations whatever, but our respected Editor forgets that it is the *principle* and not the mere facts to which we take exception; a principle which, in my humble opinion, has been propounded and, to the present time, acted upon from the very foundation of the Pharmaceutical Society. Chemists themselves were first educated; practitioners of medicine were then educated; public opinion was educated; and, finally, Parliament itself had been educated to the belief that *competent knowledge of dangerous drugs is a necessary and important qualification of the person who distributed them to the public*; and now, after forty years of up-hill, though fairly successful labour, we turn round and say, in effect, that it was all a mistake. Qualification is only necessary where grains and drachms, pennyworths and shillingworths are to be dispensed; but where gallons and sovereigns are in question, the sale may be intrusted, without any irksome precautions, to the huckster who defines tinct. camph. co. as "Paddy's got it," and the root of Exogonium Purga as "jollup." But, answer the promoters of the Bill, The Privy Council—Government—refuses to have anything to do with a measure entirely confining the sale of these acids to any class, even although it be a specially educated class. Well, what then? Our duty, as qualified pharmacists, lies very clear. Before stating what that duty is, it will be necessary for us to consider what is the *cause* of the present agitation for another Poison Bill. It is not nitric acid, nor sulphuric, nor hydrochloric, nor even carbolic acid that has raised this cry. *It is entirely the traffic in quack remedies.* Not a word has been said in Parliament, nor even, I believe, in the public press about these acids; it is only the unrestricted sale of scheduled poisons, under the protection of a Government stamp, that has excited the indignant demands for reform from, for instance, the member for Bridport. This brings us to our duty as pharmacists. Government has declared that restrictions must not be placed on these poisons. Very well; the responsibility does not rest with us; our conscience is clear. Draw up a Bill imposing all sorts of restrictions on the sale of these so-called "patent medicines;" include the various other proposals that are contained in the present draft; but do not make any mention whatever of poisonous articles or their regulation. If a lay Government, knowing little or nothing about poisons or their sale, feels sufficient confidence in its own abilities to undertake the task of legislating in that direction, it is welcome to try. Ministers may add the clause; but pharmacists, necessarily knowing far more about the subject than even eminent statesmen, should firmly and decidedly refuse to have anything to do with the proposal. It has been well said that if this Bill becomes an Act, the last poison has been added to part 2 of the present schedule. More; I should not be at all surprised if Parliament amalgamated *that* list with the newly proposed schedule of "Poisonous" articles; oxalic acid, for instance, having quite as large a general and, I may say, unpharmaceutical sale as carbolic.

With regard to the second opinion I have quoted from the editorial remarks in the Journal of last Saturday, there need very little be said. If carbolic and the other acids do not pertain to the proper sphere of pharmacy, neither do potassic cyanide (largely employed by workers in the noble metals), arsenic and corrosive sublimate (both used extensively in taxidermy), or that oxalic acid to which I have just referred. We must, in fact, cease talking about what *should properly* pertain to pharmacy, and think of what *does* belong to it, in England at present.

On this clause I have felt obliged to express freely my dissent from the view taken by our lawfully constituted legislators; but with all the remaining provisions of the draft Bill I am glad to say I heartily agree. I am sorry that the *Chemist and Druggist*, a journal which possesses a large amount of influence, should persist in the policy it has ever adopted of promoting disunion in the pharmaceutical body. Opposition to the Pharmaceutical Society, and above all to the Council of that Society, plainly lies at the root of the captious and irritating manner in which it refers to the "Bloomsbury Clauses" of this Bill. With all due respect to the Editor of the *Chemist and Druggist*, I would assure him that most of the old and nearly all of the new class of pharmacists consider these identical "Bloomsbury clauses" as, at least, equally important with any other portion of the Bill. Their aim—their noble and praiseworthy aim—is *union*, the consolidation of the whole heterogeneous collection of practitioners of pharmacy into a united body, holding the same title of "pharmaceutical chemist," and, it is to be hoped, by some future arrangement, of "Member of the Pharmaceutical Society." For until the two are invariably united, we shall never be able to exercise that powerful influence our numbers and educational standing should command.

At this late hour, and after hearing the interesting paper with which Mr. Davies has favoured us, it would be unthoughtful on my part to detain you longer. I wish, however, to offer my sincere thanks to all the officers, members and associates who have so kindly contributed to the general success of our meetings by their presence and support; to the Vice-President, and other gentlemen, for the courtesy they have shown in occupying the chair during my absence; and last, though by no means least, to Messrs. Haddock, A. C. Abraham, Brown, Davies, Conroy, Farmer, A. H. Samuel, Cariss, Symes and A. H. Mason for the capital papers they have provided for our instruction during the session.

A vote of thanks, moved by Mr. T. Fell Abraham, seconded by Dr. Symes, to Mr. Woodcock for his very interesting address, was put to the meeting by Mr. A. H. Mason, who said that it was his privilege as Vice-President to put that motion and that he would at the same time propose that Mr. Woodcock be unanimously re-elected.

Mr. Woodcock, however objected to this, saying that the election must be by ballot, and, at the same time, asking that no members would vote for him as he could not possibly accept the honour again; his health would not permit of his giving more time to such work than he was called upon to devote to the proper performance of his many other public duties.

Several members having urged Mr. Woodcock, without effect, to re-consider his decision, a ballot was taken. The votes were found to have been given in equal numbers for Messrs. E. Davies and Joseph Woodcock. The latter, however, as President, gave his casting vote for Mr. Davies, who was declared duly elected.

Mr. Davies expressed his thanks for the honour that had been conferred upon him, which, however, placed him in an awkward position, his other duties and the state of his health combining to render him anxious for rest, whilst he was, on the other hand, desirous of doing everything in his power to further the interests of the Association.

The proceedings then terminated.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The twelfth meeting of the session, being the annual business meeting, was held on Thursday, April 12, in the Rooms of the North British Branch, Mr. Peter Boa, President, in the chair.

The minutes of last meeting having been read and confirmed, the Treasurer read the Financial Statement, after which the Secretary read the Annual Report.

The Report commenced with a reference to the highly satisfactory state of the finances of the Association. The income from annual subscriptions last year showed an increase of £1 18*s.* 10*d.* over the previous session; and this year there was a further increase of £1 8*s.* 6*d.* The Association therefore continued to make steady and satisfactory progress. The new scheme of apprentices' prizes, the open meetings, etc., have led to a considerable increase in the expenditure, but notwithstanding this the Committee have been enabled to carry forward a balance of £10 14*s.* 4½*d.* The Committee then drew attention to the gratifying increase in the membership of the Association, which had not been due so much to any special effort on the part of the executive, as to an extended interest in and appreciation of such an Association on the part of assistants and apprentices. In the previous year the membership had shown an increase of thirteen over the previous session; this year there was a further increase of fourteen. The membership last year was fifty-eight and this year seventy-two. The arrangement for having fortnightly instead of monthly meetings had been successfully continued during the present session, all the papers being contributed by members of the Association. As an evidence of the growing importance of the Association the Committee mention, that at the opening meeting of the present session the members had been honoured with the presence and cordial expressions of goodwill of the President and three prominent members of the Council of the North British Branch. Two open meetings had been held during the session; one in November and the other in January. Both were largely attended and seemed to be highly appreciated by the members generally. The attendance during the session again compared very favourably with the previous ones. One of the most important changes during the present session had been the institution of the new scheme of apprentices' prizes, which was unanimously resolved upon at a special meeting of the Association, held on May 18, 1882, and the Committee congratulated the Association on the success which attended the carrying out of the scheme. The examination papers were of a very high order. The Committee next recommended that the sum of one guinea be devoted, as formerly, to the Benevolent Fund of the Pharmaceutical Society. It also recorded its high appreciation of the important and valuable assistance invariably received from the Secretary to the North British Branch.

On the motion of Mr. A. L. Fraser, seconded by Mr. J. Low, the Financial Statement and Report, together with the recommendations, were unanimously adopted, and on the motion of Mr. J. B. Robertson, seconded by Mr. MacEwan, a vote of thanks to the retiring office bearers and Committee was heartily accorded.

The office bearers and Committee for next session were then elected as follows:—President, Mr. Claude F. Henry; Vice-President, Mr. W. S. Turnbull; Secretary, Mr. S. G. Crowden; Assistant Secretary, Mr. William Pirie; Treasurer, Mr. W. S. Adamson, and as members of Committee, Messrs. Duncan, Dunlop, Forret, Fowler, Fraser, Hendry, Robbie and Stephenson. An Apprentices' Prize Committee was also appointed, consisting of the President, Vice-President, Secretary, and Messrs. Boa, Hill and MacEwan.

The remaining business having been disposed of, the meeting was closed.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 3, Dr. W. H. Perkin, F.R.S., President, in the chair

The following certificates were read for the first time:—

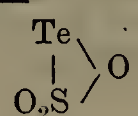
G. S. Bowler, A. Esilman, C. T. Heycock, H. Heap, W. J. Livingstone.

The Secretary then read a paper from Japan—

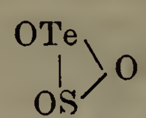
On a New Oxide of Tellurium. By E. DIVERS and M. SHIMOSÉ.—When the compound of sulphur trioxide and tellurium, SO_3Te, which was prepared almost simultaneously by R. Weber and the authors of the present paper, is heated *in vacuo*, it decomposes between 180° and 230°, evolving sulphur dioxide, and forming a new oxide of tellurium, TeO. This oxide can be prepared in small quantity by the action of water on the sulphoxide. The oxide is black in colour with a slight brown shade and shows, when pressed with a hard body, a graphitic lustre; it is quite stable in dry air at ordinary temperature. Potassium hydrate has but little action upon this substance, but it is readily decomposed by acids. No compound of TeO could be obtained; but the authors have specially compared this substance with a mixture of tellurium and tellurium dioxide and find that its behaviour with chemical reagents is quite distinct from the reactions of the mixture.

Two papers by the same authors were also read—

On Tellurium Sulphide.—The authors state that they had discovered this body before the arrival of the *Berichte* and the *Journal of the Chemical Society* which contained R. Weber's account of its formation. Their results are not, in some respects, quite in accord with those obtained by the above chemist. The tellurium was obtained from the mud in the lead chambers of the Imperial Japanese sulphuric acid works in Osaka. The liquid sulphur trioxide was poured on to the tellurium, both substances being contained in a sealed glass tube. The sulphur trioxide adhering to the sulphoxide was removed by heating the latter to 35° and exhausting with a Sprengel pump; a long tube packed with borax being interposed to absorb the trioxide. The sulphoxide is a red amorphous solid which softens without melting about 30°. It is vesicular in structure and, when pure, is quite stable, at ordinary temperatures, in sealed tubes. Details of its analysis are given. When this sulphoxide is heated to 90° in a vacuum its colour changes to a bright fawn colour, no gas is evolved, and its composition remains unaltered. The authors suggest for the red variety the cosnstitution—



and for the brown—



Similar modifications of selenium sulphoxide seem to exist.

On a New Reaction of Tellurium Compounds.—Sulphuric acid dissolves only small quantities of tellurium dioxide or its sulphate, but this solution furnishes a most delicate reaction for the presence of tellurium. By pouring some of it into a hydrogen apparatus containing zinc and dilute sulphuric acid and passing the escaping hydrogen telluride through a second portion of the telluretted sulphuric acid, the red colour of tellurium sulphoxide is rapidly developed in the previously colourless liquid.

$$2TeH_2 + TeO_2 + 3H_2SO_4 = 3SO_3Te + 5H_2O.$$

Dr. Williamson was strongly impressed with the care shown by the authors in this research and with the value of their results; the existence of this protoxide raised some interesting points bearing on theoretical questions. In the first place the evidence adduced by the authors of the difference between this oxide and a mixture of tellurium and dioxide seemed to him decisive in establishing its existence, but it was curious that the authors could not prepare any corresponding compound. Now, although it has generally been required that an oxide should have its corresponding chloride, etc., as a guarantee of its existence, yet it seemed that there was no reason why an oxide should not exist without a corresponding chloride, so that the non-discovery of the chloride must not be taken as a proof that the oxide did not exist.

The Secretary then read a paper—

On a Simple Modification of the Ordinary Method for Effecting the Combustion of Volatile Liquids in Glaser's Furnace with the Open Tube. By WATSON SMITH.—The author having observed that some of the students in the Chemical Laboratory of the Owens College were not able to make presentable analyses of a sample of chemically pure benzene when using Glaser's furnace, etc., devised this modification. The end of the combustion tube containing the liquid in a bulb is made to project from the furnace, beyond the liquid is inserted a plug of oxidized copper. This plug is warmed by a Bunsen burner, and thus the gas current is heated sufficiently to volatilize the liquid slowly and regularly. Two analyses of benzene and absolute ether are given, the results closely approximate to the theoretical numbers.

Mr. G. BEILBY then read a paper—

On the Production of Ammonia from the Nitrogen of Minerals.—In the present paper the author, who has worked at the distillation of coals and shales in connection with William Young for some years, gives the results obtained by distilling two shales, one a typical oil shale from Midlothian, the second a coal shale from Ayrshire. These shales were distilled (1) by the usual process of distilling at a low red heat; (2) at a low red heat in a current of steam; (3) at a low red heat in a current of steam, the residual coke being afterwards subjected to the prolonged action of steam at such a temperature that the whole or a large part of the carbon being consumed by the steam, the nitrogen is liberated as ammonia. The soda lime process was used for the determination of the nitrogen. The results are given in pounds of N per ton. No. 1 shale gave with the first process 2·70 pounds of N as NH_3 in the watery distillate and 1·20 pounds in the coke. The nitrogen combined with carbon amounted to 8·88 pounds in the coke. By using the second process, all the ammonia in the coke came over in the distillate, and 3·9 pounds of N as NH_3 were found in the watery distillate, the N combined with carbon remaining untouched. In the third process, however, the N as NH_3 in the watery distillate amounted to 12·0 pounds; the N combined amounted to only 0·78 pounds. Similar results were obtained with No. 2 shale. In the third process the carbon, steam and temperature should be so adjusted that the reaction is $C + 2H_2O = CO_2 + 2H_2$.

Mr. BEILBY also read a short paper—

On the Specific Gravity of Paraffin Wax, Solid, Liquid, and in Solution.—The specimen melted at 38° C. Its specific gravity solid at 21° C. was 0·874; when dissolved at 21° in heavy paraffin oil, 0·7956. By taking the specific gravity of fused samples at various temperatures and continuing the curve thus obtained, the specific gravity of fused paraffin at 21° would be ·796.

In reply to Dr. Armstrong the author stated that the above improved process (No. 3) of distillation was very successful commercially, the results being startling. In one case a coal shale which furnished only 18 pounds of ammonium sulphate per ton, now yielded from 75 to 98 pounds. The whole of the nitrogen could not be economically obtained; much difficulty was met with in the fusion of the ash. If the coke was valuable no one would dream of burning it away; the process was particularly useful with small and bad coal.

The Society then adjourned to May 17, when Captain Abney will deliver a lecture on "Photographic Action Studied Spectroscopically."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, April 26. Mr. R. H. Parker, Vice-President, in the chair.

Mr. T. S. Dymond read a paper upon the "Synthesis of Uric Acid."

The author gave an account of the synthesis of uric acid which had recently been made by Horbaczewski from glycocol and urea. Horbaczewski stated that when these substances were heated together to a temperature of 230° C. uric acid resulted, but had not in any way explained the nature of the decomposition which occurred. Mr. Dymond had made two experiments, closely following the directions given by Horbaczewski, but had failed to obtain any evidence of the formation of uric acid; but he was still working upon the subject, and hoped to communicate his results to the Association at a future meeting. In the meanwhile, the above experiments must not in any way be taken to indicate that uric acid is not formed in the above reaction, but only that the directions given by Horbaczewski are evidently insufficient. The paper included a detailed account of previous work, showing the constitution of glycocol, hippuric and uric acids, specimens prepared by the author being exhibited.

A discussion followed the reading of the paper, in which the Chairman, Secretary, and other members took part.

A vote of thanks was passed to Mr. Dymond.

Mr. R. A. Cripps read a paper upon the "United States Pharmacopœia Process for the Estimation of Hydrocyanic Acid," which is printed upon page 917. In the discussion that followed, the Chairman, Secretary, Dr. Senier and Messrs. Greenish, Short and Taylor took part.

A vote of thanks was passed to Mr. Cripps.

The Reporter upon Pharmacology, Mr. H. G. Greenish, then made a Report upon "Convallaria majalis," which will be published in a future number of this Journal. A discussion followed the reading of the Report, in which the Chairman, Secretary, Dr. Senier and Messrs. Corder, Cripps, Crow, Elworthy, Hamilton and Ranken took part.

After the discussion had concluded,

The Chairman said that he had an announcement to make which he knew would be heard with extreme regret by all present, the death of their former Vice-President and Reporter, Mr. Charles Herbert Hutchinson. Mr. Parker had known Mr. Hutchinson since his student days at the School of Pharmacy, when they worked next to each other in the laboratories, and felt very much grieved at his premature death.

Dr. Senier then moved the following resolution:—"That the School of Pharmacy Students' Association hears with deep sorrow of the death of Mr. Charles Herbert Hutchinson, in whom the Association loses a former Vice-President and one of its most active and distinguished members, and that the members of the Association take this opportunity of expressing their sincere sympathy with the relatives of their late fellow worker."

Dr. Senier in moving the above resolution spoke in high terms of Mr. Hutchinson, whom he had known and admired since Mr. Hutchinson first became a student under him in the laboratories of the Pharmaceutical Society.

The Secretary (Mr. Dunstan), in seconding the resolution, referred to his high regard for Mr. Hutchinson's scientific and personal worth, and specially dwelt upon Mr. Hutchinson's connection with and exertions for the Association.

The resolution was supported with the same feeling by Messrs. A. J. G. Lowe, H. G. Greenish and F. W. Short, and upon being put to the meeting was carried unanimously.

The meeting then adjourned.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Professors and the Pharmacopœia.

Sir,—It appears from the report of the last Council meeting, as published in your Journal, that some remarks were made relating to our position in connection with the Pharmacopœia, which we think are not justified by the facts of the case; and as the general tendency of the discussion is calculated, through its publication, to create a prejudice to our serious injury, we beg to offer the following brief statement in reply.

The appointment of editor or editors is a preliminary step required to be taken by those who are responsible for the production of a work such as the Pharmacopœia, in the compilation of which information has to be obtained from many sources. One of us has occupied the position of editor in connection with the present Pharmacopœia, its additions and reprints, for the last eighteen years, during which time nothing has ever been said to indicate that he had done wrong in accepting or retaining the office. On the present occasion when applied to with a view to the renewal of similar duties, seeing that there would be a large amount of new work to be performed, he wished to be relieved of part of the duties of the office, and, with that object, preferred to be associated with his colleagues in Bloomsbury Square rather than with any other persons. This arrangement was suggested and discussed in the latter part of last year, at which time the Medical Bill had not made its appearance, nor had any special attempt been made by the Pharmaceutical Council to obtain an alteration of the law which assigns to the Medical Council the duty of causing new editions of the Pharmacopœia to be published, when required, under their direction.

When application was made last August by the Sub-Committee of the Medical Council to their former editor for a renewal of his services, he suggested that a committee appointed by the Pharmaceutical Society would be of great assistance to the editors in collecting and preparing matter for the new edition, but he was informed that arrangements of that description must have the sanction of the Medical Council, which would not meet for several months. It was clearly understood, however, that medical and pharmaceutical authorities throughout the country would be invited to co-operate, as was done in producing previous editions of the work, with the view of making this edition as complete and perfect as possible.

We received our provisional appointments on the 12th of last January, but we were not at liberty to make public the arrangements then made, partly because they were only provisional, and partly because it was contemplated and thought desirable that the arrangements when confirmed by the Medical Council should be communicated by *that* body to the Council of the Pharmaceutical Society, together with the invitation for their co-operation in the work.

We regret that the announcement of the arrangements when completed have not yet been made by the Medical Council in the way that was anticipated, but we most emphatically deny that there has been any ground for the imputations made to our disparagement, nor do we consider that the interests of the Pharmaceutical Society have suffered or are likely to suffer from our action in this matter.

T. Redwood.
Robert Bentley.
John Attfield.

Sir,—I write to express my indignation with the action of the Professors in engaging themselves in the work of such a very important matter as a revision of the Pharmacopœia without consulting the Council.

Men of "light and leading" amongst pharmacists have been striving for a considerable period to have their claim to a share in the production of the national Pharmacopœia acknowledged, and that such action should have been taken by the Professors just when the goal was well in sight, suddenly placing the prospect under a blacker cloud than ever, is a very disheartening fact.

The question remains, What is to be done? At any rate I hope that the false steps already taken will be retrieved, as far as possible, by prompt action on the part of the Council.

Perhaps thorough discussion of the subject would discover a loop-hole from which to escape from the present embarrassing situation.

The Pharmacy, E. Bridges Walton, Ph.C.
Richmond, Yorks.

Pharmacopœia Revision.

Sir,—In last week's article on Pharmacopœia revision, you refer to a proposed recognition of the fact, that absolute purity in chemicals is not attainable. It is, however, to be hoped that, whilst being protected from the excessive zeal of a too officious analyst, we may not be deprived of some standard to guide us in the examination of our drugs and chemicals.

As the tests of purity at present stand, it is impossible for anyone, however anxious, to get chemicals in all cases up to the British Pharmacopœia standard.

For example, under "Carbonate of Bismuth" we are told that when it is "added to sulphuric acid coloured with sulphate of indigo, the colour of the latter is not discharged." Can such carbonate of bismuth be prepared by the official process? I have not been able to find any such, the best out of several samples discharging the colour from ten times its weight of B.P. solution of sulphate of indigo.

Likewise under "Precipitated Carbonate of Lime," it is stated, that when dissolved in nitric acid, it produces no precipitate with nitrate of silver. But precipitated carbonate of lime, for which the best price is paid, generally contains from 0·1 to 0·4 per cent. of chlorides, and of course yields a very distinct precipitate when treated as described.

If, as in the above cases, traces of impurities are unavoidable, then recognize the fact and fix definitely the limit of such impurity.

Purified animal charcoal, we are informed, leaves on ignition "only a slight residue." Would it not be much better to state how much, say 5 or 7 per cent.? On examining a sample of this substance lately purchased, I found it left 74 per cent. ash, and returned it to the makers, stating it was "unpurified," and received in return another lot just as bad. Is 74 per cent. a slight residue?

By all means let us have a standard as high as is practically attainable, but let it be one that we may expect the manufacturers to adopt.

St. John's Wood. W. H. Symons.

The Draft Pharmacy Bill.

Sir,—The notice of motion which Mr. Sandford proposes submitting to the Annual Meeting is, I think, most desirable, but in order that the general feeling of the trade may be more fully represented than is possible at such meetings, would you allow me to suggest, through your pages, the desirability of provincial associations at once bringing the subject before their local members, and by resolution or otherwise forwarding an expression of opinion thereon to the President?

Belgrave House, West Brighton. Edwin B. Vizer.

Nigella sativa.

Sir,—The "Month" of April 28 contains a summary, in a few lines, of a recent investigation of the seeds of *Nigella sativa* by Pellacani. As these seeds have been the subject of more than one communication by myself to the *Pharmaceutical Journal*, I may be allowed to make a few observations on a point of some importance in Pellacani's research.

In the course of his paper the author alludes to the beautifully fluorescent solution yielded by the seeds and the steps taken to isolate the fluorescent substance itself.

Some time ago I drew attention in the columns of this Journal (vol. xii., p. 681) to the extensive substitution, especially in Germany, of the seeds of *Nigella damascena* for those of *N. sativa*. Amongst other characters of the former I especially noted the peculiarity that all the samples at my disposal yielded fluorescent solutions, and I stated that this was not the case with any sample of *N. sativa* I had examined.

It is, therefore, I think, more than probable that Pellacani's seeds were not those of *N. sativa* at all, but consisted, entirely or principally, of *N. damascena*. The latter may be recognized by their rounded form, the transverse furrows, and the fragrant odour of strawberries they exhale when crushed. Whether the seeds to which Dr. Canolle referred in the *Journal de Medicine*, Feb., 1882 (a paper, by the way, that I have been unable to trace) were identical with those examined by Pellacani still remains to be shown. And the latter will, I fear, have made but a slight addition to our knowledge unless he can satisfy us of the origin and freedom from impurity of the seeds he has worked upon.

H. G. Greenish.

Salicylic Acid for Corns.

Sir,—For nearly twelve months past I have made and used a mixture, similar to that described on p. 884 of the Journal, as a remedy for corns. I soon found it dvantageous to employ a certain proportion of flexile ollodion, and also to make the relation of the alcohol to ether somewhat higher, in order to obtain a satisfactory, adherent, and permanent film. Care, too, is requisite in making the mixture, or gelatinization ensues, in which condition the application is neither so easy to use nor so efficacious.

South Norwood, S.E. J. H. Baldock.

Syrup of the Phosphates and Potassium Chlorate.

Sir,—A conclusion one might draw from the letter of one of your correspondents is that potassium chlorate would have no reaction on a compound syrup of phosphates carefully prepared with pure phosphoric acid and free from HCl. I think, however, the following data will show that a reaction, quite as remarkable in another way as the one which has been under discussion, does take place.

A sample was prepared in the proportion mentioned by Mr. Prosser and allowed to stand four days; shortly after mixing, turbidity ensued, and at the end of the time mentioned a distinct precipitate had formed while the colour had gradually lightened. The precipitate collected on a filter and washed was found to consist of the phosphates of iron and calcium; the filtrate contained the phosphates of sodium and potassium with a trace of calcium and the colouring matter.

The reaction would probably be as follows:—

$$2\,KClO_3 + H_3PO_4 = K_2HPO_4 + 2\,HClO_3$$

The free phosphoric acid by which the phosphates were held in solution being decomposed, the insoluble phosphates of iron and calcium would be precipitated, the soluble ones of potassium and sodium remaining in solution; the action of the chloric acid formed being to gradually oxidize the colouring matter.

30, *Weston Road, Hove.* Ernest F. Salmon.

Royal Naval Reserve Dispensing.

Sir,—Could any reader of the Journal state whether it is usual for the Admiralty and other governmental branches to hand over their dispensing to medical men? The reason I ask is this. In our locality there is a Naval Reserve and Coast Guard station, and during the course of each year a considerable amount of medicine is consumed by the men on drill. This, however, is all supplied by the medical man who prescribes it, who is an M.D., and one of that, alas! numerous family of M.D.'s who consider it madness to send a recipe to a druggist.

We enquired at the Director-General, Admiralty, for the conditions on which the dispensing was undertaken, and asked, as registered dispensers, to be allowed to offer, but we were informed that the Director-General must "decline" to deprive the medical man of the dispensing.

Now, sir, here is a grievance, and in our opinion a very glaring one. If the executive of H.M.'s Government encourages dispensing by medical men, who, we may ask, will discourage it?

We trust you will give this note a place in the columns of the *Pharmaceutical Journal*, with the view of eliciting any suggestions and shedding some light on the subject.

Quærens.

D. B. Shearer.—See the *Pharm. Journ.* for Dec. 23 last, p. 510.

E. P. Reid.—We are unable to comply with your request.

W. B. Jevons.—Hardwich's 'Manual of Photographic Chemistry,' the ninth edition of which has been published recently by Messrs. Churchill.

Junior.—(1) Dip the bottles into warm water for about a minute after the pomade has cooled. (2) A colouring may be made by digesting gamboge in olive oil.

J. Knight.—The following is quoted in Cooley's Cyclopædia:—Blanched almonds, 2 oz.; rose water, 8 oz.; orange-flower water, 2 oz. Make an emulsion, strain, and add sal ammoniac., 1 dr.; simple tincture of benzoin, 2 dr.

B. J. Kent.—The prescription is probably a German one, and the artificial Carlsbad salt ordered is official in the German Pharmacopœia. A formula will be found in the present volume of this Journal, before, p. 26.

S. H.—The Pharmacopœia is the final authority upon the point in question.

Communications, Letters, etc., have been received from Messrs. Kingzett, Howard, Alcock, Presley, Rhei.

SOME FACTS CONCERNING FILTRATION.

BY CHARLES SYMES.*

The process of percolation has engaged so much attention of late years that it is not surprising to find the less important although kindred one, filtration, somewhat neglected. It may be thought that all has been accomplished that could reasonably be desired for rendering this operation as complete as it can be, or that it is too simple to merit much consideration. Be this as it may, practical pharmacists know quite well that they are not unfrequently troubled to conduct it to their entire satisfaction.

The more serious difficulties connected therewith do not perhaps occur to each individual very often, hence the danger that the experience gained on one occasion is overlooked or not made available when circumstances again arise for its application.

The subject seems naturally to divide itself under three heads, viz.:—The liquid to be filtered, the medium through which it is to pass, and the form in which that medium is presented. As it is not intended, however, to make these notes exhaustive, it will be unnecessary to deal with it in precisely this order. Let us rather take some facts as they occur and see if we can by their consideration render available anything of practical value for every-day use.

The most simple operation of this kind is to filter through paper in small quantity a liquid containing a solid body for which it has no affinity.

Text-books tell us at the outset that it is very necessary to use a funnel the sides of which form an angle of 60°, this being the angle formed by the folded paper. Now I take exception to this very exacting requirement. We do not get our straining bags or percolators made of such a shape, and that because our experience teaches us how much more suitable is a form in which the angle is decidedly more acute; the same volume of liquid in this latter form producing a longer column, and consequently a greater downward pressure. Then, as to the paper fitting the funnel; we know quite well that all else being equal, the less perfectly it fits, the more rapidly filtration proceeds, so that, for any useful purpose it is quite unnecessary to insist on this very orthodox shape. One has, say, a pint of fluid to filter, and for this purpose a funnel of about 8 ozs. or 10 ozs. capacity is taken. I would use one of the long French pattern, fold the filter in plaits and before opening it out, place it fairly well down in its position in the funnel; or if there were reasons for not plaiting the filter, then it should be folded first in half, and then the two outer portions, representing rather more than one-eighth each of the entire paper, should be turned back so as to overlap each other slightly at the top, and not to form a very acute point. In either case, the paper whilst being fairly well supported would have comparatively little surface adhesion and but small resistance would be offered to the passage of the fluid in any part. Funnels of this shape in much larger sizes can be used with advantage, but it is then desirable to have them ribbed. The ribs of funnels (especially of large ones) to be of any real value should be much deeper than they usually are, and should not run vertically, but spirally. A piece of muslin placed between the paper and funnel not only strengthens and supports the paper, but assists filtration by preventing adhesion; a cone formed of coarse hair cloth is still better. For larger sizes, say of from 4 to 8 pints, it is advantageous to dispense with the funnel altogether, and to use an inverted cone formed of linen or stout calico; the edges being fastened to a wooden hoop, which, resting on a deep earthenware pan, forms an efficient support for the paper, the liquid passing through with equal facility over the entire surface, a suitable cover placed over it excluding the air, and the process goes on under comparatively satisfactory conditions. A self-feeding arrangement can be fitted to this, if it be so desired, in a very simple manner.

When, by exhausting the receiver, atmospheric pressure is brought to bear on the liquid in a funnel, then the latter should be of the *orthodox* shape, as with it air is less likely to pass; but this requirement militates against the advantages that such a method would otherwise possess. The point of the filter should be supported by a cone of platinum or zinc, or by a packing of tow or prepared wool.

English paper makers do not appear to have devoted much attention to the production of filters in any variety, and for this reason we derive our supplies chiefly from the continent. It is a well-known fact that holding almost any of the common filters up before a strong light they are seen to be perforated more or less with minute pinholes, so that when in use it is only after these have become filled up that the whole of the solid matter is separated, and the liquid passes through bright. Each time a fresh portion of liquid is added, the disturbance caused thereby is liable to remove some of the particles which are acting as a filling, and if this occurs filtration again becomes imperfect. These filters, although very cheap, do not pay to use if time and convenience are taken into consideration. There is, however, considerable difference in the efficiency of the various kinds of filtering papers, even when free from this defect. The presence of animal matter, as in the grey filter, increases the strength, but diminishes its working capabilities, and the existence of mineral matters therein does the latter but not the former. The papers specially prepared by Messrs. Schleicher and Schüll are practically free from all extraneous matters, the pulp having been treated with hydrochloric and hydrofluoric acids, etc. They are an example of what can be accomplished in this respect, but at the same time they are too expensive for general pharmaceutical purposes, and, indeed, are only made in comparatively small sizes suitable for analytical work. For operations requiring filters of 7 inches diameter (before folding), the Rhenish papers, No. 595, are, in my opinion, the most suitable; for larger sizes the French stout plaited or plain papers, taken in all their qualities, give the best results. The French also make a paper specially suitable for syrups, thick to support the weight, and yet sufficiently pervious to allow of fairly rapid filtration. I find, however, in very large sizes, a double sheet of Rhenish paper in an inverted case of linen, as already described, answers even better.

Some fabrics, such as swansdown, close textured twilled calico, etc., filter as brightly as paper does, and may be used for that purpose as distinct from ordinary straining, provided the solid particles separate from the liquid in which they are suspended with ease, but when this is not the case they are of much less value; indeed, with paper as a medium, slimy

* Read before the Liverpool Chemists' Association.

deposits present considerable difficulty. Pepsine wine, prepared from the fresh, undried pepsine, might be regarded as typical of this class of liquids; the tendency being to choke up the pores of the filter almost immediately the operation commences. In such cases some kind of coarse straining material placed within the paper cone helps materially to obviate the difficulty. Hair cloth and thin coarse flannel answer well for this purpose; they operate by collecting on their rough projecting surfaces the larger proportion of the undissolved slimy matter, without becoming sufficiently choked up to materially impede the progress of the operation.

Succus taraxaci, as expressed from the root and mixed with spirit according to the B.P. instructions, is typical of a class containing a large quantity of starchy matter and where subsidence in a closed vessel previous to filtration is of great service. The liquor from poppy capsules, in the process of preparing syrupus papaveris alb., furnishes us with an example of a liquid containing a large quantity of albuminous matter and mucilage which, when coagulated by spirit, has to be filtered off, and here again subsidence in a closed vessel helps the separation materially. The greater portion of the liquor can, after a time, be poured almost bright into the filter, and the remaining soft mass can with care be slowly pressed almost dry; the chief difficulty in this latter operation being to press sufficiently slowly to separate the liquid from the solid, and yet not to expose it to the air long enough to lose much spirit by evaporation, as in that case some of the solid portion would be again taken up in imperfect solution.

For removing suspended particles from strong acids, spun glass, known as 'glass wool,' answers best, but this might be regarded as straining rather than filtration. With ordinary liquids, when there is but little insoluble matter, absorbent cotton not only strains, but by fairly tight packing filters brightly. In cases where it is desired to save the deposit, and possibly to dry or incinerate it, asbestos paper can be recommended; the liquid passes through it slowly, but it is very strong, and it is indestructible by heat. Paper lint, as introduced from America some few years ago, answered well as a filtering medium, being both strong and absorbent; but I am not certain whether its manufacture has been continued.

So far we have considered filtration as conducted only in funnels or funnel-shaped arrangements, as the various forms in which atmospheric pressure is commonly employed are described in works which treat of such matters. They are chiefly those in which a long column of liquid is carried above the point of filtration, as in Mr. Proctor's arrangement; where exhaustion is obtained by means of a syringe underneath; or suction by means of a bent tube, as described by Mr. Schacht at the meeting of the Conference at Birmingham in 1865. Recently there has been advertised a "Filtre Rapide," in which the filtering material is placed on a frame or support rising up within the cylinder and forming a space in the centre into which the filtered liquid flows laterally to a receiver below. It is a compact and ingenious arrangement, but I have not any experience from which to speak of its usefulness.

To my mind upward filtration is the direction in which we should work, and from which we may expect the best results.

Some years ago Mr. William R. Warner, of Philadelphia, invented an oil filter on this principle, consisting of two vessels in superposition, measuring altogether about 40 inches in height by 10 inches in diameter, and which is said to be capable of filtering a barrel of oil per day. This of course would depend on the nature of the oil and the temperature at which it is used.

Recently I have devised a form of upward filter in one vessel only, and have added to it a suction tube. It occupies comparatively little space, is simple in construction, efficient in action, and can be made by any tinman at little cost.

It consists of a plain tin cylindrical vessel (A) with a tap-hole (B) 1½ inch from the bottom; it is 22 inches high and 8 inches diameter. A tin tray (C and fig. 2), 7 inches in diameter, with a vertical rim 1 inch or 1¼ inch deep, has a hole (B′) in the rim; this and the hole near the bottom of the cylinder being fitted with a short

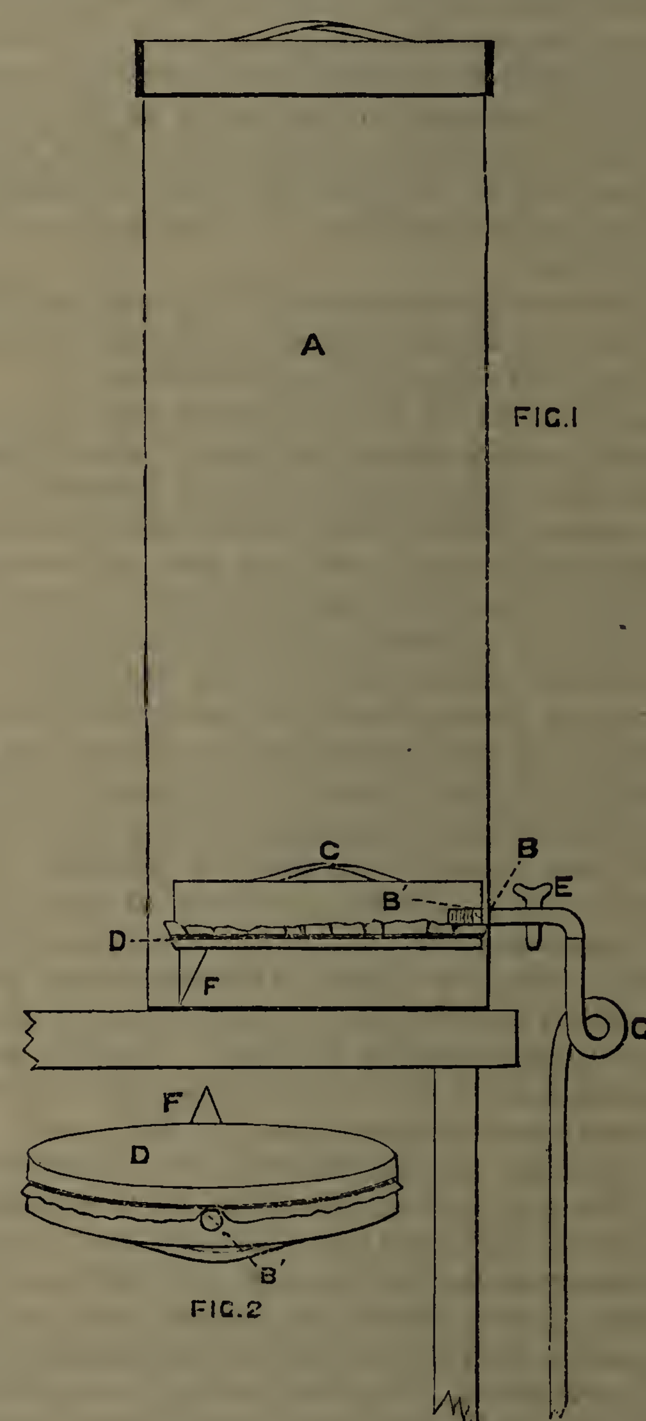


FIG. 1

FIG. 2

female screw of the same pitch of thread. Over the tray the filtering material (D) (flannel, calico, paper supported by muslin, or any other that may be suited to the liquid to be operated on) is tied securely; it is then inverted and placed in the cylinder so that the holes B and B′ are exactly opposite one other. A tap (E) with a bend at a right angle is screwed in so that it holds the two together and assists a short leg (F) in supporting the tray in position. To the end of the tap is attached an india-rubber tube turned on itself (G), or a long glass tube of similar construction (in fact like a large safety funnel deprived of the thistle head), which can be attached by a short piece of rubber tube. It will be obvious that any communication between the tap and the contents of the vessel must be made through the filtering medium which covers the inverted tray and that any deposition which takes place must be on the bottom of the vessel itself or on the opposite side of the tray, but not on the filtering surface, and herein lies the special advantages of the filter I now introduce. The use of a long delivery tube is not new; it formed part of an oil filter patented by Mr. Britten, of Liverpool, some years before Mr. Schacht's application of it to his filter. Neither is upward filtration new, as already stated; but the combination of the two and in this particular form will, I believe, commend itself to anyone who will give it a trial.

The dimensions given furnish a filter of about 3 gallons capacity at a cost of some ten or twelve shillings.

COLOURED INSECT POWDER.

BY W. L. HOWIE, PH.C., F.C.S.

Mr. Conroy has done good service in calling the attention of the trade to the adulteration of insect powder in the paper read before the Liverpool Chemists, Association and published in a recent Journal.* I have been working on the same subject for some time past, and as my experience and results differ from Mr. Conroy's, I think it well, without further delay, to throw my notes into form for publication.

The adulterant mentioned in the report of the Liverpool meeting as having been found by Mr. Conroy is fustic, which is one I have not met with although particularly looked for. I have not yet, however, hit upon a satisfactory method by which one can readily detect small proportions of this substance, as well as other yellow dye stuffs, which I have reason to suspect are used to "reduce" the powder. I have found microscopical examination unreliable, artificially coloured insect powders, to my knowledge, being passed as genuine even by a skilled microscopist, and I have found comparison with test samples prepared by blending various pigments with genuine powder in a mortar very misleading, as little difficulty is then experienced in detecting the specks of the colouring ingredient, but in the commercial powders the pigment is without doubt added during the grinding process, and if well selected, becomes so incorporated with the vegetable tissue as to escape any but an experienced eye, even when aided with the polariscope. I have, therefore, not relied upon the microscope as far as my investigation has proceeded, finding chemical method more exact and trustworthy.

I have examined about twenty samples, none of which was supplied to me specially for examination, but purchased in packets, or obtained as *boná fide* samples offered by wholesale dealers to retailers in the ordinary way of business. With the exception of No. 3 following, all are powders from well-known firms, most of whom claim to be grinders. Selecting twelve as typical, both as to source and general character, I placed them side by side and arranged them according to their depth of yellow colour, with the following result:—

* *See* before, p. 869.

Vendor's Definition.	Colour.	Adulterant.
No.		
1. "Insect Powder" .	Drab . . .	Genuine.
2. " " .	" . . .	"
3.	Olive drab .	"
4. "From closed Flowers" . . .	Yellowish . .	"
5. "All closed Flowers" . . .	" . .	"
6. "Open Flowers" .	" . .	"
7. Packet Powder . .	Yellow . .	Chrome.
8. " " . .	" . .	"
9. "Opt"	" . .	"
10. "All closed Flowers" . . .	" . .	Turmeric and chrome.
11. "Foreign" . . .	" . .	Chrome.
12. "Dalmatian" . .	Very yellow .	Turmeric.

After arranging the powders in this manner by the eye, it was apparent that between the colours of 6 and 7 there was a preceptible gap, and when by testing it was proved that Nos. 7 to 12 were artificially coloured, it will be seen that appearance is some indication of genuineness.

For further examination I discarded the first suggested plan of igniting the powder with potassium nitrate and testing the residue, and prefer what I think a more delicate and easy, if somewhat crude method. Incinerate say 20 grains of the suspected powder on platinum foil and carefully weigh the ash as well as note its character. For example, take No. 3, which had been reduced to powder in a mortar by myself from authenticated flowers. The ash was grey in colour and weighed 1·2 grain. This is placed in a test-tube, and a few drops of strong hydrochloric acid added, which causes some effervescence; heat is then applied to dissolve the ash, which consists chiefly of potash salts. The solution is colourless and the addition of a little water prepares it for the application of the usual tests.

Sulphuretted hydrogen gives no precipitate nor potassium iodide a yellow colour nor precipitate; but it ought to be here noted that ammonium sulphide and potassium ferrocyanide give the characteristic reactions indicating iron, which I found in small quantity in the ash of the genuine flowers, as well as in all the powders. This metal seems to exist in greater abundance in the florets, and in much less proportion in the seeds, and the indications of iron must be noted, as I have found two powders containing it in such quantity as to suggest that some ferruginous earth, such as ochre, had been used to make weight or colour. One of these powders is a proprietary article, and the other a small odd sample, which I cannot replace, therefore neither appears amongst the selected twelve.

The behaviour of a powder coloured with the usual adulterant, viz., yellow chrome, is quite different. The ash is brownish, or showing brown patches at the most exposed parts and the weight is greater; thus No. 7 yielded 2·1 grains. There is the same effervescence with HCl; but part is insoluble and the solution on heating becomes distinctly green, which with a black precipitate with H_2S may be taken as conclusive proof of the presence of lead chromate. KI gives a yellow colour, and if the HCl be not in excess a yellow crystalline precipitate separates.

Any attempt to judge of the amount of added chrome by estimation of the lead present I found futile, which is readily understood when it is remembered that the finer chromes are said to be "struck" on magnesia, and undoubtedly the alkaline earths are found to bulk largely in the composition of many.

No. 12, although of a strikingly deep yellow colour, gave only 1·2 grain of grey ash, and thus suggested that some vegetable colouring had been used, and on the sample being tested by the method devised by myself for the detection of artificial colouring in rhubarb and other powders (*Pharm. Journ.*, [3], vol. iv., 354) the supposition proved to be correct.

Pieces of white blotting paper corresponding to the number of samples are taken and named or numbered, and a few grains of the suspected powder placed in the centre and pressed compactly down with a piece of paper or a spatula. Chloroform (or other menstruum) is then carefully dropped from a pipette on the centre of the powder till it has moistened all and extended some distance beyond the powder. The paper is then allowed to dry, wiped free of the powder, and the stain if any, tested by suitable reagents.

Treated in this manner the genuine powder yields a slight yellow colour to the paper; but No. 12, and in less degree No. 10, gave a very distinct stain, which an atom of boracic acid and a drop of HCl at once identified as due to turmeric. The stain from genuine powder becomes bluish green with nitric acid, brownish with sulphuric, and only exhibits a slight darkening with potash solution. The turmeric stain becomes reddish brown with nitric acid, dark brown with sulphuric acid or potash. Fustic seems to yield nothing to chloroform, but a yellow stain obtained with alcohol becomes a distinct brown with nitric acid and shows little change with sulphuric acid or potash. Solution of a ferric salt strikes a bluish black both with the fustic and pyrethrum stain obtained with alcohol.

When fustic is boiled for some time in water with zinc and sulphuric acid, the solution gradually assumes a bright red colour owing to the transformation of one of the colouring principles, morintannic acid, into phloro-glucine and machromine.

The flowers of *Pyrethrum cinerariæfolium* treated in the same fashion show no change, but I have been unable to get this very promising reaction to indicate distinctly anything under 20 per cent. of fustic in insect powder, although I am hopeful that an improved method may yet result in greater delicacy.

No.	Percentage of ash.	No.	Percentage of ash.
1	6·2	7	10·5
2	7·1	8	9·6
3	6·	9	9·2
4	6·8	10	8·0
5	6·2	11	9·4
6	6·2	12	6·0

The above table shows the percentage of ash yielded by the twelve samples, and comparing that with the names given by the vendors little relation will be observed between them. From more exact analysis I take the first six to be genuine powders, with the exception of No. 6 which has a suspicion of some dye wood, which I have not yet identified, attached to it. Numbers 7 to 11 are adulterated with chrome from 3 per cent. to nearly 6 per cent. No. 10 has the addition of a very small percentage of turmeric, and No. 12 quite 5 per cent. of that root. It is not to be assumed that excepting these slight admixtures these powders are genuine; for although undoubtedly it is bad enough when having ordered a hundredweight of insect powder one finds 5 to 7 pounds of chrome yellow, costing 4*d.* to 10*d.* per pound, as part of the delivery, the presence of such extraneous colour is suggestive of its being merely a cloak for a more weighty adulteration, such as Mr. Conroy has discovered, or as that referred to by Mr. E. V. Riley (*Pharm. Journ.*, [3], vol. xii., 789), who says that "the stalks and leaves are ground with the flowers in the proportion of one-third of their weight;" whilst on the authority H. Kalbruner (*Pharm. Journ.*, [3], vol. v., 305), "The plant itself (minus the flowers) powdered appears to be quite inactive."

In face of the foregoing facts it seems advisable that purchasers should avoid the foreign powder, which seems to be always coloured, and not too trustingly accept any guarantee, even of professed grinders, but verify for themselves each purchase, which by the means above stated can readily be done in a few minutes even by a junior assistant.

NOTE ON VORTMANN'S METHOD FOR THE SEPARATION OF CHLORIDES, BROMIDES AND IODIDES.*

BY J. B. BARNES, JUN.

In 1880, G. Vortmann (*Ber.*, xiii., 325–326) proposed a process for the detection and estimation of chlorine in the presence of iodine and bromine. The method was based on the different action of manganese dioxide and lead dioxide towards the halogen elements. The author stated that iodides are decomposed by either of the oxides even in a neutral solution, and that the separation of iodine is complete if the liquid be boiled with acetic acid. Bromides are not decomposed by either oxide in a neutral solution; but in the presence of acetic acid, lead dioxide causes the separation of bromine, while manganese dioxide has no action. Chlorides, on the other hand, are not affected by either oxide in neutral or acid solutions. Chlorine is detected in the presence of the other halogen elements by boiling the substance with lead dioxide and acetic acid until the liquid becomes colourless and ceases to smell of iodine or bromine. Any lead iodate that may have been formed is separated by filtration together with excess of oxide used; the filtrate contains all the chlorine free from bromine and iodine. When chlorine is present with a large quantity of iodine, the use of manganese dioxide is to be preferred, to avoid the formation of the difficultly soluble lead chloride, and when there is a large quantity of chlorine in the presence of bromine, potassium sulphate should be added so that the chlorine may exist as a potassium salt.

The above process has been examined by C. L. Müller and G. Kircher (*Ber.*, xv., 812–818), who stated that they found chlorides to be decomposed by lead dioxide and acetic acid with liberation of chlorine and formation of mono-chloracetic acid, which is partially oxidized to carbonic anhydride, lead chloride being formed at the same time. When manganese dioxide was used no chlorine was liberated, but carbonic anhydride and manganese chloride formed. The action of lead dioxide and acetic acid on bromides and iodides was confirmed, but manganese dioxide and acetic acid were said to act alike on iodides and bromides. Both oxides acted slowly on iodides and bromides in neutral solutions, but neither had any action on chlorides.

Vortmann replied to this in a short paper (*Ber.*, xv., 1106), in which he stated that potassium chloride is not decomposed by lead dioxide when evaporated with a 2 to 3 per cent. solution of acetic acid, even when the

* A paper read before the School of Pharmacy Students' Association, March 29, 1883.

evaporation is repeated five or six times, whilst potassium iodide when similarly treated is readily decomposed, and potassium bromide, although with greater difficulty, is completely decomposed on repeated evaporation. Potassium chloride is decomposed with difficulty by the use of 5 per cent. acetic acid. Again, manganese dioxide with 2 to 3 per cent. acetic acid readily decomposes potassium iodide, but has no action on potassium bromide. With 10 per cent. acid only traces of bromine are liberated.

Since the publication of his last paper Vortmann (*Monatsh. Chem.*, iii., 510–530) has given detailed methods for the estimation of chlorides, bromides and iodides, by his process, of which the following is a brief *résumé*.

Estimation of Chlorine in Presence of Bromine.—The mixture of chloride and bromide is evaporated two or three times over a water-bath with lead dioxide and acetic acid 2 to 3 per cent. Bromine is evolved, the residue is treated with water, sulphuretted hydrogen passed to precipitate lead, solution filtered, and chlorine estimated by precipitation with silver nitrate.

Estimation of Chlorine in Presence of Iodine.—This may also be effected by the same method, or by using manganese dioxide in the place of lead dioxide. The latter method is preferable.

Estimation of Bromine in Presence of Iodine.—This estimation is easily effected by evaporating the mixture of iodide and bromide with manganese dioxide and dilute acetic acid several times over a water-bath.

Estimation of Chlorine in Presence of Iodine and Bromine.—Two processes are given. 1st. The mixture is boiled down several times with lead dioxide and dilute acetic acid, the lead dioxide being added to the mixed acidified solutions when in a state of ebullition, to prevent the formation of iodic acid, produced by the mutual action of the iodine on the bromine. The lead is then separated by sulphuretted hydrogen, and chlorine estimated in the usual manner. 2nd. The mixture is heated with manganese dioxide and dilute acetic acid till all the iodine is evolved, lead dioxide is now added and the boiling continued till the expulsion of bromine is effected; the filtrate, after separation of lead, is then employed for the estimation of chlorine. The latter process is said to give more exact results, as the iodine and bromine are expelled without the formation of oxy-acids. The author remarks that he has obtained satisfactory estimations of chlorine in the presence of iodine and bromine, when relatively large quantities of chlorine are present, but when much bromine is present the results came out rather too high. The estimation of iodine in the presence of bromine and chlorine gave good results; while that of bromine is at present unsatisfactory.

The experiments recorded in the following note had for their object the testing of the process as one for use in qualitative analysis.

(1.) 10 c.c. of a 5 per cent. solution of potassium iodide were mixed with 10 c.c. of 3 per cent. acetic acid and excess of lead dioxide, and evaporated nearly to dryness with constant stirring in a porcelain dish over a gas flame. The vapour of iodine was evolved. 10 c.c. more of acetic acid the same strength were added, evaporation and stirring being continued as before. This was repeated a third and fourth time. During the third experiment iodine was still evolved. The residue after the fourth evaporation was then treated with water, filtered, lead separated with dilute sulphuric acid, and again filtered. Potassium nitrite gave no coloration to the filtered liquid and silver nitrate produced only a slight turbidity.

(2.) In this experiment the same quantities of the solution of potassium iodide and acetic acid were taken, but manganese dioxide substituted for lead dioxide. The process was similar to the first experiment. Potassium nitrite imparted only a slight brown colour to the acidified solution, and silver nitrate gave a slight turbidity.

The inference to be drawn from these experiments is that iodine is practically wholly expelled from a solution of an iodide by lead dioxide or manganese dioxide in the presence of 3 per cent. acetic acid.

(3.) In this experiment, three separate portions of a 5 per cent. solution of potassium bromide were boiled with manganese dioxide and acetic acid of various strengths. The strengths used were 3 per cent., 33 per cent. and about 60 per cent. Paper moistened with solution of potassium iodide and starch paste was held over each dish. The third solution, in which the strongest acid was used, was the only one from which bromine was evolved.

This explains the apparent conflict between the result of Vortmann's experiments and those of Müller and Kircher; for while the former employed 2 to 3 per cent. acetic acid the latter used 50 per cent.

(4.) Here 10 c.c. of a 5 per cent. solution of potassium bromide, 40 c.c. of acetic acid (33 per cent.), and excess of lead dioxide were taken and treated in the same manner as in the first experiment, using 10 c.c. of the acid after each evaporation. After separation of lead, chloroform when shaken with a portion of the solution and a few drops of chlorine water was not coloured. Silver nitrate gave a slight turbidity.

(5.) The last experiment was repeated, but 3 per cent. acetic acid substituted for the stronger. After separation of lead, chlorine water and chloroform were added and the liquid shaken; a distinct red colour was imparted to the chloroform, silver nitrate gave a fair amount of a yellowish white precipitate, insoluble in nitric acid, sparingly soluble in ammonia; proving that 3 per cent. acetic acid and lead dioxide were incapable of removing all the bromine from the solution, even after four evaporations; while stronger acetic acid practically removed it all under similar circumstances.

(6.) In this experiment 10 c.c. of a 5 per cent. solution of sodium chloride, 40 c.c. of strong acetic acid, and excess of lead dioxide were taken and treated in the same manner as in the first experiment. After the fourth evaporation and separation of lead, silver nitrate gave a copious white precipitate, insoluble in nitric acid, soluble in ammonia; proving that the chloride was slightly or not at all affected.

(7.) In this experiment, 5 c.c. each of the 5 per cent. solutions of potassium iodide and potassium bromide, 40 c.c of acetic acid (33 per cent.) and excess of lead dioxide were taken and treated as before, but the acidified solutions were first boiled and the lead dioxide added, little by little, whilst in a state of ebullition. After the fourth evaporation and separation of lead, potassium nitrite gave no coloration, chloroform when shaken with another portion of the solution and a few drops of chlorine water was not coloured, and silver nitrate gave only a slight turbidity; proving that both iodine and bromine were wholly removed. If lead dioxide be added to the cold acidified solutions and heat subsequently applied, the mass, as it approaches dryness, changes from brown to yellow, accompanied by rather violent action; on further heating it blackens and chars, and finally assumes a yellowish red colour, due doubtless to the formation of litharge. The residue when treated with water yields a coloured liquid which contains no lead but a large quantity of iodine. Vortmann notices this action and indicates as its cause the formation of oxy-acids of iodine.

(8.) In this experiment 3·3 c.c. each of the 5 per cent. solutions of potassium iodide, potassium bromide and sodium chloride, together with 40 c.c. of acetic acid (33 per cent.) and excess of lead dioxide were taken. The evaporation was carried on as in the other cases, using 10 c.c. of acid each time and lead dioxide being added to the boiling solutions. After the fourth evaporation and separation of lead, the filtrate gave no coloration with potassium nitrite, chloroform when shaken with another portion of the solution and a few drops of chlorine water was not coloured, while silver nitrate gave a copious white precipitate insoluble in nitric acid, soluble in ammonia, proving that all the iodine and bromine had been removed, but that chlorine still remained.

(9.) In this the same quantities of the three solutions were taken and the experiment conducted as in No. 8, except that the iodine was first expelled by manganese dioxide. A small portion of the mass was then tested, and bromine and chlorine found to be present. Lead dioxide was added and evaporation continued with acetic acid till bromine was expelled. Water was added to the mass as before, the liquid filtered, lead separated by sulphuric acid, again filtered, and silver nitrate added, which gave a copious white precipitate insoluble in nitric acid, soluble in ammonia.

From these experiments it will be seen that bromine cannot be removed from a solution of a bromide by using 3 per cent. acetic acid and lead dioxide, although by using a stronger acid this may be effected.

There is one disadvantage in using manganese dioxide, namely, the tendency the solution has to spurt whilst evaporating, which necessitates incessant stirring; this makes the use of lead dioxide more advantageous where the isolation of iodine and bromine is not required. The primary reactions in the above process may be shown thus:—

$$2KI + 4HC_2H_3O_2 + PbO_2 = I_2 + 2KC_2H_3O_2 + Pb2C_2H_3O_2 + 2H_2O,$$

$$2KBr + 4HC_2H_3O_2 + PbO_2 = Br_2 + 2KC_2H_3O_2 + Pb_2C_2H_3O_2 + 2H_2O.$$

$$2KI + 4HC_2H_3O_2 + MnO_2 = I_2 + 2KC_2H_3O_2 + Mn2C_2H_3O_2 + 2H_2O.$$

The results of these experiments indicate that the following modification of the process might be used with advantage in many cases where a solution has to be analysed for any or all of the halogen elements. Add ordinary acetic acid (33 per cent.) to the solution, boil in an open dish, add a few grains of manganese dioxide; if iodine be present the liquid will instantly turn brown. More manganese dioxide must then be added, and the whole briskly boiled till a glass rod moistened with starch paste and held over the dish ceases to be coloured blue, showing that all iodine has been removed. If no coloration be produced when manganese dioxide is added, the solution may be at once tested for bromine After the separation of iodine treat the residue with water and test a portion for bromine. If it be present add lead dioxide and continue the ebullition with acetic acid till a glass rod moistened with solution of potassium iodide and starch paste and held over the dish ceases to be coloured blue, indicating that all bromine has been removed. Treat the residue with water, filter, separate the lead with dilute sulphuric acid or sulphuretted hydrogen and test the clear filtrate for chlorine with silver nitrate.

In conclusion, I have to thank our Secretary, Mr. Dunstan, both for suggesting this process as a subject for a paper and also for the valuable aid he has given me in working it out.

THE ACTIVE PRINCIPLE OF THE ROOT OF APOCYNUM CANNABINUM.*

BY O. SCHMIEDEBERG.

Husemann was the first to point out that the *Apocynum cannabinum*, L., which is used as a remedy in dropsy and like the oleander belongs to the Apocynaceæ, might contain a heart poison belonging to the digitalin class. In fact, from the root of this plant, which in its native country, North America, is official, two substances belonging to the digitalin group can easily be prepared, analogous to oleandrin and neriin.†

Apocynin is a resinous amorphous substance, very easily soluble in alcohol and in ether, but almost insoluble in water, of which a very small quantity is capable of producing the systolic pause in the heart of a frog with the characteristic phenomena. It does not appear to be a glucoside although upon boiling it in alcoholic solution, or suspended in water, with tolerably concentrated hydrochloric acid, a liquid is obtained which reduces cupric oxide in the presence of alkalies pretty freely; but this may be due to other decomposition products resulting from the strong action of the acid. The greater part of the resinous mass appears to remain unaltered; it has, however, become inert, not only in respect to the heart, but generally, and especially a picrotoxin-like action is no longer perceptible.

The second constituent is apocynein, which is a glucoside, and in its characters and solubilities agrees essentially with neriin, or digitalein. But like apocynin, it gives no remarkable reaction with sulphuric acid and bromine.

The preparation and purification of the two substances is effected in a manner similar to that followed for the constituents of the oleander.*

THE ACTION OF CERTAIN METALS ON OILS.†

BY A. LIVACHE.

The action of metals on oils and particularly on drying oils has been made, by M. Chevreul, the object of studies of very great importance. From these studies it follows that under certain circumstances metals exercise a considerable influence on the oxidation of oils. Linseed oil, for example, rapidly becomes drying when it is spread upon the surface of a plate of lead. I have thought that the action of metals might be more efficacious if they were used not in the form of metallic plates, as M. Chevreul did, but in the state of fine division as obtained by precipitation. Experience has verified this supposition.

I have particularly studied the action exercised upon oils by lead, copper and tin; of these metals lead acts the most energetically.

Lead used in the experiments was prepared by precipitation from a solution of some of its salts by means of a plate of zinc; it was washed quickly, by water first, then by alcohol, then by ether, and dried rapidly *in vacuo*. If the lead thus prepared is moistened with a certain quantity of oil and exposed to the air, its weight will increase in a short time, and this increase of weight is greater as the oil is naturally more of a drying oil. Operating for example with raw linseed oil, the increase of weight reaches its maximum in thirty-six hours, whereas, exposed by itself to the air, this oil requires several months to reach its maximum. At the same time it appears to form a solid and elastic substance, analogous to that obtained in exposing boiled linseed oil to the air. With non-drying oils, the increase of weight, much less in amount, requires more time for its complete development.

The results which I propose to detail cannot be attributed to a simple mechanical division of the matter, which permits the air to circulate more freely through the mass, because the same experiment made with different substances in fine powder shows no analogous augmentation of weight; the process of oxidation goes on just as in the case of an oil exposed simply to the air in a thin layer.

The preceding experiment, made with different oils, shows that the increase of weight is practically proportional, except for cotton seed oil, to that observed with the fatty acids of the same oils, exposed to the air for several months. The drying is only more rapid because of the difficulty with which the air penetrates into the solid mass of the fatty acids. This is shown in the following table:—

† From *Comptes Rendus*. Reprinted from the *Oil, Paint, and Drug Reporter*.

Oils experimented with, using precipitated lead.	Increase of maximum weight, after 2 days per ct.	after 3 days per ct.	Increase of weight of fatty acids exposed to the air for a period of 8 months, per cent.
Linseed oil . .	14·3	—	11·
Nut oil . . .	7·9	—	6·
Poppy seed oil .	6·8	—	3·7
Cotton seed oil .	5·9	—	0·8
Beech nut oil . .	4·3	—	2·6
Colza oil . .	0·0	2·9	2·6
Sesame oil . .	0·0	2·4	2·0
Peanut oil . .	0·0	1·8	1·3
Cabbage seed oil	0·0	2·9	0·9
Olive oil . . .	0·0	1·7	0·7

Cotton seed oil, which is a drying oil, presents the only exception, the fatty acids, which are derived from it only acquire a slight increase of weight. This is, without doubt, the reason why they can, in the industrial arts, make it play the *rôle* of drying or not drying oil, in mixing it with either linseed oil or olive oil.

Again it is the direct action of the metal, and not, as might be supposed, the action of the air, to which is due the transformation which gives the oil power of increasing its weight and changing its physical state in oxidizing. If, in fact, linseed oil and a small quantity of precipitated lead are mixed and kept out of exposure to the air and light from time to time, the oil will soon be seen to acquire a slightly reddish tint; then if this oil be spread upon a plate of glass, the oil bleaches, and dries as rapidly as boiled oil, undergoing also as great an increase in its weight. The contact with precipitated lead, with exclusion of air, has communicated to the oil the property of rapidly absorbing oxygen.

In studying the oxidation of oils, M. Clorez has shown that this oxidation is always accompanied with total disappearance of glycerine; it appears, probably on account of the phenomena I am about to describe, that it is upon this glycerine that the precipitated lead exerts an equal part of its influence in modifying it. In effect, if we place in a flask, from which air is extracted, glycerine and precipitated lead, the lead will rapidly disappear, oxidizing at the expense of a part of the product and then dissolving. If raw linseed oil is taken in one instance, and in another instance boiled oil which has been acted on by precipitated lead with exclusion of air is taken; then if precipitated lead is moistened with these two oils, and each sample exposed to the air, an identical increase in weight will be observed, and consequently an equal capacity for absorbing oxygen, proportional, as I have shown, to the increase of weight acquired by the isolated fatty acids.

The preceding facts explain besides how, by a simple digestion at the natural temperature of linseed oil and litharge or minium, prolonged for some time, oil drying rapidly in the air can be obtained; nevertheless the oil thus obtained always retains some fatty matter (*du gras*); it dries less well and less rapidly than boiled oil. The boiling, especially if prolonged, and if the temperature is high enough, has the effect of producing a partial decomposition of the glycerine.

The study of the action of other precipitated metals, such as copper and tin, fails to give any results of interest; they only slightly increase in drying power. M. Chevreul already has announced this fact, from his experiments with plates of these metals.

Finally, it seems probable that the action of precipitated lead on the drying oils can be utilized to a certain extent in the arts.

In the first place, in the facts which I have made known will be found a rapid method for distinguishing drying oils (nut, linseed, beech nut, cabbage seed and cotton seed oils), from non-drying oils. The addition, now so frequent of cotton seed oil, for example, to linseed oil can be easily detected.

In the second place they give a means of substituting for the old-fashioned boiling, a simple agitation or stirring of the oils, or better yet, with exposure to air and at the natural temperature, the linseed oil can be circulated over plates of iron or zinc, on the surfaces of which metallic lead is precipitated. Oils thus obtained will be always less coloured, and will preserve a high degree of fluidity, while at the same time the disagreeable odours and danger of fire encountered in the present process will be avoided.

SYRUP OF SQUILL AND SYRUP OF IPECAC, SIMPLE AND COMPOUND.*

BY R. ROTHER.

It is almost a truism that, where there is a ceaseless effort to improve some process, there must abide a radical and obnoxious defect. Now, if the obstacle is radical in its nature, the aberrant cause becomes the dominant feature in the process, and remains a rich source of of empirical methods, until its principle is understood. For a long time fermenting syrups were a standing menace to elegant pharmacy. Not until alcohol in sufficient proportion was applied did the agitation in this regard end. For an equally extended period the pectose derivatives spoiled tinctures and syrups, until alkalies were employed to suppress the odious jellies. Many resins, which long were troublesome, likewise yielded to the solvent action of alkalies, especially in the presence of sugar. An extensive array of tinctures presented various defects in the way of turbidity, deficient strength, and retarded percolation and filtration, owing to the use of too weak alcohol in their preparation. An increased strength of the alcoholic menstrua swept away this multitude of grievous objections. Saline menstrua now serving excellent special purposes will eventually become more generally important. Acidulated menstrua have many particular uses, but some mischief and positive inconvenience has resulted from their too general employment, where their aid was by no means indicated. Syrup of squill is an example of such cases. Vinegars and wines are probably relics of primitive pharmacy. The fermented liquors earliest in use were so deficient in alcohol that acetic acid was speedily developed by secondary fermentation. The resulting vinegar being found possessed of antiseptic qualities naturally met with frequent application for this purpose. Hence, medicines as well as perishable articles of food were prepared with this acidulated solvent and preservative. Wines, perhaps, came later into use when improved methods produced them of greater alcoholic strength. When, however, distillation yielded still stronger alcohol, its use became general, and vinegars and wines dwindled to lingering rudiments in the modern organism of pharmacy. Syrups were originally made from medicated vinegars, and syrup of squill is prepared in that manner to this day. But an acidulated preparation of squill is contra-indicated in all its therapeutical applications. Squill is almost invariably given in connection with alkaline, saline or neutral mixtures. In pharmacy, also, a great disadvantage results when such mixtures are compounded, owing to the fact that physicians forget the acid nature of syrup of squill. This syrup is not only medicinally and chemically incompatible with alkalies and carbonates, but also mechanically with the latter by reason of the persistent frothy effeverscence set up in a syrupy liquid. Furthermore, when a fresh vinegar of squill is converted into syrup, the yet unchanged pectose derivative becomes insoluble as a bulky gelatinous precipitate.

The activity of squill is readily extracted by water, but a mixture of the drug and water gets rapidly putrid; if, however, an aqueous menstruum, containing one-eighth its volume of alcohol, is used, putrefaction and fermentation are prevented. Such an extraction yields no precipitate with sugar, and produces an elegant syrup, readily miscible with alkalies and acids without change. When the filtered macerate is treated with ammonia, a

* From the *American Journal of Pharmacy*, Feb., 1883.

considerable greenish precipitate is formed, which rapidly subsides and again quickly dissolves on the addition of sugar, but is wholly prevented when the order of mixture is reversed. Pharmacists will find a neutral syrup of squill very convenient in all such cases where the ordinary syrup is incompatible.

In the preparation of this syrup as well as of others, and also many tinctures, the method of remaceration proposed by the writer is far preferable to percolation and often more exact. Most crude drugs, such as roots, barks, and leaves, have a pretty definite normal of absorption, that is capacity for imbibing and holding menstrua. When this has been determined, a simple mathematical calculation will show how much loss is sustained, after obtaining a certain measure of decanted liquid. The normal of absorption of squill with one-eighth alcohol, is rather high, but since the drug is cheap, a loss of 20 per cent. is immaterial, when there is more than a corresponding gain in definiteness and quality of the product and facility in the process.

The application of heat in the preparation of syrups is chiefly objectionable on account of the large volume of liquid to be heated, and the difficulty of straining it whilst hot. To obviate all this, percolation was suggested. But this presents so many objections, that its few advantages were small by comparison. The cold process, by simple mixture and agitation, is so vastly superior to all others that it is fast coming into general favour. In cases of very dense syrups and such containing much alcohol, some difficulty is found in dissolving the last portions of the sugar. In preparing simple syrup such a residue is not objectionable, but in all other cases complete solution is imperative. To this end the writer divided the menstruum and used portions successively on the saccharine residue. However, an equally effective, but more facile method consists in mixing the whole, then stirring until most of the sugar has dissolved, decanting the syrup, heating the remainder until dissolved, uniting the whole, and straining. One gallon of neutral syrup of squill is prepared as follows:

Take of—

Squill, whole	10 troy ounces.
Sugar, granulated . . .	96 „
Alcohol } Water }	of each sufficient.

Mix alcohol and water in the proportion of one measure of the first and seven measures of the second, and pour 57 fluid ounces of the mixture upon the squill contained in a wide-mouthed bottle. Macerate this mixture for three or four days, with occasional shaking, and decant 32 fluid ounces of the liquid. Upon the residue pour 32 fluid ounces of the menstruum, and after three or four days decant as before. Mix the two decantates, filter and pour the filtrate on the sugar contained in an appropriate vessel; stir the mixture until most of the sugar is dissolved, decant about six pints of the syrup, heat the residue until dissolved, then mix the whole and strain.

Syrup of ipecac is another one of those protean compounds whose radical fault not being understood has caused it to pass through a great variety of changes. In this case the presence of a small amount of pectosic matter is, however, only part of the difficulty. The main cause of aberration resides in the large amount of resin that is contained in the root. In some of the former processes for this syrup it was assumed, on the statement that emetine, the active principle, being insoluble in water, that acetic acid must be used to render this soluble. But acetic acid brought no advantages for preventing a cloudiness which invariably appeared in the syrup. The resin was excluded in subsequent methods by mixing a fluid extract or a condensed alcoholic extraction with water, filtering and then adding the sugar; but the cloudiness still appeared although less obtrusively. The great and particular defect in this method was the fact that the acid resin carried with it a considerable portion of the activity. Later the writer extracted the root with acidulated water containing only enough alcohol to prevent fermentation. Under these conditions the gelatinous cloud was yet manifest, but subsiding rapidly left the supernatant syrup clear and bright. Deeming the jelly to be of pectosic origin and finding that a fluid extract of ipecac when mixed with ammonia remained clear the writer then employed an ammoniacal menstruum and found that both emetine and resin were readily and completely exhausted. The resulting deep brown solution produced a magnificent dark brown, clear, and permanent syrup on the addition of sugar.

The resin of ipecac is distinct from ipecacuic acid. The resin is insoluble in water, but extremely soluble in alkalies, especially ammonia. The thorough exhaustion of the root by means of an ammoniacal menstruum lends the appearance that if the acid resin formed native insoluble compounds with emetine these were dissolved by the ammonia. But this assumption is superfluous, since the statement of the investigators of emetine in regard to its insolubility in water is incorrect. Although emetine is precipitated from moderately concentrated solutions of its salts by ammonia and unaffected by an excess of the latter, it is yet quite freely and amply soluble in the large volume of water used in its extraction from the root. The writer found that when the ammoniacal extraction is evaporated to a syrupy liquid, again alkalinified with ammonia and shaken with a mixture of equal volumes of ether and acetic ether, a yellowish ethereal solution of emetine is obtained. This solution, on spontaneous evaporation left a yellowish crystalline residue of emetine. This when treated with water is converted into a cream coloured amorphous emetine hydrate. The crystals as well as the hydrate are promptly and perfectly soluble in acids from which ammonia precipitates bulky flakes of the hydrate in not too dilute solutions. Emetine is further remarkable in being much more bitter than its salts. Acetic ether is the great solvent of emetine, but owing to the ready miscibility of ethyl acetate with watery liquids, ordinary ether is advantageously added in the extraction from the crude residue. Emetine, although insoluble in ethyl oxide, is yet soluble in a mixture of the two ethers.

Returning now to syrup of ipecac, we have the formula for 4 pints, as follows:—

Take of

Ipecac, coarsely bruised . .	$4\frac{1}{2}$ troy ounces.
Sugar, granulated	48 troy ounces.
Calcium carbonate	$\frac{1}{2}$ troy ounce.
Ammonia water	$\frac{1}{4}$ fluid ounce.
Alcohol, } Water, }	of each sufficient.

Mix alcohol and water in the proportion of one volume of the first and seven of the second, and pour 25 fluid ounces of the mixture together with ammonia water upon the ipacac contained in a wide-mouthed bottle. Macerate the mixture for three or four days, shaking it up occasionally; then decant 16 fluid ounces of the liquid. On the residue pour 16 fluid ounces of the menstruum, and after three or four days' maceration decant 16 fluid ounces as before. Mix the two decantates, add the calcium carbonate, agitate and filter. Pour the filtrate on the sugar contained in a proper vessel, stir until most of the sugar has dissolved and decant about 3 pints of the syrup. Heat the remainder until solution is effected, then mix the whole and strain.

The compound syrup of ipecac, or substitute for Dover's powder, is extensively in use. But it is not properly prepared, being fermentable and otherwise unsatisfactory. A permanent and elegant syrup containing $\frac{1}{2}$ a grain each of opium and ipecac in the fluidram is prepared by the following ready formula:—

Take of—

Deodorized tincture opium . .	8 fluidrams.
Syrup of ipecac	10 „
Simple syrup, sufficient to make.	75 „

Mix.

The Pharmaceutical Journal.

SATURDAY, MAY 19, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

REPORTS OF THE GOVERNMENT VISITORS ON THE PHARMACEUTICAL EXAMINATIONS.

THE reports of the Government visitors on the examinations conducted by the Pharmaceutical Society, which have lately been published, are more than ordinarily interesting this year, since they deal with several of the proposed alterations which have received the approval of the Council as well as with the general results of the examinations during the past. Dr. GREENHOW'S report refers only to the year 1882, but Dr. MACLAGAN'S report embraces a period of three years ending in January of the present year. In one very important point both reports concur most thoroughly, viz., the opinion that all who pass the qualifying examination as at present conducted are fit to carry on the business of a chemist and druggist with safety to the public. Dr. GREENHOW with justice regards this as the essential purpose and requirement of the Pharmacy Act, and Dr. MACLAGAN expresses his belief that the Minor examination affords ample security for the public safety at the hands of those who obtain these diplomas. But while agreeing in this view with Dr. GREENHOW, he admits that there is still need for the creation of a class of pharmaceutical practitioners possessing higher scientific qualifications than either the Minor or even the Major examination provides for, and he expresses a hope that if the proposed alterations are carried out the standard of the qualifying or pass examination may be raised at least up to the level of the present Major.

It may, therefore, we think, be inferred that the satisfaction felt by Dr. MACLAGAN, at least in the results arrived at by the system now in force, is due rather to the efficient manner in which the examinations are conducted than to any profound belief in the sufficiency of the regulations applying to them. It is indeed conceivable that with a less careful and conscientious body of examiners the results obtained under the present regulations might be far less satisfactory even from this point of view which is taken by the Government visitors. If this be a correct inference, it would to a great extent justify the recommendations of the Council with a view to making the examinations a more complete test of competence. In fact, Dr. GREENHOW, in reviewing the effects of various changes that have already been made from time to time, admits that those changes have unquestionably raised the standard of the Minor, and he expresses his approval of this result, which he considers to have been inevitable and necessary if the intention of the Pharmacy Act was to be fulfilled. He well points out that in commencing a system of compulsory examination it would have been manifestly inequitable to have passed at once from the laxity which previous to the enactment of the Pharmacy Act permitted persons to carry on the trade of a chemist and druggist without any recognized qualification, and to have exercised a degree of strictness which would have made the examinations press hardly upon a large number of candidates whose education had been commenced before the Act came into operation. At the same time he also admits, what is really the logical consequence of such a considerate application of the system of examination, that at a later period it was quite proper to make the examinations more thorough and practical, and to introduce such changes as experience may have shown to be desirable.

It would, we think, be unwise to assume that the necessity for such a gradual raising of the standard of the qualifying examination has ceased to exist, for whatever may be thought of the competence of those who pass it, we must not lose sight of the fact that the large number of rejected candidates furnishes evidence of a want of adequate preparation for the ordeal, and, as Dr. MACLAGAN says, of ignorance of what constitutes preparedness. The great desire with too many is to pass, and merely to pass by any means, without any proper regard to what is requisite in order to make the passing of the examination a matter of course.

The provision that passing the Preliminary examination should be essential before the commencement of the period of apprenticeship or pupilage would no doubt contribute largely to reduction in the number of candidates rejected at the Minor examination, and we are glad to see that the proposed alteration has the entire approval of Dr. GREENHOW, as well as that requiring the candidates for the Minor examination to produce evidence of apprenticeship or pupilage of not less than three years with a duly registered chemist and druggist.

Dr. GREENHOW is a strong advocate for adherence to the system of apprenticeship, and he thinks the Pharmacy Act to be defective in not having made it compulsory. His argument in favour of that opinion is a strong one, and we are quite in accord with him as to the value of long and constant practice as a means of acquiring practical acquaintance with drugs and the manipulative skill required in compounding them. But it must not be forgotten that compulsory apprenticeship affords no sufficient guarantee that the apprentice will be enabled to gain the knowledge and skill desirable, and Dr. Maclagan very pointedly refers to this circumstance in his report by stating that there can be little doubt members of the pharmaceutical profession to a large extent do not do their duty properly to their apprentices. He adds that if the apprentice is merely to learn the routine duties which fall on anyone standing behind a counter, six months would be enough for the purpose, and the three years' apprenticeship might be abolished with advantage.

It behoves those who complain of the difficulty in obtaining apprentices to consider well the remarks of Dr. Maclagan on this subject, and to inquire whether they may not be to blame for the want they experience rather than any supposed undue stringency of the examinations which is sometimes put forward as the reason why apprentices cannot be obtained. If the apprenticeship system is to be merely a device for obtaining cheap labour it can but contribute towards the maintainance of the large number of rejected candidates for the Minor examinations, and if, as now intended, it is to furnish evidence that candidates have had opportunities for acquiring practical skill and knowledge of their business, it should imply a certain responsibility on the part of the master for the pupil's progress.

On the general subject of a curriculum of study the opinions of the two Government visitors of examinations are less in accord. While Dr. Maclagan, in referring to his previously expressed recognition of the necessity for pharmaceutical students going through a regular curriculum of study, again states that the results of the last three years have led him to observe how much candidates, whether successful or not, require more methodical instruction, Dr. Greenhow is not disposed to think it necessary to enforce attendance on a regular course of lectures, though he would not discourage candidates from attending such a course of instruction at their option.

Dr. Greenhow's opinion on this point is based upon the statement in the preamble of the Pharmacy Act, that for the safety of the public it is expedient that persons keeping open shop as chemists and druggists, etc., should possess a competent practical knowledge of their business. He infers from this that no restriction beyond what is necessary for the safety of the public was intended to be imposed upon pharmacists, namely, that they should be examined as to their practical knowledge. We have on previous occasions pointed out that though this view is one that is sound from the standpoint of a public official it fails to take into account what is requisite for the advancement of pharmacy or for attaining the objects set forth in the preamble of the Pharmacy Act, 1852, and in the Society's Charter of Incorporation.

ELECTRICAL UNITS OF MEASUREMENT.

The last of the series of lectures on the practical applications of electricity, arranged by the Council of the Institution of Civil Engineers, was delivered by Sir William Thompson on the 3rd inst., the subject being "Electrical Units of Measurement." Premising that no real advance is possible in any branch of physical science until practical methods for a numerical reckoning of phenomena have been established, the lecturer pointed out that the first advances towards a system of measurement in electrical science were made in the last century by Cavendish and Coulomb, and that further and rapid progress towards a complete foundation of the system was effected by Ampère, Poisson, Green, Gauss, and others. But as late as ten years ago, regular and systematic measurement in electrical science was almost unknown in the chief physical laboratories of the world. Now, however, electric measurements are of daily occurrence, not only in scientific laboratories, but in workshops; ohms, volts, ampères, coulombs and microfarads have become common terms, and measurements in these units are commonly practised to within 1 per cent. of accuracy. It seems indeed as if the commercial requirements of the application of electricity to lighting and other uses of every-day life are destined to give an important impulse to the higher region of scientific investigation.

Sir William described the first step towards the numerical reckoning of properties of matter to be the discovery of a continuously-varying action of some kind, and the means of observing and measuring it in terms of some arbitrary unit or scale division; while the second step would necessarily be that of fixing on something absolutely definite as the unit of reckoning. Gauss's principle of absolute measurement of magnetism and electricity is merely an extension of the astronomer's method of reckoning mass in terms of what may be called the universal gravitation unit of matter, and the reckoning of force, according to which the unit of force is that force which acting on unit of mass for unit of time generates a velocity equal to the unit of velocity. Gauss's work was of great importance, as was that of Weber. But it was the British Association Committee which, after eight years of labour, fairly launched the absolute system of measurement, subsequently accepted at the International Conference for the Determination of Electrical Units, held in Paris in 1882, and which also effected arrangements for the supply of resistance coils, in terms of a unit, afterwards named an "ohm," to be as nearly as possible 10^9 centimetres per second.

The ultimate principles of scientific measurement were illustrated by the case of an ideal traveller through the universe who desired to make for himself a metrical system agreeing with that which he had left behind him on the earth, but who possessed no weights, measures, watch, chronometer, standard vibrator, or spring balance, but merely Everett's 'Units and Physical Constants' and a complete memory and understanding of its contents. It was shown experimentally how he could readily and accurately recover his centimetre by ascertaining how many wave-lengths of sodium light there were in the distance between the bars of a grating that he could engrave for himself upon a piece of glass. Having recovered his centimetre measure, he would have the choice of various methods for recovering the unit of time. One way would be to take an accurately measured Leyden jar of known capacity, arrange a mechanism for charging it to an accurately measured potential and discharge it at frequent regular intervals through a galvanometer coil; this would give an intermittent current of known average strength, measurable in electro-magnetic measure by an ordinary galvanometer. The number found upon dividing the electrostatic reckoning of the current by the experimentally found electromagnetic reckoning of the same is v in centimetres per the arbitrary unit of time which the experimenter has used in his electrostatic and electromagnetic details. It is hoped that before long the value of v will be known within one-tenth per cent., but at present it is only known that it does not probably differ 3 per cent. from $2{\cdot}9 \times 10^9$ centimetres per mean solar second.

The remainder of the lecture was occupied with an explanation of the application of the absolute system in all the branches of electric measurement, and the definition of the practical units founded on it, now known as ohms, volts, farads, microfarads, ampères, coulombs and watts. In addition the name "mho"—being the word "ohm" reversed—was suggested for a unit of conductivity, the reciprocal of resistance, together with the subdivision "millimho," which would be exceedingly convenient for the designation of incandescence lamps.

We understand it is probable that the company at the Annual Dinner on Tuesday next will be more numerous than on any similar occasion for some years past. It is therefore extremely desirable that persons still requiring tickets should communicate at once with the Honorary Secretary, Mr. Richard Bremridge, as it will be imperatively necessary to close the sale sufficiently early to enable proper arrangements to be made.

* * *

It may interest some of our readers to learn that at the Society's Conversazione on Wednesday next the music in the North Court of the South Kensington Museum will be performed by the Hungarian Band, under the direction of John Kalozdy, and that the glee singing in the Lecture Theatre will be supplemented by the singing of ballads by Miss Clara Samuell.

The second reading of the Medical Acts Amendment Bill, which was fixed for the 10th inst., has been deferred until Monday, the 21st inst. As, however, it is preceded in the list by seven other orders of the day, some of them of considerable importance, a further postponement seems inevitable, especially as the Bill is "blocked" and, therefore, cannot be brought on after half-past twelve.

* * *

From a memorandum by Professor Chandler Roberts on the recently issued Report of the Deputy-Master of the Mint it appears that the expression of the composition of gold ingots by the carat system, which has survived from the earliest times of which there are Mint records, is likely to be abandoned in favour of a decimal expression. As is known, the "carat" system consists in recording the alloy to be so many carats "better" or "worse" than standard, and is founded on an ideal unit, the "carat pound," which is divided into twenty-four parts, termed "carats," British standard gold containing twenty-two carats of gold and two carats of alloy in every twenty-four parts. The "carat" is sub-divided into four "carat grains," the "carat grains" into "eighths of a carat grain," and these are again subdivided into seven and a half parts, constituting "excess grains," being each equal to $\frac{1}{5760}$ of the carat pound. The method newly adopted is the decimal form, the report being expressed to the 0·0001 part.

The *British Medical Journal* quotes a curious instance of the curative effects following the scientific use of the imagination, though not in exactly the sense intended by the inventor of the phrase. A hysterical patient, who had previously suffered from chorea, was received into the Charité, unable to raise herself in bed and with marked contraction of the lower limbs. After one or two hypodermic injections of morphia, she was given "a more energetic remedy," which she was told to use cautiously. The patient finding herself in possession of such a medicine was seized with a desire to poison herself with an overdose and swallowed the whole. The immediate effects she described as being terrible; but soon afterwards she found herself able to walk, and the cure was completed by a further dose of—bread pills!

* * *

The Executive Committee of the International Pharmaceutical Exhibition to be held in Vienna next August, under the presidency of Herr A. von Waldheim, appears to be sparing no pains to ensure its success. It has just issued a circular to pharmaceutical associations generally, as well as individual pharmacists, asking them to contribute towards its success by exhibiting old documents and other objects of antiquarian interest, as well as pharmaceutical collections and apparatus. In consideration of the scientific object of the exhibition the Imperial Foreign Office has expressed a wish that all possible assistance may be given to it by the consular staff. The time for receiving applications for space will definitely expire on the 31st inst.

* * *

The Programme of the Meeting of the British Association at Southport in September next has just been issued. The first general meeting will be held on Wednesday, September 19, at 8 p.m., when Sir C. W. Siemens will resign the chair, and Professor Cayley will assume the presidency and deliver an address. On the next evening there will be a soirée and another on Tuesday, the 25th. On Friday evening, September 21, Professor R. S. Ball, Astronomer-Royal for Ireland, will deliver a discourse on "Recent Researches on the Distance of the Sun," and on Monday evening, September 24, Professor McKendrick will deliver a discourse on "Galvani and Animal Electricity." The concluding general meeting will be held on Wednesday, September 26. Dr. J. H. Gladstone will be the President of the Chemical Science Section.

* * *

The second Annual Meeting of the British Association of Inspectors of Weights and Measures is to be held in Sheffield on Thursday, May 31, and following day.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Draft Pharmacy Acts Amendment Bill.

A special meeting of the Chemists and Druggists' Association of Glasgow was held on the evening of Wednesday, May 2, in Anderson's College, Glasgow, for the purpose of discussing the paper by Mr. Daniel Frazer, delivered to the Association on April 10 (see before, pp. 845 and 865), on the proposed changes in the Pharmacy Act of 1868. Mr. McAdam (of the Glasgow Apothecaries' Company), President of the Association, occupied the chair. There was a large attendance of members.

The Chairman said the Secretary had endeavoured to fix this adjourned meeting so that Mr. Frazer could have been present, but, unfortunately, Mr. Frazer had had to go to London, so that the arrangement had not suited him. It was, therefore, necessary to proceed in his absence, and he would be glad to hear the opinion of members upon the subject.

Mr. A. Kinninmont, after a passing reference to Mr. Giles's paper in the *Pharmaceutical Journal*, said while listening to Mr. Frazer's lecture he had been irritated to hear one word reiterated throughout the whole of it, and that was the word "monopoly." "Monopoly" was a word now only used in a bad sense. It was something to throw at an opponent and to condemn his position without argument; it was begging the question by an epithet. He entirely denied that the present trade of chemists and druggists was in any sense a monopoly. In the preamble of the Act it was said, "Whereas, it is expedient for the safety of the public that sales of poisonous articles should be regulated;" that showed that the trade was a restricted one, and that the restrictions existed not for the purpose of bringing profit to those who carried it on, but for the safety of the public. The trade stood in a similar position to many other businesses. For instance, you may wish to manufacture dynamite or gunpowder: the trade is open to you, but before you can do so you must comply with certain conditions intended to insure the public safety. Before you can become the captain of a ship you must qualify yourself for the duty, and no ship is allowed to sail unless on board it there are at least two persons holding masters' certificates. These were restrictions, but not monopolies, and the trade of a chemist and druggist was similarly placed. To call it a monopoly was an abuse of terms. It was a word that would prejudice their case, because in these days of free trade the words monopoly and protection went together in the popular mind. As for the Bill he had no objection to the preamble. Mr. Frazer objected to the definition clause; but if any one wished to get a thorough understanding of it he should read the decision in the case of the Pharmaceutical Society against Mackness, and he would then see the necessity for this clause. He would see that in that case, because the word "corporation" was not included in the Pharmacy Act of 1868, that the judges were of opinion that corporations could do things that individuals had no power to do. That was a most dangerous doctrine, but he thought this Bill would put an end to it. Mr. Frazer seemed to be very angry about the sale of "poisonous" articles. But chemists now claimed no special right to sell these "poisonous" articles. All the articles that were proposed to be called "poisonous" were sold by anybody; by ironmongers, by hucksters and by many others. But what objection could there be, on the ground of public safety, to the proposals in the Bill? They knew that when a man in the dark drank a bottle of poison in the belief that it was ale or something of the kind, that there was one fool less in the world. Still, it was necessary to guard against accidents, and if a man found a label on a bottle he would be cautious before he drank its contents. This was an unselfish proposal; it was made solely in the interests of public safety. Mr. Frazer underrated the danger. There could be little objection to drysalters being compelled to label the poisons they sell, the same as chemists always do, with the name and address of the seller. Then as regarded wholesale houses it was provided that every wholesale dealer shall keep a record in writing of the name of such poison, the quantity sold, the name and address of the purchaser, and the date of sale, and should preserve such record for twelve calendar months. He could not see that there was any hardship in that. It affected only certain sales. Some of his hearers might remember the case of poisoning in Glasgow by Dr. Pritchard. Many members of the Glasgow Druggists' Association were examined in evidence upon that case, and the poisoning was brought home to the criminal solely by the fact that the doctor had purchased some poison, which he did not pay for at the time, and had he paid for it the crime might never have been traced. This would show the necessity for this clause in the interests of public safety. Then there was the clause as to the labelling of patent medicines being or containing a poison. It had always been his opinion that patent medicines containing poisons were not covered by the Pharmacy Act of 1868. An Act of Parliament could not have a private interpretation, and it could not be stated with certainty what an Act meant until a judge's opinion on it was obtained, as a decision carried authority with it and settled the question. But a passage in the Act seemed to settle the question. In section 16 it says:—"Nothing hereinbefore contained shall extend to or interfere with the making or dealing in patent medicines," and, observe, "nor with the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing." In section 17 it says—"It shall be unlawful to sell any poisons, either by wholesale or retail, unless the box, vessel, wrapper or cover, in which such poison is contained, has the name and address of the seller." If the intention had been to have covered patent medicines it would have been distinctly stated. Mr. Frazer spoke of the strength of the patent medicine interest. But what was that patent medicine interest? Mr. J. Walker gave some statistics about it a month ago. The whole transactions in patent medicines would give each holder of a patent medicine licence at the very most £67 a year. As he (Mr. Kinninmont) held licences for two shops, Mr. Frazer for two, and the Apothecaries' Company for two, it could be seen what a small trade it was. This trade, before which Mr. Frazer bids the Pharmaceutical Society recoil, meant a yearly value of about £650,000, and that included stamps. The proposed clause was necessary in the public interest. He would pass over several clauses now, for he could not find any fault with them. Mr. Frazer, however, objected strongly to the 9th clause—"Duly qualified persons to sell medical prescriptions and sell poisons." It seemed to him (Mr. Kinninmont) that the dispensing of medical prescriptions should be restricted to competent people. He did not see on what grounds Mr. Frazer thought that in this there was any breach of free trade. He could not see how Mr. Frazer came to that conclusion, unless on the ground that having never been in any shop but his own, and having never seen trade as conducted by ignorant people outside, he did not know the danger the public were in. Many of his hearers who had been about the country would be able to recall instances where want of skill, while not perhaps endangering life, at least hindered recovery. A customer should get exactly what is ordered for him, and only competent and skilled persons could give that. Then there was the clause as to the registration of the names of proprietors of shops. That was a very important question. As Local Secretary of the Pharmaceutical Society, he had occasion to go about asking the names of proprietors of shops; and although the question was not a pleasant one, he had never had an uncivil answer, or been received uncivilly, during his expeditions; still there was great difficulty sometimes in finding out who was the real proprietor of a shop. He thought this clause would settle the question. As regarded penalties, that was a thing they could not say much about. Section 12 of the Bill raised a most important question. As at present carried on he thought—and he had been an examiner for some years—the examinations were quite equal to all requirements for the safety of the public; and while he would wish to do nothing in regard to the subdivision of examination that would make it easier for a candidate, he would oppose anything that would make it more difficult or more expensive. He was not afraid of any action of the Council of the Pharmaceutical Society in this matter. Observe the class of men who were the leading pharmaceutists in London; they were all men in high position. In this matter they had nothing to gain by the advancement of the trade generally, but everything to lose. Their skill and position raised them above the trade generally, and their efforts to elevate the trade to their own level tended to make their prominence less. As regarded these examinations, he held, like Mr. Frazer, that it would be sufficient for the public safety, and for the candidate's convenience, that they should be made by a society like the Pharmaceutical Society. He thought, too, these examinations were needed for the public safety. He could not say that they brought chemists profit, but they might bring them position. The public was not sufficiently thankful to them for the care they took in insuring its safety. One reason was that it did not know. There was one thing that had struck him very much in connection with the discussion on this Bill, and that was Mr. Frazer's "pharmaceutical politics." He talked as if the Bill were directed against stores, such as co-operative and civil service stores. That was a mistake; he (Mr. Kinninmont) did not think the Bill was directed against these stores, nor did he think anything chemists could do could prevent these stores from dispensing. On a previous evening he had explained how easily it could be avoided by stores engaging a qualified man, and putting up "John Smith, pharmaceutical chemist, in connection with the Civil Service Association." In concluding, Mr. Kinninmont said he would be glad to answer any question that might be put to him on this subject.

On the suggestion of Mr. D. Lees it was agreed to go over the Bill clause by clause, the Secretary (Mr. Paris) reading each clause as it came up for discussion.

Mr. D. Lees moved, and Mr. J. Walker seconded, that the preamble be approved; and the motion was adopted.

Mr. D. Lees proposed to reject the definition clause. It was admitted that this clause was directed entirely against stores. The Bill was for the safety of the public, but was there any more safety offered to the public by a man having a branch over which he could take no control than by a co-operative store managed by a qualified assistant? He would object to co-operative stores being allowed to have shops without qualified assistants; but at the same time he would object to chemists and druggists having more shops than one. He thought it would be necessary either to leave out the eighth clause of the Bill, giving chemists the privilege of having branch shops, or to reject this definition clause.

Mr. Chalmers seconded the motion.

Mr. A. Kinninmont objected very strongly to the motion, because every member of a co-operative store might call himself a pharmaceutical chemist because there happened to be one on the premises. He claimed the right to have as many branches as he chose. The law did not require there should be a qualified man in any of them; but a co-operative store might open a hundred branches and not have a qualified man in the whole concern. Mr. Lees seemed to think there was no difference between an unqualified man carrying on business and a qualified man, but he would find himself much mistaken. Let him try to manage a business for which he was not qualified, and he would see his mistake. Although a man might have twenty branches and only visit them once a week, he could still exercise an oversight and care over everything that was done in them. He (Mr. Kinninmont) had a dislike to branches in his youth, because he was so much troubled with them, but he now considered the objection to branches a pharmaceutical phantasy. He would move as an amendment that the definition clause be supported.

Mr. John McMillan seconded the amendment.

On a vote, the amendment was carried by a majority of three votes.

The second clause was then taken up.

Mr. R. Brodie said some of the articles proposed to be included in the "poisonous" schedule were more dangerous than some of the things which were included in the original schedule. For instance, more accidents had arisen through the misuse of carbolic acid than almost any other thing, and that not through the carelessness of the chemist, but through the carelessness of people who drank it without first smelling it.

Mr. A. Kinninmont said carbolic acid was largely sold by ironmongers in the country for sheep-dip; that brought them again into the monopoly question, about which Mr. Frazer talked.

Mr. R. Brodie said he was not aware it was used for that purpose.

Mr. J. Walker moved that this clause be supported. He failed to see what difference there could be between a bottle labelled by an ironmonger and one labelled by a druggist; the labelling of poisons was what was wanted.

Mr. J. Walker said the third clause affected the wholesale trade, and if the meaning of it was that a separate poisons book had to be kept, such as was kept by retailers, he would oppose the clause simply on the ground that it was not necessary, except in the sense Mr. Kinninmont referred to in his remarks on cash sales. In all the wholesale houses he ever heard of, all that would be necessary would be to look over their wholesale books.

Mr. A. Kinninmont said the clause was framed to cover such cases as Lamson's, Pritchard's and such like.

The clause was adopted.

On clause 4, Mr. J. Walker said it would be quite competent for the seller to put the word "poison" on the outermost wrapper if the maker did not do so, because in the case of patent medicines coming from France and America, unless this could be done, the question would be raised as to whether it would be safe to keep them.

Mr. R. Brodie said he did not know which patent medicines contained poisons. Winslow's Syrup contained a poison, yet the editor of the *Chemist and Druggist* said a few years ago that he had tested it in all manner of ways to see if it contained morphia, but he failed to discover any, and he had no hesitation in saying that it did not contain poison. How was the seller to find out such as contain poison?

Ultimately the clause was adopted.

Clauses 5, 6, and 7 were then adopted without comment.

On clause 8, Mr. Lees said he should have had something to say on this had the definition clause been rejected, but since it had been approved he would offer no objection to clause 8.

The clause was approved,

On clause 9, Mr. J. Walker moved that this clause be not approved of, in so far as that part relating to patent medicines is concerned. Notwithstanding the remarks of Mr. Kinninmont, there could be no doubt that a great deal of these things were put in—it might be called monopoly or anything else—to keep their trade to the chemists and druggists. There was no use in saying it was for the benefit of the public, for they had passed a clause which would compel all persons who sell patent medicines containing poisons to label them as such. The public was no safer by a chemist selling patent medicines than by a grocer.

Mr. A. Kinninmont said in England many places of business held patent medicines licences, and it was as much against these as anything else that the clause was directed. If they were to admit—which he did not—that the patent medicine stamp covered poison, then any poison could be sold as a patent medicine. He did not think the clause would interfere with any legitimate business.

The amendment was dropped, and the clause was adopted.

Clauses 10 and 11 were approved.

On clause 12, Mr. Lees said, as an amendment to this clause, he would move that the following part be omitted, "and to require and regulate periods of time and of practical experience, or any course of study, lectures, examinations, or any divisions of the same." The part he wished left out was the part which would give the Pharmaceutical Society the power of enforcing a curriculum. This curriculum was recommended because it was said the examinations were imperfect at the present time and afforded no sufficient test of a candidate's ability. The real question was, supposing the examinations were imperfect, could an enforced course of study be a sufficient remedy? He did not think so. It was possible for students to attend classes or lectures and be very ignorant of the subjects they were supposed to be studying until within the last month or so, and then cram up for the examinations. It was impossible to prevent students from adopting some such method as that. So long as the knowledge was secured it was not easy to understand why any objection should be urged against it. Students might, also, only get up the subjects to be set before them for examination, without understanding those subjects or their relations to each other. He thought the proper way was to let a student get his knowledge how and where he pleased, so long as he passed his examination. He approved, however, of giving the Pharmaceutical Society power to subdivide their examination. It was a mistake to conduct the examination in one day. At all events, the examination should be conducted so as to afford undoubted proof of the candidate's ability. He would not object to making the examination more stringent, but he very strongly objected to a particular course of instruction, as it was neither necessary nor desirable. It would be a pleasant change for an assistant to leave the counter for a few months, but by doing so he might lose a comfortable situation and his master a valuable assistant. It would involve a considerable pecuniary loss, scarcely to be compensated by £70 or £80 a year. He admitted that the trade was overcrowded, but he did not think that an enforced curriculum would be a sufficient remedy for the evil.

Mr. A. Boyd seconded the motion.

Mr. A. Kinninmont said that the examiners at present resembled London University. They say, "Where is the knowledge?" and not "Where did you get it?"

Mr. A. B. Chalmers said it was a pretty general opinion in Glasgow that while there is no doubt that this curriculum might be injurious to the prospects of many who are at present connected with the business, there was but one opinion as to its practical utility. Any young men about to enter the business would be prepared, of course, to undergo this curriculum and they would go about their work in a systematic manner. The result could be nothing but gain to themselves and their business. For himself, and many more in the same position, it would have been satisfactory if the Pharmaceutical Society had enforced a curriculum ten or twelve years ago, because in that case they would have stood in a very different position in regard to it now.

The clause was adopted with Mr. D. Lees's amendment.

On clause 13, Mr. A. Kinninmont said he objected to that clause in the Council, but he had been told it did not apply to Scotland, seeing that they did not bind apprentices there. It was intended for the protection of apprentices.

Mr. W. Paris proposed that this clause be not approved of. He said he was in the trade twelve months before he knew there was such a thing as an examination at all.

Mr. J. Arnot seconded the motion.

The motion was adopted, and the clause rejected.

Clauses 14, 15, 16, 17, 18, 19, 20, 21 and 22 were agreed to without comment.

On clause 23,

Mr. Lees said he would propose an extension of the time for the Act coming into force on the date stated. He was not afraid of it passing this session, but he did not want to admit that it would be desirable to let it come into force in 1884. He thought a year or two should intervene, so that all might be prepared for it.

The suggestion by Mr. D. Lees was adopted generally.

The Bill as amended was then approved of generally, and it was agreed to transmit the amendments and suggestions to the Council of the Pharmaceutical Society and to all interested in the Bill.

The meeting then separated.

HAWICK PHARMACEUTICAL ASSOCIATION.

At a meeting of chemists' assistants and apprentices, held in the Chemical Laboratory, on Tuesday, 17th ult., it was resolved, after a short discussion, to form the Hawick Pharmaceutical Association. A constitution having been adopted, the following office bearers were elected:—Honorary President, Mr. Thomas Maben; President, Mr. John Grieve; Secretary and Treasurer, Mr. James A. Hislop; Librarian, Mr. W. B. Rawlinson.

The first meeting of the Association was held on Tuesday, 15th inst., when there was a good attendance. The President, Mr. John Grieve, occupied the chair and, after a few preliminary remarks, briefly introduced Mr. Maben, who delivered the following inaugural address on—

The Pharmacy of the Future.

It was with very great pleasure that I heard of the formation of this Association by the young men connected with pharmacy in Hawick, although that pleasure was not quite unalloyed when you requested me to become its Honorary President. I feel it, however, to be my duty not to shirk the responsibility, and having consented to take the position you so kindly assigned me, it is I presume, in the usual course that we meet to-night to hear the inaugural address, so that in some formal manner the work of the Association may be begun.

The formation of this Association ought to mark the beginning of a new era in the pharmacy of our old border burgh, while its inception will, we trust, be happily coincident with the greater epoch in the pharmaceutical history of the country which, it is hoped, will render memorable the year 1883. In view of the upheaval which is now going on, and which threatens to obliterate some of the old landmarks of our profession, or rather proposes to remove them further out, so that we who are within may have more scope for our energies and more space to breathe, it is pre-eminently fit that you should have seized the present as the opportunity for establishing an Association, the object of which is the pharmaceutic and scientific enlightenment of its members. If pharmacy is to improve its position, the younger men must prepare themselves to be ready to enter in and "possess the land," and no surer means to that end can possibly be made use of than the work of an association such as this. Since 1868, the old order of things, which few of us know anything about, has been rapidly passing away; the present is a time of transition, a probationary period, if I may so speak, and we are now standing on the threshold of the new order which must soon develop itself. What the pharmacy of the future is to be lies absolutely in our own hands, and it is a matter of the utmost concern, not only that the present crisis should be well and safely over, but that the youth among us should be wisely and judiciously trained in view of the time when on them shall have fallen the mantle of those to whom it is given for a season to mould the destinies of the profession. I propose to-night to give you my idea of the pharmacy of the future, but in order that you may have an intelligent appreciation of the whole question, I shall refer briefly to the past, then give a short sketch of what is being done at present, and from these we may be able to forecast what is in store for us.

The passing of the Pharmacy Act of 1868, beyond which we need not go, constituted a most important epoch in the history of pharmacy. Previous to this any person, qualified or unqualified, was at liberty to retail poisons, with what results all of us may readily imagine. The condition of pharmacy was, in the opinion of an eminent member of the Medical Council, a disgrace to the country, and the safety of the public, not to speak of other considerations, urgently demanded reform. The outcome of the agitation which had been going on for many years previous to 1868 was the passing, in that year, of the Act to which I have just referred. This Act was for all practical purposes simply a Poisons Act, though as a necessary consequence it provided for the qualification of those who should be entitled legally to sell poisons. It may be not unfairly summarized as an Act to provide for the registration of all pharmaceutical chemists and chemists and druggists, qualified by examination or otherwise, who alone could legally sell by retail certain specified poisons. These poisons, however, are in such constant requisition by the public, and occur so frequently in medical prescriptions, that the Act practically prevents all unqualified persons from engaging in the business of a chemist and druggist. This enactment, the result of an agitation carried on more or less vigorously for the previous twenty-five years, marks the beginning of what I have already called our present period of probation.

The fifteen years that have since gone by have more than proved that this Act cannot be regarded as a final settlement of the question, and this is just what might have been expected. That from the comparative chaos which previously existed, a perfect cosmos should at the first attempt have been produced was improbable, and it is a gratifying circumstance that the progress already made has been so marked. But though pharmacy occupies a much higher position now than twenty years ago, we are still very far from the goal towards which we may legitimately aspire.

There are several points in which the Act of 1868 has proved defective, and these I shall as briefly as possible indicate.

1. While it is true that the law relating to such poisons as arsenic, strychnine or opium may be stringent enough, there are a class of very dangerous substances which are not, but which ought to be included in its scope. Provision was made in the Act for adding from time to time to the list of scheduled poisons, the ultimate authority in such cases being the Privy Council, and several additions have consequently been made, such as chloral hydrate and nux vomica and its preparations. There still remain, however, a large number of other poisons, *e.g.*, carbolic, hydrochloric, nitric and sulphuric acids, butter of antimony and hellebore, which, although as liable to fatal misuse as any poison in the schedule, are not regarded as poisons by law. Without doubt, every druggist with a reputation to sustain, is careful to label these articles "poison;" but he is under no legal obligation to do so, and any person is at perfect liberty to deal in them to any extent he chooses. In the course of last year, the Council of the Pharmaceutical Society resolved that these articles should be poisons within the meaning of the Act, but the requisite sanction was refused by the Privy Council, the nominal reason being that the change was inexpedient in view of probable early legislation on the whole subject.

2. It is a remarkable fact that a druggist cannot retail solution of morphia without labelling it "poison," while he or any one else may sell it in any quantity under the name, *e.g.*, soothing syrup, provided only there is a patent medicine stamp on the bottle; and whereas a poisonous dose of prussic acid could be got with the utmost difficulty and only after elaborate precautions had been taken, a would-be suicide might obtain from the nearest patent medicine dealer, twenty doses of poison and no questions asked if only he invests in a bottle of somebody's chlorodyne. This is an utterly anomalous condition of things, and one that demands immediate remedy. It is of grave importance that the public should know that when they use certain patent medicines they are handling deadly poisons, but as a rule there is no indication on the labels that this is so, and hence there need be little wonder that repeated deplorable accidents should occur through the lack of proper precautions in this respect. Perhaps it is somewhat out of place for me to refer to this matter here, but I would fain give expression to the feeling of disgust with which every true pharmacist regards the patent medicine trade. Were it not that by keeping it in our hands we can, to a certain extent, restrain the evil, I am certain that very many among us would throw the whole traffic overboard.

3. Another point where the Act has failed is in what I may call personal qualification. Before a person can be duly qualified to open a shop and conduct business he must pass at least two examinations. The first of these is Preliminary, the object being to ascertain whether or not the candidate has received such an elementary education as will fit him for the position to which he aspires, and give a guarantee that he will, so far, be capable of going forward to the qualifying or Minor examination with a prospect of success. In addition to passing the Preliminary the student requires to be engaged for three years in practical pharmacy before he is permitted to attempt the Minor examination. The possession of the Minor certificate is sufficient to qualify a man to keep open shop, but it has been found by experience that a large number of candidates come up to the examination who are not educated, but simply stuffed full of words and phrases and answers to questions. Undoubtedly a certain proportion of these pass the examination in the same way as the turkeys whose crops were loaded with shot took the prizes at a Cumberland show the other day; but alike in the examination and in the show, success is the result of fraud, though in the former case discovery comes too late, the now disgorged examinee being safe with his certificate. But there are one or two particular instances in which the Act breaks down in this matter of personal qualification, independently altogether of what is called "cram." The first of these is branch shops. At the present moment a druggist may have any number of branch shops, and may carry them on by means of apprentices if he choose to do so. For example, any Hawick druggist might open shops in Melrose, Jedburgh or Galashiels, and put mere boys in them, and no one could interfere with him, even though he were in them only once a month. This would be a palpable evasion of the law, and yet the detestable system is carried on to a very large extent. Again, there is a second and quite a common case, where an unqualified person opens a druggist's shop and borrows for the signboard and labels the name of a qualified pharmacist or even of a medical man, though the latter may have no connection whatever with the business, save perhaps that he draws a few pounds per annum for the use of his name! There is still a third case in which the law is being systematically evaded in certain parts of the country. A number of unqualified men form themselves into a company, open a shop, and employ a qualified assistant, whose name is printed on the labels, though he is in no sense the owner of the business, but simply the servant of the company; and while this is undoubtedly a violation of the spirit of the Act, the courts of law have decided that it is not out of harmony with its letter.

Fortunately, we here are free from any such equivocal methods of construing the Act; we do not ourselves indulge in the doubtful luxury of branch shops, nor are we harassed by the undue competition of unqualified traders. Not a prescription is dispensed in town save by one or other of the druggists, and enjoying, as we do, the confidence on the one hand of the medical profession, and on the other of the public, we may fairly conclude that we are quite as well off as most of our brethren, and that our lives have certainly not fallen to us in unpleasant places.

4. When the Act was passed the Pharmaceutical Society was appointed to carry out its provisions. Two classes of pharmacists are eligible for the membership of the Society, those who were in business before 1868 and those who pass the Major examination. All others, *i.e.*, those who pass the Minor examination, are eligible as associates, the practical difference between member and associate being that the former only can occupy positions of honour and responsibility in the Society. As a matter of fact the one is as good as the other in the eyes of the law, in so far as his ability to conduct a business is concerned. It has been found that relatively to the number who enter the profession, too few go up for the Major examination, and the inevitable result is, or will by-and-by be, that the governing body of the Society will be very much out of proportion to the remainder, who are already in a large majority. This certainly was not contemplated in 1868, the idea rather being that quite a large number would take the higher qualification. In this respect the framers of the Bill "reckoned without their host," as the percentage of Major passes has, during the past few years, been miserably small, and, therefore, it is clear that the Act requires amendment in so far as the constitution of the governing body is concerned.

If I have dwelt on some lengths on these points, it is only that you may be in a position to understand clearly the drift of a new Bill which has been framed by the Council of the Pharmaceutical Society, and is about to be introduced into Parliament, as well as any comments I may make concerning its provisions. Regarding these, the most diverse opinions have been expressed, but no more weighty utterances have been published than the addresses of Mr. Giles and Mr. Frazer delivered some six weeks ago, the one in London in defence (so far), the other in Glasgow in condemnation of the Bill. The former took up the position that the Bill is the logical conclusion of all our past efforts, and if we know our own minds, we are bound to hail it with delight and enthusiasm. Mr. Frazer, on the other hand, entered into a caustic criticism of what he seems to think is the culmination of a long series of errors, and urged that members should, at the Annual Meeting, demand its immediate withdrawal. It is somewhat difficult to understand how any two men can hold such diverse opinions on the same subject. Here are two leading pharmacists, equally high in the profession. both able and eloquent, both earnest and eager in their endeavours to promote the welfare of their brethren and their craft, and yet when a measure is brought forward with a view to the settlement of some disturbing questions in connection with the latter, we find the opinion of the one diametrically opposed to that of the other. This seems strange at first sight, but it ceases to be so when we remember that parallel cases may be found every day in our political, social, and even theological life. The curious thing is that in this instance the natural order is reversed. Mr. Giles seems to represent what I may call the Conservative side of pharmacy, yet he strongly advocates progress and reform, whilst Mr. Frazer, whose tendencies are of a distinctly Radical type, goes in as strongly for the *status quo*, forgetful, apparently, that—

"Progress is nature's unexcepted law,
Stagnation is an universal curse."

The Bill consists of twenty-three clauses, together with a schedule of poisonous articles, and without going into a separate examination of each clause, I shall briefly indicate the main features.

1. *Poisonous Articles.*—The previous Pharmacy Acts took cognizance only of "poisons," but this Bill introduces, in addition to these, a number of "poisonous articles." The appended schedule of these consists of sulphuric, hydrochloric, nitric and carbolic acids and butter of antimony. The Bill requires that each of these shall be labelled with its name, the word "poisonous," and the name and address of the seller. Their sale is not confined to pharmacists; any person may deal in them, provided they are duly labelled as above.

This provision seemed to me at first sight to be a mistake, but I find a difficulty in suggesting any change if we are not to allow matters to remain as they are. The safety of the public demands that something should be done with reference to these articles, and since the Privy Council has declined to place them in the list of scheduled poisons, the next best course is to take the utmost precautions possible in order to prevent calamitous accidents, and I am therefore compelled to conclude that the framers of this clause have really chosen the least of several evils.

2. *Patent Medicines.*—All patent medicines containing poisons within the meaning of the Pharmacy Act, 1868, must "be labelled with the name and address of the first seller, the name of the patent medicine and the word 'poison.'"

To most minds this would seem to embody, what I may call, a self-evident proposition, but there will no doubt be a few individuals who will, with the patent medicine proprietors, oppose it tooth and nail. Mr. Frazer is one of these exceptions, and though he has not a shred of argument to advance in support of his position, he is loud in his protest against what he calls the assimilation of our laws to those that obtain on the continent. For my part, I am of opinion that the time has now arrived when an effort should be made, in connection either with our own Bill or the Medical Bill, to "assimilate" at least to this extent, viz., to make it compulsory for all proprietors of patent medicines to publish the formulæ of such, or at all events to submit them to some authorized body.

Whilst I heartily agree with the principle of the clauses, I freely admit that the subject is a difficult one, and I certainly think that better means for recovering the penalties might be devised, as it is obvious that the process provided for in the Bill will render litigation exceedingly tedious, expensive and annoying. This portion of the Bill will probably not pass without alteration, more especially if the motion of which Mr. Sandford has given notice for the Annual Meeting receives anything like strong support. In the event of the Bill becoming law as it stands, I would not hesitate to label any patent medicine with the word "poison" should there be the slightest suspicion that the first seller was evading the law.

3. *Prescriptions.*—By the Act of 1868, the only articles of which the sale was confined to pharmacists, were poisons. The new Bill proposes to include physicians' prescriptions in this restriction, so that no one shall be allowed to dispense them, save properly qualified pharmacists, and also, of course, medical men.

In my opinion, the change here proposed is superfluous. At present we have comparatively little to complain of in this respect, and if the remainder of the Bill becomes law, there would be small chance of much harm to the public, seeing that the amount of illicit dispensing would be reduced to a minimum.

4. *Branch Shops.*—Every branch shop must be conducted by a duly qualified assistant.

Every keeper of an open shop shall be liable for his assistants and apprentices; the latter being deemed to be the agents of the seller on whose behalf the sale is made.

5. *Companies.*—The shareholders of companies keeping

open shops must, as proprietors of said shops, be duly qualified, failing which they are liable to a penalty. This is not stated in so many words, but is the meaning of the legal phraseology employed.

To all of these provisions I give my hearty assent, as they embody the principle of personal qualification, which the 1868 Act in some instances has failed to secure.

6. *Preliminary Examination.*—This must be passed previous to apprenticeship, and any pharmacist who shall take as an apprentice a person who has not so passed, shall be liable to a penalty. The Bill also seeks extended powers with reference to the other examinations, and in this connection I may say that the Council of the Pharmaceutical Society has resolved to require evidence of a regular curriculum of study at some recognized school or university from all candidates for the Minor examination after a certain date.

Generally speaking, this meets with my warmest approval and support. Some time ago I made a note of all the young men whom I have known personally in Hawick as apprentices. There were in all fourteen, not including those who are still here. Of these fourteen, two passed the necessary examinations and are now in business. Three are engaged as assistants, but have not yet passed the Preliminary examination, and one has emigrated. Of the remaining eight, one passed the Preliminary during apprenticeship, but owing to ill health took up another occupation; while the other seven who had not passed have each and all left what to them could never be anything but the "trade." Now these statistics point their own moral, and prove more conclusively than any amount of argument, the desirability, if not the absolute necessity of this provision. Had it been in force since 1868, all these young men would have required to attempt the Preliminary before apprenticeship. If they had failed there would have been an end of it, and some of their best years would have been spent in other walks of life; if they had passed (as most of them doubtless would), instead of 50 per cent. leaving the *trade* because they could never reach the *profession*, we would have had 50 per cent. of them fully qualified men. I somewhat fear, however, that the penalty clause will be found to be unworkable. A druggist who wished to evade it could do so with the utmost ease by simply making an arrangement whereby the apprentice would be styled the message boy, while on the other hand many conscientious pharmacists, who desire to do their duty towards their apprentices, but have a difficulty in obtaining them, will hardly thank the Legislature for hanging the sword over their heads in this fashion. The desired end would in most cases be obtained by adopting the recommendation made by the Council's Committee last year, viz., requiring three years' attendance in a shop after the Preliminary is passed, before the candidate is eligible for the Minor.

7. *Membership of Pharmaceutical Society.*—All chemists and druggists, as well as all pharmaceutical chemists, shall be eligible for membership of the Pharmaceutical Society; and further, every person who shall pass the qualifying examination after December 31, 1886, shall be entitled to be placed on the Register of Pharmaceutical Chemists.

As I have already indicated, the former of these provisions is rendered necessary on grounds of policy, and it is almost certain to meet with unanimous approval. The latter will tend to abolish in course of time the unnecessary distinctions among pharmacists, while it does not bind the Society not to have an honorary title should such be desired.

This completes the hurried review of the present aspect of things, and more especially of the Bill which every true pharmacist hopes soon to see on the statute book of the country, and there now only remains for me time to indicate in a sentence what, in my opinion, are likely to be the characteristic features of the pharmacy of the future.

In the first place, the pharmacy of the future will be in the hands of a uniform body of highly educated men, a statement the truth of which is so self-evident that I need not enlarge upon it. As a natural consequence, these men, by virtue of their higher education, will possess, more than this generation does, the confidence of the medical profession. For our part, we in Hawick are well off, as I have already shown, and the same remark may be applied to Scotch druggists generally; but things are different in many districts in England, where the druggists are regarded by the medical men with suspicion,—a suspicion, I fear, sometimes not unwarranted. This increase of confidence will have the effect of diminishing dispensing by the medical men, while the increase of education will tend to diminish prescribing by the druggists. It will generally be found to be the case that the pharmacists who know their own profession best, are least ready to intrude on the domain of the doctor; and so long as we have a class of druggists who have "a little learning," just so long will we have this "dangerous" system of counter prescribing pursued. It is an everyday experience of all of us that the man who pretends to know all about his neighbour's trade knows little about his own, while the converse is equally true. Again, the pharmacist of the future will, as an educated man, command the respect and confidence of the public, who rarely fail to know a genuine article when they see it.

All these conditions will, by a process of natural selection, inevitably tend to bring about a pure pharmacy, where there shall be no taint of the grocer, drysalter, or oil and colour merchant. It is impossible to be perfect in two or three businesses at the same time, and the sooner a regular divorce is brought about, by which pharmacy will "come out from among them," the better will it be for all concerned. Finally, we shall have a great and united Pharmaceutical Society, truly representative of the educated pharmacists of the country. This will give pharmacy a position and power that it has never yet possessed, divided as it has been into several different parties, each of which has "its own hatchet to grind." It is only by uniformly raising the standard of education and qualification that all these sections can by-and-by be fused into one mass.

And now, perhaps, you will ask me what all this has to do with our Association? It has to do with it and with us to this extent, that it shows us we have a history behind us, and the possibilities of a great future in us. It is not for us, the "heirs of all the ages," to decline the responsibility which the present brings, and the remembrance of what has been done in the past will help to nerve us to do our duty in and for the future. This Association, if modestly carried on and kept faithfully in the lines laid down in its constitution, will do something towards bringing about the state of matters I have tried to depict; and even if its original members fail to see the ultimate triumph of the cause of progress and reform, they may rest assured that their labours will not have been in vain.

A vote of thanks having been accorded to Mr. Maben, on the motion of Mr. Dechan, seconded by Mr. J. A. Hislop,

Dr. Penman, on the invitation of the Chairman, expressed the pleasure with which he had listened to Mr. Maben's address. The medical men, he said, ought to be interested in a society of this nature, as they had to depend entirely on pharmacists for the proper treatment of their patients. He did not know much about dispensing, all that he had learned during a three months' course at a pharmaceutical chemist's having been to make a few seidlitz powders. He might say that in Hawick there was no dispensing done by the medical men, and he thought that the two things should be kept entirely separate. He was much pleased with the strong remarks made regarding patent medicines, and thought the Government should insert in the Bill very strong provisions against the selling of these. Many diseases were caused and many were much aggravated by injudicious mothers giving these medicines to their children.

Mr. Maben, in reply, hoped that every member would try and do something to further the interest and usefulness of the Association. They should not go too far afield for subjects, but take those near at hand.

After a number of gentlemen had been proposed as honorary members and members, the Secretary intimated that the library would be opened on June 6, and that the next meeting of the Association would be held on June 12.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The ordinary monthly meeting was held in the Society's Room, Market Place, on Wednesday evening, May 9. In the absence of the President, the chair was taken by Mr. G. Carr, Vice-President, when a paper was read by Mr. E. R. Learoyd, entitled "Notes on the Organs of Vision."

Mr. Newsholme proposed, and Mr. Furness seconded, that the best thanks of the meeting be given to Mr. Learoyd for his interesting and valuable paper, which was carried unanimously.

MEETING OF CHEMISTS AND DRUGGISTS AT LEICESTER.

On Thursday, May 3, a meeting of the chemists of the town was held at the Masonic Hall, to discuss the proposed Pharmacy Bill.

Mr. W. Thirlby was voted to the chair, and in a few preliminary remarks, explained the reasons for calling the meeting and the nature of the business to be brought forward.

Mr. W. B. Clark then gave a very able *résumé* of the proposed Bill, calling special attention to the clauses dealing with the labelling patent medicines "poison," and the peculiar position a retailer would be placed in through any inadvertence on the part of the original vendor.

A long and interesting discussion ensued, and ultimately the following resolution was carried unanimously:—"That this meeting approves generally of the Pharmacy Act Amendment Bill, but specially wishes to point out that clause 4 may prove injurious to some proprietors of patent medicines, in cases where the quantity of poison in the whole package is very small."

A hearty vote of thanks to Mr. Clark for his paper, and to the Chairman for presiding, brought the meeting to a close.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 10, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. H. S. Elworthy read a paper upon "Acetic Acid and its Derivatives," in which a detailed account of the constitution of acetic acid was given and also of its more important derivatives. The action of various reagents upon acetic acid was fully entered into, and the constitution and properties of the compounds thus produced were fully described.

A discussion followed the reading of the paper, in which the Chairman, Messrs. Baily, Cripps, Crow and Ranken took part.

A vote of thanks was passed to Mr. Elworthy.

Mr. R. A. Cripps, the Reporter upon Practical Pharmacy, then read some—

NOTES ON THE UNITED STATES PHARMACOPŒIA.

This subject was treated botanically, pharmaceutically and chemically, the sources of official drugs being discussed, and the various chemical tests and pharmaceutical operations criticized. The chief points of interest in the Pharmacopœia were gone into, such as the preparation and composition of abstracts, fluid extracts, etc.; the use of glycerin in tinctures, fluid and solid extracts; the preparation of unofficial infusions, decoctions, etc., for which formulæ are given under the various series of preparations; and the use of oil of theobroma for suppositories instead of the B.P. basis. Observations were made upon the more important drugs, with special reference to the following:—Cinchona, conium, elaterin, balsam of Peru, citrate of iron and quinine, aloes, digitalis, jalap and asafœtida. The paper also included the following:—

Note on the Estimation of Water in Carbolic Acid.

The United States Pharmacopœia states that if a definite volume of carbolic acid be mixed with an equal volume of chloroform the water will rise to the surface and will represent the percentage of water present.

The following experiments were made with the object of determining the value of this test.

1. A solution of carbolic acid was made containing 20 per cent. of water. 450 parts by volume of this were taken and mixed with 450 parts of chloroform. On standing till the water had completely separated (which was about sixteen hours) only 63 parts were obtained, corresponding to 14 per cent. of water.

2. One hundred parts of 50 per cent. carbolic acid were shaken with 100 parts of chloroform and yielded 44 parts of water, corresponding to 44 per cent.

3. Ninety-five parts of carbolic acid were mixed with 5 parts of water and 100 parts of chloroform added and well shaken; a perfectly clear liquid resulted, with not the least separation of water.

4. The same experiment was repeated, using carbolic acid containing 8 per cent. of water; a clear solution resulted, from which no water separated after fourteen hours.

The addition of a very small quantity of water to the last solution caused a cloudiness, and after a time the separation of about ·5 per cent. of water.

From these experiments it will be seen that the method is quite useless, an acid containing as much as 8 per cent. of water being passed as pure.

In the discussion that followed, the Chairman, Secretary, Messrs. Crow, Ranken and Ransom took part, after which the meeting adjourned.

Parliamentary and Law Proceedings.

POISONING BY LAUDANUM.

On Tuesday an inquest was held by Mr. Hawkes, Birmingham borough coroner, at his court, Moor Street, on the body of Margaret Mycock, aged 54 years.

The deceased's daughter said for the past three months her mother had suffered from bronchitis and rheumatics, and could not sleep at night. Last Friday night deceased directed witness to fetch her a pennyworth of paregoric and a pennyworth of laudanum, which she drank. Witness had fetched the same kind of poison for her on two previous occasions, and about two months ago she purchased some from Mr. William Henry Reedman, chemist, of 404, Monument Road. When she obtained it she was not asked either her name or residence, neither did she sign any book. Witness did not tell the chemist what she wanted it for.

The Coroner: Do you mean to say that you, a perfect stranger, go to a chemist's where you are not known, and there purchase a pennyworth of laudanum and a pennyworth of paregoric without being asked anything about it?—Yes, sir.

And the chemist puts a poison label upon the bottle. Is that what you mean to say?—Yes, sir.

Last Friday you went again to the shop, and got another bottleful.—Yes, sir.

Witness added that she put the contents of the bottle into some water, and deceased drank it at about 10 o'clock the same night. Deceased took the same quantity when it was bought for her two months before. In half-an-hour after that she went into her room and found that deceased was unconscious. From that time to the time when the doctor came she did not regain consciousness. They made no effort to get a doctor during the night, because they thought she was sleeping.

Evidence of a similar character was given by one of the sons of the deceased, who also stated that deceased's friends would be entitled to about £11 4*s.* from an insurance office in consequence of her death.

Mr. Leech said he had attended the deceased in April last, when she was suffering from bronchitis, Bright's disease and rheumatism. When he saw her at about 1 o'clock on Saturday morning she was in a state of coma. Altogether she had taken 6½ grains of opium, which was therefore dangerous. He endeavoured to restore animation, but failed, and deceased died shortly after 2 o'clock. He did not think, even if prompt means had been taken, that she would have lived, because of her diseased condition.

Mr. Reedman, the chemist from whose shop the poison was purchased, said the laudanum and paregoric were served by his assistant. He had conformed to the Act regulating the sale of such drugs by putting a label on the bottle stating that it contained poison.

The Coroner said he simply wished to know whether there had been any irregularity in the selling of the poison.

The Coroner summed up, and the Jury returned a verdict "That death had been caused through misadventure."—*Birmingham Daily Post.*

Review.

Notes and Statistics of Cinchona Bark. By John Hamilton. London: J. W. Collings.

This little pamphlet of seventeen pages professes to give rough statistics of the importation of cinchona bark into some of the leading European countries and into the United States. The compilation of tables of statistics might appear, at first sight, to be an easy matter; but there are so many possible sources of error, and so many difficulties in the way of obtaining information, that the author may be congratulated upon being able to obtain even rough statistics on so complicated a subject as the commerce of cinchona bark. Mr. Hamilton has evidently taken much pains to collect reliable information, yet he has been unable to obtain any account from Spain and Austria; from the latter country because all importations of drugs are classed under one heading. There must naturally be much difficulty in making divergent accounts from different sources agree, and hence it can hardly be wondered at, that the statements on page 6, of the amount of cinchona bark exported in 1881 from England to France and the United States does not agree with that of the quantity imported from England in the same year by those countries, on pages 10 and 11. This is more especially the case when one is at the mercy of printers. Thus in a foot-note on page 6, Mr. Hamilton remarks that he received the following reply anent the Table A, when making inquiries as to the difference between statements obtained from the Board of Trade and others published in the *Ceylon Observer*:—

"The Board of Trade monthly accounts only give approximate quantities and value; the great difference in the values of 1878 arises from a printer's error in the monthly accounts."

Nevertheless tabular statements are always of considerable value, if even only approximately correct, and must of necessity afford abundant food for reflection. Thus the conclusion is arrived at that England is the chief market of the world for cinchona bark, and the value of its importations is shown to have increased from £218,565 in 1870 to £1,816,501 in 1881. Although more than half of the imports are again sent out of the country the value of the exports is less than that of the portion retained, indicating that the best cinchona barks remain in Great Britain. It is also an instructive fact that the value of the imports of East Indian Barks has increased from £22,682 in 1876 to £248,894 in 1881.

Comparatively little is said concerning the West Indian barks, these having only entered into commerce within the last few years. There could, however, be no difficulty in obtaining information from Jamaica under the present active administration of the Botanical Department. So far as can be gathered from the tables, it would appear that most of these barks find a market in the United States.

Another singular fact revealed by these statistics is the speculation which takes place in the cinchona market. The variation in the price of quinine, of which 6*s.* 6*d.* in 1875 and 13*s.* in 1878 may be taken as examples, has led to frequent interchanges of bark where least expected. Thus England has imported cinchona bark from France and Germany, although it has sent back in the same year more than it received. America also has imported cinchona bark from twenty-eight different countries, instead of only from those which produce it.

It is interesting to note also that while the Java bark received in Amsterdam in 1881 amounted to only 268,540 lbs., in the same year 1,864,912 lbs. of East Indian bark was imported into the United Kingdom. The care taken in the cultivation indirectly comes out in the fact that the Java *Ledgeriana* bark has steadily increased in percentage of quinine from the maximum percentage of 5·48 in 1872 to 9·00 in 1881. There are many other important facts and much useful information afforded by this little *brochure*, which should be in the hands of every one connected with the cinchona trade.

It may be hoped that in a second edition the author will be able to add some tables of the respective values of the different varieties of cinchona barks, such as would give to planters same idea as to the species which would pay best in cultivation, and as to the country which would afford the best market for special varieties.

Obituary.

Notice has been received of the death of the following:—

On the 5th of April, Mr. Felix Padman Hubbard, Chemist and Druggist, Walsall.

On the 23rd of April, Mr. Richard Morgan Evans, Chemist and Druggist, Porth, Rhondda Valley. Aged 39 years.

On the 23rd of April, Mr. William Walpole, Chemist and Druggist, White Lion Opening, Great Yarmouth. Aged 75 years.

On the 24th of April, Mr. John Maitland, Pharmaceutical Chemist, Chester Place, Hyde Park Square, W. Mr. Maitland was one of the Founders of the Pharmaceutical Society.

BOOKS RECEIVED.

Kommentar zur zweiten Auflage der Pharmacopœa Germanica, nebst Uebersetzung des Textes sowie einer Anleitung zur Massanalyse. Zum praktischen Gebrauche bearbeitet von O. Schlickum. Leipzig: Gunther. 1883. From the Publisher.

Proceedings of the American Pharmaceutical Association at the Thirtieth Annual Meeting. Philadelphia: 1883. From the Association.

Address on the Treatment of Pulmonary Consumption, with a Note of a Visit to Davos-Platz. By Dr. M'Call Anderson. Glasgow: Maclehose and Sons. 1883.

Disease and Putrescent Air. By Thomas Rowan. London: E. and F. N. Spon. 1883.

Dispensatory of the United States. By Dr. Geo. B. Wood and Dr. Franklin Bache. Fifteenth edition, re-arranged, thoroughly revised and largely re-written. By H. C. Wood, M.D.; Joseph P. Remington, Ph.G.; and Samuel P. Sadtler, Ph.D., F.C.S. Philadelphia and London: Lippincott and Co. 1883. From the Publishers.

Materia Medica. A Manual for the Use of Students. By Isambard Owen, M.D. London: J. and A. Churchill. 1883. From the Publishers.

The Professors and the Pharmacopœia.

Sir,—So far as I know, our own and similar corporations cannot afford to, and do not retain the whole of the time and services of professors. That being so, our Council, in expecting our Professors to announce an engagement with the Medical Council, expected what might amount to disloyalty to the latter Council, a fault which the long services of our Professors forbid us to assume they possess.

As to any unofficial intimation of their appointment, not only have we now their own statement that they were not at liberty to mention it, but I hear on indisputable authority, that for ordinary business reasons, unconnected with pharmacy, the editors were requested not to anticipate the Medical Council in the announcement.

The anger of Mr. Schacht, the sadness of Mr. Hampson, and the *non-sequiturs* of Mr. Symes may be disregarded; but I am sure that Mr. Young and others at the last Pharmaceutical Council Meeting, would not have said what they did, had Mr. Greenish, in reading what he termed the words of the Report of the Pharmacopœia Committee, read the whole of those words, those in which the Medical Council state that they will themselves communicate with the Pharmaceutical Council. Besides, personal charges by our Council against those they employ should be made in committee, and with reasonable opportunity for defence, and only published, if at all, after the most rigid scrutiny.

I think an apology is due to our Professors for this publication of such ill-founded defamatory censure.

We are, in my opinion, distinctly nearer to pharmaceutical representation on the Pharmacopœia Committee than when no pharmaceutical officer was editor, and nearer than when only one pharmaceutical professor and one other expert were editors. Let us be careful to avoid alienating by unjustifiable reflections the goodwill of three pharmaceutical officers of the Pharmacopœia Committee who have shown that they sympathize with our aspirations as regards pharmaceutical representation on that Committee, and whose loyalty to the Pharmaceutical Society is shown by all their public acts during the past twenty to forty years.

It would have struck me that not only the Council, but the whole of our body of all grades, would have been jubilant at the appointment of our Professors to these offices or functions, an appointment shedding indirect recognition of our claims for fair consideration in this important national work.

280, *Walworth Road, S.E.* Wm. Fred. Smith.

Sir,—When we consider the nature of the work which has to be performed in compiling a new edition of the Pharmacopœia, and the important interests which chemists have at stake while the chains which, in future, are to fetter them are being forged, it is not surprising that a neglect upon the part of the Medical Council to provide due representation upon the Revision Committee should cause a feeling in our ranks somewhat akin to indignation.

The advantage of employing Professor Redwood as Scientific Editor of a new edition of the Pharmacopœia was demonstrated very clearly in the issue of 1867 by comparison with the original British Pharmacopœia of 1864. Consequently, no one can be surprised that the Medical Council should seek to follow up so manifest an advantage by adding the remaining two Professors connected with our school to his staff. Such a course is obviously necessary to prevent a repetition of the unscientific blunders contained in the original edition, and to render the new one as perfect as possible in the present stage of scientific advance; and every chemist will heartily welcome this well-deserved recognition of our able Professors' merits. But surely it is unjust to stop there, for it was fondly hoped that the time had now arrived when the position of the legally qualified chemist would be recognized fully, in that he being engaged in applying his knowledge in a practical form upon the various preparations contained in the Pharmacopœia was indispensable as the element of actual experience in any future Committee of Revision which was formed under a new Act of Parliament.

The question is, Have chemists an interest in the Pharmacopœia? It would be idle to contend for a moment that they had not. If so, it must follow that the only way to secure legitimate interest is by adequate representation. And I venture to ask my fellow chemists "Are they satisfied to be represented by the Professors of our school only?" I will yield to no one in my appreciation of the gentlemen to whom, personally, I owe so much, but I refuse to admit for one moment that such an established body as is represented by the Pharmaceutical Society has received fair play at the hands of the Medical Council by their appointment, especially as it seems to me to have been effected behind the backs of its representatives. I was pleased to see the letter signed by the Professors repudiating any share in the transaction prejudicial to the Society's interests, and, I honestly believe, notwithstanding that in my humble judgment it would have been better for those interests if the Pharmaceutical Council had been made aware of the negotiations while they were being conducted, that our Professors would not in any way knowingly compromise the least of our interests, for it would be a poor compliment to their past labours if after all their years of pupilage no greater advance could be granted to their pass men than merely to stand on one side and see them do the work. What a future! What a relation to exist between Pharmacy and the State!

But I am thankful to see from the discussion which took place at our last Council that this matter is not to be allowed to drift, and that prompt measures will be taken to assert our claims. Let us country members also do our share and further the petitions to the utmost of our ability, for if we fail, pharmacy will sink from her position of handmaid to become the very slave of the medical profession.

Mardol, Shrewsbury. W. Gowen Cross.

"*Edina.*"—(1) *Chrysosplenium oppositifolium*; (2) *Anemone nemorosa*; (3) *Luzula sylvatica*; (4) *Doronicum Pardalianches*, probably: send it when in flower.

J. E. S.—The preparation appears to be a proprietary one, and we do not know that the formula has been published.

O. R.—No, he cannot do so legally.

G. F. Cock.—A little mucilage of acacia added before the liq. quin. ammon. will keep the alkaloid suspended in a minutely divided condition.

Communications, Letters, etc., have been received from Messrs. Deck, Newsholme, Southall, Stark, Pharmacist, Inquirer, Rheim, Quercus, and Querist.

THE ANNUAL DINNER.

The Annual Dinner of the members of the Pharmaceutical Society and their friends was held on Tuesday Evening, at Willis's Rooms, St. James's, and was very numerously attended. Thanks, however, to the introduction of the electric light, in the incandescent form, in the chandeliers, the temperature of the banqueting-hall was appreciably lower than attendants at this festival had been accustomed to. The Chair was occupied by Mr. Michael Carteighe, President of the Society.

Grace having been sung—

The PRESIDENT proposed "The Health of the Queen," which was drunk with the usual loyal enthusiasm; as was also

The next toast, "The Prince and Princess of Wales, and the rest of the Royal Family."

The third toast was rather an innovation at these meetings, being "The Houses of Parliament," proposed by the PRESIDENT, who remarked that it was generally understood that in those elevated regions there was so much time spent in talking that there was very little left for thinking. As speaking, therefore, was essentially the function of members of the House of Commons, he would leave the speaking to the gentleman whose name he would couple with the toast—Mr. McCullagh Torrens.

MR. MCCULLAGH TORRENS, M.P., said it was but seldom that any gentleman who had the honour of responding to such a toast addressed such a truly representative assembly as the one he saw before him. He felt the responsibility which attached to him as a member of the House of Commons, but he must say that increasing years and experience in Parliament in no way led him to wish that that sense of responsibility should be lessened. On the contrary, he felt the responsibility of his position more and more, and never lost the opportunity of seeking counsel and advice from those with whom he came in contact as to the due discharge of the duties which devolved upon him as a member of the Legislature. Measures of great importance to the public interest were constantly coming forward, and he understood that the House of Commons would shortly be asked to discuss in the interests of the medical profession and the public at large a new Medical Bill, to which he had felt it his duty to give some attention. He must say he was somewhat struck in reading over its clauses to find that no mention was made of the body which he now had the honour of addressing, and especially with regard to the preparation of the Pharmacopœia, which, it seemed to him, ought to be a *résumé* of the advancement of science in that particular department, and that unless it were so it must fall behind the requirements of the day. In the preparation of the Pharmacopœia it seemed to him that pharmacists were specially interested, and were specially qualified to take part; and he could only say that in the House of Commons they never ventured on an opinion on any scientific question without calling in the assistance of experts and practical men. He understood that some petitions would be presented in connection with this matter; and though petitions might be lightly esteemed by some people, he would remind them that though the weight of a snowflake was almost inappreciable, the effects of a snowstorm were by no means to be despised.

The PRESIDENT next proposed "The Lord Mayor, the Sheriffs and the Corporation of London." He said he had been informed that this toast ought properly to have been divided, as the Sheriffs represented the county; but by the gracious permission of the Lord Mayor and the Sheriffs, the two toasts would be proposed as one. Some of the earliest combinations of Englishmen for self-protection were to be found in the ancient city of London, and in very early times the great guilds united either to assist the Sovereign or in some cases to resist his encroachment. He would prefer, however, as a pharmacist whose occupation was a very sedentary one, to speak of the great benefits which had been conferred on the whole of greater London in recent times by the Corporation, in being the means of preserving open spaces around the metropolis. The man who after long confinement wanted to feel the turf under his feet, could go to Epping Forest, or Burnham Beeches, or Coulsdon Common, or some other place which had been preserved to the public by the public spirit of the Corporation. He might remind his country friends, who were not so directly interested in these local matters, that the people of London were solely indebted to the public spirit and liberality of this great Corporation for the opportunities they had of enjoying these open spaces; and for this reason, if for no other, he had no doubt the toast would be received with acclamation.

The LORD MAYOR, in responding said, after some few months of experience, he had come to the conclusion that wherever the Lord Mayor happened to show his face, it was expected that the sound of his voice should be heard. He only wished that he could find something fresh to say, but his ideas were naturally led in the direction of the company he had the honour to address, and probably a large section of those he saw before him would expect him to give them a long dissertation on the qualities of certain drugs, and the effects which might be obtained by the admixture of certain essences. He feared, however, if he trespassed on the ground be should be somewhat in the position of the little girl who, when her companion said they had had rhubarb pie and that the rhubarb was grown in her own garden, replied that she also had had rhubarb pie, but that her's came from Turkey. Another section might expect him to enter into a learned dissertation on the art of surgery, and that he would unveil the whole mystery of taking the human heart from the body, cleansing it from all impurities, and setting it to work. But he did not propose to trouble his hearers with either of these subjects, though he was quite convinced that if a Lord Mayor was expected to do so he should have to do it. Only a few weeks since he had the pleasure of dining with the Royal Academy, and there, in returning thanks for the same toast, he had to call attention to the fact that the first Royal Academy owed its existence to the fostering care of the Corporation of London. The Paper Stainers' Company constituted the first Royal Academy, and all the great painters of the time were freemen of that Company, and from that Company at last the Royal Academy was established. It was something similar with regard to the Pharmaceutical Society, which might be said to have owed its origin to the Apothecaries' Company of London. When that body began to practise medicine it was found necsssary that there should be a real Pharmaceutical Society, and hence one was established. The President had been good enough to refer to the past history of the Corporation; he would not presume to go into that subject, for if he did the time at his disposal would not enable him to deal with anything like all the good works it had performed. With regard to the preservation of open spaces, though some of these were a considerable distance from the metropolis, they felt that they were legislating for posterity, and that the time would come when those who came after them would bless the old Corporation of London for having in its foresight taken care to secure those places for their use which, though now far removed, would then be surrounded by the busy haunts of men.

Mr. Sheriff SAVORY in responding, said the Lord Mayor had responded for the ancient corporations, but the institution which he represented was far more ancient. Being a company of pharmacists who were accustomed to follow their motto, "*Habenda ratio valetudinis*," they would understand the blessings of health and would not expect him to make a long after-dinner speech. If, however, it were necessary to show the connection between the sheriffs and the Society it would not be difficult to do so. The sheriffs of London and Middlesex were two pharmacists, inasmuch as they maintained law and order, which contributed more than anything else to the health and welfare of any state or city. It was not necessary for him to refer to the well-known maxim, *Salus populi suprema est lex*, to prove that the welfare of the people must always depend on the maintenance of that order which the sheriffs were appointed to secure.

The VICE-PRESIDENT, in proposing "The Health of the Learned Scientific Societies," said the historian of the nineteenth century would remark one thing particularly, that in the latter half of it there was no lack of scientific research. He would notice the extraordinary activity in scientific investigation which was one of its principal features. In past ages there had been many remarkable men, great geniuses, who had struck out original paths, such as Galileo, Newton, and, in later days, Darwin and Pasteur; but the great contrast between the past and the present was this: the great thinkers of the past threw out their ideas on somewhat barren soil, inasmuch as there were no scientific societies to take part in them, and in many cases they were long years before their ages, and often had to suffer ostracism from the orthodox of society. But in our own day, no sooner did Darwin suggest his great thought of evolution, or Pasteur that of life from germs, but immediately a Tyndall, a Huxley, and a host of eminent workers took up these great thoughts and worked them out in manifold forms. There was not an atom of matter in the heavens above, or in the earth beneath, or in the waters under the earth, that science did not investigate. If there was a trace of 1 ad in Saturn, or the slightest smell of sulphur about Mars, or the faintest possible tinge of tender emotion in Venus, the scientific chemists would immediately show it in delicate colours by spectroscopic investigation. Savants went forth as challengers to the deep, deep sea, and called upon it to yield up its secrets. All this was not simply for the dignity of man, or to ennoble his reason, or to grace his home, but it had a strictly utilitarian aspect. Except the highest form of moral science, there was nothing in the world which had done so much for man as science. By the lessening of human pain and suffering, they showed the truest form of the international and the wisest form of communism; and in all these matters pharmacists were deeply interested. They claimed to be most anxious and interested observers of the work of scientific men; and he was quite confident the toast would be well received, especially as he had leave to couple with it the name of a gentleman of very great eminence in original research, one of the Past-Presidents of the Chemical Society and the present President of the Institute of Chemistry, Dr. Odling.

Dr. ODLING, F.R.S., said if he felt incapable of replying adequately to the toast which had been proposed in such flattering terms he should only confess a feeling which men far more worthy than himself would feel if placed in a similar position. He spoke in the presence of a past president of the British Association, and he must say that to respond adequately he should have to embody the substance of five presidential addresses, and even then he should fall short of the subject. He ought indeed to trouble them not only with five past addresses, but with the quintessence of the addresses of the fifty-two past presidents of the Association, and further to derive from his inner consciousness what the fifty next presidents were likely to say; he must, therefore, withdraw from a task which he felt to be insurmountable, and content himself with replying in a modest way to the good feeling which had been expressed by the Vice-President. Speaking with all seriousness it did seem to him that in a large gathering like that it was not unfit that there should be some recognition of the mutual ties and obligations which subsisted between the learned societies, whose fundamental aim was the advancement of human knowledge, and bodies like the Pharmaceutical Society and the Institute of Chemistry, of which he was the unworthy president; bodies which were devoted mainly, though not exclusively, to the professional applications of knowledge. He might remimd them of some words of wisdom spoken by Sir William Siemens at Southampton, in which, after paying a just tribute to the scientific few who devoted themselves exclusively to the investigation of scientific principles, he observed that our great advances in science, and the civilization which resulted from science, nevertheless depended on the exertions of the much larger classes of persons whose efforts brought them daily more and more into union, and tended to fuse them into one body. He referred to scientific men who, like his distinguished friend Sir Frederick Abel, did not think it beneath them to apply their excellent abilities to the solutions of practical questions, and on the other hand to the busy men of practice who did not disdain to devote a portion of their time to the investigation of scientific problems. Among this last class he need scarcely say the Pharmaceutical Society justly claimed to have furnished a by no means inconsiderable contingent, regard being had either to numbers or eminence. The Royal Society enrolled amongst its members many distinguished practising members of the Pharmaceutical Society, and the Linnean Society and the Chemical Society also found amongst them some of their most esteemed and active colleagues. In connection with this idea of the association of busy men with scientific pursuits he might refer for a moment or two to the association which existed between the Pharmaceutical Society and the Institute of Chemistry. He sometimes heard it said that the golden days of pharmacy were past and that pharmacy was a declining profession, although judging from the brilliant gathering that evening no one could for a moment believe that these expressions could have a substantial foundation. Nevertheless, they were told that there was a pharmaceutical depression as there was an agricultural depression, that the prospects of pharmacy were by no means brilliant, and that the pharmacist, if he wished to hold his own in the race for life, must with the agriculturist wander into fresh fields and pastures new. He did not believe this was the case, but however that might be he could only say that the prospects of professional chemistry were not declining; they were advancing, and in view of the association which subsisted between the two bodies, and in which they recognized the Pharmaceutical Society as their elder brother—though they did not quite acquiesce in its claim to be sole legal proprietor of the title of chemist—at the same time he would say to pharmacists that if their prospects were declining there was no reason why they should not advance their professional prospects. In every town throughout the kingdom there was an increasing demand for professional chemical aid, and it became a question whether the young men entering the pharmaceutical profession might not also have an eye to the chemical profession, and of qualifying themselves and becoming associates in the Institute of Chemistry. However this might be, it was gratifying to recognize the harmony which existed between the two bodies who, he had no doubt, would in the future go forward hand in hand to promote the great cause which they both had at heart.

The PRESIDENT next proposed the toast of "The Medical Profession," the noble profession with which they were daily and hourly brought in contact, a profession which required for its exercise an enormous amount of self-denial. Some pharmacists were apt to complain of the way in which they were daily and hourly at the public call, and thought they were the hardest worked and worst paid body in existence. He should be sorry to dispel the pleasant illusion, but he thought the medical profession had a claim to priority in that respect. After long years of study and patient practice, the medical man had to submit to an amount of selfishness on the part of the British public to which no other profession would for a moment submit. In addition to this self-abnegation, most practising physicians had some branch of science to which they were attached, and on which they contributed original researches, often worked out late at night or early in the morning, and which did not often bring in the pecuniary reward that such labour would produce in other occupations. Pharmacists, being more associated with the medical profession than most people, were better able to judge of these matters than the outside public, and were, therefore, prepared to welcome them at such gatherings, to drink their health and wish them good speed, not only in the particular art which they practised, but also in those original researches by which they added to the sum of knowledge. He would couple with the toast the name of a member of the profession who had not only distinguished himself in the treatment of disease, but who years ago and up to the present time was regarded by biologists as one of the most eminent of his class—Sir Joseph Fayrer, President of the Medical Society of London. He had been long known as a diligent worker in biological science, and he had much pleasure in congratulating him on the position he had attained.

Sir JOSEPH FAYRER, C.S.I., F.R.S., in responding, said the physician and the pharmacist were very old allies. They had both, since the practice of medicine began, been engaged in the struggle which was going on, and ever must go on, with disease and suffering, and also in efforts which ameliorate the condition of life. It was only right that medical men should freely declare how much their branch of the profession owed to pharmacists for the success they had obtained, and it was a very pleasing feature of the present day to see the great strides which both physiology and pharmacy were making. He hoped their success might be as great in the future as it had been in the past.

Dr. FARQUHARSON, M.P., next proposed "Prosperity to the Pharmaceutical Society, and the Health of the President." On some occasions he was able to pose as a politician; but on this occasion he should prefer to pose as a member of the medical profession, and as one who endeavoured, however humbly, to instruct pupils at one of the metropolitan hospitals in pharmacy and therapeutics, which those whom he addressed worked at so successfully every day. He need not say anything farther on the mutual relations of the pharmacist and the doctor. That Society was known in many ways, it was well known by the gathering they were all looking forward to next evening as one of the events of the London season; it was also known by its annual dinner and also by the excellent Museum to which so many in his profession were glad to go occasionally to refresh their memories, but it was much more widely known as the great educational medium which was so widely spreading over the country men who by their beneficent acts and accuracy of prescribing and in a great number of other ways were doing good and faithful service to the public. Again, in scientific research, he had only to mention the names of one or two distinguished men who had passed through its rooms in former days. He would only refer to the honoured names of Hanbury, Bell, Squire and Attfield, or of a gentleman, whom, not to know, was to argue yourself unknown, Thomas Hyde Hills. He could not sit down, however, without saying that in addition to the toast of the Pharmaceutical Society, he had to propose "The Health of the Chairman, Mr. Carteighe." They all knew what his distinguished position had been in the past, and what was his present scientific status, and he could only hope that he would live many years to keep up the dignity of the Society over which he so worthily presided.

The PRESIDENT, whilst thanking Dr. Farquharson for the very complimentary manner in which he had proposed this toast, felt bound to say that he regarded it purely as an official toast, and as a recognition of what had been done in pharmacy by those who had preceded him in that chair. He remembered a celebrated cartoon which appeared in *Punch* many years ago, when a distinguished member of the Conservative party, Mr. Disraeli, was described as having stolen the clothes of the Whigs while they were bathing, and he feared he was very much in that position, having reaped the reward earned by his predecessors. He felt he did not deserve personally the complimentary terms which had been employed, but on behalf of the Society which he represented he thanked Dr. Farquharson for them, and if as a Society they did not deserve those compliments now, he hoped they would all continue to work until such time as they did. Their desire was to aid the physician in the cure of the sick, for the benefit of the public, and to advance the knowledge of the great art by which human suffering could be reduced and human lives preserved. Pharmacists were all anxious to assist in that great work, and if in the smallest degree that Society succeeded, its existence was amply justified.

The President then proposed the last toast, "Our Guests," coupled with the name of Sir Frederick Abel. They had amongst them many gentlemen of reputation, both in medicine and science, and amongst these gentlemen who had laboured for many years in the cause of pure science, and in the applications of that science to many useful arts, none had been more successful than the gentleman whose name he associated with the toast. Some might think it very improper for a distinguished man to devote his knowledge to an examination of explosives and things of that kind, but on the general principle that to be well armed was to be well prepared, if you wished to preserve the peace of the world, it appeared to him that such a course was perfectly justified. At any rate, he might say how sincerely they congratulated Sir Frederick on the honours which his Sovereign had lately bestowed on him, and how thoroughly they all felt that those honours were deserved. To their many other guests he wished, on the part of the Society, to express his grateful acknowledgments for their kindness in coming amongst them, and he was sorry that from want of time he could not ask them all to respond to the toast.

Sir Frederick Abel, F.R.S., said it was indeed an honour that the President should have selected him from amongst the many guests whom the Society had invited that evening, but it was a still greater honour that his name had been so cordially received. It had been his privilege and pleasure to be the guest of the Society on several occasions, and in several different functions, as President of the Chemical Society and as the predecessor of Professor Odling at the Institute of Chemistry. It had been his duty and pleasure to address meetings certainly not more numerous than that, and on several occasions it had been his special pleasure to speak from his heart with regard to the important functions performed by the Society so splendidly represented that evening. He could not in making himself a mouthpiece of the various guests do better than say that the various members of the different professions whom he saw round him, and the different learned and scientific societies, felt especially honoured in being connected,—a connection which increased in intimacy year by year,—with so useful a body as he had the honour of addressing. It had been his pleasure to be associated with the President in working out the details of younger societies, and they had profited in no small degree by the wisdom which had been accumulated in years past by this Society, and he hoped that in the future the same thing might take place.

The President then called on Dr. Andrew Clark to respond for their medical guests.

Dr. Andrew Clark said there was no explanation to be given to the inconsistency of human nature. When he entered the room that evening he did so with the intention of enjoying himself, and that feeling was heightened by knowing that he would not have to reply to any toast. He hated after-dinner speaking, and nothing would have induced him to break the resolution never to speak after dinner if he could help it but one thing, and that was that he felt that in all that had been said that evening not anything like justice had been done to the Pharmaceutical Society of Great Britain. For twenty-eight years he had been practising medicine and he felt that in the practice of the art of medicine there was a great guild of medicine, every element and person of which was related one to the other, and if they did not uphold each other and do the best they could for each other no good would come of it. Instead of Mr. President and Gentlemen, he would say Brethren of the great guild of medicine, which had for its business of all sorts and classes the relief of human suffering and the prolongation of human life. That evening had been very pleasant to him in many ways, and in none more than when he heard one speaker speak of the great functions which the Pharmaceutical Society bore in the important business of the relief of human suffering. He had noticed since he had been in practice that there had been a steadily growing attention to accuracy, minuteness and fidelity in the work of dispensing prescriptions. It might be said that that was a small thing, a mechanical thing. But it was not a mechanical thing; he held that if a great body such as that was could with one mind come together and say, This is the work we have to do, we shall do it to the letter and in the spirit as well, it would not end there. It was not merely doing a thing accurately and well which would benefit them; it might benefit them in a certain mechanical and pecuniary sense; but it also benefited them in a higher sense, in a sense which the Pharmaceutical Society of Great Britain ought to feel, a sense which should animate them all to take their proper position in the social scale—it was that in every work they did it should be a real and true work, and that every faculty they could bring to bear upon it should be brought to bear, and in so doing they would lift up their whole nature. He would only say that if they accustomed themselves to do the smallest act, to make up the pettiest prescription, with the highest idea of perfect accuracy and loyalty, they did a good thing; and it did not end with the idea of doing a good thing, but the repetition of that good thing made in them a nature, a purpose, a feeling, a habit, which would lift up not only the individual, but every member of the Society, and thereby justified them in rising to the station they ought to occupy in the social organization. He as a practising doctor had seen and recognized gratefully the assistance which he had derived from members of that Society, often rendered at great inconvenience, and every member of the medical profession appreciated it. The knowledge they possessed entitled them to a higher position than they had yet occupied. This was very pleasant to say; but there was one thing he had to say which was not so pleasant, one thing which would prevent them, if they did not stop it, from occupying the position they ought to hold in the social scheme. There was rising up amongst the chemists of this country a tendency to bring forward special remedies, secret remedies, to advertise them, and to take all sorts of indirect means of pushing them. The result of that was that it made one or two excessively or undesirably rich, while it injured the whole body. If they took his advice they would not allow any man who did such a thing to hold a place of honour in the pharmaceutical organization. They should have all their work clear, open, straightforward, honest as the day, and then nothing could hinder it. If they did that, they might depend upon it that, like the medical profession—which was their analogue—they would take their just position, which they had not yet reached, in society.

The musical arrangements were under the direction of Mr. Winn, and a selection of part-songs and solos was sung at intervals during the evening with great effect.

The Pharmaceutical Journal.

SATURDAY, MAY 26, 1883.

Communications for the Editorial department of the Journal, books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL MEETING.

THE number of pages in the present Journal devoted to the Report of the Proceedings at the Annual Meeting of the Pharmaceutical Society on Wednesday last, whilst rendering unnecessary in these columns more than a reference in general terms to what took place, will bear evidence to a satisfactory amount of interest taken by the Members and Associates of the Society in the management of its affairs. Many gentlemen present had travelled long distances in order to attend this meeting, and during nearly five hours the topics mentioned in the Annual Report were discussed with unflagging energy and, except in respect to one subject, with a practically unanimous endorsement of the action of the outgoing Council. In commencing the proceedings the President departed somewhat from the usual custom, and, instead of delivering a formal address, he gave an able exposition of and running commentary upon the different subjects mentioned in the Report. In order to save time and prevent unnecessary confusion of topics it was agreed that all reference to the subject of the clauses in the draft Bill relating to the penalty for selling patent medicines containing poisons without proper labelling, upon which Mr. SANDFORD had given notice of his intention to propose a resolution, should be deferred until the report of the Council had been disposed of. After the adoption of the Report had been moved by the President and seconded by the Vice-President, an amendment was moved by Mr. VIZER, but as the discussion which followed was necessarily discursive it may be convenient to follow pretty closely the order adopted by the Chairman in treating the principal topics.

In the first place the President referred to the subject of the finances of the Society, and especially to the decision as to changing the mode of investment of part of the capital of the Society by laying it out in freehold ground rents. In defence of this change he argued that corporations, not being hampered, like individuals, with the necessity for realizing the largest possible returns during the limit of a lifetime, should consider what was best for the future welfare of the body, and he hinted that the time might come when, as one result of the new departure, what has recently been termed "unearned increment" might render it possible to carry on the business of the Society without calling on the members for subscriptions. Mr. FRAZER, however, pleaded the "canniness" of a Scotchman as not allowing him to view the change in quite so favourable a light, and Mr. SANDFORD protested strongly against the innovation, which he foresaw would involve an army of collectors and, perhaps, of decorators.

Another subject upon which the President enlarged, and to which several subsequent speakers referred, was the revision of the Pharmacopœia. After detailing the steps taken by the Council to utilize the opportunity afforded by the introduction into Parliament of the Medical Acts Amendment Bill, he pointed out that the question to be discussed was not the appointment of editors and assistants, or the conduct of individuals, but whether pharmacists should not have the legal right of being represented on the Pharmacopœia Committee by members of their own body competent to see that experts and others did not make suggestions that were impracticable for British pharmacists. With the exception of Mr. FRAZER, who looks upon the Pharmacopœia as simply the physicians' prescription book, this view was indorsed heartily by every speaker who referred to the subject. Mr. GILES, especially, in an able speech, pointed out that in 1809, when the apothecaries had not yet attained the legal recognition as medical practitioners afterwards accorded to them by the Act of 1815, they were represented on the committee that drew up the London Pharmacopœia. At the time of the passing of the Medical Act of 1858 apothecaries had already ceased to represent pharmacy proper, but pharmacists were then too recently organized to put forward an effective claim to take their place on the Pharmacopœia Committee. Now, however, that the Pharmaceutical Society has been in existence more than forty years this disability has ceased, and to stop short of attaining this position he considered would be a dereliction of duty towards the republic of pharmacy. That the Society does not yet enjoy a more satisfactory recognition in respect to the revision of the Pharmacopœia Mr. GILES attributed to the lowering of its *personnel* from various causes, and also to the calibre of the Council of to-day not being equal to what it was or ought to be, an expression of opinion that roused a considerable amount of dissent. As will be seen by the report on p. 963 the subject of Pharmacopœia revision had already been under the consideration of the Council that morning, on the occasion of the receipt of a printed memorandum, enclosed in a transferred note from the Registrar of the Medical Council. We understand that similar applications for suggestions have been received by many pharmaceutical associations and individual pharmacists in different parts of the country, and we presume that as soon as a Pharmacopœia committee is constituted in which pharmacy is properly represented they will willingly render it all the assistance that lies in their power.

Another point in the Report that requires to be mentioned, because it formed the subject of an amendment, is the epitome of the curriculum scheme. Mr. VIZER moved that the third and fourth recommendations should be modified by reducing from three to two years the time to be spent in a pharmacy after passing the Preliminary examination before going up for the first part of the qualifying examination, shortening the interval between the two parts of the qualifying examination from twelve to six months, and allowing the student to pass through a portion of his curriculum during the period of his apprenticeship. The object of the amendment was to enable a person to become registered, if he so desired, within three years of passing the Preliminary examination; but it obtained scarcely any support, and, as pointed out by Mr. MARTINDALE, if the person had commenced his pharmaceutical career before he was eighteen years of age, he would still have to wait until he was twenty-one before he could become registered. Indeed there were some decided expressions of opinion that a compulsory apprenticeship of four or even five years would not be too long. Mr. BLAND entered a vigorous protest against the institution of a curriculum and the encyclopædic character of the syllabus, as being out of proportion with any privileges enjoyed by the registered chemist and druggist. From Scotland, too, there came an objection to the enforcement of the passing of the Preliminary examination before apprenticeship, Mr. PATERSON alleging that it would exclude a class of lads from whom a large number of apprentices are now drawn in that country. The feeling of the meeting was, however, manifestly in favour of the recommendations of the Council, and after rejecting Mr. VIZER's amendment, and another to the effect that no change in the educational arrangements should at present be made, the Report was adopted *nem. con.*

Mr. SANDFORD then moved the resolution of which he had given notice, expressing the objection of the meeting to the provisions in the fourth, fifth and sixth clauses of the draft Bill, under which the seller would be rendered liable for payment of any penalty for a sale of a patent medicine containing a scheduled poison. Mr. SANDFORD maintained that the action for the recovery of the penalty should lie directly against the proprietor or importer of the article, and enlarged upon the hardship of imposing upon the seller responsibilities in respect to the sale of preparations of the composition of which he knew nothing. On the other hand, the President described the difficulties that would attend attempts to proceed directly against proprietors who might not reside in the country, or importers, and pointed out that the right of recovery, which the retail seller would have against the person from whom he bought the goods, would make the wholesale dealer very careful to satisfy himself as to the nature of a proprietary article before introducing it to the retailer. Mr. SANDFORD's arguments, however, found favour with the meeting, and notwithstanding a suggestion to refer the subject for re-consideration to the incoming Council, the motion was carried by a small majority.

We have the pleasure of being able to state that the two *réunions* which have now become almost an integral part of the Annual Meeting of the Pharmaceutical Society have this year been even more than usually successful. At the Dinner of the Members of the Pharmaceutical Society and their friends, at Willis's Rooms, on Tuesday last, the company numbered about two hundred and twenty, and included pharmacists from all parts of the country. Among the guests were the Right Hon. the Lord Mayor, Mr. Alderman and Sheriff De Keyser, Mr. Sheriff Savory, the President of the Society of Chemical Industry (Sir F. Abel), the President of the Medical Society (Sir Joseph Fayrer), the President of the Metropolitan Branch of the British Medical Association (Dr. T. Bridgwater), the President of the Clinical Society (Dr. Andrew Clark), the President of the Obstetrical Society (Dr. Gervis), the President of the Odontological Society (Dr. Walker), the President of the Harveian Society (Dr. E. Symes Thompson), the President of the Institute of Chemistry (Professor Odling), the Master of the Society of Apothecaries, Dr. Farquharson, M.P., W. McCullogh Torrens, Esq., M.P., Professor Allman, W. T. Thiselton Dyer, Esq., Dr. Langdon Down, Wyndham Cottle, Esq., and Dr. T. Stretch Dowse.

* * *

On Wednesday evening, by the kind permission of the Lords of the Committee of Council on Education, the Annual Conversazione of the Pharmaceutical Society was held in the South Kensington Museum. Upwards of two thousand five hundred ladies and gentlemen responded on this occasion to the invitation of the President and Council, amongst whom were the Right Honourable the Lord Mayor and the Lady Mayoress, Mr. Alderman and Sheriff De Keyser and Mrs. De Keyser, and Mr. Sheriff Savory and Mrs. Savory. The company were received in the Architectural Court by the President and Mrs. Carteighe, the Vice-President and Mrs. Atkins, the Treasurer and Mrs. Robbins, and the other Members of the Council, most of whom were accompanied by ladies.

* * *

We understand that several communications have been addressed to the Secretary in reference to the circular issued on behalf of the Pharmacopœia Committee of the Medical General Council, asking for information on the subject. From the nature of these communications, and some of the replies that have already been addressed to the Medical Council, there is good reason to believe that those most capable of rendering the assistance asked for consider that the request should have been made through the medium of the Pharmaceutical Society. Indeed, as a fair expression of the feeling on the subject, we may refer to a letter from Mr. T. B. Groves, of Weymouth, who says he will be very pleased to render all the assistance in his power towards perfecting the new edition of the British Pharmacopœia, "when requested by the pharmaceutical authority, *i.e.*, the Pharmaceutical Society of Great Britain," of which he is a member.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 23, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes and Williams.

Portrait of Mr. Squire.

The President drew attention to a portrait of Mr. Peter Squire, which had been kindly presented to the Society by Mr. J. E. Mayall, and on his motion, seconded by the Vice-President, a cordial vote of thanks was passed to Mr. Mayall for his gift.

Pharmacopœia Revision.

The President read the following circular which had been addressed to the President and Council. He also mentioned that a similar application had been addressed to him individually, and he understood that a considerable number had been issued to pharmaceutical associations and individual pharmacists throughout the country.

"General Medical Council Office,
"299, Oxford Street, London, W.
"*May* 18th, 1883.

"Sir,—I am directed to forward you the enclosed 'memorandum' in reference to a new edition of the 'British Pharmacopœia' and to express the hope that you will, at your early convenience, favour me with an answer to be submitted to the Pharmacopœia Committee.

"I am, Sir,
"Your obedient servant,
"W. J. C. Miller,
"*Registrar.*

"The President of the
"Pharmaceutical Society of Great Britain."

"General Council of Medical Education and
"Registration of the United Kingdom,
"299, Oxford Street, London, W.
"*May* 18, 1883.

"*Memorandum.*

"The General Medical Council, having decided on issuing a new edition of the British Pharmacopœia, have appointed a Committee to make the necessary arrangemenns for carrying this object into effect under the direction of the Council.

"In the performance of this duty the Committee are desirous of enlisting the co-operation of the several medical and pharmaceutical authorities, and of such persons as may be able to furnish useful information, with the view of rendering the work as complete and accurate as possible. In furtherance of this object the Committee invite, and will be happy to receive such suggestions as may be made to them by the above named authorities, and to give these suggestions their most attentive consideration.

(Signed) "Richard Quain, M.D.,
"*Chairman of the Pharmacopœia Committee.*

"To the President and Council of the
"Pharmaceutical Society of Great Britain."

The consideration of a reply to this circular was deferred.

Several former Members, Associates and Apprentices were restored to their status in the Society on payment of the current yea 's subscription and a fine.

A copy of the following Memorial to the Privy Council on the subject of Pharmacopœia Revision was laid on the table:—

"*Memorial of the Council of the Pharmaceutical Society of Great Britain to Her Majesty's Privy Council.*

"Medical Acts Amendment Bill.

"The Council of the Pharmaceutical Society of Great Britain begs to call the attention of the Privy Council to the provisions of this Act relating to the preparation and revision of the British Pharmacopœia (clauses 60 to 63, page 35 of the Bill).

"According to the provisions of the Bill, this work is to be published under the direction of the Medical Council.

"For the purpose of compiling and revising the Pharmacopœia previous to its publication, it has always been found necessary to appoint a special Pharmacopœia Committee.

"In this country, hitherto, that Committee has consisted solely of members of the Medical Council, assisted by professional experts, whereas in all other European countries, the constitution of that Committee is fixed by law, and in every case it includes a considerable number of pharmaceutical chemists. In the United States of America, pharmaceutical chemists form a majority of the Committee of Revision.

"The decision as to what drugs or medicines shall be introduced into or expunged from the Pharmacopœia rests with the medical members of the Committee, and the responsibility as to the working out of the chemistry and pharmacy of the preparations, and the manner in which they should be made, rests with the pharmaceutical members.

"The Council of this Society considers that this or some such method should be followed in this country, and laid down in the Bill now in the House of Commons It is supported in this view by many members of the medical profession and by the medical press generally. Moreover, inasmuch as by the Pharmacy Act, 1868, and the Sale of Food and Drugs Act, the Pharmacopœia is taken as the standard of purity and strength of such drugs and medicines as are contained therein, it seems desirable and equitable in the public interest that the practical experience of pharmaceutical chemists should be made available on the said Committee.

"Since the time when the apothecaries commenced to practise medicine, pharmacy has been more and more neglected by medical practitioners and the medical licensing bodies; whereas the Pharmaceutical Society of Great Britain, since its incorporation by Royal Charter in 1843, has occupied the position abandoned by the Apothecaries, and continuously directed its efforts to the improvement and extension of those special branches of knowledge on which pharmacy proper is based. In 1852, Parliament recognized the public ultility of the Society's exertions by passing the Pharmacy Act, 1852, on the ground that it is expedient for the safety of the public that persons exercising the business or calling of pharmaceutical chemists should possess a competent practical knowledge of pharmaceutical and general chemistry and other branches of useful knowledge.

"Since the value of the Pharmacopœia as a legal standard depends very much on the loyalty with which pharmaceutical chemists and chemists and druggists conform to its instructions, it seems politic to associate members of the pharmaceutical body with the representatives of the medical profession on the Committee.

"The Council of the Pharmaceutical Society of Great Britain therefore ventures to suggest that a clause to the following effect be inserted in the Bill after clause 63:—

"'For the purpose of compiling the said Pharmacopœia there shall be established a Pharmacopœia Committee consisting of six medical practitioners, to be nominated by the Medical Council, and five pharmaceutical chemists, four to be nominated by the Council of the Pharmaceutical Society of Great Britain (one of the four to be resident in Scotland) and one by the Council of the Pharmaceutical Society of Ireland.'"

The Council then adjourned to the Annual General Meeting.

FORTY-SECOND ANNUAL GENERAL MEETING.

The Forty-second Annual General Meeting of the Members and Associates in Business of the Society was held on Wednesday, the 23rd inst.

The PRESIDENT took the chair at twelve o'clock.

The SECRETARY having read the notice convening the meeting, it was agreed that the Report should be taken as read.

THE ANNUAL REPORT.

From the financial statement it will be seen that the income of the Society for the year 1882 exceeded the expenditure by £1297 3*s.* 1*d.* The gross receipts from subscribing members, associates, and apprentices are somewhat less than in the previous year, the deficiency being principally due to a reduction in the number of members, while the income from the class of associates shows a steady and progressive increase. Examination fees have produced a slightly larger revenue than during the year 1881. On the Journal account, after paying all the expenses involved in the production of the Journal, a balance remains in favour of the Society of £417 5*s.* 5*d.*

The propriety of changing the investments of the Society's capital has from time to time engaged the attention of the Council, and at the meeting in March last it was resolved that a sum not exceeding three-fourths of the invested capital should be re-invested, as occasion may offer, in freehold ground rents or freehold land. Having regard to the exceptionally high price of Government stock at the present time and the desirability of choosing a form of investment in which a fair average interest is obtainable and an increased value of the capital can in course of time be secured, the Council believes that this change will conduce to the permanent welfare of the Society.

The number of candidates for examination during the year 1882 was in excess of that of the previous year by seventy-three. The number of "Minor" candidates was precisely the same, while for the "Major" the numbers show a decrease of four, for the "Modified" a decrease of five, and for the "Preliminary" an increase of eighty-two.

With the object of rendering the Preliminary examination as satisfactory as possible to all classes of candidates, the Council, acting on recommendations received from the Boards of Examiners, passed a resolution at its meeting in December embracing the following new regulations:—

"That in future the time allowed for the Preliminary examination be four and a half hours, in two periods of three hours and one hour and a half, with an interval of one hour between the two portions of the examinations.

"That the three hours be devoted to Arithmetic and Latin, and the one hour and a half to English.

"That in Latin the present regulation requiring translation into English of a paragraph from the first book of Cæsar (De Bello Gallico) be extended by the addition of Virgil—first book of the Æneid.

"That in each examination paper a passage from both of the authors be given, but that a candidate shall be required to translate one only of such passages.

"That this regulation shall come into force in January, 1884."

The *Library* continues to receive the attention which its importance demands. No less than five hundred books and pamphlets have been added during the year 1882 and it is gratifying to be able to report that there have been upwards of a thousand more readers than in the preceding year.

The *Museum* has been enriched during the year by several important additions. From the Botanical Gardens, at Ceylon, a fine collection of medicinal plants has been received. A number of interesting drugs from Madagascar have also been received through Dr. Parker. From the Colonial Office a valuable collection of the cinchona barks grown in Jamaica has been received, with notes and a catalogue compiled by Mr. Morris, the director of the plantations in that island. From Madras the finest and most complete collection hitherto made of Indian grown barks and species of cinchona cultivated in the Nilgiris has been sent by order of the Secretary of State for India. The collection is accompanied by a catalogue, with notes compiled by Surgeon-Major Bidie, by whom the collection was made.

The *Evening Meetings* during the session have attracted a larger number of members than usual and the numerous and important papers read have excited general interest. It is gratifying to observe that the younger members take a large part in the various discussions and materially assist in sustaining the character and tone of these meetings.

Infringements of the Pharmacy Act, 1868, were, reported during 1882, to the number of one hundred and fifty-five. In the large majority of cases in which it was found necessary to institute legal proceedings, the penalties were paid before the hearing, a few only having been carried into court. The amount recovered is duly entered in the financial statement.

It will be remembered that in the Report of the Council presented at the last Annual Meeting, it was stated that the Council had, for reasons mentioned in that Report, recommended by resolution that certain articles should be added to Part II. of Schedule A. of the Pharmacy Act, 1868. The Privy Council, on whom rests the responsibility of confirming such resolutions, informed the Council by letter, at the end of July, that "pending the consideration of the expediency of further legislation with reference to the sale of poisons it was not desirable to add to the restrictions on the sale of the acids and other articles referred to in the resolution." The Privy Council, however, approved the resolution so far as it affects nux vomica and its preparations, which have accordingly become poisons within the meaning of the Act and are included in the second part of the schedule thereto.

It was also mentioned in the last Report that it had been arranged at an interview between a deputation of the Council and the Home Secretary to send a written statement of suggestions for the amendment of the law for the further consideration of the Secretary of State. A statement of the views of the Council on the subject was accordingly sent to the Home Office, and about the same time reports from the College of Physicians, College of Surgeons, Institute of Chemistry and Society of Apothecaries were addressed by his request to the Secretary of State. These various reports were subsequently passed over to the Privy Council Office and on due consideration that department after consulting with your President decided that it is desirable that there should be further legislation. With that object a letter was sent in November last requesting the Council to submit its views in regard to the sale of poisons for the consideration of the Lords of the Council in the form of a draft Bill amending the existing law.

As a consequence the Council has prepared and submitted a draft Bill embodying its views, and this Bill is now engaging the attention of the Government. The general approval which the Bill has received at the hands of the members and the trade at large encourages the Council to hope that the Government may see fit to introduce it into Parliament with such amendments as further consideration may render necessary.

It ought not, however, to be forgotten that in order that any Pharmacy Acts Amendment Bill shall become *law*, it is essential that the members of the Society and the trade at large be thoroughly united in the support of the measure both *in* and *out* of Parliament.

The introduction into Parliament of a Medical Acts Amendment Bill has naturally excited some interest amongst those who practise pharmacy. This Bill does not propose to interfere in any way with the legitimate exercise of the business of chemists and druggists; but one of the duties imposed upon the Medical Council is the production and publication from time to time of the British Pharmacopœia. Your Council has resolved that it is desirable that pharmacists should be represented on the Pharmacopœia Committee, and is taking steps with a view to have the clauses referring to this subject amended in committee when the Bill is under consideration in the House of Commons.

The relation of pharmaceutical education to examination formed an important paragraph in the last Report. As, however, the conclusions arrived at up to the issue of that Report were scarcely so matured as to render it practicable for any scheme based upon them to be satisfactorily carried out, the Council in July appointed a Special Committee to consider the best method of giving effect to the resolutions on the subject previously adopted. This Committee presented its report, which was received and adopted by the Council, in March last. That report included, among other suggestions, the following important recommendations, which the Council believes to be eminently calculated to advance pharmacy as well as to conduce to the best interests of the public:—

"1st. Every candidate for qualification to practise pharmacy must pass the Preliminary examination of the Pharmaceutical Society, or one of the examinations the certificates of which are accepted in lieu thereof, and be registered as a Pharmaceutical Student.

"2nd. The pharmaceutical student must then enter the pharmacy of a pharmaceutical chemist, or a registered chemist and druggist who keeps an open shop, as an apprentice or pupil, or in some other capacity as a learner; and be so employed for three years.

Note.—During these three years he may or may not, at discretion, attend one or more of the courses of lectures that form part of the "curriculum" approved by the Council in April, 1882 (*Pharm. Journ.*, April 15, 1882, p. 846).

"3rd. After the expiration of the three years' shop experience, the pharmaceutical student is eligible to offer himself for the *first portion* of the qualifying examination on production of evidence of registration as a pharmaceutical student and of having been employed for three years subsequent to such registration in the shop of a pharmaceutical chemist or a registered chemist and druggist.

"This *first portion* of the qualifying examination to be a written one and to include the following subjects:—Prescriptions, Pharmacy and Theoretical Chemistry.

"This *first portion* of the qualifying examination to be conducted in London, Edinburgh, and such a number of centres in the provinces as will allow the superintendence of each examination by a member of the Board of Examiners.

"4th. An interval of not less than *one year* must elapse between the date of passing the *first portion* of the qualifying examination and the date of entering for the *second portion* of that examination. During that interval the above-named "curriculum" *must be completed.*

"5th. On entering for the *second and final portion* of the qualifying examination, the pharmaceutical student must produce evidence of being twenty-one years of age and of having fulfilled the conditions mentioned in the previous paragraph.

"This *second and final portion* of the qualifying examination to be practical and "*vivâ voce*," and to include the following subjects:—Practical Dispensing, Botany, Materia Medica and Chemistry.

"This *second and final portion* of the qualifying examination to be conducted in London and Edinburgh only.

The Benevolent Fund has been augmented by three legacies of £100 each, under the wills of the late Robert Howden, of London, Arthur Lloyd, of London, and Charles James Pearson, of Swansea, and shows in addition an increase in donations and subscriptions of over £700. This very satisfactory result in regard to subscriptions is mainly due to the zeal and perseverance with which the claims of the Fund have been urged by the local secretaries. Their services in this and other matters affecting the interests of the Society are highly appreciated by the Council and deserve recognition from the members at large.

The annual publication of a local list of subscriptions and donations was commenced in February last in the *Pharmaceutical Journal*. This will, it is hoped, materially assist the local secretaries and others in advocating the claims of the Fund amongst those who have not hitherto had their attention called to the pressing claims for relief which the Council receives every month from persons in all parts of the country.

With the view of associating with the Society distinguished pharmacists and others residing per-

} *Auditors.*

February 28th, 1883.

manently outside the United Kingdom, the Council has decided to recommend the members at an early convenient opportunity to pass a new bye-law to enable it to elect such persons as *corresponding members.* It is desirable that the interest which so many of these eminent men take in pharmacy should be enhanced by official recognition on the part of the Society, in the same manner as the labours and and services of British pharmacists are recognized by Continental and American Associations.

In concluding this Report the Council has to regret the loss, among other valued members of the Society, of Alfred Allchin, S. U. Jones, of Leamington, Robert Howden and Matthew Pound. Mr. Allchin was for many years associated with the Executive of the Society, first as a demonstrator in the Society's laboratory and afterwards as an examiner, and had endeared himself to all those with whom he came in contact. Mr. S. U. Jones, Mr. Howden and Mr. Pound were each well known to, and regretted by, a wide circle of friends. They did not fail to avail themselves of every opportunity for advancing the interests of the Society and earning the goodwill of their brother pharmacists.

The President, in moving the adoption of the Report, said the first paragraph dealt with the finances, and, as usual, they expected to be criticized on that point, but probably not so severely as if they were in a position of having to declare a dividend. He did not propose to say much about the annual receipts and expenses, but would pass to the second paragraph, which referred to the propriety of changing the investments of the Society. It was well known to many of the older members that from time to time this question had been discussed, and during his tenure of office the Council had decided at length that it was desirable to change a portion both of the Benevolent Fund and General Fund investments and to invest the money in freehold ground rents or land. The object contemplated was, on the one hand, to get a higher rate of interest, with ample security, and on the other, to provide for increased stability in the future. When the Society's capital was very small, it was natural and convenient to invest in Government stock, but having regard to the present high price of stock and the possibility that there might be a conversion, as was now being carried out in France, it was desirable that corporate bodies like themselves, having large funds to deal with, should consider what was best for the future welfare of the body. It seemed to the Council wise to invest in such a way that they might sooner or later, perhaps in fifty or sixty years, be able to carry on the business of the Society without calling for subscriptions at all. If they could do that without imposing any additional burden on the pharmacists of the present generation they would all agree that the Council was wise in thus dealing with the Society's capital. It was well known that it was difficult to get more than 3 per cent. for investments in Government funds, but on freehold ground rents it was possible, as a rule, to get 4 per cent. Their information, gathered from all sources and based on actual observation during the last two months, showed that a freehold ground rent was worth actually 4 per cent. when the reversion was tolerably distant. One of the reasons why these investments were fairly good for corporate bodies was that they did not die. Individuals died, and ground rents were slightly inconvenient for trustees of deceased persons to deal with; therefore it was that persons in that position generally invested in Government securities; but corporate bodies, like themselves, might very fairly invest in ground rents without the possibility of having to sell out and divide at any particular time. With regard to the number of candidates who presented themselves for examination, the clause spoke for itself. It seemed pretty clear that the number presenting themselves was still very large, though he deeply deplored that so many were turned back. They must all regret the waste of time on the part of so many candidates which this disclosed. Of course, it was the duty of the examiners, representing the Government of the country, to reject men who were not competent to perform the duties to be placed in their hands; but, at the same time they could not but think how much better it would be if by better training beforehand, the Board of Examiners were able to certify that a much larger percentage of each batch of candidates was fit to be entrusted with this important duty. The Preliminary examination had received some consideration with a view to giving a wider range and greater latitude in the Latin subjects. He need not refer further to that point, but it was, of course, very important that the Preliminary examination of men who were to be future pharmacists should be fairly good, and although the process was an improving one, so far as his experience went, it was not improving so rapidly as they could wish. It was a fact that many of the candidates had been placed in a difficulty when having to deal with three subjects in so short a time as three hours, and it was therefore proposed that after next year the candidate should be examined for an hour and a half in Latin, then in arithmetic for another hour and a half, and after luncheon another hour and a half would be devoted to English. In that way it was thought that many boys, who did the first portion pretty well but said they had not time for the English, would be assisted in giving the examiners a better idea of their capacity. The Library and Museum continued to make satisfactory progress, as was stated in the Report. They were indebted to a number of members, to gentlemen outside the Society, and various Government departments for gifts not only to the Library but to the Museum. He might also remind members that they had the nucleus of a very excellent library in Edinburgh and he was sure there were many members who had old works on pharmacy and medicine, who would perhaps like to present them to the Society, but hesitated to do so because they knew that in London they had a complete collection of such works. In the Society's library in Edinburgh, they were not very strong in ancient works on pharmacy or science. A considerable number of infringements of the Pharmacy Act had been reported during the year, and in many cases the offender had paid the fine and had not gone into court at all. Sometimes he went on doing wrong after he had paid one fine and had to pay a second fine, so that there was some difficulty even by the enforcement of fines in preventing individuals from breaking the law. Nevertheless, if the members of the Society knew how many hours the Council spent in considering these matters they would be more considerate than they sometimes were in the remarks which they made on this topic. It was not possible to publish all they knew in various cases of infringement, nor was it possible for the Secretary to write to every local secretary who gave information, stating the reasons which actuated the Council in either moving or not moving in reported cases; but they might all be assured when he told them that the members of the Council every month devoted the best part of Tuesday evening to considering cases which were sent up to them, and that every case was thoroughly sifted on its merits. On the question of poisons the next paragraph referred to the report presented at the last meeting. It was then proposed that certain strong acids should be placed in part 2 of the schedule, but the Privy Council did not see its way to adopt that resolution; in writing on the subject they said "pending the expediency of further legislation they did not see their way to confirm the resolution. As was mentioned in the Report, the Government had said that some sort of legislation was necessary, and the Council of the Society, acting at the request of the Privy Council, had prepared a Bill which had been before the members for some time. He should suggest that any discussion on that Bill should be deferred until Mr. Sandford proposed his resolution. But he was anxious to impress on the members the fact that this Bill was put into the hands of the Privy Council to be brought forward as a Government measure; it was not a Bill which the Society proposed to bring into Parliament as a private measure, and, therefore, some of the provisions were drafted in such a manner as to meet the views of important Government officials, who had considered various matters connected with the working of the present law, and who thought some deviation from the law as it had hitherto been was desirable. In saying this he did not wish to divest either himself or the Council of any responsibility in the matter, but it was important that this should be borne in mind. What might be done hereafter it was not for him to say. The Government might decline to introduce the Bill into Parliament, or they might suggest amendments; but when that time came, when they got a definite statement of the views of the Government, they would take care to deal with the Bill so as to adopt, as far as they could, the amendments which were practicable and for the general good. The introduction of the Medical Act Amendment Bill was also referred to in the Report, and the Council had thought it desirable, besides the letter which he was instructed to write some weeks ago to the Lord President of the Council, to send a memorial to Mr. Mundella, setting forth the views of the Society's Council, and which he believed would be the views of most pharmacists, as to what they thought would be a proper way of dealing with Pharmacopœia revision. In connection with this subject it was not necessary or desirable to criticize the action of individuals. The question was really a public one: how far pharmacists should be appointed on a Committee for revising the Pharmacopœia. The question of what experts should be appointed, whether as editors or assistants, was outside the question. The sole question for them was, were they not reasonable in asking that there should be competent pharmacists on the Committee to see that the experts and others did not make suggestions which were impracticable and unworkable. He felt sure that the more the subject was brought before the medical profession, the more certainly would they adopt, by a large majority, the view that there should be educated representative pharmacists on that Committee. Pharmaceutical education occupied a long paragraph, in which was inserted an abstract from the report of the Committee, who had spent a long time in considering the subject. On this Mr. Vizer had given notice of a slight amendment. He did not propose to say anything upon it until he heard Mr. Vizer's views; but he semed to agree with the Committee, as far as he understood, up to a certain point, but would allow the candidate to come up for the first portion of a technical examination two years after he had been in the shop. Perhaps Mr. Vizer would be able to convince the members that that was an advantage, but up to the present time he and his colleagues had thought three years were essential and a great advantage to the candidate himself. The Benevolent Fund had made satisfactory progress during the year, the members at large, the local secretaries and the officers of the Society spread over Great Britain had worked very well for it, and there was a hope that they might be able to stir up not only those connected with the Society, but a large number of others who were on the Register, and who did not see the importance of this Fund to all chemists and druggists. He might say the great majority of applications for relief were from registered chemists and druggists who had never been connected with the Society at all. The Society was truly catholic in its distribution of this Fund; it looked on the whole trade as being part of one body corporate when applying for assistance, and, therefore, it had some claim to ask those who were outside to give more support to the Fund. The last paragraph but one referred to the election of corresponding members, and that might require a little explanation. The Bye-laws at the present time only contemplated the election of a certain class of non-paying members, called honorary members, but the Council was anxious to have power to appoint distinguished men who assisted in various ways, to the position of corresponding members. Many comparatively young members of the Society who had made a position for themselves in the world of pharmacy or science were recognized in this way by Continental and American associations, and it seemed desirable that the Council should be able to do the same thing in return. In the last paragraph, the Council had to regret the loss of some of the members who had died during the year. Of course there were many others who had passed away, and who had done good work in their time, but who had not held office, and as to whose position and labours they were not officially informed. They were quite aware that there were a number of men in quiet nooks and corners of the country who were doing very good work in pharmacy, but whose names never appeared in public. Their work was none the less appreciated; but it was essential in this official Report to confine it, in order not to be misunderstood, to the mention of those who had held office and taken part in the various public works connected with pharmacy. He would conclude by moving—

"That the Annual Report of the Council now read be received and adopted, and printed in the Society's Journal and Transactions."

The Vice-President seconded the resolution, and said he would reserve the right of making any remarks till later, if necessary.

Mr. Vizer (Brighton) then moved the following amendment, of which he had given notice:—

"That the Report be adopted, etc., with the exception of the third and fourth recommendations of the Special Committee in relation to pharmaceutical education and examination, in respect to which the following alterations are considered desirable:—That in Recommendation No. 3, the term of *two* years should be substituted for *three* years; in Recommendation No. 4, "six months" should be substituted for "one year"; and that the syllabus of the proposed Curriculum should be so altered as to enable a student to pursue the necessary studies during the three years' apprenticeship if so desired."

His object in moving this resolution was strictly with a view of endeavouring to assist the Council in bringing about such a curriculum as would be a boon. Many present knew that his views had always been in favour of raising the standard of education, and they all owed to the President and Council a debt of gratitude for the extreme care which had been taken in bringing forward this scheme, but there were certain points in it which he he could not help feeling needed a little adjustment. With regard to the first recommendation, that every candidate should pass a preliminary examination, that seemed to him a *sine quâ non.* The second recommendation was that three years' apprenticeship should be served, and that also he fully endorsed. But when they came to three, where a hard and fast line was drawn without any allowance being made for differences of young men's educational powers, opportunities, and privileges, it seemed to him likely to prevent young men utilizing their time to the greatest advantage. It stated that at the expiration of three years a student is eligible to offer himself for the first portion of the examination, and then the fourth clause was that an interval of not less than one year must elapse between the date of passing the first portion of the qualifying examination and the date of entering on the second portion. Now it seemed to him exceedingly hard that a young man entering a business should be compelled to pass three years before he had any possibility of passing the examination, and that after he had spent three years another twelve months should have to be spent in preparing and going through a certain course of lectures and practical chemistry which possibly he might have had an opportunity of pursuing during his apprenticeship. If a young man had extra abilities or advantages, and if his master did his duty by him, by the expiration of two years he ought to be thoroughly prepared to pass the first portion of such an examination, and at the end of the next year, by a little extra application, he believed there would be no difficulty in many instances in his coming up at the end of his apprenticeship and passing the full examination. To say that a young man must, notwithstanding, still remain a student for another year would be exceedingly hard both on the student and on his master, and anything which could be done to remove that difficulty seemed desirable. His amendment was drawn with a view to meet that. It was said that this was done in order to forward the interests of the public, but he would venture to ask, how far was this borne out by daily experience? Was it absolutely necessary for the interests of the public that this extra time should be spent beyond a legitimate apprenticeship? Both of the Government visitors stated most distinctly that it was not necessary. (Mr. Vizer here read extracts from the reports of the Government visitors as confirming of his views.) It was not found either that the medical profession required anything further than was at present imposed. As a rule medical men in their respective towns did not support and recommend those chemists and druggists who possessed the pharmaceutical diploma. Again, did the public demand it? The answer was when they looked round they saw that the public did not appreciate examined men in comparison with the amateur shopkeepers who employed registered men as their assistants. All this proved to demonstration that it was not desirable to lay a heavier burden on students than was absolutely necessary; but on the other hand, they should endeavour if possible to enable them to pass the examinations as easily as was practicable. These regulations were introduced with the idea of doing away with cramming, and no one could abhor that more than he did, but it seemed to him that this would rather encourage it. Both master and student would naturally argue if the apprentice was necessarily to go through twelve months' curriculum at the school, was it worth while to forego his services during his apprenticeship? The master would make the most he could of him, and at the end of the time the student would come up and endeavour to cram up the technical knowledge required; on the other hand, as he proposed, both master and apprentice would be interested in making the utmost they could of their time, in order that the student, if possible, might pass his examination before the expiration of his apprenticeship. He, therefore, asked the meeting to take the subject carefully into consideration.

Mr. Wheeler seconded the amendment.

Mr. Whittle thought it was a wise decision of the Council to invest in freehold ground rents, but he hoped they would not invest in land, which was rather speculative. They might also turn their attention to railway debentures and preference stocks, which often paid 4 per cent. and sometimes more. The President had suggested that they should say but little about the Pharmacopœia, but he was quite certain that every assistant and every chemist had for years felt it of the greatest importance that they should be represented on the Pharmacopœia Committee, and they felt very strongly the action of the Professors in not communicating with the Council on this matter. They knew the Medical Council could not do this work by themselves, and felt it very strange that the Professors should have acted in the way they had. Mr. Vizer had not convinced him at all; he thought three years was quite short enough, and it was only by an increase of education that they could advance their status at all. They could only go to Parliament on the plea of having a superior qualification, and two years was not long enough, and even if a few were capable of passing at that time the extra year would do them no harm.

Mr. Allen said, this question which Mr. Vizer had brought forward was one he felt great interest in, especially as it was not so very long since he had himself been a student. The recent regulations had altered to a certain extent the character of the trade. The three years' qualification which was now insisted upon was not required immediately after the passing of the Pharmacy Act, in 1868; but since its introduction, three years' apprenticeships were the order of the day, and a large number of young men came to London from the country, who had served that time. It was a question for those present, how far the three years' apprenticeship had qualified these young men to serve as junior assistants. As a rule, these young men came to London and took the proper course of obtaining situations as improvers in some London pharmacy, and, after a time, entered the

School of Pharmacy and so went through some form of curriculum, and by-and-by qualified as members of the trade. When he was apprenticed, the ordinary rule was five years, or occasionally four, and he must say he thought the five years' apprenticeship turned out a better class of men than the three years' term did. Young men now came to London after three years' apprenticeship, went straight into the school and in four months qualified to pass the Minor; they were then scarcely content to take the position of a junior, and if this amendment were passed he feared that two years' apprenticeship would be the rule. He was one who, unfortunately never went through any form of curriculum, and he now looked back with regret to think that he was unfortunate enough to qualify for his examination without doing so, and sometimes wished he had time even now to attend the regular courses of lectures. It was really a question whether two years' apprenticeship was sufficient.

Mr. VIZER said he did not advocate a two years' apprenticeship.

The PRESIDENT said Mr. Allen's observation was quite fair; his argument being that, inasmuch as during the past seven years, when the three years' regulations had been in force, the term of apprenticeship had been diminished to three years; so if Mr. Vizer's proposal were adopted there might be a disposition to shorten that period to two years.

Mr. MARTINDALE thought the meeting would fail to see the force of Mr. Vizer's argument. In any case a man could not pass the second portion of the examination until he was twenty-one, and if he was apprenticed at sixteen four years might be passed in a practical pharmacy and there would still be a year left for the curriculum.

Mr. URWICK thought three years was quite short enough; if anything, too short. He did not think that young men who had passed through short periods of apprenticeship, when they came to London, made such good assistants as those who came to London in old times, and certainly two years would be much too short. With regard to twelve months' interval between the two portions of the examination, he agreed with Mr. Vizer.

Mr. RIMMINGTON said three years might be enough for some, but not a bit too much, and four years was not too much for any young man to master the details of a chemist's shop. He might be very clever and pass any examination, he might be a great genius, but he was not a shopman and could not manage a business. His experience was that most sensible parents would not like their sons to be out of their apprenticeship before they were twenty years of age. He had for some years taken apprentices for four years, sometimes four and a half, and would not take them for less. The success of conducting a chemist's shop did not depend altogether on scientific knowledge; in fact, there was a great deal more of practical science required than of exact science.

Mr. BLAND said he should for many reasons have prepared to remain silent, were he not convinced that a crisis had now arrived in which their interests as pharmacists were seriously imperilled, and which might involve disaster and even ruin to the Society. Looking back to the objects of the Society when it was founded, two were mentioned, first, the protection of chemists from the outward attack of their enemies, whose name was legion, and secondly, the establishment of a School of Pharmacy, which should furnish a succession of able and competent men for the discharge of the functions of their office. With regard to the latter object they were entitled to say that the pharmacist of the present day was a far superior man to the average chemist and druggist of forty years ago. It was clear and undeniable that the articles supplied to the public in the shape of drugs and medicinal preparations were far superior to those generally obtainable then. There were few places on the Continent, where scientific pharmacy had been cultivated to the highest extent, where the practical duties were better performed than they were in England. But with regard to the other object contemplated by the originators of the Society, he must say that he thought it had resulted in a miserable failure. They had an Act of Parliament passed for their protection, and to give them a legal status, whatever that might mean. What had been the result? If they looked to the leaders in the profession, the old historical houses which they often heard of, did they not find that a number of those houses had come down from the lofty position which they once occupied, and had taken up the weapons of Professor Holloway and Professor Chlorodyne Browne. Was their status any better? If they looked to the position of the rank and file, they had an actual and legal title which other men could not encroach upon, but as far as his experience went, nine hundred and ninety-nine out of every thousand of the public did not know or care a button about the meaning of the words "pharmaceutical chemist." What was the protection of the Act of Parliament? They were placed under the most severe restriction as to their qualification, and as to the sale of poisons; there was a poison clause which everybody who looked into the matter knew could not be strictly and literally carried out. He could easily conceive that gentlemen living in the West End might find it easy to comply with it, but he would mention a case which would show it was not so easy. Near him there was a large firm employing, perhaps, two hundred men, who constantly required to use cyanide of potassium in their business; they sent for it on a printed order, signed by a clerk, whose name and handwriting he knew perfectly well. The Act said he must have the signature of the person in his register. But the boy or man who came for the article was not the purchaser; the master was the purchaser; and if he were to send the messenger back to say that one of those gentlemen must himself come and sign the poison book, any one could imagine what the consequence would be. The Pharmacy Act put them under all sorts of restrictions, and yet it allowed all manner of interlopers to come and filch away 90 per cent. of their legitimate trade. With regard to the preparation of a new Pharmacopœia, in process of time of course the British Pharmacopœia had become somewhat antiquated, and it was necessary that a new edition should be issued. Although there were a few medical men who had had some experience of the theoretical part of pharmacy, and there might be many pharmacists who were ignorant of what they ought to know, he did not hesitate to say, taking them all round, that they knew more of pharmacy than medical men did. Then why should a body of men who knew more of the matter than anybody else be left out in the cold? Suppose the Government thought a new treatise on the practice of medicine should be published, and certain laws laid down on the diagnosis and treatment of disease, and after stating what they wanted, sent and imposed on the Council of the Pharmaceutical Society the preparation of such a book. Would not medical men soon cry out about that, even if the Pharmaceutical Society were told that they might, if they thought desirable, call in for consultation one or two persons from some of the universities, or even ask one or two eminent physicians for their assistance, but only on condition that they should come round and offer it at the back door? Yet that would be a very apt parallel to what was now taking place. Something had been said about the influence of the Pharmaceutical Society with the Government; but it appeared to him that although the Privy Council had on certain occasions asked the opinions of the Council on certain matters, that had been done more for the purpose of snubbing the Council than from any desire to get real assistance. There were representative scientific men capable of giving advice in the matter, under whose auspices they might hope for a better Pharmacopœia than could be obtained without them; but if that assistance was not to be rendered in a fair and straightforward manner, he should recommend every pharmacist to stand aloof, to let the medical men do it by themselves, and see what sort of a book they could turn out. Then when it came out, they would look at it and tell them what they thought of it. There was another matter on which he held opinions which he feared would not be quite in accordance with the Council, and with those of many members present, and this was on this question of the curriculum. He believed that if this were passed and became law, it would be a heavy blow, and great discouragement to the profession of pharmacy. He took this so-called curriculum, and found a syllabus of lectures to be gone through by the student, which occupied simply in cataloguing the names of the subjects two pages of the Journal. The idea was that a student would generally master those subjects in one, two or three years, but instead of that a lifetime would be scarcely sufficient. He could point out subjects which had occupied the whole lives of eminent men, and yet they confessed that they had very far from exhausted the subject. Yet here were young men whose faculties were scarcely matured, who had just come from their apprenticeship, where their progress must be very rapid if, in three years, they could acquire a good practical knowledge of a chemist's business, and they were supposed to come and swallow down the whole of these subjects in two or three years. He thought the Council might very much have simplified the matter if they had passed a resolution that no candidate should be permitted to present himself for examination until he had swallowed the last edition of the 'Encyclopædia Britannica,' and was further prepared to undergo an examination in Dioscorides. When he had done that, what was the splendid reward open to him? He was permitted to sell a pennyworth of oxalic acid or white precipitate, and he might even sell a pennyworth of nux vomica if he were prepared to do sixpennyworth of writing about it, and spent another quarter of an hour in instructing his customer as to the necessity of putting his signature in the poison book. He was looking over his poison register the other day, and saw an immense amount of writing, which, if it had been done by some pettifogging lawyer's clerk or deputy registrar of births and deaths, would be paid for in pounds; but he was expected to do all that for nothing and to find his own books. And yet he could truly say that that register had never been of any earthly use to any person whatever. All this made him think that they should be very careful about increasing the burdens on young pharmacists. There was another question which had not often been raised, but was of some importance: What became of the better class of students who were turned out of the School of Pharmacy? Was it not a fact, that failing to find a scope for the scientific attainments which they had reached, they turned to something else which was more remunerative? He could point to a number of men trained in that School whose services were now altogether lost to the profession. He thought, therefore, they should be very careful how they increased the difficulties in the way of entering the profession. One further remark he would make on the syllabus of lectures, and that was, the remarkable omission of any mention of the construction and use of the microscope. Now, if one thing more than another was necessary for an accomplished pharmacist of the present day to be acquainted with it was the use of the microscope.

Mr. Giles said he should like to be permitted to reply to one or two of the observations which had been made, more especially because the last speaker had addressed himself to the really important question which awaited the consideration of the meeting. He began by saying that the prominent objects of the Pharmaceutical Society at its institution were the protection of members of the trade; that he most emphatically denied. It was undoubtedly true that an attack on the trading interest of chemists and druggists was the cause of bringing together a defence association, but that defence association most prominently set forward in its programme that its first object was the elevation of pharmacy. It could scarcely overlook the rights and protection of members, which were associated in a second place in the declaration; but that which they most prominently asserted, and that which gave vitality to their organization, and which had preserved it to this day, in strong contrast to all other organizations which had risen from temporary causes, was that they identified themselves with the elevation of pharmacy. That was the essential policy of the Pharmaceutical Society, though it had sometimes been a little lost sight of. Very often mischief had been done to the interests of the Society by losing sight of that fact, and by showing rather a tendency on the part of some persons to degrade it into a trades union of pharmacists, instead of making it an association for the elevation of pharmacy. Another observation made by Mr. Bland was that he did not understand the meaning of legal status. Now that was a matter of immense importance; it was the only thing which enabled them to put forward a claim to be participators in the compilation of the Pharmacopœia. Would it not be supposed that where a country possessed a recognized body of pharmacists, where it had sanctioned the existence of an institution especially charged with carrying on pharmaceutical affairs, that it would also proceed in natural sequence to refer all pharmaceutical affairs to the care of that body and of that institution, and emphatically first and foremost that in the compilation of the Pharmacopæia it would call in the aid of that body through the operation of that institution? It amounted to a truism to say that that should be so, but as a matter of fact it was not so; and why was it not so? There was no rational answer why it should not be so; but if they asked why it was not so, a little time might usefully be spent in considering it. First of all, pharmacy had very seriously retrogaded in this century, in reference to the relation it held to the Pharmacopœia. In the year 1809 the pharmacists, that is to say, the apothecaries, for there were then no pharmacists except the apothecaries, formed part of a joint committee to frame the Pharmacopœia, together with Fellows of the College of Physicians; but the Society of Apothecaries soon renounced the practice of pharmacy, and directed their attention to other matters, and then chemists and druggists rose up to occupy the place that apothecaries had previously held. But they did not immediately fill it in a satisfactory manner; they did not place themselves in such a position. In fact they had no position; they were a disorganized, disassociated mass of matter; they had no organized unit through which they could make their claim known, and, therefore, they had no claim to be consulted on the matter of the Pharmacopœia. In point of fact, a national work of that character could not with any propriety be placed in the hands of private persons, however qualified they might have been, even if there had been, which there was not, any organization through which their qualifications could have been made known. So they came to 1841 and 1843, when the Society was instituted there was still no change. The duty of preparing the Pharmacopœia remained still in the hands of the College of Physicians until the year 1858, when the Medical Bill was passed, which transferred that function from the College of Physicians to the General Council of Medical Registration and Education. At that time the Pharmaceutical Society was six or seven years old, for it had had a very slight measure of recognition from Parliament in 1852, and it wisely, perhaps, abstained from urging claims which it would not have been in a position to justify; so it happened that the Pharmaceutical Society was still left out in the cold with regard to the Pharmacopœia. But that was some twenty-five years ago. How was it that in 1883 they still found themselves in the same position, with distinct unwillingness on the part of medical bodies to accept official equal co-operation from the pharmacists? That was a question the meeting had to consider. It seemed to him that the Council would be committing an unpardonable breach of duty if they refrained from pressing their claim, whether it were accepted or not, for they should never be parties to being excluded from such a work. The Pharmacopœia was a pharmaceutical laboratory book, and was there any sense in committing it to men who had no knowledge of pharmacy, and excluding from it persons who were bound by law to have that knowledge? The thing was monstrous and absurd. What did Dr. Redwood say at Southampton about the Pharmacopœia? That it was not the business of the compilers of the Pharmacopœia to invent new remedies, but to select and adopt them. Who invented them? The pharmacist; the pharmacist did everything except receive the credit. Were they content to go on any longer in that position? Was it right that the work should be done for the Medical Council, who acknowledged by their acts that they were incompetent to do the things themselves? Why did this state of things exist? He was sorry to say he must assume an unpleasant duty in reference to this question, for he thought the Pharmaceutical Society had something to blame itself for in this matter. The last forty years had certainly been years of enormous progress of pharmacy; all that existed had been developed from nothing in that time, but it was not forty years of uninterrupted progress. There were times of agitation, cavilling and opposition to the legitimate policy of the Society, by which great mischief had been done, and this had had the effect of lowering the *personnel* of the Society. He must say in the presence of the Council, many of whom he knew, and many of whom he did not, that the calibre of the Council was not what it was or ought to be. In saying that he said nothing which should give offence to any one member of the Council. They, on the other hand, should understand better than anybody else how true it was. He believed the fact to be that the Medical Council were not willing to accept into a Committee the individual members who constituted the representatives of the Society at the present day. He said this with great respect individually for those members whom he knew, but was it not the fact that they had not got now, even if they could be found, such men as he remembered on the Council, men like Jacob Bell, Deane, Morson, Savory, Squire, Hanbury, and men of that calibre, who had a mere dead weight of influence and importance which would help the Society very much in its present condition. How was this to be avoided? Good candidates had, he believed, been deterred from some lamentable electioneering tactics which took place some time ago when good men were rejected and men of less note were chosen. They did not come forward, and, therefore, it was not possible for the members of the Society to elect them. But it was possible for the Council to find good men if there were good men, and to create vacancies and bring them in, and he thought they might fairly ask that from the patriotism of the Council. There were no doubt some who had been there so long that they were desirous of retiring if they could find eligible successors, and it was also important that they should have more London members having London influence. However good a gentleman might be, and however much respected in his own locality, gentlemen from the country were not known to the bodies with whom the Society had relations in London. It was a serious matter, as he saw by the statement of accounts, that the travelling expenses during the last twelve months had been £403, which was quite a little annuity, and this charge had been increasing in a geometrical progression ever since the beginning of the Society. For the first period ending in 1850 the travelling expenses were £45; for the years ending 1860 they came up to £90; for the years ending 1870 they came up to £156; for the years ending 1880, £360; and for the last two years it was £403. By all means let this expense be incurred if it was any good; but if instead of being any good it prevented their having on the Council men who had an influence which could not be ignored it was very desirable to have another change and retrace their steps to the condition of things which existed formerly. He had heard of one case of a most eligible member having felt himself kept back from the Council, not because he was not willing to devote his time to it, but because since the new arrangements of reporting the Council proceedings had been introduced, so much time was wasted in talk that he really could not afford to sit it out. Speeches were addressed, not to him or to those that sat around the table, not to the business in hand, but to the constituency outside. He had always disapproved of reporting the Council proceedings. He remembered the argument at the time was that all representative bodies were reported, the proceedings and speeches in Parliament were reported, and so should the proceedings of the Council; but they forgot that that meeting was the parliament; the Council was the government, and the government was not in the habit of reporting their speeches. When he was on the Council for two or three years, one gentleman there possessed undoubtedly important influence, both in the Council and out of it, but if everything which that gentleman (Mr. Hanbury) had uttered during the whole of the meetings he attended had been reported in the Journal it would not have filled one page; at the same time nobody ever sat at that Council Board without feeling the influence of Mr. Hanbury, and when he spoke they perfectly well knew what he meant. The conclusion he came to was that the Medical Council were more willing to have to do with the Professors, whose services they could retain for a certain consideration, than to accept into their Committee the said Professors' masters on equal terms. Very small and mean influences often governed the world, and that kind of thing had a great deal of influence in the present state of the relations between themselves and the medical body. He did not know whether it would be quite in order to refer to a communication which took place between that Council and the Medical Council, but he understood a letter was on one occasion addressed to the Medical Council, which courteously and respectfully asked that the Pharmaceutical Society should be allowed to nominate members to co-operate on the Pharmacopœia Committee. He understood that that communication was treated with the greatest disrespect; its receipt was acknowledged and no further notice was taken of it. He trusted that was forgotten and that better times were coming, and that by conciliation and by approaching the medical bodies courteously and temperately their co-operation might be obtained. But they must not rest there. They had a claim which no body could possibly resist for pharmacy to be represented in connection with the Pharmacopœia. That was universally recognized in every nation throughout the civilized world, and if they submitted to a stigma, which might or might not be deserved, they were responsible for bringing on the republic of pharmacy throughout the world a reproach under which it ought not to suffer.

Mr. Frazer said it was his intention to have sat silent, having inflicted on his friends who chose to read it a pamphlet giving his views; but questions had arisen which were not before him when he penned that pamphlet, and, therefore, he must be excused for saying a few words. He must say that his views with regard to the Pharmacopœia were not in harmony with those expressed by Mr. Giles, or, he believed, with the sense of the meeting. His opinion was that they, as pharmacists, had no legal position in the matter; the pharmacists had no right to interfere with the medical man's prescriptions, and he considered the Pharmacopœia was the medical man's prescription book. The medical man found it convenient to give in one line what he might put in six or a dozen; he might give the formula of every pill and every ointment he prescribed, and then they could not assert any right to interfere with them. That was the principle he went upon, that the medical man was within his right in asserting sole supremacy in saying what the Pharmacopœia should contain. At the same time, he thought, as a matter of policy, it would be wise for the medical men to invite co-operation. Mr. Giles said the apothecaries were antecedents of the Society, and that, originally, apothecaries formed a part of the Pharmacopœia Committee; but, as he understood, the apothecaries of that day were entitled to prescribe, to feel pulses, and to employ the stethoscope, and if that were so, they were not in the position of apothecaries, not being by law allowed to prescribe and take fees for it.

Mr. Giles said he believed at that time apothecaries were not recognized prescribers; but there was a quarrel between the physicians and the apothecaries whether the latter could prescribe, as it was still a quarrel whether chemists might prescribe or not.

Mr. Frazer said Mr. Giles had also remarked that pharmacists brought in new remedies, but they did not put them in the Pharmacopœia; it was not medical men who brought in the new remedies and adopted them. He could not sympathize with Mr. Giles as to the standing of the Council. Going to another point which had been mentioned he thought it was a great mistake to change the investments; in Scotland those investments which of late years had proved most disastrous were in connection with real property, and, therefore, he hoped the Council would be very careful in this matter.

Mr. Long said the question was, How was the Pharmaceutical Society to be constituted? They must have members, and if there were no inducement for members to join, how was it likely they were going to maintain their status? Mr. Giles said they were deteriorating and that the Council was not what it ought to be; but that was the fault of the members, not the fault of the Council. Mr. Frazer thought that if a man had bought a suit of clothes he ought not to be allowed to wear them. He did not believe in monopoly, but he believed in a man's right, and he was very much disgusted to see after all the time they had been trying to benefit the public that anybody could do what they did except call himself a chemist and sell poisons. One of the questions before them that day was the Pharmacy Acts Amendment Bill. It was not the Pharmaceutical Society's Bill. They could not pass an Act or they would pass it exactly according to their own liking; but they had to go to Parliament, and they knew how difficult it was to get even the most legitimate thing passed there on account of the large vested interests which were there represented. The great thing to be done was for pharmacists to look well to themselves. They all ought to belong to the Society, and with regard to this Act they must show they wanted something. The first thing was to decide on what they wanted, and the next thing was to trust the Council. With regard to Mr. Vizer's amendment, some people said education was of no use and some said they were not educated enough. There was no doubt the more educated you were the more prepared you were. Entry into the Society had been greatly facilitated, for when he first joined it membership was only obtainable by examination; shortly afterwards, a new principle was established, that any man who had been in business so many years might divide his examination. Then came the Pharmacy Act of 1868, which established the Minor qualification; and now came another change, under which there was to be one examination which would constitute every one who passed it a pharmaceutical chemist. He did not think they could have too much education; failures resulted from want of preparation, and that could not be obtained without going through the legalized studies. At the same time he thought it would be a good thing if they had an assistants' examination.

Mr. Hampson said he did not feel himself of very much importance on the Council, and was quite willing to give place to Mr. Giles or anybody else who could better fill his place; but he must say that that gentleman had given one piece of bad advice, namely, that the Council should take upon itself the duty of interposing in an irregular manner with the constitution of the Council. He believed the safest method was the straightforward one; that men ought to sit on the Council who were sent by the suffrages of the members, and that any deviation of the kind suggested, if followed, would simply lead to very baneful results. There would be no confidence left in the Council; little as there appeared to be in Mr. Giles's mind at present, there would be a great deal less, if it became a hole and corner business transacted in some chosen spot in London. He heartily supported his views with respect to their position with reference to the national Pharmacopœia, and he believed the reason they had not attained that position was that they had not had the opportunity. Medical Bills did not come in every year; there were occasional opportunities and he hoped they had seized this opportunity to properly represent the position of the Society. But after all it did not depend so much on this much mistrusted Council, but on the members at large. The Council, good, bad, or indifferent, had only a certain power; but if every member of the Society exercised his legitimate influence with his member of Parliament the thing would be perfectly easy, because their case was absolutely perfect. They had a claim which could be resisted very little longer.

Mr. Mackenzie said he was very far from endorsing a good deal of what Mr. Giles had said. The Society included Scotland, but Mr. Giles' remarks did not apply to Scotland, because there were druggists in existence in Edinburgh two hundred years ago. Though he was not there as a defender of the Council, and might differ from them in some respects, he thought Mr. Giles' attack was most unwarranted, and that his remarks were not pertinent to the question before the meeting, because whatever the Council was, it was what the Society made it. The members of the Society looked to the members of the Council to do their duty, and if they found they were not doing what they wanted, they knew what to do when the voting papers came round.

Mr. Paterson (Aberdeen) thought the educational portion of the report had not received the attention it deserved. Speaking from a part of the country where a large number of apprentices were grown for the benefit of their English friends, he wished to say a few words upon this subject. He most decidedly objected to the first proposition that every man should pass the Preliminary examination before he was entitled to enter his apprenticeship. He did not know what it might be in England, though he always understood that there education was rather behind that in Scotland, but in many country districts there—and they were legislating not only for the cities but for the country also—secondary education was not obtainable, and until a lad had served an apprenticeship under a chemist he was not in a position to get the classical education he required to pass the examination. It would be a great hardship to preclude lads in that position from entering on their apprenticeship. He preferred to take boys from the country even without a classical education, and that they should get it when with him, to having them from the towns, for as a rule they applied themselves better to the business. Again, there were many young men who came into the business in an inferior position, who, by their intelligence, raised themselves and were able to obtain a classical education and become chemists and druggists. There were many members of the Society who had come in as errand boys, with no intention of following out the calling, but who were now very good pharmacists indeed, and had passsd the examinations very creditably. These regulations would put a needless block in the way of such persons in the future, and he thought that if the requisite knowledge were insisted upon before the diploma was conferred, that was all which could fairly be required. In Scotland the period of apprenticeship was generally five years, never less than four, and if that were to be continued and students were allowed to take the examination when most convenient to themselves, there would be less cramming and more thorough knowledge. The education required should be given during apprenticeship, and each master ought to feel himself bound to see that his apprentice got his education while under his charge. But where were they to get this education? If the Pharmaceutical Society, when it obtained this power from Government, had set itself to give educational facilities in the provinces, they would have had some reason to speak on this matter; but he held they had none. They had concentrated their whole efforts on the central establishment in London and had done nothing for the provinces, and therefore he did not think they were entitled to talk as they did about the deplorable fact of so many young men coming up unprepared. It seemed to him they were themselves greatly to blame for not having encouraged apprentices to acquire their education. If in connection with the Science and Art Department, the Pharmaceutical Society had set itself to promote pharmaceutical education in the provinces, they would not have had this deplorable condition of things, where so many young men were turned back, and they would have had a much better educated class of assistants. They cried out against cramming: but the whole system had led to cramming. In many country districts it was impossible to get teachers paid except in connection with the Science and Art Department. Some of the great London companies were doing a great work in the country by offering prizes and paying teachers to conduct classes in particular branches of study in which they were interested, and it seemed to him that the Pharmaceutical Society might set itself to something of the kind, so as to diffuse education throughout the country; and if they did not the same cry would always be coming forward about cramming, and about imperfectly educated assistants and apprentices. It might be possible for the sons of the gentlemen around him to spend five or ten months in study, but that was perfectly impossible for the great mass of the people—in Scotland at any rate—who joined the trade; and the class from whom they got apprentices could not afford to pay for the education which was now required, unless they could get it on the spot when serving their apprenticeship. The feeling in Scotland was that all this was being done that they might draw cheap assistants to London. He should therefore move, when in order, that there should be no change in the matter of education at present; that apprentices should be allowed to get their education in any way, and come up for their examination as heretofore. The first paragraph in the regulations would impose a great injustice on those who had entered the business, because according to this a lad who had just come out of his apprenticeship, and had not passed the Preliminary, would have to do so, and then spend three years more in a chemist's shop before passing the examination.

The President said there would be four years before the regulation would affect those who were now in the trade.

Mr. Lomas said one of the objects of the Society was education. That being the case, boys should not be taken as errand boys, thinking they were going to become sufficiently able to pass the examination. All those who were to become pharmacists should receive a good general education before entering on their apprenticeship.

Mr. Broad thought what had been said by Mr. Paterson with regard to boys entering on their apprenticeship without passing the Preliminary was most illogical. He said an errand boy might be educated by his master to pass his examination; then he would become a master, and how could he educate his apprentices? It was an utterly absurd idea. The Pharmacopœia revision was a point which he felt very strongly on, and he could not agree with Mr. Frazer that it should be entirely in the physician's hands. If the physician wrote a prescription the pharmacist had no right to interfere; but if he wrote, as physicians used to do, and sometimes did now, so and so *secundum artem*, it required the pharmacist to interpret that and to practically make the Pharmacopœia, because the Pharmacopœia really was the mode of preparing these preparations. If physicians wished for a certain preparation of nux vomica, pharmacists told them how to prepare it. With regard to Mr. Giles' remarks about the Council, he was sorry to say that some pharmacists he knew were not content with the calibre of the present Council. Several of them said they did not care about the Society, which was not managed as it used to be, and therefore he thought Mr. Giles was perfectly justified. Mr. Bland attacked the old Pharmacy Act; but he thought it was not to be complained of so much if it were carried out in its entirety, and he should like to see some one appointed by the Society to go round the various districts and see that the Act was properly carried out.

Mr. Cross (Shrewsbury) said after the remarks made on this amendment by several speakers, and notably by Mr. Giles, he felt that having come some one hundred and fifty miles he ought not to go back without expressing an opinion. He was not vain enough to suppose that he could add much to the force of the eloquence which had been directed against some portions of Mr. Giles' speech, but he was a distinct believer in representation, and he felt that unless they came up from the country periodically to confer with their friends in London, pharmacy would degenerate into a very hole and corner sort of business. It seemed to him most inopportune, when they were concentrating their whole energies on improving the regulations for educating students, that they should be told that after forty years of education the educated men were selecting worse men for the Council than their predecessors did. He believed every member, if he considered the immense amount of work which devolved on the members of the Council, would say that they deserved their heartfelt thanks, and would not accept the statement that some of them were men who were not fit to be associated with medical men. With regard to the publication of the reports in the Journal, it would be most unfortunate to those who resided in the country if they had not an opportunity of reading from time to time what took place in the Council. Mr. Giles said a large sum, which was annually increasing, was spent in the travelling expenses of country members, and intimated that the money was thrown away, but that he must contradict. The more they got the influence of various parts of the country brought to bear on the question of pharmacy, the better the legislation would be for pharmacy as a whole, for it did not exist only in London. In conclusion, he believed that if the country chemists took more political action in pharmaceutical matters they would have fewer of these bickerings which Mr. Giles had referred to.

Mr. Ellinor (Sheffield) said if it was said that London members should form a larger proportion of a Council he believed the country members would object, and would cease to subscribe; and if, as he believed was the case, the country members subscribed a great deal more than the London members, it must be conceded that they should have the privilege of sending members to the Council. They all knew it was a great convenience to have a sufficient number of London members, in fact, the Society could not be worked without, because emergencies cropped up which could only be attended to by London members. As to their liability, it depended on those who sent them to select suitable members, and he had no fault to find with the present Council. Coming to the question of the Pharmacopœia he thought its compilation should be in the hands both of medical men and pharmacists, and nothing less should satisfy them, because if they had pains and penalties imposed on them, if it was a contract, and the parties named in the contract should be fairly represented. The Pharmacopœia was not a physician's prescription book in the sense Mr. Frazer gave it; it was really a guide and a standard, and therefore it was not the production of one man or the invention of one individual practitioner, it was a number of formulæ compiled for the guidance both of pharmacy and medicine, and both branches should be equally represented on the Committee which prepared it. He thought there should be one pharmacist from Scotland and Ireland, and four appointed by the Council, and if six members of the medical profession were joined with them, that would form a committee which would work well. The senior member for Sheffield had charge of the Medical Bill, and it was his intention to appeal to him and put this very vividly before him; and having met Mr. Mundella many times he knew his plan of reasoning, and should have great pleasure in going before him, because he knew he should receive the courtesy of a man of intelligence who was desirous of doing that which would be best for all concerned. As regards apprenticeships, if Mr. Paterson was desirous of taking in these youths, let them have their two years' classical education before they became apprentices. The difference would then be solved. The Science and Art Department lectures were not suitable for pharmacists. It had been found in Sheffield and other large centres that their students would not go to them, because they were of no use to them. He considered that in all large centres there should be schools established, and it should be made the aim of young men to qualify themselves in a sufficient number to give lectures on these scientific subjects. If they were properly qualified they ought to be qualified to teach. The plan had been tried in Sheffield, but failed owing to the want of a sufficient number of students. Lectures had been organized and some members had given lectures, and even provided specimens and materials without charge; but unfortunately the students did not come forward in such numbers as they ought to have done, and even those who received the benefits and were materially aided in their preparation to pass the examinations, though they had afterwards commenced business in the town, had not even joined the Society. This was a thing which was much to be regretted, and was not creditable to the parties concerned. Every one connected with pharmacy ought to be a member of the Society, as the door of membership was now open to them. He hoped the country associations would be better supported by different members in the trade, for it was disheartening to find that in large centres only a few members could be got together when an interesting paper was to be read. They all knew of the case of the citrate of caffeine poisoning, and he should like to ask how far the Adulteration Act interfered with the operation of the Pharmacy Act and the discretion of chemists. The chemist who dispensed that citrate of caffeine was told by the medical man that he ought to have known better than to have given it; but if he had done otherwise in dispensing that prescription, would what he supplied have been of the nature and substance of the article demanded? He had written to the editor of the *Lancet* to ask this question. The reply he had was that his letter would be published in the following number, but it was not published, and he still remained without this important information, which he hoped to have obtained from such a high authority, whether the responsibility which rested on the chemist was or was not interfered with by the Adulteration Act. They had had prescriptions written by medical men taken to an analyst, in order to test the chemist. If a chemist were to be tested by a prescription containing a large dose of poison, say 20 grains of iodide of potassium, when they knew that 2½ grains would sometimes produce very serious effects, and they could not get any information who had written the prescription or what it was for, were they to use their discretion or not? And if they were compelled to dispense it as it was written and any mistake arose, who would be responsible?

Mr. Howard Hall said he rose principally because Mr. Giles had cast some unfounded aspersions, as he considered, on the outgoing Council. He thought they had every reason to be satisfied with the report, which was one of the most encouraging they had had for several years. The income was not only larger by £194 than last year, but it showed a considerable increase on the year 1880, whilst the expenditure also showed a great saving. He was sorry to see the decrease in the number of pharmaceutical chemists, which was a very serious fact which had been alluded to at former meetings, and if it went on the time must come when there would be none left. The number of those who passed the Minor examination showed an increase which was gratifying, and so were the figures in connection with the Journal, which showed a profit of upwards of £400. The question with regard to the surplus was, What did the Council intend to do with it? Could they not improve the character of the Journal? Why should they not improve the character of the Journal? Why should they not spend £100 or £200 more in original contributions and in engravings? Why should they look to America and other foreign countries for matter for the Journal, and why should there be so much reprint from kindred publications? He would ask those who managed it to try and make it a truly representative organ. The travelling expenses of country members had been referred to, and he would ask why should not country members pay the expenses of their representatives in coming up to attend the Council meetings?

Mr. G. W. Sandford asked whether the proposal to change the investments of the Society included the property of the Benevolent Fund.

The President said, Yes; both the Benevolent Fund and the General Fund.

Mr. Sandford said he entirely disapproved of the change, and thought it would not benefit the Society financially; they would have to set up a staff of collectors, clerks, and decorators, and probably get less return for their capital in the end than at present. He remembered perfectly well that this subject was discussed in Council whilst he was a member of it over and over again, and was always decided in the negative. There were great difficulties in the way; in the first place, by the Charter they could not invest more than sufficient to yield a certain income in property, and they could not at any time sell or dispose of that property without calling a general meeting of the Society. He feared these difficulties had been scarcely calculated on in coming to this resolution; he should make no motion about it, but he felt it his duty to leave a protest on the records of the Society that he thought it bad on principle and most unwise. With regard to the question of pupilage he was quite of opinion that a preliminary examination should be passed before any youth was taken into a pharmacy at all, but he wished to know whether the regulation meant that he must spend three years in one special shop; the words would seem to imply that he must enter upon his apprenticeship immediately after passing the Preliminary examination, though that perhaps was not intended, and also that he should pass the three years in one shop.

The President said that was not the intention.

Mr. Stacey entirely endorsed Mr. Sandford's view with regard to the proposal to alter the investments. He would not detain the meeting further on the education clauses, though there were many points he might raise a serious objection to. He thought the scheme was incomplete and wanted more consideration, and was sorry it had come forward in this report in the form it had. He should, therefore, have been glad if these two parts of the report could have been referred to the incoming Council. When Mr. Paterson referred to the first and second clauses in the educational part of the report, the President corrected him in his reading, but it seemed to him very clear that the young man was to pass his Preliminary examination before he could take up his apprenticeship, or become a pharmaceutical student. Mr.

Martindale had referred to youths being apprenticed at sixteen, and having four years before they need go through the curriculum, but he thought he had lost sight of the possibility of a parent wishing his son, who might have attained the age of eighteen, nineteen, or even twenty, to become a pharmaceutical chemist, and he thought it would be a pity to throw any difficulty in the way of those coming forward later in life.

Mr. HUMPAGE said he very much respected the opinion of Mr. Sandford, but with regard to the change in the investments, it appeared to him that when they had twenty-one men on the Council, men of intelligence and judgment who had the interest of the Society at heart, he could not suppose they would do anything unjust, and, therefore, when they came forward and said it was their intention to do so and so, he must confess, individually, he felt more confidence in what they proposed than in what outsiders might think. With respect to apprenticeship, he was decidedly of opinion that three years was not too long; in fact, it was not long enough. It was said that young men of genius were prevented from qualifying themselves and going into business early; but he had never known an exception to this rule, that when a young man had been able to pass the examination young, and go into business at an early period, he regretted afterwards he had not waited a few years longer, therefore anything which tended to defer the time of entering business was rather an advantage than otherwise.

Mr. RICHARDSON said he wished to say one word in answer to the cruel remarks of Mr. Giles—

Mr. GILES said he had not said a word which reflected on a single member of the Council. He was himself a member of the Council in 1853, and thought he was entitled to be there; but it would have been a deplorable thing if the Council had consisted of twenty-one R. W. Giles's. All he had said was, that whatever the claims of any one individual to represent any one locality might be, it was a pity that the calibre of the Council did not, as a rule, stand as high as it did twenty-five years ago.

Mr. RICHARDSON said it was a great pity that Mr. Giles should have retired from the Council at all; he was sure its calibre would be sustained by his eminent presence, if he would return to it. He should be very sorry to sit there as an exhausted volcano, and to have such strictures passed on their efforts to represent the great body of pharmacy, and he did take exception to Mr. Giles's dictum as to the members of the Council being selected exclusively from the London members of the trade. The country members constantly complained that they were not properly represented, and the town members did not thoroughly understand the method of conducting business which their country brethren had to go through.

The VICE-PRESIDENT said he would not say much with regard to what Mr. Giles had said as to the composition of the Council. He had now made a further explanation which did not, however, much affect the matter. Of course he did not say anything with regard to any particular member. He had too much respect for Mr. Giles's reasoning powers, as well as for his knowledge of the history of pharmacy, to question much that he had said, but he did take exception to his view of the position of the Council. No doubt in those glorious old days of the past, to which they were always poetically referring, there was the grand array of heroes to which he referred, but as he belonged to the unknown class, he could very fairly point to the President, and was quite ready to compare him with any man who had gone before. If there was a good all round man, not simply a scientific man, but one capable of representing the Society anywhere and with anyone, it was the President. It would be a great pity if the question of town and country were ever raised with regard to representation. Both great sections of pharmacists had their fair claim to representation, and he thought the present condition of things was relatively perfect. Those in the country felt that they owed a debt of gratitude to the London members, some of whom, like the President, were almost entirely absorbed with the work of the Society. There was often work which required prompt, immediate and urgent action, which must be taken in hand before members could be summoned from the country. The country pharmacists were fairly represented in quantity, whatever might be said about the quality, and the London members were most ably represented. He emphatically disclaimed the idea that the Society did not originally contemplate the protection of the trade. There were three things set forth at the foundation of the Society; and they were all included in the charter; education came first and a long way in advance of any other, but then came the protection which every incorporated body did contemplate, and, thirdly, benevolence. The two great points in the Report seemed to be these: Pharmacopœia revision, on which there seemed very little difference of opinion; but he wished to express his view very distinctly that they should ask for nothing less than a co-ordinate power in the preparation of the Pharmacopœia. He did not mean a departure from the existing lines by certain individuals eminent men being asked to assist, or that the Medical Council should come and ask them as a Council for assistance, although that would be a great gain, but they wanted the Legislature to enact in some Bill that in the preparation of the Pharmacopœia pharmacists should have a co-ordinate power. With regard to the curriculum, so much had been already said that he would only add that their object as a Council was not to place additional difficulties in the way of students entering the calling. The fundamental thought was this, to facilitate the progress of all duly qualified young men, and it was because they had seen so large a percentage of failures arising from want of due preparation that this scheme was devised. They could not legislate for exceptional cases or for genius, but for average men. Some charges had been made by previous speakers against the Society for not fostering provincial associations and providing the means of pharmaceutical education in the country; but as long as he could remember, one of the great things which had been constantly urged in the Journal and talked about in the Council meetings was the fostering of such associations. They had always said, let the schools be formed and they shall receive assistance, and that was what they said now. There were a few very valuable and flourishing organizations in the country, but not so many as he should like to see.

Mr. Vizer's amendment was then put to the meeting and lost by an overwhelming majority.

Mr. PATERSON then moved the following amendment:—

"That no change in the examinations be made at present."

When speaking before, the President said that the rights of present apprentices would be respected, but he would call his attention to the last note in the transactions of the Journal of March 10, 1883, which seemed to indicate that those at present in the business, unless they passed the Preliminary before the end of the present year, would have to do so, and then under this regulation go back for three years' apprenticeship, which would be a great hardship and ought not to be inflicted on anyone. He did not object to the educational standard at which they were aiming, and all he wanted was they should not shut the door against possible candidates without any good being effected. When he spoke of errand boys, he did not mean that they were to take every errand boy and make him a chemist; but if an errand boy showed exceptional ability and perseverance, why should he not be allowed to go on and pass his examination without requiring him to spend a length of time, which people in his circumstances could very ill afford. With regard to provincial education, in Aberdeen a fully equipped school of pharmacy was started and they applied for a grant from the Society, the result of which was they were offered the liberal donation of a loan of £10 worth of glass instruments to be returned in the same condition three years afterwards. Under the Endowed Schools Act they had been able to get over all the difficulties; they had a large and growing technical school, and at the request of the Association the college had taken up the matter of pharmaceutical education and was giving both the classical and technical education necessary for chemists. He therefore spoke in no sense as seeking anything for Aberdeen, because they were thoroughly provided with the means of education, and he therefore felt more freedom in speaking for those parts of the country which did not enjoy the same privileges. It was a great hardship on lads who were not in the same position to get the education necessary that they should be put to the trouble and expense which this proposed curriculum would impose upon them. Mr. Ellinor said the instruction given by the Science and Art Department was not suitable for their students; this he was quite aware of, but why should it not be made suitable? A plan had been suggested which would meet the difficulty, namely, that those who came up to London and completed their studies should return to the country and give lectures, receiving from the Science and Art Department that remuneration which they would not otherwise obtain. He wanted to see education brought to the doors of the young men as far as practicable, and when that was done, he saw no reason why examinations should not also be held locally. In Aberdeen, doctors could receive their diploma, and he did not see why medical men should be sent out to prescribe and at the same time their apprentices could not be qualified to dispense their prescriptions.

Mr. Candy seconded the amendment.

Mr. Whittle did not think it expedient to have errand boys turned into chemists. He believed what these gentlemen wanted was cheap labour.

The President said this question had been thoroughly discussed over and over again for several years, and he would therefore now put the amendment.

The amendment was put and lost, and the original motion adopting the Report of the Council was then carried almost unanimously.

Mr. Sandford then moved the following resolution of which he had given notice, namely:

"That in the opinion of this meeting certain provisions set forth in the proposed Bill to regulate the Sale of Poisons and alter and amend the Pharmacy Acts require alteration, especially clauses 4 and 5, which render retail vendors of patent or proprietary medicines who have not and cannot have any control over the required labelling of such medicines liable to prosecution for insufficient labelling, for which offence the proprietors only should be and can be made responsible."

It might seem that having been so long associated with his friends on the Council, to which association he looked back with great pleasure, that he should be very chary in finding fault with anything they had done; but he felt that he had a duty to the Society as well as to his old friends on the Council, and if members joined him in this protest against what he considered a most unjust proposition, the Council would be relieved from a great burden, because if the thing passed as they proposed it, it would be a perpetual blister, and a very ill reflection on those who framed the measure. The President had said that the Bill had been framed somewhat in obedience to the wishes of the Government. No doubt it was framed at the request of the Government, but it was framed by their own Council, and while it should be framed to fully protect the public from all harm which might arise from neglect, it should be so framed as not to inflict on chemists and druggists, whom he might call innocent persons, a great hardship. The first objection brought forward to his proposal was the necessity for proving the purchase; but the necessity for proving the purchase of a patent medicine did not exist as it did in the case of an ordinary poison, inasmuch as patent medicines were not purchased for criminal purposes. They did sometimes inflict mischief by careless use, and sometimes he was afraid they were used as intoxicants, at all events they got a character of that kind, and it was on that particular point the Government were anxious to have restriction. He remembered a case in which a prosecution was instituted, in the matter of Hunter's chloral, for instance. Another objection put forward was that chemists in selling poisons should be treated as grocers and all other people were in the sale of adulterated articles, but he submitted that the two cases were entirely different. The man who sold adulterated mustard or jalap was supposed to be a man educated for his business and to know when he handled his mustard or jalap what he was handling. Therefore, if a qualified man sold an ounce of jalap which was adulterated he became *particeps criminis*, and should be punished accordingly; but not so with a patent medicine which was sealed up. If he opened the packet he destroyed the seal, and therefore he had no means of knowing whether it was labelled "poison" or not, and in many cases there were no means of knowing whether the article contained poison or not. If this Poison Bill were passed for patent medicines there would be a greater tendency than ever to send out patent medicines containing poisons without a label of that kind, because the word "poison" would to a great extent hinder the sale of a patent medicine, and therefore chemists would be placed in more direct danger, since if the maker did not describe it as poisonous, they did not know that it was so and could not open it and examine it. He regarded the seller of a patent medicine simply as a postman delivering a sealed letter. Then they were told that the retailer must be immediately attacked, because it was difficult to get at the proprietor. He said it was not; every patent or proprietary medicine had on it the name of the proprietor, and if you could not get at the proprietor of the medicine, how were they, who had been fined, to get at him to be reimbursed. They were to be fined £5 for selling a patent medicine improperly labelled, and their names would be sent forth to the world as having been convicted of an offence, which was not pleasant. They would know amongst themselves that it was no offence, but the world outside would not know it. The sixth clause provided that they could recover from the person from whom they bought, either from any intermediate seller, or from the proprietor, and this would lead to a nice little crop of law suits. Then again, they were to recover from the proprietor the amount expended in the penalty and costs; but he should like to ask what would be done in such a case as this. If he committed a first offence in the selling of Hunter's chloral, he would be fined £5; a month after he might commit another offence by selling somebody else's patent medicine improperly labelled; that would be a second offence, for which he might be fined £10. But would the proprietor of the second medicine have to reimburse him his £10 and the expenses he had been put to in the matter; it would certainly be a great hardship on him if it were so. If he could canvass the Council individually he believed they would agree with him that this clause should be struck out. It was perfectly easy; he had a clause written which would make it easy at once to attack the proprietor. He knew there was something said about patent medicines or proprietary medicines brought from abroad, but he would provide for that by enacting that every maker of a patent or proprietary medicine in Great Britain or Ireland should mark it with his name and address and the word "poison" or "dangerous," or whatever was required, and he would have the same requirement on every importer of foreign medicines of the same character. There were one or two other blemishes in the Bill, but this was the most important, and he thought it would be best to confine themselves to this point first.

Mr. Urwick seconded the motion.

Mr. Mackenzie was delighted to see the position taken up by Mr. Sandford, and had great pleasure in supporting it, for he had objected to this all along as being most unfair. He believed the clause would never pass the House of Commons in its present form, but he hoped every individual would bring his personal influence to bear to get all that was good in the Bill and expunge that which was objectionable. If it were passed as at present it would be a constant source of irritation. Whatever went to Parliament it should really do what it represented, and he remembered a case where a Bill was turned out because it did not correspond with its title. Was it right that sulphuric acid should come under the class of things no longer to be labelled "poison," but only "poisonous"? It would look like changing the meaning of words, and that was a precedent which ought not to go from that Society.

The President said he would appeal to the meeting if it were at all likely that twenty-one members of Council would deliberately tie their hands by any proposition unless there were good grounds for it. He had before him the clauses which Mr. Sandford referred to, about importers and so on, and he seemed to think it was a very easy matter. But not having so much perception gained by long experience as Mr. Sandford, he failed to see how the clauses he had drawn would meet the case. If the sale of poisonous patent medicines were to be restricted to registered persons these clauses would not meet the case. If they did not want any responsibility whatever they must leave the patent medicine poison question altogether; but they desired that the sale should be restricted to registered persons, and they had had requests from other bodies that they should be so restricted. If this were so some responsibility must be thrown on the seller. Why should the chemist and druggist be allowed to sell these things without any responsibility at all? It was out of harmony with all previous legislation. It might be desirable not to touch the patent medicines containing poisons, but the subject was not one to be dealt with off hand in that way. With regard to the penalties, Mr. Sandford certainly had a case. A cumulative penalty might probably prove inconvenient and could easily be struck out. But some of them had had experience in working out the provisions of the existing law, and knew how difficult it was to carry out the Act satisfactorily. Their object was to draw clauses which when passed should work. But supposing Mr. Sandford disapproved of their action with regard to all poisons and became a disconsolate member of the drug trade and retired to Boulogne, what was there to prevent his inundating the whole of this country with poisonous patent medicines through an assistant at Folkestone having his name, "George Webb Sandford, Boulogne-sur-Mer," on every package? He was the proprietor, and how was he to be approached. You could not summon a man who lived at Boulogne, because he was out of the jurisdiction. It was the commonest thing for men who owned proprietary medicines which were not allowed to be imported into a foreign country to go there, make them, and put a label on the article with their proper domicile, and persons anxious to create a trade in poisonous patent medicines would adopt some such plan for evading the law. It was because they were advised that they could not satisfactorily deal with such cases and further reasons that this dreadful clause six was put in the Bill. It seemed very hard that when a man sold a patent medicine improperly labelled he should be fined; but he thought it necessary that pharmacists should exercise judgment even in connection with these patent medicines, if they claimed to have the exclusive right to sell them. While he objected to anything which would tend to involve anyone in law suits, they knew that the patent laws could only be worked on the basis that the person who sold the article which was infringed was made liable. No doubt in this case the damage to the reputation of a chemist was greater than that to an ordinary tradesman who infringed a patent, and he was willing to meet Mr. Sandford as far as possible; but he could not see his way to draft a clause which would meet all the difficulties which would crop up. He, therefore, asked members to place confidence in the Council and not to run away with the notion that they were to be sacrificed for a mere whim. As regards importation, Mr. Sandford said the importer should have his name on the medicine; but who was the importer? Every one in the room might, at some time, import a foreign patent medicine, but he did not consider himself the importer. Mr. Sandford would, no doubt, consider that one particular person was the sole importer of any particular article; but that would never be so in the present condition of trade. Some men would send to New York or Philadelphia and give their orders direct, while others would obtain the medicine through Barclay's, or some other wholesale house. The practical working of it would be that whenever a man bought a new patent medicine about which he had the slightest suspicion, he should ask whether it contained poison, and the large patent medicine houses would decline to touch anything which contained poison unless it were declared so, in order that they might be protected, and it would be for the good of the public that it should be so.

Mr. Hampson asked if Mr. Sandford would be satisfied if this clause were remitted to the Council for re-consideration. There would then be an opportunity of reviewing the matter, and if it could be amended with the help of Mr. Sandford, they would all be glad to do so. The view presented by the President was quite as strong as that presented by Mr. Sandford, and he believed those who prepared these articles would find it to their interest to conform to the law, whatever it might be.

Mr. Long said the difficulty would be this, he might be asked for a box of Snook's Pills or Thompson's Elixir and supply it; then the next day he might hear that the person had died, and that might be the first he knew that the article contained poison. It was a pig in a poke altogether. He did not see why they should have a Bill which put a yoke on their own necks. If they knew an article was poisonous they would conform to the regulations. Supposing a manufacturer forgot to label a bottle by accident, the chemist would be liable to a £5 penalty.

Mr. Johnson asked if this Bill were carried would the Pharmaceutical Society undertake to define what patent medicines required the name and address of the seller, otherwise they would not find out until after an accident happened whether it contained poison or not.

The President said there were various ways in which the Society might protect the members, and it would, no doubt, be willing to do so.

A Member asked if it was not possible to make manufacturers register the contents of their medicines.

The President said that might be possible, but then there would be the difficulty with importations.

Mr. Christopher Wheeler said there were numbers of things constantly coming out which were not patent medicines, but only nostrums covered by a Government stamp. If it was the duty of anybody to put on the poisonous label it should be the manufacturer. They should not put the saddle on the wrong horse if they could help it. He believed there was no such thing in the country as a patent medicine; they were all secret nostrums, and the maker of the nostrum, if it were dangerous, should be compelled to label it.

Mr. Urwick asked if a medical man prescribed Fellows' Syrup, would it be necessary to mark it poison.

The President said not when it formed part of a prescription. If they sold an original bottle of any preparation containing poison without a label, it was a question whether, under the existing law, they were not liable to be fined.

Mr. JOHNSON said he had had a prescription simply "one bottle of Fellows' Syrup"; how was that to be dealt with?

The PRESIDENT said his opinion was that in such a case if the preparation contained poison that it should be labelled.

Mr. ALLEN said if they were to ask for legislation sanctioning the making and vending by unqualified men of poisonous preparations, they were going altogether from their position.

Mr. HUMPAGE thought the matter had better be referred back to the Council with the assistance of Mr. Sandford.

Mr. SANDFORD said, seeing what the Council had done in the matter, he was not inclined to leave it in that way. It had with its eyes open committed a great blunder, and proposed inflicting a great hardship on the trade. This was not a proposition by the Government, it was the proposition of the Council itself, and they should not leave the room without an expression of opinion that it was disapproved of. The President had spoken of an Englishman going to France, and then sending his patent medicine to England, but it then became at once an imported article.

The PRESIDENT said that was not the case he put, but of an Englishman making the preparation in England, but residing in France.

Mr. SANDFORD said that would be a very exceptional case. They were asked if they were not to give some equivalent. An equivalent for what? for confiding to the qualified body the sale of those patent medicines which contained poison, not patent medicines generally, but simply those which were dangerous. Was that to be an equivalent for subjecting themselves to such penalties and disgrace as might be brought upon them by this clause? It was altogether unreasonable. He had prepared a clause that would take the place of clauses 4, 5 and 6, and be just as much protection to the public, whilst it would not expose chemists and druggists to what they were now threatened with. He hoped the members would support his motion.

Mr. SCHACHT asked whether the resolution, if adopted, was to be a direction to the Council to make a new clause in accordance with the motion.

The PRESIDENT said it would be the opinion expressed by the meeting that it was desirable the clause should be amended. They could not do more than that.

Mr. SCHACHT asked if the next General Meeting might not think it rather hard if they were told that the resolution could not be carried out. Yet that was really the position. The matter had been very carefully considered and the Council did not see the possibility of doing what was desired.

Mr. WILLIAMS said he should not have spoken, but for what had fallen from Mr. Schacht. But he must now be allowed to say that throughout he had been in opposition to the majority of the Council on this point. He thought Mr. Sandford's proposal was the right and reasonable one.

Mr. HAMPSON said that he would move an amendment—

"That the clause be remitted to the incoming Council for further consideration."

Mr. SANDFORD thought it was unfair to move an amendment after he had replied.

The PRESIDENT said it was quite in order to move an amendment before the resolution was put.

Mr. HAMPSON said his amendment was very much in harmony with Mr. Sandford's proposition. The clause had not been framed without considerable care, and very full legal opinion had been obtained. He was quite sure the incoming Council would bear in mind the strong expression of opinion which had been given against the clause as it stood, but he was quite prepared to go into the whole question again.

Mr. REES seconded the amendment. He thought the resolution would only have the effect of facilitating the general sale of patent medicines wholesale by everybody. If everybody were allowed to sell poison in the form of patent medicine, why not sell it in the form of a vermin killer? That was why it was proposed to restrict it solely to chemists. He thought the dilemma which it was said they would fall into was purely imaginary. If the proprietor of a patent medicine was made to pay one fine he would take good care not to incur the penalty a second time.

Mr. SANDFORD said they knew the next Council would be almost identical with the present, and he was not prepared to leave it to the next Council without a strong vote on the part of the meeting, as a message to the Council to the effect that they would in every way oppose a Bill containing such a proposition if it were placed before Parliament.

The amendment was then put to the meeting and lost, the votes being 46 in favour of it, and 49 against.

The resolution as moved by Mr. Sandford was then put and carried.

Mr. SANDFORD said there were one or two other clauses in the Bill which required notice. In the clause referring to persons having more than one shop, he would strike out the word "branch," and insist on every man who kept more than one shop having a qualified assistant in each. You could not tell which was the branch shop and which was the parent shop. The proprietor must leave his shop to go to the branch, and it might become a question which was the branch shop and which was the other. One other point was that clause 3 did not go sufficiently far; it was framed after the trial and conviction of Lamson, and it was thought desirable to prevent such offences in future. The clause as it stood might perhaps bring a murderer to justice, but it would not prevent a murder. What they wanted was certain power, which some exercised already, to prevent the sale of certain potent drugs on personal application to men pretending to be doctors. He did not in any way wish to affect wholesale dealing in the ordinary acceptation of the term. To give an instance, a man came into his shop not long ago and ordered a very strong preparation of morphia. He happened to see the prescription, and asked to see the person who had ordered it; he was told the man had written the prescription on the counter, and was going to call for it. He told the assistant not to let him have it, and when the person called he told him he could not sell such a medicine as that to a stranger; the reply was, why did they take the order? He said because it was thought he was a medical man, which he at once disclaimed, and that was just the difficulty. Some people did not like to offend an apparently respectable man, and therefore he would give them the same kind of authority as they had for selling the articles in Part 1 of the Schedule, namely, requiring personal knowledge or introduction. He thought it would be a great relief to chemists generally if they had that kind of authority for refusing to sell to a stranger two grains of aconitine or strychnine; he would not interfere with morphia or opium, because it would sometimes be very inconvenient. The clause for keeping orders for twelve months would still remain in force. He was told that this might be a great hardship on a medical man who was called into a country town, and wanted to give a patient aconitine. Such a thing would scarcely ever happen, and if it did, the medical man would have been summoned by someone in the town who would be known to some chemist, and would vouch for the medical man who wanted the article.

Mr. MARTINDALE agreed that the word "branch" might be omitted, but he thought the last proposal would be impracticable. Would Mr. Sandford apply it to hypodermic injections. He thought they ought not to make laws to meet particular cases; the end desired would be much better met by requiring medical men to write their orders on a printed form, giving their name and address, so that the chemist might know who was the prescriber. He knew it was a rule of the College of Physicians that a physician should not sign his name in full to a prescription, but he thought the rule was very absurd, and that the public safety should override such regulations.

Mr. SCHACHT, referring to the resolution already passed, said he did not feel at all pleased at the prospect of having to alter the clause in accordance with the instructions the meeting had given, because, as far as he could see, it could not be altered. He would suggest that the meeting should appoint a small committee to confer with the Council to see whether it could be done, his opinion being they would find, on investigation, that it could not. What was the offence which was to be punished? The offence was the retailing of the poison, and that was not committed by the manufacturer.

Mr. SANDFORD said it was out of order to raise the question again.

Mr. SCHACHT said he thought it was quite regular in order to carry it out that a committee should be appointed.

Mr. UMNEY seconded the proposal; it would be very unwise to come to any hurried conclusion in the matter, and it would be far better to appoint a sub-committee consisting of three gentlemen, to confer with the Council.

Mr. SANDFORD said his resolution was that the clause, as drawn, should not be carried out to make the retailer responsible; there was no difficulty whatever about it, and no occasion to appoint a committee. It would be quite useless to appoint three gentlemen to meet twenty-one.

The PRESIDENT said he agreed with Mr. Schacht's proposition, but he thought perhaps it would be better not to press it.

Mr. SCHACHT said he thought such a committee ought to be appointed, and he would move that the Committee consist of Messrs. Sandford, Umney and Martindale.

Mr. SYMES asked Mr. Schacht to withdraw the resolution; almost everyone present had discussed the matter, the Council was fully in possession of the opinion of the meeting, and would no doubt do its utmost, notwithstanding what had been said about the impossibility, to bring the clauses to which attention had been drawn as far as possible into conformity with Mr. Sandford's wishes. He rather regretted that while Mr. Sandford would release the trade from one difficulty he should try to saddle them with two more, because such a regulation as he had just suggested would be of no use unless surrounded by pains and penalties.

Mr. FRAZER wished Mr. Schacht would withdraw the motion.

Mr. SCHACHT said though a great many opinions had been expressed in favour of Mr. Sandford's resolution, the view on the other side had only been put forward by the President, and though he might accord in what had been said, the whole of the case had not been stated. He therefore thought it better to have a small committee, who should have an interview with the Council and hear what could be said on the other side.

Mr. SANDFORD said he could not sit on the committee, as he did not now reside in London.

Mr. GILES said supposing the committee were formed, and were to come to a new conclusion, how was the resolution to be carried out.

Mr. WILLIAMS asked to whom the committee were to report.

The VICE-PRESIDENT said he was quite sure the incoming Council would respect the opinions which had been expressed. It was always an unpopular suggestion to make that the *vox populi* at a public meeting was not always the *vox Dei*, but such might be the case. He had no particular affection for the clause, and was quite willing to go into the whole matter again; but if having done so, the Council failed to alter its deliberate opinion, he feared some members might think it had played them false.

Mr. EKIN was afraid the Council would be rather open to that imputation; the vote was very close, and on that ground he would urge that the Committee should be appointed, and also to save the Council from any imputation of falseness. Certain members of the Council said it could not be done, whilst Mr. Sandford said it could; if, therefore, a committee were appointed to confer, it would save the Council from the responsibility of refusing to carry out the resolution.

Mr. STACEY said the resolution had been passed, and he thought it was the duty of the Council to carry it out. He was sure the Society would not feel that confidence in the Council which they ought if the Council imposed such burdens upon them as that they should pay for other people's faults.

Mr. HAMPSON said that supposing after consulting their legal adviser and taking counsel's opinion they were told that a clause such as Mr. Sandford desired could not be framed, what should be done then?

Mr. SANDFORD said he should laugh at any counsel's opinion to such an effect. This clause was nothing but one for the multiplication of law suits.

Mr. CANDY asked if Mr. Sandford could make an alternative proposition. The resolution had been carried only by a narrow majority, but if it represented the sense of the meeting, the meeting ought to take some steps to assist in carrying it out.

The motion for the appointment of a committee was then put and negatived.

Scrutineers of the voting papers were then appointed.

The Registrar laid on the table the various Registers as required by the Act of Parliament.

Mr. SANDFORD moved a vote of thanks to the President and Council, who he was sure had worked most heartily for the good of the Society during the past year.

Mr. GILES seconded the motion, which was carried unanimously.

The meeting was then adjourned until Friday, the 25th inst., at twelve o'clock, to receive the report of the Scrutineers.

ADJOURNED GENERAL MEETING.

Friday, May 25, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The adjourned meeting for receiving the report of the Scrutineers was held on Friday, May 25.

Mr. HOPKIN, as Chairman of the Scrutineers, in presenting the report, remarked that although the number of voting papers received this year was slightly in excess of that of last year, nearly two-thirds of the Members and Associates in Business had failed to exercise their right of voting in the election of Members of Council.

The SECRETARY stated that failures to return voting papers were about equally distributed among the three classes of Pharmaceutical Chemist and Chemist and Druggist Members and Associates in Business.

The following is the—

SCRUTINEERS' REPORT.

We, the undersigned scrutineers, appointed at the Forty-second Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting papers reported by the Secretary to have been issued	3662	
Voting papers received	1370	
Voting papers issued but not returned . .		2292
Voting papers received		1370
Voting papers disallowed:—

The New Council.

The Chairman then declared that the following gentlemen would constitute the Council for the ensuing year:—

Andrews, Frederick, 34, Leinster Terrace, Hyde Park, W.

Atkins, Samuel Ralph, Market Place, Salisbury.

Borland, John, 7, King Street, Kilmarnock.

Bottle, Alexander, 37, Townwall Street, Dover.

Butt, Edward Northway, 13, Curzon Street, Mayfair, W.

Carteighe, Michael, 180, New Bond Street, W.

Churchill, Walter John, 46, New Street, Birmingham.

Gostling, Thomas Preston, Market Hill, Diss.

Greenish, Thomas, 20, New Street, Dorset Square, N.W.

Hampson, Robert, 205, St. John Street Road, E.C.

Hills, Walter, 225, Oxford Street, W.

Radley, William Valentine, 42, Hampton Road, Southport.

Richardson, J. G. F., Elmfield, Stoneygate, Leicester.

Robbins, John, 147, Oxford Street, W.

Savage, William Dawson, 4, Park Road East, Brighton.

Schacht, George F., 52, Royal York Crescent, Clifton, Bristol.

Squire, Peter Wyatt, 413, Oxford Street, W.

Symes, Charles, 14, Hardman Street, Liverpool.

Williams, John, 16, Cross Street, Hatton Garden, E.C.

Woolley, George Stephen, 69, Market Street, Manchester.

Young, James Robertson, 17, North Bridge, Edinburgh.

Auditors.

There being only the requisite number of candidates (five) for the office of Auditors, the Chairman declared the following duly elected for the ensuing twelve months:—

Hodgkinson, William, 198, Upper Whitecross Street, E.C.

Lescher, Frank H., 60, Bartholomew Close, E.C.

Stacey, S. Lloyd, 300, High Holborn, W.C.

Thompson, Henry A., 22, Worship Street, E.C.

Watts, William H., 32, Lower Whitecross Street, E.C.

Chemists and Druggists' Trade Association of Great Britain.

The seventh annual meeting of this Association was held on Tuesday last. The proceedings commenced with the meeting of the Executive Committee at 11, when the chair was taken by Mr. R. Hampson. He announced with regret that Mr. Haydon, the Secretary, was unable to be present from illness.

The Report which had been printed was taken as read.

The Annual Report.

The Report commenced by stating that acting under the instructions of your Committee, the Solicitor and Secretary had considered numerous cases of illegal trading in poisons. Proceedings had been taken during the past year by the Association, under the 17th section of the Pharmacy Act, against nine persons residing in London, Halifax, Nottingham, Northampton, and Hyde, for having sold poisons improperly labelled, the evidence for which was obtained by the Assistant-Secretary. A fine was in each case inflicted by the magistrates, varying in amount from one shilling to five pounds. The proceedings at the hearing of these cases were fully reported in the trade journals. The Secretary had also reported several cases of illegal trading under the 15th section of the Act to the Secretary and Registrar of the Pharmaceutical Society, in one of which a fine of £5 was inflicted.

Two cases of prosecution under the Sale of Food and Drugs Act had come under the notice of the Committee during the past year. In one, a member of the Association was prosecuted for having sold, to the prejudice of the purchaser, two ounces of mustard which was not of the nature, substance, and quality of the article demanded. It was ascertained that the inspector had asked for mustard, and had been supplied with Colman's mustard condiment, no label being affixed to the packet sold; it was, therefore, decided not to defend the case. In the second case a member was summoned to appear before the Longton magistrates for having sold lime water not of the nature, substance, and quality of the article demanded by the purchaser. From information obtained, and acting on the recommendation of the Analytical Referee of the Association, who had analysed a sealed sample of the lime water in question, the Law and Parliamentary Committee declined to defend. These had been the only prosecutions under this statute which had been submitted to the Association since the issue of the last report, but it was claimed that the prompt action of the Association in defending every legitimate case that had from time to time arisen, had tended to stamp out the frivolous, though very annoying, proceedings under the Act which were so frequent in the early days of its existence.

A member of the Association residing at Handsworth, Staffordshire, had been proceeded against, under the Weights and Measures Act, for having certain weights in his possession which were below the standard, and a grant of one guinea had been made towards the expenses of defending on the grounds that the usual notice of the intention of the inspector to examine the weights of traders residing in the defendant's district had not been given. A merely nominal fine was inflicted by the Bench.

A member of the Association having been threatened with an action by the proprietors of Jenner's Liver Mixture, for having made use of the title "Liver Mixture," the Committee had ordered the Solicitor to defend on the grounds that the words "liver mixture" have been for many years in common use in the trade, and that it is not advisable in the interest of the members that any person or firm should establish a monopoly over such common trade terms. No writ had, however, been issued and it was concluded that the proprietors of the trade mark now deemed it inexpedient to appeal to the law.

A member of the Association having been threatened with an action for damages for having improperly and unskilfully treated the cut finger of a child, the Executive had arrived at the decision that the chemist had not in any way exceeded the legitimate bounds of his business, and therefore instructed the Solicitor to defend the case if proceedings were commenced. Up to the date of the Report no writ had been issued.

The Committee had carefully considered the Pharmacy Act Amendment Bill, 1883, prepared and printed by the Pharmaceutical Council, and the following suggested amendments had been transmitted to the Secretary of the Pharmaceutical Society, viz:—

Clause 2.—"That the whole of this clause be erased, and that the articles in the special schedule referred to in the clause be added to part 2 of Schedule A, to the Pharmacy Act."

Clause 4.—"Insert the word 'and' after the word 'contained' in the twenty-eighth line, and the words 'the name of the poison contained therein' after the word 'medicine' in the thirty-first line."

Clause 9.—"Add the words following at the end of the clause, viz.:—Notwithstanding the provisions of Section 16 of the Pharmacy Act, 1868, or of this Act, it shall not be lawful for any executors, administrators, or trustees of a deceased pharmaceutical chemist, or chemist and druggist, to continue the business of such pharmaceutical chemist, or chemist and druggist, for a longer period than three years, unless by permission of the Council of the Pharmaceutical Society of Great Britain."

Insert in the Bill a clause to the following effect:—

"Every person registered, or who shall be registered under the provisions of the Pharmacy Act, 1852, or of the Pharmacy Act, 1868, as a chemist and druggist, and who shall be in business on his own account, shall be exempt from serving on all juries and inquests whatsoever."

A committee had also been appointed to take such steps as might be deemed desirable to carry out the wishes of the Executive in amending the Bill. Whilst offering these suggestions to amend the Bill, the Executive expressed an earnest hope that on the introduction of the Bill into Parliament the whole trade would cordially unite in supporting it, so that it may obtain the sanction of the Legislature.

After referring to the Medical Act Amendment Bill now before Parliament, the Report mentioned the meeting of the London members of the trade, held in December last, the proceedings of which were reported at the time in this Journal.

In accordance with the request expressed at the last meeting of the General Committee held in London, the Executive had appointed local secretaries in all towns in England or Wales containing six or more registered chemists and druggists. A list of the names of these gentlemen appeared as an annex to the Report. The appointment of local secretaries in Scotland had been postponed until the Committee of the Scottish Branch had made recommendations for these posts, and the appointment of local secretaries to the Metropolitan districts had been relegated to the London Committee.

The Committee of the Scottish Branch of the Association in July last having ascertained that an application was about to be made by the Edinburgh University Court to Her Majesty in Council, for powers to make attendance at this University in practical classes in physiology, pathology and materia medica imperative, and that the instruction accepted as equivalent to a course of practical materia medica be apprenticeship for not less than two years in compounding and dispensing drugs under a registered medical practitioner, or a member of the Pharmaceutical Society of Great Britain, and as this ordinance would have precluded chemists and druggists, who were not members of the Pharmaceutical Society, from educating such students in materia medica, it prepared a memorial on the subject and transmitted to the Secretary of the Court. The Faculty of Medicine in reply stated it had been recommended that apprenticeship should be restricted to a member of the Pharmaceutical Society of Great Britain, because the fact of such membership afforded a guarantee that an education had been undergone which rendered the members of that Society, in many respects, qualified to give such instruction to their apprentices as a University might be justified in recognizing, whilst the education of registered chemists and druggists was of the most varying description, and the title failed to afford a guarantee of equal value to the title of Member of the Pharmaceutical Society of Great Britain. At the same time, taking into consideration the fact that the alternative qualification of apprenticeship to a pharmacist would affect only a limited number of students, and that the class of students so affected would generally be one whose pecuniary resources were limited, the Faculty of Medicine would be willing to coincide in the suggestion of the Chemists and Druggists' Trade Association and the University Court considered it desirable to adopt it.

Two cases had occurred in which members had been threatened with prosecution by the Board of Inland Revenue for having sold as "finish," methylated spirit, said to contain an insufficient quantity of gum resin, although the sellers maintained that the spirit, when sold, met the requirements of the general order of the Board in that particular. The Executive proposed, at an early date, to take into consideration the advisability of urging the Board to issue an additional order, making it compulsory on the excise officers to leave with the seller of spirit a portion of the finish, etc., purchased, as a protection to him in the event of errors being made by the officials who subsequently deal with the spirit.

The Report then referred to the death, after a protracted illness, of Mr. S. Urwick Jones, the first President of the Association, who occupied the chair three years in succession, and of Mr. T. B. Stead, a member of the Committee. It also stated that Mr. Alfred Wright had been appointed assistant-secretary, *vice* Mr. G. R. Templeman, resigned.

In conclusion, the Report stated that the total number of Members on the Register of the Association at the present time is 3851. The financial statement which is annexed shows that 2743 annual subscriptions and donations to the amount of £63 4*s*. 6*d*. have been received during the current year, being a considerable decrease in the amount of donations from the previous year. From this it will be seen that 1108 members are in arrear with their subscriptions.

The Financial Statement.

The Financial Statement from 15th April, 1881, to 16th April, 1883, was as follows:—

Receipts.

		£ *s*. *d*.	£ *s*. *d*.

Mr. Urwick (London) moved that the Report be adopted. He said there had been fewer cases than usual of prosecution, but he hoped this would not lead to any lukewarmness on the part of the members.

Mr. Green (Woolwich) seconded the motion.

Mr. Barclay remarked that the Executive were always glad to have their work criticized, but he considered it a very pleasing feature in the Report that the number of cases had been so few in which proceedings had to be taken; it was not because cases had been neglected, but there was much less illegal trading now than when the Society was founded. There were four cases now outstanding, but they had only recently been reported.

Mr. Harrison (Vice-President) regretted to see that the finances were by no means in a satisfactory state; in fact, if they went on for another year in the same way they would come to the end of their tether and have to stop. The question was, what was to be done, and there seemed to be only two courses open, either to advance the rate of subscription or increase the number of members. He had always thought that the amount of subscription should be kept if possible at the old figure, because they wanted moral strength, which could only be obtained by numbers. The only other course seemed to be for every member in his own locality to seek out those who were not yet members and induce them to become so. This might be done by showing them what the Association had done. Seven years ago, when the Association was started there were threatened prosecutions almost every week, either by public analysts or medical societies, and everyone was wondering whose turn would come next. The Association, however, had gone on quietly doing its work, until now there were very few such cases, and no better test could be given of the success of the organization. A great general had said that the best guarantee of peace was to be well prepared for war, and to a certain extent that was no doubt true. If they wished not to be molested either from above or below they must be prepared to show a united and powerful front. He hoped, therefore, that every member would do his utmost to avoid the financial collapse with which they were threatened.

Mr. Parker (Nottingham) suggested that the Secretary should visit the various towns and call meetings with the view of getting new members.

Mr. Jervis (Sheffield) said that had been done and did not prove remarkably successful.

Mr. Green (Woolwich) hoped the subscription would not be raised. Everyone in Woolwich belonging to the trade had joined the Association simply through his calling upon them.

Mr. Williams (Manchester) thought it would be an advantage if the subscription were not fixed at 5*s.* Many could well afford to give more, and at such a time as this they ought to feel it their duty to do so.

Mr. Symes (Liverpool) was opposed to any increase in the subscription. The great difficulty was the lethargy of the trade, as shown by the number who were now in arrears; but if any increase were made in the subscription, many would hail it as an excuse for withdrawing altogether. He did not agree with Mr. Williams's suggestion that the subscription should be indefinite, because there was a donation list open. He was quite sure the advantages of the society were worth more than 5*s.* a year to the smallest tradesman in the country. An idea had occurred to him, which he would mention, though he had not thoroughly matured it. Many who subscribed 5*s.* and gave a guinea as a donation hardly felt that they had a right to the services of the Association if they were attacked; but perhaps an insurance fund might be started, by which a man paying five guineas a year would be entitled to defence by the Society. Some might say that this would be offering a premium to carelessness, but he did not see how it could act in that way, for whatever the pecuniary result there would always be a stigma on a man who had acted carelessly.

Mr. Mackenzie (Edinburgh) did not think the idea just thrown out would be of any assistance in getting them out of their present difficulties. The members were practically insured now, as the Executive took up every *bonâ fide* case; but he did not think this fact was sufficiently utilized in convassing for new members. He thought it would be well to adopt the suggestion of having the subscription 5*s.* and upwards, and let it be thoroughly understood that unless more money were forthcoming either the prosecution or defence of cases would have to be abandoned.

Mr. Cross (Shrewsbury) agreed with the last speaker. He thought the funds had suffered from the collectors having two columns to fill up, one for subscriptions and another for donations. This year, especially, it should be made plain to all their constituents that it was absolutely essential that those who could afford it should give more than the minimum. He thought the members of the Executive in their different districts ought to call the trade together and put before them the financial state of the Association and ask them whether it was to go on doing the work it had been doing, or cease altogether, for it certainly must cease altogether unless it had further support. He felt sure, in his locality, although there were no particularly burning questions to be discussed, it would be sufficient for them to see that there was the probability of a Pharmacy Bill to make chemists immediately feel that now was their opportunity to have such a thing well discussed before it became law. An Act of Parliament was not simply a charter giving more liberty, but was also a fetter on their freedom of action, and it would be a very serious thing if at such a juncture the Association should cease to exist. He had every confidence in the Pharmaceutical Council, but there was an element which the members of a trade association ought never to lose sight of. It was not to be supposed that the Pharmaceutical Council could have that knowledge of the wants of the trade as a trading community which was necessary to pass such an Act as he had referred to.

Mr. Mason (Liverpool) opposed the idea of having subscriptions of different amounts, and thought they should rely more on the action of the local secretaries. He also doubted whether it was advisable to always hold the annual meeting in London. He would suggest that it might be held at the time of the Pharmaceutical Conference; for instance it might be held at Southport this year. He should also oppose any suggestion to raise the subscriptions.

Mr. Paterson (Aberdeen) thought it was a good suggestion that the Secretary should go from time to time to various centres and hold meetings; he would then hear if there were any local grievances to be redressed and whether the Association could without much expense devote a little time and energy to such particular localities.

Mr. Jervis said he should object to what Mr. Paterson proposed. It had already been tried. He remembered when Mr. Haydon came to Sheffield and the visit was well advertised there were about six chemists came to the meeting, who were all subscribers already. It would require a great deal of money to send the Secretary down to Scotland, and they had not the money to spend.

Mr. Harrison thought it would be better if the Secretary prepared a list of the towns where the Association was numerically weak and communicate with a member of the General Committee in those districts and ask him to call a meeting of the trade with the view of discussing trade matters and increasing the number of members.

Mr. Mackenzie thought it would be more useful to visit gentlemen individually.

Mr. Cross said there were different classes of people; some were most affected by meetings, others by personal interviews, and he suggested they should combine the two.

Mr. Bell (Hull) said he should object to the subscriptions being raised. Five shillings was a fair sum, and if when the Association was started it had been fixed at a higher rate it would not now have been in existence. It had done an immense deal of good, and they should all do the best they could to get in more money. If the resolution were passed, asking the local secretaries to call meetings in the various towns, it might be one means of getting more members and further subscriptions; but if the Secretary were sent it would cause a great deal of expense. When he came to Hull there was a good meeting, but very few new members were made.

Mr. Urwick said he often called on chemists in any town he happened to be in, and generally mentioned the Association, and had found good results from it.

Mr. Barclay said some valuable suggestions had been made, but the most important of these was to go into the country and holding meetings. Although Mr. Jervis had not much faith in that mode, having taken considerable part in the formation of the Association itself, he felt sure that if the thing were taken up by the Executive a great deal of good might be done. Mr. Williams's suggestion was also worth attention; he felt sure from the donation list there would be many who would be willing to subscribe a guinea, but he should be sorry to raise the subscription.

The President, in putting the motion, said they had now arrived at a point when it was absolutely necessary for those interested in the maintenance of the Society to put their shoulders to the wheel, and make sure that the vehicle was not stopped in its progress. He believed that the Society had done immense good, and that it was absolutely desirable that it should continue to exist. There was always a large amount of apathy in the minds of chemists and druggists; but it was not confined to them by any means. The Executive when re-constituted would have to face this matter, and consider the various suggestions which had been made. Perhaps it would be a happy thing if some analyst would give them a tickling up; but irrespective of any outside attack of that sort, the common self-interest of the trade ought to be sufficient to hold them together. He could not make up his mind at the moment as to the propriety of the various proposals, particularly with regard to the amount of subscriptions being optional, instead of a separate donation list. He did not see much difference between the two, but he thought they might appeal with confidence to all those who could afford to give more to support the society better.

The motion was then put and carried unanimously.

Mr. Urwick and Mr. Paterson were appointed scrutineers of the voting list for the members of the Executive Committee to be recommended to the general meeting.

The General Meeting.

The President having taken the chair, the notice was read by the Assistant Secretary.

The report was agreed to be taken as read.

Mr. Harrison (Vice-President) having referred with regret to the absence of the Secretary, and expressed a hope that he would soon recover his wonted health, proposed the adoption of the Report. One very satisfactory feature was that the work the Association had been called upon to do during the year had been exceedingly small, and there could be no better test of the efficiency of the Association than the fact that there was so little work for them to do. The state of things was very different now to what it was seven years ago. The immunity from persecution which they now enjoyed was, he believed, entirely owing to the action of the Association. It would be noticed, too, that in one or two cases which had been brought forward the prompt action of the Society had prevented their going further; it was one thing to attack an individual and another to attack a powerful Association; and he might remark also that the Executive had been very careful never to undertake a defence unless there were good grounds for doing so. One feature in the Report which was not so gratifying and which deserved most careful attention was the financial position. The expenditure was exceeding the income by a considerable sum, and unless they had a larger income during the coming year by that time next year they would probably find themselves without any funds at all. The expenditure was really of so trifling a character that it was not creditable to so large and fairly affluent a body to allow an Association like that to languish for want of funds. It being granted that there was work to do, and that it did the work, the munitions of war ought to be freely forthcoming. He might say, however, that the Executive had always been bold enough to defend a case, whatever the state of the funds might be, and he believed at any time if there were a serious call on their funds the trade would respond liberally to any demand made upon them. At the same time he would urge that it was not good, either for associations or individuals, to be always just on the border line; they liked to have something to stand by, so that in case of emergency it should not be necessary to make a special appeal. He believed it would be a disastrous policy to attempt to increase the rate of subscriptions, and the only other method was to endeavour to increase the number of members, and he hoped every gentleman in the room that day would make up his mind that there should be no chemist in his district not a member who should not be appealed to directly with a view to inducing him to become one. Nothing of very startling importance had occurred during the year; there had been no burning questions, but at the last moment there was a poison question, on which there was difference of opinion. He referred to the proposed amendment of the Pharmacy Act. This had received the attention of the late Executive, and certain amendments had been proposed, which, it was believed, would make the Bill of some little use to the trade at large. The more he looked at it the more he was convinced that in its present form it would be of very little use indeed. The principle of the Act of 1868 was briefly that no man who had not proved his qualification for the sale of poisons should be allowed to sell them, and certain articles were enumerated, and restrictions put upon their sale. He did not think the principle of that Act had ever been attacked; it had received the sanction of the Legislature and of the public. The Act itself failed to give effect to the principle which it contained, and hence, from time to time, they had been called upon to make amendments and improvements, and the time seemed now fairly to have come for doing so. Instead of amending the Act by giving full effect to the principle which it contained, an entirely new principle was introduced, and with all due deference, the principle enunciated in this amending Act was altogether destructive of the principle of the former one; in fact, it might be called a Pharmacy Act Annihilation Bill. He believed the placing of a variety of strong acids under the name of 'poisonous' substances was a great mistake. Certain bodies were called 'poisons,' and certain others of a much stronger character were only of a 'poisonous' nature. Now an Act of Parliament, whatever else it did, should have some regard to common sense and the ordinary meaning of language, but in the present case he believed the term was grossly misleading, and would lead to innumerable blunders. The proposed Bill contained a clause that any patent medicine containing poison should only be sold by a registered chemist and druggist, and be labelled with the word "poison," the name of the poison contained in it, and the name and address of the seller. This was reasonable and proper, but it also enacted that when it left the hands of the makers it should be properly labelled so that all the seller had to do was to hand it over to the purchaser in the state in which he received it. No great skill was required for this unless the purchaser required some advice as to the taking of it. But with regard to poisonous substances, men more or less illiterate might deal with them who had no knowledge of what these substances were, but would be allowed to sell them indiscriminately provided they labelled them "poisonous," and put their name and address upon them. He considered this a gross injustice. There was much more skill required in the sale of these poisonous substances than in the sale of patent medicines. He did not say, do the one and leave the other, but place them both in the hands of the chemist, and if that were not possible leave the law as it was. If Parliament would not place the sale of these things in qualified hands let Parliament take the responsibility, but he did not think they ought to go to Parliament and say it would be safe for any person to deal in such things. It was one thing to accept a proposal like that if it came from Parliament, and quite a different thing to suggest that such a thing should be done. One other matter referred to in the report was adopting a memorial to the Inland Revenue authorities, with reference to the sale of methylated finish. At present, anyone from the Inland Revenue Office could purchase methylated finish and send it to Somerset House for analysis, and if the chemists there said it did not contain the proper quantity of gum the seller was liable to a fine. A case of this kind came under his notice a short time ago, in which the vendor said distinctly that he had put in the full quantity of resin, but he had no means of knowing that the precise article which he sold had been analysed. It was proposed, therefore, to send a memorial suggesting that the method followed under the Adulteration Act should be adopted here, and that when a purchase was made for the purpose of analysis it should be divided into three portions, and sealed up, one of which should be retained by the vendor, which would be a protection to him. He concluded by urging on all members to do their utmost to increase the adherents to the Association.

Mr. Green (Woolwich) seconded the motion. He felt it would be very injudicious to raise the amount of subscription, and he also disagreed with the idea which had been thrown out that morning that there should be a minimum subscription of 5*s.* If that were put forward he believed they would lose one-third of the present members. Many who now gave 5*s.* if they were aware that other members gave 10*s.* or £1 would not be disposed to subscribe so much and would not give at all. The number of members depended on the individual action of the Secretary and the local members.

Mr. Wilkinson (Manchester), referring to the Pharmacy Act Amendment Bill, said it was not generally understood that this Bill was the result of a compromise between the Pharmaceutical Society and the Government. The Society, as they all knew, was very anxious to include every article referred to in the list of scheduled poisons, but the Government refused to hear of anything of the kind. Those articles which were called poisonous were very largely used and sold by persons not in the trade, and it would be quite impossible to restrict their sale to members of the trade. He thought it was a mistake to put them in the Bill at all, and that they should rather have left that clause entirely out, and said to the Privy Council, if you choose to put this clause in as an amendment, we will accept it. With regard to the methylated finish question, any difficulty with regard to it was easily avoided by a chemist taking out a licence, in which case he would be perfectly safe. With regard to patent medicines it seemed simple to say that these patent medicines should be labelled "poison" and sold only by chemists and druggists; but it was not really so. Probably there was not one present who did not make up a cough medicine which did not contain 5 or 6 drops of laudanum in a dose. Was that to be called poison? if not, where could the line be drawn? He had no objection to the sale of patent medicines being restricted to chemists, but he did not care much about it, and they ought to be very careful in legislating, or they might tie their own hands much more than those of other people.

Mr. Symes was much surprised to find the Vice-President condemning the Pharmacy Act Amendment Bill, which would imply that the chemists and druggists were perfectly satisfied with the state of pharmacy now existing. But he could not take that view, because they had been complaining for a great many years that some different regulations were required, and the only advantage they possessed under the present Act was the monopoly of a few poisons, the sale of which they would rather be without. Now an attempt had been made to improve the state of the present law with regard to pharmacy; whether it would be a failure or success he was not prepared to say, but he certainly thought it was wise to make the attempt. The Vice-President seemed to imply that these few poisons that chemists had not thought worth while selling were everything; that it was very sad to have anybody selling poison who was not a chemist and druggist, although it might be used to a large extent commercially, as Mr. Wilkinson had said. It was a well-known fact that the Government wanted a Poison Bill, but they, the chemists, wanted a Pharmacy Bill, and a compromise had been struck between the two. The original Pharmacy Bill of 1868 was really brought forward as a Poison Bill. The beginning of the title was, "An Act for Regulating the Sale of Poisons," and that was a predominant thing in the mind of the Government at the time, and the same was the case now. The Government would only act in a public point of view, and whatever would benefit the public the Government was willing to accede to. They, on the other hand, believed that if they were to educate the people who were to sell poisons, that was better than putting them under restrictions. Under these circumstances, it seemed to him wise to go as far as they had gone. The new Bill would not, in his mind, destroy in any way the principle involved in the previous Act; it only showed how two persons might look at the same thing from opposite points of view. He could not see how anyone was injured, because these few poisons were left in the hands of those who now sold them.

Mr. Candy thought they all ought to be glad that someone came forward with some attempt to remedy the condition of things, though he was by no means at one with the Pharmaceutical Society in the Bill they had brought forward. It must be borne in mind, however, that the Pharmaceutical Council never professed to act in the interests of the trade, but in the interests of the public, and to a certain extent they were justified in doing so, because, as Mr. Symes said, it was no use going to Parliament with any class interest. To a certain extent he agreed with the Bill if the ninth clause could be passed, but he did not believe that Parliament would ever pass such a clause. He also objected to the educational clause. He did not object to education *per se*, but to people being bound to acquire a certain education, unless subsequently they had some probability of receiving some remuneration for the time, labour and expense they were put to. With regard to these few miserable poisons that had been spoken about, who was it that wanted to sell a lot of oil of vitriol or nitric acid? The profits were slender and the trade was dirty. What they wanted was more of a monopoly in the medicine line, in the dispensing and sale of drugs. Neither did he think that if they passed a law to say that these things should be labelled "poisonous" that they would be. It was not like a small trade. The late Baron Liebig said that the sale of oil of vitrol indicated the civilization of a nation, and that being so, it being used so largely in the manufactures and arts, it was altogether out of their sphere. He did not believe the House of Commons would ever pass the ninth clause, for many of them were members of co-operative stores. With regard to the sale of poisons he thought the responsibility should rest on the proprietor, and not on the vendor. It was all very well to say that a prosecution might not occur, but it was a serious thing to anyone who was prosecuted, especially in small towns where the stigma of it would attach to his name for ever. It was true he had his remedy against the wholesale dealer or the manufacturer, but the subsequent intelligence of his having recovered the penalty from someone else would never reach the public, and they did not want to live in daily fear of prosecution. With regard to methylated finish he thought the remedy was in their own hands, but at the same time what Mr. Harrison had said was perfectly true, that when an analysis was to be made on which a prosecution might be based it was only just that a sample should be left with the vendor. With regard to the question of subscriptions, when any great crisis occurred in the trade, members would come forward with the necessary money; but at present they were sailing in smooth waters, and many members thought more of saving their 5*s*. Besides which, some of them were beginning to think that the Association was very much the double of the Pharmaceutical Society, and that it was no use supporting both, and, therefore, he feared their subscriptions would fall off from year to year, unless something occurred to make them rally round again. He believed there was a sphere for both Societies, and should support both, but at the same time he did not want to see so many of the same faces at both meetings.

Mr. Mackenzie hoped that it would always be kept distinctly before the trade that they were not, and were not likely to become, the double of the Pharmaceutical Society. They had a distinct policy, which was that of trade interests. With regard to this Bill he was prepared to give the Council credit for having done their best, but after all it was only their 'prentice hand, and there was an old adage, "If at first you don't succeed, try again," and he thought it would be for the benefit of the trade if the Bill were withdrawn and they did try their hands again. It seemed to him there was more to condemn it than to justify it. With regard to the prosecutions on the sale of patent medicines it was a great pity there should be such a roundabout process to be gone through by the retailer who was prosecuted in order to set himself right, and he thought the penalty ought to be imposed in the first place on the manufacturer. There was a clause about apprentices which had only been accepted in Scotland on the interpretation of someone who was not responsible for it, and he thought it was very dangerous to accept any such interpretation which was not clearly expressed in the lauguage of the clause. The only consolation he had was that the Bill was so unlikely ever to become law that they need not trouble much about it.

Mr. Long (Notting Hill) said some gentlemen seemed to think that they had only to walk down to Westminster and mention what they wanted to be told, "Oh, yes; it shall be attended to;" but that was a grievous mistake. How far it was advisable to go, what they should ask for, and what they were likely to get, were very different things. How were they likely to succeed in an Act of Parliament when the vital interests of a large body of men were represented by the few gentlemen then present? Mr. Candy objected to seeing the same faces there and at Bloomsbury Square; but he feared that if they lost them at one they would lose them at the other. It was those men who were most alive to their interests professionally and financially who were the backbone of both Societies. He candidly believed that if the Pharmaceutical Society had put its foot down firmly when its rights were being invaded they would be now in a very different position; but they had been so exalted, so honourable, so far above the shop that they never discussed anything but the public advantage. It was no use, however, talking about the Bill; they could only leave it in the hands of the Council, and if they did not believe in the Council they must turn them out and put other men in. As to the advisability of putting the poisonous schedule in, he thought if they stood more on their own rights and were not quite so anxious about the welfare of the public,—not that he wished to injure the public, only he wanted to live,—it would be just as well, and they need not go out of their way to be so extremely careful of the public. He was sorry to hear so many gentlemen had not paid their subscriptions, but he thought the blame must lie at headquarters. He thought if Mr. Haydon would write down to a member of the Committee in places where gentlemen had not paid they would go round and get subscriptions. He had introduced some dozen members, and if he found they did not pay he would endeavour to persuade them to do so, and he could not accept the notion that any of these gentlemen could not find the 5*s*.

Mr. Allen (Kilburn) said there was no doubt a great apathy and want of cohesion in the trade; but this might be partly caused by circumstances, gentlemen being so much confined in their business they were not able to meet together. The meeting was not large, but it was a representative one. He thought it was very important that they should come to some definite conclusion as to what position should be taken up with regard to the Pharmacy Act. He understood that the Executive had to a certain extent endorsed the Bill, but the Vice-President did not agree with the schedule of poisonous articles. It would be a great point to come to some conclusion on this matter, which appeared to him to be the great question of the present time. The poisonous schedule was certainly an innovation, but many believed that this would not detract from their position. He had been accustomed to see large quantities of acid sold whilst living in a mining district, and he should be sorry if pharmacists were mixed up in the sale of these articles. They knew perfectly well that the Privy Council would not accept strong acids as poisons. As far as patent medicines were concerned, if it was thought that the proprietor should be responsible for the label, he should support the amendment, but the time was really come when they should decide whether to support this Bill or not. If they could support it he would ask those who could not exactly agree with it to forego their individual opinions and do what seemed to be for the best of the whole trade.

The President said there had been some difference of view about the Pharmacy Bill, and it was considered desirable that the Executive Committee should send a deputation to the Pharmaceutical Council with regard to it, so that they might discuss these minor points. He need not say how important it was that the trade should be united.

Mr. Whittle was very sorry to see the subscriptions had fallen off in the way they had. He considered every chemist in business ought to feel himself bound to support an association of this kind, because everybody must feel that it had not spent money extravagantly and had done good service to the trade at large. Who could say how many prosecutions there might have been if the Association had not existed? He remembered when there was a two guineas licence for the sale of patent medicines, and some gentlemen complained then that they did not sell two guineas' worth in a year, and after a great deal of agitation they got the licence reduced to 5*s*., and now they found barbers, drapers and stationers all selling patent medicines; and judging by what appeared in the journals, it would seem as if the whole of their trade consisted in patent medicines. What they really wanted was dispensing, and he believed if they could only let the public know how some of it was done, instead of going to the doctor's they would go to the chemist. They did not want to sell strong acids, but at the same time he did not think it was for them to go to Government and propose to move in the matter. Though the Bill was not all he could wish, he thought it was calculated to do some good, and he hoped it would be supported unanimously. The last Bill would have been a much better Bill than it was if it had been backed up by the whole trade.

Mr. Barclay said this was a very important crisis in the history of the trade, and he could not insist too strongly on the sentiment just expressed that it was of the utmost importance to present a united front. Some one had said that the same faces might be seen there and at Bloomsbury Square, and he took it that was the right thing, that the men who felt the responsibility of guiding the trade, or the profession, should exercise the two functions, one of looking after the public and the other of looking after the trade. It was not the business of the Pharmaceutical Society so much to look after the trade side as the professional side, and therefore this Association had sprung into existence and had taken root. Mr. Richard Reynolds at the outset spoke of the Trade Association and the Pharmaceutical Society as being like the old country weathercocks, where the man came out in the stormy weather and the old lady came out in fine weather. He would not say which was to be the old lady, but he thought they ought to work together, and he hoped one of the results of the meeting would be an instruction to the Executive to ask for an interview with the Council of the Pharmaceutical Society so that their differences might be arranged. Differences did exist and it was very well they should. As a trade Association they went further than perhaps the Pharmaceutical Society could see their way to ask from the Government. For instance, he was surprised to find that the jury question had not cropped up, for he expected some inquiry would be made why it was that this Bill did not contain a clause exempting chemists from jury service.

Mr. Allen said the making of all in the trade pharmaceutical chemists in future would eventually exempt everyone from jury service.

The President said this matter was not considered proper for insertion in the Pharmacy Bill at all, and there was a fear that if it was brought forward even pharmaceutical chemists might lose the exemption they now enjoyed.

Mr. Barclay said all this showed the desirability of a conference between the two bodies. Every one must admit there were germs of good in the Bill, and he was very thankful to the Council for having done what they had in the matter. With regard to the question about methylated finish, he was sorry to say there were many who were unable to pay the 10*s*. 6*d*. licence; who did not sell 10*s*. worth of finish in the year. A case had just occurred which led to the introduction of that clause in the report. A chemist was called upon for some finish which he made himself and asserted positively that the proper amount of gum was there, but six weeks afterwards he was called upon and told that the stuff had gone to the Inland Revenue Department, had been analysed, and that there was not the proper quantity of gum in the preparation, and he expected to be summoned. If he had had a sealed sample left behind he would have had his remedy. He could have come to the Trade Association, have had it examined, and if he were right he would have been protected. Another case had occurred in Wales, where a gentleman was asked for spirit of wine and supplied camphorated spirit of wine, telling the purchaser he was not allowed to sell it pure. But he had heard that he was going to be summoned likewise; and the stuff having gone from his hands, he was not in a proper position to defend himself.

Mr. Paterson said if the Bill were to be gone into in detail, the question of education ought to be discussed, and he believed they would have to go much further in that direction before long. Education ought to be brought home to the doors of the young men who were apprenticed to the business, and it was quite possible that arrangements might be made with the Science and Art Department for providing pharmaceutical education in great centres, so that examinations might take place there.

Mr. Harrison, in reply, said in many cases it was a hardship to a chemist to have to pay 10*s*. for a licence to sell spirit, and if he did, he was restricted to selling 1 gallon per day to any one customer; and the same difficulty might arise with regard to that. The real question was, whether a man was to be left at the mercy of any unprincipled person who might buy the spirit. Some little misapprehension had arisen with regard to what he said about the sale of poisonous substances. He did not argue that they should apply to Parliament to restrict the sale of these matters to chemists, but that they should not go to Parliament to ask them to regulate the sale by other people; but if they dealt with them at all, it should be only in one way—in a spirit of loyalty to the former Pharmacy Act. His contention was that they ought not to teach the Government that it was safe for uneducated people to deal with these strong substances. It had been contended that the Government had refused to legislate in the direction he advocated, but all the evidence was that some time ago the Pharmaceutical Society applied to the Privy Council that certain articles should be added to the schedule of poisons, and the reply was that nux vomica should be added, but all the other articles should be left over until a more convenient season, when they might legislate on the whole matter. This convenient season appeared now to have arisen, but it seemed to be taken for granted that the refusal of the Government to do what was asked at one time was a refusal to do it at any time. As the Government accepted the principle of the Act of 1868, he thought it was their duty to keep to that principle and endeavour to strengthen the working of it. With regard to jury service, he had advocated it so many years that he feared it would be only trespassing on the patience of the meeting if he had brought it forward again, but he was as strongly convinced as ever of the justness of the claim. He hoped the different opinions which had been expressed would conduce to levelling down some of the inequalities, and that as a result they might be more unanimous in what they intended to apply for.

The President, before putting the motion, said he had always maintained the view that a seat on the Council did not disqualify him from taking part in any matters with reference to the trade; he still maintained that position, and he hoped he should find his judgment had been correct. With regard to the Pharmacy Bill, he had a somewhat difficult position to fill, inasmuch as on the Pharmaceutical Council he had taken the responsibility of moving its acceptance. He had served for many months on committees which had gone into details of the measure, and had endeavoured to weigh as carefully as possible the divergent views, some of which had been very well presented that day; but looking all round and looking at the intrinsic merits of the Bill, he considered it was an excellent Bill. With regard to the much vexed question of the poisonous schedule, the position was simply this. The Government contemplated bringing in a general measure with reference to poisons, and the question was, were they prepared to have such a measure brought in and pharmaceutical legislation ignored. The Pharmaceutical Council thought it extremely desirable that any interference with the sale of poisons should be included in the Bill, although the method proposed in the Bill was not exactly the method they liked; but the danger was this, such was the feeling of the public mind, that there was a tendency on the part of the Government to legislate with regard to poisons quite apart from all consideration of chemists, and he believed that in accepting the 'poisonous' schedule they had done the right thing, although it might wound the sentimental susceptibilities of some gentlemen. Even in countries where pharmaceutical legislation was much more stringent than in England, even under despotic governments, it was found impossible to restrict the sale of these things to chemists, and he maintained that it was good policy to have included this scheme; but apart from his individual opinion on the matter, their only chance of getting legislation at all was being thoroughly united. If they assumed the attitude of some gentlemen who talked about destroying the Bill because it did not meet their views, they would never have a Bill at all. In legislation of any kind you could never get all you desired; you must move by stages, and if the Bill included a considerable amount of good, the wise policy was to accept it. At the same time, he thought it very desirable that the Executive should have a conference with the Pharmaceutical Council, and if possible come to an amicable and substantial agreement.

The motion for the adoption of the Report was then put and carried unanimously.

The President then moved that the following names, recommended by the General Committee, be accepted as the Executive Committee for the ensuing year:—

Andrews, Frederick, London.	Holdsworth, T. W., Birmingham.
Arblaster, C. J., Birmingham.	ervis, W., Sheffield.
Barclay, Thomas, Birmingham.	Jones, O., Llanwrst.
Barnaby, Henry, Rochester.	Maltby, J., Lincoln.
Bell, C. B., Hull.	Mason, A. H., Liverpool.
Chapman, Henry, Scarborough.	Parker, W. H., Nottingham.
Churchill, W. J., Birmingham.	Southall, William, Birmingham.
Cross, W. G., Shrewsbury.	Symes, Charles, Liverpool.
Ellinor, G., Sheffield.	Walker, G., Coventry.
Hampson, Robert, London.	Williams, F. P., Manchester.
Harrison, John, Sunderland.	Yewdall, E., Leeds.

For Scotland:—Messrs. G. H. Laird, Edinburgh; James Mackenzie, Edinburgh, and James Paterson, Aberdeen.

Messrs. Urwick and Paterson were then appointed scrutineers of the ballot papers for the election of officers.

Mr. Bell moved—

"That it is most desirable that chemists and druggists generally should be united in support of the Pharmacy Bill, it being an instruction to the incoming Executive to arrange an interview with the Pharmaceutical Council to promote that object."

Mr. Williams (Manchester) seconded the resolution, which was carried unanimously.

Mr. Mackenzie then moved—

"That a memorial be presented to the House of Commons in support of the claims of pharmacists to be associated with members of the medical profession in a legally constituted committee for the purpose of preparing the British Pharmacopœia, and that the Executive Committee be requested to take the requisite steps to obtain an amendment in the Medical Bill now before Parliament in furtherance of their claims."

He believed that such a resolution would commend itself to every member of the trade; it was a question of justice and fair play, and he thought it would commend itself also to the common sense of Parliament.

Mr. Allen seconded the motion.

Mr. Holdsworth asked what stage the Bill was in.

The President said the Bill was down for second reading on Thursday. It was the intention of the Pharmaceutical Society to ask some Member of Parliament to move an amendment in the direction of this resolution.

Mr. Holdsworth suggested that a memorial should be sent from that meeting in order to save time.

Mr. Long said there could not be much doubt about the advisability of taking some action in the matter. The Medical Council had proved their incompetency to prepare the book called the Pharmacopœia, and had made such a hash of it that they were obliged to call in experts to assist them. When there was an attack made by the apothecaries on chemists, he communicated with both Members of Parliament for his borough, and one wrote saying he should oppose it, and the other wrote asking for information.

Mr. Mackenzie said this resolution would not prevent the right of any individual member to speak to his own representative on the subject.

Mr. Andrews said this subject was of very great importance, and he had no doubt many gentlemen would take the opportunity of speaking to their members upon it. They might be told that they had already got what they wanted, because their three Professors had been appointed to aid the Medical Council, but his answer was, those gentlemen were not appointed by the Pharmaceutical Society, they were simply paid servants of the Medical Council. They did not wish in any way to share in the profits of the Pharmacopœia, but simply to be recognised as proper persons in conjunction with medical men to frame this book, and in so doing they only asked what was accorded to pharmacists in every other civilized country.

The scrutineers here returned, and it was announced that Mr. Harrison (Sunderland) was elected President, Mr. Cross (Shrewsbury), Vice-President, Mr. Southall, Treasurer, and Mr. Churchill, Hon. Secretary.

Mr. Harrison accordingly took his seat as President. He thanked the meeting for the honour done him. He regretted very deeply that his old friend, Mr. Hampson, had thought proper to retire, for to him it was a matter of great satisfaction to have been his lieutenant, and he should like to have continued in that capacity for another year. Mr. Hampson, however, had thought otherwise, and no doubt for sufficient reasons. He felt very unworthy to follow in the footsteps of his distinguished predecessor, but he would do his best that the work of the Society should not suffer.

Mr. Cross also thanked the meeting for the honour done him, which was to him one of the greatest surprises he ever met with in his life.

The President then proposed a vote of thanks to Mr. Hampson for the very able manner in which he had discharged the duties of his office. This was seconded by Mr. Long, and supported by Mr. Barclay, and carried by acclamation.

Mr. Hampson said he was extremely obliged to the meeting for this kind expression. He should still remain on the Executive and do his best in that position.

The President then read Mr. Mackenzie's motion, altered to meet the views expressed, as follows—

"That a memorial signed by the officers of the Association be presented to the House of Commons in support of the claim of pharmacists to be associated with the members of the medical profession in a legally constituted Committee for the purpose of framing the British Pharmacopœia, and that the Executive be instructed to take such steps as they think desirable to carry out this resolution."

The motion was carried unanimously.

Mr. Jervis said no one present was more glad to see Mr. Harrison in the chair then he was, but he thought the mode of electing the officers was very unsatisfactory, and it would be much better if the President were proposed and seconded.

The President said the rules provided that the officers should be elected by ballot, but not that there should be any nomination. If Mr. Jervis thought it was unsatisfactory, he must give ten days' notice next year of his intention to propose an alteration in the rules.

Mr. Wilson (Grimsby) said the question of prescribing by chemists was so important that he thought some attempt should be made to obtain a definition as to what was illegal, and he hoped the Executive would take the matter into consideration. He begged to move—

"That the Executive be requested to take speedy steps in this matter."

The motion was not seconded.

Mr. Paterson thought, with regard to the previous resolution, it would be well if some steps were taken to let members of Parliament know that there was a movement in the matter.

Mr. Hampson said the Pharmaceutical Society would shortly present petitions, and it would be desirable the Association should do so at the same time.

Mr. Urwick suggested that each town should petition its own member, and if they could get every chemist in the town to write independently it would do more good than 10,000 printed papers.

Mr. Mason suggested that the Secretary should send to each Local Secretary suggesting pressure being brought to bear upon Parliament.

Mr. Long then moved a vote of thanks to Mr. Hampson and Mr. Harrison for their conduct in the chair, which was seconded by Mr. Barclay and carried unanimously.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

A meeting of the Association was held in the Town Hall on Wednesday evening, May 16, being called to consider the resolution which Mr. Sandford purposed moving at the Annual Meeting of the Pharmaceutical Society.

Mr. W. D. Savage occupied the chair.

Mr. Vizer introduced the subject, strongly condemning clauses 4 and 5 of the proposed Bill to alter and amend the Pharmacy Act, and moved the following resolution: "That in the opinion of this meeting clauses 4 and 5 of the proposed Bill to amend the Pharmacy Act, 1852, by which proprietary medicines containing a poison within the meaning of the Pharmacy Act, 1868, will be required to be labelled 'poison,' and in default thereof that the retail vendor of such proprietary medicine shall be liable to prosecution, will act most injuriously to the interests of such proprietors and throw the responsibility upon retail vendors for an offence over which they have no personal control. This meeting therefore appeals to the Council to erase the said clauses from the proposed Bill."

The motion was seconded by Mr. H. Barton.

After some discussion, in which Messrs. Savage, Cox, Higham, Vizer, Barton and Leigh took part,

Mr. Marshall Leigh moved the following amendment, which was seconded by Mr. Gwatkin:—"That this meeting is of opinion that the original makers or their agents should alone be subject to a penalty for not labelling a patent medicine according to clause 4 of the Bill to amend the Pharmacy Act, 1852."

On being put to the meeting, four voted for the amendment and two for the original motion.

The amendment was therefore declared carried.

A vote of thanks to the Chairman brought the meeting to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 17, Dr. W. H. Perkin, President, in the chair.

The following certificates were read for the first time:—

T. H. Coleman, B. Hobbs, B. P. Lascelles, M. F. Purcell, W. R. Reffell, D. Wilson.

It was announced that a ballot for the election of Fellows would be held at the next meeting of the Society, on June 7.

The President then called on Captain W. de W. Abney, F.R.S., to deliver a lecture—

On Photographic Action Studied Spectroscopically.—The lecturer said that he wished all chemists to become photographers, for photography occupied the borderland between chemistry and physics. The days had been long past when black fingers were a necessary concomitant of photography. At the present time there was a vast number of amateur photographers, but there were only a few who studied the scientific aspect of photography; by most experimenters it was looked upon as a servant to be abused rather than used, and the majority were content with working by rule of thumb. The lecturer was firmly impressed with the fact that photographic action is interatomic. He had already shown in a previous paper that throughout the absorption spectra of a series of organic compounds, the absorption due to hydrogen could be recognized; something of the same kind seemed to occur in inorganic chemistry. Probably the first photographic action with which most chemists become acquainted is the blackening of chloride of silver by light. Now if this salt be perfectly dry and perfectly free from organic matter, etc., it will not blacken when exposed to light. Two tubes were exhibited, both of which had been exposed for some time to the action of light; in one the chloride was quite white, in the second the chloride, which was moist, had blackened. The action of developers was then discussed. A picture on iodide of silver paper, which had been previously exposed, was developed before the meeting with gallic acid and solution of silver nitrate. The action of the light is to liberate free iodine, and the developer precipitates metallic silver to form the image. The number of particles acted on by the light must be extremely small. The image can be washed off with nitric acid and a fresh picture taken on the same film. A second image was developed with citrate and oxalate of iron; in this case the metallic silver must have been obtained from the film itself. Some other experiments were shown proving the truth of this statement. Development is not a chemical but a physical action. It was found on photographing the solar spectrum that the amounts of energy in different parts were very varied and irregularly distributed. Recourse was had to the positive pole of the electric arc light; the incandescent light has not sufficient energy, but the positive pole furnishes a spectrum which has sufficient energy and is much more uniform than the solar spectrum. For producing the spectrum, everyone would probably first choose the diffraction grating; but it was found that a perfect grating did not exist, and one grating differed so much from another, owing to minute differences in the ruling, that eventually a glass prism was adopted, as the grating could not be relied on for quantitative work. Films of chloride, bromide and iodide of silver were successively interposed in the beam of the electric lamp, and it was shown that the chloride partially cut off the violet end of the spectrum, the iodide absorbed the whole of the violet, but the bromide cut off part of the blue as well as the violet. An image of the spectrum was then shown on films containing respectively silver chloride, bromide and iodide, and the plates were developed with ferrous oxalate; it was seen that with the chloride but a small portion of the spectrum had acted on the silver salt, and that with the bromide a very much longer image was obtained. The action of sensitizers was next considered; the part played by a sensitizer is the taking up of the chlorine, bromine and iodine set free by the action of light. To demonstrate this action, an image was thrown on to a sensitive plate, and during the exposure, a streak was made across the plate with a solution of sodium sulphite; on developing, a black stripe indicated the position of the sodium sulphite, this salt having rendered the silver salt in its vicinity more sensitive. A sensitizer is useless unless it be close to the salt on which it is to act; so all sensitizers are more or less hygroscopic, or they may act in solution or as vapour. Almost any organic compound acts as a sensitizer. The lecturer then gave instances of coloured sensitizers, and photographs of the spectrum were taken on films coloured with cyanin blue and with eosin, the plates were developed, and the relation between the portion of the spectrum photographed and the portion absorbed by these pigments demonstrated. Thus cyanin blue absorbs the yellow, and the photograph of the spectrum on the film, coloured with cyanin blue, exhibits a band in the yellow where the absorption had been previously seen. It is very remarkable that one salt of silver may act as a sensitizer to another salt of silver. Thus a film, containing bromiodide of silver, photographs much more of the spectrum than two films containing the one bromide and the other iodide. It is easy to destroy the results of photographic action. If a film during exposure be washed with any oxidizing agent, as potassium permanganate or bichromate, dilute nitric acid, peroxide of hydrogen, etc., the image is completely effaced. Thus if plates which are foggy from accidental exposure be dipped in dilute bichromate of potash and well washed, they are restored to their original condition. This bleaching effect was demonstrated by throwing a picture on a sensitive plate and during exposure making a streak with bichromate solution across the plate. On developing this streak was seen to be white. A sensitive plate after exposure to light was soaked in dilute nitric acid containing 1 drop of acid in 8 ounces of water, and then exposed to the spectrum. The tendency of the nitric acid was to oxidize; at the violet end, where the reducing power of the light was at its maximum, this tendency was overcome, but the red end was perfectly white. A method of obtaining a reverse image was demonstrated. A sheet of iodized paper was exposed to light, then immersed in potassium bromide solution, a picture was then thrown on it, on developing it was found to be reversed. An instructive experiment was also shown of an easy means of preventing the bad results of over exposure. An extremely sensitive dry plate was soaked in sodium sulphite solution and exposed for sixty seconds to a bright spectrum. On developing a good picture came out not in the least reversed. So a picture cannot be reversed if some substance is present in the film having a great affinity for oxygen. A beam of light was transmitted through films of the three varieties of silver bromide; the ordinary variety was orange, the film used in the gelatin dry plates a sort of French grey; the film used for photographing the ultra red portion of the spectrum, green

In conclusion, the lecturer said he had endeavoured to point out to the chemists present some of the pitfalls which beset the practice of photography.

The President, in proposing a hearty vote of thanks to Captain Abney, said that all must feel that they had had a great scientific treat; most chemists had dabbled in photography and must have felt how many points required investigation. He hoped that Captain Abney would continue his researches, and he was sure that no one was more able to carry them out to a successful issue.

The vote of thanks was passed by the crowded meeting with acclamation, and the Society adjourned to June 7, when a ballot for the election of Fellows will be held and the following paper read:—"Laboratory Notes, by Dr. Gladstone and Mr. Tribe.—1. On the Action of Light and Heat on Cane and Invert Sugar; 2. On Hydroxylamin; 3. Recovery of Iodine from Organic Iodide Residues; 4. A Residual Phenomenon of the Electrolysis of Oil of Vitriol; 5. On an Alleged Test for Alcohol; 6. Reaction of the Copper Zinc Couple on Nitric Oxide; 7. On the Reducing Action of Spongy Lead."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Professors and the Pharmacopœia.

Sir,—Mr. Frederick Smith, in his letter in last week's Journal, makes the statement that certain members of Council "would not have said what they did, had Mr. Greenish, in reading what he termed the words of the Report of the Pharmacopœia Committee, read the whole of the words there in which the Medical Council state that they will themselves communicate with the Pharmaceutical Council." Had he himself quoted the precise words to which he alludes this communication would have been rendered unnecessary.

I will, however, give the paragraph in its entirety.

"The Committee, in conclusion, beg to state that it is their intention to apply to the several medical authorities, to the Pharmaceutical and Chemical Societies, and to such persons as may be likely to furnish useful information, with a view of making the work as complete and perfect as possible."

I fail to see that the whole of the words now quoted alters the aspect of the case, but Mr. Smith is entitled to any comfort that he may be able to derive from the publication.

20, *New St., Dorset Sq., Marylebone Rd.* Thomas Greenish.

"Distance lends Enchantment to the View."

Sir,—To save time of the annual meeting I omitted two things fully on my mind, in reference to Mr. Giles's remarks What was the standing of the "dead lions" of twenty-five years ago in the eyes of their contemporaries? Was it a higher one than that now occupied in the eyes of their contemporaries by such men as Messrs. Carteighe, Schacht, Williams, Bottle, Greenish, Squire, Robbins, etc., etc.

I also quite intended to say, that to show my estimate of the *personnel* of the existing Council, and that notwithstanding the difference between their views and my own on so many questions of interest to pharmacists, I have recorded my votes for the entire number (14) of retiring councillors, and I trust, most sincerely, that they will all continue on the Council for the coming year.

Daniel Frazer.

Communications, Letters, etc., have been received from Messrs. Bate, Maben, Landerer, Druce, Watt, Wrighton, Smith, Sinapis, John, Sterlini Oppidum, Cymro, Chrysosplenum, J. H.

"THE MONTH."

Although the proverbial May flowers were very slack in putting in an appearance during the early part of the month, the hot sunny weather of the last two weeks has made up in great measure for the backwardness of the season, the leaves and flowers having burst forth with a rapidity almost like that of a Scandinavian summer. Most of the medicinal plants usually in bloom in May can now be seen at the various Botanical Gardens; *Podophyllum peltatum*, *Carum Carui*, *Iris florentina*, *Polygonum Bistorta*, and many others, may be noticed in their respective natural orders. In the country, the heathy commons and railway banks are decked with the golden broom in the full blaze of its vernal beauty, undimmed by rain or wind. In bogs, where it is hardly safe to tread, one of the most beautiful of our wild plants, the bogbean (*Menyanthes trifoliata*), is putting forth its shortlived blossoms, and the male fern is unrolling its tender green fronds. On the wayside hedges and in cottage gardens the official aconite, *A. Napellus*, and *Vinca major* are coming into flower. Among the rare or less common British plants, *Geranium phœum*, *G. sylvaticum*, *Myrrhis odorata*, *Pinguicula grandiflora*, *Meconopsis cambrica*, *Gymnogramma leptophylla* and *Carex depauperata* may now be looked for. Most of these are now in blossom at Kew, where those who do not know these plants may make their acquaintance under the most favourable circumstances.

The change of colour in various boraginaceous flowers would seem to bear relation to their fertilization. Hermann Muller remarks in *Nature* (May 24, p. 81) that he has observed that insects visit exclusively those which are red or just beginning to change to blue. All the blue flowers which he examined in a locality about 2 yards broad and 20 long, where many hundred flowers of *Pulmonaria* were in all stages of development, proved to be empty of honey, and all which he observed with the aid of a lens had the stigma already supplied with pollen; so that it would appear that, as in *Lantana* and *Ribes aureum*, the change of tint serves as a guide to insects visiting the flower.

At this time of year it is not an uncommon thing to find the stem of *Juniperus Sabina* attacked by a fungus known as *Podisoma Sabinœ*. Hitherto it has been supposed that this fungus, which consists of a mass of teleutospores, immersed in a peculiar glutinous jelly, is a particular stage of development of a fungus found in autumn on pear leaves, called *Rœstelia cancellata*, and that the teleutospores of the savin fungus do not directly give rise to another growth of *Podisoma*, but to the *Rœstelia*. That eminent fungologist, Mr. Worthington G. Smith, states (*Gard. Chron.*, p. 604), on the contrary, that having put some of the *Podisoma* in water to moisten it, he found forty-eight hours afterwards that those teleutospores which had been moistened had germinated and had produced an enormous amount of promycelium and a prodigious number of secondary spores, some of which in their turn had germinated on the surface of the water; while of the portion of *Podisoma* unmoistened not a single teleutospore had germinated.

According to Mr. D. Morris (*Gard. Chron.*, May 12, p. 594) the *Stillingia sebifera*, the tree whose seeds yield the tallow so largely used in China for making candles, is now completely naturalized in the Southern States of America, and forms avenues in all open spaces in the city of New Orleans. It is said to be the only tree that has been found, so far, to stand the tremor or shaking of the ground caused by the continual passing of street cars.

Dr. Pritchard has called attention in the *Lancet* (May 12, p. 851) to the poisonous effects of a plant which is being sold under the name of *Ampelopsis japonica*, and which causes raised patches of inflammation, at first resembling nettle rash, but followed by large blisters, lasting for nearly three weeks, and in some cases returning a second and third time with almost equal severity after intervals of six weeks and two months respectively without fresh contact. This plant has been since identified as the *Rhus Toxicodendron*, which partakes of the poisonous nature of many of the Anacardiaceæ. To the action of this poison some persons are much more sensitive than others.

Another curious case of poisoning by some vegetable poison is recorded in the same Journal (*Lancet*, p. 843), in which the effects produced were doubtfully attributed in part to *Urtica urens* or *U. dioica*, and, indeed, somewhat resembled those attributed by Mr. N. E. Brown to *Laportea gigas* (*Pharm. Journ.*, [3], xiii., 441), an exotic member of the same natural order, and in part to some plant nearly allied to *Artemisia*, judging from the fact that the patient complained that everything seemed green to him.

About four years ago, Mr. Moens, of Java, succeeded in grafting successfully the *Cinchona Ledgeriana* and *C. succirubra*, and these seemed at first to bear out the opinion usually held by horticulturists that there is no transfusion of quality from stock to graft or *vice versâ*. The results of the recent analyses of bark from these two seem to prove, however, that while the bark of the *C. succirubra* is rendered abnormally rich in quinine by its junction with the *Ledgeriana* graft, the bark of the latter is deteriorated, so that it yields chiefly cinchonidine and cinchonine. Such results seem almost to indicate some accidental transposition of the barks before analysis, but if subsequent careful experiments confirm the asserted results, the stock and not the graft will be of the greater importance in the future (*Gard. Chron.*, May 26, p. 666).

Cinchona trees are now being cultivated in the Cape de Verde Islands, especially at St. Antao and St. Thomé, where, according to Professor Henriquez (*Gard. Chronicle*, May 5, p. 568), there are already thousands of plants of *C. succirubra*, *officinalis* and *Ledgeriana*, most of which have been sent from the Botanic Garden at Coimbra. Analyses of the bark of some of the trees have been made and with most satisfactory results. This is interesting, as the cinchona cultivation seems to have been a failure at St. Helena.

The conditions under which an infusion of the seeds of *Abrus precatorius* produce a purulent ophthalmia have been studied by M. de Wecker, who reports that it is due to the presence of a bacillus (*Comptes Rendus*, xcvi., 1440). He has found that if an infusion of jequerity seeds be sterilized, it is no longer capable of setting up the inflammation; but that if the bacillus be removed and cultivated separately, this will provoke the factitious ophthalmia which is the object of the treatment of the eyes with the infusion. M. de Wecker makes the important statement that when these inoculations of the mucus are carried very far, a transmission to the lymphatic glands takes place, causing suppuration and erysipelatous symptoms, as well as a distinctly febrile condition.

In the *Lancet* Dr. P. S. Brito mentions the leaves of the "muringai" as being used in India in the treatment of hydrophobia, and suggests whether some constituent of the leaves may modify or counteract, in short, act as an antidote to the poison contained in the saliva, and asks for statistics and reliable experiments. The botanical name of the tree, which appears to be unknown to him, is *Moringa pterygosperma*, the native name having become the generic one. The tree is commonly known to European residents in India and Ceylon as the horseradish tree, from possessing similar properties to that plant. Its use in hydrophobia is unknown to Dr. Ondaatje, of Ceylon, and it is difficult to see how it could act as an antidote, unless the sulphuretted volatile oil it contains is proved to have a lethal effect on the bacillus of the disease.

Dr. Prosser James writes in the *Medical Press and Circular* (April 25, p. 353), recommending the fluid extract of *Rhamnus Purshiana* as an aperient, a drachm of this preparation being stated to act as freely as a pill or black draught, but like the latter it, unfortunately, has a bitter taste. In catarrh, when the stools are scanty, pale and putty-like, it appears to be of considerable service, acting partly as a cholagogue, while it irritates so slightly that it may be given when the patient is suffering from hæmorrhoids. Otherwise, this new American drug does not seem to possess any advantage over *Rhamnus Frangula*.

Dr. A. Hill Hassall has communicated to the *Lancet* (May 5, p. 765) the results of some experiments, made with various antiseptics, with a view to ascertain their degree of volatility at ordinary temperatures, and how far such substances are really useful in phthisis, when inhaled. He appears to have arrived at some singular results. Phenol was found to be very slightly volatile, and of the small quantity which passed off in vapour, part was lost in the respirator and part absorbed by the mucous membrane of the nose, mouth and fauces. The sputa did not smell of carbolic acid after inhalation, nor could the acid be detected in distilled water through which the expired air was passed. When dissolved in alcohol and chloroform, its volatility was lessened instead of being increased. Creasote was found to be slightly less volatile than carbolic acid, and thymol scarcely volatile at all at ordinary temperatures. Iodine, although very volatile, was found to be altered into an iodide by the saliva and mucus of the mouth and throat. Dr. Hassall concludes from his experiments that the most practical method of causing antiseptics to reach the substance of the lungs is by means of an inhalation chamber. Inasmuch as his experiments were performed at a temperature of about 48° F., the results he has arrived at need confirmation by experiments made with hot water before it can be taken as proved that antiseptics inhaled through an inhaler do not enter the lungs, since it is well known that many substances are volatile in steam which are not so at ordinary temperatures.

According to Dr. P. M. Chapman (*Practitioner*, May, p. 354) distilled water is not always the best vehicle for eye lotions, and a collyrium made with ordinary tap-water is less irritating than one prepared with the purest distilled water. This he accounts for by the fact that the normal lachrymal secretion contains about 1 per cent. of solids, chiefly chloride of sodium, and that water containing no salts approaches less nearly to the natural secretion than a water containing a small percentage. As a practical result of his experiments made from this point of view, he finds that the addition of 2½ grains of chloride of sodium to the ounce of distilled water renders any lotion intended to be of a soothing character much more beneficial.

In a paper read before the Berlin Medical Society (*Pharm. Zeit.*, p. 190) Dr. Levin has recently called attention to the manner of action of santonin. Whilst this substance is practically insoluble in water and dilute acids, it is more or less dissolved by saliva, the juices of the stomach, liver, intestines and pancreas, as well as by fats. All these, except the oily solutions, can be absorbed in the stomach, but the last only in the bowels. Santonin, as usually administered, acts most rapidly upon ascarides which reside in the small intestine, where the greater part is absorbed and takes effect, and does not consequently act upon the more deeply seated worms in the cœcum. Dr. Levin prefers, therefore, to use a solution in oil as being more gradual in its action, and not injuriously affecting the central nervous system. If such a solution be administered in capsules, an addition of a little oleum cinæ is recommended to assist its action.

With respect to the new hypnotic, paraldehyde, Dr. Quinlan reports (*Med. Press*, May 9, p. 401) that he has tried it on himself and others with satisfactory results, it producing quiet dreamless and refreshing sleep. Its action appears to resemble that of chloral hydrate, except that it has no depressing influence on the heart; neither does it interfere with the secretions, except sometimes to increase that of the kidneys. The dose for adults is from thirty to sixty minims, but Dr. Quinlan has not observed whether it becomes gradually tolerated so as to require the dose to be increased. The principal drawback is its persistent and acrid after-taste, which is said to be overcome by the following formula:—

℞	Paraldehydi	♏xxx.
	Aquæ	ad ℥jss.
	Syrupi aurantii	ʒij.
	Spt. chloroformi	♏xxx.

M. fiat haustus. Horâ somni sumend.

If the dose of paraldehyde be larger, the quantity of spirit of chloroform must also be increased. The recumbent position and complete quiet after administration are desirable.

Kairine, or oxychinoline methylhydrate, the new antipyretic introduced by Professor Filhne (see before, p. 444), is the subject of a paper recently read before the Paris Hospital Medical Society by Dr. Hallopeau (*Med. Times and Gaz.*, May 19, p. 574). The hydrochlorate of the base, in doses of 30 to 50 centigrams, given in a fever of moderate intensity every hour or hour and a half, is found to lower the temperature from the first dose, and after the third or fourth dose to bring it to the normal point, or even lower, the reduction being accompanied by profuse sweating, which, however, soon ceases if the normal temperature be maintained by means of fresh doses of the drug. Dr. Hallopeau has come to the conclusion that the action of kairine is more certain, powerful and rapid than that of any other antipyretic in non-poisonous doses.

In the *Practitioner* for March, Dr. Matthew Hay directed attention to the use of nitrite of sodium as a substitute for nitrite of amyl. As the result of careful experiment, he found that although the action of the sodium nitrite did not manifest itself for two or three minutes, yet it completely relieved the pain of angina pectoris, instead of only dulling it, as is the case with nitrite of amyl, and that the action also persisted for a longer period than that of the amyl compound. He also found it less liable than nitroglycerine to produce throbbing pain in the head and giddiness. The only disagreeable effect met with was the eructation of nitrous acid gas when a full dose of the salt was given; but subsequent experiments, published in the May number of the same periodical, tended to show that unless compounds containing nitrous acid give rise to its liberation in the body, no remedial effect is produced in the treatment of angina pectoris, and that, therefore, this effect is favourable rather than otherwise. His experiments further lead to the conclusion that although all nitrites which have been tried on this dreadful disease owe their efficacy to the nitrous acid they contain, yet the nitrite of amyl owes it, in some degree, also to the amylic constituent. The dose of the nitrite of sodium varies from 1 to 4 or 5 grains, according to the purity of the salt. Dr. Hay states that he has had some difficulty in obtaining it pure; even when obtained from a London manufacturing firm of the highest eminence, he was astonished to find that the specimen analysed did not contain more than 33 per cent. of the nitrite. Another specimen, which he procured nearly two years previously, contained only a trace of the nitrite. If quite pure, Dr. Hay thinks that a dose of 2 grains, or even 1 grain, would probably be a sufficient dose. Its purity is, he states, easily estimated by means of a standard solution of permanganate of potassium.

In the *Practitioner* (March, p. 175) Mr. H. T. Butlin recommends the use of chromic acid in syphilitic affections of the tongue and lips and secondary affections of the tonsils and palate. The acid is used in the form of lotion of the strength of 10 grains to 1 ounce of water, the solution being painted on three or four times a day with a camel's hair brush. The application is said to give only a little pain at first.

The use of iodine associated with the sedative alkaloids of opium is advocated by M. Delbovier, in a paper submitted to the Academy of Sciences (*Comptes Rendus*, xcvi., 1412), as a preventive of typhoid fever, and as a remedy of that disease if administered in its early stages. In the latter case it is alleged to control the fever, so that the temperature remains normal and there is an absence of delirium and complications of any kind. When administered later the remedy is not so efficacious, which M. Delbovier appears to attribute to the fact that whilst it is capable of preventing the injurious action of the microbes to which the fever is due, it is ineffective to repair the damage when done. No particulars are given as to the dose or manner of administration.

Another new dressing for wounds has been introduced by Professor Bruns (*Med. Times and Gaz.*, May 26, p. 587) under the name of "wood-wool." The raw material consists of disintegrated fibre of fine-grained wood, such as is used in paper making, the fibre of *Pinus picea* being preferred, as being poorer in resin than the wood of other pines and firs. The ordinary fibre is reduced to a finer state of division by being rubbed through a wire sieve; it is then dried and afterwards saturated with an antiseptic. The antiseptic recommended is $\frac{1}{2}$ per cent. of corrosive sublimate and 10 per cent. of glycerine, this percentage apparently referring to the ratio between these substances and the wood-wool. This wood-wool is said to possess the property of absorbing liquids to the extraordinary extent of taking up twelve times its own weight, so that 10 grains of it when completely saturated weighs 130 grains.

According to M. Izard (*Bull. Soc. Ph. du Sud-Ouest*, vii., 82) a solution of ferrous iodide, which will retain permanently the green colour characteristic of the proto-salts of iron, may be obtained by adding a few drops of alcohol to the preparation as soon as the combination of the iodine with the iron is completed. M. Izard appears to think that the alcohol undergoes dehydrogenation, and that the resulting aldehyde is capable of neutralizing the action of oxygen.

The researches initiated by M. Pasteur upon the alcoholic ferments promise to have an important influence not only upon beer brewing but upon the apparently less artificially conducted process of fermentation that goes on in the production of wine. It seems quite probable that the quality of the wine of any year is as much affected by the particular mould which predominates during the fermentation as by the amount of sunshine or rain during the growth of the grapes or even the passage of a comet through the sky. In Germany it is already the practice to sterilize the must and then to sow it with some selected ferment, a process favourable to the elimination of various "false" ferments (species of *Dematiei*) that are common to the surface of the grape and other fruit, whilst the custom in some southern countries of decanting the must as soon as the first foaming appears may have the same effect. In a recent communication (*Comptes Rendus*, xcvi., 1369) M. Le Bel incidentally remarks that last year none of the grape collection with which he had to do underwent fermentation influenced by what Pasteur considers to be the true wine ferment, *Saccharomyces ellipsoides*, Rees, but was all fermented by *S. pastorianus*. M. Le Bel also states that a natural must yields a larger proportion of the higher alcohols than a solution of sugar fermented with the same ferment. This observation has an important bearing upon the keeping of the "wines" now so largely manufactured from sugar solution in which grape skins have been steeped.

The opinion that the higher alcohols of the ethylic series are more poisonous in proportion as the complexity of the molecule increases has been expressed by various authorities, especially Nothnagel and Rossbach, and this opinion now receives confirmation by a series of experiments published in the *Practitioner* (p. 339) by Drs. Ringer and Sainsbury, who prove (at least, with regard to the heart of the frog) that the different members of the ethylic series have a similarity of action and indicate the probability that the constant chemical difference between these alcohols is corresponded to by a constant physiological difference, each CH_2 group increasing the activity by a definite amount. By their direct action on the tissue of the heart these alcohols are paralysing in their effect from the first without any preceding increase of action. The importance of having alcoholic drinks free from the higher alcohols of the ethylic series is therefore clearly proved.

In the last number of *Archives Italiennes de Biologie* a further account is given of the ptomaines by MM. Guareschi and A. Mosso. From decomposing fibrin they obtained a base having in all probability the formula $C_{10}H_{13}N$, isomeric with tetrahydromethylquinoline of Jackson, a compound having also similar properties to that of the ptomaines. They also obtained a ptomaine from decomposed human brain, which in its physiological effect upon frogs resembled curare, though feebler and more transient in its action. The ptomaine from fibrin had a similar effect to that obtained from brain, the chloroform solution of the former being more powerful than the hydrochlorate. Great care was taken by the experimentalists to ascertain the purity of the alcohol used for extracting the ptomaines and its freedom from poisonous alkaloids. Operating on about 50 litres of alcohol they found in it a small quantity of a base which was either pyridine or closely allied to it. This base is also sometimes found in amylic alcohol in as high proportion as 1 per cent., and being itself toxic, might lead to serious error. Other investigators have also demonstrated the presence in commercial alcohol of a mixture of substances belonging to the picoline series and also of collidine (*Lancet*, May 12, p. 828).

The *Répertoire de Pharmacie* quotes, upon the authority of Dr. Nessler, a recipe for an insecticide which is said to have a great reputation among German horticulturists. It consists of soft soap, 4 parts; extract of tobacco, 6 parts; amylic alcohol, 5 parts; methylic alcohol, 20 parts; water to make 1000 parts. The extract of tobacco is made by boiling together equal parts of roll tobacco and water for half an hour, adding water to make up for what is evaporated. The soft soap is first dissolved in the water with the aid of a gentle heat, and the other ingredients are then added. The mixture requires to be well stirred before it is used, and is applied by means of a brush or a garden syringe fitted with a small rose.

A substance resembling copaiba balsam, but of unknown botanical origin, which, in 1854, was imported under the name of "lagam balsam," from Padang in Sumatra into Rotterdam, where it passed into the hands of Dr. De Vrij, has been closely investigated by Herr Haussner (*Archiv*, xxi., 241). He found that lagam balsam yields upon distillation about one-third of its weight of an essential oil, having the same composition ($C_{20}H_{32}$) as those from gurjun balsam and copaiba balsam. Indeed, lagam balsam appears to differ from gurjun balsam only in an acid resin, which could not be got to crystallize, whilst the acid resin obtained by Werner from gurjun balsam ('Pharmacographia,' 2nd edit., p. 90) was crystallizable and probably had a higher molecular value. Herr Haussner assumes therefore that lagam balsam has a botanical origin similar to gurjun balsam, or wood oil, which is referred to species of *Dipterocarpus*.

The composition of the larch agaric (*Polyporus officinalis*) has been the subject of varying statements, which will now probably be disposed of by an investigation carried out by Herr Jahns. He states (*Archiv*, xxi., 260) that he finds it to yield to hot alcohol: (1) 16 to 18 per cent. of a bibasic triatomic acid (Fleury's "agaricic acid"), homologous with malic acid, being represented by the formula $C_{16}H_{30}O_5 + H_2O$, and which melts at 138° to 139° C.; (2) 3 to 5 per cent. of a neutral body, apparently an alcohol, crystallizing in needles, melting at 271° to 272° and capable of sublimation; (3) 3 to 4 per cent. of a white amorphous body, which separates in a gelatinous form from solutions; and (4) 25 to 30 per cent. of an amorphous red resinous mixture, of acid reaction, easily soluble in alcohol and ether, and having a bitter taste. This mixture contains the active purgative principle of *Polyporus officinalis*, and is the "larch fungus resin" and "red resin" of other authors. Herr Jahns considers agaricic acid, which Fleury represented by the formula $C_{24}H_{44}O_7$ (*Pharm. Journ.*, [3], vi., 862), to be identical with the "laricin" of Martius and essentially the same as the "agaracin" of Schoonbroodt and probably as the "pseudowax" of Trommsdorff. The silver, potassium, sodium, ammonium and barium salts of agaricic acid are described.

Under the name of "cinchocerotin," Herr Kerner sent to the exhibition in Paris in 1859 a substance which had gradually been deposited in some copper tubing during the cooling of an alcoholic decoction of a dried paste of South American flat calisaya bark and milk of lime. It has been recently examined by Herr Helms, who states that the crude brown cinchocerotin yields two different constituents, one easily soluble in alcohol, white and crystalline, and a much smaller quantity of a yellowish-white substance difficultly soluble in alcohol. The crystalline substance, for which he proposes to retain the name "cinchocerotin," melts at 130° C., sublimes with partial decomposition when heated higher, and is freely soluble in ether, chloroform and alcohol, but insoluble when boiled with water, hydrochloric acid, dilute sulphuric acid and acetic acid. Its composition is represented by the formula $C_{27}H_{48}O_2$, but the behaviour of the acid resulting from its oxidation indicates that it has possibly a higher molecular weight. From the results obtained it is evident that cinchocerotin is neither a wax nor a fat, and its properties and occurrence probably place it in the neighbourhood of betulin and cerin.

Professor Flückiger in a note to the *Berichte* (xvi., 1143) points out that he has described a potassium carbonate similar to that investigated by Rammelsberg (*Ber.*, xvi., 273, and before, p. 800) in the *Swiss Journal of Pharmacy* for 1856. It was obtained from an efflorescent mass of crude potash which had been exposed to the air. The salt dissolved in 3 parts of water at 15° C., giving a solution which was not precipitated by the addition of magnesium sulphate. It may be considered as formed upon the type of an acid produced by the abstraction of one molecule of water from three molecules of carbonic acid, thus— $3\,H_2CO_3 - H_2O = H_4C_3O_8$. The potassium salt of this acid would have the formula $K_4C_3O_8$ which agrees with the formula induced from the figures obtained by the analysis of the above salt. This potassium pyrocarbonate, as it may by analogy be called, crystallizes in white needles containing six molecules of water, so that the formula of the crystalline salt would be $K_4C_3O_8 \cdot 6\,H_2O$, or representing it as a compound of one molecule of normal potassium carbonate with two molecules of acid potassium carbonate ($K_2CO_3, 2\,KHCO_3, 3\,H_2O$).

The experiments of Messrs. Heumann and Koechlin (*Ber.*, xvi., 479) had led these observers to state that the vapour density of pyrosulphuryl ($S_2O_5Cl_2$)

is abnormal at a temperature at 184° C.; the theoretical vapour density being 7·4, while at this temperature the vapour density was found to be only 5·84. At higher temperatures the density becomes still less, thus at 212° C. it is 4·77, and at 452° C. 2·58. These authors ascribed this abnormality to the gradual dissociation of the pyrosulphuryl chloride, which is complete at 442° C., thus, $S_2O_5Cl_2 = SO_2 + SO_3 + Cl_2$; that is, 2 volumes of pyrosulphuryl chloride become dissociated into 6 volumes. The substance used in these experiments was prepared by two different methods: first, by the method of Rose by the distillation of sulphuric anhydride with chloride of sulphur; and second, by a method proposed by Heumann and Koechlin, consisting in the distillation of chlorosulphonic acid with phosphoric anhydride. Herr Konowalow (*Ber.*, xvi., 1127) criticizes the work of the above observers, and maintains, in accordance with his former experiments (*Compt. Rend.*, xcvi., 1059), that pure pyrosulphuryl chloride, which has a boiling point of 153° C., does not suffer dissociation at 184° C. or even at 210° C., but has the normal density of 7·4. Konowalow attributes the abnormal vapour densities obtained by Heumann and Koechlin to the employment of impure pyrosulphuryl chloride. He details experiments which show that by the method of Rose it is extremely difficult to obtain the pure substance. By two successive fractional distillations and collection of the portion distilling between 152° and 153° C., pyrosulphuryl chloride was obtained, which gave the vapour density 7·2; that is, it was normal. A similar difficulty was experienced in obtaining pure pyrosulphuryl chloride by the action of phosphoric anhydride upon chlorosulphonic acid. The distillate thus obtained gave extremely abnormal vapour densities in accordance with the experiments of Heumann and Koechlin; but after constantly distilling the mixture and collecting the portion boiling between 152° and 153° C., the distillate gave a vapour density of 7·1. Konowalow shows that it is fallacious to rely, as Heumann and Koechlin did, upon chemical analysis as an indication of the purity of this body. An admixture of chlorosulphonic acid sufficient to give an abnormal vapour density is not revealed by chemical analysis, that is, the results only show an error that would usually be allowed as experimental. The boiling point of the substance is the most trustworthy guide to its purity. Another source of error is also pointed out and experimentally proved by Konowalow. Pyrosulphuryl chloride is decomposed by the least trace of moisture (*Compt. Rend.*, xciv., 217), and consequently, when V. Meyer's method is employed, as it was by Heumann and Koechlin, for determining the vapour density, the apparatus must be filled with dry air before the experiment is commenced. Neglect of this precaution is shown to reduce the normal vapour density to 5·9.

Professor Spring, whose researches upon the formation of chemical compounds by pressure are well known, has obtained (*Ber.*, xvi., 999) a great number of the metallic sulphides by submitting a mixture of the two elements in a fine state of division to a pressure of 6500 atmospheres. In the case of magnesium a polysulphide was obtained, which dissolved in water with a yellow colour, as well as the normal sulphide. Sulphide of zinc was obtained in a form resembling blende, and possessing a crystalline fracture. A polysulphide was also obtained. The sulphides of iron, cadmium, aluminum, bismuth, lead, silver, copper, tin and antimony were in like manner produced. Sulphur and carbon did not combine to form bisulphide of carbon, neither did amorphous phosphorus and sulphur unite. Under ordinary conditions these two latter substances, when heated together, do not combine until the temperature rises above 260° C., and at this temperature the amorphous phosphorus is converted into the yellow variety. Spring's former experiments had shown that in the case of allotropic bodies it is possible to convert, by pressure, the modification having the less specific gravity into the variety having the greater specific gravity, but not *vice versâ*; thus the present result is in harmony with this, for amorphous phosphorus has a higher specific gravity (2·1) than the yellow variety (1·8).

Professor Spring has also discovered (*Ber.*, xvi., 1142) a colloidal condition of copper sulphide, in which state it is easily and completely soluble in water. The substance was prepared by completely precipitating a dilute solution of ammonio-sulphate of copper with sulphuretted hydrogen. The black precipitate was washed by decantation for one week with sulphuretted hydrogen water, and when every trace of ammonium sulphate and sulphydrate had disappeared the copper sulphide began to dissolve, yielding a black solution with a slight green fluorescence. On filtering the dark colour is not removed, and the solution is perfectly clear. The liquid is not decomposed by boiling, and upon evaporation over a water-bath, the sulphide remains as a black varnishy residue. The solution is decomposed on the addition of even a small quantity of saline solution. The precipitated copper sulphide loses this colloidal property after it has been dried in a vacuum at ordinary temperatures. It is a remarkable fact that the dried copper sulphide is not black, but a fine dark green colour, and when exposed to a pressure of 6500 atmospheres, the mass is found to have a dark blue metallic lustre.

A remarkably sensitive double sulphate of iridium and potassium ($Ir_2.3SO_4 + 3K_2SO_4$) has been obtained by M. Boisbaudran by dissolving in water charged with neutral potassium sulphate the product of the treatment of iridic compounds with potassic bisulphate at a dull red heat (*Comptes Rendus*, xcvi., 1406). It is soluble in water or water acidulated with sulphuric acid, but is nearly insoluble in a saturated solution of neutral potassium sulphate. From a hot saturated solution it is deposited upon cooling in transparent green crystalline grains that are without action upon polarized light. The double sulphate is not modified by boiling, if the solution be fairly acid; but when the solution approaches neutrality, or contains a certain quantity of neutral potassium sulphate, the green colour rapidly gives place to a very pale rose tint. At this point the addition of ammonia or potash causes the separation of all the iridium as an oxide, soluble in dilute sulphuric acid with a rich violet colour. In a cold solution of the double salt a slight excess of potash changes the green colour to a pale blue, without any immediate precipitation; but if the liquid be heated, it develops rapidly a magnificent violet tint, and the iridium is quickly precipitated as a beautiful blue violet oxide, forming a violet solution in dilute sulphuric acid. The reactions can be utilized in the recognition of minute quantities of iridium in the presence of gold, platinum, ruthenium and rhodium.

Having succeeded in effecting the liquefaction of oxygen (see before, p. 882), Messrs. Wroblewski and Olszewski turned their attention to nitrogen (*Comptes Rendus*, xcvi., 1225), but this gas even when cooled to $-136°$ C. and submitted to a pressure of 150 atmospheres remained still unliquefied. Upon suddenly removing the pressure, a tumultuous ebullition was perceptible throughout the tube, similar to that observed when a tube containing liquefied carbonic anhydride is plunged into water at a temperature above the critical point of that body. When, however, the pressure was reduced slowly, and care taken not to reduce it below 50 atmospheres, the nitrogen was liquefied completely, forming a colourless and transparent liquid, with a very distinct meniscus, but evaporating very rapidly. In order to maintain the liquid condition for a longer time it will be necessary to reduce the gas to a temperature below the minimum point yet reached. The experimenters, by following the same method, subsequently succeeded also in liquefying carbonic oxide, obtaining it as a colourless liquid, with a distinct meniscus, and they propose to apply it in the liquefaction of other gases.

Dr. Drinkwater (*Analyst*, April) has discovered that the small quantities of selenium present in some samples of commercial sulphuric acid exert a powerful action on mineral oils distilled from shale, the use of acid thus contaminated in refining the crude shale products entailing loss together with deterioration in quality. The author believes that the olefins are chiefly acted on, compounds being formed analogous to sulphovinic acid, and further that this action increases the quantity of tar, of which a portion would be broken up during the subsequent distillation and pass over with the oil, imparting a bad colour to it. The author also states that acid containing selenium cannot be used by brass-wire workers, such acid blackening the wire; and, further, such acid, when boiled with gas liquor to form sulphate of ammonia, is found to give to the solution a dirty brown to black colour.

Professors Ayrton and Perry have contributed an interesting paper "On the Resistance of the Voltaic Arc" (*Phil. Mag.*, May, p. 346). The results obtained showed that at first the difference of potentials necessary to maintain the arc increased rapidly with the distance, and that at a distance of about one-tenth of an inch it was about 60 volts. This increase continued up to one-quarter of an inch distance, after which the difference of potentials necessary became nearly proportional to the increase of distance, being about 54 volts per inch increase. The experimenters plotted these results, and obtained a curve for the increase very like that obtained by Mr. C. F. Varley for the discharge through a vacuum tube, and by Drs. W. de la Rue and Hugo Müller for the connection between the electromotive force and the distance across which it would send a spark. The result of the experiments showed that the difference of potentials between the carbons necessary to produce an arc depends almost entirely on the distance between them, and hardly at all on the strength of the current. Messrs. Ayrton and Perry express an opinion "that in all probability the conduction from particle to particle in a microphone is of the nature of a small electric arc, or rather, perhaps, a convective discharge."

A NEW ALKALOID IN CANNABIS INDICA.

BY MATTHEW HAY, M.D.,

Demonstrator of Practical Materia Medica, University of Edinburgh.

Preliminary Notice.

Cannabis indica, or Indian hemp, is exceptional as a narcotic plant in respect of no alkaloid, possessing the action of the plant, having been as yet separated from it. The so-called cannabine obtained by T. and H. Smith, of Edinburgh, many years ago, and said by them to possess the active and narcotic properties of the cannabis, is certainly not a pure principle, and is, probably, a mixture of resin with varying proportions of the narcotic principle. It possesses almost solely the characters of a resin, and is described by the Smiths as such; but were it the true active part of the plant, it is certainly far removed from all other narcotic principles, inasmuch as none of them is chemically related to the class of resins. One specimen of cannabin which I obtained some time ago from Merck, of Darmstadt, and which, I was given to understand, was prepared exactly according to Smith's process, possessed little or no narcotic action.

A few years ago, Preobraschensky (*Pharm. Zeitsch. f. Russland*, 1876, p. 705) made a chemical examination of a quantity of haschisch which he brought with him from China, whither in 1873 he had accompanied an expedition, and was enabled, according to his own statement, to separate from it a volatile alkaloid, which he held to be identical with nicotine, and which he believed to be the active part of cannabis. This, in view of the distinctive and very different action of cannabis, was somewhat remarkable. It is highly probable, as has been suggested by Dragendorff and Marquiss (*Pharm. Zeitung*, 1877), that the haschisch used by Preobraschensky was mixed with tobacco, which it often is in Eastern countries.

Recently Louis Siebold and Bradbury have reported to the British Pharmaceutical Conference (1881) that, after an elaborate investigation, they have arrived at the conclusion of Dragendorff and Marquiss, and that in the course of their investigation they made the interesting discovery that pure cannabis does actually contain a volatile alkaloid, which does not, however, possess the characters of nicotine. They separated it in very small quantity, obtaining not more than 2 grains from 10 pounds of Indian hemp. They give to it the name of cannabinine. They record no observation as to its physiological action; and they, therefore, leave it doubtful as to whether this volatile alkaloid is the narcotic principle of cannabis.

It is evident from these and many other researches that it is no easy task to arrive at correct conclusions as to the active principle of cannabis indica.

A considerable time ago, I commenced a chemical examination of this drug, at the suggestion of Professor Schmiedeberg, of Strassburg, the results, so far, of which lead me to believe that cannabis indica contains several alkaloids. In a future communication I hope to be able to give an exact description of the distinctive characters and toxic action of each. In the meantime, I shall content myself with the description of one which I have obtained in a considerable degree of purity, and one which, rather remarkably, possesses an action similar to that of strychnia. It is evidently, therefore, quite a secondary alkaloid of the cannabis, and reminds one of the thebaine of opium.

This alkaloid was obtained from a watery infusion of powdered cannabis indica by treating it with a solution of subacetate of lead, and filtering. To the filtrate was added ammonia, and the precipitate removed by filtration. The filtrate, acidulated with sulphuric acid, was now treated with a solution of phospho-wolframic acid in order to precipitate the alkaloids present. The precipitate, which was fairly abundant, was, after the fluid had been removed by filtration and washing with dilute sulphuric acid and pressing, mixed with barium hydrate and water, which formed an insoluble wolframate and set free the alkaloids. The filtrate was now deprived of its excess of barium by means of a stream of carbonic acid gas and again filtered. The filtrate was at a gentle heat evaporated almost to dryness and acidulated with sulphuric acid and treated with absolute alcohol. The sulphate of the alkaloids thus formed was partially soluble in alcohol, partly not. It was from the soluble part that the alkaloid in question was procured. The sulphate was converted into a chloride by treatment with barium hydrate, afterwards with carbonic acid to remove excess of barium, and, finally, with hydrochloric acid to neutralization. The chloride was evaporated and treated with absolute alcohol, in which it in part dissolved. From the solution, by addition of excess of carbonate of soda and frequent shaking with ether, an alkaloid was obtained in the form of colourless needle-like crystals.

The alkaloid was easily soluble in water, soluble also in alcohol, and more slowly soluble in ether and chloroform. It caused tetanus in frogs in exactly the same manner as strychnia, increasing the excitability of the reflex centres of the spinal cord. It did not give a violet colour with sulphuric acid and bichromate of potash. It was, therefore, although similar in action to strychnia, not chemically identical with it. A solution of it in water was precipitated by the various alkaloidal precipitants, platinic chloride, iodide of potassium and mercury, phosphotungstate of soda, phospho-molybdic acid, phospho-wolframic acid, etc.

Although I obtained the alkaloid from 1 kilogram of cannabis, yet the quantity of it was so small, that it was insufficient for an elementary analysis.

To this alkaloid I propose to give the name of tetano-cannabine, as indicative of its action.

MANUFACTURE OF TARTARIC ACID.*

BY L. H. FRIEDBURG, PH.D.

In the United States, tartaric acid is hardly manufactured for its own sake, but its preparation is unavoidably attached to the manufacture of cream of tartar. Here the starting points for tartaric acid are sablons, waste liquids and residues of different kinds, which render an analytical control troublesome, so that, partly because of great dilution, the raw material is treated more or less empirically, after the known and often described methods† with chalk and chloride of calcium or gypsum.

Abroad, the manufacture of tartaric acid is not everywhere a mere appendix to cream of tartar manufacturing, but forms an independent branch of manufacture. In such cases the raw material consists either of argols or of dry sablons, or of lees.

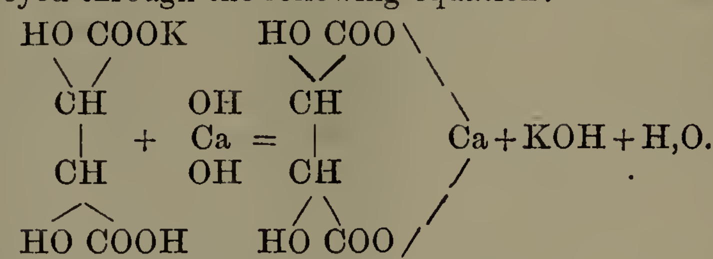
A careful analytical test has to be made before treating either of these mother-substances, and the manufacture has to be carried on with the greatest care, in order to avoid loss.

Until very recently, these tartaric acid factories worked generally after the old plan, as indicated above, viz.:—treatment with chalk and chloride of calcium or gypsum. But it has to be recorded, and I will briefly do so in the following pages, that a very neat and new patented process, which, according to my own experience, is commendable, is now also in use.

This process is based on the decomposition of the mother-substances, as named above, by slaked lime, instead of chalk. This preparation has been hidden in the European patent* under the heading, "Methods of obtaining the Potassium in the form of Hydrate, while making Tartaric Acid out of Argols."

This heading is practically speaking untrue, because, as we shall see later on, the potassium is not finally gained as hydrate, though this is in course of treatment formed, and then transformed into sulphate or chloride.

The chemical process which takes place in decomposing the bitartrate of potash in any mother-substance into tartrate of lime, by means of slaked lime, is very simply conveyed through the following equation:—



The practical difficulty which stood for so long a time in the way of realizing this decomposition for manufacturing purposes was the difficulty of making the products of decomposition easily filterable.

This the patentees have really overcome, and the method of working is smooth, and goes like clock-work.

Slaked lime, freed from coarse pieces, is taken, in necessary quantities, and a milk, not too thin, prepared therefrom.

This is heated to boiling, and argols, etc., in necessary quantity, are very gradually, and in a state of finest powder, introduced into the boiling mass.

The charging finished, boiling has to continue for two hours, the condensing steam being enough to keep the mixture in a concentrated form.

Hydrate of potash and neutral tartrate of lime are formed in this way. The nitrogenous organic impurities of the raw materials are, by the combined action on them of lime and hydrate of potash, decomposed so as to form ammonia gas, which is volatilized with the steam.

Boiling done, which takes place in an iron tank, the mixture is diluted by enough cold water, and then the potash is neutralized by either muriatic or sulphuric acid. The process is finished with the help of litmus paper.

Here the ammoniacal exhalations are to be considered, so as not to disturb the reaction. The decomposition, as described above, takes place under constant stirring by means of an iron stirrer run by machinery.

After the formation of either chloride or sulphate of potash, the mass is still more diluted with cold water, and stands best over night, stirring going on continuously, filtration then taking place the next morning. Here filter presses are used to great advantage.

It is advisable not to use too high pressure, so as to get a soft cake, which can more easily be washed out, in order to get rid of the mineral potash salts.

These latter are either boiled down, as long as the

strength of the solution makes it pay, or they might* be treated with chloride of lime (bleaching powder), and thus transformed into chlorate of potash, which I advise manufacturers to try. The cakes of brown tartrate of lime, which begin to exhale putrid odours by standing too long in a warm place (in summer time six hours' standing often will show this result), have speedily to be decomposed by sulphuric acid. This decomposition takes place in a wooden, lead-lined tank, with heavy wooden stirrer moved by steam.

The decomposition takes place in the cold, and its completion is determined easily by methyl violet test-paper.†

No analysis has to be made here, if good paper is at hand, which allows one to guide the reaction, so as to get the necessary point or the excess of sulphuric acid wished for.

The brown solution of tartaric acid is filtered through filter-presses into wooden receivers. It is not advisable to evaporate this acid down to the point of crystallization, because it contains impurities enough to spoil the mother-liquors at a too early stage. If the course of manufacturing demands a readier transformation of raw material into money, this crude acid solution might be concentrated in the leaden pans to the right concentration for crystallizing or for precipitation by the stirring process.

It is preferable to reprecipitate this acid as tartrate of lime, finishing the reaction with chalk, and using litmus test paper.

The tartrate of lime thus obtained is filtered on a vacuum filter or by centrifugal power. Of course washing takes place, though slightly. This tartrate of lime is crystalline, light greenish-yellow, and keeps perfectly well for any length of time required without decomposing.

It is decomposed in an apparatus similar to the one used for decomposition of the first brown tartrate of lime, by sulphuric acid, in the cold, and the reaction finished with the aid of methyl violet test paper. The filtration of the very white gypsum thus obtained cannot be done through filter presses, but has to take place on a vacuum filter, very thorough washing being required.

The tartaric acid solution thus obtained ought to stand between 12° and 14° B. It is ejected into the lead pans, evaporated at 80° C. to the necessary density by which dissolved gypsum is precipitated, run into the crystallizing boxes, and let stand for crystallization. The crop of brown crystals is redissolved to a liquid of the density 25° B., and treated with bone black which has been purified by muriatic acid (so as not to leave a trace of phosphates) at a medium temperature and under stirring.

The discoloured liquid is run through a filter-press, and thence into special lead pans. It is evaporated down to about 39° to 40° B., and run into lead boxes for crystallization.

The crystallization being a comparatively slow process, this liquid may be run into a proper tank with stirrer, stirred for several hours, thus yielding a crop of small crystals right away.

Either crystals are washed and dried in centrifugals by using steam for washing.

The liquid running off from the first crystallization yields after evaporation another crop of white crystals. Then it becomes a brown mother-liquor.

The mother-liquors of the brown crystals can, under careful attention, be carried along through the sixth or seventh crystallization. Then the predomination of sulphuric acid and impurities does not allow further crystallization.

The mother-liquors at that stage are diluted to a proper density, the greater part of the sulphuric acid removed by the addition of slaked lime milk, and the filtered liquid has then principally to be freed from iron salts and from phosphate of alumina.

The iron is easily expelled by taking care to keep it in the form corresponding to the protoxide, the presence of the phosphate of alumina making it necessary to treat the liquids boiling with milk of lime, thus precipitating phosphate of alumina, and forming an acid tartrate of lime which is soluble. It has to be filtered hot, and is decomposed by an addition of sulphuric acid, thus yielding very pure solution of tartaric acid.

If a transformation of the acid thus gained into bitartrate of potash should be wished for, which hardly would be prudent, the simplest way of arriving at this end would be the following:

The solution is divided into two equal parts, one half saturated by caustic or carbonate of potash, so as to form a neutral tartrate of potash, and then the other half added for the precipitation of the bitartrate.

* In case chloride of potassium was formed.

CHLORIDE OF ZINC TOW.*

BY EDWARD HIRSCHSOHN, MAG.PHARM.

The employment of tow or oakum,† as a dressing for wounds is quite old. According to Gerdy,‡ tarred tow (oakum) was much used towards the end of the time of Hippocrates. Its antiseptic property was highly recommended, and it found extensive employment in the American war of the rebellion. In 1880, Dr. Weljaminow § reported that tow, which had been treated shortly before application with a 10 per cent. carbolic spray, was used successfully in Dr. Reyher's clinic in St. Petersburg. For some time past, also, dry tow impregnated with chloride of zinc has been used as a cheap substitute for the expensive salicylated cotton in the surgical clinic of Professor von Wahl, in Dorpat. A report on the success of this method of treatment has been made by Dr. Drombowsky,|| the present clinical assistant, who states that the dressing is prepared in the following manner:—

"The tow was picked, carded, and then placed in an oven arranged for sulphur disinfection. After having been exposed for twelve hours to the vapour of sulphur, it could be assumed that any germs absorbed from the air had been destroyed. It was then saturated with an 8 to 10 per cent. solution of chloride of zinc, and the excess of the solution removed by a press, somewhat like that used by bookbinders.¶ The tow was next dried, at ordinary temperature or at a moderate heat, being repeatedly turned over, and was after twenty-four hours sufficiently dry to permit being again carded. Finally, the material was formed into flat cakes of the size of plates, about $1\frac{1}{2}$ inch thick, and transferred to air-tight tin boxes, containing caustic lime, in order to prevent its decomposition by the carbonic acid of the air."

It was now of interest to ascertain, first, whether the process here described furnishes a completely aseptic dressing, and, secondly, whether the percentage of

* From *St. Petersburger Medic. Wochenschrift*, 1882, No. 50. Reprinted from *New Remedies*, April, 1883.

† We have uniformly translated the term "schiffswerg," which the author uses, with "tow," although he specifically states, in a subsequent portion of the paper, that it is prepared from old, condemned *tarred* ropes . . . which have probably lost a good deal of their tar by long exposure. This would, under ordinary circumstances, have to be rendered into English by "oakum;" but the article usually sold here under this name usually contains too much tar to readily absorb aqueous solutions. Tarry oakum is much used for dressing, particularly in this country; but the tow or oakum meant by the author is made from *old* tarred ropes, which have lost their stiffness. And it seems to us that plain tow, which has never been tarred, will answer the purpose even better.—*Ed. New Remedies.*

¶ A common clothes-wringer is, in our experience, the best contrivance for such purposes.—*Ed. N. R.*

chloride of zinc contained therein was approximately uniform.

To decide the first-mentioned point, it seemed advisable to use a method already used by former investigators, as Pasteur, Cohn, etc., and lately, also, by Professor Frisch, of Vienna.* This consists in bringing the material to be examined for the presence of vital germs or surviving spores into a medium favourable for their development. But, as it has been shown by the experiments of Billroth,† Kuehn‡ and Boehlendorf,§ that different forms of bacteria do not develop and grow equally in all propagating media, it was necessary to use several of the latter. I selected four of them, namely, the following:—

a. Pasteur's propagating liquid, modified by Buchholz:|| Sugar (candy), 100; nitrate of ammonium, 10; neutral phosphate of potassium, 5; distilled water, 1000 parts.

b. Cohn's propagating liquid, modified by Eidam:¶ Acid phosphate of potassium, 5; sulphate of magnesium, 5; neutral tartrate of ammonium, 10; chloride of calcium, 0·5; distilled water, 1000 parts.

c. Solution of extract of meat, containing 1 per cent. of the extract.

d. Normal urine.

The three first-mentioned liquids were first filtered, boiled from one-half to three-quarters of a hour, and the evaporated water replaced by addition of boiling distilled water. The urine was prepared for use by boiling for half an hour, then filtering, and again boiling the filtrate for half an hour, the lost water being replaced as in the other cases. The prepared liquids were transferred to propagating vessels, consisting of opodeldoc glasses (holding 1½ to 2 ounces), which were closed with tight plugs of cotton. Before the liquids were introduced, the vessels and plugs were heated during one hour to 180° to 200° C. (356°–392° F.), then allowed to cool sufficiently to permit the liquids being poured in, immediately stoppered and transferred to a hatching oven.** The temperature is in the oven varied from 36° to 38° C. (about 96°–101° F.). After the vials had been in the oven for a fortnight, it was found that, with the exception of a few, all of them had remained clear. The turbid ones were removed, and in each of the others 1 gram each of the samples of tow to be examined was introduced, great caution being used to rapidly open and close the vials. To obviate the objection that the mere lifting of the plug might have been sufficient to infect the contents, a few vials, in which the plug had been lifted in the same manner, but without any tow being introduced, were placed with the others in the oven. As criterion to pronounce upon the existence and development of germs in the several liquids, the appearance of a turbidity was relied upon.

Now, since crude tow (oakum) itself had already been in use for a long time as a dressing for wounds, it was of interest to find whether this alone, unprepared, fulfilled the requirements as an antiseptic dressing, although it could be presumed *à priori* that during its long exposure to all sorts of contaminating agents it had become infected.

Results with Unprepared Tow (Oakum).—All trials made with this showed that the tow contained living germs, which became more or less rapidly developed in the propagating fluids.

Results with Sulphurized Tow.—In this case the development of germs was slower than in the preceding cases. Yet after four days all propagating liquids were turbid. The tow had been kept for twenty-four hours exposed to the vapour of burning sulphur. This apparent inability of sulphurous acid gas completely to destroy the vitality of germs is also shown by a series of experiments lately made by the German Imperial Health Department. A better result was obtained by treating the tow with chlorine gas or chlorine water.

Results with Chlorinated Tow.—Tow which had been treated for twelve hours with chlorine gas, or been kept covered for half an hour with officinal chlorine water, then expressed and introduced into the propagating vessels, failed to show the development of any germs, even after standing for months.

Results with Chloride of Zinc Tow prepared by Cold Soaking.—Picked tow was completely saturated with a 10 per cent. solution of chloride of zinc, the excess of liquid pressed out between two small boards, and the tow dried at the ordinary in-door temperature. When completely dry, the tow was carded and then used. Two separate series of experiments were undertaken, each with twelve vials. In both series all the liquids developed fungi, etc., which covered, after three weeks, the whole surface of the liquid. The results showed that a simple treatment of the tow with a 10 per cent. solution of chloride of zinc was insufficient to destroy vital germs. Now, as it is known that the latter can be killed by a temperature of 100° C. (212° F.) and over, a new trial was made, in which the tow was boiled for half an hour in the 10 per cent. solution.

Results of Chloride of Zinc Tow prepared by Boiling.—Four separate series of experiments, each with twelve vials, furnished identical results. No development of fungi, etc., could be noticed in any of the liquids, even after standing for months. On repeating the experiment with a 5 per cent, solution of chloride of zinc, the same result was obtained.

The second point which I desired to determine was, whether the percentage of chloride of zinc in the finished dressing was approximately uniform. For this purpose, Balling's* volumetric method was used, which consists in determining the zinc by means of carbonate of sodium, with phenol-phthalein as an indicator.† I employed a solution of carbonate of sodium of such a strength that 1 cubic-centimetre corresponded to 0·0209 gram of chloride of zinc. The determination was made thus:—5 grams of the air-dry chloride of zinc tow were macerated with 100 c.c. of distilled water, for twenty-four hours, in a closed vessel, under repeated stirring; then 25 c.c. were measured off, diluted with 250 c.c. of boiling distilled water in a flask heated to boiling, a few drops of an alcoholic solution of phenol-phthalein poured in, and the volumetric solution of carbonate of sodium added, until the liquid assumed a distinct rose-colour. The following results were obtained:—

a. Tow, previously carded, boiled with a 10 per cent. solution of chloride of zinc, dried in a room, and then again carded, yielded, in an air-dry condition, 14·83 per cent. of chloride of zinc as a mean between 4 determinations. In another sample 14·58 per cent. were found.

b. Tow treated exactly like the preceding, but with a 5 per cent. solution only, yielded 8·85 (another sample 8·67) per cent. of chloride of zinc.

¶ Cohn, 'Beiträge zur Biologie der Pflanzen,' i.

** For this purpose I used a double-walled box made of tinned iron, such as is used for the preparation of Lister's carbolic gauze, and has been described by me in a paper on the preparation of salicylated and benzoated dressings in the *Voyenno-Meditsink. Journ.*, 1880, July number. The box held 250 vials.

* *Chemiker-Zeitung* (1881), No. 23, p. 395.

† Before using the method, I convinced myself that an aqueous extract of crude oakum with carbonate of sodium yielded no precipitate, and that the solution was free from ammoniacal salts, since the presence of the latter, according to Balling, retards the appearance of the end-reaction.

c. Tow treated as under *a*, but dried at 60° to 70° C. (140° to 158° F.), and then carded, yielded, after one day's exposure to the air, 12·86 per cent. of soluble chloride of zinc.

d. Tow treated as under *c*, but prepared with a 5 per cent. solution, yielded 7·01 per cent. of chloride of zinc.

The preceding figures show that the dressings contain practically uniform quantities of the salt. The circumstance that tow soaked in a 10 per cent. solution of the salt retains more than 14 per cent. of the latter, is explained by the fact that it soaks up about one and a half times its weight of the solution. The quantity of the salt in the samples dried at 60° to 70° C. is smaller, which is partly due to the loss caused in the process of carding.

For the purpose of ascertaining the keeping qualities of the dry chloride of zinc tow, a new assay of the samples was made after six months.

a. Samples which had been carded and been kept loosely in filtering paper yielded 11·52 (or 10·33) per cent. $ZnCl_2$, while they had formerly contained 14·75 and 14·38 per cent., respectively.

b. Samples which had been kept, uncarded, in waxed paper, lost scarcely anything; those which originally contained 14·75 and 14·38 per cent. were found to assay 14·70 and 14·31 per cent.

Chloride of zinc tow, therefore, may be kept, practically unaltered, for a considerable time, if wrapped in waxed (or paraffined) paper.

On the basis of the results here described, I propose the following method for preparing this form of dressing, of a strength of about 15 per cent.:—

Preparation of Chloride of Zinc Tow.

Commercial, crude tow is thoroughly carded, then boiled for half an hour with ten or fifteen times its quantity of a 10 per cent. solution of chloride of zinc, in a kettle which can be closely covered. It is then pressed between two hinged boards, and dried in thin layers, at the ordinary in-door temperature. When dry, it is either at once carded, or it may be preserved uncarded in waxed paper.

If the tow is to contain 10 per cent, of chloride of zinc, a 7 per cent. solution of the dry salt is taken; and for a 5 per cent. dressing the strength of the solution is reduced to 3½ per cent.

When thus prepared, and particularly after being several times carded, the prepared tow is quite soft, and advantageously replaces salicylated cotton, owing to its cheapness.

I have also made some experiments to test the antiseptic properties of the dressing thus prepared, compared with those of salicylated cotton and jute. [The tables appended by the author must be omitted here, for want of room; the results are summarized as follows:] 3 grams of the respective kind of dressing were added, each, to 100 c.c. of fresh urine, in vials which were kept open, and at a temperature of 30° to 35° C. (86° to 95° F.). A sample of the urine alone became offensive after four days; two others treated with an 8·5 per cent. and a 14·6 per cent. chloride of zinc oakum, as well as one treated with a 10 per cent. salicylated cotton, were still clear and acid after six days; another containing some 4 per cent. salicylated cotton became turbid after three and offensive after six days; and one sample treated with some 4 per cent. salicylated jute (which had, however, been carelessly kept) became offensive after two days. In another series of experiments, 5 grams of the respective dressings were, each, added to 100 c.c. of already offensive and alkaline urine; the samples containing a 10 per cent. salicylated cotton, and that with an 8·5 per cent. chloride of zinc tow, though at first rendered neutral soon became offensive again; but the sample treated with a 14·6 per cent. chloride of zinc tow turned gradually clear and acid, and remained so at the end of the second day.

These results confirmed the decided antiseptic properties of chloride of zinc, already recognized by most surgeons.

Tow (or oakum) may also be impregnated with other antiseptics, such as carbolic, salicylic and boric acids, iodoform, etc., by slightly modifying the above process, as I have found by preliminary trials. Special directions for their preparation will be published at some future time.

TINCTURA FERRI CITRO-CHLORIDI.*

BY ARTHUR H. STILES.

This is an unofficial compound, to prepare which take of—

Citric acid	℥xviij.
Bicarbonate of sodium	℥xiv.
Solution of chloride of iron	℥xij.
Water	℥ij.
Alcohol sufficient to make	ʒvj.

Heat the water to the boiling point and, having dissolved in it the citric acid, add the bicarbonate of sodium in successive portions, stirring after each addition until effervescence ceases; then add the solution of iron, stirring well, and afterwards, sufficient alcohol to make the mixture measure 6 fluid ounces; lastly filter the solution to remove any foreign matter that may be present, and keep it in well stopped bottles.

In my first experiment, having heated the water to the boiling point and dissolved the acid, I began adding the sodium salt, but, before one-half had been added the solution took the form of a crystalline mass very hard and but slightly soluble.

Thinking that the heat had, by its continued application, driven off a part of the water, in my next trial, after dissolving the acid in the heated water, I removed the solution to a mortar, then adding the bicarbonate of sodium, triturating after each addition. By so doing I obtained a solution of a syrupy consistence, having an acid taste and a very marked reaction on blue litmus, which is an acid citrate of sodium.

Then I added the solution of iron.

The reaction which occurs here is not so easily accounted for. That there is a reaction is very evident, for, before the alcohol is added, the solution obtained by the addition of the solution of iron to that of citrate of sodium is clear, but after it has been added a precipitate is thrown down, which has the appearance of, and answers the tests for chloride of sodium.

As it appears to me, the chloride of sodium is held in solution until the alcohol is added and then, owing to its comparative insolubility in the alcohol, the salt is thrown down as a precipitate.

I have since obtained the same result by reducing the acid to a powder, adding the sodium salt and water, setting the mixture aside until solution is complete, and then adding the other ingredients as before mentioned.

The completed solution is of an emerald green colour, having the specific gravity 1·200, and containing the same amount of solution of chloride of iron as did the tinctura ferri chloridi of the U.S. Pharmacopœia of 1870, and 1·22 parts less than that of 1880.

The advantages of this preparation are its miscibility without discoloration or formation of precipitates, with preparations of barks, all tonics and Fowler's solutions; it has an agreeable taste, that of iron being almost obliterated, and it has no injurious effect on the teeth.

Its medical properties are identical with those of tinctura ferri chloridi. The dose is from 10 to 30 drops.

ENERGY AND ITS TRANSMISSION.

THE enormous progress made in the science of electricity during the last few years has attracted so much attention to this form of energy and the available means of transmitting it from one place to another, that there has been a tendency to lose sight of other sources of energy and means of transmission which, though more old-fashioned, are scarcely, if at all, less valuable. Professor OSBORNE REYNOLDS has therefore done useful and timely service in giving a little more prominence to this latter part of the general subject in his recent "CANTOR" course of lectures on "The Transmission of Energy," delivered before the Society of Arts.

Energy is, as a rule, only useful to man to the extent that it can be controlled and directed, but, as pointed out by Professor REYNOLDS, it exists to a great extent in an "undirected" condition, although by various devices it is possible to bring it largely under control. "Undirected" energy may be considered to be analogous to an undisciplined mob, which can be directed as a whole only by directing each of its separate constituents. In the case of a mob this can sometimes be accomplished, but in the case of energy, where the constituents are molecules of matter, it cannot in practice be effected. "Directed" energy is more analogous to a trained army, although it may be disciplined only to an extent sufficient to execute one manœuvre with full effect, and if compelled to execute other manœuvres would not carry them out to the fullest advantage. An illustration of this may be found in coal, the total "undirected" energy stored up in one pound of which is estimated to amount to ten to twelve million foot-pounds. Of this quantity it is possible to convert seven to nine million foot-pounds into "directed" energy; but in utilizing this energy in the steam-engine, a great loss is sustained in its passage through the plate of the boiler, and only about one-third, or from two to three million foot-pounds of "directed" energy, enters the boiler. A further loss is sustained in the transmission of this energy from the boiler to the piston, and in some cases only half a million out of the original ten or twelve million foot-pounds reach the piston as "directed" energy, whilst in the highest class of engines yet constructed, the quantity only reaches one and a half million foot-pounds. Thus it will be seen that if steam-engines should be eventually perfected so as to throw upon the piston the whole of the energy which enters the boiler, this will amount to only about one-fourth of the energy stored up in the coal.

In view of the possible eventual scarcity of coal, consequent upon the enormous demand for it as a convenient source of energy, attention has been turned in other directions. The winds have been captured and made to do service to man, and the waters have been intercepted on their way to a lower level and made to pay a toll of work. An enormous store of energy resides also in the waves of the sea, which at the present time are apparently doing no other work than gradually washing away our coasts. It has been already shown, however, that a ship may be propelled by the rocking of the waves on which it floats, and it is probable that before long the ingenuity of man will devise means for extorting a tribute from the ocean. Another source of energy mentioned by the lecturer is the oxidation of organic matter, as in the case of a draught animal fed upon corn. But if corn be used as fodder for horses, instead of coal being used for the production of steam, the cost is ten times as great to produce the same amount of energy. Accordingly, to be equally profitable, the energy obtained from a horse should be ten times as valuable as the same amount of steam-energy, and this, for certain purposes, is true, for although in some cases steam-power can be used equally as well as horse-power, yet in others, in which the energy is required to be brought in closer connection with the work, horse-power has a considerable advantage. With respect to inorganic matter, if we may judge from the enormous amount of energy expended in dissociating the oxides of metals, amounting, in the case of iron and zinc, to nearly two million foot-pounds per pound of metal, if it were possible to apply the energy of such oxidation the metals would become rivals to coal.

The distance through which energy is capable of being transmitted varies according to the medium of transmission. Thus if transmitted by water only about one part in one hundred and twenty thousand of the energy will be lost per mile, whilst if transmitted by railroad the loss will equal one part in twelve thousand; stated roughly, an amount of energy that can be transmitted by canal 120,000 miles would only pass over a railroad 12,000 miles, over a good ordinary road 1000 miles, and without a road 300 miles. There are several artificial methods of transmitting energy: (1) It may be contained in a medium which may itself be carried from place to place as in a watch; (2) By means of shafts; (3) By means of the flow of heat or electricity along material conductors. Although radiation is used both in optics and acoustics, the only example of its use in the transmission of energy is the radiation of coal through a boiler-plate.

Power stored in one form is much more available than power stored in another, and the weight of material required in each form to enable a certain amount of energy to be stored in it varies also. Thus, to store one million foot-pounds in a steel spring involves the use of material weighing about three hundred thousand pounds; compressed air in pipes, representing the same amount, would require seventy-five to two hundred pounds, water compressed in pipes fifty to one hundred and fifty pounds, FAURE's battery about seventy pounds, a locomotive (with coal and water) about fifty pounds, a horse about two hundred pounds, and coal about one and a half pounds. The relative cost is also to be considered, and taking coal as the standard, the methods of compressed air in pipes and FAURE's battery are, roughly speaking, three times as costly.

Another point to be considered is that not only power is required, but applied power; the relative capabilities of different methods for the mechanical transmission of one thousand horse-power is indicated by the following table:—

Means.	Diameter (in inches).	Loss (per mile per cent.).	Practical limit (in miles).
Shafts	4	10	7
Steel ropes (single)	·75	·5	100
Steel ropes (double)	1	1·5	33
Compressed air in pipes	30	—	100
Water compressed in pipes	12	10	7

With regard to the foregoing it may be remarked that a 4-inch shaft will not practically transmit more than 75,000 foot-pounds per second. The great advantages of a steel rope are apparent, but the compulsory use of double steel ropes in most cases tends to lower the figures considerably, and it has been found that they are practically of no use to transmit less than forty or fifty horse-power. Like steel ropes, water is most effective when used in transmitting high pressures, its great disadvantage being due to leakage; but if the diameter of the twelve-inch pipe were doubled, that is to say, if the capacity and cost were quadrupled, instead of the practical limit being seven miles it would be over two hundred. The transmission of energy by means of air compressed in pipes involves no appreciable loss from friction, and unlike other methods this will transmit high or low pressures equally well. DEPREZ has made several experiments on the transmission of energy for long distances by electricity, but although the results look well, the lecturer was of opinion that if reduced to the same standard as that of steel ropes, they would be seen to be really small. It may be remarked, however, that at the end of the course of lectures, the Chairman expressed an opinion that DEPREZ had made his experiments at a disadvantage, and moreover, Sir WILLIAM SIEMENS has recently given his reason for believing that much better results can be obtained by this method.

The second reading of the Medical Acts Amendment Bill has been again adjourned until Monday next. When speaking on Tuesday evening of the Government measures that it is intended to push through Parliament this session, the Prime Minister made no reference to this Bill, so that it is possibly looked upon as one of the "measures of secondary importance," concerning which, he said, doubts might arise as to persevering with them.

* * *

Petitions have already been presented in the House of Commons for the amendment of the Medical Bill, on behalf of the King and Queen's College of Physicians, Ireland, and the Society of Apothecaries, London. The former body asks that it may be placed on an equal footing with other medical authorities by being empowered to return three, instead of two, representatives to the proposed Medical Board for Ireland. The latter body asks for the restoration of the provision originally contained in the Bill, under which it would have chosen one of the fifteen members of the Medical Board for England.

* * *

In the petition from the Society of Apothecaries it is urged, among other pleas, that the large majority of country practitioners obtain their medical diplomas from that Society, and that it is peculiarly connected with what are called general practitioners, who form a very numerous and influential body, and who for the most part supply their own medicines and thereby satisfy a great public want.

* * *

According to the *British Medical Journal* a subcommittee appointed by the Council of the Metropolitan Counties of the British Medical Association has also decided to attempt to secure the introduction of several amendments into the Bill. One of these is to alter the fourth division of clause 27 so as to absolutely prohibit unregistered persons from practising medicine in any of its branches for gain.

* * *

At a meeting of the chemists of Rochdale, held last week, it was resolved to forward a petition to the House of Commons, praying for a clause to be inserted in the Medical Act Amendment Bill, for the purpose of placing pharmaceutical chemists on the Committee for the compiling and revision of the Pharmacopœia.

* * *

A correspondent of the *British Medical Journal* expresses an opinion that the present time, when Bills are under consideration for the amendment of both the Medical and the Pharmacy Acts, would be opportune for an endeavour to prevent druggists from prescribing medicines, of the physiological and therapeutics of which, he says, they know little or nothing. To effect this he proposes that a clause should be inserted in the Pharmacy Bill enacting that scheduled "poisons" are only to be prescribed by a legally qualified man, who shall affix his name and address to all prescriptions ordering them, without which it shall be unlawful for them to be dispensed by a pharmacist. He would also compel a pharmacist to cancel a prescription ordering a poison by writing his name upon it and make it unlawful to repeat a prescription so cancelled without the prescriber's authority. These restrictions he would also impose upon medical men keeping open shop for the dispensing of other practitioners' prescriptions.

The same gentleman expresses his sympathy with chemists and druggists in their "attempts to get the monopoly of selling and compounding all—with a few exceptions—the medicines enumerated in the British Pharmacopœia," and he thinks that such a concession would be a graceful act and only fair to them after the prolonged study and expense to which they have been put to qualify themselves. To prevent, therefore, the sale of articles used in medicine by incompetent persons he suggests that, with the exception of a few scheduled articles to be kept by the grocer and the drysalter, the dealing in all medicines should be restricted to legally qualified druggists. This correspondent does not say whether, having provided for the protection of the medical profession in the Pharmacy Bill, he would secure the interests of chemists and druggists in the Medical Bill; neither does he say how far he thinks the probability of the passage of either Bill would be affected by such a course.

* * *

A case recorded in the *British Medical Journal* last week well illustrates the perverse carelessness which is beyond the power of any poison regulations to control. A woman in a small village in the west of Ireland, finding some whitish powder in a dirty kind of trough that had been left by a previous tenant, came to the conclusion that it must be "bread-soda," and used it in the making of a cake. The result was that within an hour of partaking of the cake the whole family showed symptoms of poisoning and her husband died the next day. The "bread-soda" turned out to be arsenious acid, the residue from a batch of sheep-dressing.

* * *

A case of poisoning by butter of antimony is reported in the last number of the *Lancet*, in which death followed within two hours of swallowing the poison. The poison had been purchased a twelvemonth previously for the treatment of sheep suffering from foot-root; and the portion unused, after being carried about from place to place, appears to have fallen into the hands of the farmer's wife, who was of unsound mind. Mr. Cooke, who reports the case, appears to think that butter of antimony should be included in the first part of the poison schedule, since although in this case the bottle was labelled "poison," and with the name and address of the seller, he remarks that the now prevalent use of this substance by farmers for foot-rot may lead to more frequent cases of poisoning unless its sale be placed under more stringent regulations. He is evidently unaware that the Privy Council has recently refused to sanction its introduction into the second part of the schedule.

* * *

The medical practitioners of Illinois appear to be endeavouring to obtain an amendment of the recently passed pharmacy law of that State, so as to make it compulsory for the pharmacy board to accept medical graduates as duly qualified pharmacists without examination. The editor of the *Pharmacist* has naturally taken umbrage at this claim, and in order to illustrate the danger to the public of allowing physicians to take the place of pharmacists, tells a story sufficient to prove his case—and more! He states that a medical man, whose name is given, went to a grocery store with a patient and asked for an ounce of acetate of potash. The boy in charge, before serving him, explained that the "acetate of potash" in stock had nearly killed a man the week before, but the doctor after examining the substance in the jar pronounced it all right. The following conclusion to the story is the editor's own, italics and all. "*That jar was filled with prussiate of potash*, a deadly poison. The doctor then gave Mr. Swift one ounce of the poison—enough to kill ninety-six adults—and Mr. Swift died from its effects."

* * *

The last volunteer report on the London water supply, put forward on behalf of the Water Companies, shows that the recently expressed opinion of the President of the Local Government Board (see before p. 863) has not been without effect, since it does not purport to be addressed to that official, but is "submitted for the information of the Local Government Board." But it cannot be said that a submissive spirit pervades the report, for the writers express an opinion that "in the reports made to the Registrar general [*i.e.* the official reports], which not merely set forth the bare analytical results obtained, but profess to explain their import and signification, some statement as to the precise nature of what are so vaguely designated 'moving organisms,' and some information of their real importance, might in common fairness be expected from one who, by his persistent use of language which has been reprobated by a Royal Commission, does not a little to create an unfounded prejudice against the water supply on which he is expected impartially to report." *Tantæne animis cœlestibus iræ?*

* * *

The *Pharmaceutical Record* mentions that up to the 1st of May, the examinations for the degree of "graduate in pharmacy" at the different colleges of pharmacy in the United States had been attended by 469 students, of whom 388 had passed. This completes the record for the last session, with the exception of one college.

* * *

A course of botanical lectures and demonstrations has been commenced by Mr. J. G. Baker, F.R.S., at the Garden of the Apothecaries' Society, at Chelsea, and will be continued on successive Saturdays during the summer months. At the first lecture the room was completely filled, Mr. Baker's well-known ability as a lucid lecturer attracting large numbers. Admission to the lectures is obtained by application to the Beadle of the Society at Blackfriars.

* * *

On Monday evening next, June 4, at 8 o'clock, a meeting of the London Section of the Society of Chemical Industry will be held in the Chemical Society's rooms, Burlington House, when Mr. G. W. Wigner will read a paper on "The Packing of Goods of Delicate Odour, such as Tea, etc.;" and a communication will be read from Mr. G. Ward, "On the Salt Deposits of the Cleveland District."

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, June 7, at 8 p.m., when a paper will be read by Mr. C. Ranken, on "Some Old and New Theories concerning the Vegetable Cell." A Report upon Materia Medica will be made by Mr. W. Elborne on the subject of "Commercial Rhubarbs."

Pharmaceutical Society of Ireland.

SPECIAL MEETING OF THE COUNCIL.

Tuesday, May 15, 1883.

Present—Professor Tichborne, President; Dr. Collins, Dr. Montgomery, Messrs. Allen, Brunker, Draper, Hayes, Payne (Belfast) and Wells.

The Registrar (Mr. Fennell) read the following letter and petition:—

"Privy Council Office,
"*May 3rd*, 1883.

"Sir,—I am directed to transmit to you herewith, a copy of a petition which has been presented to the Lord Lieutenant in Council by Mr. John P. Middleton, appealing against the refusal of the Council of the Pharmaceutical Society of Ireland to admit him to the examination for their licence, and I am to request that you will move the Council of the Society to favour me, for His Excellency's information, with any observations they may desire to offer thereon.

"I am, Sir,
"Your obedient servant,
"W. S. B. Kaye.

"The Registrar,
"Pharmaceutical Society of Ireland,
"Kildare Street."

"*Petition.*

"To His Excellency the Right Honourable John Poyntz, Earl Spencer, K.G., Lord Lieutenant of Ireland in Council.

"My Lord,

"May it please your Excellency,

"The petition of the undersigned humbly showeth that whereas the 'Pharmacy Act (Ireland), 1875,' section 22, enacts that the Council of the Pharmaceutical Society 'shall cause examinations to be held at such times and in such manner as may be prescribed by regulations made in pursuance of this Act,' and that 'all persons desirous of being registered as pharmaceutical chemists under this Act, may, at any such examination, present themselves for examination, and shall be examined with respect to their knowledge of the Latin and English languages, of arithmetic, of botany, of materia medica, of pharmaceutical and general chemistry, of practical pharmacy of the British Pharmacopœia, and of such other subjects as may, from time to time, be prescribed by any regulations made in pursuance of this Act.'

"That it is my desire to present myself for examination.

"That regulations made under the sanction of your Council are placed as a bar to my examination under circumstances as set forth in accompanying declaration and correspondence, of great injustice to me.

"That Mr. George H. Grindley was admitted a licentiate of the Pharmaceutical Society in July, 1876; was elected a member in September of the same year; commenced the business of pharmaceutical chemist in 1876 in partnership under the style of Brooks and Co., Pharmaceutical Chemists, at 136, Lower Baggot Street; was elected member of the Council in October, 1880; and kept open shop for the firm until October, 1882.

"That he received me as apprentice to the business of pharmaceutical chemist in 1877, and retained me as such apprentice till the full term of five years' apprenticeship ended in June, 1882.

"That during said apprenticeship, with his knowledge and approval, I presented myself for examination in respect of my knowledge in the Latin and English languages, of arithmetic, of botany and general chemistry, and hold their certificate of having passed the Preliminary examination of the Pharmaceutical Society of Ireland, dated October, 1879.

"That the correspondence annexed showeth that the Council refuse to admit me to examination for their licence because 'Mr. Grindley was associated with an unqualified partner in business,' although his certificate sets forth he was the managing partner, and had the business in his sole control.

"I respectfully submit that I am thereby dealt with unjustly, and appeal for such review and redress as your Excellency in Council may be able to afford; in support of which I claim that Mr. Grindley was 'keeping open shop' in the terms and meaning of the regulation on page 35 of the Society's Calendar, 1883, and that said regulation is itself opposed to the plain reading of section 22 of the Act of Parliament.

"And your petitioner will ever pray.

(Signed) "John P. Middleton,
"11, Hardwicke Street, Dublin.

"*April 26th*, 1883."

The Registrar read the Report of the Certificate Committee on this matter. (See *Pharmaceutical Journal*, April 14, 1883, p. 844.) Also the following query, addressed in August, 1878, to Mr. T. A. Purcell, Q.C., and his opinion thereon.

Query:—"Is it legal for a firm, consisting of two or more members, of whom only one is a qualified apothecary or pharmaceutical chemist, to compound poisons or medical prescriptions, or to sell poisons by retail, for the mutual benefit of all the partners? This question is intended to include co-operative and limited liability companies and societies of which a small number of the members or partners are qualified apothecaries or pharmaceutical chemists."

Opinion:—"In my opinion it is not. The Act makes it unlawful for any unqualified person not only to sell, but also to keep open shop, for the retailing, dispensing, or compounding of poisons or medical prescriptions, and it does not cease to be unlawful for such unqualified persons to sell or keep open shop, because other persons, connected with them as partners, may be qualified to do so.—T. A. Purcell."

Proposed by Mr. Brunker, seconded by Mr. Allen, and resolved:—

"That the Registrar be directed to draw up a reply to the Clerk to the Privy Council stating the circumstances under which the certificate presented by Mr. Middleton was rejected, and to state that the Council were guided in the course which they adopted by the opinion of Mr. Purcell, Q.C., a copy of which is to be enclosed to the Privy Council."

The meeting then broke up.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual general meeting of this Association was held on Tuesday evening, May 22, Mr. R. Brodie, Vice-President, in the chair.

The minutes of the previous meeting having been read and approved of, the annual reports by the Secretary, Treasurer and Librarian were adopted.

The President then intimated that a communication had been received from the General Medical Council, inviting suggestions regarding the proposed new edition of the British Pharmacopœia.

After consideration, it was, on the motion of Mr. Joseph A. Clarke, remitted to the Council of the Association to consider the matter.

The following office-bearers were then elected for session 1882–83:—President, Mr. John McMillan; Vice-President, Mr. R. Brodie; Secretary, Mr. John M. Arnot; Treasurer, Mr. John Walker; Librarian, Mr. T. W. J. Law; Councillors, Messrs. J. A. Clarke, John Currie, James Dickie, Daniel Frazer, J. L. Hatrick, J. C. Hunter,

A. Kinninmont, David Lees, R. McAdam, William Maltman, R. Craig Rait and William Simpson; Auditors, Messrs. A. Paterson and W. Paris.

This being all the business, the meeting afterwards broke up.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered at the rooms of the above Association on Wednesday evening, May 23, by Mr. W. B. Clark on "Ferrum." Mr. J. Garrett presided.

The lecturer explained the chief sources of the iron found in commerce, the methods of separating it from the ore, and the preparation of cast and wrought iron, and steel. He also dealt with the chemistry of iron, specially with the different preparations of it in the B.P.

Throughout the lecturer was listened to with marked interest.

Mr. Garrett proposed a vote of thanks to Mr. Clark for his instructive lecture, which was seconded by Mr. Edwards and carried.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at The George Hotel, on Tuesday, May 29, the President, Mr. R. Fitzhugh, F.C.S., in the chair.

The minutes of the previous meeting having been read, the President called upon the Hon. Secretary to read the Annual Report.

The Report commenced by congratulating the members upon the present satisfactory state of the Association. Although the personal interest taken in the work and the attendance of members at its monthly meetings are not what could be desired, the Council feels that good and useful work has been done during the past session. The society at present numbers 52 members and 21 associates (total, 73), as against 52 members and 26 associates (total, 78) last year, showing a decrease of five associates. During the year two new members and three associates have been elected. The Treasurer's account for the past session shows a balance of £70 7*s.* 10½*d.* as against last year of £52 15*s.* 10*d.*, or an increase of £17 12*s.* 0½*d.*; and the Council suggested that the forthcoming executive should, if possible, reduce the above balance, by endeavouring to obtain suitable rooms for the library and museum, and in making additions to the library, so that the Association may become of more value to our young men. During the session six meetings have been held, the average attendance having been fairly kept up. At the social meeting, held on December 19th, Mr. W. H. Parker opened a discussion upon "The present numerous Violations of the Pharmacy Act existing in Nottingham," and after an animated discussion a sub-committee was duly appointed to consider the question. This committee reported that it had gathered the necessary information and had brought the matter under the notice of the proper authorities, and it was of opinion that the time had arrived when some definite and persistent action should be taken against unqualified men, and the large amount of illicit trading going on. It recommended to the Council and Association that a law committee be appointed every year at the annual meeting. The lectures given by Mr. Spencer and Mr. Major had been most valuabie, and thoroughly appreciated by the members and associates, and the Council feel that the thanks of the Association are due to those gentlemen. The annual supper had been as usual a marked success, over sixty members and friends being present. After the supper Mr. Holgate again introduced the subject of the Pharmaceutical Benevolent Fund, and a collection was made, when the sum of five guineas was subscribed, which had been left in the President's hands to distribute in votes on behalf the Association. During the session it had been felt by several members of the Association that he time had come when some recognition should be made to the President for his valuable services rendered to the Association since its foundation. Accordingly the Council took the matter up, and the appeal made had been most liberally responded to by the members. At the commencement of the session the executive had arranged with Professor Blake for a course of lectures upon botany, to be given at the University College, at reduced fees, to the students; but owing either to the apathy of the students, or to the time arranged being inconvenient for masters to spare their young men, only seven entered the class. A hope was expressed that this would be remedied in future sessions, as it would be impossible for the executive to organize classes for so small a number. At the present time the Council is taking steps with a view to the formation of a class during the next session at the University College, and will endeavour to make the time and fees within the reach of all students. The library contains 87 books, all in good condition. The issues have been 17 against 10 last year. The Council hopes the day is not far distant when more suitable rooms can be found, and the number of books materially increased, as it is felt the present arrangement is only a temporary one. In concluding the report, mention is made of the retirement of an old and valued member of the Council, Mr. Robert Jackson, who for five years filled the post of Honorary Secretary with great energy and zeal.

A discussion took place upon the above report, in which it was suggested the large balance in hand should be used in part by furnishing the Library with some standard medical works for the use of the members. This was decided to be discussed at the next Council Meeting, and the report was unanimously adopted.

The Treasurer's report was next presented, having been duly found correct by the Auditors, Messrs W. W. Widdowson and W. Smith, showing a balance in hand of £70 7*s.* 10½*d.*, and on the motion of Mr. Fitzhugh, seconded by Mr. Jackson, was passed.

The following Officers and Council were elected for the ensuing year. President, Mr. R. Fitzhugh, F.C.S.; Vice-President, Mr. J. Wilford; Treasurer, Mr. W. H. Parker; Honorary Secretary, Mr. C. A. Bolton. Council:—Messrs. F. White, M. H. Humphreys, T. B. Fletcher, C. W. Warriner, S. V. Holgate, J. Lewis, W. Oldershaw, and A. Smith.

During the evening, the following members and associates were admitted:—Messrs. Gill, Bull, and Rowe.

A vote of thanks, proposed by Mr. Fitzhugh, seconded by Mr. Jackson, and supported by Mr. Parker and Mr. White, was accorded to the Honorary Secretary, Mr. C. W. Warriner, upon his retirement from that office, after having held it three years.

The meeting was brought to a conclusion with the usual vote of thanks to the President for his services during the past year.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

Chemistry and Analytical Examination of Fixed Oils.*

BY ALFRED H. ALLEN.

It is a significant fact that the technical examination of oils was, until very recently, usually limited to the application of a few rough tests of a very unsatisfactory kind, the assay being commonly conducted by the oil merchant, drysalter, or engineer. That this state of things should exist is doubtless due in a great measure to the difficulties attending a more complete examination, but still more is it owing to the general indifference of chemists on the subject of oils, which indifference has necessarily reacted and prevented their services from being sought. That there are signs of a better

* Paper read before the London Section of the Society.

condition of things I think is certain, but the fixed oils, as a class, are still regarded with a kind of horror by many able chemists, and their chemistry is, I fear, considered eminently uninteresting. That there should be a feeling of this kind with respect to a class of bodies not readily yielding crystallizable or coloured products, and of indefinite chemical composition, is very excusable, but it is to be feared that the limited interest taken by the great majority of chemists in the history of the fixed oils is the main reason why we know so little of them, and so many really interesting problems relating to them still remain as far from solution as when the matter was examined by Chevreul more than half a century ago.

The natural fixed oils may be conveniently described as ethers of higher fatty acids, occurring naturally in certain parts of animals and vegetables. Thus defined, the waxes are included under fixed oils, and although they present a marked difference in constitution from the majority of fixed oils, it will be seen afterwards that any sharper definition of the latter would introduce difficulties. Under the general term of fixed oils I include those members of the group which, like tallow and palm oil, are solid at the ordinary temperature. In a molten state the fats are true fixed oils.

It is well known that when treated with a strong base, or subjected to the action of superheated steam, the fixed oils are decomposed, in the same manner as artificial ethers, into an alcohol, and one or more fatty acids, which latter are obtained in a free state if steam be the agent employed, but in the form of a soap or salt of the fatty acid if a metallic base be used for the decomposition. On treating the resultant soap with a strong acid the fatty acids are set free.

The nature of the fatty acids obtained varies with the kind of oil operated on, but the following list of fatty acids obtainable by the saponification of natural fixed oils shows that the variety is much greater than is commonly imagined.

Name of Acids.	Formula.	Chief mode of occurrence.
1. Formic . . .	CH_2O_2	Butter fat. (?)
2. Acetic . . .	$C_2H_4O_2$	Butter fat.
4. Butyric . . .	$C_4H_8O_2$	Butter fat.
5. Valeric . . .	$C_5H_{10}O_2$	Whale oil.
6. Caproic . . .	$C_6H_{12}O_2$	Cocoanut oil, butter fat.
8. Caprylic . . .	$C_8H_{16}O_2$	Cocoanut oil, butter fat.
10. Capric or Rutic	$C_{10}H_{20}O_2$	Cocoanut oil, butter fat.
12. Lauric . . .	$C_{12}H_{24}O_2$	Cocoanut oil, spermaceti, fat of the bay-tree, pichurum beans.
14. Myristic . .	$C_{14}H_{28}O_2$	Cocoanut oil, spermaceti, nutmeg-butter.
16. Palmitic . .	$C_{16}H_{32}O_2$	Most natural fats, notably palm oil, spermaceti, and beeswax.
18. Stearic . . .	$C_{18}H_{36}O_2$	Most animal fats, and in some of vegetable origin.
20. Arachidic . .	$C_{20}H_{40}O_2$	Arachis, or earthnut oil.
22. Behenic . . .	$C_{22}H_{44}O_2$	Oil of ben.
25. Hyænic . . .	$C_{25}H_{50}O_2$	Glandular pouches of the striped hyæna.
27. Cerotic . . .	$C_{27}H_{54}O_2$	Beeswax, Chinese wax.

The acids in the foregoing list all belong to what is known to chemists as the acetic or stearic series, but, besides these, the following fatty acids of other series are important constituents of certain natural fixed oils.

Name of Acids.	Formula.	Chief mode of occurrence.
Hypogœic . . .	$C_{16}H_{30}O_2$	Earthnut oil (oil of arachis-hypogœa); said to exist also in sperm oil.
Oleic	$C_{18}H_{34}O_2$	Most animal fats, and non-drying vegetable oils.
Döglic acid . . .	$C_{19}H_{36}O_2$	As an ether in bottle-nose oil.
Brassic, or Erucic .	$C_{22}H_{42}O_2$	Rape, mustard, and other oils from the Cruciferæ.

In addition to these, ricinoleic acid, $C_{18}H_{34}O_3$, is the chief product of the saponification of castor oil, while linoleic acid, $C_{16}H_{28}O_2$, exists in linseed and probably in other drying oils. It is a curious fact that the great majority of the acids obtained by the saponification of natural fats contain an even number of atoms of carbon.

By far the most important aud widely distributed of the acids of oils are the three which are obtained by the saponification of common lard and tallow. These are palmitic acid, $C_{16}H_{32}O_2$, stearic acid, $C_{18}H_{36}O_2$, and oleic acid, $C_{18}H_{34}O_2$. These three, with the linoleic acid of the drying vegetable oils, may be said to be the main products of the saponification of oils and fats.

In the great majority of fixed oils, the foregoing acids exist as "glycerides," or saturated ethers of the triad radical glycyl, C_3H_5. Thus the triolein, which constitutes the greater part of olive, almond, and lard oils, is the trioleate of glycyl.

$$\left.\begin{matrix}(C_3H_5)'''\\(C_{18}H_{33}O)_3\end{matrix}\right\}O_3$$

On saponification the fat undergoes hydrolysis, thus:—

$$C_3H_5.O_3.(C_{18}H_{33}O)_3+3H_2O=$$
$$3(C_{18}H_{33}O.OH)+C_3H_5.(OH)_3$$

Hence the glycyl trihydrate, commonly known as glycerin, but called by the Publication Committee of the Chemical Society *glycerol*, is the second product of the saponification of fixed oils.

In consequence of the similarity in the constitution of the various fixed oils, and the very nearly identical ultimate constitution of their leading proximate constituents, the majority of these yield nearly identical percentages of fatty acids and glycerin on saponification. Thus the following table shows the theoretical composition and products of saponification of the leading constituents of oils:—

	Empirical Formula.	Molecular Weight.	Products of saponification of 100 parts.	
			Fatty Acid.	Glycerin.
Glycyl tripalmitate (tripalmitin) . .	$C_{51}H_{98}O_6$	806	95·28	10·74
Glycyl tristearate (tristearin) . .	$C_{57}H_{110}O_6$	890	95·73	10·34
Glycyl trioleate (triolein) . . .	$C_{57}H_{104}O_6$	884	95·70	10·40
Glycyl trilinoleate .	$C_{57}H_{86}O_6$	794	95·21	11·58

The waxes, on the other hand, are not ethers of glycyl, but ethers of some of the higher homologues of ethyl. Accordingly they yield a much lower percentage of fatty acids when saponified, and give in place of glycerin, solid monatomic alcohols. It is evident from these considerations that the study of the product of saponification may be of essential service in the examination of those oils which do not come under the general rule of yielding from 95 to 96 per cent. of fatty acids. Again, the acids being separated, much information can be gained from a study of their melting points and combining weights. The latter method of examination was first employed by Kœttstorfer, but he makes no attempt to isolate the fatty acids, but deduces the combining weight from the amount of alkali required for the saponification of the oil. This is effected by boiling the oil with a known quantity of a standard solution of caustic potash in alcohol, and when the saponification is complete adding a few drops of a solution of phenol-phthalein, and titrating back with standard hydrochloric acid. Manifestly the alkali which has disappeared is that which has combined with the fatty acids of the oil. Each cubic centimetre of half normal caustic alkali thus utilized represents ·02805 grams of KHO, whence the saturation-equivalent of the fat can be ascertained by the following formula, in which W is the weight of oil taken, and N the number of cubic centimetres of half normal alkali taken up by the fatty acids.

$$\frac{2W}{N} = \text{saturation-equivalent.}$$

In the great majority of cases this saturation-equivalent will be one third of the mean of the molecular weights of the constituents of the oil examined.

The following table shows the milligrammes of caustic potash required by one gram of various oils, and the saturation-equivalents calculated therefrom by dividing the former number into 56,100.

Oil.	Grams of KHO required for 1000 grams of oil.		Average saturation.equivalent of oil.
A. Tripalmitin	208·8		268·67
Tristearin	189·1		296·67
Triolein	190·4		294·67
Tributyrin	557·3		100·67
B. Butter fat	221·5 to 233·4		247·1
Cocoanut and palm oils	270 „ 275		205·0
C. Dripping	197 „ 196·5		285·1
Lard	195·8 „ 195·4		286·8
Tallow	196·8		285·1
Horse oil	199·4		281·0
D. Lard oil	191 „ 196	189 to 196	296·8 to 286 7
Olive oil	191 „ 196		
Niger-seed oil	189 „ 191		
Cotton-seed oil	191 „ 196·5		
Linseed oil	189 „ 195		
Whale oil	190 „ 191		
Seal oil	191 „ 196		
E. Colza and rape oils	175 „ 179	175 to 189	320·6 to 296·8
Codfish oil	182 „ 187		
Pilchard oil	186 „ 187·5		
Castor oil	176 „ 178		
F. Sperm oil	130 „ 134·4		417 to 425·0
Bottle-nose oil	184·2		304·5
Shark oil	84·5		

The figures referring to the pure fats in class A are calculated, but all the others are the results of experiments made by Kœttstorfer, F. W. and A. F. Stoddart, L. Archbutt, or myself.

In the first place, it will be observed that, while dripping, lard and tallow have saturation-equivalents such as might be predicated from their known composition as mixtures of palmitin, stearin and olein, butter fat requires a much larger proportion of alkali for its saponification. This peculiarity is of course due to the fact that butter fat contains a notable proportion of tributyrin and glycerides of other of the lower fatty acids.* As a consequence, although it agrees with other animal fats in yielding about 95 per cent. of fatty acids, only about 87 to 88 per cent. consists of oleic and palmitic acids, the remaining being butyric acid and other acids more or less soluble in water. This peculiarity is now utilized by public analysts, at the suggestion of Messrs. Angell and Hehner, to distinguish real butter fat from "butterine" and other butter substitutes prepared from the more fusible portions of the fat of oxen, sheep, swine and other animals. The only fats which would give results on analysis at all comparable with those yielded by butter are the oils from the palm-nut and cocoa-nut,† and practical difficulties have hitherto prevented the complete success of this scientific sophistication.

(*To be continued.*)

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 24, Mr. W. E. Crow in the chair.

Mr. E. E. Sewell read a paper entitled "Notes on some Abnormal Flowers," which will be published in a future number of this Journal.

In the discussion that followed, the Chairman, Secretary, Dr. Senier, Messrs. Baily, Dymond, Ranken and Ransom took part, after which a vote of thanks was passed to Mr. Sewell.

The Secretary (Mr. Dunstan) then made a Report upon Organic Chemistry, dealing with the "Chemistry of Mel Boracis." This paper also will be published in a future number of this Journal.

A discussion followed the reading of the Report, in which the Chairman, Dr. Senier, Messrs. Baily, Barnes, Carne, Dymond, MacDermott, Ranken, Ransom and Taylor took part.

The meeting then adjourned.

Parliamentary and Law Proceedings.

Prosecutions under the Patent Medicines Act.

At the Manchester City Police Court, on May 23, Mrs. Alice Lawton, chemist and druggist, Moss Lane, Hulme, was charged with selling patent medicines, without proper Government stamps on, and in this manner evading the patent medicine duty. Mr. Alpe, who prosecuted on behalf of the Inland Revenue authorities, said the articles had been advertised by means of a handbill wrapped round the bottles of medicine, and it was in this that the offence consisted. The labels placed on the bottles did not in themselves render the seller liable to the patent medicine duty. The medicines thus illegally advertised by Mrs. Lawton were "Lawton's celebrated

* Experiments of Mr. J. Bell indicate that the glycerides of butter fat contain several acid radicles in the same molecule, and therefore the butyrin cannot be separated by any process of fractional solution from the less soluble glycerides of palmitic and oleic acids. Hence butter fat probably contains complex glycerides of the following character:—

$$(C_3H_5)''' : \begin{cases} (C_4H_7O\,.\,O) \\ (C_{16}H_{31}O\,.\,O) \\ (C_{18}H_{33}O\,.\,O) \end{cases}$$

Such a complex glyceride will yield, on saponification, fatty acids and glycerin in the same proportions as would be obtained from a mixture of butyrin, palmitin and olein in the proportion of their molecular weights.

† The lower fatty acids of these oils are chiefly capric and lauric acids.

infant preservative," "Lawton's tic-douloureux drops and pills," and "embrocation for rheumatism, pains, etc.— This embrocation is invaluable in all kinds of sprains, bruises, or contusions—relieving pain."

The defendant was fined 40*s.* and costs in each case.

Mr. William Ramsden, chemist, Upper Moss Lane, was also charged with similar offences, one with respect to a bottle of medicine advertised as "an excellent remedy for neuralgia," and the other advertised as a "concentrated essence of sarsaparilla."

Defendant said he had acted quite ignorantly in the matter. He had no intention or desire to defraud the revenue, and he was satisfied that half the chemists in Manchester were doing the same thing, though that of course did not exculpate him. He did not push the sale of the medicines in any way whatever.

Mr. Headlam imposed a fine of 20*s.* and costs in the first case and ordered the defendant to pay the costs in the second case.—*Manchester Evening News.*

At the Manchester County Police Court, before Sir John Mantell and Mr. Hulme, Mr. James Bond, chemist, of Cornbrook Street, Stretford, answered to three summonses charging him with selling medicines liable to duty without having paid such duty. In two of the cases the defendant admitted the offence, but pleaded ignorance. With regard to orange quinine wine forming part of the charge, he denied that a duty was required. It was made according to instructions given in the British Pharmacopœia, and under the Pharmacy Act no duty had to be paid.

Mr. Alpe, who conducted the cases on behalf of the Inland Revenue, proved, however, that a showcard was exhibited in the defendant's shop window, calling the attention of the public to this particular preparation, which brought it within the scope of the Act and rendered it imperative that it should be properly stamped.

Defendant said there was no desire on his part to defraud the revenue. He was simply following a practice adopted by every chemist in Manchester.

Mr. Alpe said it was not properly understood in Manchester that medicines of this class were liable to duty.

The magistrates inflicted the nominal penalty of 2*s.* 6*d.* in each case and the costs.

Poisoning by Prussic Acid.

The Plymouth Coroner, Mr. T. C. Brian, held an inquest on Thursday, May 24, at the Guildhall, touching the death of Herbert Francis Montague Evans, a junior reporter, who had committed suicide on Tuesday by taking prussic acid.

Deceased was discovered lying on the bed quite dead and cold, and a bottle was found on the window sill with a label marked "prussic acid" and "poison," the latter word in two places.

The Coroner stated that deceased had pre-arranged the act, for he had spoken to his clerk (the coroner's officer) as to the best means of getting prussic acid, and the latter told him to go to the police, which he did.

Police Constable George Ryder stated that he was on duty at the Central Station. Deceased was in the habit of frequently calling there. On Thursday morning he said to witness, "I want to get rid of a large Newfoundland dog. Which is the best way?" Witness told him to poison it, and volunteered to administer poison. On Saturday morning he again came to the station, and said the dog was not getting any better, and would witness assist him in getting some poison. He said, "You know me well enough," and witness told him he had better get sixpennyworth. They then went to Mr. Wilmot's (late Lewin's) shop and asked for sixpennyworth of prussic acid to destroy a dog. The chemist gave witness the poison without any hesitation, as he was known there officially. Deceased took the bottle and he paid for the poison. He appeared quite collected and in his right senses. He said it was his father's dog and there was no chance of its recovery. Witness suggested he should bring the dog to the Guildhall and he would destroy it, but Evans said it could not walk and that he lived at Laira Bridge Terrace.

Medical evidence having been given to the effect that death had resulted from poisoning by prussic acid, the Jury returned a verdict that "Deceased died by taking prussic acid, self-administered when in a state of temporary insanity."

Reviews.

Elementary Chemical Arithmetic. By Sydney Lupton, M.A. London: Macmillan and Co.

To know chemistry it is obviously necessary to have grasped the methods of calculating employed by chemists. Formerly, when chemical students were fewer, this knowledge was usually communicated separately to pupils, or thought out by the students themselves as occasions arose. Later, as the teaching of the subject became more developed, it formed a more important part of the formal instruction given in lectures, and at present it has become a common custom for chemical lecturers to give their classes, from time to time, examples to work as exercises.

One of the first, if not the first, efforts made to supplement oral by printed instruction was the little book published by Professor Thorpe in 1872, which was intended to be associated with elementary lectures or with an elementary text-book, such as Roscoe's 'Elementary Chemistry.' Perhaps the chief objection to Dr. Thorpe's book is that the number of examples, about two hundred, is rather small, and Mr. Lupton's book is the better one on this point, since he has collected together some eleven hundred examples from various sources.

Mr. Lupton's book may be divided into three parts, first an introduction, which deals with the methods of calculating, secondly a collection of problems, thirdly several tables of data for use in solving the problems.

The introductory portion includes all, or nearly all, the methods of calculating ordinarily employed in chemistry (though we do not notice any account of those used in analyses of mixed gases, except indirectly), and indeed, occasionally strays to matters not involving calculation at all, as on page 63, where four reasons are given for considering that molecules of elements usually consist of more than one atom. Many parts of this introduction, indeed, perhaps the greater part, will serve the author's object of supplying missing ideas to pupils who have previously grasped the subject, and the easier sections will also be valuable to beginners. We regret, however, that Mr. Lupton should have limited his aim to this. Surely lecture notes ought to be enough for those who only want to recall lost ideas; whilst those for whom lecture notes are insufficient will not, we fear, find this book in all cases a sufficient substitute, though they will probably do so, as we have said before, in the easier sections. For example it would surely have been better to have given either more or less information on the methods of determining atomic weights (page 55). Except on one point (the law of Dulong and Petit) we find it difficult to imagine that this section would help much even to recall lost ideas. Altogether, while recognizing that much of the introduction will be of great value to beginners, and much more to advanced students, we cannot help regretting that Mr. Lupton has not aimed at a more complete treatment of some points.

The collection of problems is very large and very varied, and it ought to be of great assistance to students who want to test themselves and to teachers who want to exercise their pupils; both classes will be much indebted to Mr. Lupton for the amount of very tedious labour which he must have gone through in collecting, classifying and verifying them. Their usefulness will perhaps be a little reduced by the cost of the book, and we hope that when it comes to a second edition it may be found desirable to publish a rather extended introduction separately from the collection of problems.

PRACTICAL CHEMISTRY; Analytical Tables and Exercises for Students. By J. CAMPBELL BROWN, D.Sc. (Lond.). London: J. and A. Churchill.

The production of elementary text-books on chemistry is beginning to assume a serious aspect, hardly a month passing without the appearance of a new candidate for the reviewer's approval. This over-production may partly find its explanation in the reflection that we are still accumulating experience in the methods of teaching the elements of chemistry, and having no journal specially devoted to the discussion of scientific educational questions, no sooner does a teacher think he has made an improvement in method than a text-book appears to announce, illustrate, and advocate its adoption. The perusal of many recent text-books, however, fails to disclose any advance upon the old and in many respects defective methods, and only to expose an imperfect rehash of schemes to be found in previous and more worthy works. Such productions, whose authors are evidently bent upon mere book-making, cannot be too strongly condemned, and it is the bounden duty of the critic to rigidly examine every so-called new text-book in order to see whether the contents justify its publication. The present book is perhaps exempt from this preliminary criticism by reason of its being a second edition. From its title it would be inferred that the old flimsy notion of practical chemistry, which quietly ignores more than one half of the science by excluding exercises in synthesis, is adopted. But since the book has no preface, we know not for what purpose the author intended it. Such a book consisting of analytical exercises has both its use and abuse. It is used and only rightly used when employed as a laboratory hand-book in a course of analysis, this course having been preceded by practical work in synthesis and paralleled by a course of lectures. On the other hand, if it is at once put into the hands of the beginner, which is too frequently the case, as a first course of practical chemistry, its function is mistaken and abused. For over and above the fact that synthesis is not included, the beginner who employs such a book acquires the art of chemical analysis, not rationally, but in the merest mechanical way; a knowledge of the colour of precipitates without any conception of their composition or manner of formation. Anyone who has performed the unwelcome task of examining a student who has acquired his knowledge of analytical chemistry in this way, is full well aware of the ludicrous blunders committed by such an analytical machine when it is made to work upon a substance which involves a slight departure from the routine of a "chart" and consequently the exercise of a little intelligence. A striking example of this lately occurred when such a student was given acetate of lead for examination. Lead was easily found by the application of the usual tests; the acidulous radical was next sought for, and as a matter of course barium chloride was added, with the production of a white precipitate which proved to be insoluble in nitric acid, and hence the substance was considered to be sulphate of lead.

Considering the present book as an analytical handbook, it is better than many, in that the metals and acids are separated and the various reactions of the metals are first of all performed upon known substances before the charts are employed, but this is omitted in the case of many acids; further, also, formulæ are used to indicate the nature of precipitates and reagents, but unfortunately this plan is not consistently and uniformly adopted. Nothing is more to be deprecated than the much too common practice of commencing the study of analytical chemistry by taking an unknown substance "through a chart," and recognizing it by its behaviour when thus treated, without first having separately studied its reactions. The analytical tests and tables have, on the whole, been carefully compiled, although here and there errors are to be found. The formula of "white precipitate" is written $H_4Hg_2N_2Cl_2$; this indiscriminate and unmethodical clubbing of symbols is quite illegitimate, even in an elementary text-book; in the present instance a student might well be forgiven for inferring the substance to be a tetrabasic acid. The method for separating barium and calcium is needlessly tedious. To say that the precipitate caused by sodium hydrate in a solution of a cupric salt "is insoluble in excess, except in the presence of glucose," is very loose and misleading, and the same may be said of the statement that the flame is temporarily tinged yellow or orange by ammonium salts. Hyposulphurous acid is alone used to designate the substance more properly termed thiosulphuric acid. Hydrochloric acid certainly never precipitates HBO_2 from a solution of a borate, even "if the solution is a concentrated one." No reliable or precise method is given for the separation of tartrates and citrates. The section upon the alkaloids is scant, especially the portion relating to the alkaloids of cinchona. A violet colour is attributed to aconitine under the influence of phosphoric acid, although the incorrectness of this statement has more than once been pointed out during recent years. Taking the book as a whole, it is good of its kind, but it is a poor kind.

THE ELECTION AND "CALIBRE" OF THE COUNCIL.

Sir,—The Council is in no need of any apologist, nor have I any desire to pose as such, yet I cannot refrain from expressing an opinion that Mr. Giles's impeachment of that august body is not justified in "fact."

Pharmacy did not die out with Messrs. Hanbury, Savory, Bell, or Deane, though the modern prototypes of some of these historic houses, with less of the spirit "æsthetic," and more of the wisdom "commercial," find it pays better to cater for ailing epicures, rather than write 'Pharmacographias.'

I have been curious enough to refresh my memory by looking through the Journal for the last twenty years, and during that period cannot find that any Council has existed with any right to boast of heavier calibre than the present; there is, indeed, nothing to quarrel about in the matter of quality, influence, or capacity, though of course one may sometimes have occasion to differ with their views and policy. At any rate, the members of the Council are fairly entitled to regard their re-election as a "vote of confidence" on the part of the Society; it admits of no other construction.

With very much of Mr. Giles's speech I cordially agree, but I must protest that we want no patronizing recognition of anybody's personal weight and importance. The Medical Council has, or ought to have, to deal with the Pharmaceutical Council, or its representatives, and not with any favoured individual it may choose to benignly smile upon.

Warrington. J. RYMER YOUNG.

Sir,—As I delivered myself of a speech intended as a defence of the outgoing, now substantially the re-elected Council, you may be good enough to permit me space to amplify the concluding sentence of my appeal to the country section of our members.

The provincial members have it in their power, when they choose to vote, to elect none but country members of Council; the Londoners voting as such can be left to sigh and moan in the cold shade of disfavour.

Now why cannot our provincial societies give us a fair sample of their best men? men who are known and looked up to for their tried abilities, or their well-defined social standing,—gentlemen who have held office as town councillors, mayors or justices of the peace? It seems to me such are more likely to have reached an independent position and acquired a matured experience, which would place them above the suspicion of having an excuse to come to London as the representatives of a mistaken local feeling.

Lest I should exceed the limits of your patience, let me repeat what I meant to say at the meeting, that country associations might very well relieve the Society from the incubus of the slowly increasing tax of travelling expenses. If Yorkshire, Lancashire, Scotland and the Midlands require "out and out" country representatives, let them pay their travelling expenses (and vote them salaries if necessary), if men of repute, position and independent means are not to be had. My argument resolves itself to this: you have in London (not necessarily cockneys bred and born) men possessing every qualification, who would willingly serve on your Council without pay or reward, but are deterred for reasons too plainly apparent to those who study the records.

T. Howard Hall.

Direct Representation upon the Pharmacopœia Committee.

Sir,—I have read with much interest the discussion and correspondence upon this subject, and I confess that I am not a little amused at the opposition raised against the Professors for an entirely voluntary act on their part. Indeed, it is quite evident that the Medical Council had a perfect right, in the absence of any legal arrangement to the contrary, to call in the aid of any persons from whom they hoped to obtain the most practical and useful knowledge, and for my own part I think that the Society is so far indebted to the Professors, who, by such a voluntary acknowledgment of their special skill, have really saved the doctors from getting it all their own way. On the other hand, I am glad to find that steps are being taken to get a legal clause inserted in the Medical Bill, which shall give to pharmacists at home that legal status in the compilation of the Pharmacopœia which has so long attained in other countries.

35, *Baker Street, W.* A. W. Postans.

Pharmacopœia Revision.

Sir,—The report of our Professors on the new Pharmacopœia bears evidence of the careful thought which one felt certain such capable authorities would give to so important a subject; but as to details, of course opinions will vary, since scarcely two pharmacists would quite agree to what should or should not be retained in the Pharmacopœia, each person necessarily being biassed by the preparations locally in demand. Nor we cannot expect our Professors, however well informed, to give to us a thoroughly representative book, unless pharmacists from various parts of Britain express their ideas as to what medicaments should be included in the new edition, which, it is trusted, will compare favourably even with recent continental and American Pharmacopœias. In order to ensure this may I be allowed to express a hope that the Professors and the other gentlemen acting on the Committee will err rather on the side of catholicity than restriction, so that the book may really represent the dispensing of the day. While warmly welcoming most of the additions proposed by the Professors, still it would be advisable to considerably extend the list. Would it not be better to include some of the following articles?—

Aloin.	Paraffin, solid.
Caffeine cit.	Quinine bromide.
Calamine, prep.	Sodii benz.
Croton chloral.	Styptic colloid.
Euonymin.	Syr. calc. lactophos.
Iridin.	Syr. hypophosphitum.
Liq. ferri dialysati.	Syr. Eastoni.
Malt extract.	Thymol.
Menthol.	Tinct. iod. decol.
Monobrom camphor.	Ung. ac. borac.
Ol. pini sylvestris.	Zinci sulphocarb.

as well as the various medicated cotton wools, lints; also to considerably enlarge the list of vapours, etc.

The three articles proposed to be omitted are somewhat open to criticism. The green iodide of mercury is still frequently prescribed, and although an unstable preparation it certainly seems wise to retain it in the Pharmacopœia so as to give standard tests and characters, and surely the two preparations of buckthorn might be retained in a Pharmocopœia which includes areca nuts. Less regret would probably be felt if aconitine and digitalin were to be relegated to the obsolete class.

With respect to the proposed change in weights, it should be remembered that the book is not only to be a class book, but the trade guide, and for the latter purpose the present weights, properly carried out into ounces and pounds, would, in my estimation, be far preferable, as a saving of time would certainly be made by it; but I would urge the printing in separate columns of the metrical weights, so as to give a greater impetus to the adoption of the latter than would the use of proportional parts.

The addition of the French and German names would be useful, and, finally, let the language of the book be Latin.

118, *High Street, Oxford.* G. C. Druce.

The Dispensing Question.

Sir,—From the absence of any mention of the "dispensing question," either in the reports of the meetings of the Council of the Pharmaceutical Society or the executive of the Chemists and Druggists' Association of Great Britain, anyone might think that it is a subject of little or no interest to chemists in general. But I feel certain such is not the case, and I think it is expecting too much of human nature that members of the above-mentioned bodies, who have extensive business relations with medical men and who must feel that any change in this direction will be of no advantage to them, but the reverse, will be likely to imitate or give every co-operation to any plan likely to bring about such results.

Rheum.

"*Edina.*"—(1) *Honkeneya peploides*; (2) *Cochlearia angelica.*

J. N.—We are unable to give you the definite reply you ask for, and can only say that we are unaware of the existence of any article bearing the name.

N. J. Lewis.—We do not think that the case referred to would be held to come within the meaning of the Act.

E. Presley.—We are not aware of any such difference as was referred to in your query, and consequently there was nothing to answer.

Oxonian.—Yes.

C. Ridgley.—We think it very probable it would be held that the use of such a label would render the preparation liable to stamp duty, but the Inland Revenue authorities are the only persons competent to give an authoritative answer to the question.

W. J. Smith.—So many works of the kind have been published that one may be found in almost every publisher's list.

A. Wrighton.—The work was reviewed in the *Pharmaceutical Journal* for April 6, 1882.

Cymro.—Apply for the information to the Secretary of the Royal College of Veterinary Surgeons, Camden Town, N.

"*Cymro.*"—The only popular treatise on the subject with which we are acquainted is now out of print.

Sterlini Oppidum.—We do not think there is such a work.

"*Querist.*"—Apply to the Secretary to the Royal College of Physicians, Edinburgh.

"*Pharmaceutist.*"—Presuming that the dose of the mixture would not be more than a teaspoonful, we do not think the quantity mentioned would be dangerous or excessive. But of course this might not be the case if it were administered to children.

Justice.—You are recommended to address your questions, together with the particulars, to the Registrar, 17, Bloomsbury Square.

Communications, Letters, etc., have been received from Messrs. Saul, Heger, Von Heyden, Jackson, Boutell, Roberts, Wilkinson, Inquirer, Conservative, One Interested, Major.

THE EFFECT OF ALTITUDE ON THE ALKALOID OF RED BARK.

BY J. E. HOWARD, F.R.S.

I beg to forward the enclosed published communication from Dr. Trimen, which will interest many of your readers and sustain the character of your Journal as the best repertory of information on the important subjects of which it treats.

It gives me pleasure to see that "the relationship of the alkaloids" is brought under notice in Dr. Trimen's letter. It is long since I worked at this in conjunction with Dr. Herapath, and much of the information then published is probably forgotten; and much that was inferred relative to the manner in which the molecules appear to be built up in nature (bearing on the possibility or otherwise of the artificial production of quinine) remains for further investigation. I can only remark, at present, on the universality of the relationships thus disclosed by the ray of polarized light.

The relationship is this:—

Lævogyrate.	Dextrogyrate.	Feebly Dextrogyrate.
Quinine.	Quinidine.	Quinicine.
Cinchonidine.	Cinchonine.	Cinchonicine.

Dr. Herapath, in his "Researches on the Cinchona Alkaloids" ('Proceedings of the Royal Society,' November, 1857), attempted to demonstrate this relationship on chemical grounds; and even thought that quinine and cinchonidine might be mutually convertible. He observes that "closely as the quinine and cinchonidine salts agree amongst themselves, they differ widely from the quinidine and cinchonine compounds."

In order to confirm the interesting experiments instituted by Dr. Trimen, I selected specimens given me by Dr. Morris, Jamaica, of red bark grown under somewhat similar differences of altitude; that from the lower elevation having (as in India) the best appearance; that from the higher the richer produce. I shall send portions of these to the Museum.

The bark from which the second sample was taken proceeded from trees grown in the parish of Manchester at an elevation of about 2400 feet. This is the lowest elevation at which cinchona bark trees have been cultivated in Jamaica. The trees were between eight and nine years old, growing in a sheltered situation and on a good strong red soil; the mean annual rainfall about 90 inches, and the mean annual temperature about 73° F.

As the elevation is intermediate, so the alkaloids hold a consistently intermediate position between the two samples of Ceylon bark, perhaps with a slight exception as to the amorphous alkaloid. If the circumstances of growth in other respects had been the same as in India, it is probable that the amount of quinine in the Jamaica sample of 6000 feet would have increased at the expense of the amorphous alkaloid. As it is, the Jamaica bark at this elevation scarcely equals expectations, although the botanical samples are very true to type.

Analysis of samples of *Cinchona succirubra*, sent by Drs. Trimen and Morris, at different elevations:—

Elevation above sea level.	Place of growth.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.	Amorphous.	Total alkaloids.
A. 5500 ft. .	Hakgala	2·06	3·47	0·61	Traces	0·66	6·80
5500 to 6000 . .	Jamaica	1·76	3·17	0·75		0·75	6·43
2400 . . .	Jamaica	1·50	0·86	3·06	0·06	1·13	6·61
B. 1500 ft. .	Peradeniya	0·47	0·05	1·67	0·30	1·06	3·55

The *succirubra* is, however, the wrong sort to cultivate, and (except only as regards the bark *renewed* in McIvor's method) will always be found disappointing. The *shaving* process is incomplete. It is requisite that the bark should be stripped in the wet line of the cambium. The tree then begins *de novo.* An exudation is thrown out from the peeled surface, "like the perspiration from the back of the hand," as McIvor described it to me. The formation is then *radial,* and not concentric (see Fig. 5 and 6 of Plate III. of my 'Quinology'), with abundance of cellular tissue and a consequent complete change in the alkaloids. I have objected to the *succirubra* from an early stage in the culture, but opposite counsels prevailed. The prices obtained for very inferior bark now sent home may perhaps show the planters that it would have been more to their interest to cultivate the better sorts—the *Pata de Gallinazo* introduced together with the *succirubra* by Cross, the *magnifolia* (Uritusinga?), the *robusta,*—known to them but neglected till lately. I have just received an account of the 1882 harvest of bark in Java, from which I learn that 763 bales of all sorts of succirubra bark gave on an average of 28 analyses 1·04 per cent. of quinine; but of this two lots were of "*renewed*" bark, respectively 2·2 and 2·4 per cent., and, deducting these, the percentage falls to 0·94 of quinine. This culture can hardly be profitable for quinine manufacture,* nor yet for pharmaceutical purposes, as I have shown first in my 'Quinologia,' 1862, and many times since, that the "red bark" contains a *distinctly noxious ingredient* not found in the barks better adapted for medicinal use.

The tests of the inferior Calisaya, Schukraft, Javanica and Anglica, are about 1 per cent. of quinine. Surely this cannot pay *at present*; but, even if it does, how will such plantations compete in future with the immense cultivation commencing elsewhere. Of course in Java the redeeming feature is the *Ledgeriana*; the *officinalis* seems also to promise well.

The result of these trials seems to prove that elevation above the sea level is far more important than all the other factors in the problem, but why this should be so, I confess I do not see. The true home of the Cinchona is in the clouds; direct scorching sunlight is fatal.

I am at this moment observing with interest the effect of light on some Cinchonas. In the early part of last year I sowed, almost at the same time, seed of the true *Ledgeriana* from the Yarrow estate in Ceylon, derived from trees yielding from 7 to 12 per cent. of quinine, and also seed kindly given me by Mr. Christy, from Bolivia, of the best kinds there cultivated. I watched with interest the development of the young plants, which for a considerable time entirely resembled each other—only that I found the *Ledgeriana* the more sensitive to surrounding influences. After some months' growth the Bolivian seed began to develop the characteristics

* See the Blue Book of Indian Government (June 18, 1866, p. 134), in which, after analysis of the first parcels sent home, I observed the great preponderance of cinchonidine, and notified to the Indian Government "This difficulty must be looked steadily in the face, and I would suggest that it may be obviated, either by a change being wrought in the opinion of the medical world as to the value of cinchonidine as a medicine, or by the plant being encouraged to produce quinine instead of cinchonidine." This latter Mr. McIvor afterwards succeeded in effecting by his renewing process. The Government also acted on my former suggestion.

of the *verde, morada* and the *rubra venada* of Bolivia; whilst the *Ledgeriana* showed features of difference, though at the same time of close affinity. This was shown, amongst other things, by the rich velvety surface of the leaf, marking the best Calisayas,* as also by a delicate fringe of hair at the edges of the leaves. But now that the more flourishing plants are some ten inches in height (the *rubra venada*, twenty), further diversities appear. The leaves of the *Ledgeriana* turn *red* in fading, which is said by Mr. Ledger to be characteristic of his "rojo" (*roxo*) at the flowering season, from whence it derives its name "*red*."

They are more delicately formed than the others I have named, and more easily damaged by direct sunlight. As night approaches, the top leaves gradually change their position, approaching each other so as in some cases almost to fold together. This is well shown in a fine plant of true *Ledgeriana* which I have from Darjeeling, and also in the more flourishing of my plants from Ceylon. I do not notice the same in the *verde* from Mr. Christy's Bolivian seed, of which the leaves are more robust, but the above features are not *confined* to the "rojo."

These peculiarities would scarcely be seen unless the plants were well developed under glass, but once observed it is impossible to forget or to confuse these rich varieties of Calisaya (which I described and figured as such from well ascertained specimens sent by M. Moens) with the plant described and figured by Dr. Trimen as "*C. Ledgeriana*, Moens," and which I should call *C. micrantha*, var. *Calisayoides*. Dr. Trimen had not the opportunity of comparing the plates drawn by Fitch, in my 'Quinology,' with those in the *Journal of Botany*; but the distinction is most evident, as I have endeavoured to demonstrate to the Linnean Society. My figures of *C. Calisaya*, var. *Ledgeriana*, are from trees yielding respectively (Pl. IV.) 9·06, (Pl. V.) 9·90, and (Pl. VI.) 9·97 per cent. of quinine and the fruit-bearing branch 10·90 (same plate). See the account of my herbarium, pp. 58–66.

The "rojo" (*roxo*), or *C. Calisaya*, var. *Ledgeriana*, is the queen of all the Cinchonas; but certainly possesses a delicate organization which makes the cultivation difficult. The "verde," as being a quick growing tree, flourishing at lower elevation, is found in Bolivia more profitable to cultivate than the "morada," although the latter is richer in percentage of quinine. I do not think that the *Ledgeriana* is cultivated in Bolivia, but another sort of "rojo" is extensively planted in Coroico, in the Yungas of Bolivia. "This is not so good as the Caupolican rojo." It is the *Colorada naranjada*, or *orange peel red*, only known to me by the bark, which has a character peculiarly its own. The bark of the *Ledgeriana* is most characteristic. It is thick and composed almost entirely of cellular tissue; quite contrasted with that of the "verde," which bears the stamp of more vigorous growth and has a more fibrous structure and less alkaloid. This last has for many years been familiar to me in importation from South America.

But I must defer for the present any further remarks.

From a letter from Mr. Ledger, February 7, 1881:—

"I repeatedly used to joke poor Manuel when he used at first to tell me the trees from which the thick, heavy slabs of bark (in fact the *Rojo*) came from had white flowers. The *Rojo* from Coroico and in South Yungas, though with purple red leaves underside [the *morada*], are nothing to be compared with the *Rojo* of Caupolican and Apolobamba. The *Rojo* or *Ledgeriana* is very little known in Bolivia even. According to Manuel this tree is never met with in *Manchas* (patches) like the other classes of Cinchona. It is found by itself here and there. With all cascarilleros from Pelechuco a '*slab' of Calisaya rojo* means *unsurpassable*, and is meant to say, where that is, all the rest is good or Calisaya."

* See Weddell's 'Histoire.'

(*From Ceylon Observer, April* 9, 1883.)

THE EFFECT OF ALTITUDE ON THE ALKALOIDS OF RED BARK.

Sir,—Everything that may throw any light upon the relationships of the cinchona alkaloids, or on the causes which influence their production, is of much interest; it also has a practical value to cultivators. I therefore no longer delay in making public the results of two remarkable analyses of Ceylon *C. succirubra*.

With the object of ascertaining the effects of altitude on the alkaloid production of this species, I, towards the end of last year, barked two trees growing respectively at elevations of 5500 (Hakgala) and 1500 (Peradeniya), a difference of 4000 feet. The trees were, I have every reason to believe, of common origin: both being, in all probability, raised from the original seed collected in South America by Dr. Spruce, and planted out in the midst of other trees, in or about 1863. They were therefore about nineteen years old reckoned from the planting, and both had grown up under fairly similar conditions, excepting as regards climate. Their growth, however, had been very different. The tree at Hakgala was one of the largest there, 37 feet high to the point where the stem was but 1 inch in diameter and 37 inches in girth at the base lessening to 24 inches at 5 feet from the ground. It afforded 25 lbs. of dry bark (77 lbs. of wet), and the sample sent home was large quill 18 inches long with a "brown coat." On the other hand, the Peradeniya tree, though not far off the other in height, being drawn up by the large trees around, girthed only about 20 inches near the ground and yielded about 7 lbs. of dry bark (21 of wet). The sample of small quill sent home was described as having a "grey coat."

It is to my friend, Mr. J. E. Howard, who is ever most liberal in helping to advance our knowledge of quinology, that I am indebted for the following comparative analysis of these two samples. He is himself much interested in the result, and we may, I believe, expect some observations upon it from his pen:—

	Quinine sulphate.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.	Amorphous.	Total-alkaloids.
A. Large quill grown at Hakgala, 5500 ft.	2·75	2·06	3·47	0·61	Trace	0·66	6·80
B. Small quill grown at Peradeniya, 1500 ft.	0·62	0·47	0·05	1·67	0·30	1·06	3·55

A comparison of these very different analyses suggests many observations. And at first sight we cannot but be struck with the influence for good of elevation in the production of the alkaloids as a whole, nearly double as much being produced in the higher locality. Mr. Howard remarks that as far as the *appearance* of the bark is concerned the contrary was the case, that from the low elevation being the "more attractive to those who judge merely by the eye."

The large amount of quinine in analysis A is also noteworthy in red bark from a tree nearly twenty years old, as showing that there is no necessary diminution of that alkaloid after eight or nine years, as Mr. Broughton was led to believe.

It is however as regards the proportions of the alkaloids that the comparison will be found most instructive. In A we have of quinine over 2 per cent., and of cinchonidine nearly 3½ per cent., whilst there is but 0·61 of cinchonine and a mere trace of quinidine: in B the change is very remarkable: quinine has sunk to less than ½ per cent., and cinchonidine to little more than a trace (0·05 per cent.), whilst on the other hand, cinchonine has increased to 1·67 per cent.—that is, about two and a half times as much as in A—and there is also an appreciable amount (0·30 per cent.) of quinidine. It has been remarked* that the natural or physiological relationship of the four principal alkaloids of cinchona bark is not expressed by their chemical constitution and terminology. Quinine and quinidine are, as is well known, isomeric chemical bodies, *i.e.*, both have the same empiric formula of composition, $C_{20}H_{24}N_2O_2$, and cinchonine and cinchonidine are similarly related, their common formula being $C_{20}H_{24}N_2O$. But in nature it would appear that the pairs are differently composed, and it is customary to find associated in the tissues, quinine and cinchonidine and cinchonine and quinidine and not the isomeric couples. It is indeed highly probable that, under conditions of oxidation and deoxidation at present not understood, the units in each of these naturally associated pairs are mutually convertible. The analyses before us bring out this association in a very marked manner.

The relationship of the alkaloids, to which attention is here called, is also indicated by the action of their solutions on a ray of polarized light. Quinine and cinchonidine deflect this to the left and are lævo-rotatory, whilst cinchonine and quinidine have a right hand or dextro-rotatory action.

As to the causes which in the case before us have led to the disappearance of the quinine and cinchonidine in the low-grown bark, and their partial substitution by cinchonine and quinidine we have little to guide us, but the fact is a very important one as bearing on the cultivation of red bark at low elevations. A similar substitution has been recorded before in old trees, but age alone is seen, by analysis A, to be an insufficient cause. It is probable that temperature is the more important factor, and support is given to this by the remarkable case recorded by Broughton,† of the reversed action in *C. peruviana*. This species, as grown at Neddivuttum, is remarkable for affording cinchonine in large quantity —in the experiment recorded 3·84 per cent.—and absolutely no quinine; when grown, however, at the higher elevation of Dodabetta, the cinchonine was greatly diminished, whilst quinine was present to the amount of 0·79 per cent. I am, sir, yours faithfully,

HENRY TRIMEN.

Peradeniya, April 5, 1883.

* Mr. Howard especially called attention to this so long ago as 1866 (see 'Proc. Bot. Congress in London,' p. 198).

† 'Report to Government of Madras,' September 26, 1871.

NOTE ON A SAMPLE OF "CRETA PRÆPARATA."

BY F. HARRIS ALCOCK.

A short time ago I was requested by a friend who is engaged in one of the large dispensing establishments of the West-end to examine a specimen of what had been described to him as a special brand of the above-mentioned article.

It seems that his suspicions were aroused by the fineness of the cones and their white appearance, and in order to satisfy himself on their composition he wished me to subject them to an examination, and let him know the result, which was as follows:—

Physical Characters.—In cones of almost equal size, each weighing (average of fifteen) 70 grains and measuring 1⅜ inch in height and about ⅞ inch diameter at the base; much lighter and whiter than the British Pharmacopœia variety and having a satiny touch, free from grittiness. Under the microscope, a little of the powder scraped off one of the pieces was seen to consist of very small uniform prismatic crystals when viewed with a ¼-inch objective, whereas a sample prepared by elutriation as officially directed was found to be amorphous when similarly examined.

Chemical Characters.—As I had some weeks before had occasion to use some "blackboard chalk" for an experiment (thinking it to be carbonate of calcium) and finding that it only slightly effervesced with diluted hydrochloric acid, and that it was chiefly sulphate of calcium, I suspected the same substitution in the substance under examination. This proved to be the case, for when diluted hydrochloric acid was added to it a little effervescence resulted, but not enough for the quantity used to indicate presence of carbonate of calcium only; on the application of a little heat a perfect solution was obtained, and this gave evidence of the calcium when the usual tests for the compounds of that metal were applied. When, to a similar solution, chloride of barium was added a copious precipitate fell, which corresponded in every particular to the usual behaviour of the sulphate radical. On further examination of the substance it proved to be chiefly a mixture of calcium sulphate ($CaSO_4,2H_2O$) with calcium carbonate.

To obtain an idea as to the amount of sulphate present I made three quantitative experiments, the mean of which gave 67·016 per cent. (calculated as $CaSO_4,2H_2O$), and the amount of the carbonic anhydride which was obtained from a given weight of the substance by the usual means recommended for estimating that gas showed the presence of 32·379 per cent. calcium carbonate, the rest being a trace of iron, silica and chloride.

My object in writing this is to call the attention of pharmacists to this matter, to enable them to examine their specimens to see if they are genuine and free from such an impurity.

Of course for cosmetic purposes gypsum is largely used, but not so much as an internal remedial agent, and consequently it might prove objectionable rather than otherwise when used in such cases as when true "creta præparata" would be required.

I am informed that when tooth powders containing chalk and soap, etc., are made up with the above material, the usual frothing does not take place and altogether a disagreeable result is obtained.

PICRIC ACID AS A TEST FOR ALBUMEN AND SUGAR IN THE URINE.*

BY GEORGE JOHNSON, M.D., F.R.S.,

Physician to King's College Hospital and Professor of Clinical Medicine in King's College

During a period of about two years, I have been in the habit of using picric acid as a test for albumen in the urine. I was induced to employ this test by my son, G. Stillingfleet Johnson, one of the Demonstrators of Chemistry at King's College, who, while working at the compounds of albumen with the mineral acids, the results of which he published in the *Journal of the Chemical Society* (August, 1874), found that picric acid

* Paper read before the Clinical Society, March 9, 1883. Communicated by the Author.

caused coagulation in all the acid compounds of albumen; and he therefore suggested that it might be found a valuable test for albumen in the urine. At that time, we were not aware that it had ever been employed as a test for albumen; and in a communication to the *Lancet* (November 4, 1882), I spoke of it as a new test; but, a few days after the publication of my paper, I chanced to come upon a leading article in the *Medical Times and Gazette* (vol. ii. for 1874, p. 366), in which picric acid is mentioned as having been recommended as a test for albumen by a French physician, M. Galippe. There is, therefore, no novelty in the suggestion; but, so far as I can learn, the true value of the test has not hitherto been appreciated, and therefore it has not come into general use. The test may be used in the form of a saturated aqueous solution, or in the form of powder or crystals. The aqueous solution is most suitable for home use, while the powder or crystals may conveniently be carried in a urinary pocket test-case.* A saturated aqueous solution may be quickly made by dissolving the dry acid in distilled or rain water in the proportion of seven grains to the fluid-ounce; a portion of the acid will crystallize out on cooling, leaving a transparent yellow supernatant liquid. This solution, being added to an equal volume of albuminous urine in a test-tube, immediately coagulates the albumen. The coagulated picrate of albumen is soluble in alkalies; if, therefore, the urine be highly alkaline, it must be acidulated by a vegetable or a mineral acid before adding the picric acid solution. In my numerous testings for albumen with picric acid, I have not once found it necessary to acidulate the urine. The picric acid solution is itself sufficiently acid to dissolve the phosphatic sediment which results from boiling a neutral or alkaline specimen of urine.

To detect a very minute quantity of albumen, the following method is the best. Into a test-tube about six inches long, the urine is poured to within two inches of the top; then, the tube being held in a slanting position, about an inch of the picric acid solution is gently poured on the surface of the urine, where, in consequence of its low specific gravity (1003), it only partly mixes with the upper layer of the urine; and, as far as the yellow colour of the picric solution extends, there will be more or less turbidity from coagulated albumen, contrasting with the pellucid unstained urine below. If, then, the tube be placed in a stand, the coagulated albumen will gradually subside, and form a delicate horizontal film at the junction of the coloured and the unstained stratum of urine; the yellow liquid above and the uncoloured urine below being quite free from turbidity. If the urine should be turbid with urates, it must be cleared by heat before the addition of the picric acid solution.

As a result of numerous careful observations, I have arrived at the conclusion that picric acid applied in this way is a more delicate, and therefore more trustworthy, test for albumen than nitric acid in cold urine, whether the latter be employed by the method of dropping the acid into the cold urine or by pouring the urine on the acid previously placed in the tube. The simplest and most satisfactory mode of comparing the two tests as regards their relative delicacy, is to dilute a specimen of albuminous urine until one or the other test fails to act; and it will be found that the picric acid solution shows the presence of albumen in a specimen diluted considerably beyond the point at which the nitric acid fails to give any indication. The picric acid, too, often causes an immediate albuminous opalescence in specimens in which nitric acid only slowly, and after an interval of some minutes, gives a similar, but sometimes a doubtful, indication.

It scarcely need be insisted on that, for example, during convalescence from acute albuminuria, it is of the greatest practical importance to be assured that no trace of albumen remains.

* Such a case has been made for me by Hawksley, 357, Oxford Street.

Here it may be well to mention that the albuminous opalescence with picric acid which always occurs immediately, if at all, may readily be distinguished from the coarse granular particles of urate of soda, which, after a delay of some minutes, sometimes result from the acidity of the picric solution. These granular masses of urate, sometimes mixed with crystals of free uric acid, quickly fall to the bottom of the test-tube, and carry with them so much of the picric colouring matter, that, when placed under the microscope, they are so opaque as to appear almost black.

In testing with the powder or crystals, as much as is equal in bulk to a peppercorn may be shaken up in a test-tube, with a column of urine about an inch in height. As the powder dissolves, the urine becomes turbid with coagulated albumen. The object is to add as much of the test as the urine will dissolve, and no more. The solution of the picric acid in the urine, and the coagulation of the albumen, are quickened by heating the tube over a spirit-lamp or a candle, or by immersing the tube in hot water.

Another convenient mode of using the powder or crystals is to add fifteen or twenty minims of water to the peppercorn bulk of the acid in the tube, and quicken the solution by the application of heat; an equal bulk of urine is then gradually added to the hot solution, when albumen, if present, is at once detected.

The value of picric acid, as a test for clinical use, is much increased by the fact that, when boiled with a solution of potash, it forms a most delicate test for glucose. As I have stated, in a letter which I addressed to the *Lancet* (November 18, 1882), I stumbled upon this fact by adding some picric acid solution to a boiling specimen of saccharine urine which had previously been mixed with half its volume of liquor potassæ. I was at that time not aware of the fact, that the reaction of picric acid with grape sugar had been observed by Braun, a German chemist, nearly twenty years ago. I am indebted to Dr. Pavy for a reference to Braun's paper ("Ueber die Umwandlung der Pikrinsäure in Pikramminsäure, und ueber die Nachweisung der Trauben-Zucker." C. D. Braun.—*Zeitschrift fur Chemie*, 1865). In this paper, it is shown that grape-sugar, when boiled with picric acid and potash, reduces the yellow picric acid to the deep red picramic acid, the depth of colour depending on the amount of sugar present. I am not aware that hitherto any attempt has been made to utilize this as a qualitative clinical test for sugar in the urine, or as a means of accurately estimating the amount of sugar in a saccharine solution. I trust, however, to be able to establish its value for both purposes.

Take a fluid drachm of a solution of grape-sugar, in the proportion of a grain to the fluid ounce; mix it with half a drachm of liquor potassæ (B.P.), and ten minims of a saturated solution of picric acid; and make up the mixture to four drachms with distilled water. The mixture is conveniently made in a boiling tube, ten inches long and three-fourths of an inch in diameter, which may be marked below at the height of two and four drachms. With a long boiling tube, there is little risk of the liquid boiling over; and, the steam, condensing in the upper cool part of the tube, flows back as liquid, so that there is little loss by evaporation. The liquid is now raised to the boiling point, and the boiling is continued for sixty seconds by the watch, so as to insure the complete reaction between the sugar and the picric acid. During the process of boiling, the pale yellow colour of the liquid is changed to a beautiful claret red.

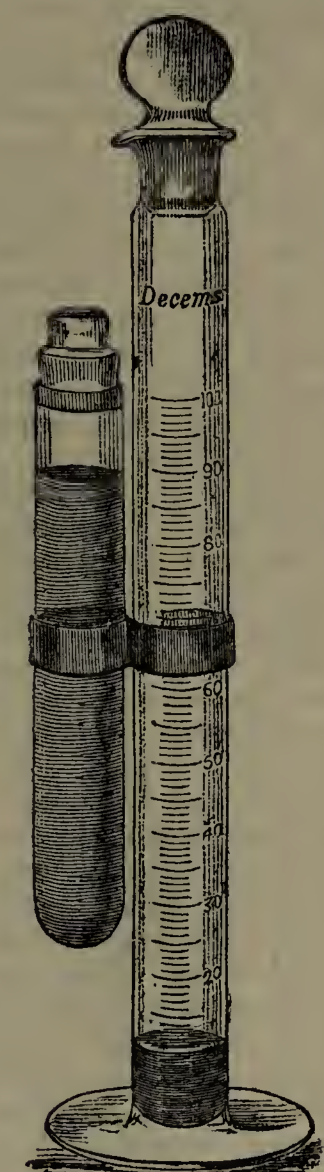
The liquid having been cooled, by cautiously immersing the tube in cold water, and it having been ascertained that its level is that of the four-drachm mark on the tube, or, if below the mark, it having been brought up to it by the addition of distilled water, the colour is that which results from decomposition of picric acid, by a grain of sugar to the ounce, four times diluted; in other words, it indicates one-fourth of a grain of sugar to the ounce; and this colour is a convenient standard for comparison in making a volumetric analysis. The picramic acid solution, however, on exposure to light, even for a few hours, becomes paler; but the colour may be exactly imitated by a solution of ferric acetate, with a slight excess of acetic acid and an excess of ferric chloride. The iron solution, we have found to retain its colour unchanged for a fortnight, even when exposed to a strong light; and we expect that, when light is excluded, it may be kept for an indefinite period; and it is, therefore, a convenient standard for comparison.*

If, now, a drachm of a solution of grape-sugar, containing two grains to the ounce, be mixed with the same quantity of liquor potassæ (half a drachm) as before, but with double the amount of picric acid (*i.e.*, twenty minims), and made up to four drachms in the boiling tube, the result of boiling the mixture as before for sixty seconds, will be the production of a much darker colour than when the one-grain solution was acted upon; but if now the dark liquid be diluted with its own volume of water, the colour will be the same as that of the one-grain solution.

The dilution is accurately done in a stoppered tube, twelve inches long and three quarters of an inch in diameter, graduated into $\frac{1}{10}$ and $\frac{1}{100}$ equal divisions. By the side of this tube, and held in position by an S-shaped band of metal, is a stoppered tube of equal diameter, and about six inches long, containing the standard iron solution.†

Sufficient of the dark saccharine liquid to be analysed is poured in to occupy exactly ten divisions of the graduated tube. Distilled water is then added cautiously, until the colour approaches that of the standard. The level of the liquid is then read off and noted. A more exact comparison of the saccharine liquid with the standard is made by pouring into a flat-bottomed colourless tube, about six inches long and an inch in diameter, as much of the standard as will form a column of liquid about an inch in height, and an exactly equal column of the saccharine liquid in a precisely similar tube. The operator then looks down, through both tubes at once, one being held in each hand, upon the surface of a white porcelain slab, or a piece of white paper. In this way a slight difference of tint is readily recognized, and if the liquid to be analysed be found to be darker than the standard, it is returned to the graduated tube, and diluted until the two liquids are found to be identical in colour, when the final reading is taken. The saccharine liquid having been diluted four times before it was boiled, a colour equal to that of the quarter-grain standard would indicate one grain of sugar per fluid ounce. If further dilution were required—say from ten to twenty divisions—the proportion of sugar would be two grains per ounce, and so on to thirty or forty or upwards, or to intermediate divisions. Thus dilution from ten to thirty-five divisions would indicate 3·5 grains of sugar per ounce.

We have found, by experiment, that ten minims of a cold saturated solution of picric acid are rather more than sufficient for decomposition by one drachm of a solution of grape sugar in the proportion of one grain to the ounce. A drachm of the solution would, of course, contain one eighth of a grain of sugar. In making an analysis, the



The picro-saccharimeter, as described in the text. The shading of the side tube indicates the ferric acetate standard. The darker shading at the bottom of the graduated tube shows the saccharine fluid, darkened by boiling with picric acid and potash, and occupying ten divisions before dilution.

picric acid must be added in proportion to the amount of sugar. If the proportion of sugar be as high as six grains per ounce, a drachm of the picric acid solution will be required. If the proportion of sugar be higher than this, the saccharine fluid should be diluted with distilled water in a definite proportion before commencing the analysis, and the product of the analysis of the diluted fluid is then to be multiplied by the degree of dilution—two, five, or ten, as the case may be, to which the original liquid has been subjected.

Distilled water, or clear rain-water, should be used for diluting. Hard water, containing salts of lime, is rendered turbid by the carbonate of lime precipitated by mixture with caustic potash, and any turbidity in the liquid interferes with the estimation of the depth of colour. In testing undiluted urine, a slight turbidity often results from separation of phosphates by the potash. This turbidity may be removed by allowing the phosphates to form a sediment, or more speedily by filtration. When a highly saccharine liquid is diluted five or ten times before mixture with the testing materials, no phosphatic turbidity occurs. In making a volumetric analysis, care must, of course, be taken that the measurements and dilutions are accurately made.

The preliminary dilution of a strongly saccharine specimen may be made in the graduated tube; or into a flask graduated to contain fifty cubic centimetres; five or ten cubic centimetres of the saccharine liquid may be delivered from a graduated pipette; then the flask being filled up to the graduation with distilled water, the dilution will be ten times with five cubic centimetres, and

---

* I hope and believe that our friends and fellow-workers, the pharmaceutical chemists, will prepare standard sugar solutions, and also the ferric acetate standard for those who require them. We have made the ferric acetate by adding ferric chloride to ammonium acetate. It is of primary importance that the standard be correct.

[We have been kindly supplied with the following form for a "standard sugar solution," which is, we believe, due to the suggestion of Mr. G. Stillingfleet Johnson.—Ed. P. J.

Liq. ferri perchlor. fort.	ʒj.
Liq. ammon. acet.	ʒiv.
Acid. acet. glacial.	ʒiv.

The colour of this is equal to a quarter of a grain of grape sugar to the ounce. Of course this wants checking every time it is made.]

† This picro-saccharimeter was made for me by E. Cetti, 36, Brooke Street, Holborn, E.C.

five times with ten cubic centimetres of the liquid to be analysed.

Another important point is that, while the amount of potash remains the same, the picric acid must be in proportion to the amount of sugar in solution. It has already been mentioned that ten minims of the picric acid solution are more than equal to one-eighth of a grain of glucose, which is the amount contained in one drachm of a solution, in the proportion of a grain to a fluid ounce. A slight or even a considerable excess of picric acid does not appreciably affect the colour of the picramic acid, while a deficiency would, of course, lead to an underestimate of the amount of sugar. If an analysis with thirty minims of picric acid solution indicate, say, from three to four grains of sugar, it is probable that some sugar has been left undecomposed, and a second analysis, with a larger proportion of picric acid, might therefore give a higher and a more correct result. If, on the other hand, a second analysis, with a larger proportion of picric acid, give an identical result, we may feel certain that the whole of the sugar has been decomposed, and the amount indicated by the resulting picramic coloration. In any case, when the amount of sugar indicated is less than would suffice to react upon the amount of picric acid employed, the result may be relied upon as correct.

The presence of albumen, even in large amount, has but little influence on the picric acid test for sugar. In illustration of this, the following experiments will suffice. A specimen of urine, normal as regards the amount of saccharine or saccharoid material, but containing a large amount of albumen, was boiled with picric acid and potash with sufficient water to dilute the urine by its own volume of liquid. A second portion was treated in the same way after the separation of the albumen by boiling and filtration, and the first specimen gave a darker tint than the second to a degree that might be considered to indicate one-tenth of a grain of sugar per ounce. Another portion of the urine was decolorized by repeated filtering through charcoal; and, of this, one specimen was tested while it retained its albumen, another after the separation of the albumen — the result being that both yielded identical tints of colour, and this was very slightly paler than that of the specimen which was tested after having been deprived of its albumen without previous decolorization by charcoal. The explanation is, that pure albumen has no reducing influence on picric acid when boiled with dilute potash, such as is used in testing for sugar; but with seralbumen, as with white of egg, there is associated a colouring matter which is partly separated by filtering off the coagulated albumen, and entirely removed by repeated filtering through charcoal. The colouring matter in question has a reducing influence on picric acid, although the colouring matter of normal urine has been found to have none. The coagulated albumen collected on the filter, after being thoroughly washed, gives no red reaction when boiled with picric acid and potash diluted in the same proportion as that employed in testing for sugar. This has been proved by repeated experiments.*

The accuracy of the picric acid method of volumetric sugar analysis has been fully and fairly tested. Our plan has been to compare the results of this process with those obtained by Dr. Pavy's beautiful and accurate ammonio-cupric method. We have analysed the same specimens, many of them albuminous as well as saccharine, by the two processes, my son employing Dr. Pavy's method in the laboratory at King's College, and I the picric acid process at home; and our results are found to be practically identical, the differences being only such as are due to unavoidable slight errors in conducting an experiment. Both methods, in fact, are based upon the same chemical principle—namely, that glucose, when heated with potash in the presence of an oxidizing agent, has a tendency to rob it of its oxygen. In the one process, the reducing action of the sugar is exerted upon an oxide of copper; in the other, on picric acid, A definite weight of sugar reduces, in the one case, a proportional amount of cupric oxide, and in the other an equivalent proportion of picric acid, with resulting picramic acid, and a corresponding measurable intensity of colour.

The proportion of sugar in the specimens analysed has varied from one grain to fifty grains per fluid ounce. The following may be taken as examples of practically identical results.

1.	13·5 grs. per fluid oz. . .	13·5 grs. per fluid oz.
2.	33 " " . .	32 " "
3.	31·2 " " . .	30·5 " "
4.	36.4 " " . .	36 " "
5.	10.3 " " . .	9·5 " "
6.	1·28 " " . .	1 " "
7.	11·5 " " . .	11 " "
8.	36·4 " " . .	36 " "
9.	2·57 " " . .	2·5 " "
10.	3·1 " " . .	2·9 " "
11.	7·27 " " . .	7 " "
12.	16·8 " " . .	16 " "
13.	48·5 " " . .	47·5 " "
14.	27·7 " " . .	27 " "
15.	48·4 " " . .	48 " "
16.	17·47 " " . .	17 " "
17.	49·6 " " . .	49 " "
18.	9·3 " " . .	8·5 " "
19.	9·9 " " . .	10 " "
20.	6·05 " " . .	6 " "

It will be seen that in the majority of cases, the ammonio-cupric process gives results slightly in excess of the picric acid method. This excess is due to some non-saccharine ingredients in the urine, which reduce cupric oxide, but not picric acid.

During the last three months, I have tested with the picric acid and potash a large number of specimens of normal urine (about 300), with the almost uniform result of a depth of colour indicating the proportion of 0·6 grain of sugar in the fluid ounce, the indications usually varying between the limits 0·5 and 0·7 grain in the fluid ounce. In a considerable number of cases, my son has tested the same specimens by the ammonio-cupric method, with the indication usually of from 0·7 grain to 0·9 grain in the fluid ounce; *i.e.*, an excess of that obtained by picric acid of from 0·1 to 0·3 grain in the fluid ounce.

The following have been the proportions of the various liquids: a drachm of urine, ½ a drachm of liquor potassæ, 10 minims of picric acid solution, made up to 2 drachms with distilled water. The mixture is kept boiling for a minute, and, when cooled, is compared with the standard. The urine having been diluted by its own volume, a depth of colour equal to that of the standard would indicate 0·5 grain of sugar; but in nearly every case I have found it so much darker than the standard, as to require further dilution equal to 0·1 grain before the standard colour is reached, thus giving an indication of 0·6 grain.

So constant is this degree of coloration with normal urine that if, instead of diluting up to 2 drachms, the dilution be carried further by 24 minims, the resulting colour might be taken as an approximation to an exact quarter-grain standard, and, in the absence of a more exact standard, might be used for making an analysis. The question arises—Does normal urine contain as much as 0·6 to 0·7 grain of glucose in the fluid ounce? We are

* A chemical result of boiling albumen with potash, and the question of the formation of alkaline sulphide, was discussed at some length in the columns of the *Lancet* during the months of December and January last. For the final communication from my son, in which he demonstrates that the apparently contradictory results obtained by different observers are explained by the varying proportions of the caustic potash employed, the *Lancet* could not find space, but it is published in the *Chemical News*, February 23, 1883, page 87.

not prepared to assert this without further evidence than we have as yet been able to obtain; but, if it be not glucose which gives these almost identical analytical results with the two processes, it must surely be some nearly allied substance.

There are certain facts connected with the behaviour of this reducing agent so constantly found, and in such constant quantities in normal urine, which point to its saccharine nature. 1. Its reducing effect upon both cupric oxide and picric acid is equal to that which would be exhibited by an equal weight of pure glucose. This is remarkable, since any other substance than glucose or an isomeric sugar would probably reduce more or less either of the picric acid or of the cupric oxide. 2. It is completely destroyed by prolonged ebullition with dilute caustic alkalies. On the other hand, we are unable to assert positively that it is glucose, since it is unfermentable by yeast, and the most careful analyses have failed to produce more than those traces of grape-sugar from normal urine which were obtained by Brücke and Bence Jones ($\frac{1}{50}$ of a grain per fluid ounce). The results of careful analyses of normal urines tend to show that the secretion of the healthy human kidney contains two distinct classes of cupric oxide-reducing substances, viz., (1) such substances as uric acid, etc., which are not destroyed by boiling, with dilute caustic potash; and (2) what may be described as saccharoid bodies which *are* disintegrated by such treatment. Moreover, it appears that picric acid is reduced only by the second, or saccharoid group of normal urinary constituents; for the results of analyses by the ammonio-cupric method of healthy urine which has undergone sufficiently prolonged boiling with dilute potash to completely destroy everything which is capable of reducing picric acid—*i.e.*, everything belonging to group 2, or the saccharoids—invariably show the presence of more or less cupric oxide-reducing substance which has escaped disintegration by the boiling alkali; and on deducting this reduction from the total cupric oxide-reduction effected by the original urine, an indication of (?) glucose is obtained equal to that given by the picric acid method with the original urine.

The results of some such analyses are tabulated below, in which all reduction is expressed in grains of glucose in the fluid ounce.

I. Total indication by picric acid.	II. Total indication by Ammonio-cupric method.	III. Indication by Ammonio-cupric method after boiling with potash.	IV. Difference between II. and III. Saccharoid substance.
gr. per fl. oz.	gr. per fl. oz.	gr. per fl. oz.	gr. per fl. oz.
(1). 0·6	0·909	0·276	0·63
(2). 0·5	0·607	0·09	0·517
(3). 0·35	0·546	0·145	0·401
(4). 0·8	1·245	0·437	0·808

All reductions expressed as grains of glucose per fluid ounce.

These results are explained by the fact that those ingredients of healthy urine which reduce cupric oxide, and are not destroyed by boiling with potash, such as uric acid and urates, have been found to exert no reducing action upon picric acid.

There are at least two undoubted sugars, viz., sorbite and eucalin, which reduce cupric oxide from potassio-cupric tartrate, and are destroyed by boiling with dilute potash, but do not undergo the vinous fermentation under the influence of yeast; and both these sugars are isomeric with glucose. Hence, though the evidence of the indentity of the saccharoid ingredient of normal human urine with glucose is incomplete, it is at least probable from its behaviour and reactions that it may be a true sugar.

I trust that the method of saccharimetry which I have described, will enable every practitioner who has the will, to estimate with ease and accuracy the amount of sugar in any specimen of urine.

ALGIN: A NEW SUBSTANCE OBTAINED FROM SOME OF THE COMMONER SPECIES OF MARINE ALGÆ.*

BY E. C. C. STANFORD, F.C.S.

The utilization of hitherto waste materials presents a large field for chemical investigation, and many important industries have within the last twenty years resulted from such researches.

There are few materials so abundant, so general, and so easily obtained as the commoner kinds of seaweed thrown up on all our coasts, but especially on those exposed to the waves and storms of the Atlantic. The species I refer to—the laminaria and fuci—are found growing on all rocky shores. And it may also be remarked that, except as manure, the great bulk of this material has been long practically unutilized. It is true that, when burnt into the rough slag known as kelp, this material was formerly the means of securing large revenues to the proprietors of the Western Islands. For several well-known reasons, that manufacture has long ceased to be profitable, and it never could have been considered as utilizing the seaweed, except in the sense that burning down a forest could be called utilizing it, when it ought to be cut into timber and really utilized in building houses or making furniture.

In 1862, the writer introduced a method of carbonizing the seaweed in retorts, and thus converting the material into charcoal instead of kelp, and preventing the great loss of iodine arising from open-air burning. This was simply another step of improvement, and, comparing it again with the forest, was merely equal to making the timber into charcoal instead of burning it into ash. It is not, in a proper and fuller sense, utilizing the seaweed. The results of further attempts in this direction form the subject of this paper. When we remark that the present wide-spread destitution and want of employment amongst the poor cottars is most severe in just those districts in Ireland and the Highlands where this material is most abundant, the importance of this inquiry will be at once seen. Indeed, if a remunerative price can be paid for a waste material that every child in a large family can easily assist in collecting at their own doors, it would go far to settle many existing difficulties, of which the worst is always hunger. And this brings me to mention the value of the algæ as a food material. In my paper, read before the Society of Arts, in 1862, on "The Economic Applications of Seaweed," the various kinds so used were described, and I have called attention more recently, in a paper read before the Chemical Society, to the fact that the analysis of the charcoal obtained from the various algæ approximates more nearly to that of a product of the animal than of the vegetable kingdom. I believe the algæ, generally, to be quite as valuable food products as the fungi, with the advantage that we are unaware of any poisonous species. Both are, however, equally neglected in this country. As the edible fungi are much consumed by other European nations, so the edible algæ are largely enjoyed and realize a high price in China and Japan. A sample of one of the Japanese varieties before us yielded on analysis a composition closely similar to our laminaria. It has, however, evidently been cut up, and presents the appearance of long shreds, and is coloured green by the action of an alkali. The poor people in Donegal are now eating the *Fucus vesiculosus* with Indian meal, and it is a common thing to see the Highland cattle browsing on this plant at low tide. The *Aliaria esculenta*, or murlins, of which a fine specimen is on the table, may be called our edible species, but the *Rhodomenia palmata*, or dulse, is perhaps better known in Glasgow, being regularly sold on the streets.

The most important species consumed in this country is the *Chondrus crispus*, or Irish moss. This plant contains

* Read before the Chemical Section of the Glasgow Philosophical Society, April 2, 1883. Communicated by the Author.

79 per cent. of caragheenin, a substance of great gelatizing power, and largely used in jellies and puddings. This seaweed would, no doubt, secure a considerable market as a size for fabrics, but it cannot be obtained in any great quantity. It is only uncovered at low spring tides, and any very large demand would soon exhaust the supplies. A recent application of Irish moss is being worked by a limited company, under the name of "velo-plastic," which is said to be made of refuse leather, dried and finely ground and mixed with caragheenin. I am indebted to Mr. John A. Walker, of Dublin, for specimens of green and yellow morocco, poplin, and satin damask, and watered silk, all of which appear to be most successful imitations. The new substance to be described in this paper would probably answer equally well for this application.

Another still more powerful gelatizing substance is gelose. This was first imported into France from China in 1856. It has ten times the gelatizing power of isinglass, and will set into a jelly five hundred times its weight of water. It is not nitrogenous, and contains—carbon, 42·8; hydrogen, 5·8; oxygen, 51·4. It has not superseded isinglass for jellies, as the fusing point of the jelly is too high to melt in the mouth. I found some years ago, in experiments on every variety of seaweed that could be procured, that this gelatizing principle was confined to two British species—the *Chondrus crispus* and the *Gelideum corneum.* An Australian alga, the *Euchemia spinosa*, or agar agar, is also a jelly-yielding species. Several articles have recently been introduced under various names, such as thao, fucyne, etc., all of which appear to be modifications of, or products from, these plants.

The application of seaweed as manure is very general where it can be obtained. In fact the practical value placed on it is far above its actual chemical valuation. It usually contains 80 per cent. of water, so that 4 tons of water are carted to the land for every ton of dry seaweed, and even when dried there is not a large saving in carriage, as it is then very bulky. It is, however, carried long distances in some places, and there is no doubt that it is very valuable on soils that are all sand; but it is more of a mechanical value, as its use is not to *manure* but to *make* the soil—a rather expensive manufacture. Kelp waste, a ton of which, dry, represents 40 tons of wet seaweed, and contains all the phosphates of the weed in a convenient form—is absolutely unsaleable to farmers in this country at any price.

The only other important proposed application of seaweed has been to the manufacture of paper, and about twenty years ago several patents were taken out with this object, and some specimens were exhibited at the Society of Arts on the occasion before referred to. They were all made, however, from the *Zostera marina*, or grass wrack—a marine plant with flowers growing in the sea, but not one of the algæ—and this plant makes a very good paper. It created a good deal of attention at that time, having been proposed as a substitute for cotton during the cotton famine. It is not, however, available in large quantity, and contains very little fibre. The algæ generally contain no fibre, but, as far as my experiments have gone, nearly every species yields a very pure cellulose, which makes a tough, rather transparent paper. The tissue of the plant consists of simple cells of various shapes laid end to end, and in the fuci containing a dark pigment. This cellulose fabric, which forms the paper material, amounts, when quite dry, to 10 per cent. of the air-dry plant. In working on the fuci and the laminariæ my attempts to make a paper pulp were much impeded by a peculiar substance common to both these species, which was found at first difficult to remove, and the presence of which rendered the paper brittle. In fact this appeared to be always the case unless the cellulose was obtained quite pure. This substance is present in large quantity, and forms the bulk of the plant after the salts are removed.

Any one observing the long flat fronds of the laminaria lying on the sea shore must have noticed two things. 1st, that these are easily bleached by exposure to light; 2nd, that, after exposure to rain, the fronds contain in their interior sacs of fluid. These are derived from the endosmosis of the water through the outside membranes, dissolving a peculiar glutinous principle. Upon opening one of these sacs, a neutral glairy, almost colourless, liquid escapes. Sometimes it may be seen partially evaporated on the surface of the frond as a jelly-like substance, which may be drawn out by the fingers in long, tenacious strings. This fluid contains a unique substance of remarkable properties, and to which, from its source, I have given the name of algin. The vesicles are only seen in the long fronds of the various laminaria, especially *L. stenophylla*, known in the Highlands as bar-darrig, or red-top. The large stems or tangle, and the fuci, although containing it in considerable quantity, do not exhibit this appearance.

If the liquid be evaporated to dryness, the scales so produced resemble albumen, and are not all soluble in water, but very soluble on the addition of a little alkali. Several other instances of the solubility of substances when endosmosed or dialysed are well known. The fluid thus naturally obtained is miscible with water, but coagulated by alcohol and by mineral acids. It cannot be obtained in sufficient quantity for exhaustive analysis, but it contains calcium, magnesium and sodium, in small quantity, in combination with algin. If the laminaria fronds are cut up and macerated in dilute hydrochloric acid, the liquid in the vesicles assumes the form of a colourless, insoluble jelly. If the laminaria fronds are immersed in water containing a little alkali—by preference sodium carbonate—the whole plant becomes disintegrated, and presents a gelatinous mass, consisting of a thick, glutinous, gummy liquid, containing the cellular fabric of the plant completely broken up. This occurs in twenty-four hours in the cold. The mass, although it only contains 2 per cent. of the algin, is so glutinous that it cannot be poured out of the bottle. It is very difficult to deal with, on account of its extraordinary thickness. In fact, as it is, no method of filtration is possible (all known methods, with and without pressure, have been tried). The cells to be removed are so minute that, if pressure be applied, the whole mass passes through any filter or not at all. By cautiously heating the mass, it can, however, be filtered. The medium employed is a coarse linen sacking in the form of a Taylor's filter. The cellulose is left behind as a gelatinous mass, amounting, when dry, to about 10 per cent. of the air-dried plant.

The algin solution is then evaporated in a somewhat similar manner to gelatin, and, when dry, presents an appearance which is not unlike gum-tragacanth; but it may also be obtained in thin transparent flexible sheets. The solution is slightly alkaline; but care must be taken that no great excess of sodium carbonate is present, or the solution decomposes, and in a week, if dilute, becomes quite thin, and contains no algin. This action of the alkali I cannot yet clearly explain. The solution can be neutralized by the careful addition of hydrochloric acid without gelatinizing; but an excess at once precipitates it. A solution of only 2 per cent. becomes semi-solid, treated in this way. The following reactions are obtained with various reagents. For some of these the solution must be carefully neutralized with acetic acid, which does not gelatinize it.

Dilute hydrochloric, nitric, sulphuric, sulphurous, phosphoric and mineral acids generally, coagulate it. Boracic acid has no effect.

Lime water, baryta water, and salts of calcium, barium and strontium, give white precipitates.

Salts of magnesium do not affect it. Acetic, formic, citric, tartaric and benzoic acids do not affect it.

It is precipitated by alcohol.

Perchloride of iron gives a dark brown coagulum.

Salts of copper, zinc, aluminium, tin, antimony, cobalt and nickel, all precipitate it.

Protonitrate of mercury forms a white precipitate, but bichloride of mercury and silver nitrate have no effect.

Acetate and subacetate of lead both give white precipitates.

Potassium silicate and bichromate, sodium biborate* and potassium ferrocyanide, permanganate, sodium tungstate, stannate and succinate do not affect it. No precipitate is produced by tannin.

Concentrated sulphuric acid dissolves it; concentrated nitric acid converts it into oxidation products, amongst which are oxalic acid.

It is distinguished from albumen by not coagulating on heating, and by not precipitating silver nitrate—from gelose by not gelatinizing on cooling, and by containing nitrogen, which gelose does not; and being soluble in cold, weak, alkaline solutions, which gelose is not; and being insoluble in boiling water, in which gelose is soluble. The laminaria has been boiled in water for a month without effecting any solution, and for a week under 40 lbs. pressure with a similar result.

It is distinguished from gelatine by not giving any reaction with tannin—from starch by giving no reaction with iodine; from dextrine, gum-arabic, gum, tragacanth and pectin, by its insolubility in dilute alcohol and in dilute mineral acids.

I notice as particularly remarkable that it should precipitate all the salts of the alkaline earths except those of magnesium, and most of the metals except silver and mercury, and with regard to the latter that it should precipitate the protonitrate but not the bichloride; and that it gives no precipitate with potassium silicate.

The gelatinous precipitate produced by a mineral acid represents the algin in its pure insoluble form. It dries up to a hard, horny substance. A specimen can scarcely be distinguished from horn. I have not yet succeeded in getting it pure and definite enough to be certain of its composition; but I am indebted to Professor Ferguson for a combustion of the soda compound. This had been carefully dialysed to avoid the presence of excess of alkali, and gave the following numbers:—

Carbon	35·65
Hydrogen	4·40
Nitrogen	3·03
Oxygen	37·23
Ash	19·69
	100·00

This gives the following composition for the algin. I have appended also that of gelatin, isinglass, gelose, and chitin. In nitrogen it is intermediate between gelose and gelatin, but it approaches nearer to chitin than any other substance. Fremy, however, denies the presence of nitrogen in this substance. It differs entirely from algin in being insoluble in alkalies.

	Algin.	Gelatin.	Isinglass.	Gelose.	Chitin.
Carbon	44·39	50·0	50·1	42·77	46·64
Hydrogen	5·47	6·5	6·6	5·77	6·60
Nitrogen	3·77	17·5	18·3	—	6·56
Oxygen	46·37	26·0	25·0	51·46	40·20
	100·00	100·0	100·0	100·00	100·00

(Sulphur, ·12.)

The percentage of ash in the soda compound does not materially vary. The two following were made—one with sodium hydrate, and the other with sodium carbonate, and yielded almost the same amount of ash:—

Sodium hydrate—percentage of ash	31·51
Sodium carbonate, do.	31·37
Mean	31·44

* It can be extracted by a solution of borax.

Although I believe the composition to be stated correctly, I cannot construct a formula from these figures; and all attempts to procure definite compounds for analysis have as yet been unsuccessful. The following compounds have been prepared and investigated with this view:—Compounds with calcium, aluminium, barium and lead—but the results have not been uniform enough to show that we have been examining definite compounds.

The sodium carbonate appears to be unaltered in the compound, but completely masked. The carbonic acid comes off only when acidified with an excess of hydrochloric acid, and heated.

The acid has also some decomposing effect, and produces a small quantity of a substance which precipitates Fehling's solution, but does not appear to be glucose.

A solution, 1000 grs. measure, containing 13·2 grs. of algin, was precipitated by standard sulphuric acid, and redissolved by standard sodium hydrate, six times in succession.

1st precipitation took of sulphuric acid (SO_3), grains	5·430
2nd „ „ „	4·070
3rd „ „ „	3·086
4th „ „ „	1·975
5th „ „ „	0·617
6th „ „ „	0·617
1st resolution took of soda (Na_2O), grains	3·778
2nd „ „ „	2·871
3rd „ „ „	2·052
4th „ „ „	1·530
5th „ „ „	0·670
6th „ „ „	0·478

As the precipitate is not soluble in sodium sulphate, there appears to be some decomposition continually going on, and this has not yet been sufficiently investigated to enable me to ascertain the exact action of the hydrochloric acid.

The process proposed to deal with the seaweed is first of all to wash out the salts by simple maceration in cold water. This is very easily done, the salts being almost entirely removed, even by two macerations. On account of the bulk of the material it is, however, advisable to wash a number of vats exhaustively in turns, in the usual manner of lixiviation common in alkali works. The water removes about a third of the weight of the seaweed, and when evaporated to dryness presents a treacly mass containing the salts and a considerable quantity of a saccharine matter which resembles mannite, but which precipitates Fehling's solution equal to 15 per cent. of glucose. It is, however, unfermentable, and I have not yet succeeded in getting it pure enough for analysis, on account of the great difficulty of separating it from the alkaline chlorides which are soluble in alcohol. By the use of sulphate of silver I have separated a small quantity, but still not sufficiently pure. If this can be separated commercially, and is a sugar having sweetness but unfermentable, it would be available for replacing glycerine in some of its applications. Until, however, more is known of its properties it must be sacrificed by carbonizing the salts, the charcoal, of which it yields about 50 per cent., being then treated in the usual manner for separating the iodine and salts. The salts vary from 35 to 55 per cent. of the whole; or 12 to 18 per cent. of the original air-dry weed in the laminaria. This is more than is obtained by burning the weed into ash, which does not, as a rule, yield more than 10 per cent. of salts on the air-dried weed.

It is interesting to notice the way in which these salts come out, and analyses have been made with this view. The results are shown in the following tables:—Calcium sulphate and magnesium chloride are both present in the aqueous solution of the laminaria and in the residue of the fuci—carbonates generally in the salts of the fuci and the residue of the laminaria. In the latter, which is always submerged, the relation of the magnesium to the calcium is singularly like that existing in sea water.

Within certain limits the composition of the salts differs considerably, the age of the plant and the time of gathering both affecting it.

(*To be continued.*)

THE PRESERVATION OF SYRUP OF IODIDE OF IRON.*

BY C. VAN WISSELINGH.

Some time ago J. de Groot published a paper in the *Pharmaceutisch Weekblad* (Sept. 17, 1882), in which he states that syrup of iodide of iron which has been kept in an open burette, and which was protected from contact with air by a layer of oil, was found to have lost 3 per cent. of its ferrous iodide. This statement induced the author of the present paper to examine the subject carefully, and his results are detailed below.

Three burettes of 100 c.c. capacity were nearly filled with freshly-prepared syrup of iodide of iron, and a layer of 5 c.c. of some fixed oil poured on top of each, the following oils being selected: almond oil, olive oil and castor oil. A small quantity of fixed oil would have served equally well to prevent contact with the air. I took a larger quantity to see what effect the oil itself would have on the syrup.

The percentage of ferrous iodide was determined by titration with a solution of mercuric chloride. As is well known, the addition of this reagent to a solution containing ferrous iodide in excess produces a red precipitate of mercuric iodide which is dissolved on stirring, as it forms a soluble double salt with the still undecomposed ferrous iodide. Whenever the precipitate no longer redissolves on stirring no more ferrous iodide remains undecomposed, and the reaction is completed. The solution of mercuric chloride is made of such a strength that 10 c.c. of it are required, in presence of 1 gram of ferrous iodide, to reach the point when a further addition will produce a permanent precipitate. In the actual titration I employed 5 grams of the syrup carefully weighed and afterward diluted with 5 c.c. of distilled water. In order to convince me that the above method yields correct results, the percentage of iodine was also determined by distillation with ferric chloride, by titration with hyposulphite of sodium and also with nitrate of silver, chromate of potassium being used as indicator in the last named case. The results of all these methods of assay were found to agree well among themselves, and with that above detailed.

Immediately after being prepared, the syrup in the different burettes contained, theoretically, 19 per cent. of ferrous iodide. The different assays gave figures varying from 19 to 19·2. Several times during each week, in the course of one month, the assay of the syrup in each burette was renewed, and no diminution of the percentage noticed. After four months the assay again yielded from 19 to 19·2 per cent. of ferrous iodide.

Now I determined to examine that portion of the syrup which was immediately below the layer of oil. Enough syrup was drawn from each burette to retain about 10 c.c. of which two separate assays were made. The mean results obtained were the following.

Syrup kept under almond oil . . .	19·17 per cent.
Syrup kept under olive oil . . .	19·17 per cent.
Syrup kept under castor oil . . .	19·13 per cent.

Finally the oils were examined. They all had acquired a more or less brown colour; the castor oil was very dark, less so the olive oil, and the almond oil had assumed only a brown tint. To estimate any iodine present in the oils, I used the following method. The oil was saponified with alcoholic solution of potash, by the aid of a few hours' heating on the water-bath, in a porcelain capsule. The soap was then carefully heated and carbonized in the capsule, the mass lixiviated with water, the solution acidulated with hydrochloric acid, and any iodide of potassium present determined by solution of mercuric chloride, three times more dilute than that mentioned above. A preliminary experiment convinced me of the reliability of this method. Although in all three solutions the presence of traces of iodine could be detected by chlorine water and chloroform as well as by nitrate of silver, yet the quantity was so minute that I could not estimate it quantitatively.

These results show that de Groot's statements cannot be correct. He states that he found a diminution of 2·941 per cent. of ferrous iodide in a syrup standing two months. I could not detect any diminution of the percentage even after four months, and only noticed the syrup becoming somewhat lighter of colour, while the oils took up only a minute trace of iodine.—After *Nieuw Tijdschrift voor de Pharmacie*, 1883, 77.

Note.—Many years ago, we have made experiments on the keeping of syrup of iodide of iron, and have found that it may be kept in bulk, in any quantity, if it be protected from contact with air by a layer of oil on the surface. A large stone jar with a glass faucet at the bottom will be found a useful receptacle. Or a glass siphon may be kept in the jar, reaching nearly to the bottom, the outer arm being provided with a short piece of rubber tubing and a pinchcock.—*Ed. N. R.*

TESTING EXTRACT OF LICORICE.*

Professor C. L. Diehl, of Louisville, Ky., having had occasion to examine some commercial licorice paste as to purity, devised a modified method for the estimation of its constituents, and published the same in the February issue of the *Pharmazeutische Rundschau*.

I. Expose 1·0 gram of the mass to a gentle heat until it experiences no further loss in weight. Calculate this loss as moisture.

II. Digest 10·0 grams of the mass contained in a flask with 100·0 grams of distilled water until it is fully disintegrated; when cold cautiously pour on 200·0 grams of alcohol and vigorously shake the flask. By this procedure the precipitate produced will be prevented from adhering to the sides of the vessel. Allow it to stand for several hours, shaking occasionally, then pour on a double thick filter of sufficient size, and wash the remaining dregs with a mixture of two parts of alcohol and one part of water until the filtrate begins to pass colourless.

III. After the foregoing residue has become air-dry, exhaust the same with distilled water, so that the filtrate may pass colourless; reduce the latter to a small volume and then transfer to a small tared porcelain capsule, being careful to remove any residue from the larger evaporating dish by means of a little warm distilled water, adding the rinsing to the contents of the small capsules. Evaporate to dryness by means of a gentle heat, and calculate the residue as gummy matter.

IV. Carefully dry the dregs remaining on the filter under III., employ the outer filter as counterbalance and calculate as insoluble substance.

V. Carefully concentrate the alcoholic filtrate obtained under II. to the consistence of syrup and redissolve in distilled water. Then, to the clear solution, add dilute sulphuric acid gradually until a precipitate (glycyrrhizin) ceases to be produced. Wash the glycyrrhizin with cold water, allow to dry at the ordinary temperature, and dissolve in strong alcohol, whereby about fifteen per cent. of insoluble tastless residue will remain, which, however, is soluble in ammonia. Now filter the alcoholic solution of glycyrrhizin, wash the filter with alcohol, evaporate the combined filtrates to dryness, then redissolve the residue in a small quantity of ammonia, again evaporate to dryness in a tared capsule, and estimate as ammoniated glycyrrhizin.

THE "CRITICAL POINT" OF GASES.

NOTWITHSTANDING the many able investigators who have studied the phenomena attending the liquefaction of gases under the influence of pressure there are several points which are still imperfectly understood, and especially has there been a divergence of opinion respecting the significance of one of the most curious of them, the peculiar appearance manifested at what has been designated by Dr. ANDREWS the "critical point." It is well known that this distinguished physicist's experiments led him to think that under certain conditions of temperature and pressure there is a point at which matter exists in a condition that cannot be described either as liquid or gaseous, but is intermediate between the two states, and from which, under a definite variation of the conditions, it is capable of passing almost imperceptibly into either. This view has not gone unchallenged, and only a short time since Dr. HANNAY, after making a large number of experiments wherein hydrogen was submitted to pressure over various liquids in which it is insoluble, deliberately expressed his opinion that the gaseous and liquid states of matter are not more continuous than the liquid and solid states.

The success which has recently attended the efforts of two Polish experimenters to effect the liquefaction of oxygen, nitrogen and carbonic oxide, under conditions in which the resulting liquid can be retained for observation, has redirected attention to the general subject, and M. JAMIN has seized the opportunity to lay before the French Academy of Sciences some conclusions at which he has arrived. M. JAMIN, who maintains that gases are liquefiable at any temperature if the pressure be sufficient, gives the following explanation of the "critical point." Taking one of the earlier experiments of CAGNIARD-LATOUR, where a thick glass tube, two-thirds full of water under the pressure of its own vapour, is sealed and heated to 300° or 400° C., he points out that according to known laws the quantity of vapour lying above the liquid augments very rapidly, and that its density increases in the same ratio as its weight, while, on the other hand, the remaining portion of the liquid undergoes a growing expansion which eventually exceeds that of the gas: it follows therefore, as a consequence of these inverse variations, that a limit of temperature is reached where equal volumes of the liquid and the vapour have the same weight. At this point they cease to remain separate; the meniscus disappears; the liquid and vapour become mixed, presenting undulating striæ such as are characteristic of a mixture of liquids of different densities, and finally the whole takes a homogeneous form which has been supposed to be gaseous. This is the "critical point," which M. JAMIN defines as the "temperature at which a liquid and its saturated vapour have the same density." Although no liquid is now perceptible it still remains diffused through the gas at its boiling point and maximum tension in virtue of its equal density; but as the temperature rises the tension continues to increase until the entire volatilization of the liquid, when, and not till then, there remains only a dry vapour or gas above its point of liquefaction. The inability to recognize the presence of the liquid in the gas is attributed to the fact that the conditions which ordinarily allow of a saturated vapour being distinguished from the liquid from which it is generated are not present, there being no difference in the density of the two, whilst no heat becomes latent, since there is no change of volume and consequently no expansion. So also the experiments of Dr. ANDREWS have shown that when a gas is submitted to gradually increasing pressure in a closed tube a definite limit is reached, the maximum tension, upon passing which the gas is condensed; this is the point of liquefaction, or boiling point at this pressure, and this pressure of liquefaction augments rapidly with the temperature without any known limit.

M. JAMIN argues that this theory of the equalization of the densities brings the phenomena into accord with all the laws as to the formation and condensation of vapours and explains the apparent anomalies in connection with the "critical point." For instance, in 1880, M. CAILLETET had stated that in submitting to pressure, in his apparatus, a mixture consisting of one part of air and five parts of carbonic acid, it was observed the latter gas took the liquid form at a moderate pressure; but upon increasing the pressure to one hundred and fifty or two hundred atmospheres the liquid already formed entirely disappeared. This observation had remained unexplained; but M. JAMIN, applying his theory to it, inferred that a portion of the carbonic acid having become liquefied at a moderate pressure, it was not further affected by continued reduction of the volume of the containing vessel, having already attained its maximum density, whilst the pressure upon the gaseous air increased, and with that its density, until this equalled the density of the liquefied carbonic acid, and intermixture followed. If this inference were correct, it would follow that upon substituting a gas of less density, such as hydrogen, for the air in the mixture, the equalization of the densities, and the consequent disappearance of the liquified carbonic acid, would be retarded. The question was submitted to the crucial test of experiment by M. CAILLETET, who obtained results quite in accord with M. JAMIN'S theory. M. CAILLETET made two mixtures, one containing five volumes of carbonic acid and one of air, the other five volumes of carbonic acid and one of hydrogen, and submitted them to pressure. In both cases he obtained the liquefaction of the carbonic acid under moderate pressure, and the total disappearance of the liquid under more powerful compression. First the meniscus disappeared at the moment when the densities of the liquid and the air became equal, and afterwards the liquid disappeared, and, in conformity with the theory, at a pressure very different and much more considerable with the mixture containing hydrogen than with that containing air. Thus whilst at a temperature of 15° C., a pressure of one hundred and thirty-five atmospheres was coincident with the disappearance of the carbonic acid first liquefied from a mixture containing air, a pressure of two hundred and forty-five atmospheres was reached before a similar phenomenon occurred with a mixture of carbonic acid and hydrogen. At 20° C. the pressures at which the liquid disappeared were with carbonic acid and air, one hundred and eight atmospheres, and with carbonic acid and hydrogen, one hundred and ninety-nine atmospheres; whilst at 25° they were seventy-nine atmospheres and one hundred and fifty-three atmospheres respectively. When the mixture was less rich in carbonic acid, M. CAILLETET found that the evident liquefaction of this gas was retarded and sometimes unattainable. The explanation offered is that when a mixture of air and gas is reduced to a smaller volume by pressure they undergo equal reduction, but not the same increase of tension; that of air being directly as the decrease of volume, whilst that of carbonic acid augments less rapidly, since MARIOTTE'S law no longer applies. Liquefaction of the carbonic acid does not therefore take place relatively at so early a period, and when eventually it does attain its maximum tension, its density may be the same, or sometimes below, that of the air above it. It is consequently in a state in which it will readily become diffused through the air and escape recognition as a liquid; this might lead to the supposition that under such conditions carbonic acid gas is incapable of liquefaction, whilst it has only lost the property of collecting at the bottom of the containing vessel in virtue of a relatively greater density. M. JAMIN hoped that by increasing the pressure the carbonic acid would continue to liquefy, and that as in so doing its density would vary only slightly, whilst that of the air would augment indefinitely and eventually become superior, a point would be reached at which separation would take place, and the curious result would be obtained that the liquefied carbonic acid would float above the denser, but still unliquefied air. At present, however, all attempts made M. CAILLETET in this direction have been unsuccessful.

We are requested by the Secretary, Mr. Bremridge, to say that he will be glad to receive votes for the election to the London Orphan Asylum, on the 25th inst., in order to secure the admission of an orphan in whom the Society is interested.

* * *

Once more the second reading of the Medical Acts Amendment Bill has been postponed, and it is now set down for Monday next. On Thursday, in reply to a question put by Lord Randolph Churchill, as to the intention of the Government with respect to this Bill, Mr. Gladstone declined to say anything which would lead to the supposition that it would interfere with the Tenants' Compensation Bill. He remarked, however, that the Bill had been the product of very great labour and he believed it had received the very general consent of the medical profession; under these circumstances, he thought it would be favourably received in the House of Commons and he looked forward to seeing it passed during the present session.

* * *

According to the "Votes and Proceedings," petitions for the alteration of the Medical Bill were on Tuesday presented from the "Chemists', etc., Association and Glasgow." If, as appears possible, petitions from two associations of chemists and druggists in respect to the proper representation of pharmacists upon the Pharmacopœia Committee are indicated under this curt description, it is regrettable that their presentation was not delayed until a period nearer to the time when this particular subject is likely to come under the notice of the House, during the passage of the Bill through Committee.

* * *

In reply to a deputation of "Medical Herbalists," who were afraid that the Medical Acts Amendment Bill, if passed, would be prejudicial to their interests, Mr. Mundella said, on Tuesday last, that the Bill would not affect them at all, as long as they abstained from using improper titles.

* * *

By the courtesy of the Secretary of State for Foreign Affairs we are informed that a dispatch has been received from Her Majesty's Ambassador at Rome, reporting that in answer to representations addressed by him to the Head of the Italian Commercial Department respecting the restrictions on the sale of patent medicines in Italy, that officer has explained that the object of the Medical Board was to prevent the introduction of patent medicines containing drugs injurious to health, and that if it could be shown that the medicines for which admission was applied for were sanctioned in any properly authorized pharmacopœia, there would probably be no difficulty as to their admission.

* * *

It will be seen from a letter published on another page that Mr. R. Barrington Cooke, to whose remarks on the necessity for placing the sale of butter of antimony under more stringent regulations we referred last week, has been in communication with Mr. Mundella on the subject, and has "every reason to believe" that his suggestion "will be carefully considered and probably adopted." Whilst gratified to observe this practical endorsement of the recent action of the Council, we are unable to think that the point which was refused to the body charged by the Legislature with the initiative in making additions to the poison schedule will be conceded to a private individual.

* * *

Sanitary reformers may well be satisfied with the increased attention now paid by the general public to their teachings. A few years since they were looked upon as visionary, and rather troublesome, enthusiasts, but on Saturday last, the occasion of the opening of an exhibition of hygienic dress and sanitary domestic appliances and decoration at Knightsbridge, under the auspices of the National Health Society, attracted a distinguished company of civic dignitaries, leaders of the medical profession, and others. Mr. Ernest Hart described the nature and object of the exhibition, and in doing so incidentally presented some statistics that were sufficiently remarkable to arrest the attention of those of his audience whose municipal position may enable them to exercise a salutary influence in favour of improved hygiene. Briefly, Mr. Hart estimates that the saving of life effected in the metropolis during the last ten years by improved sanitation at 480,000 lives, or 48,000 lives annually, which means a yearly money saving with respect to sickness and funerals alone of at least a quarter of a million sterling. Some further figures quoted respecting the buildings of the Artizans' Improved Dwellings were so remarkable as almost to suggest some other explanation of them than the one implied; for, according to Mr. Hart, in these buildings the death rate has been reduced, in the case of infants, from 47 to 24 per 1000, and in the case of adults, from 17 to 10 per 100. The Lord Mayor formally declared the exhibition open, and whilst it was in accordance with a very prevalent idea that his thoughts should flow towards the subject of good dinners, he was undoubtedly quite right in pointing out that much remains to be done in the direction of teaching people how to cook their food without spoiling it and depriving it of its nutritious properties.

* * *

The first subject of research in connection with the quadrennial Discovery Prize of £1000 recently instituted by the Grocers' Company (see before, p. 807) has now been announced by the Committee, and the problem set lies quite within the field of experiment open to many of our readers. It is "to discover a method by which the vaccine contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic: the method to be such that the contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of generations shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymphs." Competitors for the prize, who may belong to any nation, must submit their treatises on or before December 31, 1886, and the award will be made not later than May, 1887. The Scientific Committee, under whose advice the Grocers' Company is acting, consists of Dr. Simon, Professor Tyndall, Dr. J. Burdon Sanderson and Dr. George Buchanan. The Grocers' Company has issued a circular stating the conditions of candidature and award, copies of which may be obtained from the Clerk to the Company.

The report of a case of prosecution by the Inland Revenue authorities, which was published in this Journal last week, shows that notwithstanding all that has been said there still exists misapprehension as to the sale of quinine wine. It cannot be too clearly understood that the permission to sell quinine without a licence or stamp only extends to it when prepared of the strength and according to the directions of the Pharmacopoeia, and supplied as such. If the "wine" sold does not represent the Pharmacopœia preparation, the seller must hold a wine licence, whilst, in any case, if it be recommended for the cure of disease, it must be stamped as a "patent medicine."

* * *

Another subject upon which we have reason to believe some misconception exists is the extent to which rectified and methylated spirit may be supplied by chemists and druggists. It is not likely that the excise authorities will attempt to interfere with the supply within reasonable limits of ordinary alcohol as medicine on the prescription of a medical man. But this tolerance must not be assumed to extend to the supply without a licence of methylated spirit, the use of which in the preparation of any medicine capable of being used internally is expressly forbidden under the 130th section of the "Spirits Act, 1880."

* * *

The use of liquefied carbonic acid in the preparation of carbonated beverages is recommended by Mr. Apotheker Volk, of Ratzeburg, who states that experiments have proved it to be the purest, most suitable and best method of impregnating mineral waters. It is also claimed that by using the carbonic acid in this form the more expensive part of the apparatus now used in the manufacture could be dispensed with. It is evident, however, that even should a sufficiently cheap supply of pure liquefied carbonic acid be forthcoming, special precautions will have to be adopted as to the containing vessels and the manner in which they are stored, as the gas requires at 0° C. for its liquefaction a pressure of 36 atmospheres, which increases rapidly with a rise of temperature. It would be worth while to carry the experiment a little further and try the solidified acid, the relatively slow evaporation of which, even when exposed to the air, might facilitate manipulation.

* * *

An extraordinary dispensing mistake is recorded by the *St. Louis Druggist* as having occurred in the City Hospital, St. Louis. Two patients were ordered to be supplied with "30 drachms of sulphate of magnesia in cinnamon water," and a third with 25 drachms. In some unexplained way the hospital dispenser substituted chloral hydrate for sulphate of magnesia, with the result that within an hour of taking the medicine two of the patients were dead and the other in a dangerous condition. A coroner's jury returned a verdict of "death through culpable negligence," and the dispenser has been lodged in prison to await his trial.

* * *

At the Second Annual Meeting of the Virginia State Pharmaceutical Association, held last month in the city of Norfolk, Professor Attfield was unanimously elected an Honorary Member of the Association.

* * *

The name of Sir Frederick Augustus Abel, K.C.B., F.R.S., occurs in the list of names of gentlemen upon whom it is proposed that the University of Oxford shall confer the degree of D.C.L., at a Convocation to be held on Wednesday next.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, June 6, 1883.

Present—Messrs. Andrews, Atkins, Borland, Bottle, Butt, Carteighe, Churchill, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

Mr. Carteighe having taken the chair, the minutes of the Council meetings of May 2 and 23 were read and confirmed.

Election of President.

A ballot having been taken in the usual way—

MR. MICHAEL CARTEIGHE

was re-elected President.

The President thanked the Council for this renewed mark of its confidence, and said he hoped he should be able to continue to serve the Council and the Society with satisfaction to all concerned.

Election of Vice-President.

On a ballot being taken—

MR. SAMUEL RALPH ATKINS

was re-elected Vice-President.

The Vice-President also briefly thanked his colleagues for the honour they had done him.

Election of Treasurer.

A ballot having been taken—

MR. JOHN ROBBINS

was re-elected Treasurer.

Mr. Robbins expressed his thanks, and said it was always gratifying to anyone who filled such a position to find that he had an ample reserve to draw upon and that he left office at the end of the year with the finances in a better state than when he commenced his duties.

Standing Orders.

The Standing Orders were then adopted for the ensuing year.

Secretary and Registrar.

Mr. Elias Bremridge was unanimously re-appointed Secretary and Registrar.

Assistant Secretary and Deputy Registrar.

Mr. Richard Bremridge was also unanimously re-appointed Assistant Secretary and Deputy Registrar.

Elections.

PHARMACEUTICAL CHEMIST.

Joshua David Pidgeon, of New Cross, having passed the Major examination and tendered his subscription for the current year, was elected a "Member" of the Society.

CHEMISTS AND DRUGGISTS.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Bowman, William..................Liverpool.
March, William............Queenstown, Cape Colony.
Williams, Edward ....Mold.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Alpe, Robert Bird ....Wymondham,
Beck, Albert Neve ....Hastings.
Ellis, George Waddington ......Birkdale
Furness, Thomas ....Chesterfield.
Hewitt, John Richard............London.
Mansergh, William ....Manchester.
Swift, Philip Dickerson ....Tottenham.
Thresh, Arthur.....................Buxton.
Waddington, John William ...Hungerford.

ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Brunt, George Henry ....Norwich.
Campion, Martin Hand ....Louth.
Fitzjohn, Francis ....Whittlesea.
Fraser, John ....Edinburgh.
Hickson, Robert William ......Hull.
Low, David ....Hexham.
Norman, William Francis ......Towcester.
Pearson, William Jackson ......Little Gonerby.
Richards, Arthur..................Swansea.
Simpson, Charles ....Aberdeen.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Cox, Frederick Hudson ....Southampton.
Day, John Thomas ....London.
Denham, Albert Shaw ....Preston.
Ellerington, John Parker ......Hexham.
Hallawell, Joseph L. ....Ayr.
Hollis, Henry ....Birmingham.
Jackson, Harold ....Manchester.
Lees, James ....Leighton Buzzard.
McLanachan, John ....Sheffield.
Metcalf, Rowland Alfred ......Uxbridge.
Muskett, Frederic James ......Newport Pagnel.
Ogdon, William ....Derby.
Peacock, George ....Heslerton.
Ryall, Frederick John.............Devonport.
Scholey, John ....Burnham.
Scott, Sack Noy ....St. Austell.
Smith, Edwin Wells ....Sheffield.
Stark, George Miller ....Gatehouse.
Thacker, Harry Ransby ....Nottingham,

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restorations to the Register.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

William George Clapperton, 610, Myrtle Avenue, Brooklyn, U.S.A.
John Henry Hateley, 4, Shawclough, Rochdale.

Additions to the Register.

The Registrar reported that—
David Fairbrother, 2, Flitcroft Street, Manchester;
Joseph Woods, Tunstall, Staffs;
Sarah Craig, Howgate, Kilwinning, Ayrshire;
having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been supported by duly qualified persons, their names had been placed on the Register.

Appointment of Committees.

The Council went into committee to receive suggestions and discuss details of the committee arrangements. On resuming the following were appointed:—

General Purposes.—The whole of the Council To meet at six o'clock on the evening before the Council meeting and at such other times as may be required.

Finance.—Messrs. Andrews, Gostling, Hills, Savage, Schacht, Squire and Symes. To meet at half-past four o'clock on the afternoon preceding the Council meeting.

Library, Museum, Laboratory and House. — Messrs. Andrews, Bottle, Butt, Gostling, Greenish, Hampson, Hills, Richardson, Robbins, Schacht, Squire and Williams. To meet at eleven o'clock on the second Wednesday in every month except August and September.

Benevolent Fund. — Messrs. Bottle, Butt, Borland, Churchill, Greenish, Radley, Richardson, Robbins, Williams, Woolley and Young. To meet at half-past three o'clock on the day preceding the Council meeting.

Law and Parliamentary. — Messrs. Bottle, Butt, Greenish, Hampson, Hills, Robbins, Squire, Symes, Williams, Woolley and Young. To meet as occasion may require.

The President and Vice-President are *ex officio* on all the above committees.

Evening Meetings.—The President, Vice-President, the three Professors, the Editor and the Curator of the Museum.

Freehold Investment Committee.—The President, Vice-President, Treasurer, and Mr. Butt.

Spurious Drugs Committee.

Mr. WILLIAMS asked if it were desirable to appoint a Spurious Drugs Committee.

The President and other members having expressed the opinion that it was necessary to have such a committee ready to act at any time required, the following gentlemen were appointed:—The President, Vice-President, Messrs. Greenish, Hampson, Richardson, Symes, Williams, Woolley and Young, with power to add to their number.

APPOINTMENT OF EDITOR AND SUB-EDITOR OF THE JOURNAL.

Dr. PAUL was re-appointed Editor of the Society's Journal for the ensuing year, and Mr. PASSMORE the Sub-Editor.

APPOINTMENT OF CURATOR.

Mr. HOLMES was re-appointed Curator for the ensuing year.

LOCAL SECRETARIES.

The PRESIDENT said he was informed by the Secretary that the number of towns eligible last year to have a Local Secretary was three hundred and two. This year the number of towns eligible was three hundred and ten, thirteen having been added and five removed from the list. From two hundred and fifteen of them nominations had been received, whilst ninety-five had made no nominations.

The appointment of Local Secretaries was referred to the Library, Museum, Laboratory and House Committee for consideration and report.

THE NORTH BRITISH BRANCH.

Mr. J. B. STEPHENSON was unanimously re-elected Honorary Treasurer to the North British Branch.

Mr. P. MACEWAN was re-appointed Secretary to the Branch.

REPORTS OF COMMITTEES.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

The report of the Committee was read.

Librarian's Report.

This report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
April	Day	701	35	16	28
	Evening	203	16	4	9

Circulation of books.	Town.	No. of Entries. Country.	Total.
April	181	116	297

Carriage paid, £1 10*s.* 10½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Canning (W.), The Chemists' and Dispensers' Vade Mecum, 1882. From the COMPILER.
Collin (Eug.), Recherches sur l'Origine et la Nature de la Rhubarbe de la Chine, 1882.
— Revue des Médicaments Chimiques, 1882.
— Revue des Médicaments d'Origine Végétale, 1882.
— Des avantages que peut offrir l'Emploi du Microscope pour l'Analyse des Denrées Alimentaires, 1883. From the AUTHOR.
Hérail (J.), Les Fumariacées, thèse, 1883. From the AUTHOR, through Prof. SOUBEIRAN.
City of Boston, Report of Inspector of Vinegar, 1883. From Dr. B. F. DAVENPORT.
Nicklès (Adr.), Notes Linguistiques à propos du Recueil des Travaux du Bureau Ethnologique publié par la Smithsonian Institution à Washington. From the AUTHOR.
Méhu (C.), Remarques sur les Variations de la Composition du Sperme. From the AUTHOR.
Brozowsky (W.), Waarenkunde, 1869.
Nieuw Tijdschrift voor de pharmacie in Nederland, Jan.–April, 1883.
Parrish (E.), Treatise on pharmacy, 4th ed., 1874. From Dr. JUL. MOREL.
Mueller (F. v.), Systematic Census of Australian Plants, part 1, Vasculares, 1882. From the VICTORIAN GOVERNMENT, through the AUTHOR.

The Committee approved of the purchase of two more copies of British Pharmacopœia, and also recommended that two copies of the undermentioned work be purchased:—

United States Dispensatory, 15th ed., 1883.

Curator's Report.

The Curator had reported that the attendance in the Museum during the month of April had been:—

	Total.	Highest.	Lowest.	Average.
Morning	546	36	5	20
Evening	115	10	2	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimen of Green Ginger. From Dr. SYMES, Liverpool.
Specimens of Cinchona barks cultivated in Ceylon, with herbarium specimens of *C. officinalis*, *C. succirubra*, *C. Ledgeriana* and a *hybrid Cinchona*. Forwarded through HER MAJESTY'S SECRETARY OF STATE FOR THE COLONIES.

A series of duplicate specimens of medicinal plants had been forwarded to the York Chemists' Assistants' Association; labels had also been supplied to the Leeds School of Medicine, and to Mr. Martindale.

The Professors had attended and reported satisfactorily on their respective classes.

The Committee had considered the working of the bye-law relating to payments in commutation of arrears of subscriptions, and it was deemed desirable that the amount should not as a rule exceed two guineas; but if in any case the Secretary considered a larger amount should be paid, the particulars of the case should be submitted to the Finance Committee.

The President, in pursuance of a resolution of the Council, had sent a letter to Mr. Mundella on the subject of the Medical Acts Amendment Bill, with special reference to the Pharmacopœia, in which he had asked if Mr. Mundella would receive a deputation on the subject. Mr. Mundella had replied, saying, that as it was not proposed to alter the Bill he did not think it worth while for a deputation to attend, but he should be happy to see the President after the Whitsuntide holidays. The Committee had thereupon desired the President and Mr. Hampson to arrange for an interview, and if they thought it expedient to issue to Local Secretaries and others circulars and forms of petition to the House of Commons.

The Committee had also considered the form of amendment to the Medical Bill which it was desirable should be proposed in the House of Commons.

The Council went into committee and discussed the action to be taken with regard to the Medical Acts Amendment Bill.

On resuming, it was moved by Mr. Schacht and seconded by Mr. Churchill, that the paragraph of the report referring to the fine to be imposed on members seeking re-admission be referred back to the Committee for reconsideration.

The motion was lost by a large majority, and the report and recommendations of the Committee were received and adopted.

FINANCE.

Messrs. Butt, Carteighe, Hills and Schacht had acted as a Finance Committee, and examined the receipts and accounts sent in during the month, which were recommended for payment.

The report and recommendations were adopted.

Freehold Investments.

The Council went into committee to consider a proposal for purchasing freehold ground rents.

On resuming, the report was received and adopted.

BENEVOLENT FUND.

The President, Treasurer, and Mr. Butt had considered an application for relief from the widow of a registered chemist and druggist (who had been in business twenty-three years), and recommended that a grant of £10 be made.

The recommendation was adopted.

Pharmacopœia Revision.

The Council then went into committee to consider a communication from Mr. Miller, the Registrar of the Medical Council, enclosing a printed memorandum from the Chairman of the Pharmacopœia Committee of the Medical Council, which was laid before the Council at its meeting on the 23rd inst. (see before, p. 963). After a long discussion it was resolved that the receipt of the communication should be acknowledged, and that Mr. Miller be informed that it had been submitted to the Council.

The Sessional Address.

On the suggestion of the President it was remitted to the Library, Museum, Laboratory and House Committee to arrange for the delivery of the Sessional Address in October next.

The Pharmacy Act Amendment Bill.

Resolutions and communications in reference to this Bill had been received from various associations and individuals, and were remitted to the Law and Parliamentary Committee.

Preliminary Examination.

The Council resolved to accept the following Certificates in lieu of the Society's Preliminary Examination:—

Royal University of Ireland:—
- Matriculation.
- First University Examination.
- Second University Examination.
- Examination for a degree in Arts.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

Pharmacopœia Revision.

A meeting of the Council of this Association was held on Friday evening, June 1, to consider a communication from the Chairman of the Pharmacopœia Committee of the General Medical Council, inviting suggestions respecting the proposed new edition of the British Pharmacopœia. After full discussion, the following resolution, proposed by the Chairman and seconded by Mr. A. H. Jackson, B.Sc., was carried unanimously:—

"That whilst thanking the Pharmacopœia Committee for the opportunity afforded to the Manchester Chemists and Druggists' Association to offer suggestions regarding the proposed new edition of the British Pharmacopœia, this Council is of opinion that for the full appreciation and useful application of such suggestions as the Association might be able to make, it is essential that the Pharmacopœia Committee should include representatives of pharmacy, and it therefore awaits such an alteration in the constitution of the Committee as will give to pharmacy and pharmacists a recognized position therein."

The Secretary was instructed to forward a copy of this resolution to the Registrar of the General Medical Council and also to the *Pharmaceutical Journal* for publication.

Arrangements were made for obtaining signatures to a petition for presentation to the House of Commons in support of the memorial addressed by the Council of the Pharmaceutical Society to the Privy Council, urging the importance of establishing a Pharmacopœia Committee containing pharmacists as well as medical practitioners.

A deputation was also appointed to wait on one of the members of Parliament for the city soliciting his support.

Proceedings of Scientific Societies.

SOCIETY OF CHEMICAL INDUSTRY.

Chemistry and Analytical Examination of Fixed Oils.*

BY ALFRED H. ALLEN.

(*Continued from page* 1009.)

The oils of class D exemplify the generality of composition of products of the most varied origin, oils from seeds, fruits, and the fat of both terrestrial and marine animals having practically identical saturation-equivalents. A slight but well-defined distinction is observable between these oils and those of class E. The results yielded by pilchard and cod oils require verification, but the figures referring to rape and castor oils have been fully confirmed by Mr. L. Archbutt. Evidently, their high equivalents are a consequence of their chief constituents being the glycerides of brassic and ricinoleic acids respectively. The calculated equivalent of the glyceride of brassic acid, existing in the oil from rape and other cruciferous seeds, is 322·67, while that of ricinolein contained in castor oil is 310·67.

In drawing conclusions from the results obtained by Kœttstorfer's process, it must not be forgotten that many of the oils of commerce contain a very sensible quantity of free acid, the presence of which, if not duly taken into account, may seriously invalidate the analysis. The free acid may be sulphuric or other foreign acid, in which case it should be removed by agitating the oil with a dilute solution of sodium carbonate before taking the known quantity for saponification. More frequently the free acid of commercial oils consists of oleic or other fatty acid, either liberated by the method employed for refining the oil, or resulting from the fermentative action

* Paper read before the London Section of the Society.

of mucilaginous or albuminous matters in the crude oil. The proportion of free acid present in commercial oils is often very large, far larger than, I believe, is commonly supposed. Thus, six samples of palm oil contained respectively 12, 21, 24, 52, 53 and 79 per cent. of free acid, calculated as palmitic acid. In fifty-five samples of olive oil intended for lubricating use, Mr. Archbutt found from 4·9 to 23·8 of free (oleic) acid, the mean being 10·5. In porpoise oil, which has been brought home in contact with the blubber, and which had drained therefrom at the ordinary temperature, I found 9·02 per cent. of free oleic acid, and in oil (from the same cargo) extracted by boiling the blubber with water, the free acid amounted to 22·65 per cent. In rape oil the proportion of free acid is generally less, ranging from 2 to 5 per cent. Cotton-seed oil, which is refined by means of alkali, is usually free from any trace of free acid.

The presence of free acid in an oil is doubtless the main, if not the only, cause of its tendency to act on metals. Hence the results published by Mr. W. H. Watson and others, showing the amounts of iron and copper dissolved in equal times by different oils, have no interest or meaning apart from the particular samples of oil examined, the action on the metals being simply a function of the free acid the oils happened to contain.

Interesting results can be obtained by exposing different samples of oils in small metal cups or shallow depressions turned out of metal plates; or the oils may be placed in small porcelain dishes, and coils of bright iron or copper wire immersed in them. When copper is employed, in the course of a day or two many samples of oil acquire a bright green colour from dissolved oleate of copper. The results are only rough, as the brown colour of many samples wholly conceals the green tint. But if the oils be shaken with ether and dilute sulphuric acid, the copper passes into the acid liquid. On separating this from the ethereal layer and adding excess of ammonia, the depth of the blue coloration produced is a fairly accurate measure of the action of the oil on the copper. This method of procedure, which was devised by Mr. L. Archbutt, is capable of being applied quantitatively, and gives very useful comparative results when employed under constant conditions.

Several rough but more or less tedious methods have been described for detecting and estimating free fatty acids in oils, but the simplest and best, and one which readily yields accurate quantitative results, is as follows:—Weigh into a 10 oz. bottle 50 grams of the sample of oil to be tested, and add to it 100 c.c. of redistilled methylated spirit, containing a little phenolphthalein, and previously treated with just sufficient caustic alkali to render it faintly pink. The oil and spirit are then shaken together, when, if the sample be free from rancidity, the pink colour will remain unchanged. If it be destroyed, standard caustic soda is cautiously added and the mixture again shaken, the addition of alkali being continued until a pink colour is obtained, which persists after vigorous shaking. It is easy to read to a single drop of normal alkali, each c.c. of which corresponds to 0·282 grams or 0·564 per cent. of free oleic acid in the sample. The reaction is as definite, and the neutralization point as easy to perceive, as in the titration of mineral acids; but owing to the very high combining weight of the fatty acid, great care is necessary. In assaying palm oil, which is itself often of a rose-red colour, the titration may still be made by employing a smaller quantity. In this case 5 grams of the oil and 20 c.c. of spirit are convenient quantities, and the bottle should be placed upon a white surface. It might be supposed that the proportion of free fatty acid found would be liable to be in excess of the true amount present, owing to the alkali having a tendency to partially saponify, and therefore be neutralized by the neutral oil; but this suspicion is negatived by the fact that an oil once freed from acid by the process of titration, when again treated shows no trace of free acid.

Before leaving the subject of free acid in oils I may point out that I believe that many cases of so-called "clogging" or "gumming," commonly attributed to oxidation of oils, are really due to the action of the free acids on the metal bearings of the machinery, with consequent production of soaps. One notable instance of this sort, communicated to me by Mr. Archbutt, is that of a very viscous oil which came out of a carriage axle-box. After removing a good deal of hair and dirt, the clarified oil was very green in colour, and still viscous. On shaking with ether and dilute acid the metals were readily removed, and on distilling off the ether the residual oil was found to have the same colour and viscosity as the original oil before use. In the acid liquid much copper and zinc were found. The oil was a mixture of 1 part of neutral mineral oil with 9 of olive oil containing 4·7 per cent. of free acid. It had probably been in the bearing about three weeks, yet no corrosion was "noticed." But corrosion of bearings by oils rarely is noticed, the fact seeming to be that the wear and tear of the metal and the thickening of the oil has been attributed to other causes. Liquid oils appear to corrode metals very evenly, so that the effect is not readily observed, but with solid fats it is very different. Thus, a steel rod which was immersed in axle-grease made with soap, water, tallow and palm-oil, containing a good deal of free acid, was deeply pitted in several places in a few days, and stained all over. The pittings were quite deep, and the grease after use contained only 2·8 of free palmitic acid.

The question of the action of free fatty acids on metal becomes still more important in the case of oils used for lubricating engine cylinders, or otherwise exposed to a high temperature. Under the influence of high-pressure steam all the ordinary fat oils undergo decomposition more or less readily, with formation of free fatty acids and glycerin, and the action of the acids on the metal speedily produces an iron soap which clogs up the machinery in a very troublesome manner. It is a curious fact that the iron and magnesium soaps, and some other metallic compounds of the fatty acids, are soluble in hydrocarbon oils, though insoluble in water, the reverse being the fact with the soaps of the alkali metals. As a consequence of this, the iron soap produced in engine cylinders lubricated with tallow, castor oil, or other fat oils, gets dissolved out whenever a change is made to a mineral lubricating oil, a fact which is well known to engineers, but which has sometimes been mistaken for an abundant production of gummy matter by the mineral oil itself.

Returning for a moment to Kœttstorfer's saturation process, it is evident that the presence of any foreign matter, incapable of undergoing saponification, or otherwise neutralizing alkali, would tend to reduce the proportion of alkali required. Hence, if the nature of the oil under examination were known, the abnormal result of the titration would enable the presence of the foreign matter to be inferred, and its amount approximately estimated. But the process would give no further indication of the nature of the admixture, and hence it is frequently desirable to effect an actual separation of the adulterant or admixture from the products of the saponification of the oil itself. This can be done with great ease and accuracy by a process which I have described in detail elsewhere,* the capabilities of which have been thoroughly tested in my own laboratory, and which has given results equally satisfactory in the hands of other chemists.

The process in its most generally applicable form consists in saponifying the oil by alcoholic potash, evaporating off the alcohol, dissolving the soap in water, and removing the unsaponifiable matter by repeatedly agitating the solution with ether.† On separating the

* *Chemical News*, 44, 161.

† It is very rarely that the third treatment with ether extracts more than traces of unsaponifiable matter. The

ethereal layer from the aqueous liquid, evaporating off the ether, the residual unsaponified matter may be weighed and submitted to further examination. The following table indicates the chief probable constituents of the aqueous and ethereal layers on saponifying various fatty matters:—

Dissolved by the Ether.	*Remaining in the Aqueous Liquid.*
Hydrocarbon oils, including	Fatty acids } In the form of potassium salts.
Shale and petroleum products.	Resin acids
Resin oil.	Carbolic and
Coal-tar oil.	Cresylic acids
Vaseline.	
Paraffin wax and ozokerite.	Glycerin.
Neutral resins.	
Unsaponified oil or fat.	Excess of caustic alkali.
Unsaponifiable matter, as cholesterin.	
Myricyl alcohol, from beeswax	
Cetyl alcohol, from spermaceti.	
"Spermyl alcohol," from sperm oil.	
Colouring matters, as from palm oil.	

Of the bodies which pass into solution in ether, the hydrocarbon oils are of course intentional admixtures, and hence may vary from a trifling proportion up to a very large percentage; but when a pure animal or vegetable oil is subjected to the process, mere traces of non-volatile matter commonly pass into the ethereal solution. As a rule, the ethereal residue is under 1 per cent. of the weight of oil employed, and it very rarely exceeds 1·5 per cent. Its nature depends chiefly upon the character of the oil examined. Thus, in the case of palm oil, some of the red colouring matter is found in the ethereal extract. Butter and cod-liver oil give ether-residues which consist mainly of cholesterin, which may be obtained in characteristic crystalline tablets by warming the ethereal extract with alcohol and allowing the solution to cool.

The waxes, as a class, are well known to differ from the true fixed oils or fats, in the fact that they are not ethers of glycyl, and hence do not yield glycerin on saponification, but, on the other hand, furnish fatty acids and certain higher monatomic alcohols of the ethyl series. Thus, on saponifying beeswax, myricyl alcohol, $C_{30}H_{62}O$, is obtained; Chinese wax yields ceryl alcohol, $C_{27}H_{56}O$; while spermaceti gives cetyl alcohol, $C_{16}H_{34}O$. In the course of an investigation as to the accuracy of the process of saponification and ether-treatment for estimating hydrocarbon oils in fatty oils, I was struck with the anomalous results yielded by sperm oil. Samples of oil from several different sources, in some cases obtained direct from the importer, and of undeniable authenticity, yielded proportions of ether-residue very different from those obtained from the majority of fatty oils. Thus, while, as already stated, ordinary oils yield at most some 1 or 2 per cent. of matter to ether, sperm oil gave ether residues varying from 38 to 42 per cent., the fatty acids ranging from 60 to 65 per cent., instead of fully 95, as in the case of other fatty oils. This startling result was fully borne out by the results obtained when using Kœttstorfer's process for the examination of sperm oil, the proportion of alkali neutralized being much less than in the case of ordinary oils. Of course the analytical results yielded by sperm oil pointed to a very different constitution from that of ordinary oils, a fact which was observed by Chevreul as long ago as 1823, who writes of sperm oil as yielding, by saponification, margaric acid, oleic acid, and "a non-acid fatty matter fusible at about 20°, which appears to be a congener of ethal"—the monatomic alcohol of spermaceti.*

From these results it appears probable that sperm oil ought to be classed with the waxes rather than with the true fixed oils. Until recently sperm oil was the only natural product known to me which was fluid at ordinary temperatures and yet had a constitution apparently similar to that of the waxes; but during the last autumn I was called on to make an examination of the oil from the bottle-nose whale, several cargoes of which have been recently disposed of. The blubber is brought home in tuns, and the oil is extracted from it in the ports on the eastern coast of Scotland by boiling with water, heated by means of steam. The oil is run off and allowed to stand so that the water may separate. On cooling to about 10° C. it gives a notable quantity of "foots" or deposit. This "foots" consists in reality of crude spermaceti, and a sample which I examined yielded me 60 per cent. of the refined wax. I have also a specimen, broken off a large cake, of very finely crystallized spermaceti, which was extracted from bottle-nose oil by a well-known firm. I may here remark that the statement often met with in books that spermaceti is found simply in the head cavities of the sperm whale is a mistake, the fact being that it is obtained from the oil of the blubber and all parts of the body whenever there is a sufficient reduction in the temperature. Specimens of sperm oil and bottle-nose oil, which are quite clear at 10° C., give a further deposit of spermaceti at a lower temperature, but the separation appears to be almost wholly complete at 4° C. The oil from the bottle-nose whale gives, on subjection to saponification and ether extraction, results almost absolutely identical with those yielded by the oil from the true sperm whale, the ether residue varying from 38 to 41 per cent., and the fatty acids from 60 to 65 per cent. In viscosity, behaviour with sulphuric acid, and in fact generally, bottle-nose oil gives results practically identical with sperm oil. It is, however, worthy of remark that the blubber of the sperm whale is commonly boiled down for extraction of the oil immediately after the death of the animal, whereas the bottle-nose oil which has hitherto appeared in the market has been prepared by boiling the blubber after it has arrived in England, and when it has undergone more or less putrefactive change. As a consequence, commercial bottle-nose oil commonly contains from 1 to 2 per cent. of free fatty acid, which causes it to act somewhat vigorously on copper, but when properly refined this objectionable tendency is wholly removed. Such oil would appear likely to prove a very valuable substitute for sperm oil. At the same time it is worthy of attention that in certain cases in which sperm and bottle-nose oil are said to have been used under strictly parallel conditions, the bottle-nose oil has been found defective, but the oil thus found wanting had undergone no refining beyond simple filtration, and was probably more or less rancid. Besides, there is the significant fact that bottle-nose oil has been extensively mixed with or substituted for sperm oil without acknowledgment, and yet the users do not appear to have found fault with it.†

The exact nature of the ether extracts from saponified bottle-nose and sperm oils is an interesting subject for future investigation. The two products differ slightly in fusibility, but appear to be almost identical. They distil at a high temperature, apparently without decomposition, and condense to a liquid as colourless as water, which, on cooling, forms a white crystalline solid. From the ether

fact that repeated treatment is requisite at all is probably due to the very considerable solubility of ether in solutions of soap. Petroleum spirit and chloroform do not readily separate from alkaline liquids.

* *Recherches Chimiques sur les Corps Gras d'Origine Animale*, p. 238.

† The curiously-close resemblance in the chemical and physical characters of sperm and bottle-nose oils renders their anatomical relationship of interest. Huxley classes the true sperm whales (*Physeter*) and the bottle-nose whales (*Hyperoodon*) in the same family of *Physeteridæ*; the dolphin, porpoise, grampus and narwhal belonging to a separate family (*Delphinidæ*).

residue of bottle-nose oil I have obtained a body giving on combustion figures agreeing fairly with the formula $C_{12}H_{26}O$, but this is not the only substance present.*

The oils from the sperm and bottle-nose whales having yielded such curious results, it appeared of interest to ascertain the chemical nature of the oils from other cetaceans. As a preliminary guide the specific gravity of the oil is a useful indication, for while the great majority of fixed oils have a density exceeding ·914, sperm and bottle-nose whale oils show a density of about ·880 only, and hence the gravity may be regarded as showing whether the oil is a glyceride or a liquid wax. On applying this test, it is found that northern and southern whale oils and porpoise oil have a density of fully ·920, and on saponification they yield about 95 per cent. of fatty acids, and only 1 per cent. or so of ether residue. They may therefore be safely regarded as triglycerides. There are, however, two oils known in the market as "shark-liver oil" and "African fish oil." In the former case the name sufficiently indicates its origin, but I am not certain of the animal or animals which yield the latter oil. The basking-shark or sunfish (*Squalus maximus*) is the species from which shark oil is most commonly obtained. As far as I have at present ascertained, "African fish oil" has a constitution similar to that of shark-liver oil. These two oils are fully as light, and even lighter, than sperm and bottle-nose oils. Although in the case of shark-liver oil, at any rate, the oil is not derived from a cetacean, I fully expected it would prove to have a constitution similar to that of sperm and bottle-nose oils. I am not yet prepared to say anything definite respecting it, for the simple reason that it has hitherto resisted every attempt to saponify it. I have tried to effect its decomposition by aqueous potash, by a solution of potash in absolute alcohol, by heating it with solid potash to 200° C., and by treatment with moderately strong sulphuric acid. In some cases the experiments have been made under the ordinary atmospheric pressure, and in others in sealed tubes at temperatures varying from 100° to 150° C. So far I have been unsuccessful; at least the shark oil has yielded over 80 per cent. of unsaponifiable matter to ether. Whether this result be due to the remarkable difficulty of saponifying the oil remains to be seen; but I am inclined to suspect the anomalous behaviour to be due to quite another cause, namely, that the oil consists in large proportion of a body allied to cholesterin, but fluid at ordinary temperatures. That an oily liquid obtained from the liver of an animal should contain a large proportion of a cholesterinoid body is not on the face of it improbable.

(*To be continued.*)

* Cetyl-alcohol produced by the saponification of spermaceti contains $C_{16}H_{34}O$; but there is some evidence that lower and higher homologues are also present. Similarly, the alcohol from bottle-nose oil appears to consist chiefly of $C_{12}H_{26}O$. At the time I read this paper I imagined the discovery of this alcohol, and of the constitution of bottle-nose oil, to be new, but my attention has since been called by Mr. W. H. Deering, to the researches of Scharling, who in 1847 described the oil as consisting mainly of the doeglate of doeglyl, having the composition $C_{12}H_{25},C_{19}H_{35}O_2$. This formula corresponds curiously closely with the proportions of ether residue and fatty acid yielded by the saponification of bottle-nose oil. I intend to make a further examination of the constituents of sperm and bottle-nose oils.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the Annual Meeting of this Association held on Wednesday, May 16, the following Report of the Council for the session ending April 30, was read and adopted.

REPORT.

"The Council has pleasure in presenting the Annual Report of the sixth session. The Association numbers 90 ordinary and 17 honorary members, 55 new members having been enrolled du-ing the session, showing an increased numerical strength of 29 for the current year.

"It is gratifying to note, that the financial position of the Association is highly satisfactory, as will be seen by the accompanying balance sheet.

"Your Council perceives with satisfaction that the departure from the custom of past sessions and the adoption of more frequent meetings have realized its most sanguine expectations; it is enabled to chronicle 22 ordinary meetings, with an aggregate attendance of 508 being an average of 23.

"The issuing of the programme in two parts (Octob and January) has also proved advantageous, and with one exception the papers have been contributed by members of the Association, as follows:—W. Elborne, H. H. Millhouse, F. H. Alcock, H. Cracknell, R. Winfrey, C. E. Stuart, B.Sc., W. A. Wrenn, W. T. Cooper, jun., C. Thompson, C. E. Palmer, C. L. Wyatt, W. R. Dodd, R. W. Giles.

"Five social meetings have also been held, and an evening devoted to the discussion of a resolution approving in the main of the Draft Pharmacy Acts Amendment Bill.

"A Conversazione held at St. James's Hall in November was well attended, and the Annual Dinner held in February, under the Presidency of Michael Carteighe, Esq., supported by Dr. Langdon Down and several leading pharmacists, was successful in a marked degree.

"Your Council, taking into consideration the expense incurred each session by hire of pianoforte, has thought it wise to purchase one, and trusts this addition will be fully utilized and appreciated.

"In conclusion, your Council tenders its sincere thanks to the authors of papers, and to all those who have in any way contributed towards making the session so successful. The primary object of the Association has been in a large degree attained, and it is hoped the incoming Council will receive that support from members generally which will enable it to maintain and augment the usefulness of the Association."

The following gentlemen were elected members of the Council for the ensuing year:—Messrs. F. A. Alcock, J. O. Braithwaite, W. T. Cooper, jun., H. Cracknell, W. R. Dodd, J. H. Hartridge, H. H. Millhouse, C. Parkinson, T. F. Perkins. G. S. Snow, C. Thompson, R. Winfrey, and W. A. Wrenn.

Obituary.

Notice has been received of the death of the following:—

On the 3rd of February, Mr. Nicholas Curry, Chemist and Druggist, Spennymoor, Durham. Aged 24 years. Mr. Curry was an Associate in Business of the Pharmaceutical Society.

On the 15th of May, Mr. William Waples Leete, Chemist and Druggist, Herne Hill. Aged 46 years.

On the 20th of May, Mr. Charles Hadfield, Chemist and Druggist, Mill Street, Macclesfield. Aged 68 years.

On the 20th of May, Mr. Thomas Thompson, Pharmaceutical Chemist, Market Place, Richmond, Yorkshire. Aged 61 years. Mr. Thompson had been a Member of the Pharmaceutical Society since 1850.

On the 24th of May, Mr. William Hutchings Brooks, Chemist and Druggist, Shadwell, E. Aged 49 years. Mr. Brooks had been a Member of the Pharmaceutical Society since 1869.

On the 27th of May, Mr. John Hampton Davies, Chemist and Druggist, Kensington, Liverpool. Aged 38 years.

On the 27th of May, Mr. George Henry White, Chemist and Druggist, Mountain Ash, Glamorganshire. Aged 44 years. Mr. White had been a Member of th Pharmaceutical Society since 1870.

Review.

THE MEDICAL MAN'S HANDY BOOK. Edited by WILLIAM SHEPPERSON. London: J. and A. Churchill.

This is a little compilation for which we see no *raison d'être*. The bulk of the book is made up of a list of incompatibles and a table of doses. Thrown in with these are three tables from Barber and one from Attfield, a posological table for different ages, and some antidotes to poisons.

Mere lists of incompatibles are simply useless. A knowledge of incompatibility should depend upon a knowledge of the principles on which incompatibility depends, and it is often the case that those things which are put down by an author as incompatible are designedly brought together by the medical man who knows his work. Thus in Mr. Shepperson's table we find that "hydrargyri perchloridum corrosivum" is incompatible with iodide of potassium. We venture to say thousands of gallons of mixture containing these two substances are during the year prescribed, and advisedly prescribed, by medical men. What does it matter to the prescriber if iodide of potassium and perchloride of mercury give a red precipitate when mixed in certain proportions? He knows that when mixed in the proportion in which he always prescribes them they will form a clear solution and that that solution has a definite effect. The following are singularly useless statements of incompatibility:—"Cassia fistula with alcohol;" "camphora with strong sulphuric and nitric acids;" "ferri sulphuretum with acids which unite with iron;" "sulphur with boiling solution of soda;" "benzoinum with the acids and alkalies;" "cannabis indica with waters and watery infusions." The author surely does not mean that no preparation of cannabis indica can possibly be prescribed in a watery vehicle.

Another absurdity in the book is making some antidotes absolute which are simply retardants. Thus vegetable astringents are given, without qualification, as antidotes for antimony and its salts, and hydrated peroxide of iron (recently made) for arsenic and its compounds. Soon after this we are told to use the stomach pump for barium and its salts. The only inference to be drawn from this is that a cup or two of tea is all that is required in antimony poisoning and that doses of ferric hydrate given freely destroy the poisonous activity of arsenic.

The table of doses looks useful from the fact that doses of unofficial drugs are given; but its value is greatly impaired by the fact that the strengths of the unofficial preparations, such as tinct. lactucarii, tinct. gelsem. semper., etc., are not given with the doses. The full dose of croton chloral is given as 3 grains. We have much more frequently seen 10 grains prescribed.

The pill excipients are not worthy of notice, excepting perhaps that ung. resinæ is recommended as a pill excipient for ferri et quin. cit. Altogether the book is fairly harmless, but absolutely useless to any pharmacist worthy of the name. It is addressed to medical men, and the editor expresses a hope that it "may find a place among other books of reference on the consulting-room table." We can only hope that our own family doctor's knowledge is not of such a kind that he has to run to a production like this for information.

LECTURES ON PRACTICAL PHARMACY. By BARNARD S. PROCTOR. Second Edition. London: J. and A. Churchill. 1883. From the Publisher.

THE VEGETABLE MATERIA MEDICA OF WESTERN INDIA. By W. DYMOCK. Part I. London: Trubner.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE SALE OF BUTTER OF ANTIMONY.

Sir,—In your issue of June 2, I observe an editorial note calling attention to the case of poisoning by butter of antimony, recorded by me in the *Lancet*, of May 19, in which death followed within two hours after the poison was swallowed.

In the report of the case, I ventured to call attention to the importance of restricting the sale of this corrosive fluid, and mentioned the fact that it was not scheduled under the "Poisons Act." Since then I have been in communication with Mr. Mundella, in reference to the subject, and I have every reason to believe that although as you remark "the Privy Council has recently refused to sanction its introduction into the second part of the schedule," my suggestion will be carefully considered, and probably adopted.

Under present circumstances, it is possible for a farm labourer to purchase for a few pence a sufficient quantity of this dangerons article to poison a mistress or illegitimate child, if he be so disposed, under the pretext of using it for "foot rot" in sheep.

It is a "dynamite" of its own for evil purposes, and may easily be administered to murder unsuspecting persons, in milk, gruel, tea or treacle without their being sensible of its deadly properties.

R. BARRINGTON COOKE,
Consulting Surgeon, Royal Northern Sea Bathing Infirmary.
Scarborough.

THE PURITY OF SODIUM NITRITE.

Sir,—In the "Month," in your last week's issue, you quote, from the *Practitioner* for March, some remarks of Dr. Matthew Hay on the purity of sodium nitrite, which he recommends for angina pectoris. Dr. Hay states that he has some difficulty in obtaining the salt pure, that even when obtained from a London manufacturer of the highest eminence he only found it to contain 33 per cent. of nitrite, and that another specimen only contained a trace.

This experience is the more remarkable because as a matter of fact sodium nitrite is one of the purest salts to be met with in commerce. I buy and use many tons annually and have no difficulty in obtaining it guaranteed to contain 98 per cent. of real nitrite, the 2 per cent. of impurity consisting chiefly of moisture.

Dr. Hay says that the purity of the salt is easily estimated by means of a standard solution of permanganate of potassium. This is, of course, perfectly true, but the estimation gives unreliable results if certain essential precautions, which will readily suggest themselves to the experienced operator, are not taken into account. Even supposing, however, the possibilty of error in the estimation, this will hardly account for the presence of only a mere trace.

With reference to the contemplated new edition of the Pharmacopœia, and considering the purity and cheapness of sodium nitrite as now met with in commerce, I suggest the return to the old process of making spirit of nitrous ether from it as giving better results and presenting other advantages over the present B.P. process.

CHARLES EKIN.

"Inquirer."—(1) *Cardamine pratensis*; (2) Probably *Cochlearia angelica*: send lower leaves; (3) Send another specimen; (4) *Vicia sativa*; (5) *Lathyrus macrorrhizum*; (6) *Asperula odorata*; (7) Send a better specimen, in fruit; (8) *Ballotta fœtida*, probably: send a specimen in flower; (9) *Lotus corniculatus*; (10) *Polygala vulgaris*; (11) *Viola tricolor*; (12) Send a specimen, in flower.

R. Roberts.—Nos. 1 and 2 are named correctly; No. 3 is *Saxifraga granulata.*

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Postans, Davies, Summers, N.D.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 838.)

Oleum Morrhuæ, U.S.P.; Oleum Jecoris Aselli, P.G.—The U.S.P. permits the use of oil derived from other species of *Gadus* besides *G. Morrhua*, L., but without specifying their names. The P.G., on the other hand, gives only *G. Morrhua* as the source of the oil, omitting the other species named in the last edition. The P.G. does not give the sp. gr., but in the U.S.P. it is given as 0·920 to 0·925. With nitric acid the oil should give a purple colour changing to brown. It is said that seal oil has lately been largely used to adulterate cod liver oil, and a test for detecting the presence of it would be desirable in any future Pharmacopœia.

Oleum Myrciæ, U.S.P.—This oil, which forms the chief ingredient in bay rum, is obtained from the leaves of *Myrcia acris*, and is described as a brownish or dark brown liquid, with an aromatic, somewhat clove-like odour and a slightly acid reaction; sp. gr. 1·040. It should be soluble in half its weight of alcohol and form a semi-solid mass with a concentrated solution of potash.

Oleum Myristicæ, U.S.P.; Oleum Macidis, P.G.—The U.S.P. directs that it be obtained from nutmeg and the P.G. from mace, the fatty oil known in this country as oil of mace being the "oleum nucistæ" of the P.G. It should be remembered, therefore, by English pharmacists, that "oleum macidis," when occurring in a German prescription, refers to the volatile oil.

Oleum Nucistæ, P.G.—The P.G. gives as a test of its purity that caustic ammonia should not give a reddish, or, if any, only a slight brownish colour to the pale yellowish tincture made by heating the oil with ten times its weight of spirit and subsequently cooling it. This appears to be intended to detect turmeric, with which an artificial product might be coloured.

Oleum Olivæ, U.S.P.; Oleum Olivarum, P.G.—Both Pharmacopœias give the same sp. gr., 0·915 to 0·918. The elaidin test by which cotton seed and other oils giving a coloured mass with nitric acid may be detected is given. Under *Oleum olivarum commune*, the P.G. gives a test which is apparently intended to detect the presence of crude rape oil. This consists in strongly shaking 5 grams of the oil with 2 drops of sulphuric acid, when the mixture should have a greenish colour, which when the vessel is immersed in boiling water should not turn to black.

Oleum Rapæ, P.G.—Refined rape oil is apparently intended, since unrefined oil would become bluish-black when the sulphuric acid test is applied.

Oleum Picis Liquidæ, U.S.P.—The sp. gr. should be about 0·970, and the oil should be readily soluble in alcohol and have an acid reaction.

Oleum Ricini, U.S.P. and P.G.—The sp. gr. should be 0·950 to 0·970. The U.S.P. states that it should be soluble in an equal weight of alcohol. According to the P.G., it should be soluble in 1 to 3 parts of spirit. Three grams of castor oil mixed with 3 of bisulphide of carbon, and shaken with 2 grams of castor oil for a short time, should not give a blackish brown colour.

Oleum Rosæ, U.S.P. and P.G.—The P.G. does not refer the oil to any particular species; the U.S.P. refers it to *Rosa damascena*, Mill. The U.S.P. gives the sp. gr. as about 0·860, and the other tests given are chiefly those of Baur ('Pharmacographia,' 1st edit., p. 238). The P.G. directs that, when 1 part is diluted with 5 parts of chloroform and 20 parts of spirit added, the spirituous solution should not redden moistened litmus paper, indicating the absence of solid fatty acids soluble in alcohol.

Oleum Santali, U.S.P.—The sp. gr. is given as about 0·945. The oil is to be derived from *Santalum album*. Although this species yields an oil which has been used in native Indian practice for gonorrhœa, the oil which was recommended by Dr. T. B. Henderson, who appears to have been the first to introduced it into medical practice, was derived from *S. myrtifolium* (*Med. Times and Gaz.*, June, 1865, p. 571).

Oleum Sinapis volatile, U.S.P.; Oleum Sinapis, P.G.—As there is a fixed oil of mustard which is occasionally used in embrocations, the designation used in the P.G. is unfortunate. The U.S.P. requires that on heating the oil to 50° C. (122° F.), in a flask connected with a well-cooled condenser, no liquid having the odour and characteristics of disulphide of carbon should pass over.

Ononidis Radix, P.G.—The time for collection of the root (*O. spinosa*) is now omitted.

Phellandrii Fructus, P.G.—The dimensions of the seeds are now added, and the warning against the use of the sub-globular or ovate fruits of *Cicuta virosa* and *Sium latifolium* is omitted.

Pimpinellæ Radix, P.G.—The roots of *P. magna* and *P. Saxifraga* are still official, but the caution against the use of the root of *Peucedanum Oreoselinum*, Moench, and *Heracleum Sphondylium*, L., is now omitted.

Prinos, U.S.P.—Black alder bark, *Prinos verticillatus*, L., is retained from the secondary list, probably in deference to the esteem in which it is held as a domestic remedy for cutaneous diseases and sluggish ulcers. In spite of its name it bears no relation to the alders, although it grows in similar situations, but is nearly allied to the holly.

Prunus virginiana, U.S.P.—*Prunus serotina*, Ehrh., is now given (*Cerasus serotina*, Lois.), instead of *Cerasus serotina*, Dec., as the name of the tree from which the bark is derived. The bark is to be collected in autumn, at which time it contains more prussic acid (*Amer. Journ. Pharm.*, xxiv., iii.), and gives a darker infusion (*ibid.*, July, 1872, p. 304). The bark of the small branches is to be rejected. The bark from the old wood deprived of its corky layer is admissible. The bark is apt to deteriorate on keeping and is best preserved in a tin box or closed vessel.

Pulsatilla, U.S.P.—Under this name the herb of *Anemone Pulsatilla*, L., *A. pratensis*, L., and *A. patens*, L., var. *Nuttalliana*, Gray, are official. The plants should be collected soon after flowering, carefully preserved, and not be kept longer than one year. This remedy appears to have been borrowed from the homœopaths, although the first-named plant is not official in the Homœopathic Pharmacopœia. The attention which has recently been directed to *A. pratensis* and *A. Pulsatilla*, L. (*Practitioner*, July, 1882, p. 32) may perhaps have led to the adoption of the last-named species.

Pyrethrum, U.S.P.—The root of *Anacyclus Pyrethrum*, D.C., is now adopted from the secondary list and a tincture of pellitory introduced. The German pellitory root, *Anacyclus officinarum*, Hayne, is omitted from the new German Pharmacopœia.

QUILLAIA, U.S.P.—Probably introduced on account of its use in certain skin diseases and as an emulsifying agent for oils and oleoresins, etc. (*Pharm. Journ.*, [3], vol. x., pp. 187, 236).

RESINA, U.S.P.; COLOPHONIUM, P.G.—The U.S.P. gives the melting point as 135° C. (275° F.), and the sp. gr. as 1·070 to 1·080. According to the P.G. the sp. gr. is 1·068 to 1·070. American colophony is specially ndicated in the P.G., although that from other sources is admissible.

RESINA COPAIBÆ, U.S.P.—This should be soluble in alcohol, benzol, or amylic alcohol. Its recommendation by Dr. S. Wilks (*Lancet*, June, 1873), as having certain therapeutic advantages over the oleoresin, may have had some influence in obtaining it a place in the new Pharmacopœia.

RESINA DAMMAR, P.G.—This is new to the German Pharmacopœia, and is given as the produce of *Dammara alba* (*Agathis alba*), *Dammara orientalis*, *Hopea micrantha*, *Hopea splendida*, and other trees of southern India. The powder should not soften at 100° C., but should be easily soluble in ether, chloroform and bisulphide of carbon and less so in spirit and petroleum benzin.

RESINA JALAPÆ, U.S.P. and P.G.—The additional tests now given in the U.S.P. are that it is insoluble in bisulphide of carbon, but that one part is soluble in 50 parts of warmed water of ammonia and that the solution when cooled does not gelatinize and remains clear after being supersaturated with acids. The ammoniacal solution quickly evaporated should leave a residue soluble in water. Similar tests are given in the P.G., except that it is there stated that the resin is soluble in 5 parts of warm solution of caustic ammonia.

RESINA PODOPHYLLI, U.S.P.; PODOPHYLLINUM, P.G.—Although podophyllin is now official in the P.G., the rhizome from which it is derived is not so. The U.S.P. now allows the powdered root to be macerated before percolation for forty-eight hours only instead of four days. The quantity of hydrochloric acid to be used in precipitating the resin has been lessened and the resin is directed to be dried by exposure to the air in a cool place. It gives no description of the resin of podophyllin, but states that it is partly soluble in ether, and the residue when dissolved in solution of potash is precipitated by the addition of dilute hydrochloric acid in excess. No use appears to have been made of Messrs. Power's* or Podwissotzki's† researches on the constitution of podophyllin to improve the process for its manufacture, although they have shown that the portion insoluble in ether has no action on the system and that the pains in the intestine produced by podophyllin are due to podophyllo-quercetin and that podophyllotoxin is the active principle. The P.G. describes podophyllin as a yellow powder or loose friable mass of a yellowish or brownish-grey colour, this latitude as regards appearance being perhaps dependent on the researches of Senier and Lowe and others which showed that the colour is in great measure dependent on the fineness of division of the powder and does not affect the physiological activity of the preparation (*Pharm. Journ.*, [3], viii., 444). According to the P.G., at a temperature of 100° C., podophyllin gradually assumes a darker colour, but does not melt; when shaken with water and filtered it gives a liquid almost free from colour, of a bitter taste, turning brown on the addition of sesquichloride of iron. When solution of subacetate of lead is added to it it assumes a yellow colour and slight opalescence, reddish-yellow flocks subsiding after a time. The yellowish brown solution made by dissolving podophyllin in 100 parts of caustic solution of ammonia does not become turbid when diluted with water, but if neutralized deposits brown flakes. The intensely brown solution made by dissolving podophyllin in 10 parts of spirit throws down greyish-brown flakes on the addition of water. Podophyllin should be only partly soluble in ether and still less so in bisulphide of carbon.

RESINA SCAMMONIÆ, U.S.P.—This is omitted from the P.G., which does not now contain the drug in any form. The U.S.P. remarks that it is entirely soluble in ether and dissolves in solution of potash, and the heated solution is not precipitated by the addition of hydrochloric acid.

RHAMNI CATHARTICÆ FRUCTUS, P.G.—The distinction between the fruits of *R. Frangula* and *R. cathartica* is now omitted.

RHEUM, U.S.P.; RADIX RHEI, P.G.—In both the U.S.P. and the P.G. rhubarb is now stated to be the produce of *Rheum officinale*, Baillon, and other undetermined species, by which and by the accurate description of Chinese rhubarb it may be supposed that the cultivated rhubarbs of commerce are intended to be excluded, although the wording apart from the description would leave the dispenser at liberty to use any rhubarb of unknown source. The "white, elongated meshes," characteristic of Chinese rhubarb, may be sought for in vain in the *Rheum officinale*, as cultivated in this country. The directions forbidding the use of Austrian or English rhubarb are now omitted from the P.G., being apparently deemed superfluous when Chinese rhubarb is directed to be used.

RHUS GLABRA, U.S.P.—The gender of the specific name is now changed from the neuter to the feminine, and a short description of the fruit, which is the part of the plant used, is now given. The drug was in the secondary list in the last edition.

RHUS TOXICODENDRON, U.S.P.—This has been retained from the secondary list of the last edition, where it appeared as *Toxicodendron*. From the P.G. it is now omitted. *R. radicans*, L., which differs in having entire and glabrous leaflets, is also official. The leaves of these species should not be confounded with those of *Ptelea trifoliata*, which have sessile leaflets. The drug is apt to lose its properties when kept.

ROSA CENTIFOLIA, U.S.P.; FLORES ROSÆ, P.G.—The U.S.P. remarks that when it is desired to keep fresh "pale rose" for some time, it may be preserved by mixing it well with half its weight of chloride of sodium, pressing the mixture into a suitable jar, and keeping it well closed in a cool place.

ROSA GALLICA, U.S.P.—Not official in the P.G. In the U.S.P. the petals are now directed to be collected before expanding.

RUBUS, U.S.P.—The bark of the root of *Rubus trivialis*, Mich., as well as of *R. villosus*, L., and *R. canadensis*, is now official.

RUBUS IDÆUS, U.S.P.—The fruit of this species is one of the additions to the United States Pharmacopœia. The closely allied light red fruit of *R. strigosus*, Mich., and the purplish black fruit of *R. occidentalis*, L., may be employed in place of the

* 'Proc. Amer. Phar. Assoc.,' 1877, p. 420; *Amer. Jour. Phar.*, 1878, p. 369.

† *Ph. Journ.*, [3], xii., pp. 217, 1012.

above. The official preparation is a syrup, but it would be scarcely politic to use the purplish syrup of *R. occidentalis* in a mixture in which the red syrup of the other species had previously been dispensed. In any case it would be advisable for the prescriber, in order to prevent doubts arising, to indicate which syrup he intends to be used.

Rumex, U.S.P.—This is retained from the secondary list of the last Pharmacopœia. A description is given, which, it may be supposed, refers only to the root of *R. crispus*, but other species are also now official.

Sabina, U.S.P.—A description is now given, but the time for collection of the tops is not indicated.

Salix, U.S.P.—Other species besides *Salix alba*, L., are now official, but a description is given which may be presumed to apply to the bark of *S. alba* only.

Salvia, U.S.P.; Folia Salviæ, P.G.—The time of collection (before the plant opens its flowers) is now omitted from the P.G.

Sambucus, U.S.P.; Flores Sambuci, P.G.—The flowers of *S. canadensis*, L., are official in the U.S.P., but in the P.G. those of *S. nigra*. The latter should not be of a brown colour.

Sanguinaria, U.S.P.—A fluid extract prepared from the rhizome of *S. canadensis*, L., is now added to the official preparations, and a description of the crude drug is given.

Santalum rubrum, U.S.P.—The drug should not impart any red colour to water when macerated in it. It is to be regretted that the erroneous name of *Santalum* should be perpetuated, more especially as the drug itself is hardly ever ordered in prescriptions, and that there is therefore less reason for the retention of the name.

Santonica, U.S.P.—The botanical source is now stated to be *Artemisia maritima*, var. *Stechmanniana*, Besser, and a description of the drug is given.

Sarsaparilla, U.S.P.; Radix Sarsaparillæ, P.G.—The root of *S. medica*, Schlecht, is now official in the U.S.P. as well as that of *S. officinalis*, Kth., and other species. In the P.G. Honduras sarsaparilla is official, but no botanical source is given. Both Pharmacopœias direct that the rhizome should be rejected.

Sassafras, U.S.P.—A description of the official parts, which are the root-bark and pith, is given. The mucilage obtainable from the pith should not be precipitated by alcohol.

Scammonium, U.S.P.—Ether should dissolve at least 75 per cent. of the drug. Scammony is stated to yield a greenish emulsion when triturated with water.

Scilla, U.S.P.; Bulbus Scillæ, P.G.—*Urginea Scilla*, Steinheil, is now given in the U.S.P., and *Urginea maritima* in the P.G. as the botanical source of the drug.

Scoparius, U.S.P.—Koch is now given as the authority for the botanical name, *Sarothamnus scoparius*, instead of Wimmer, and a description of the twigs is given.

Scutellaria, U.S.P.—A description of the plant, *S. lateriflora*, L., is now given. The drug, which was official in the secondary list of the previous Pharmacopœia, appears to have increased in estimation, since a fluid extract of it is now official. It is highly appreciated as a nervine tonic in domestic medicine in the United States, and by herbalists in this country.

(*To be continued.*)

RECENT PROGRESS IN THE OZOKERITE INDUSTRY IN THE EAST.*

BY E. SAUERLANDT.

Ozokerite or mineral wax frequently accompanies petroleum, and traces of it are found in many places in Eastern and Western Galicia, and in the Caucasian and American petroleum territory, but it is rarely found in such quantities as to furnish a remunerative source of this valuable mineral. It is highly probable that many more workable deposits of ozokerite will be discovered yet, but hitherto the discovery of deposits that yield paying quantities have been so rare that we are greatly pleased to be able to announce that the past year did not pass without some success in this direction.

At the baths of Truskawiec, some five miles from Boryslaw, a deposit of this substance was found at a slight depth, of such extent that 50 tons have already been taken out and sold. The wax contains sulphur, and hence the oils produced in making paraffine from it must be used with some special precautions. This discovery of ozokerite in Truskawiec is the more interesting because Leo Strippelmann several years ago, in his well-known work on the petroleum industry of Galicia, had referred to this place as particularly worthy of examination for the occurrence of ozokerite.

The same mineral is also reported as occurring in the neighbourhood of Agram in Croatia, and investigations made there have proved the existence of deposits of considerable extent and tolerable thickness. Whether the hopes based thereon will be actually realized, the future must decide. At all events, this notice and the announcements of recent discoveries of ozokerite in Russia, must be received with caution, for such announcements have frequently been made and no important results followed.

Other places in Eastern Galicia which may be looked upon as sources of ozokerite, besides Truskawiec, are Boryslaw, Dwiniacz, and Starunia, with Boryslaw at the head as hitherto. In all three of these places the wax is found in Miocene clay shales and clay marls with the intermediate sandstone, and frequently it accompanies rock salt and gypsum. While shafts have been sunk in Boryslaw to the depth of 200 metres (nearly 700 feet), they have not penetrated deeper than 30 or 40 metres (100 or 130 feet) in Starunia and Dwiniacz.

In Boryslaw the majority of the shafts are at present in the possession of three large companies, the oldest of which, "The French Mineral Wax and Petroleum Society," has been in existence for years, while the "Lemberger Credit Bank" and the firm of Gortenberg, Liebermann and Co. have commenced operations within the past year by the purchase of numerous shafts. In the first half of last year the first-named society could point to a large production, but they have almost completely exhausted their present horizon and are now going deeper, but with a smaller yield. The two other societies had, and still have, to contend with the drainage of their long-neglected shafts, and hence their production is not as large as could be desired.

In Boryslaw-Wolanka the production of mineral wax in the year 1882 was less than in the preceding year, but in view of the difficulties to be overcome, it must be considered relatively speaking as favourable, and cannot be much less than that of 1877, which was 8300 tons.

The price fluctuated from January, 1882, when it was $27\frac{1}{2}$ Austrian florins (about £2 15*s.*) per 100 kilos, to 25 florins in May, then steadily rose until the highest point ($31\frac{1}{2}$ florins) was reached in November, and there it remains. It is very questionable if the manufacturers can use it profitably at this price, and several establishments have already imported American paraffine to take its place, and with good results. As it may be expected

* From the *Chemiker Zeitung*. Reprinted from the *Scientific American*, May 19, 1883.

that the production of ozokerite will increase in the immediate future, we may predict a fall in the price.

Dwiniacz and Starunia yield about 25 tons per month, which at present prices pays well.

Before passing to the method of working it up, we must first consider how it is obtained, as one of the methods yields a product already partially purified. We refer to the extraction of the wax from the gangue called "lep." By melting it under water the greater part of the ozokerite is removed, but the residue still contains as much as 12 per cent. of wax. These residues collect in enormous quantities, and hitherto were only considered as a nuisance, although the wax still in them represented an enormous capital. It is surprising that this capital was allowed to lie idle so long. It cannot be due to the small quantity of wax in it, because at the Brown coal works in Halle it pays to work coal which only yields 10 per cent. of tar, or 12 to 15 per cent. of tarry resins. The cause may be sought chiefly in the difficulty of working the residues, since the high price of fuel prevents them being liquated or distilled on the spot, and there is no suitable apparatus for extracting so dense a substance as clay and shale. According to the *Neue Freie Presse*, an ozokerite mechanic made an apparatus in 1879 that would make 6600 to 7700 pounds of pure wax from ten times that quantity of ore daily, yet this apparatus of the unnamed workman has never been in operation.

In the past year J. Merz, in Boryslaw-Wolanka, first succeeded in working these residues in his extraction apparatus, which has been patented in most countries. If the extractors now in use have not been constructed on so large a scale and capable of so large a daily yield as the one made in 1879, they have the undeniable advantage that they work, not merely on paper, but in reality.

About one-third of the ozokerite that comes into the market is worked into paraffine, and two-thirds into ceresine. The use of mineral wax for making paraffine has increased, especially in Galicia, and here, too, distillation in superheated steam is commonly employed. A large portion of the paraffine made is consumed there for making the Sabbath candles used in their religious rites by the Jewish inhabitants. It is not so carefully purified for this purpose as is done elsewhere.

The Galician factories for the most part refine the largest possible quantity (50 to 70 per cent.) of the waxy distillate directly with fuming sulphuric acid and without pressing it. Of course the resulting paraffine is not free from oil, but it is tolerably white in colour and useful for the purpose mentioned.

Very little has been made public concerning improvements in making paraffine from ozokerite, and manufacturers keep their experience as secret as posible.

In 1881 E. Van Haecht and J. Schreier obtained a patent for purifying paraffine by blowing out the contaminating oils with superheated steam. It can be used for paraffines containing as an impurity light oils, as is the case, in careful distillation, with the first portion of the wax distillate and só long as the paraffine already present in the wax goes over undecomposed. The crude paraffines resulting from the decomposition of resinous bodies, as for example in the dry distillation of brown coal, or of the resin obtained by distilling ozokerite, cannot be purified by this method, as they contain oils specifically heavier than and often having as high a boiling point as the paraffine itself.

In 1881, H. Ujhely took a patent for refining and hardening paraffine. According to the English specification, the crude paraffine was melted with a mixture of petroleum benzine, and alcohol (methylic, ethylic, or amylic), and after cooling slowly it was expressed. The advantages gained in this way over the common use of benzine (photogen) alone, in our opinion, consists merely in obtaining an oil more free from paraffine, since paraffine is considerably less soluble in alcohol than in benzine. Whether this is sufficient to counterbalance the disadvantages of working with alcohol, we will not attempt to say. We know, however, that in 1873 a paraffine factory added fusel oil to the paraffine for pressing, but after a few months returned to the use of benzine.

The yield of paraffine is essentially increased when superheated steam is employed in the distillation of the ozokerite, and in working a wax suitable for making paraffine it amounts to 60 or 70 per cent. Hence we can no longer adhere to the data hitherto published, which place the limits at 36 to 50 per cent.

In making ceresine the chief improvements consist in a profitable utilization of the residues. Two methods are chiefly employed in the factories themselves. The first and simpler consists in heating the ozokerite with fuming and common oil of vitriol to 200° C. (392° Fahr). until the greater part of the acid is removed either by decomposition or evaporation, and then treating it at a suitable temperature with neutralizing and decolorizing agents such as alumina, silicates, bone coal, the refuse of prussiate factories, etc. By the second method the resinous and discolouring constituents of the wax are also removed with acid, but at a relatively low temperature, thus avoiding so thorough a decomposition.

To bleach ozokerite perfectly on a large scale without the use of acids has as yet remained an unfulfilled desire, although in 1879 a method for accomplishing it was announced as a new discovery of H. Ujhely in Vienna. Without going into a discussion of priority, we must remark that George Gwynne in his English patent of 1871 for "treating fatty and hydrocarbon bodies," etc., describes a process for bleaching ozokerite which possesses a striking resemblance to that of Ujhely. Gwynne removes the mechanical impurities and then dissolves it in benzine, filters through bone black, and removes the solvent by blowing in air. This method is identical in principle with Ujhely's. Gwynne did not obtain any practical results, nor has Ujhely, nor Ofenheim, who took a patent on the same thing in 1879. The statement made then, that a factory was being built with a large apparatus on Ujhely's system, was based on facts; but it must be added that the building stopped before it was finished, and that the unfinished building has been in that state for two years, while the large apparatus remains in the workshop awaiting payment by the man who ordered it.

Even if the difficulties that beset the working of Ujhely's patent on a large scale were overcome, and the consumption of decolouring agents reduced to a minimum, the product obtained would find only a very limited field of sale. Ujhely's "bleached mineral wax" would not be in much demand as an independent illuminant, owing to the large quantity of oxygenated resin in it, most of which is removed by the present method of treating it with sulphuric acid.

Finally, we may be permitted one short remark about a circumstance which has hitherto received too little attention.

Ceresine and paraffine are largely employed, as everyone knows, for adulterating beeswax, and the methods in use for the detection of such adulterations are frequently based upon a determination of the specific gravity of the specimen in question. A short time ago a table was published (*Chemiker Zeitung*, vi., page 74), giving the specific gravity of different kinds of wax and their mixtures, but in our opinion it is of very little use because it sets out with false premises in assigning a definite specific gravity to paraffine and ceresine. The specific gravity varies from 0·869 for that which melts at 100° Fahr. to 0·943 for that melting at 180° Fahr., as was shown by the author as early as 1878.

The following table shows the melting points of ozokerite paraffine:—

Solidifying points.		Spec. gravity.
56° C.	133° F.	0·912
61° „	142° „	0·922
67° „	153° „	0·927
72° „	162° „	0·935
76° „	169° „	0·939
82° „	180° „	0·943

Since the specific gravity of paraffines that solidify at different temperatures is different, ozokerite and the ceresine made from it must differ in specific gravity. Then we must consider that commercial ceresine frequently receives an addition of paraffine, resin, carnauba wax, etc., by the manufacturers themselves.

ALGIN: A NEW SUBSTANCE OBTAINED FROM SOME OF THE COMMONER SPECIES OF MARINE ALGÆ.*

BY E. C. C. STANFORD, F.C.S.

(Concluded from page 1022.)

The following samples are from a considerable bulk of mixed salts evaporated:—

Analyses of the Salts.

	Laminaria Stenophylla.	Fucus Vesiculosus.
Calcium sulphate	1·69	4·33
Potassium sulphate	11·29	23·62
Potassium chloride	19·90	13·71
Sodium chloride	60·96	58·20
Magnesium chloride	4·35	—
Sodium carbonate	·53	—
Sodium iodide	1·26	·12
	99·98	99·98

In the following tables the composition of the salts is shown as they come out in six successive macerations in cold water.

The residues are always carbonized, and then washed and again ignited—that being the only way to insure perfect combustion in the presence of such an excess of saline constituents.

Laminaria Stenophylla—Air dried, containing 14·8 moisture. 4 oz. = 1750 grains. Six macerations in cold water—all evaporated, and residues weighed:—

	Grs.	Per cent.	Grs.	Per cent.

	100·06	5·2400

After the salts have been removed, the weed is bleached by a weak solution of chlorinated lime, about 2° Twad. The laminaria bleaches easily in a few hours, but the fuci require prolonged and repeated treatment. I would call attention to the extreme beauty of some of the algæ when thus bleached; even in the common *Fucus vesiculosus*, or black wrack, you can trace the spores in the cells and the lining of the air-vessels. The specimen of *Sargassum bacciferum* (gulf weed) is beautifully transparent. Other specimens shown are *Laminaria digitata*, stems and fronds, the former looking like sticks of ivory, *L. stenophylla, Fucus nodosus, F. serratus, Aliaria esculenta, Halidrys siliquosa, Rhodomenia palmata, Rhodomela pinnastroides, Zostera marina, Enteromorpha compressa*, etc. When sufficiently white, the weed is soured by a very weak solution of sulphuric or hydrochloric acid, and well washed. If the acid be added with the bleach the action is quicker. It is then acted on in the cold by about a tenth of its weight of sodium carbonate for twenty-four hours, then heated, filtered, and evaporated. The residual cellulose is pressed into cakes for use as a paper material. It is already bleached, and has only to be put at once into the paper beater. There are plenty of fibrous materials in the market, but there is no real substitute for rags, as, I believe, this will to a great extent prove to be.

The whole of the plant is thus accounted for; in the laminaria, the average yield is as follows:—

On the air-dried plant—

Extracted by water	30
Extracted by acid	5
Extracted by sodium carbonate = algin . .	35
Cellulose	10
Moisture	20
	100

This plant is the only one now employed in making kelp; the least exposure to rain washes out the salts, and renders it useless for this purpose. It does not, however, interfere with its use for extracting the algin, which is insoluble in water. For this purpose, if the salts are sacrificed, it is improved by exposure to rain and light. The wet weed, however, keeps perfectly well if access of air be prevented, for instance in a properly constructed "silo," and there is no reason that any of it should be lost.

Applications of Algin.

Algin has properties which should make it useful for several applications in the soluble form. As a stiffener of fabrics, although not so rigid as starch, it fills the cloth better, is tougher, more elastic, and more transparent. It mixes in all proportions with starch and dextrine, and imparts to the mixture these properties. Unbleached, it forms a cheap material for dressing winseys and such dark goods. Passed through an acid bath, the coating becomes glossy and insoluble, and thus a vegetable mordant is available for dyeing. Lime-water, and salts of calcium, barium, and several metallic salts, may be employed for a similar purpose; one of its peculiarities being the ease with which it is rendered insoluble.

I shall only just refer to its probable value as a food material on account of its nitrogenous character, as I have no edible specimens on the table which can be passed round for immediate consumption. As a cattle food there is a large opening for such a material. The agglutinating power of algin enables us to convert into solid blocks many substances which are with difficulty made to cohere. Silica, lime, magnesia, oxide of zinc, phosphate of lime, alumina, chalk, plumbago, charcoal, and many other such substances can be converted into solid hard blocks. All of these and many more are exhibited. Some of these compounds may be made by mixing the algin with a solution, where both form a joint precipitate with another solution — *e.g.*, sodium silicate, and calcium chloride. One application of this agglutinating character has already assumed importance. Charcoal has been long known as our best solid non-conductor of heat, and no doubt it would have been employed long ago as a covering for our steam-boilers, had any medium been known capable of agglutinating it. That is now attained by this substance. My "carbon cement,"* for this purpose, contains 97 per cent. of charcoal, 3 per cent. of algin being sufficient to make it cohere; and as that charcoal is made from seaweed, it is a remarkable fact that the whole covering is derived from that material. My friend Mr. Spiller, a high authority on the subject, has also found the solution of algin the best thing yet discovered for arresting incrustation in steam-boilers. We are not much troubled with this in Glasgow, but in the south, where the waters are hard, many such fluids are employed. Most of these are organic compounds combined with alkalies. One of the earliest and best was introduced some years ago by Mr. Spiller himself, and I am entirely indebted to him for suggesting the application of algin to this purpose. He speaks of it as highly efficient in precipitating the lime in such a fine state of division that it can easily be blown off from the cock. So that we now propose seaweed in one form or other as a most comfortable internal and external application to our steam-boilers. In fact several large steamers are already ploughing the ocean, assisted in their daily conflicts with heavy seas by weapons borrowed from these opponents.

The insoluble form of algin is very like horn, and as it can be pressed into moulds of any size it may be used instead of that article.

It also appears to be an excellent non-conductor of electricity, and in combination with certain other substances may assist in providing the cheap non-conducting material, which shall be impervious to moisture, now so much required for underground telegraph and telephone wires.

It is an efficient agent for emulsifying oils, and, being coagulated by alcohol, for fining wines and spirits.

These are some of the probable applications of algin, and, seeing that the substance is new, and the source abundant, I shall not be bold enough to predict what it may *not* be used for.

PHARMACEUTICAL PREPARATIONS OF CORN SILK.†

BY GEORGE W. KENNEDY, PH.G.

During the past year several physicians of Schuylkill county have been using different preparations of the stigmata of Zea Mays for catarrh of the bladder and similar diseases, with very good results. The preparations should be made from the fresh article, as the dried seems to be worthless, at least that is the experience of those who have had the subject under investigation; cases under treatment, which were not benefited by the powder or other preparations made from the dried article, yielded to a tincture prepared from the fresh or green stigmata. It would be advisable to gather the drug before it begins to change in colour, or select only that portion having a green or greenish-yellow colour. The writer manufactured a quantity of the tincture last September, which has all been prescribed and used by our physicians, and is now compelled to purchase the fluid extract to supply the demands. One of our medical practitioners, who is very particular, has great confidence in the curative properties of corn silk; his choice of all the preparations is the syrup which I have made and would recommend to be made from the fluid extract. This is an expeditious mode of making the syrup, and one which is entirely satisfactory, the syrup containing only a very small percentage of alcohol. The diseases for which corn silk is recommended are of such a nature — generally of an inflammatory character — that the patient should not use alcohol in any form, because it produces irritation, and irritants should be left out of the preparations as much as possible.

Should the drug prove to be as valuable a remedy as some medical men consider it to be, there is no doubt but its use would become general. Either the fluid extract or the syrup, or both, would be the best preparations to recommend for introduction, although the tincture gave fair satisfaction; yet I do not believe it to be the most suitable preparation.

It should be remembered that the fresh drug contains a large amount of moisture; it contains certainly not less than 50 per cent., and likely considerably more. I would suggest that not less than double the quantity of the drug be used; for example, if 100 parts of syrup or tincture was to represent 12 parts of the dried material, then 24 parts of the fresh or green corn silk should be used. I would recommend the following formulas: —

Tincture of Corn Silk.

Take of—

Corn silk, green, twenty-four parts . . .	24
Diluted alcohol, sufficient to make one hundred parts	100

Cut the silk into small pieces, either with a large pair of scissors or a tobacco cutter; after which, place in a mortar and beat into a pulp with a small quantity of the diluted alcohol. Prepare a cylindrical glass percolator, by closing the lower orifice with a cork; transfer the silk pulp to the percolator, and add sufficient of the menstruum to form a layer over the pulp; cover the percolator closely and allow to macerate for forty-eight hours; then loosen the cork enough to permit percolation to proceed at the rate of 40 drops per minute; add enough diluted alcohol and continue the percolation until 100 parts are obtained. The tincture possesses the characteristic odour of corn silk, is of a yellow-straw colour, and of a pleasant, sweetish taste. Dose for an adult, 1 or 2 fluid drachms (gm. 4 to 8).

Fluid Extract of Corn Silk.

Corn silk, green, two hundred grams . .	200
Glycerin, twenty grams	20
Diluted alcohol, a sufficient quantity to make one hundred cubic centimetres .	100

Cut the silk into small pieces. Mix the glycerin with 80 grams of diluted alcohol. Place the cut corn silk into a mortar, and beat into a pulp with a portion of the menstruum; after which, pack in a cylindrical glass percolator; add sufficient of the mixture to cover the pulpy mass, and when the liquid commences to drop

* Carbon cement forms a very light, inodorous, and cheap material for covering steam-boilers. Over 20,000 square feet have already been applied to boilers and piping.

† From the *American Journal of Pharmacy*, May, 1883.

from the percolator close the lower orifice; cover the percolator tightly, and allow to macerate for forty-eight hours; then permit percolation to go on slowly, about 40 drops per minute; add the remainder of the glycerin mixture, and then diluted alcohol until the drug is exhausted, reserving the first 70 cubic centimetres of the percolate; evaporate the remainder to 30 cubic centimetres, and mix with the reserved portion, making in all 100 cubic centimetres. The odour and taste is similar to that of the tincture, but much stronger, and the colour is a shade or two darker. Dose for an adult, from ½ to 1 fluid drachm (gm. 2 to 4).

Syrup of Corn Silk.

Fluid extract of corn silk, twelve parts	12
Syrup, eighty-eight parts	88
To make one hundred parts	100

Dose from 1 to 2 fluid drachms (gm. 4 to 8).

CALCIUM IODIDE.*

BY R. ROTHER.

As there are always new medicinal agents coming into use which are not often found in the market until the demand becomes quite general, the pharmacist is occasionally called upon to exercise the primitive function of preparing compounds obtainable in no other way. For such and similar cases only, the Pharmacopœia gives processes, in connection with those that are pre-eminently pharmacopœial. These are, however, rapidly improved in most cases, so that the early official method is not always the best after a ten years' period of general progress.

Calcium iodide is one of those compounds occasionally called for, which is not generally kept nor very easily prepared in a proper form. When caustic lime is triturated with iodine, a peculiar black combination is obtained in which chemical union of some kind is exerted. Similar compounds are produced when dry iodides are mixed with iodine in a like manner. Some of these bodies are soluble in alcohol, and then yield crystals of definite superiodide even of the monad metals. Water decomposes them, however, with the liberation of iodine. On boiling the black calcium oxide and iodine compound with water, a colourless solution of calcium iodide and iodate is obtained, whilst the excess of lime remains as hydrate. There is no convenient way of separating these salts, neither is the reduction of the attendant iodate practicable. Hence this process does not answer for the preparation of calcium iodide.

Calcium iodide may be prepared by dissolving calcium hydrate, or better, carbonate in hydriodic acid. The difficulty in this case is the preparation of the acid by a practical and convenient method, which so far has not been found. The usual process for preparing calcium iodide consists in decomposing ferrous iodide or ferric iodide with calcium hydrate. In the first instance the iron is precipitated as ferrous hydrate, and in the second as ferric oxy-hydrate. Both precipitates are excessively bulky, and require much washing to secure all of the generated calcium iodide. A correspondingly large volume of water will then have to be evaporated.

The process which embodies the most advantage consists in decomposing ferric iodide with calcium carbonate. In this case the iron is precipitated as the compact non-gelatinous ferric hydrocarbonate, according to the following reaction :—

$$2(FeI_3) + 3(CaCO_3) + 2(OH_2) = 3(CaI_2) + Fe_2CO_3(OH)_4 + 2(CO_2).$$

* From the *American Journal of Pharmacy*, May, 1883.

A very concentrated solution of calcium iodide is thus obtained, which cannot be properly filtered through paper in an undiluted condition. Its destructive action upon the paper results in soluble coloured products, which interfere with the whiteness of the dried salt. The affinity of calcium iodide for water is so great that when a very concentrated solution of it is mixed with an equally strong solution of dipotassic carbonate, no double decomposition occurs, but the potassic carbonate separates as a gelatinous magma. No calcium carbonate results until more water is added, when the calcium is immediately thrown down as white carbonate.

The calcium iodide on evaporation of its solution is obtained as a white or colourless crystalline salt containing water. The solution must be concentrated until a dense pellicle forms over the surface. The fused mass is then poured on a smooth surface and well covered to prevent deliquescence. On cooling, the salt is readily detached in large fragments. These may then be broken into smaller pieces and preserved in well-stopped bottles. Large, shallow capsules or ordinary dinner plates with bright smooth surfaces are the most suitable vessels for cooling the fused salt. During this part of the operation it is essential that moist air be excluded to prevent deliquesence. For this reason the salt is best dried under a bell-glass over sulphuric acid.

In the preparation of calcium iodide the use of iron filings is not admissible, because of the large amount and the peculiar form of the carbon contained in them. In this instance, a yellow organic acid is generated, which yields colourless ferrous salts and orange ferric salts not precipitable by calcium carbonate, but decomposable by calcium hydrate. The resulting calcium salt of this acid is also orange tinted, but is destroyed on fusion of the iodide, the carbonaceous residue imparting to this a greyish, unsightly appearance. Re-solution of the fused mass and filtration of the solution now produces a colourless salt. Iron wire also contains some carbon, but in a different state of combination, so that none of the peculiar acid is produced. With its use the iron is wholly precipitated by calcium carbonate, even in the presence of excess of iodine, and a white salt is directly obtained on evaporation. The contact of organic matter must, however, be carefully prevented in the manipulation, and the filtration of a too concentrated solution through paper must be avoided.

From these considerations, the following formula is derived:—

Iron in fine wire	56 parts.
Iodine	381 „
Calcium carbonate	150 „
Water sufficient.	

Mix 56 parts or any moderate excess of iron wire with 1200 parts of water and 254 parts of iodine gradually added. When the reaction is completed and a light green solution is obtained, filter this and add to it the remainder of the iodine. Then, when this has all dissolved with the formation of a brown-red solution, add the calcium carbonate (150 to 160 parts) by degrees, and warm the mixture when the effervescence slackens, until the evolution of gas has ceased and all the iron is precipitated. Let the dense precipitate subside and decant the supernatant liquid. Mix the residue with enough water to restore the original weight; let subside, and again decant. Mix the two decantates, pour the solution upon a filter, and when all has passed through, pour the sediment into the filter and wash it with water until practically free from calcium iodide. Unite all the filtrates and evaporate the mixture until a dense pellicle forms over the surface and boiling continues only at a narrow vent. Now pour the fused salt into a shallow plate of suitable size, cover it well, and when cooled, detach the hardened mass, break it up and preserve it in well-stopped bottles.

PROVIDENT DISPENSARIES AND PHARMACY.

THE occurrence of "Hospital Sunday" in the metropolis since the issue of the last number of this Journal has been the occasion of many earnest appeals and not illiberal responses on behalf of the sick poor of this great city. As a result many of the noble institutions of which the dwellers in London have just reason to be proud will receive timely help in tiding over financial difficulties such as are almost necessarily the chronic accompaniments of their every-day work. No one with a human heart would think of saying a word that would tend in the least degree to check the outflow of benevolence towards the vast amount of helpless suffering that is to be found on every side; and all will rejoice should it turn out that contributions this year reach a larger amount than in any previous year since this movement has been started. But many who will have done all that lies in their power to meet the urgent necessities pressed upon them, will know that there are some very unsatisfactory features recognizable in the hospital system, or perhaps, more correctly, want of system. One of these, in which the readers of this Journal are not very remotely interested, is the extent to which people of the working class, and even some of the tradesman class, are becoming educated to seek and receive medical advice and medicine gratuitously, long before the pinch has been reached at which, with a proper amount of self-respect, they would allow themselves to enter into competition with the really destitute for a share in available charitable medical relief. We use the word "educated" advisedly, because not only is that the tendency of the free and frequently indiscriminate relief which, up to a certain point, can be obtained by almost everybody that chooses to ask for it, but the practice is also sometimes inculcated by the very language in which appeals for subscriptions are couched. This point was well illustrated recently by the *Lancet*, when alluding to an appeal on behalf of a well-known metropolitan hospital, which was based on an assumption that it was necessary to provide for the medical relief of a number equal to the whole population of the quarter of the metropolis in which the institution was situated. Nevertheless, it was estimated that amongst that population there were at least as many persons capable of subscribing five shillings a year as might thus make up a sum more than double the amount of the entire ordinary subscription of the hospital. Whilst, however, the number of patients receiving free relief in this particular district goes on increasing rapidly, attempts to cultivate more self-reliance in this direction among the working classes in the district have not been successful, and in the words of a clergyman who has made the trial, "it is hopeless to expect that they will put "aside even a penny a week for medicine and a "doctor's attendance when they can obtain as much "for the mere asking."

Like the results from most evil practices the influence of this demoralization, for such it undoubtedly is, cannot be confined to those with whom it originates; in fact its effects upon the practice of medicine, as well as of pharmacy, are most injurious. It is in just the localities where it obtains that medical men are to be found eking out an insufficiency of inadequately remunerated practice by dabbling in a business for which they have had no training and competing with neighbouring chemists—not for the dispensing of prescriptions, since there are none—but for the privilege of supplying the public with drugs and chemicals and even the "et ceteras" which are looked upon as excrescences of the chemists' stock-in-trade. In doing so they assimilate their establishments in every respect to a shop, and obliterate every characteristic feature that would help the general public to distinguish between the doctor and the druggist. It is not, therefore, surprising that, as one result of this confusion, the British workman, and many above him in the social scale, should fail to discriminate between the "doctor" who is always to be found behind his coloured bottles and the "doctor" who goes out visiting, or that they should resort to the chemist's shop for remedies in such cases of illness as do not seem to them to necessitate the loss of time involved in attendance at a hospital or the expense consequent upon consulting a regular medical practitioner. Neither is it to be wondered at that the chemist in the absence of occupation with his legitimate work, and pressed by the trade competition of his medical neighbour, should sometimes put a rather wide construction on the phrase "simple ailments." At any rate it is in respect to districts where the barriers between medicine and pharmacy are thus thrown down that complaints are loudest from medical men concerning what they are pleased to term "chemists' prescribing." In saying this we do not lose sight of the fact that for the existing confusion between medicine and pharmacy the "apothecaries" are largely responsible, in that their acquisition of the privileges of the medical profession did not induce them to curb more effectually their trading instincts. For this reason we are inclined to think that some of the arguments used in the recent petition of the Society of Apothecaries to Parliament for reinstatement on the Divisional Medical Board, especially those relating to the supply of medicine, were just such as should militate against the granting of the request.

There is no immediate prospect of pharmacists in Great Britain obtaining the same amount of protection as is afforded their *confrères* in down-trodden Ireland, where the right of a medical man to dispense prescriptions is strictly limited to the dispensing of those written by himself. It is true that, as may be seen from a report on another page, just now the continuance of this protection is endangered by an alteration made in the Medical Bill now before the House of Commons during its passage through the upper House; but the committee of the Irish Pharmaceutical Society that has the business in charge will probably—*more Hibernico*—succeed in impressing Parliament with the justness of its claims. But British pharmacists can only hope to attain at some future day to the privileges already enjoyed by the pharmacists of the sister isle. Meanwhile, we are glad to welcome any movement that, by helping to diffuse sounder notions among the public as to the reasonable remuneration of medical services rendered, will also tend to remove the conditions which are so detrimental to the best interests of medicine and pharmacy; for we are strongly inclined to believe that every retrogression from the questionable position taken up by many medical practitioners upon the domain of pharmacy will be at least balanced by an equal abandonment of doubtful points by pharmacists. It will probably be only in proportion as medical men find themselves able to confine their operations within the limits to which their studies have been particularly directed, and pharmacists are left to do the work for which they are specially qualified, that the jealousies and bickerings concerning "counter prescribing" *et hoc genus omne* will disappear.

As indirectly promoting the attainment of this end we think it is very satisfactory to find that considerable progress has been made lately in establishing self-supporting medical institutions for the industrial classes in London under the auspices of the Provident Medical Association. At a meeting of the supporters of this movement, recently held at the residence of Sir CHARLES TREVELYAN, it was stated that since 1881 six new provident dispensaries have been established in different parts of the metropolis, three others that were previously in existence have been taken over by the Association, and arrangements are being made for the starting of four more. Of the nine provident dispensaries at present in operation, three have already become self-supporting, four are making steady progress towards that position, and concerning the other two, notwithstanding that they are heavily weighted through having to compete with medical charities in the same neighbourhoods, hopes are entertained that they will eventually pay their own way. About fifteen thousand persons of both sexes and all ages are now entitled, in virtue of a money payment, to medical aid, when required, from these dispensaries, and the number is increasing daily. We hope that the progress will be maintained until the objects of the Association are fully attained. Apart from the fact that, in the words of the Chairman of the meeting, "there could "be no greater misfortune happen to the country "that that men should lose the sense of inde-"pendence and self-reliance, and seek to obtain all "they require by State-aided schemes, municipal "government and public charity," the creation of a more healthy tone in the public mind in regard to responsibilities in respect to the receipt of medical assistance must help to improve the position of a large number of medical practitioners, and this, for the reasons before hinted at, cannot happen without conferring a similar boon upon the practitioners of pharmacy.

We understand it has been decided by the Council of the Pharmaceutical Society to extend a privilege until now limited to Members and Associates in Business, and supply gratuitously to each Associate and Registered Apprentice of the Society who chooses to apply for it a copy of the Catalogue of the Society's Museum. We hope that this boon will be widely appreciated, for the volume is of much wider interest than is implied by the title, and would prove a valuable addition to the library of any student of materia medica, even though he might never enjoy the privilege of seeing the museum to which it specially refers.

* * *

On Monday the second reading of the Medical Acts Amendment Bill was postponed until Thursday, but at the time of going to press it has not been reached, and judging from its position on the business paper it is hardly likely to be. Two deputations have been received this week by Mr. Mundella on the subject of the constitution of the proposed Medical Boards, one from Scotland urging the predominant claims of universities to representation, and the other from Ireland seeking the restoration of the Apothecaries' Society of Ireland to the position it originally held in the Bill. Replying to the latter, Mr. Mundella said that there had been great opposition to either the English or the Irish Society of Apothecaries being empowered to send representatives to the respective Medical Boards, to which also the report of the Royal Commission had been unfavourable, and eventually a compromise had been arrived at in the House of Lords between Lord Cairns and the Lord President to eliminate both those bodies. He promised to lay the views of the deputation before Lord Carlingford, but said he was unable to hold out any hope of the desired reinstatement in teeth of the agreement made.

* * *

The Commission appointed by the French Chamber of Deputies to examine the Pharmacy Bill introduced by M. Faure, has just agreed upon its report, and the principal recommendations in it have been communicated to the public press by M. Naquet, by whom it was drawn up. These are

(1) the suppression of pharmacists of the second class and of herbalists; (2) liberty of sale by any person of a series of harmless plants and drugs, included in a list to be inserted in the Codex; (3) liberty to pharmacists to sell, upon their own responsibility and that of the buyer, any substances, whatever may be their nature, which are expressly demanded by the purchaser, but not to grant consultations or practise medicine, unless they possess the double qualification; and (4) that any person possessing the diploma of a pharmacien shall have the right to prepare, advertise, and sell by wholesale and retail any medicine that is not "secret," in the grammatical sense of the word, that is, of which the composition is known. Whilst the subject was under consideration the Commission refused categorically to hear any outside opinions; but after the report had been drawn up, it gave an audience to the Minister of Commerce, and made some modifications to meet his wishes in favour of the retention of certain existing regulations as to the sale of poisonous substances and the inspection of pharmacies.

* * *

It is announced that Professor Lord Rayleigh has been nominated by the Council of the British Association as President for the meeting at Montreal in 1884. It has been suggested in an American contemporary that if next year's meeting of the American Association for the Advancement of Science could be fixed for some north-eastern city in the States, sufficiently near to Montreal, and could be timed so as to occur a week before or after the meeting of the British Association in the latter city, many members of each Association would be able and willing to attend both meetings.

* * *

A case is undergoing investigation at Partick, near Glasgow, in which the death of a young man followed the administration of a medicine made up from a prescription under conditions appearing to indicate that the man was poisoned. It has been suggested that a mistake was made in dispensing the mixture, but the information received up to the present time is not sufficient to justify us in offering any opinion on the subject.

* * *

The Edinburgh Chemists' Assistants and Apprentices Association has issued a circular announcing its intention to offer for competition among the Apprentice members two prizes, one of the value of £2 2*s.*, and the other of 12*s.* 6*d.*, and to these the President of the Association has added a third. The subjects of the examination, which is to take place in October next, are—Latin, English, Arithmetic, Elementary Chemistry, and some questions on the processes by which the official decoctions, infusions, pills and tinctures are made.

* * *

The Council of the Sanitary Assurance Association had before it this week a resolution asking it to consider whether it could not recommend legislation making it compulsory on builders of all new dwellings to obtain an authoritative certificate as to the sanitary condition of such houses before it shall be lawful for them to be used as habitations. Eventually, a sub-committee was appointed to draw up a Bill, if it should be deemed desirable, and report to the Council.

* * *

While referring to this subject it may be mentioned, that on Saturday, the 16th inst., Mrs. Buckton will give, in connection with the Health Society's exhibition at Knightsbridge, the last of a series of three demonstrations upon models of a sanitary and an unsanitary house.

* * *

A conference between a committee representing the interests of proprietary medicine manufacturers and dealers and a representative of the Massachusetts Pharmaceutical Association has resulted in agreement in respect to a plan to be recommended for adoption as likely to prevent the continuance of the "cutting system" in selling such articles. The proposition is that all proprietary articles shall be sold by the jobbers in the first place at a reduction of two-pence in the shilling upon the retail price, each package having a coupon attached to be removed at the time of sale by the retailer, and which shall entitle him to a further specified rebate, provided that he does not in the meanwhile render himself liable to complaints for underselling. It is not, however, clear what is to prevent the removal of the coupons and the claiming of the rebate before the goods are sold, if the retailer chooses to make a false statement.

* * *

From time to time reference has been made in this country to the advantages presented by the arrangement under which in the United States imports of drugs of inferior quality are intercepted at the custom house; but in the light of a statement in one of our exchanges this guardianship would appear to be a broken reed to lean upon. According to the *Oil, Paint and Drug Reporter* an application was made recently to the bureau of statistics at Washington for information as to the quantity of "cassia vera" annually imported into the country. The preliminary question, "What is cassia vera?" proved a stumbling block, and after it had been passed from one *employé* to another it was discovered that the sum total of the knowledge on the subject possessed by the custom-house experts was that there are two articles of a similar character, called cinnamon and cassia, the former coming from Ceylon and paying a duty of twenty cents per pound, the other coming from China and paying only half that amount of duty. Inquiries spread over a wider area raised the doubt whether the greater part of the cinnamon imported into the United States during recent years has not been entered—and passed—as cassia, payment of the higher rate of duty being thus avoided.

* * *

We are glad to notice that within about eighteen months of its first publication, Mr. Joseph Ince's capital little 'Latin Grammar of Pharmacy' has reached a second edition. There can be no doubt as to the usefulness of such a book to pharmaceutical students.

* * *

At the meeting of the Chemical Society on Thursday next there will be a ballot for the election of Fellows, and the following papers will be read:—"On Evaporation in Vacuo," by Professor H. McLeod, F.R.S.; "Note on Hydrocarbons from Camphor," and "Note on some Substitution Derivatives of Camphor," by Professor H. E. Armstrong; and "On the Decomposition of Ammonium Nitrate, an Investigation into the Rate of Chemical Change," by V. H. Veley.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, June 6, in the College of Physicians, Dublin, at three o'clock.

The President, Professor Tichborne, in the chair.

The other members of the Council present were:—The Vice-President, Dr. Aquilla Smith, and Messrs. Allen, Brunker, Doran (Bray), Draper, Grindley, Hayes, Hodgson, McIlwaine (Newry), Simpson and Wells.

Mr. Hugh J. Fennell, the Registrar, read the minutes of the last meeting and of a special meeting, which were confirmed.

Read, a letter from Mr. W. J. C. Miller, Registrar of the General Medical Council, enclosing a printed circular from Dr. Quain, Chairman of the Pharmacopœia Committee of that Council, stating that the Committee was very desirous of enlisting the co-operation of the several medical and pharmaceutical authorities in the bringing out of the new edition of the Pharmacopœia, and inviting suggestions with that view, which it was stated would receive most attentive consideration.

Mr. Draper said the office of making suggestions was a very thankless one.

The President: I think it should be courteous to reply to the letter.

Mr. Brunker: I think it would be well to appoint a Committee on the subject, which could report to the Council.

The Vice-President: The book will not be published for two years.

Mr. Hodgson: How did the Pharmaceutical Society of Great Britain take it up?

The President: We should be rather stultifying ourselves if we took any action on this letter when we are memorializing the Government to give us representation on the Medical Council.

Mr. Hodgson: I do not see how we can give suggestions to a committee on which we are not represented and of which we think we ought to be a component part.

The President: I would suggest that for the present, Mr. Fennell be directed to acknowledge the receipt of this letter. We can take up the matter afterwards, if necessary.

An order was made accordingly.

The President submitted a correspondence with Mr. Carteighe, President of the Pharmaceutical Society of Great Britain, showing the action which that Society had taken for the purpose of obtaining the insertion in the Medical Acts Amendment Bill of a clause providing that pharmaceutical authorities shall be represented on the Committee intended to be established under the Bill for the revision of the Pharmacopœia. The correspondence included copies of the memorial and petition which the English Society has adopted on the subject.

The President said that the Council had already discussed this point about the representation and the English Society was pressing on. It was requested, however, that no petition should be sent in until the Bill was going into Committee. But there was another point which the English Society did not seem to have taken cognizance of. One of the clauses of the Medical Bill provided that the "general medical practitioner," who had passed the State examination, should have a right o compound prescriptions. As the law at present stood medical practitioners were only given the right to compound prescriptions for their own patients. When the Bill in question was in the House of Lords an alteration was made in the clause in question, apparently advisedly, the effect of which would be to give every man who should have passed the State examination, the power of compounding for the public. The Apothecaries' Hall of Ireland had already petitioned against this; and he (the President) thought it was the duty of the Pharmaceutical Society of Ireland, also, to petition against it.

Mr. Brunker: It does not affect the English society so much as it affects us.

The President: It does, because if the clause as it stands becomes law, surgeons may not only compound for themselves but also for the public. I think a committee should be appointed to report on the two matters. It should be done at once. The clause should be altered by the introduction of the words "for their own patients."

Mr. Draper: I think it is a very important point.

On the motion of the President, seconded by Mr. Allen, a Committee, consisting of Mr. Draper, Mr. Hayes and the mover and seconder, were appointed to draw up a petition to the House of Commons, praying for amendments in the Medical Acts Amendment Bill in reference to the revision of the Pharmacopœia and the open dispensing for the public by general practitioners.

As it would be necessary to take action in the matter before the expiration of a month, the President and Registrar were empowered to affix the seal of the Society to whatever petition the Committee drafted.

A letter was read from Dr. J. W. Moore, Registrar of the College of Physicians, stating that as that body were pressed for library space, they were anxious to resume possession of the room rented by the Society; but they wished to afford the Pharmaceutical Society ample time to make the arrangements consequent on its surrender of the room.

The President said a committee had better be appointed to consider what should be done.

Mr. Hodgson observed that if they rented premises for themselves they would have to incur a considerable amount of expense in fitting them up so as to make them suitable for their purposes. They would have to buy furniture for an examination room. The £400 they had in hand would go a very little way towards that. Why should they not follow the example of the College of Physicians and raise funds by the issue of debenture stock for the erection of a building suitable for their requirements?

The Vice-President said that the College of Physicians raised first £6000 and afterwards £2000 more by the issue of debenture stock, and now it was all paid off.

Mr. Hodgson said that the Society had sustained a loss in its last year's operations. The income from fees had been £190, and the income from subscriptions, £78. Against that the expenditure had been £238, exclusive of rent and the cost of prosecutions, and some other matters, which would bring it up to £314.

The Vice-President: There has been a falling off in the number of members during the last few years.

The President said the matter was a very important one, and should receive careful consideration. A committee should be appointed with full power to make inquiries as to what premises could be had, and as to whether it would be desirable for the Society to hire rooms or to issue debenture stock for the purpose of providing a building of its own.

On the motion of Mr. Brunker, seconded by Mr. Doran, the following committee was appointed for that purpose:—The President, the Treasurer, Messrs. Draper, Grindley, Simpson, Hayes, and the mover and seconder.

A letter was received from Mr. Henry Webb, of Kanturk, complaining that a person who was neither an apothecary nor a pharmaceutical chemist had opened shop and was compounding prescriptions in that town.

Mr. Hodgson: Mr. Webb is not a member of the Pharmaceutical Society.

The Register was directed to inform Mr. Webb that as he was not a pharmaceutical chemist the Society could not entertain his letter.

A letter was read from Mr. Bernard J. Costello, of Killarney, in reference to his candidature for the office of apothecary of the Killarney Workhouse, and complaining of the result of the election.

The Registrar was directed to refer Mr. Costello to the Local Government Board.

A letter was read from Mr. Samuel Curham, dated May 26, and stating that he had been informed that the Council had passed a resolution that candidates who had not passed the Preliminary examination previous to January, 1883, would have to serve an apprenticeship of four years, but that that resolution was not to come into force until January, 1884. He wished to know whether candidates passing the Preliminary examinations to be held in July and October next would be admitted after two years' service. He also asked for information on another point. Mr. Hardy, who was a partner of Mr. Beater, of Sackville Street, and who passed the pharmaceutical examination some time ago had, by agreement with the firm, opened on his own account and responsibility, a compounding department in the premises of the said Beater and Co. Would an apprenticeship served to him, and his certificate thereof, be accepted by the Council?

The Registrar said he had already answered the first of the questions asked by Mr. Curham by informing him that any candidate who had not passed the Preliminary examination before April, 1883, would have to spend four years in the study of practical pharmacy.

The President: I think our best course with reference to the other question is to inform Mr. Curham that we cannot give a legal opinion. You have refused a certificate in the case of Mr. Middleton; he has appealed, and you are awaiting the result of that appeal.

Mr. Hodgson said it was hard upon Mr. Curham not to be able to give him an answer at once.

Mr. Brunker: We are not in a position to say that we cannot accept his certificate.

Mr. Hayes: I think we are in a position to say that we must refuse his certificate; and then he can appeal to the Castle as Mr. Middleton did.

Mr. Hodgson moved the following resolution:—

"That having refused a similar application, and as an appeal has been carried to the Privy Council, we await the result of that appeal before giving Mr. Curham a decided answer."

Mr. Brunker seconded the motion, which was passed unanimously.

The President gave the following notice of motion:—

"That on and after the 1st of October, 1883, the office of President of the Society shall not be held for more than three consecutive years by the same person."

A letter was received from Mr. Thomas S. Hance, of Limerick, in reference to the refusal of the Council to accept certificates given by him on the ground of his not keeping an open shop. He maintained that he did keep an open shop for the compounding of medical prescriptions and the preparation of medicine in general. The Local Government Board had sanctioned his taking pupils in pharmacy, under prescribed rules, a copy of which he enclosed. He had been giving certificates for four years and these had never been questioned by any other medical board in the three kingdoms. Between 40,000 and 50,000 prescriptions, he said, were prepared annually under his personal superintendence, and he submitted that the Act of Parliament did not mean that because a qualified man kept an open shop within certain gates and did not receive money over the counter he was not to have his legal rights.

Mr. Brunker: I think we are right in our decision. He does not keep an open shop. He keeps the dispensary of the workhouse.

Mr. Wells: If he only has a shop within the workhouse walls it is not an open shop.

The consideration of the letter was postponed in order that inquiries might be made.

A report from the Certificate Committee was adopted.

Mr. Hodgson said he had been requested on the previous day by an apprentice, who was about being bound, to obtain an answer to the following question:—The 32nd section of the Pharmacy Act provided that upon the decease of a pharmaceutical chemist or chemist and druggist, his executor, administrator, or trustee, might carry on his business so long as it was *bonâ fide* conducted by a duly qualified assistant who should be a pharmaceutical chemist or a chemist and druggist. Would the certificate of the party carrying on the business in such a manner, given to an apprentice, be accepted for the Major examination?

Mr. Brunker: As a matter of fact such certificates have been recognized and have never been questioned.

Mr. Hayes: If the establishment is kept open regularly and according to the requirements of the Act, I do not see how we can refuse the certificate. I think you may definitely answer that the certificate will be accepted.

The Council then adjourned.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting of the above Association was held at the "Museum and Library," Bristol, on Friday, June 1, the President, Mr. G. F. Schacht, in the chair.

The report of the Council was read by the Honorary Secretary, Mr. Warren, and the statement of accounts, which showed a balance in hand of £2 5*s*., by the Treasurer, Mr. White.

These were approved and formally adopted.

The new Council was then elected. It consisted of Messrs. Allen, Berry, Pitman, Schacht, Stroud, Warren, White and Wretts.

A communication, addressed to the President and members of the Bristol Pharmaceutical Association by the Registrar of the General Medical Council, and accompanied by a "memorandum" signed by the Chairman of the Pharmacopœia Committee, was submitted for consideration and was fully discussed.

It was unanimously resolved that the incoming President be requested to reply upon the following lines:—

"To W. J. C. Miller, Esq.,
"Registrar of the General Medical Council.

"Sir,—As President of the Bristol Pharmaceutical Association, I duly received on the 19th ult. a communication from yourself and a circular signed by the Chairman of the Pharmacopœia Committee, in which the Association was invited to 'offer suggestions with a view to rendering a new edition of the British Pharmacopœia as complete and accurate as possible.'

"The documents were in due course laid before the Association and were fully considered.

"I am now requested to reply that the Bristol Pharmaceutical Association is of opinion that the Pharmaceutical Society of Great Britain is the recognized centre of pharmaceutical activity in this country, its claims thereto being identical with those by virtue of which the General Medical Council represents medicine, namely, the decrees of Parliament, and, therefore, that any application on the part of the Pharmacopœia Committee for practical pharmaceutical co-operation in the construction of a National Pharmacopœia ought to be made primarily, if not solely, to the Pharmaceutical Society of Great Britain.

"I am further requested to say, on the part of the individual members of this Association, that they would feel disinclined to offer any suggestions upon the important subjects submitted to them except at the request and through the medium of their official representative the Council of the Pharmaceutical Society of Great Britain.

"I have the honour to be, Sir,
"Your obedient servant,
"
"*President, Bristol Pharmaceutical*
"*Association.*"

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A meeting of the General Committee of the above Association was held at 23, Burlington Chambers, New Street, Birmingham, on May 31, 1883. The President (Mr. Joseph Lucas) in the chair.

Mr. Stokes Dewson having tendered his resignation as Honorary Secretary to the Association, the following resolution was unanimously carried, "That Mr. Charles Thompson and Mr. Alfred Wright be requested to act as joint Honorary Secretaries to the Association *pro tem.*"

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, June 7. Mr. R. H. Parker, Vice-President, in the chair. Mr. C. Ranken read a paper upon :—

Some Old and New Theories concerning the Vegetable Cell.

After pointing out the necessity of a knowledge of the elementary parts of vegetable tissues in physiological botany, the author proceeded to review some of the most important theories which have been advanced to account for the different phenomena presented by cells, starting with Robert Hooke's observations, which showed that tissues were composed of a continuous homogeneous substance, permeated by innumerable cavities, but did not recognize the individuality of cells. Malpighi first pointed out that cells were separable one from another, and gave to each the name "utriculus." Wolff in 1780 again enunciated the homogeneous theory, which was held by some physiologists for a considerable period, Huxley writing in its favour in 1853. The discovery of the *nucleus* by Robert Brown gave rise to an amount of controversy; some botanists doubted its existence, whilst Schleiden made the belief in its existence the "first article of the faith botanical." Nägeli contended that it was a universal and unexceptional phenomenon in vegetable cells. Huxley looked upon both protoplasm and nucleus as accidental anatomical modifications of the primordial utricle. It is only within a comparatively few years that histologists have been able to demonstrate clearly the true distinctions which exist between the cell-wall and the cell-contents; most agree with Beale's definition which describes cells as consisting of three parts: (1) germinal matter or bioplasm; (2) formed matter or tissue; (3) nutrient matter. The bioplasm or protoplasm, being the most important part of the cell, is the immediate cause of cell formation and every process of organic life. The theories advanced to account for the growth of the cell-wall were next noticed, and a detailed account of Nägeli's intussusception theory was given, which shows that the substance—probably some soluble carbohydrate readily converted into cellulose—is diffused between the micellæ of the cell-wall, where it becomes deposited in the solid state either upon the pre-existing micellæ, or it forms new micellæ, by which means the wall increases in size and thickness. An account of the growth of starch granules was also given.

In the discussion that followed, the Chairman, Secretary, Messrs Crow and Sewell took part. A vote of thanks was passed to Mr. Ranken.

The Reporter upon Materia Medica, Mr. W. Elborne, then made a Report upon Commercial Rhubarbs, which was copiously illustrated by specimens from the Museum of the Pharmaceutical Society.

Commercial Rhubarbs.

BY WILLIAM ELBORNE,

Assistant Curator of Pharmaceutical Society's Museum.

Rheum is the botanical name of the genus of plants yielding the important drug familiarly known as rhubarb. The genus, a member of the Polygonaceæ, consists of twenty species, natives of the Siberian Himalayas and the East. They are perennials, with large root-stocks, from which the large sheathing leaves and flower stalks are given off. The inflorescence consists of much-branched panicles bearing a great number of white or pinkish flowers which have a petaloid six-parted perianth, enclosing nine stamens attached to its base. The three-sided ovary is surmounted by three spreading styles. The three-cornered fruit is winged and encircled at the base by the withered remnants of the perianth.

The fact of rhubarb being one of the most ancient valuable remedial agents of our materia medica will perhaps admit of a few preliminary remarks concerning its history.

The properties of rhubarb, which appear to have been known from a very remote period, find their earliest record in the Chinese herbal called 'Pen-king,' supposed to have been written about 2700 B.C.

As regards the ancient literature of Western Asia and Europe, it also occurs in the early writings of Dioscorides and Pliny; but whether then produced in the regions of Asia Minor or merely received thence from remoter countries, is a question which cannot be solved. A sketch of the history of rhubarb would be comparatively incomplete without some reference to the various routes by which the drug has been conveyed to Europe from the Western provinces of the Chinese empire and which have given rise to the familiar designations of Russian, Turkey and China rhubarb.

The first route is that over the barren steppes of Central Asia by way of Yarkand, Turkestan and the Caspian, to Russia; the second by the Indus or the Persian Gulf to the Red Sea and Alexandria, or by Persia to Syria and Asia Minor; and the third by way of Canton, the only port of the Chinese empire which previous to the year 1842 held direct communication with Europe. In 1653 China first permitted Russia to trade on her actual frontiers. The traffic in Chinese goods was thereupon diverted from the line of the Caspian and Black Sea further north, taking its way from Tangut across the steppes of the high Gobi and through Siberia by Tobolsk to Moscow.

Consequent on the rectification of the frontier in 1728, a line of custom houses was established by treaty between Russia and China, whereby the commerce, previously restricted, was limited only to the Government caravans which passed the frontier at Kiachta and Maimatchin, which towns ultimately became the staple depôts of rhubarb. In 1704, the Russian Government monopolized the trading in this drug and caravans fitted out by the Crown alone brought the drug to Moscow.

Under the surveillance of the Russian Minister of War, a special office was established at Kiachta, where the whole of the drug was submitted to careful inspection and examination by competent apothecaries, with the object of removing inferior and spurious pieces and to improve the selected drug by trimming, paring and boring. It was then dried and packed in chests which were sewn up in linen and rendered impervious to wet being pitched.

So long as China kept all her ports closed to foreign commerce, except Canton in the extreme south, most of the finest rhubarb consequently found its way to Europe by way of Russia. Owing, however, to the unpleasant accompaniments of the Russian supervision being so rigorously exercised, the Chinese were very ready to accept any easier and more reasonable outlet for their goods: consequently we find that the opening of a number of ports in the north of China exerted a most depressing influence on the trade of Kiachta. Thus the overland rhubarb trade became gradually destroyed, inasmuch as the Chinese, tempted by the increased demand from the trading ports, became negligent in the art of growing and collecting the root with such scrupulous care as formerly insisted upon by the Russian Government. Thereby the so-called Russian, Muscovite, or Crown rhubarb, which, from its uniformly good quality long enjoyed the highest reputation, has become a thing of the past and can only now be found in museum collections.

The second route is by the Indus or Persian Gulf to the Red Sea and Alexandria, or by Persia to Syria and Asia Minor.

From the Levant ports of Aleppo, Tripoli, Alexandria and Smyrna, it reached Europe and became known as "Turkey" rhubarb. This, however, did not long survive the Russian route; and as the imports in this direction ceased, the same name of "Turkey" was erroneously applied to the drug brought again by the original route through Russia.

The third line is by way of Chinese ports, hence our supplies from these quarters being known as Chinese, "Canton" or East Indian rhubarb.

With the view of classifying the numerous varieties of the drug the rhubarbs may be divided into two great classes, namely, those which are produced in Central Asia, and those which are cultivated in Europe.

Asiatic Rhubarbs.

Chinese	Russian, Muscovy or Turkey. Canton or East Indian. Batavian or Dutch, trimmed.	yielded by	*Rheum palmatum* var. *Tanguticum?* or *Rheum officinale?*
Siberian		"	*R. rhaponticum.*
Himalayan (large)		"	*R. Emodi.*
" (small)		"	*R. Webbiani.*
Bucharian		"	*R. undulatum.*
European.			
English		"	*R. rhaponticum.* *R. officinale.*
French		"	*R. rhaponticum.* *R. compactum.* *R. undulatum.*
Austrian (Moravian)		"	*R. rhaponticum.*

Asiatic Rhubarb, Chinese.—Owing to the fact that the greater part of the regions of Shensi, Kansu and Szechuen, where the plants grow, is as yet unexplored by botanists, and, perhaps, owing to the jealous reticence of the Chinese, the exact species yielding the true drug is not known with certainty.

The bulk of the commercial drug imported into this country, however, is considered to be afforded by two species, viz.:—*Rheum officinale* and a variety of *R. palmatum*, called *tanguticum.* The former is a native of the south eastern part of Thibet, and of various parts of West and North-Western China, where it is in a measure cultivated. The second species is said by Prejevalsky, a celebrated Russian colonel, to afford the excellent rhubarb of Thibet.

China rhubarb, as imported into Europe, consists of portions of a massive root which display considerable diversity of form, arising from the various operations of paring, slicing and trimming to which they have been subjected. Thus some pieces are cylindrical or rather barrel shaped, others conical, while a large portion are plano-convex. These forms are not found in the same package, the drug being usually sorted into what are commonly known as "rounds" and "flats." In dimensions we find them from 4 to 6 inches in length, and about 2 inches thick. The outer surface of the root is somewhat shrivelled, often exhibiting portions of dark cortical portions that have not been pared away.

Many pieces are pierced with a hole in which may be found the remains of the string used to suspend the root while drying.

The drug is dusted over with a bright yellowish powder, on removal of which the outer side of the root is seen to have a rusty brown hue, or viewed with a lens to be marked by the medullary rays, which appear as an infinity of short broken white lines traversing a brownish ground. The character which most readily distinguishes the rhubarb of China is, that well-developed pieces broken transversely display these dark lines arranged as an internal ring of *star-like spots.* Although this character is by no means obvious in every piece of Chinese rhubarb, it is of some utility from the fact that in European rhubarb such spots are generally wholly wanting or at most occur very sparingly and isolated.

Although Russian rhubarb has ceased to be an article of commerce since 1860, a few remarks respecting its character will not be out of place when we consider the very high repute it has always maintained and the many attempts made at the present day of slicing and trimming the East Indian drug with a view of simulating it.

The true Russian rhubarb, which is now very scarce, appears as though it had been freely sliced with a sharp knife, and each piece shows evidence of having been rigorously examined and inspected, by possessing a *large* hole (not a string hole) bored to its centre by the authorities at Kiachta. Another very distinguishing character is the net-veined appearance of its outer surface.

East Indian rhubarb of commerce is the variety which is chiefly imported to England. It is supposed to be derived from the same species as the former and distinguished by the small size, dark colour, and irregular shape of the holes with which it is pierced, these holes being generally plugged with the remains of string used in drying; also by the outer surface being frequently marked with whitish reticulations, which are more evident when the powder has been rubbed off, and by the transverse surface showing a number of star-like marks, but no distinct cortical layer. Canton stick rhubarb is probably obtained from the root branches of the same plants.

East Indian rhubarb is now purchased for the European market chiefly at Hankow on the upper Yangtsze, whither it is sent to Shanghai for exportation. The exports from Shanghai in 1878 were 5942 *piculs* (picul = $133\frac{1}{3}$ lbs.), valued at £40,000. Since that date no return, to my knowledge, has been issued.

Batavian or Dutch trimmed differs from the East Indian in having an angular appearance, owing to the surface having been sliced off. It is not now met with in English commerce as a distinct variety, but used to be imported from Canton and Singapore.

Siberian Rhubarb.—Small quantities of this kind have been imported occasionally, and have been proved to be those called by Grassman and others Siberian rhapontic root. This occurs in long, thin, almost cylindrical or spindle-shaped pieces, decorticated and perforated by a hole. Since it is yielded by the same species which is cultivated in England at Banbury, Dr. Pereira has justly compared it with English stick rhubarb.

Himalayan Rhubarb.—The cultivation of rhubarb in India has hitherto been unsuccessful rather than otherwise. The large Himalayan root is, however, furnished by *Rheum Emodi*, a large plant having a thick stem, growing from Bhotan and Sikkim to Kaschmir on the India side of the Himalayas, frequently reaching a height of more than 6 feet, and also indigenous to Western Thibet, but less abundant. In most districts of North-Eastern and Central Asia its efficacy is greatly praised, while in the damp and warm districts of Sikkim and Bhotan the root seems to be inefficacious. The smaller rhubarb of *Rheum Webbianum* is indigenous to the vicinity of Simla, at an elevation of more than 12,000 feet; it was tried by Dr. Royle in both military and civil hospitals at Saharunpore, and found to be of very good quality. Both varieties differ much in appearance from that of the Chinese drug, in that the brown cortical portion of the root has not been removed. The texture is radiated, rather spongy and the colour of the powder a dull brownish yellow.

Bucharian Rhubarb, which makes its way to Vienna by Brody and Nischny, seems, from specimens and information afforded by Faber to Dr. Pereira, to consist of inferior kinds of the Russian drug.

European Rhubarbs.

In various parts of Europe, particularly in England, France and Germany, the rhubarb plants have been cultivated for many years.

English Rhubarb occurs generally in two forms, one in which the root is cut, trimmed and bored in imitation of the Russian; the other in sticks. The former occurs in various sized flat and irregular pieces, commonly about 6 inches long. English rhubarb is lighter and more spongy than the Asiatic, and when broken exhibits a more regular marbling, the pink lines being arranged like rays from the centre towards the circumference. The star-like spots are either wanting or very sparingly scattered. The whole of the English rhubarb in the market is grown by Mr. Rufus Usher, at Bodicote, near Banbury. To him I am indebted for his kindness in having furnished me with authentic specimens of the home-grown roots of *R. rhaponticum* and *R. officinale*, and also with statistics relative to the annual production. He informs me that this amounts to 7000 lbs. of the drug, of which about 4000 lbs. is exported.

French Rhubarbs.—The rhubarbs of France are derived from *R. rhaponticum*, *R. undulatum* and *R. compactum*. That which comes from the department of Doubs is furnished by *Rheum rhaponticum*, and that from Provence by *Rheum undulatum*. French rhubarbs possess somewhat similar characters to those which exist in the Chinese drug. They, however, show such an analogy to each other that it is very difficult to distinguish from which species commercial samples of the drug may have been derived, since in appearance it much resembles the drug grown in England, and occurs in similarly shaped pieces. The remarks concerning English rhubarb will apply equally to the French drug, the cultivation of which is rapidly decreasing.

Austrian.—This rhubarb occurs in smooth decorticated pieces, fairly compact, and weighing about 4 ounces each. It possesses a very clear yellowish appearance, with small reddish-brown spots interspersed. The transverse section of this rhubarb presents a regular radiate structure.

Of these several varieties of rhubarb, nearly all of which still constitute the commercial products of countries abroad, only two varieties occur in English commerce at the present day, they are the Chinese (East Indian) drug (*R. palmatum*, var. *tanguticum*), and that grown in our own country (*R. rhaponticum*).

In the discussion that followed, the Chairman, Secretary, Messrs. Corder, Crow, Hamilton and Ransom took part.

SOCIETY OF CHEMICAL INDUSTRY.

Chemistry and Analytical Examination of Fixed Oils.*

BY ALFRED H. ALLEN.

(*Concluded from page 1031.*)

I fear I owe the Society an apology for dilating so largely on the subject of the oil from marine animals, but the comparative novelty of the subject must be my justification, and in addition I may point out the very important bearing the peculiar chemical constitution of these oils has upon the methods of detecting their adulteration. That bottle-nose oil is now frequently substituted for sperm oil without acknowledgment is a fact well known, and the great similarity between them renders it difficult to devise any method by which the substitution can be positively detected, but the admixture of any of the ordinary oils with sperm or bottle-nose oil would be at once detected by the saponification process, the fatty acids being increased and the ether residue diminished by any admixture of sperm or bottle-nose oil with a glyceride. A properly-contrived mixture of a mineral oil with a glyceride could be made to simulate sperm oil in density, and approximately in the proportion of ether residue and fatty acids, but the sum of these two would be sensibly below 100, instead of several units above, as in the case of genuine sperm and bottle-nose oils.

I have already referred to the dependence of the density of fixed oils on their chemical constitution, and it is of interest to see how far oils of similar chemical character may be correctly grouped by their density. The following table shows the results of such arrangement when applied to the best-known fluid fixed oils:—

A.—OILS OF LESS DENSITY THAN ·883.

1. *Liquid Waxes*:

Sperm oil	·875 to ·883
Bottle-nose oil	·876 to ·880

2. *Unknown Constitution*:

Shark-liver oil	·865 to ·867
African fish oil	·867

B.—OILS HAVING A DENSITY BETWEEN ·883 AND ·912.

Oil from the head-cavity of the bottle-nose whale (specific gravity ·908), giving on analysis figures proving it to be a mixture of a fluid wax and a glyceride.

C.—OILS HAVING A DENSITY BETWEEN ·912 AND ·92 (NON-DRYING OILS).

1. *Vegetable Oils*:

Almond oil	·917 to ·920
Earthnut oil	·916 to ·920
Olive oil	·914 to ·917
Rape or colza oils	·914 to ·917
Mustard oil	·914 to ·920

2. *Marine Animal Oils*: None.

3. *Terrestrial Animal Oils*:

Lard oil	·915
Tallow oil	·916
Neatsfoot oil	·914 to ·916
Bone oil	·914 to ·916

D.—OILS HAVING A DENSITY BETWEEN ·920 AND ·937.

1. *Vegetable Oils*:

(*a*) *Moderately drying*—Density below ·930.

Cotton-seed oil	·922 to ·930
Sesame oil	·923 to ·924
Sunflower oil	·924 to ·926
Niger-seed oil	·926 to ·928

(*b*) *Strongly drying.*

Hempseed oil	·925 to ·931
Linseed oil	·930 to ·935
Poppy seed oil	·924 to ·237
Walnut oil	·925 to ·926

2. *Marine Animal Oils*:

Cod oil	·923 to ·930
Menhaden oil	·929 to ·932
Seal oil	·924 to ·929
Porpoise oil	·920 to ·923
Whale oil	·920 to ·930

3. *Terrestrial Animal Oils*: None.

* Paper read before the London Section of the Society.

E.—OILS HAVING A DENSITY ABOVE ·937.

1. *Vegetable Oils—Purgative*:

Croton oil	·942 to ·943
Castor oil	·960 to ·964

(Boiled linseed oil.)

2. *Animal Oils*: None.

The peculiarity of the composition of the oils of Class A I have already referred to at length, and the single oil in Class B requires no further notice. The oils of Class C present a very close general resemblance. They consist chiefly of the glycerides of oleic acid and its homologues. Thus the oils from almonds, olives, lard, tallow, neatsfoot, and bones, consist mainly of triolein. Arachis or earthnut oil is peculiar in containing the glyceride of hypogœic acid, which stands in the same relation to palmitic acid that oleic does to stearic acid. Rape and mustard oils contain the glyceride of brassic or erucic acid, which is said to be homologous with oleic acid. The lead salt, however, is insoluble in ether, while oleate and hypogœate of lead are soluble. Oleic and hypogœic acids and their respective glycerides agree in yielding isomeric bodies of comparatively high melting point under the action of nitrous acid, while brassic acid does not yield a solid product under the same conditions. Similarly, rape and mustard oils, which in large part consist of the glyceride of brassic acid, give but little elaidin, that which is formed being doubtless due to the true olein present together with the glyceride of brassic acid. In Class D we have several distinct groups of oils. The chemistry of the oils of the cotton-seed group—which are sometimes called the "partially-drying oils"—is very imperfectly understood. The fatty acids obtained on saponifying cotton-seed oil have a remarkably high melting point, but can scarcely contain much palmitic or stearic acid, or the oil would be solid at ordinary temperatures. The true drying oils, of which linseed oil is the type, are well known to absorb oxygen with great facility, especially after being exposed to a high temperature. That they have a distinct chemical constitution from the non-drying oils is indicated not only by this fact, but also by their giving no solid elaidin with nitrous acid, and by their high density and fluidity. They also give a much greater increase of temperature when treated with strong sulphuric acid than is the case with the oils of either of the previous classes. Although, from their general resemblance to linseed oil, the oils of walnut, hempseed and poppy seed may be assumed to consist largely of the glyceride of linoleic acid, I am not aware that this has been definitely proved to be the case. It is worthy of notice that the animal oils which have a density higher than ·916 are in every case of marine origin. They yield but little solid elaidin, and hence contain but little true olein, in which respect they present a marked contrast with bottle-nose oil, which gives a fairly solid product, as also do its separated fatty acids. On the other hand, the "fish oils" do not dry readily; hence their chemistry is still somewhat obscure.

The only fixed oils which in a natural state have a density higher than ·937 are castor and croton oils. Castor oil has properties and constitution which appear to be perfectly unique. It consists chiefly of the glyceride of ricinoleic acid, $C_{18}H_{34}O_3$, is remarkably viscous, and has a density of upwards of ·960. It differs from all the other fixed oils (except croton oil) in its ready solubility in alcohol, being miscible in all proportions with absolute alcohol, and completely soluble at 30° C. in twice its volume of rectified spirit. But a still more remarkable peculiarity is its insolubility in petroleum spirit, which appears to be miscible in all proportions with the generality of fixed oils. Castor oil itself dissolves its own measure of petroleum spirit and somewhat less of the heavier petroleum products, but the mineral oil takes up little or no castor oil. For lubricating purposes it is often desired to effect a mixture of castor with mineral oil, and this is usually done by the addition of an animal olein.

The fixed oils which are solid at ordinary temperatures also vary in density according to their chemical constitution, those which contain glycerides of the lower fatty acids being distinctly denser than the fats consisting wholly of palmitin, stearin and olein. This fact, on the suggestion of Mr. J. Bell, has been utilized for examining butter. The following are the densities of molten fats at 100° C., compared with water at 15° C.

F.—FATS CONTAINING NO GLYCERIDES OF LOWER FATTY ACIDS.

1. *Vegetable Fats.*

Cacao butter	·857
Palm oil	·857
Japan "wax"	·873

2. *Animal Fats.*

Lard	·861
Tallow	·860
Horse fat	·861
Butterine	·859

G.—FATS CONTAINING GLYCERIDES OF LOWER FATTY ACIDS.

1. *Vegetable Fats.*

Cocoanut oil	·868
Palmnut oil	·866

2. *Animal Fat.*

Butter fat	·865 to ·868

The figures referring to the densities of the animal fats are by König, and it is not certain whether water at 4° or at 15° C. was taken as unity.

It will be noticed that melted "Japan wax" exhibits an anomalous density, and this is true also of the solid body. It is alleged to consist of nearly pure palmitin; but this seems highly improbable on several accounts. However, I find only 1·14 per cent. of unsaponifiable matter on saponifying and treating with ether, so that it is not a true *wax*, and the peculiarity probably lies in the nature of the fatty acid.

Although it will be seen that observation of the density of oils is capable of giving much more valuable information than is usually gleaned from the rule-of-thumb application of the test, the conclusions from the experiment are apt to be vitiated by the presence of any large proportion of free fatty acid. This will be evident when it is remembered that free oleic acid has a density not exceeding ·900 at 15° C., and hence rancidity generally tends to reduce the specific gravity of an oil. The error from this cause may be avoided by the troublesome plan of saponifying the oil, and taking the density of the resultant fatty acids. Unfortunately, there are not at present sufficient data to render the plan generally useful, but in taking observations of this kind I should strongly recommend the mode of operating adopted by Mr. L. Archbutt. He takes the density of the oil at a steam heat, and hence is able to compare all fatty acids, whether liquid or solid, at ordinary temperatures. For the experiment, he employs a small Sprengel tube, which is hung by the horizontal capillary portions in the neck of a 20-ounce flask, containing water in rapid ebullition. A watch-glass or porcelain crucible cover is placed over the neck of the flask so as to prevent cooling. Two little mouths on opposite sides of the neck of the flask allow the ends of the Sprengel tube to project, while the flask is pretty tightly closed by the porcelain cover. When no further expansion of the oil is observed to occur, the nose of the Sprengel tube is touched with a piece of filter paper, to remove adhering oil, and the tube is then removed, wiped dry, cooled, and weighed. Operating in this way, Mr. Archbutt has observed the following densities for fatty acids from various sources, compared with water at 100° C. taken as unity. For convenience I add some observations of melting points also observed by him.

Source of Fatty Acids.	Density at 100° C.	Melting Point Deg. F.
Pure olive oil	·8444	75 to 76
„	·8429	—
Earthnut oil	·8475	82·3
Pure rape oil	·8439	65
Colza oil	·8464	65
Cotton-seed oil	·8494	95·5
Niger-seed oil	·8562	76·5 to 80·0
Linseed oil	·8599	52·5
Train oil	·8597	87·0
Palm oil	·8389	—

In observing the melting point of fatty acids and similar substances very good results may be obtained by the capillary-tube method, provided that the following points are rigidly adhered to: (1) To allow the fat to solidify *slowly*, avoiding all artificial means of cooling. (2) To allow at least an hour to elapse after solidification before taking the fusing point. (3) To heat the water extremely slowly.

A convenient apparatus for taking fusing points consists of a 20-ounce flask, from which the neck has been removed. The flask is filled with water, and a small beaker fitted into the mouth, and itself filled with water. The capillary tube should be in close proximity to the bulb of the thermometer.

A good alternative method (due to Dr. Redwood) is to half fill the beaker with clean mercury, and place a small fragment of the fatty acid on the surface of the metal. The thermometer bulb must be wholly immersed in the mercury. The melting point is very readily observed, and several samples can be readily tested simultaneously. When sufficient of the fatty acid is available, Dalican's method of taking the solidifying point is very useful.

I have already pointed out several errors which the unsuspected presence of free fatty acid in an oil is apt to occasion. Another is the vitiation of the colour test for oils, based on the reaction of the sample with polysulphide of barium or calcium. Chateau, who first devised the test, and Muter, who modified it, observed that certain oils decolorized the reagent, whereas others gave a yellow colour. I believe the differences observed were mainly, if not entirely, due to the presence or absence of free acid in the samples of oil examined. Direct experiments made by mixing olive and cotton-seed oils with increasing quantities of pure oleic acid fully confirmed this view. Similar objections apply to the majority of colour tests for oils, the fact being that the albuminous, resinous and other foreign matters, on the presence of which the colour reactions depend, are more or less completely removed by the processes employed in refining the oil. A notable case of this kind is that of cotton-seed oil, which, in the unrefined state, gives a fine violet-blue colour with caustic soda, and a magnificent red with sulphuric acid. The violet colour produced on treating a liver oil with sulphuric acid is one of the most striking and reliable of the colour reactions of oils.

Among Chateau's colour tests for fixed oils is anhydrous stannic chloride, which has been applied by Renard to the detection of resin oil. On adding a drop of stannic chloride to ten or twelve of resin oil and stirring the mixture a fine purple colorization is produced. The test is a good and useful one, but anhydrous stannic chloride is not always at hand, and is troublesome to prepare. I have, therefore, employed stannic bromide instead, and find it to answer equally well. I make it by agitating bromine in a separator with strong sulphuric acid, to remove water, and then allow the bromine to drop slowly on granulated tin, contained in a well cooled flask.

Maumené's test for oils by observing the rise of temperature produced on mixing 50 grams of the oil with 10 c.c. of acid is a useful test dependent on the chemical constitution of the oils examined, and, when carefully conducted, it gives remarkably constant indications. The following are essential conditions of success: (1) Always to use an acid of exactly the same specific gravity, and to preserve it most jealously from the air. (2) To bring the oil and acid to exactly the same temperature before commencing an experiment. (3) To mix the oil and acid thoroughly by means of a thermometer, stirring the whole time, and not reading off the temperature till the mercury begins to fall. (4) To work with the same apparatus, and to prevent loss of heat by enclosing the beaker in a non-conducting substance. In the case of the vegetable oils, the rise of temperature increases very regularly with the drying tendencies of the oil—olive oil developing about the least heat and linseed oil the most. Among the oils from marine animals, sperm and bottle-nose oils give only a moderate rise of temperature, while whale and cod oils develop great heat.

In examining olive oil the elaïdin test is very serviceable, though the result cannot be readily expressed in figures. The elaïdin test depends on the property of olein and oleic acid to yield isomeric bodies of comparatively high melting point under the action of nitrous acid. The reagent may be applied in various ways. Nitrous fumes may be allowed to bubble through the oil; a mixture of dilute sulphuric acid and sodium nitrite may be used; or the oil may be treated with a freshly prepared solution of mercurous nitrate, which has a remarkable power of retaining nitrous acid. The first process I have not personally employed, and the second appears apt to give erratic results. With care the third method gives very constant indications. For the test 12 grams of mercury should be dissolved in 11 c.c. of cold nitric acid of 1·35 specific gravity, and 8 grams of the newly made solution are shaken with 96 grams of the oil, and the agitation repeated every ten minutes during two hours. When treated in this way, olive oil, and other animal and vegetable oils consisting chiefly of olein, give solid elaïdin, while the drying oils remain liquid. Cótton-seed oil and others of the same group give intermediate results. With the exception of bottle-nose or sperm oils the oils from marine animals give little solid elaïdin. The elaïdin reactions of rape and mustard oils have already been described. Olive oil is remarkable for the canary or lemon-yellow colour, and the great firmness of the product, which, after twenty-four hours, is impervious to and sometimes rings when struck with a glass rod, but this peculiarity is common to arachis and lard oils. Of the physical characters of oils, the specific gravity is of the first importance. The solidifying point is not generally capable of accurate observation, and is apt to vary considerably with different samples of the same kind of oil. The absorption spectrum is simply of service in detecting the presence of chlorophyll, and, therefore, by inference, of a vegetable oil; but its indications become less distinct the older an oil is, or the more carefully it has been refined.

The viscosity of an oil is a valuable and highly practical characteristic, but to make the observations of value they must be conducted with more care than is commonly the case. Thus, a sample of rape oil, which will flow out of a tube with a small orifice in three hundred seconds when the temperature is 38° C., will require three hundred and nineteen seconds at a temperature of 37° C. Hence the most scrupulous care is necessary to bring the sample to be tested to the standard temperature, and to keep it at that temperature during the operation.

I have not attempted in this paper to give an account of or even mention all the tests and processes of greater or less value which may be employed for examining oils, but have rather attempted to lay stress on those details of manipulation which have been neglected, and those pecularities of constitution which are likely to prove of practical value in discriminating between different kinds of fixed oils. It must, however, be remembered that a fixed oil is at least only a natural product, varying in character with the age, habitat, and personal idiosyncrasy of the plant or animal which has produced it, and hence is not of absolutely constant composition. Again, oils from different sources, though slightly different in constitution, possess so many properties in common that any proximate separation of the two is out of the question, and the presence of the oil forming the minor part of the mixture is often only a matter of inference from the abnormal physical and chemical characters of the sample. But if chemists can see little hope of detecting in all cases the exact nature of complex mixtures of oils, they are now in a position to indicate with considerable certainty whether a given sample of oil is fitted for its intended purpose, and in this manner may do great service, and relieve the engineer and manufacturer from the crying evils of corrosive lubricating oils, non-drying linseed oils, and objectionable sophistications of all kinds.

In conclusion, I may call your attention to a very ingenious arrangement devised by Soxhlet for extracting oils from seeds, etc., but which is capable of numerous other applications. A flask containing ether or other volatile solvent is heated by means of water contained in an outer vessel of tinned iron or copper. Fitted to the neck of the flask by means of a cork is the Soxhlet tube, which consists of a kind of large test tube furnished with a siphon. The vapour passes into the upper part of this tube by means of the side tube, and thence rises into the Liebig condenser, where it is condensed, and drops upon the sample, which, in my apparatus, is contained in a loose inner test tube, having a hole at the bottom closed by a plug of glass-wool. When the condensed solvent, having the oil in solution, rises sufficiently high, it passes into the siphon, and forthwith runs back into the flask, to be again evaporated, condensed and utilized. When the exhaustion is complete it is only necessary to remove the inner tube, when the apparatus is ready for another extraction.

Reviews.

PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION at the Thirtieth Annual Meeting; also the Constitution, By-Laws and Roll of Members. Philadelphia. 1883.

This year the annual volume of the American Pharmaceutical Association came to hand later than customary, but not too late to be welcome. As usual the Report on Pharmacy by Professor Diehl constitutes a large portion of the volume, extending over about 440 octavo pages. We have referred in former years to the nature of the arrangement adopted in these reports as bringing into juxtaposition abstracts referring to kindred subjects, and have only to say now that this plan is well carried out in the present volume. The report is very creditably executed, and although it is more inclusive than the corresponding section in the Conference Year-Book, we see little in it to object to on that ground. One valuable feature, in which it certainly has the advantage of its British contemporary, is the extent to which it is illustrated by means of woodcuts, especially in abstracts where any new apparatus may be described.

An epitome of the papers read at the meeting at Niagara Falls in September last has already been given in this Journal. These papers and the discussions following them are now printed *in extenso* in the volume before us. We do not think that the plan of printing the papers in one section and the discussions in another is at all a convenient one, besides which it probably tends to the ignoring of the latter.

We are frequently applied to for information respecting the laws regulating the practice of pharmacy in the United States and have sometimes felt much difficulty in complying with such a request in consequence of the multiplicity of existing laws, and the constant changes that are still being made. But as is well known the American Pharmaceutical Association appoints every year a Committee on Legislation, whose special duty it is to keep the knowledge of the members *au courant* with the legislative changes affecting their calling in different parts of the Union. The last report states that during the previous year new laws regulating the practice of pharmacy had been enacted and approved in the states of Georgia and Wisconsin, and amendments to previously enacted pharmacy laws had received the sanction of the proper authorities in Connecticut, Iowa and West Virginia. Laws intended to prevent the adulteration of food and drugs had been enacted in Louisiana and Massachusetts, and in Connecticut a new licence law contained a clause referring to the supply of alcoholic liquors for medicinal purposes. In pursuing its inquiries the Committee became acquainted with the fact that there were in operation several laws affecting the practice of pharmacy that had escaped notice in previous years, and extracts from these are now given. The present volume, therefore, contains an unusual amount of information on this subject.

THE CHINESE OPIUM SMOKER. London: S. W. Partridge and Co. 1883.

Hitherto we have carefully abstained from introducing the subject of the opium controversy into these pages, and only refer to it now in order to direct the attention of our readers to a pamphlet bearing the above title on account of its artistic merits. It consists mainly of twelve illustrations, fac similes of Chinese drawings, depicting the downward stages of the opium smoker. It is stated in the preface that the pictures were originally published in the form of cartoons in China, and that in that country they have been posted up in the wayside tea-houses, as well as on the walls of public places, and circulated far and wide among the Chinese people at the expense of native gentlemen who have become alarmed at the spread of opium smoking, or who have wished to store up merit for themselves by circulating tracts and leaflets exhorting men to virtue. About six years ago the Chinese Anti-Opium Society of Canton republished a set of these pictures with a descriptive text, and an English resident in Hankow, thinking that people in this country might be reached by pictures who would not read ordinary anti-opium literature, sent home a set coloured by a native artist. It is from this set that the fac similes have been taken; the pictures have been beautifully executed, and each is accompanied by a translation of the original Chinese description. It is not probable that the sum of sixpence, the price at which the pamphlet is published, represents more than a portion of the cost of bringing it out.

CACAO: HOW TO GROW AND HOW TO CURE IT. By D. MORRIS, M.A., F.G.S. London: S. W. Silver and Co.

This little manual contains the substance of a lecture delivered under the auspices of the Institute of Jamaica by the indefatigable Director of Public Gardens and Plantations in that island, which had for its primary object the diffusion of information respecting the cultivation and preparation of cacoa, with a view to a further development of the industry. After historical and descriptive accounts of the cacao plant, the author deals with the methods of cultivation, the gathering of the crop, and the subsequent sweating and curing of the beans, and he also gives some information valuable to intending planters as to the cost of establishing a cacao estate and its relation to the average yield of the trees. We learn that a good cacao tree in good soil yields from fifty to several hundred pods per annum; the average for well cultivated trees at seven years old is between eighty and one hundred pods, about eleven pods being required to yield one pound of cured cacao. Certainly the author holds out a tempting inducement to those in a position to take up the cultivation in Jamaica, for he tells them that by combining on the same plantation the cultivation of the cacao and the banana, sufficient profit may be derived from the sale of the banana fruit to cover the entire expenditure during the first four or five years required for the maturation of the cacao plants. The book contains a considerable amount of interesting reading, though many of the details will be of use only to those who can give them practical application.

Cannabin.

Sir,—Dr. Matthew Hay states in the *Pharmaceutical Journal*, No. 675, 1883, that he has discovered in the Indian hemp an alkaloid, to which, from its action, he gives the name of tetano-cannabine.

This gentleman at the same time remarks that he received, some considerable time ago, from Messrs. T. and H. Smith and Co., of Edinburgh, under the name of cannabine, a preparation which was not pure, but which, probably, consisted of a mixture of resin and varying quantities of the active principle of the hemp, while a cannabine supplied to him by me, apparently prepared in a similar manner to that of Messrs. Smith, possessed very little or no narcotic action.

Replying in self-defence to Dr. Hay's remark, I beg to mention that I have in my price-current two entirely different preparations from Cannabis indica, viz., firstly, cannabin, being the ordinary commercial resin from Indian hemp; and secondly, cannabin. tannic. (Merck).

The first cannabin mentioned, and described by Dr. Hay, is a resinous body which, from long custom, still goes under the name of cannabine, but the action of which, as I had long since discovered, is far from being certain or reliable. In consequence, I have made it the study of many years to isolate the active principle of the Indian hemp, a task in which I have, I flatter myself, after very considerable labour and trouble, succeeded.

This is the cannabin. tannic. (Merck) referred to above, and which glucoside has nothing whatever in common with the ordinary resinous cannabin.

A series of experiments, as to the effect of my cannabin. tannic. has been made, and I give here a few extracts from my report on "New Remedies," of February of this year, on the subject.

"*Cannabin. Tannic.* (*Merck*).—The preparation which I introduced under this name is a glucoside contained in Indian hemp, combined with tannin. Endeavours have been repeatedly made to discover and isolate, in a form suitable for medicine, the active principle of this plant, which has long been treasured for its medicinal properties. A cannabin has long been in vogue, which, however, under this name, was really little more than a very pure extract of cannabis indica.

"After numerous experiments, involving much time and trouble, I succeeded in producing this new preparation, which in the very short time of its existence has gained for itself a considerable reputation.

"As already mentioned, this cannabin is of a glucoside nature, and resembles, in its chemical comportment, solanin and allied preparations, in that it shows an alkaloid reaction. The combination with tannin has been chosen in order to give to the glucoside, which is of a nature very liable to decomposition, a handy and durable form.

"The action of cannabin. tannicum is narcotic, viz., soothing and soporific, without any bad after effects, as is often the case after the use of morphia and other opiates. With regard to its practical use, we have an article by Dr. Fronmüller in the *Memorabilien von Betz*, 1882, No. 51, which says:—'The patients to whom this cannabin was administered were afflicted with almost every variety of disease, and were at the same time suffering to a high degree from nervous sleeplessness, for which they had nearly all taken opium or morphia without effect.'

"The dose of cannabin. tannicum varies in different cases from 0·1–1·5 gram, but the most usual was 0·2–0·5 gram, administered, as a rule, at about half-past nine in the evening. Only in the case of very large doses, 1·0 or 1·5 gram (in the case of very delicate individuals, also, naturally, with smaller doses), were appearances of unconsciousness occasionally observed, which, however, quickly disappeared on the use of acetic ether.

"Most important is the fact, that neither were the digestive organs in any way affected, nor retarded motion of the bowels produced, as is generally the result from the use of other opiates.

"Dr. Hiller (Charité Berlin) also referred, at the January meeting of the 'Verein f. i. Medicin,' to my cannabin. tannic, and his observations agreed with those of Dr. Fronmüller. He described it as a mild and agreeable hypnotic, especially in cases where morphia cannot be administered on account of unfavourable after effects of the latter drug on the patient. It also appears that the use of cannabin. tannic. will have a very large and important field in asylums for the insane.

"I am indebted to Dr. Karrer, of the *Kreisirrenanstalt Erlangen*, for various communications, according to which highly satisfactory results were obtained with my cannabin. tannic. in cases of excited and restless lunatics."

In the interest of myself, and also of others, I deem it advisable to give publicity to the above, inasmuch as Dr. Hay does not seem to be acquainted with my cannabin. tannic., to which he does not in any way refer.

Darmstadt. E. Merck.

Purity of Sodium Nitrite.

Sir,—I am sorry that a mistake in the "Month's" abstract of my paper on the "Nitrite of Sodium in Angina Pectoris" has misled Mr. Ekin in his letter to you in the issue of June 9.

The abstract is so far right in stating that a specimen of nitrite of sodium procured from a London firm of acknowledged eminence contained actually only 33 per cent. of the nitrite, the remainder being nitrate. But it is wrong in attributing to me the statement that in another specimen, purchased two years previously, I found only a trace of the nitrite. What I really said was—a trace of the nitrate.

It is due to the London firm alluded to that I should add that a specimen of the nitrite, which they have recently forwarded to me, is as pure as could be expected.

The purity of the nitrite depends much on the process of its manufacture. Employing the proper process it is not difficult to obtain a comparatively pure nitrite. But I confess I am agreeably surprised to observe that, according to Mr. Ekin, nitrite of sodium is "one of the purest salts to be met with in commerce." It may be so when prepared under a guarantee, as for Mr. Ekin, but I fear it is not commonly so pure.

12, *Hope Street, Edinburgh.* Matthew Hay, M.D.

W. J. Williams.—The Secretary to the Institute of Chemistry is Mr. C. E. Groves, Somerset House Terrace, Strand, W.C.

M. C. Summers.—We cannot refer you to a book such as you describe, neither are we acquainted with the work mentioned.

"*Pharm.*"—(1) "Tinct. Ferri Perchlor. ℥j; Bals. Copaib. ℥j; Sp. Æth. Nit. ℥j; P. Cubeb. ℥ss." This mixture presents no difficulty. The ingredients require only to be mixed; no attempt should be made to emulsify with mucilage. (2) "Potass. Permang. ℈j; Syr. Aurant. ℥j; Aq. ad ℥viij." In this case reduction takes place and the mixture gelatinizes.

R. Modlen.—It has already been observed that a mixture containing spirit of nitrous ether and sodium salicylate becomes discoloured more or less; dependent on the condition of the spirit of nitrous ether.

"*Rhei.*"—"Iodoform, Creasote, aa gr. j: fiat pil." One grain of bread crumb to each pill answers very well as an excipient.

"*Provident*" is recommended to communicate his suggestion to the Council of the Chemists' Assistants' Association.

"*Pill Coater.*"—You do not mention the material you wish to use. For a process of coating pills with gelatine, see before, p. 506. A number of other communications on the general subject have been published in this Journal, references to which may be found in the indexes to the different volumes.

Communications, Letters, etc., have been received from Messrs. Gillman, O. Jones, Cowan, Miller, Mumbray, Kinninmont, Crinis, J. D. N.

THE ANALYSIS OF SOME AUTHENTIC SPECIMENS OF NUX VOMICA.

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry,
AND F. W. SHORT,
Assistant Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

The specimens of the seeds of *Strychnos Nux-vomica* which form the subject of the present communication came into our possession through the kind interest of Professor Bentley,* who had already† laid stress upon the desirability of a chemical examination of the seeds from different districts being made. During the discussion of our paper upon "The Assay of Nux Vomica," at a meeting of the Pharmaceutical Society in February last, Professor Bentley again alluded to the matter, when we promised to make a chemical examination of such authentic specimens as could be obtained (*Pharm. Journ.*, [3], xiii., 677). The seeds of nux vomica appear to come into the English market under three heads: "Bombay," "Cochin" and "Madras." Of these the "Bombay" is the most highly prized by manufacturers. No analysis of these seeds has been published, and in fact, so far as we can find, there is no analysis upon record of an authentic specimen of this important drug. Two series of specimens are in our possession, the one collected in 1877, the other in the present year. The first series were labelled "Bombay Fine," "Bombay Ordinary," "Cochin," "Madras." The second series, "Bombay," "Cochin," "Madras." The seeds labelled "Bombay Fine" had evidently been assorted from "Bombay Ordinary," the selection being apparently based upon the acute edge and satiny texture. The appended table embodies the principal physical characters of the specimens. One of us has spent some time in endeavouring to identify the source or sources of the above specimens, but with little success. The authentic specimens of the entire plant in this country are so scant, often mutilated, and so seldom accompanied by the seeds, that no certain conclusion could be arrived at from their examination. It is unnecessary to enter into a description of the specimens of the plant in this country. The description of the following specimens in the Kew Herbarium may be taken as representative, and are worthy of record:—

Strychnos Nux-vomica—

Large tree, grows from 25 to 40 feet. Larger trees, excepting shoots at base, seem thornless. Smaller, thorny in parts.

On the Kala Nuddi. Dr. Ritchie, December, 1852.

Description by W. R. D.

Leaves: veins, five. Three veins very marked, two indistinct.

[Largest leaf: *breadth*, maxim. 66·54 mm.; *length* from apex to stalk, 127 mm. *Apex*, accuminate, distinct.]

[Smallest leaf: *breadth*, maxim. 57·15 mm.; *length* from apex to stalk, 69·8 mm. *Apex*, indistinct.]

Seeds: concavo-convex, rounded at edge; breadth, maxim. 25·4 mm.

Strychnos Nux-vomica—

From the Herbarium of the late East India Company. Grown at Birmah.

Description by W. R. D.

Leaves: veins, five. Three veins very marked, two indistinct, but more distinct than in K. N.

[Largest leaf: *breadth*, maxim. 10·79 m.m.; *length* from apex to stalk, 69·8 mm. inch.]

Seeds: edges acute, seed very fleshy in centre; *breadth*, maxim. 19·05 mm., *length*, 22·09 mm.

In connection with the physical characters of the seeds, two points should be noticed. Pereira ('Materia Medica,' vol. 2, pt. 1, p. 635), states that the seeds of commerce are scarcely one inch (25·4 mm) in diameter, and also Flückiger and Hanbury ('Pharmacographia,' p. 385). Bentley and Trimen (Med. Pl., 178) state that they are about one inch, averaging seven-eighths of an inch (22·09 mm.): compare the plate of the nux-vomica plant in this work. Many of the seeds at present described have a diameter of 1·1 inch (28 mm.) and average 0·9 inch (23 mm.). The specimens in the Kew Herbarium much more nearly coincide with the descriptions of the authorities above cited.

Again, Pereira ('Materia Medica,' vol, ii., pt. 1, p. 636) describes the cotyledons as "triple ribbed;" but it will be observed that in all the seeds now examined the cotyledons are seven-veined, although in some specimens the two lateral veins are indistinct. Flückiger and Hanbury ('Pharmacographia,' p. 385) state that the cotyledons are from five to seven-veined.

We hope, before long, to obtain some information which will lead to the identification of the plants yielding the seeds which enter the British market and thus to settle the question whether the various seeds originate from different species of the plant.

Method of Analysis.—A difficulty was encountered at the outset when it was attempted to obtain the seeds in a fine state of division. The extreme toughness of the seeds is well known, and upon the small scale, unless special appliances are at hand, a very laborious process is involved in obtaining them as a fine powder by direct pulverization. The method commonly recommended for this purpose, for instance, by the British Pharmacopœia, is to expose the seeds to a process of steaming, and subsequently to dry before powdering. This method answers well as far as the attainment of a fine powder is concerned, but in the present instance was obviously open to objection, for during the steaming condensation of water upon the seeds inevitably occurs, and as boiling water was found to extract no inconsiderable amount of alkaloid it was evident that some other method must be resorted to. The method which we finally adopted was to dry the previously split seeds at a temperature not exceeding 100° C. for three hours and then to reduce to powder in a drug mill. The seeds were found to lose from 10 to 11 per cent. of water when dried at 100° C., and the seeds thus dried very rapidly reabsorbed this amount of water upon exposure to the air. In this way we had no difficulty in obtaining the seeds in a fit state for analysis. Exposure at temperatures from 120° C. to 150° C. was found to effect a decomposition in the constituents of the seeds and thus to complicate matters at a subsequent stage; yet an examination of commercially ground specimens has shown that this procedure is far from uncommon. Some care has to be observed in grinding the seeds, in order that the specimen taken for analysis may be uniform and representative. In grinding, the greater part of the outer

* The seeds were collected in the drug market by Mr. William Hodgkinson, of the firm of Hodgkinson, Stead and Treacher, to whose genuine concern in this matter we are much indebted.

† Bentley and Trimen, 'Medicinal Plants,' 178.

coating of the seeds comes through in the form of light fluffy particles which aggregate together, and if care be not taken these will become separated from the more dense albuminous portions which subsequently comes through the mill. The specimens having been prepared for analysis in the manner above described, the amount of total alkaloid (strychnine and brucine) was estimated by the process proposed by us in a previous paper (*Pharm. Journ.*, [3], xiii., 665). This process consists in the extraction of the alkaloidal salts direct from the seeds by chloroform containing 25 per cent. by volume of alcohol, the extraction of the alkaloids as acid sulphates from this solvent by agitation with dilute sulphuric acid, and finally, the extraction of the alkaloids from the acid solution with chloroform after the addition of excess of ammonium hydrate.

It has been noted above that the powdered nux vomica of commerce has frequently been dried at a temperature exceeding 100° C., with the consequent alteration of certain constituents of the seeds. When this is the case it will be found that the chloroform-alcohol percolate is dark in colour, and often the final alkaloidal residue is brown. Before the cause of this abnormality had been discovered, we had made some experiments with the view of purifying the original percolate. It was found that this could be very effectively done by agitation with a solution of sodium carbonate containing 5 per cent. of the crystalline salt, the dark colour of the chloroform-alcohol percolate being by this means entirely removed. In ordinary cases the colouring matter dissolved by the solvent is retained by the ammonia in the final treatment, but when the seeds have been dried at a high temperature some of the colouring matter is not thus retained, but is dissolved with the alkaloid by the chloroform. It is true that the amount of this impurity in the alkaloidal residue is not very appreciable, as is shown by the following experiments, and when approximate results only are required the preliminary treatment with sodium carbonate may be omitted. In other cases, where strict accuracy is required, it should be adopted when the percolate exceeds dark yellow in colour. Again, in the manufacture of the alkaloidal salts by this process treatment with sodium carbonate is advantageously employed, for the removal of this colouring matter together with the alcohol greatly facilitates subsequent crystallization.

The following results from highly dried seeds show the influence of sodium carbonate as a purifying agent: (α) the percentage of alkaloid obtained normally, (β) the percentage of alkaloid found after treatment with sodium carbonate.

	α.	β.
1.	2·75	2·62
2.	3·32	3·20
3.	2·45	2·36

The solution of sodium carbonate was also used in the analysis of normally dried seeds (100° C.). The experiments show that its use in such cases is unnecessary—

	α.	β.
1.	3·16	3·12
2.	3·48	3·45
3.	3·12	3·18
4.	3·61	3·55

We have previously noticed (paper above cited) that the method of ascertaining the purity of the final alkaloidal residue by precipitation with tannin is not altogether satisfactory, for we found that tannin was incapable of entirely precipitating the alkaloids from even slightly acid solutions. We have since made a great number of experiments on this point. In the first place we find that with the hydrates or carbonates of ammonium, sodium, and potassium, even when added until the solution is only faintly alkaline, it is impossible to precipitate the whole of the alkaloids from solution; this is especially the case with brucine. With reference to other precipitants, none of those employed by us are applicable in acid solution, and the experiments included platinum chloride, potassium mercuric iodide, potassium bismuth iodide, phospho-tungstic acid, phospho-molybdic acid, tannin, picric acid, and potassium chromate. Most of the experiments were quantitative, and showed errors far beyond the limits of the experimental equation. Fairly satisfactory results were obtained with platinum chloride in neutral solutions, and still better with tannin made faintly alkaline with ammonia. The alkaloidal residue to be tested was dissolved in dilute sulphuric acid, the solution made exactly neutral with ammonia, precipitated with excess of the ammonia-tannin solution, the precipitate washed with the same solution, then dissolved by a saturated solution of sodium carbonate, and the alkaloid extracted with chloroform from this solution. This process answers well, although, owing to the large field for experimental error, the process did not give exactly coincident results, even when the pure alkaloids were employed, yet when carefully performed the results are always sufficiently near to pronounce upon the purity of an alkaloidal residue. The following table exhibits some typical results obtained from the residues obtained in the course of analysis: (α) percentage of alkaloid normally found, (β) percentage found after the treatment of the residue with ammonia-tannin:—

	α.	β.
1.	1·68	1·66
2.	2·64	2·57
3.	3·04	2·94
4.	3·90	3·84

The amount of residue used in the above experiments varied from 0 10 to 0·15 gram, that is to say, it was obtained from 5 grams of nux vomica, and to this quantity we were restricted by the great ease with which the alkaloids were decomposed when exposed in a solid state for any considerable length of time at 100° C. We attempted to ascertain by the tannin process the purity of a comparatively large quantity of the alkaloidal residue weighing about 1·0 gram, this being extracted from 30 grams of nux vomica. This quantity gradually lost weight during six hours when exposed on the water-bath, and at the end of this time was dark brown in colour and did not wholly dissolve in dilute sulphuric acid. The same quantity of the pure alkaloids behaved in a precisely similar manner. A further result of this decomposition is the preclusion of the use in analysis of more than 5 grams of nux vomica; for this quantity yields a residue which requires one hour for complete drying, and after this time begins gradually to decompose, consequently the length of time necessary for complete desiccation, in cases where a larger amount of residue than this is obtained would involve the decomposition of the alkaloids in the manner we have just described.

In view of the results described above the following method was adopted for the analysis of the seeds: Five grams of the finely divided seeds, after drying at 100° C., were exhausted with 40 c.c. of chloroform containing 25 per cent. by volume of alcohol. For this exhaustion the extraction apparatus described by us in a former paper (*Pharm. Journ.*, [3], xiii., 663) was employed and the hot digestion and repercolation continued until a few drops of the solvent after passing through the marc left no residue on evaporation. The percolate was agitated with 25 c.c. of a 5 per cent. solution of sulphuric acid, the chloroform separated and agitated again with 10 c.c. of the dilute acid. The mixed acid solutions were filtered if necessary, rendered alkaline with ammonium hydrate, and shaken with two successive 15 c.c. of chloroform, or with a sufficient quantity to thoroughly extract the alkaloid. The chloroform was separated, if necessary filtered, evaporated, and dried at 100° C., until constant in weight, which usually occupied one hour. Some little trouble is always experienced in the separation of chloroform from aqueous liquids, especially when alkaline; the separation is much facilitated by heat, but even then, often much depends upon the ingenuity and dexterity of the experimenter. It may here be stated that in the filtration of aqueous liquids containing chloroform if the filter-paper is well wetted with chloroform the chloroform alone will pass through from the mixture, leaving the aqueous liquid; but if on the other hand the paper be wetted with water the aqueous liquid will flow through, leaving the chloroform upon the filter.

The appended tables show the results of our analysis of the two series of specimens of nux vomica. It will be observed that although the specimens in the two series differ in alkaloidal content, the order of content in each series is precisely the same, that is, Bombay first, Cochin second, and Madras third. These results are at once interesting and important. The specimen of "Bombay" in the second series contains the largest percentage of alkaloid yet recorded in the seeds of *Strychnos Nux-vomica* (3·90). Of the specimens (? source) examined by Dragendorff,* the highest percentage of total alkaloid found was 2·88. In the series of commercially powdered nux vomica previously analysed by us (*Pharm. Journ.*, [3], xiii., 665), the richest specimen yielded 3·57 per cent. The present results also show that these above-mentioned specimens of powdered nux vomica were of good quality and free from adulteration. The pharmaceutical aspect of the great difference in the alkaloidal content of the various specimens of *Strychnos Nux-vomica* disclosed by these results is of no small moment; upon this point we shall dwell at a future time. We also hope to perfect an accurate method for the separation of strychnine and brucine.

* Die Chemische Werthbestimmung einiger Starkwirkender Droguen, p. 65.

Series I. (collected 1877).

Specimen	Diameter.	Thickness.	Circumference.	Nature of Edge.	Texture	Form.	Interior.	Percentage of strychnine and brucine.
Bombay Fine.	20·25 to 25·5 mm. average 23·0.	4·0 mm.	60·0 to 82·5 mm. average 70·0.	Generally acute.	Very silky.	Nearly flat; fairly regular; few concavo-convex and bent.	Cotyledons 7-veined; two outer veins small.	3·46
Bombay Ordinary	19·0 to 28·0 mm. average 23·0.	5·0 mm.	60·0 to 82·5 mm. average 70·0.	Generally rounded; some acute.	Silky.	Nearly flat; some irregular; few concavo-convex.	Cotyledons 7-veined; two outer veins small.	3·14
Cochin	19·0 to 28·0 mm. average 23·0.	4·0 to 6·0 mm. average 5·0.	57·0 to 79·0 mm. average 68·0.	Round; few acute.	Silky.	Nearly flat; some concavo-convex; many irregular.	Cotyledons 7-veined; two outer veins small.	3·04
Madras .	12·5 to 23·0 mm. average 18·0.	4·0 to 5·0 mm. average 4·5.	38·0 to 71·0 mm. average 57·0.	Generally round; seldom acute.	Dull.	Nearly flat; some slightly concavo-convex; some irregular.	Cotyledons 7-veined; two outer veins small; albumen resinous.	2·74

Series II. (collected 1883).

Specimen	Diameter.	Thickness.	Circumference.	Nature of Edge.	Texture	Form.	Interior.	Percentage of strychnine and brucine.
Bombay .	20·0 to 28·0 mm. average 23·0.	2·25 to 4·0 mm. average 3·5.	59·0 to 84·0 mm. average 73·0.	Nearly all acute.	Very silky.	Nearly flat; fairly regular; some concavo-convex.	Cotyledons 7-veined; two lateral veins small and sometimes indistinct.	3·90
Cochin .	19·0 to 28·0 mm. average 25·0.	4·0 to 5·0 mm. average 4·5.	57·0 to 84·0 mm. average 74·0.	Round.	Slightly silky.	Nearly flat; few slightly concavo-convex.	Cotyledons 7-veined; two lateral veins indistinct.	3·60
Madras .	12·5 to 21·5 mm. average 19·0.	4·0 to 5·0 mm. average 4·75.	38·0 to 65·0 mm. average 57·0.	Round.	Dull.	Nearly flat; some slightly concavo-convex.	Cotyledons 7-veined; two lateral veins indistinct; albumen resinous.	3·15

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 1035.)

Senega, U.S.P.; Radix Senegæ, P.G.—A description of the root is now given in the U.S.P., in which the length is given as 10 centimetres, but the average width is omitted. The P.G. gives the limit of width of the rootstock as 1½ centimetres, and the length of the root branches as 2 decimetres, while the bark should not exceed 1 millimetre in diameter. Both Pharmacopœias mention the keel which is characteristic of senega root of good quality. The rootstock of the Northern senega, now so frequent in commerce, derived from the *P. senega*, var. *latifolia*, much exceeds the dimensions here given, and is therefore excluded from the P.G. by the limits imposed.

Senna, U.S.P.; Folia Sennæ, P.G.—The U.S.P. omits *Cassia obovata*, D.C. Alexandria senna should be freed from stalks and from argel leaves, which are thicker, veined, glaucous, and even at the base. India senna should be free from stalks, discoloured leaves and other admixtures. Alexandria senna is described as nearly smooth and India senna as slightly pubescent, the reverse being the case in English commerce. The P.G. now admits the leaves of Tinnevelly senna, and mentions *Cassia angustifolia* as their botanical source. It states that the leaflets of *Cynanchum Arghel* are commonly mixed with those of *Cassia acutifolia*, but does not order their removal, remarking only that senna leaves should not be brownish or yellowish. It states that the argel leaves may be easily recognized by the ornament of short rigid hairs. This, however, is not the case, since both Alexandria and Tinnevelly sennas have similar hairs. The minutely wrinkled surface of the argel leaves is the best character by which to recognize them with the naked eye, especially when the base of the leaf is broken off.

Serpentaria, U.S.P.—The root is now omitted from the P.G. The U.S.P. restricts the official drug to the roots of *Aristolochia Serpentaria*, L., and *A. reticulata*, Nuttall, remarking that the roots of *A. reticulata* are coarser, longer, and less interlaced than those of *A. Serpentaria.* It is *A. reticulata* which is generally sold in English commerce as the root of *A. Serpentaria.*

Serpylli herba, P.G.—It must be borne in mind by those who have to dispense German prescriptions that *Herba Serpylli* and *Herba Thymi* are not synonyms for the same plant, but that the former indicates *Thymus Serpyllum* and the latter *Thymus vulgaris.*

Sinapis nigra, U.S.P.; Semen Sinapis, P.G.—The seeds of *Sinapis alba* are not official in the P.G., but both species are noticed separately in the U.S.P. The P.G. states that the cooled and filtered decoction of powdered seeds should not afford a blue colour with iodine water.

Spigelia, U.S.P.—The rhizome and rootlets only are official. The rhizome should be 2 inches or more long and about ⅛ inch thick, and the rootlets purplish dark brown. It should not be confounded with the underground portion of *Phlox Carolina*, L., the rootlets of which are brownish yellow, rather coarse, straight, and contain a straw-coloured wood underneath a readily removable bark.

Staphisagria, U.S.P.—The seeds of *Delphinium taphisagria*, L., are now official, but the seed of *D. Consolida*, formerly official in the secondary list under the name of Delphinium, is omitted.

Stillingia, U.S.P.—The root of *Stillingia sylvatica*, L., is described as being about 12 inches long and nearly 2 inches thick, sub-cylindrical, slightly branched, compact, wrinkled, tough, greyish-brown, breaking with a fibrous fracture, showing a thick bark and porous wood, the mixed bark and medullary rays with numerous yellowish-brown resin cells; odour, peculiar; taste unpleasant, bitter, acrid and pungent. The root, as usually seen in this country, is rarely an inch in diameter. Attention has recently been called to this drug by Dr. Marion Sims as a remedy in syphilis (*Brit. Med. J.*, March 10, p. 449).

Stramonii Folia, U.S.P.; Folia Stramonii, P.G.—The P.G. directs that the leaves should be collected during the period of flowering, and gives the maximum dose of the leaves as 0·2 gram. The seeds are official in the U.S.P., but omitted from the P.G.

Sumbul, U.S.P.—The root is referred to *Ferula Sumbul*, Hook. f. The Indian sumbul is not mentioned; an example which might well be followed in a future British Pharmacopœia, since there can be little doubt that the reddish kind mentioned in the last edition of that work is false sumbul, prepared by colouring and perfuming ammoniacum root. As a tincture is official in the U.S.P., and the tincture of the false sumbul is much darker in colour than that of the true drug when made of the same strength, a colour test would have been an advantage.

Tabacum, U.S.P.; Folia Nicotianæ, P.G.—The U.S.P. directs the commercial dried leaves of *N. Tabacum*, L., up to 20 inches in length, but the P.G. orders leaves "*modicæ magnitudinis specierum cultarum quas habet Nicotiana Tabacum, aere nulla arte adhibita siccata.*" By which it may be supposed that medium-sized leaves of any cultivated variety of *Nicotiana Tabacum* are intended, dried without previous fermentation; but these are not easily obtained in commerce, at least in this country.

Tamarindus, U.S.P.; Pulpa tamarindorum cruda, P.G.—No mention is now made in the P.G. of the Egyptian and West Indian tamarinds, which in the last edition were ordered to be rejected; but judging from the description, the East Indian tamarinds are still the official kind, while the U.S.P. apparently intends the West Indian to be used, since it describes tamarinds as a reddish-brown, sweet, subacid, pulpy mass. The test for copper is not given.

Taraxacum, U.S.P. Radix Taraxaci is now omitted from the P.G., but Radix Taraxaci cum Herba is retained. It is to be collected in spring before flowering, and dried, and the extract is to be prepared from the dried plant. This plan, as the extract is made with cold water, presents the advantage of excluding the large quantity of inulin often present in extracts made in the autumn.

Terebinthina, U.S.P. and P.G.—The American turpentine is now attributed to *Pinus australis*, Michaux; this name being a synonym of *P. palustris*, Mill. The drug corresponds with the *Thus Americanum* of the B.P. German turpentine is now chiefly that made from *Pinus pinaster* and *P. Laricio.* It should contain 70 or 80 per cent. of resin and 30 to 15 per cent. of essential oil. The crystalline sediment in it should dissolve when the turpentine is heated in a water-bath, and the liquid should form a clear solution with five times its weight of spirit, the solution strongly reddening moistened litmus paper. Venice turpentine is no longer official in the P.G.

Terebinthina Canadensis, U.S.P.—This should be completely soluble in ether, chloroform or benzol.

Thuja, U.S.P.—The twigs of *Thuja occidentalis* are the part official. This drug apparently owes its introduction to its extensive use amongst the homœopathic section of the community in the United States. Although recommended in Philip's 'Materia Medica' as valuable in certain diseases, it does not appear to have been received with much favour as yet by allopaths.

Tiliæ Flores, P.G.—The botanical names *Tilia ulmifolia* and *T. platyphyllos*, Scopoli, have been adopted instead of *T. parvifolia* and *T. grandiflora*, for the official plants. The warning against the use of the leaves of *T. tomentosa* is now omitted.

Tormentillæ rhizoma, P.G.—The root should give, with forty times its weight of water, an astringent liquor, which with the addition of a small quantity of sulphate of iron should give a bluish-black colour and on the addition of lime water an intense violet sediment.

Tragacantha, U.S.P. and P.G.—The U.S.P. now gives *Astragalus gummifer*, Labill., and other species, as the botanical source. The P.G. mentions *A. ascendens*, *A. leiocládos*, *A. brachycalyx*, *A. gummifer*, *A. microcephalus*, *A. pycnoclados*, and *A. verus*, as yielding the gum. The flakes should not be more than 1 to 3 millimetres thick, nor less than ½ centimetre broad, and should be white and diaphanous. The mucilage made by mixing the powder with 50 parts of water should give a yellow colour with solution of caustic soda; the mucilage, when filtered, should yield a filtrate which will not give a blue colour with iodine, although the insoluble matter in the filter should do so.

Trifolii Fibrini Folia, P.G.—Under this name the leaves of *Menyanthes trifoliata* are still official.

Triticum, U.S.P.—The rhizome of *Triticum repens*, L., deprived of the rootlets and collected in spring is official. The segments should be hollow in the centre, about $\frac{1}{12}$th of an inch in diameter, and have a straw-yellow colour and sweet taste.

Ulmus, U.S.P.—The inner bark of *Ulmus fulva*, Michaux, is alone included under this name. *Cortex ulmi*, prescribed in America, would not be at all represented by the *Cortex ulmi* of the B.P. The bark of *Ulmus fulva* has a remarkably mucilaginous taste, which, although described in the U.S.P. as peculiar, can scarcely be said to be so, since it is met with in fœnugreek, *Melilotus cœrulea*, and in several umbelliferous roots.

Ustilago, U.S.P.—Under this name *Ustilago maydis*, grown upon *Zea Mays*, L., is intended. This new introduction into the U.S.P. should consist of irregular masses, sometimes 6 inches thick, enclosed in a blackish membrane containing brownish-black globular, nodular spores. It should be preserved in a dry place and not kept longer than a year.

Uva Ursi, U.S.P.; Folia Uvæ Ursi, P.G. The description in the U.S.P. is so worded as to imply that the leaves are reticulated on the lower surface only, the upper surface being the more strongly reticulated of the two. The P.G. remarks that there should be no glandular dots on the lower surface of the leaves. An infusion of one part of the leaves in 50 parts of water, set aside for some hours and filtered, should give a red colour, becoming violet when a granule of sulphate of iron is added and shaken up with it, depositing after a little while a sediment of an intense violet colour.

Valeriana, U.S.P.; Radix Valerianæ, P.G.—It should be remembered that the upright rhizome of valerian is about 2 centimetres thick, while the horizontal rhizome of cypripedium, which is commonly sold in this country as American valerian, is only 3 millimetres thick and has numerous cup-shaped scars on the curly brittle rootlets. Occasionally this root has been sold in this country as valerian by dealers in herbs.

Vanilla, U.S.P.; Fructus Vanillæ, P.G.—The botanical source is now more correctly given in the U.S.P., as in the P.G., as *Vanilla planifolia*, Andrews. The U.S.P. uses the term "somewhat warty" in describing vanilla, but this character must surely be of exceptional occurrence.

Veratrum viride, U.S.P.—The rhizome is described as upright, obconical, simple, or divided. *Veratrum album* is the only species official in the P.G., but that Pharmacopœia orders the roots to have the yellowish rootlets present, in which condition it is almost impossible to distinguish with certainty between the roots of the two species, the usually more wrinkled and yellowish rootlets of *V. viride* being an unreliable characteristic.

Verbasci flores, P.G.—The species now adopted is *V. phlomoides*; the use of the flowers of *V. thapsiforme* being also permissible. The size and character of the corolla is now given. The flowers should not be of a brown colour.

Viburnum, U.S.P.—The bark of *Viburnum prunifolium* or black haw, is a new introduction, due probably to the reputation it has recently obtained in the United States as a uterine tonic. The bark is described as occurring in thin pieces or quills of a glossy purplish brown colour, with scattered warts and minute black dots; when collected from old wood greyish-brown; the thin corky layer easily removed from the green layer; the inner surface whitish, smooth; fracture short; inodorous, somewhat astringent and bitter. A fluid extract is the only official preparation.

Viola tricolor, U.S.P.; Herba Violæ tricoloris, P.G.—This new introduction into the U.S.P. is probably inserted with a view to the requirements of the German element in the United States, although no preparation is official in that Pharmacopœia. The plant is a common weed in this country.

Xanthoxylum, U.S.P.—The bark of *X. fraxineum* and *X. carolinianum* are still official. The latter is chiefly distinguished by large conical corky projections and stout brown spines arising from a corky base. Xanthoxylum should not be confounded with the bark of *Aralia spinosa*, which is nearly smooth externally, and beset with slender prickles in transverse rows. The bark of *X. fraxineum* occurs in thin, greyish, quilled fragments, about 1 millimetre in thickness; it has a very pungent taste. Under a lens it exhibits minute crystals, a feature not mentioned in the U.S.P.

Zingiber, U.S.P.; Rhizoma Zingiberis, P.G.—The whitened ginger is not official in either Pharmacopœia.

Zedoariæ Rhizoma, P.G.—The root of *Curcuma zedoaria*. Under this name is intended the greyish root with a camphoraceous taste produced by *Curcuma Zerumbel*, Roxb., and not the yellow root formerly known as "cassumunar root," which is obtained from *Curcuma zedoaria*, Roxb.

CONVALLARIA MAJALIS.*

BY H. G. GREENISH.

It has frequently been remarked that the *Convallaria majalis*, or lily of the valley, can scarcely be classed with the so-called "new remedies" as it is in reality a very old one. But nevertheless with regard to its application in medicine it is truly a "new remedy."

Although in many of the recent publications on Convallaria allusion has been made to its employment by the Russian peasants from time immemorial as a remedy for dropsy, its history in more modern times and in our own country has received but little attention. As the latter possesses for us a greater attraction, and is not without interest, I may be permitted to trace it, as well as I can, for the last three or four centuries.

Apart, therefore, from the mention made of it by Dioscorides and from its use in Russia, a description of the plant was published in 1517 in the 'Ortus Sanitatis' and illustrated by a woodcut, which, though rough, sufficiently resembles it to allow of recognition.

"Neither the leaves nor the roots," says the author, "are used in medicine; the virtues reside in the flowers;" to these aperient properties are attributed. They are prepared for medicinal use by infusing in white wine, distilling the infusion and mixing it with lavender water and pepper. This exclusive use of the flowers and the method of preparing them continued general for centuries.

In 1586 Rovillius honoured the lily of the valley with a lengthy notice in his 'Historia Plantarum.' The flowers and fruit are said to be warm and dry; the former are useful in apoplexy, epilepsy, vertigo, palsy and other diseases proceeding from a cold and damp brain; hence the juice or a decoction of the plant is administered in such cases. It is also said to be employed to cure leprosy, to remedy blindness or indistinct vision, and to counteract the bites of poisonous animals. Some persons, according to Rovillius, make a preparation by infusing the flowers in white wine and distilling as just described.

In 1633, we find it mentioned in Gerard's 'Herbal.' In 1639 it is admitted into the Pharmacopœia Londinensis, in which it constitutes an ingredient in the Aqua Antepileptica. The flowers were infused in white wine and distilled, but any specially anti-epileptic property this preparation may have possessed might have been attributable to some other of the nineteen substances that entered into its composition. Possibly it was found to be unsatisfactory, either in its effects or in the number of ingredients it contained, for in the next edition, the latter is increased to twenty-seven and the name changed to a much more familiar one, viz., "Spiritus Lavandulæ Compositus." This preparation still contained the flowers of the lily of the valley, *flores lilii convallii*, and appears to have been a more effectual preparation, as it remained in the Pharmacopæia till 1746.

The lily of the valley must certainly about this time have been held in high estimation. Schröder, in his 'Compleat Chemical Dispensatory,' mentions six preparations of the flowers, the roots being but seldom used. He ascribes hot and dry virtues to them, and powdered, he says they form an excellent sneezing powder. And its celebrity was not confined to our own country. In France, Germany and Belgium it was a well-known drug. The Royal Pharmacopœia of France, published in 1678, contains several preparations into the composition of which it enters, as for instance, an "apopletick water," a "paralitick water," a "corrected antiepileptic water of Langius," which latter is said to be much bettered by the addition to it of shavings of human skull.

In Germany it was the subject of dissertations by Doederlinus in Altorf, 1718; Senckberg in Göttingen, 1737; Mossdorp in Magdeburg, Schulze in Halle, 1742.

From this time until its re-introduction some years since by the Russians but little is heard of the plant. In 1810, Lewis, in his 'Complete Dictionary of Materia Medica,' observes that the watery or spirituous extracts of the flowers act as gently stimulating aperients and laxatives and seem to partake of the purgative virtues as well as the bitterness of aloes. The roots possess the same properties in a greater, the leaves in a lesser degree.

The properties that have been attributed to the lily of the valley are, as we have seen, manifold. It was well known as an aperient and is mentioned as such in the 'Ortus Sanitatis.' It has even been proposed as a substitute for scammony. But the prevailing idea was that a distillate of the flowers was a remedy for epilepsy and apoplexy.

Of the real properties of the drug and of its composition little or nothing was known until Walz, in 1857, isolated the active principles, and Marmé, ten years later, determined their physiological action. In 1865, Martin announced the presence of an alkaloid, majaline, but Tanret was unsuccessful in his endeavours to isolate it. The experiments of Marmé showed that the convallamarin, which possesses a bitter taste and is soluble in water, was a powerful cardiac poison, and acted also, in large doses, as an emetic, whilst the convallarin produced purgative effects without any secondary symptoms.

A few words on the botanical and chemical relationships of Convallaria and its active principles may not be out of place here.

The lily of the valley is generally placed in the natural order Liliaceæ, sub-order Asparagaceæ; its nearest botanical allies are, therefore, the various species of Polygonatum or Solomon's Seal, Majanthemum, Paris and others of the same sub-order, whilst the sub-order Smilaceæ is but little further removed. The first of these, Polygonatum, probably contains active principles similar to or identical with those of the Convallaria. The paridin and and paristyphnin found by Walz in the *Paris quadrifolia* await closer investigation; possibly they may be shown to exercise a similar physiological action. The various species of Smilax contain parillin, which agrees with convallarin in bearing a certain resemblance to saponin. Several species of Trillium and Medeola, both of which are closely allied to Convallaria, are reputed to possess emetic and diuretic properties, and may, therefore, prove to contain cardiac poisons. It is a remarkable fact, says Professor Husemann, that all well-established cardiac poisons are glucosides. Many of them are accompanied in the plants yielding them by other principles possessing a different physiological action; as, for instance, the digitonin of digitalis, which has no action on the heart, the helleborin of hellebore, the convallarin of convallaria. Most of them, in addition to their action on the heart also produce emetic and diuretic effects. Thus several species of squills have long been known as diuretics. One of them only, *Scilla maritima*, has been closely investigated; it has yielded in addition to other principles a powerful cardiac poison, scillitoxin, and an inert substance, scillin.

In 1880, Troitzky and Bojojawlkensky, two Russian physicians, conducted some experiments with Convallaria, but their investigations do not appear to have attracted much attention. Soon afterwards another of their countrymen, Professor Botkin, of St. Petersburg, published a case of neurosis of the cardiac apparatus taking the form of angina pectoris accompanied by palpitation and dyspnœa, in which the palpitation and dyspnœa were almost immediately relieved by the Convallaria. "Our usual cardiac remedies," say Professor Botkin, "digitalis and adonis, have no effect whatever in the vast majority of cases of cardiac neurosis, whilst Convallaria generally acts as a specific."

About the same time Dr. Alfayef, military surgeon in the Caucasus, where the flowers of the Convallaria have a great reputation amongst the people as a remedy for intermittent fever, reported the trial of them in thirty-eight such cases, but the success he met with was in-

* Report on Pharmacology, read before the School of Pharmacy Students' Association.

different. Small doses, he found, invigorated the pulse much more noticeably than large ones, and possessed at the same time a marked diuretic action. "I am, therefore, inclined to think that the convallaria acts as a diuretic only as it stimulates the heart's action, and consequently increases lateral blood pressure, being similar in this respect to digitalis. But its great advantage over digitalis is that it is quite harmless, even in overdoses." There is, however, probably a limit to the overdose that may thus be taken with impunity.

Dr. Ott experimented upon rabbits with an extract of the roots, and concluded that it acted probably directly on the muscular tissue of the heart, whilst the action of digitalis was due to cardio-inhibitory excitation.

Professor Sée found an extract of convallaria in doses of 5 to 8 grains relieved cardiac distress in severe cases of mitral regurgitation and considered it might be used in all forms of heart failure, as it had none of the nauseating effects of digitalis and did not exhaust the contractility of the heart and arteries. Dr. Sansom employed it as a substitute for digitalis, and though convinced of its action in promoting a stronger ventricular contraction was not convinced of its superiority to digitalis.

The preparation of convallaria most suited for administration in heart disease is a matter of interest to us all. As the active principle is not volatile, the distilled waters that we have seen were the favourite preparations up to the end of the previous century are out of the question. Professor Sée, in 1883, undertook to solve the question, and with this object instituted a series of experiments in his clinical practice at the Hotel Dieu, in Paris. Aqueous and alcoholic infusions and extracts were tested, and they were classed by Professor Sée in order of merit as follows:—

1. Aqueous extract of the leaves, which requires a dose three times as large as the extract from other parts of the plant.

2. Extract of the flowers which exercises a very intense action on animals, much less so on man.

3. Extract of the whole plant, including flowers, stalks and roots (and ? leaves).

The dose was ascertained to be about 1 to 2 grams of the extract of the flowers or double that of the extract of leaves.

The order of merit should evidently be reversed, as Nos. 2 and 3 are both more active than No. 1.

About the same time, M. Langlebert published a similar paper. He found that the extract of the flowers and stalks gave good results, unaccompanied by vomiting or purging.

The preparations of the roots and of the leaves fulfilled the therapeutic indications, but possessed emetic and purgative properties if the dose given were too high. He attributes this action, which was exhibited by a series of extracts, to the presence of too large a proportion of roots in the crude material. The best results were obtained with an extract prepared from the flowers and stalks to which one-third of their weight of roots and leaves had been added. Dose from $\frac{1}{2}$ to 2 grams.

The reason for the addition of the roots and leaves is not stated, and is by no means evident. If they produce unpleasant emetic and purgative properties why add them at all? It must be observed that the dose is much larger than that recommended by Alfayef, viz., 5 to 10 grains of flowers or 20 to 30 drops of the tincture (1 to 4). Such small doses are said to act much better than larger ones (1 to 4 drachms of tincture). Is it not possible that the emetic action observed by Professor Sée was due to the greater activity of the extract of the leaves, for Marmé expressly states that the convallamarin itself when administered in large doses produces vomiting? The purging would be attributable to the convallarin.

Tanret comments upon the unsatisfactory nature of Messrs. Sée and Langlebert's results, and advises the administration of the active principle, which can easily be obtained in a state of approximate purity. Unless, however, the amount of impurity be constant it is difficult to see the desirability of this step.

The pharmacist that is desirous of adding a preparation of convallaria to his stock of drugs may well be at a loss to know which part of the plant he should select. Shall he, with Dr. Alfayef, make a tincture of the flowers, 1 in 4? or follow Professor Sée's advice and, having mixed flowers, leaves and stalks in certain proportions for reasons he is unable to fathom, proceed to make from them an extract? Or again, shall he act upon Tanret's suggestion and prepare the active principle in a state of approximate purity? From the literature on the subject no satisfactory answer is to be obtained; but is it not probable that any part of the plant, flowers, leaves or roots, that contains the convallamarin may be used; that the average dose will vary directly with the amount of that principle present, and that in each individual case a series of experiments must be made to determine the individual dose?

Digitalis, it is said, fails in the majority of cases in which it is tried, and the want of a drug exerting a more constant and uniform action on the heart is generally acknowledged. Nothing but a lengthy and systematic trial can, I think, show whether or not digitalis is likely to be superseded by the *Convallaria majalis.*

COMMERCIAL POWDERED RHUBARB AS COMPARED WITH A PERFECT STANDARD.*

BY GEO. W. HAYES.

The "Standard" rhubarb with which the "samples" were compared was personally selected by Mr. Charles Bullock, of the well-known firm of Bullock and Crenshaw, Philadelphia. I have Mr. Bullock's word for it that it "is a fair representative of the market at the present time—*of a good article*—of Chinese rhubarb." "To make assurance doubly sure," I carefully inspected each *piece*, and compared it with the description found in the 'National Dispensatory' (Stille and Maisch), and found it to agree to every characteristic of a first-class article. It was obtained from one of the most reputable houses in the country; selected by one of America's most prominent pharmacists and judges of the quality of drugs; and was then rigidly compared with one of the best authorities on the subject. The "standard" was broken into pieces; carefully dried; powdered in a scrupulously clean iron mortar; sifted; and placed in a tin box with a tightly fitting lid.

The "Samples" were obtained strictly according to the spirit and letter required by the rules of the competition. A friend of the writer obtained all the Philadelphia "samples," in order that the firms from whom they were obtained might not suspect the purpose to which they were to be put. In order to make the tests entirely free from *bias*, caused by knowing the price, source, etc., of the different specimens, each was placed in a tin box with a tight-fitting lid, by a friend, a young pharmacist, each was then carefully marked by him with an appropriate letter or figure, and all information respecting them, together with their corresponding symbols, placed by him in a sealed envelope, not to be opened until the investigation was completed. The only thing the writer knew was the source, etc., of the "standard." Twelve average "samples" were thus obtained and subjected to all the tests. Thinking that the examination for the presence of turmeric was worthy the examination of a much larger number of samples, seventeen additional samples were obtained, and the entire number (thirty in all, including the "standard") tested for this adulterant.

* Extract from the first-prize essay written in competition for prizes offered by Allaire, Woodward and Co., Peoria, Ill. Reprinted from the *The Druggists' Circular and Chemical Gazette.*

The tests were made entirely independently of one another, and were not in any way compared, until the entire investigation was finished. This was done for the purpose of avoiding any undue favourable or unfavourable bias, which one test might exercise upon the results of another. The writer believes that he can most conscientiously say that he has made a most thorough examination of the literature on the subject of Tests for Rhubarb, and that but very little has been written upon this subject which he has not consulted. Some tests, not previously disputed, have proved themselves valueless in his hands. A list of these will be found accompanying this essay. (See appendix.)

The tests are divided into five sections, namely: 1. Physical; 2. Pharmaceutical; 3. Chemical; 4. Microscopical; 5. Physiological.

1. *Physical Tests.*

I. *Colour.*
II. *Smell.*
III. *Taste.*
IV. *Action in the mouth.*

2. *Pharmaceutical Tests.*

These tests were all tried under exactly the same circumstances; in similar vessels, same amount made in each case, as nearly as possible at the same time, etc.

V. *Infusion.*—Four grains in 2 fluid ounces of water at ordinary temperature. Allowed to infuse two days, then noted colour of infusion.

VI. *Decoction.*—Four grains in 2 fluid ounces of water. Boiled for a few minutes, and, when cold, added water to make 2 fluid ounces. Set aside for a day, then noted colour and apparent value of sample, as before. All but three were rather turbid.

VII. *Alcoholic Tincture.*—Ten grains to 2 fluid ounces of stronger alcohol (95 per cent.) allowed to macerate for thirty-eight days, then noted colour. The samples gave but very slight variation in the colour of their tinctures, consequently it is impossible to arrange them in a graded series, as in the case of the infusion and decoction.

VIII. *Chloroformic Tincture Stain on Filtering Paper.*—Three grains to 1 fluid drachm of chloroform. Allowed to stand for a day. The clear tincture was then carefully poured over a piece of filtering paper, and the paper dried. The different stained papers were then compared and their colours graded. This test is a modification of Howie's test. Of the stain produced Mr. Howie says: "With really fine, bright-coloured East Indian rhubarb, this stain is scarcely perceptible, but cheaper and darker samples may yield a brilliant yellow stain, while even the finest bright-coloured English rhubarb will give a yellow stain as deep, and in most cases deeper, than the darkest East Indian."

Ethereal Tinctures of the different samples did not give sufficient variability of colour to be used as a test.

IX. *Solid Aqueous Extract.*—Distilled water being used; and, in each case, the drug was *thoroughly* exhausted and the extract thoroughly dried. It is but fair to state that Dr. Squibb says in regard to this test: "The foolish test of an aqueous extract does more harm than good. . . . Our *garden* rhubarbs will yield over 40 per cent. of aqueous extract at any time." Yet it appears to be possessed of enough value to entitle it to be used in connection with other tests.

X. *Moisture.*

XI. *Portion Insoluble.*—After *thoroughly* percolating drug with cold distilled water.

XII. *Height of Sample* in beaker after allowing 100 grains of it to infuse in 7 fluid ounces of distilled water for fifteen hours. Height from bottom of beaker to surface of water equals 4·25 inches. This test was used by Mr. Greenish, one of Dragendorff's pupils.

XIII. *Test with Calcined Magnesia and Essence of Anise*, B.P.—Rillot's test. Three grains were triturated with 3 grains of calcined magnesia in a perfectly clean mortar. Two drops of essentia anisi, Br.P., was then added, and the mixture triturated thoroughly. The mixture was then placed on a clean piece of white paper, flattened out on the top with a spatula, and allowed to stand two days. The colour of the sample was then noted. According to Rillot, if any rhapontic rhubarb be present, the colour of the mixture will be more or less "decidedly rose." All of the mixtures changed colour somewhat, after the essence of anise was added and the mixture allowed to stand, but only those containing rhapontic rhubarb changed to a more or less "decidedly rose;" the colour of the other mixtures varied from a bright salmon to a light brownish-yellow.

3. *Chemical Tests.*

Tests for Turmeric.—As before remarked, thirty samples in all (including the "standard") were tested for turmeric by Howie's test. Three grains were placed, in the form of a cone, on a piece of fine white filtering paper, and 50 drops of purified chloroform were slowly and carefully dropped on the apex of the cone; a stain was left. When dry, the powder was brushed away, and a pinch of borax placed on the most stained portion of the paper, and a drop of hydrochloric acid allowed to fall upon the pinch of borax. According to Howie, "If turmeric is present, a red colour is produced, . . . while no change, or only a slight bleaching, occurs, if the rhubarb is pure." In order to be very accurate, each of the samples was tested twice. Two gave a most conclusive red colour in both testings. As neither of them belonged to the regular samples (the twelve powdered "samples" and the "standard"), it may be of interest to state that the *first* came from a small wholesale drug house of Philadelphia. The proprietor of the place stated, when the sample was obtained, that the drug was "powdered for us from SELECTED roots. We KNOW it is PURE". His price for this PURE article was sixty cents a pound. The *second* came from a well-known large wholesale house of Philadelphia, price, fifty cents a pound. It must have been either bought already powdered, or been coloured by some drug miller, who was more anxious to turn out a nice-looking article than to maintain his customer's professional reputation. I feel confident that the firm is too honest and too rich to be a conscious party to any sophistication.

In regard to the active principles of rhubarb, there appears to be some uncertainty. After a very careful consideration of the subject, from a practical as well as theoretical standpoint, it appears that cathartic acid is the purgative principle, and chrysophanic acid and tannic acid the tonic principles. The last two are conceded by all to be contained in rhubarb. The first is most positively asserted to be a constituent of rhubarb, by such chemists as Dragendorff and Greenish; and in their published analyses of rhubarb, is given as being the only purgative principle. Watts's 'Dictionary of Chemistry' says; "Cathartic acid appears to be the purgative and tannin and chrysophan the tonic principles of rhubarb." Again, in the 'Proceedings of the American Pharmaceutical Association,' 1879, p. 151, it is stated that "the active principles of rhubarb are cathartic acid, chrysophan, tannin." Mr. John E. Cook, Assistant Professor of Materia Medica, Philadelphia College of Pharmacy, stated the other day, in the writer's presence, that "rheocathartic acid is the cathartic principle of rhubarb." If the writer may be excused the liberty of referring to his own experiments, in such a connection, it appears to him beyond doubt that cathartic acid is the cathartic principle.

The course of analysis is essentially that of Mr. Henry G. Greenish (see *Pharm. Journ. and Trans.*, May 17, 1879, pp. 933–936).

XIV. *Mucilaginous Matter.*—One hundred grains was completely exhausted with cold distilled water, the percolate was carefully evaporated to 30 cubic centimetres, and when cool, to this was added 45 c.c. of stronger alcohol (95 per cent.); the mixture was well shaken and set aside for twenty-four hours. The precipitate was then carefully collected on a tared filter, well washed with stronger alcohol, dried and weighed.

XV. *Cathartic Acid.*—The filtrate was then carefully evaporated to dryness, and carefully dissolved in stronger alcohol, with the very smallest amount of distilled water, to make a clear solution of 15 c.c. To this was added 120 c.c. of absolute alcohol, Squibb's (warranted not below 99·75 per cent.), and the vessel well corked and set aside for twenty-four hours. The precipitate was then collected, washed with absolute alcohol, dried, etc.

XVI. *Chrysophanic and Tannic Acids.*—The filtrate was carefully evaporated to dryness, and dissolved into distilled water with just sufficient stronger alcohol to make a clear solution of 30 c.c. To this was added, as long as it produced a precipitate, a solution of acetate of copper, C. P. The precipitate was rapidly collected, washed with the smallest amount of distilled water, dried, weighed, etc. This precipitate consisting of a mixture of chrysophanate and tannate of copper, it was necessary to subtract from its weight the weight of the oxide of copper it contained, which, according to the mean of several of Mr. Greenish's analyses, equalled 26·82 per cent. This being subtracted, the remainder was placed as *chrysophanic and tannic acid.*

4. *A Microscopical Test.*

XVII. Each of the samples was examined by means of the microscope. A power of 100 diameters was found best. Each sample was tried by transmitted as well as reflected light. Was unable to find any adulterant by this means, though somewhat of a difference was noticed in the relative amounts of the three different colours (yellow, white, red).

5. *Physiological Test.*

Eight grains of each of the "samples" (including the "standard") was taken internally by the writer at about the same time in the morning, at periods sufficiently distant from one another, so as not to in any way interfere. Each sample was tested as nearly as possible under the same circumstances. As a result, it was found that in almost every case, the purgative activity of the drug was in almost direct proportion to the amount of cathartic acid found in it; making, of course, due allowance for the counteracting tendency exerted by the presence of a small or large proportion of chrysophanic and tannic acid.

Price, etc., of the Samples.

XVIII. Every precaution was taken to keep the seller from suspecting the purpose to which the sample was to be put. The only reason why his *claim*—in regard to the sample gotten from him—was obtained, was for the purpose of ascertaining where to locate the deception, in case of such, as well as to make the essay, in a measure, more complete.

It may be well to state here that it was the writer's original intention to make a complete test, by all the methods given above, of 30 *samples* (including the "standard"); but he soon found that it would require almost a year to properly do so, so he has had to content himself himself with the twelve "samples" and the "standard." The tests have occupied all of the writer's available time for the past three months.

General Conclusions.

1. Out of twelve "samples," four (4), or 33 *per cent.*, were adulterated with *rhapontic rhubarb.*

2. Out of twenty-nine "samples" two (2), or nearly 7 *per cent.* were *adulterated* with *turmeric.*

3. From test VIII., together with the "Chemical Tests," it is believed that at least one-quarter of the "samples," or 25 *per cent.* were *adulterated* with *inferior, poor, dark-coloured, perhaps worm-eaten rhubarb.*

4. Taking all of the "Pharmaceutical Tests" together *none* of the "samples" *equalled* the "standard."

5. Chemically the "standard" was the *fourth* (4th) in *purgative power* (cathartic acid) and the *second* (2nd) in *tonic constituents* (chrysophanic and tannic acids). It contained almost *twice* as much cathartic acid as one sample, and over *four* times as much *chrysophanic and tannic acid* as another.

6. The *price* is no *just criterion of* either the *cathartic* or *tonic* power of the drug.

APPENDIX.

Tests that have been found in the writer's hands to be unreliable:—

Physical.

Dr. Squibb's. — "When two powders (rhubarb) are exposed on a table to the action of light and air for two weeks, the powder of the bad or mixed rhubarb turns of a *very light colour*; it changes its colour entirely, while the good rhubarb does not change to anything like the same extent."

On the contrary after repeated trials, I have found that any sample of powdered rhubarb, instead of becoming lighter, will in every case become darker, after being exposed to light and air for two weeks.

Pharmaceutical.

Dragendorff's.—"According to Dragendorff, the presence of chrysophanic acid in a condition (free) extractable by cold petroleum spirit, is a test of the quality of the rhubarb. Good rhubarb yields a colourless extract with petroleum spirit, while a rhapontic rhubarb yields an intensely yellow extract."

All the "samples" (including the "standard") gave exactly the same coloured solution, namely, a bright yellow.

Chemical.

Normandy's.—Gamboge "may be readily detected by digesting a portion of the powder in ether, and pouring a few drops of the solution in water. If gamboge is present, a film of an opaque yellow colour will be observed floating on the surface, which, on adding potash, is dissolved with an intensely red colour."

All the samples acted the same way with this test, giving a red colour. A small portion of the "standard" was purposely adulterated with 5 per cent. of gamboge, and both it and some of the unadulterated "standard" tested by this test. No difference could be observed; both solutions becoming red.

NEW COLOUR REACTIONS OF THE ALKALOIDS.*

BY B. ARNOLD.

The author describes the behaviour of various alkaloids with certain reagents; the most distinctive are the following:—

Conine.—One drop, when mixed with a few drops of syrupy phosphoric acid, and the mixture evaporated in a white porcelain capsule over a small flame, becomes a fine green to blue-green.

Nicotine similarly treated gives a deep yellow to orange, the residue is soluble in water; the same colour. The reaction is more surely obtained when the mixture is heated for five to ten minutes on the water-bath. Conine when so heated shows a clearer green.

Aconitine.—The well-known violet colour given by this alkaloid when evaporated with phosphoric acid, is obtained easily and surely by agitating a few particles with syrupy phosphoric acid and warming ten to fifteen minutes on the water-bath.

The syrupy acid used as the reagent is obtained by dissolving the anhydride or the glacial acid in the officinal phosphoric acid of the German Pharmacopœia.

The author suggests that the ptomaconine of Selmi should be tested by this reagent.

---

* *Arch. Pharm.*, [3], xx., 561–566. Reprinted from the *Journal of the Chemical Society*, March, 1883.

Portions of other alkaloids yielded characteristic reactions when rubbed with a few drops of concentrated sulphuric acid and gently warmed; alcoholic or aqueous potash solution (30 to 40 per cent.) is then dropped in by means of a capillary tube with constant stirring until in excess. Narcotine, morphine and codeine give the most striking reactions.

Narcotine, in course of heating with the acid, takes a yellow, or if warmed longer, a violet colour. On the addition of alcoholic potash, it becomes a fine orange-red, which on adding water passes to yellow; treated with *aqueous* potash solution, the final reaction shows a gamboge-yellow, soluble, unchanged in water.

Morphine on the addition of the alcoholic solution becomes yellowish to dirty red, then turns to steel-blue and sky-blue. The continued addition of the potash solution causes, after a short time, a transition to a fine cherry-red. Water partially dissolves the residue to a red-violet colour: the residue is a fine blue to blue-green, and dissolves with that colour on adding water. Treated with *aqueous* potash solution it passes from red to a fine moss-green, and on further addition of the potash solution to a dirty yellow-brown. The more strongly the morphine is heated with the acid, the more intense is the blue produced on the addition of alcoholic potash.

Codeine gives no reaction with alcoholic potash: with the aqueous solution it passes from reddish to pure green, and then to a dirty white; if it is heated with sulphuric acid until it begins to brown, it gives all the reactions of morphine, and seems to change into that body.

Solanine with the alcoholic solution passes from yellow to blue or red-violet, particularly after standing some time; with more potash it becomes whitish-grey. Sulphuric acid dropped into the mixture to excess causes a cherry-red, which disappears on adding water. Solanine treated with the aqueous potash solution passes from yellow to violet, then to green, and finally dirty yellow-brown. Sulphuric acid added as above causes the same reactions, but the process must be carefully conducted. The cherry-red and its disappearance are very strongly characteristic of this alkaloid. The reaction is most successful when the substance is dissolved in *cold* sulphuric acid and warmed, but not until the solanine becomes brown, as in that case the colour reactions do not take place.

Another method of examination adopted by the author is to rub small portions of certain alkaloids with concentrated sulphuric acid on a white porcelain slab; to the mixture he then adds a few crystals of sodium nitrite. Certain changes of colour occur, which again alter when alcoholic or aqueous potash solution employed in the previous experiments is added in drops, with constant stirring, until in excess; previous warming with the sulphuric acid is not desirable, unless when specially directed.

Atropine with sodium nitrite shows a deep yellow to orange. Alcoholic potash produces a splendid red-violet, quickly passing into pale rose: the more nitrite used, the deeper the colour. Aqueous potash does not produce a colour reaction.

Narceine with sodium nitrite first gives a dirty brown-green, then clear blue margin, the mixture gradually passes to a fine violet, red-violet, and a blood-red. Alcoholic potash changes this to a yellow, but aqueous potash causes the violet to pass through yellow to a dirty brown. When the blue margin appears as above, if the mixture is very gently warmed, it becomes a magnificent blue-violet.

Narcotine with sodium nitrite passes gradually through red, brown and green into a cherry-red. Alcoholic potash added changes this to a dirty orange; *aqueous* potash when dropped into the mixture after the sodium nitrite, shows a green spot after each drop. When it has been added in excess, all becomes a dirty green; when narcotine is warmed with sulphuric acid until yellow, or till the characteristic violet appears, and sodium nitrite is then added, a fine cherry-red immediately makes its appearance.

Strychnine with sodium nitrite gives a dirty yellow. Alcoholic potash changes it to a fine orange-red, the aqueous solution causes it to turn brownish-green, and finally dirty red-brown.

Digitaline with sodium nitrite gives a brown to dirty cherry-red colour, changed by alcoholic potash to a dirty yellow-grey, by aqueous potash to brown: the reaction with the sulphuric acid and sodium nitrite is peculiar to this alkaloid.

Two or three samples of each alkaloid were obtained from different sources. The processes followed in the experiments require a considerable amount of practice, and it is sometimes difficult to exactly specify the shade of colour, for example, whether one should be called brownish-green or greenish-brown; yet with practice the characteristic reactions can be very accurately produced.

CALX SULPHURATA AND SULPHIDE OF CALCIUM.*

A peculiar product obtained by calcining about seven parts of finely-powdered gypsum and one part of powdered charcoal in a covered crucible has long been used in medicine, and has been officinal in various pharmacopœias. The proportion of gypsum and charcoal vary in the latter between eight and three of the former to one of the latter. Soubeiran advises to mix eight of gypsum, four of lampblack and enough of a fatty oil to make a mass. Other formulæ prescribe caustic lime and sulphur. The homœopaths prepare it by heating equal parts of finely-powdered oyster-shells and flowers of sulphur for ten minutes to a white heat. One of the old names of this preparation is *Hepar Sulphuris Calcareum*, and this is the name it is known by in homœopathic practice. None of the above processes yields a pure sulphide of calcium (CaS), the product being always contaminated with other substances, either undecomposed gypsum or carbonate of calcium, or free lime or free carbon. A *pure* sulphide of calcium can be prepared only with some difficulty.

It is not at all necessary that the "sulphide of calcium" used in medicine shall be absolutely pure. All previous reports of the therapeutic effects of the compound are based on the commercial article—chiefly on that made from oyster-shells and sulphur—and the quality of this, though it only consists in part of CaS, has remained tolerably uniform.

The pharmacopœia only wished to recognize the article already in use, and knowing that the ordinary name by which it was known in practice and in trade, viz., sulphide of calcium, was wrong, inasmuch as the preparation contained only about thirty-three per cent. of the pure sulphide, the revisers selected the more correct old name, which expresses only the fact that the compound is prepared from *lime* and contains *sulphur*, "Calx Sulphurata" = sulphurated lime. A test was, however, appended to estimate the amount of pure calcium sulphide present, and the lowest limit of percentage was placed at thirty-six.

Perfectly pure sulphide of calcium, if ever introduced into medicine, will have to receive the title "Calcii Sulphidum" in the pharmacopœia.

Whether calx sulphurata or calcii sulphidum be prescribed in the United States, the patient will always receive the same substance. It is never "mixed" artificially, the admixtures being inevitable in process of preparation. A fair estimate of the good quality of a sample may be obtained from the odour of the substance, which should be that of a sulphydric acid and should be quite distinct. As a rule we have obtained a better article in the United States from homœopathic manufacturers than from any other source. This is probably owing, at least partly, to the fact that they prepare it more frequently than others, and are thereby enabled to dispense it in a much fresher state.

THE CHEMISTRY OF STORAGE BATTERIES.

ALTHOUGH the sanguine expectations which were raised by some of the statements that accompanied the introduction of FAURE'S modification of the PLANTÉ battery have not all been fulfilled, enough has been realized to demonstrate that it would be an enormous gain to electrical science if a secondary or storage battery could be devised which should not be too cumbersome and should be capable of giving up, after a reasonable time and at the will of the operator, a large proportion of the energy that has been previously stored up in it. One reason, perhaps, why there has been an apparent delay in the practical application of M. FAURE'S invention is that the physical and chemical conditions which obtain when a current of electricity is passed through a series of lead plates arranged in a bath of dilute sulphuric acid are still imperfectly understood. True, it is known that the first plate in the series, or the one by which the current enters, becomes coated with peroxide of lead, whilst on the last plate of the series a loose covering of metallic lead is formed, and that those conditions become reversed as the plates become depolarized by the discharge of the cell; but the changes leading up to this result have been variously explained. Some writers contend that much of the storage effect depends upon the occlusion of oxygen and hydrogen by the positive and negative plates or their coatings, others that the lead sulphate which is formed plays an important part, whilst others maintain that this lead sulphate undergoes no chemical change. Some of the researches of Messrs. GLADSTONE and TRIBE which throw light upon this subject have already been referred to in this volume (see before, p. 221), and a further important elucidation of it is furnished in a paper recently read before the Royal Society by Dr. FRANKLAND and published in the latest number of the 'Proceedings.'

It may be stated at once that the first-mentioned theory has now been eliminated from the discussion, since the results obtained by Dr. FRANKLAND in some preliminary experiments justify the conclusion that occluded gases play practically no part in the phenomena of the storage cell. The function of the lead sulphate formed appears, however, to be much more important and so far as it has been traced is exceedingly interesting. During the "formation" of a cell a thin superficial deposit of insoluble lead sulphate is soon formed on both the positive and negative surfaces of the plates; but the amount of sulphuric acid which disappears from the liquid contents of the cell is much more than sufficient to account for the apparent result and is probably used up in the formation of other lead sulphate that is obscured by the chocolate-coloured peroxide formed simultaneously. Unless the coated plates have been immersed previously for several days in dilute sulphuric acid, this disappearance of acid during their "formation" continues for ten or twelve days. At length, however, as the charging goes on, the strength of the acid ceases to diminish, and soon afterwards it begins to augment, the increase continuing until the maximum charge has been reached and abundance of oxygen and hydrogen gases begin to be discharged from the plates. At this point the current becomes occupied exclusively, or nearly so, in the electrolysis of hexabasic sulphuric acid (SO_6H_6), which appears to be the central point with which all the chemical reactions that occur in the cell are connected. On the other hand, during the discharge of the cell the specific gravity of the acid continually decreases until the discharge is finished, when it is found to have sunk to about the same point from which it began to increase during the charging. Hence it is apparent that during the discharge lead sulphate, which has been continuously decomposed in charging, is continually reformed. Dr. FRANKLAND concludes that the chief if not the only chemical changes occurring during the charging of a storage battery are (1) the electrolysis of hexabasic sulphuric acid into sulphuric anhydride and oxygen, eliminated on the positive plate, and hydrogen eliminated on the negative plate; (2) the reconversion in the presence of water of sulphuric anhydride into sulphuric acid; (3) the chemical action of the eliminated oxygen on the coating of the positive plate, resulting in the presence of water in the formation of lead peroxide and hexabasic sulphuric acid; and (4) the chemical action of the eliminated hydrogen on the coating of the negative plate, resulting through an analogous reaction in the formation of spongy metallic lead and hexabasic sulphuric acid. In the discharge of a storage cell, Dr. FRANKLAND supposes the chemical changes to be (1) the electrolysis of hexabasic sulphuric acid as in charging; (2) the reconversion of sulphuric anhydride into hexabasic sulphuric acid, as already described; (3) the chemical action of eliminated hydrogen upon the coating of what was before the positive plate or electrode, but which now becomes the negative plate of the cell,—that is to say the plate from which the positive current issues to the external circuit,—resulting in the reduction of the lead peroxide formed during the charging into lead oxide, which is immediately converted into lead sulphate by the sulphuric acid present; and (4) the chemical action of eliminated oxygen upon the coating of what has now become the positive plate of the cell, resulting in the formation of lead oxide, which also is at once converted into lead sulphate.

To sum up, Dr. FRANKLAND concludes that the initial action in the charging of a storage cell is the electrolysis of hexabasic sulphuric acid, each molecule of which throws upon the positive plate three atoms of oxygen, and upon the negative plate six atoms or three molecules of hydrogen. Each atom of oxygen decomposes one molecule of lead sulphate on the positive plate, producing one molecule of lead peroxide and one of sulphuric anhydride, the latter instantly uniting with three molecules of water to form hexabasic sulphuric acid. In discharging, as in charging, the initial action is the electrolysis of hexabasic sulphuric acid. The oxygen eliminated on the positive plate reconverts the reduced metal of that plate into lead oxide, whilst the hydrogen transforms the lead peroxide on the negative plate into the same oxide, which in both cases is immediately converted into lead sulphate by the surrounding sulphuric acid, thus restoring both plates to their original condition before the charging began. The discharge of a cell does not proceed so far as to undo the work of "formation;" in fact it is highly probable that in the ordinary use of a storage cell the discharge is never completed.

One practical result of Dr. FRANKLAND'S investigation is that he has been able to suggest an extremely convenient chemical method for ascertaining the extent to which a storage cell is charged, based upon the observation mentioned before that in a "formed" cell the specific gravity of the dilute sulphuric acid increases regularly during the charge, and decreases during the discharge of the cell. The specific gravity and consequent strength of the dilute sulphuric acid of a "formed" cell being known in its uncharged and also in its fully charged condition, it is only necessary to take the specific gravity of the acid at any time in order to ascertain the proportion of its full charge which the cell contains at that moment, and if the duty of the cell is known, the amount of energy stored will also be thereby indicated. In a cell experimented with, containing about seven quarts of dilute sulphuric acid, each increase of ·005 in the specific gravity of the acid meant a storage of energy equal to 20 ampères of current for one hour obtainable on discharge.

In conclusion, it may be mentioned that Messrs. GLADSTONE and TRIBE have recently published a further communication as to the result of their researches upon this subject, in which they deal mainly with the influence of the strength of the acid used in the cell. They state that they have obtained the best results as to the oxygen fixed on the positive plate by using dilute sulphuric acid of a strength of 1 to 10. When a dilution of the strength of 1 to 1000 was used, the amount of oxygen fixed was double as compared with the strength of 1 to 10, but a considerable quantity was taken up in the formation of a basic lead sulphate, with a consequent diminution in the amount of peroxide formed.

As expected, the Medical Acts Amendment Bill did not come on for second reading on Thursday of last week. It was postponed until Monday, and then again until Tuesday, when although it was second on the list, it was not reached. It was then set down for Thursday, but as seventeenth on the list, so that at the time of going to press it had not been reached, nor is it likely to be. A petition to amend the Bill was presented on Friday, the 15th inst., from the Pharmaceutical Society of Ireland. Our readers will notice with satisfaction the continued unanimity amongst pharmacists as to the action taken by the Council of the Society in respect to the Pharmacopœia clause of this Bill, which is further indicated in the resolution passed by the Sheffield Pharmaceutical and Chemical Society, and printed in another part of this Journal.

* * *

Referring to the scheme for the revision of the British Pharmacopœia, as disclosed in the recent report of the Pharmacopœia Committee, *New Remedies* remarks that it is to be regretted that the General Medical Council has not been "more liberally inclined towards the pharmaceutical profession as a body," and given it an opportunity to participitate in the work, rather than pursue the course it has chosen to adopt. Our contemporary thinks that since the General Medical Council is notoriously obliged to go outside of its own organization to secure the necessary skill for revising a work which is as much the property of the pharmaceutical as of the medical profession, "the course pursued in the present instance is not calculated to add to the dignity of the Council, or serve as an example of the fair-play in which our British cousins have so much pride."

* * *

It is not expected that there will be time left for the French Pharmacy Bill to be considered by the present Chamber. The report of the Commission, to which reference was made last week, shows a strong disposition to free pharmacy from all regulations, only restrained by the difficulty of passing from one extreme to the other. It defines, in, so many words, the duty which society owes to its members, in assisting them to form a judgment in such matters, as being limited to saying, "Here is a competent medical man, or a skilful pharmacist; you know that if you resort to him you will be in the hands of a trustworthy man; but if you prefer to go to the bone-setter or to the druggist, which you are free to do, it is not for the law to protect you against your own stupidity." The present time is, therefore, looked upon as one of transition, when there should be nearly complete liberty under the guarantee of a diploma. The conclusions of the Commission appear, however, to be in advance of public opinion in some quarters, for the proposition to allow pharmacists to sell any substance expressly demanded by the purchaser has been denounced in the *Intransigeant* by M. Rochefort as the liberty to poison, and he maintains that laws and regulations in respect to pharmacists cannot be too rigorous. The Minister of Commerce has also succeeded in introducing into the Bill a prohibition of the sale of poisons without the order of a medical man.

* * *

Just now, when some attention has been directed to the position of pharmacists in this country in relation to the supply of alcohol, it may be interesting to mention some privileges that have been accorded to registered pharmacists in the Dominion of Canada, under a new "Licence Act." In this Act it is provided that a registered chemist and druggist shall not be prohibited from keeping, having or selling alcoholic liquors for purely medicinal purposes, but no sales are to be made in quantities of more than six ounces at a time, except under an order from a registered medical practitioner. Further, all supplies of alcoholic liquor are to be registered in a book, which is to be open to inspection, and in no case may the liquor supplied be consumed on the premises of the chemist and druggist supplying it.

* * *

In the discussion which followed the reading of a paper at the Plymouth meeting of the Pharmaceutical Conference, in which a denial was given to the then prevailing belief that the presence of a salt of copper in preserved peas was prejudicial to the health of persons eating them, statements were made as to the longevity of persons subjected to the influence of "copper smoke" or who drink water containing copper. These find strong confirmation in the results of an inquiry made in reference to the circumstances attending the epidemics of typhoid fever that prevailed in Paris in the years 1876–77 and 1882–83. In the former epidemics 2462 persons died from typhoid, of whom only two were workers in copper, whereas fifty would hardly have represented the relative proportion of copper workers to the population. In the more recent epidemic the deaths amongst workers in copper and bronze were equally below the average. A similar immunity has been observed in respect to cholera. A more striking illustration is quoted in the "Bon Accord" Society, consisting of between three and four hundred members, who are all turners, fitters and workers in bronze; this Society has not lost a single member by death from typhoid fever or cholera since its establishment in 1819, and very few from small-pox or diphtheria.

* * *

There appears to be a prospect of a decided improvement in the bark and quinine market in this country. We understand that within the last two weeks large quantities of bark have been sold.

* * *

According to a Report on the Drug Trade of New York, drawn upby Mr. D. C. Robbins, the importations of quinine into the United States during the year ending June 30, 1882, amounted to 794,495 ounces, against 408,851 ounces in the previous year. During the year ending December, 1882, the importation of cinchona bark reached 29,200 bales, against 31,700 bales in the year 1881. This large increase in the amount of manufactured quinine imported and the decrease in the quantity of raw material are attributed to the removal of the high duty on quinine that was formerly levied.

* * *

We understand that the patent rights in kairine, the latest proposed substitute for quinine, have been acquired by the Colour Manufacturing Company in Höchst, formerly Meister, Lucius and Co., by whom it is now being made under the superintendence of Professor Laubenheimer. It appears that two kinds of the drug are to be met with, one called "karin M," which is said to present some advantages, and the other simply "kairin," which represents the substance with which the original clinical experiments were made. Whether kairin will be more successful in ousting quinine as a febrifuge than chinoline, from which so much was expected, appears very doubtful, and we are more inclined to think that the cinchona alkaloids, produced at the moderate price which the spreading cultivation of the cinchona plant appears to bring within a measurable distance, will eventually beat every competitor from the field.

* * *

Some cultivators evidently have faith in the future of cinchona cultivation in India. A writer in the *Madras Times*, who advocates a more free utilization of the assistance that chemists are able to give in selecting the most valuable varieties suitable to particular soils, prophesies that in the event of this being done the average richness of quinine in the total bark gathered, which is taken by the writer to be in that Presidency at present 1½ per cent., will, possibly, by the year 2000, have reached 4½ per cent. If so, should any of the fellow-countrymen of Macaulay's oft-quoted New Zealander happen then to be engaged in the quinine manufacture, they will be within reach of a supply of good bark.

* * *

According to the official report on the Government Cinchona enterprise in Java for the first quarter of the present year, a translation of which appears in the *Ceylon Observer*, the fears that were entertained as to the deteriorating influence of a "succirubra" stem on a "Ledgeriana" graft have proved groundless. Analyses of bark taken from twenty three-year old grafts failed to reveal a trace of cinchonidine, whilst the yield of quinine reached 7·37 per cent. A recent visitor to Java has stated that one private proprietor in that island has five thousand acres of land occupied in *Cinchona Ledgeriana* cultivation, and that the plantation is in a flourishing condition.

* * *

In connection with an Exhibition to be held in Colombo in August, under the auspices of the Colombo Agri-Horticultural Society, a gold medal is offered for the best collection of cinchona barks, and silver medals for the best collections of barks of *C. robusta*, *C. Ledgeriana* and *C. succirubra*.

* * *

The *British Medical Journal* reports a fatal case of poisoning by carbolic acid administered in mistake for a black draught, which has taken place in the Bridgwater Workhouse. A coroner's jury returned a verdict of "Homicide by misadventure."

* * *

We understand that one of the two Research Scholarships recently instituted by the Grocers' Company has been awarded to Dr. Matthew Hay, of the University of Edinburgh, whose name will be familiar to the readers of this Journal. The scholarship is of the annual value of £250, and although the award is for one year only, the holder will be eligible for re-election at the end of that term.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday next, June 28, at 8 p.m., when a paper will be read by Mr. H. Hamilton, on "The Characteristics of the Principal Natural Orders," illustrated by specimens. A Report upon Analytical Chemistry will be made by Mr. C. Thompson on "The Estimation of Carbolic Acid."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 20, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Five* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Wedge, George Deller ....Alresford.

MINOR EXAMINATION.

Nineteen candidates were examined. *Twelve* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ashton, Frederick William ...Market Harborough.
Atkins, Alfred Edward ....Newport.
Austin, George Leonard.........Ashford.
Bachelot, Emile ....Mauritius.
Blain, William Rushton ....Bolton.
Hircock, George Walter ....Kettering.
Joye, Joseph.........................Southport.

June 21, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-two candidates were examined. *Ten* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Hamilton, Henry..................Finchley.
Handford, Thomas Edward ...Torrington.
Kitchin, John ....Ulverston.
McLanachan, John ....Sheffield.
Marsden, Charles Edwin.........Huddersfield.
Martin, John ....Redruth.
Nicholls, Reginald Edward......Lee.
Silk, Edward ....Macclesfield.
Stocker, George ....Exeter.
Thacker, Henry Ransley.........Nottingham.
Whiston, Edmund ....Wolverhampton.
Wilson, Harry ....Buxton.

MODIFIED EXAMINATION.

Two candidates were examined. *Both* passed, and were declared qualified to be registered as Chemists and Druggists:—

Castell, George Gower......... ...London.
Heathcote, Henry ....Liverpool.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Church, Albert Victor John ...Norwich.
Croasdale, James C................Ulverston.
Davison, Daniel ....Cromer.
Jolly, John ....Chorley.
Nicholson, Thomas Brough......Sunderland.
Reinhardt, Charles Emmanuel..Leeds.
Taylor, Walter........................London.

Certificates of the Faculty of Physicians and Surgeons of Glasgow.

Bolas, Samuel Brittain ....Rock Ferry.
McCurrie, John ....Port Bannantyre.

Certificate of the Royal College of Surgeons of England.

Capper, Percy ....Huyton.

Certificate of the Royal University of Ireland.

Harrold, John P....................London.

Certificate of the Society of Apothecaries.

Brown, Edgar Marshall ....Derby.

Certificates of the University of Cambridge.

Allison, Henry ....Birmingham.
Brookes, Joseph ....Northwich.
Hitchcock, Thomas Frederic ...York.
King, Lawrence Bowdler ......Turnham Green.
Miller, Edwin Frederick.........Ipswich.
Parry, John ....Llangefni.
Peck, Ernest Saville ....Cambridge.

Certificate of the University of Glasgow.

Neill, William ....Govan.

Certificate of the University of London.

Want, William Phillip............Lee.

Certificates of the University of Oxford.

Pinch, Albert Edwin ....Bath.
Smith, Arthur ....Watford.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

Pharmacopœia Revision.

At a meeting of the Council of this Society the memorandum of the Medical Council was duly discussed. It was resolved that in acknowledging the courtesy displayed in the communication, the Council desired to state that it would do its utmost to render every assistance in its power towards suggesting improvements and giving information to the Committee for the revision of the British Pharmacopœia. But the Council wished to record its desire that any such information may be allowed to be transmitted through the Pharmaceutical Society, its representative head.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

CHLORAL.*

BY W. PIRIE.

Chloral, like chloroform, was for many years on the shelf of the chemist's laboratory before its medicinal properties were known. It was discovered by Liebig in 1829 or 1830 (though not published till 1832) and for thirty-six years was looked on as merely a chemical curiosity; but in the year 1868 Dr. Otto Liebreich, of Berlin, discovered that when administered internally chloral produced hypnotic effects on the animal organism. Making some experiments, the doctor communicated the result of these to the Medical Society of Berlin, in June, 1869. The new remedy at once received attention. It was introduced for the first time into English medical practice as a soother of pain and producer of sleep in August, 1869. Nine years later it was calculated that upwards of fifty tons of chloral had been manufactured, or sufficient for some 36,000,000 doses.

Regarding the process for the manufacture of chloral, I presume all are acquainted with the bare outline given in the B.P. "Chloral, produced by the action of dry chlorine gas on anhydrous alcohol, purified by treatment, first with sulphuric acid and afterwards with a small quantity of lime." Our Pharmacopœia, however,

* Read at a meeting of the Edinburgh Chemists' Assistants and Apprentices' Association, March 7, 1883.

leaves us with but a crude notion of the preparation of chloral.

The following is the process as described by the discoverer, Liebig:—

"Chlorine gas is passed through absolute alcohol, which is kept cool at first, but afterwards raised to a continually increasing temperature, as long as hydrochloric acid continues to form; the resulting hydrate of chloral is freed from water and a small quantity of alcohol by agitation with oil of vitriol, and the decanted liquid rectified over lime. The chlorine is evolved continuously from a large retort or flask; passed through a chloride of calcium tube to dry it, and then into a bent tube, the arms of which are short and parallel to each other, but somewhat oblique towards the middle, while that portion of the middle which is directed downwards and contains the alcohol is wide, long and somewhat slating, so that the chlorine after arriving at the lowest part, is obliged to pass through the oblique column of alcohol; from this the unabsorbed chlorine, together with hydrochloric acid gas and vapour of hydrochloric ether, passes into two Woulfe's bottles and thence into the open air, so that the operator is not annoyed by it. At the commencement of the operation the alcohol is cooled by effusion of cold water, to prevent it from taking fire and depositing soot; but afterwards when the absorption of the chlorine diminishes, and the liquid assumes a yellow colour, it must be gradually heated and ultimately to the boiling point. Eight ounces of alcohol require the passage of the chlorine to be continued for twenty days, involving a consumption of 20 pounds of chlorine mixture. The alcohol becomes continually thicker, acquires a higher boiling point and is finally converted into a heavy syrup, which, after standing for some days, solidifies completely to a white crystalline mass, consisting of hydrate of chloral, together with a small quantity of hydrochloric acid and undecomposed alcohol." But how can we tell if enough chlorine has been passed into the alcohol, without having to wait for some days for the solidifying of this mass? "If a small sample of the liquid, after being agitated with four times its volume of oil of vitriol and set aside, does not in a few hours form an insoluble stratum (which is an insoluble form of chloral) above the oil of vitriol, enough chlorine has not been passed through the alcohol and of course it is necessary to continue the passage of the chlorine for a longer time. The solidified crystalline mass is heated till it melts; briskly agitated with four or six times its volume of oil of vitriol, which does not heat or blacken it, left at rest till the dehydrated chloral has risen to the top of the oil of vitriol, a result which may be accelerated by heating, and the transparent film of chloral immediately decanted by means of a pipette. If the oil of vitriol contains rather more than one atom of water it is particularly necessary to decant as quickly as possible, else the chloral will be converted into the insoluble variety. Lastly, the chloral is distilled over lime (which has been slaked and subsequently ignited) to remove hydrochloric acid, care being taken to keep the whole of the lime below the surface of the liquid, otherwise the lime will decompose the vapour and become red hot. In this manner the chloral is obtained tolerably pure, but it still contains traces of water and alcohol which may be removed by repeated treatment with oil of vitriol, the chloral being each time rectified over lime. All these operations must be performed in well-closed vessels." Such are the elaborate, though at the same time essential, details given by Liebig.

Regarding the rectification of chloral from lime, Dumas recommends a slight modification. He uses a saturated solution of common salt as well as the lime. The saturated solution of salt covers the lime and thus the vapour of chloral cannot be "fired" by coming into contact with it. True, a little hydrate remains behind, but he assures us that the distillate consists of pure chloral.

Gmelin informs us that hydrate of chloral may be obtained by saturating absolute alcohol with hydrochloric acid gas and then distilling this with black oxide of manganese and strong hydrochloric acid; or by distilling 3 parts absolute alcohol with 46 parts oil of vitriol, 32 parts common salt, and 24 parts manganese oxide. This process, however, does not appear to be advantageous.

To prepare chloral, Städeler very ingeniously does away with the use of alcohol altogether. Instead he uses either starch or sugar. One part of starch (or sugar) is added to 7 parts of commercial hydrochloric acid, which must be as free as possible from sulphurous acid. An equal volume of water is added, and the mixture gently warmed until the paste (formed when starch is used) has become liquid. This liquid when cold is introduced into a capacious flask. Three parts of manganese and a small quantity of common salt are then added (the salt is used to fix the sulphuric acid produced from the sulphurous acid in the commercial hydrochloric acid). The mixture is heated as quickly as possible to the boiling point, and then the fire is completely removed.

The mass swells up giving off a large quantity of carbonic acid, and continues to boil for some time by itself. As soon as the ebullition slackens it is kept up by fresh application of heat, and the distillate collected so long as it becomes turbid when mixed with a tolerable solution of potash. The turbidity is due to the separation of chloroform from the chloral. More hydrochloric acid is then repeatedly introduced into the flask by small portions at a time, till the distillate no longer smells of chloral or becomes turbid with the solution of potash.

The watery distillate is carefully freed from the colourless oil drops, which have been produced at the beginning of the distillation and which are heavier than water and smell strongly of chloroform. It is then saturated with common salt, in order to raise its boiling point and retain the water, distilled again and the resulting distillate freed from a sulphur-yellow very pungent smelling oil. It is then distilled several times more with common salt, removing the oily drops, in order to obtain aqueous chloral as concentrated as possible, and as free as possible from the yellow oil, which greatly impedes the purification of the chloral and thereby occasions loss. To facilitate the removal of this oil the distillate, before each successive distillation, is supersaturated with powdered chalk, which, during the boiling, decomposes a portion of the oil, but not the chloral. The concentrated chloral solution, however, always remains yellowish through oil remaining in it, and becomes turbid when mixed with a small quantity of water, but regains its transparency on heating or by mixing with more water. The concentrated solution is supersaturated with dry chloride of calcium and distilled in the oil-bath at 120°, whereupon the hydrate of chloral passes over as a colourless liquid, which soon solidifies, and consequently may stop up the neck of the retort, unless it be kept warm. By-and-by the liquid distilling over, instead of being colourless, becomes a yellowish or brown colonr, arising from the presence of a peculiar oil which passes over in oily drops simultaneously with the water. The resulting hydrate of chloral is mixed with four times its bulk of oil of vitriol and gently warmed. The chloral rises to the surface in a colourless layer whilst the oil becomes heated and blackened with the evolution of hydrochloric acid gas. The stratum of chloral, after being removed by a pipette, retains only a small quantity of hydrochloric acid, to free it from which it is boiled for a while by itself, and then rectified over a small quantity of oil of vitriol and finally over lime. This is Städeler's process; a very troublesome one, indeed.

Such are the earlier processes for the preparation of chloral. As carried on on the large scale the manufacture may be briefly described thus:—Into thirty or forty glass carboys, each containing from 108 to 144lbs. of alcohol of 98 per cent., a copious stream of chlorine (washed and dried by sulphuric acid) is passed thorough for twelve or fourteen days. The carboys are, of course, kept cool at first, then gradually heated. As soon as the specific gravity of the contents reaches 1·400 chlorination is stopped. The chlorinated alcohol is transferred to copper stills, lined with lead, and carefully boiled with an equal weight of sulphuric acid. Large quantities of ethyl chloride and hydrochloric acid gas are at first evolved. These with a whole series of valuable bye-products are condensed. After a while chloral distils over at a temperature of 94° C. When the temperature rises to 100° C. distillation is stopped. The distillate is neutralized with chalk and redistilled, the product being pure chloral.

The chemical reactions attending the production of chloral are very complex. During the chlorination step of the process we have formed aldehyde, acetal, trichloracetal, chloral alcoholate and ethyl chloride. Most of the ethyl chloride is converted into ether, then, step by step, into mono-, bi-, tri- and finally tetra-chlorinated ether. At this stage the liquid containing chloral alcoholate and tetra-chlorinated ether assumes the specific gravity 1·400 and the chlorination is stopped. If the chlorination were continued a penta-chlorinated ether would be formed which by distillation with sulphuric acid does not yield chloral.

During the distillation with sulphuric acid the chloral alcoholate splits up into chloral, water and ethyl sulphuric acid, while the tetra-chlorinated ether decomposes into chloral, hydrochloric acid gas and ethyl sulphuric acid. This ethyl sulphuric acid reacts with the hydrochloric acid gas, forming sulphuric acid and the ethyl chloride, which distils over in large quantity before the chloral.

Chloral is a thin colourless oily liquid, specific gravity 1·5439 at 0° C., while at 18° C., or about ordinary atmospheric temperature, the specific gravity is 1·502. It boils at 94·4 C. and may be distilled without change. Vapour density = 5·13. Chloral has a peculiar pungent odour and excites a copious flow of tears; has a greasy and slightly astringent taste; is also greasy to the touch and dropped on paper makes grease spots which, however, are not permanent. It acts very strongly on the skin, especially when its boiling vapour comes in contact therewith. It has no acid reaction even when dissolved in water; neither does it precipitate a solution of silver. Chloral, perfectly pure, when kept for some time in a closed vessel, gradually becomes turbid and deposits white flakes of insoluble chloral. This change will occur in a few days should the chloral be not quite pure. This insoluble chloral is also formed if chloral is allowed to stand for some time over sulphuric acid containing more than 1 atom of water. This insoluble modification will not dissolve in cold water and is only sparingly soluble in boiling water. It is insoluble in alcohol and ether, even at the boiling point. Chloral, on the other hand, is freely soluble in water, alcohol and ether. Chloral readily dissolves phosphorus, sulphur, iodine and bromine, and also absorbs a small quantity of chlorine gas, acquiring a yellow tint.

Anhydrous metallic oxides, such as baryta, strontia, lime, cupric oxide, mercuric oxide and peroxide of manganese, when heated in chloral vapour to only 100° C. become red hot and are converted with evolution of carbonic oxide gas into a metallic chloride, mixed with finely divided charcoal. Caustic alkalies also decompose chloral even at ordinary temperatures. The chloral is converted into chloroform, a formiate being formed.

The Compounds of Chloral.—Of the compounds of chloral the principal are the hydrate and alcoholate. There are, however, also a sulphide, a mercaptide, and a cyanate. Then there are combinations with aniline, toluidine, xylidin, and so on. In fact, new combinations are being formed every year.

Chloral Hydrate.—Chloral, shaken up with a small quantity of water, combines with it immediately, causing evolution of heat. In a few seconds it solidifies into a white opaque crystalline mass; this is the hydrate. Dissolved in water, and evaporated slowly to crystallizing, rhombic crystals are formed. Chloral hydrate melts at 46° and distils at 96° to 98°. It does not deliquesce on exposure to air. It has a pungent, but not acrid odour, and a pungent, but not acrid taste. On the application of a gentle heat it fuses to a colourless transparent liquid which, as it cools, begins to solidify at a temperature of 120° F.

It boils in a test tube with pieces of broken glass immersed in it at about 96° C. (evidence of due hydration), and at a slightly higher temperature it volatilizes on platinum foil without residue. It is soluble in less than its own weight of distilled water, rectified spirit or ether, and in four times its weight of chloroform. The aqueous solution is neutral or but slightly acid to test papers. A solution in chloroform when mixed by agitation with sulphuric acid does not impart colour to the acid. One hundred grains dissolved in 1 ounce distilled water and mixed with 30 grains of slaked lime submitted to careful distillation with a suitable apparatus should yield not less than 70 grains of chloroform.

From the new edition of the United States Pharmacopœia we learn that chloral hydrate is soluble in glycerine, benzol, benzine, bisulphide of carbon, and fixed and volatile oils. It also liquefies when mixed with carbolic acid or camphor. An aqueous solution soon becomes acid, but an alcoholic solution remains normal. Absence of alcoholate is confirmed by dissolving 1 grain in 2 c.c. of distilled water, warming and adding about 8 c.c. or a slight excess of a 5 per cent. test solution of caustic potash. This mixture is filtered and treated with a test solution of iodine until yellowish, when no yellow crystalline precipitate (iodoform) should appear, even after standing for half a hour. Before laying aside the United States Pharmacopœia I cannot help remarking that, from a student's point of view, it possesses a decided advantage over our own, for it explains why such and such a test is applied.

From these tests we would infer that the alcoholate is sometimes substituted for the hydrate, and such may be actually the case. Nor would the reason be far to seek, for the formula of the alcoholate being $C_2HCl_3\left\{\begin{matrix}OC_2H_5\\OH\end{matrix}\right.$ and that of the hydrate $C_2HCl_3\left\{\begin{matrix}OH\\OH\end{matrix}\right.$ the molecular weight of the alcoholate exceeds that of the hydrate by 28. By calculation we find that the excess is to the amount of 17·25 per cent., meaning, of course, a gain to the manufacturer if he can sell it for hydrate.

Now chloral hydrate has sometimes been put down as impure, through the presence of hydrochloric acid, because if a stirring rod wet with liq. ammoniæ be held over the bottle containing the hydrate, white fumes are observed. Now this results from a different cause altogether. Chloral hydrate is volatile at any but very low temperatures and, of course, when we open a bottle volatilization goes on, though we do not see it, but on bringing ammonia to the mouth of the bottle, a formiate of ammonia in the form of a white cloud is produced. This may be proved by absorbing vapour of chloral hydrate with blotting paper, saturated with a solution of ammonia and testing for the formiate in the usual way. Wash the paper with distilled water, heat to evaporate the excess of ammonia, add solution of $AgNO_3$ and heat. The mixture becomes cloudy, blackens, and a silver mirror is deposited on the sides and bottom of the vessel.

Commercial chloral hydrate varies in consistency. Some of it is soft and easy to crumble. Other samples are hard and solid. The cause of this is the degree of hydration. The softer variety is saturated with a slight excess of water, while the harder contains a little free chloral. The latter has an advantage over the former in dispensing, and contact with moisture immediately converts the minute quantity of free chloral into hydrate. Lately, however, brilliant pellucid rhombohedra have been produced by crystallizing from boiling chloroform, and they are much more capable of resisting change by contact with air than the common variety.

Chloral hydrate is sometimes used to detect the English, French and German peppermint oils. Its power of doing so became known in this curious fashion. Dr. C. Jehn had stated that peppermint oils were coloured by chloral hydrate. This statement was afterwards contradicted by Professor Flückiger and Dr. Hager. Dr. Jehn re-experimented and found that chloral hydrate gives with French peppermint oil, a red colour; with German oil, a pale brown colour; and with English oil, hardly any colour.

Chloral Alcoholate.—This is prepared by mixing chloral with absolute alcohol. The formula is $C_2HCl_3 \left\{ \begin{matrix} OC_2H_5. \\ OH. \end{matrix} \right.$ This is a crystalline body melting at 56° C. and boiling at 114°–115° C. It is decomposed by strong sulphuric acid with reproduction of chloral. It is easily soluble in alcohol, ether, acetic ether and petroleum, and on cooling, a hot concentrated solution crystallizes out in long beautiful needles. They have much the smell and taste of the hydrate, but dissolve less easily in water. Heated with 2 volumes of water, the alcoholate melts at the bottom of the tube and solidifies again on cooling. (The hydrate would dissolve.) Treated with sulphuric acid the liquid becomes brown; hydrate would not. Lastly, if the alcoholate be warmed in nitric acid of specific gravity 1·2, violent reaction ensues with evolution of nitrous acid; hydrate treated in this way gives, at the most, a very small quantity of yellowish vapour.

There is a pretty experiment which is almost distinctive between the alcoholate and the hydrate. A glass is filled with water. A few crystals are dropped into it. If the salt is the hydrate, it will sink at once and dissolve, with, perhaps, the exception of one or two minute flakes. If the salt be the alcoholate, only the large crystals will sink to the bottom and lie there some time before they gradually disappear; but small crystals or fragments of crystals will float on the surface of the water, and in a second or two they will become, apparently, imparted with life. They begin to spin round and round and dart from one side of the vessel to the other. The sight is very amusing. Slightly tepid water makes their motions more rapid and jerking. The cause of the movements is the slight current of saline solution from each crystal sinking down.

Chloral Sulphydrate.—This body is prepared by passing dried sulphuretted hydrogen through anhydrous chloral. It is purified by crystallization either from anhydrous alcohol or ether. It crystallizes in white rhomboidal plates or four-sided right prisms. It has a disagreeable odour and a peculiar taste recalling that of the hydrate. It melts at 77° C. and boils at 123° C. Its vapour darkens paper, saturated with a solution of a soluble salt of lead. It is soluble in all proportions in anhydrous alcohol, ether and chloroform. In the presence of water the sulphydrate is slowly decomposed, with deposition of sulphur, formation of hydrogen sulphide which escapes, and hydrochloric acid and chloral which are found in the water. There is also deposited a small quantity of liquid which has the appearance of tetrachloride of carbon. It is certain that this decomposition in water is very complex, because part of the hydrogen sulphide reduces the chloral, as shown by the deposit of sulphur and formation of hydrochloric acid and carbon tetrachloride.

The formula of the sulphydrate is $C_2HCl_3 \left\{ \begin{matrix} OH. \\ SH. \end{matrix} \right.$

When aniline is mixed with chloral great heat is evolved and a thick liquid is formed. This becomes crystalline when it cools, and may be recrystallized from alcohol in fine tables with well developed faces. This body has basic properties and forms with perchloride of platinum golden coloured scales. It has the formula—

$$C_{14}H_{13}N_2Cl_3 \text{ or } CCl_3 - CH \begin{matrix} \diagup NH - C_6H_5. \\ \diagdown NH - C_6H_5. \end{matrix}$$

The body is trichlorethylidine-diphenyldiamine.

When toluidine is mixed with chloral great heat is evolved and the compound becomes solid on cooling. This body, trichlorethylidine-ditolyldiamine, forms with acids salts of toluidine. It melts and is decomposed by water. Formula—

$$CCl_3 \begin{matrix} \diagup OC_2H_5. \\ \diagdown NHC_6H_4CH_3. \end{matrix}$$

A compound of xylidine and chloral is also formed similar to the above—

$$CCl_3 . CH \begin{matrix} \diagup NH . C_6H_3(CH_3)_2. \\ \diagdown NH . C_6H_3(CH_3)_2. \end{matrix}$$

Now, having looked at our subject only as a chemical, let us deal with it in its application as a medicinal agent. Chloral hydrate is the compound invariably prescribed. As before stated, Liebreich was the first to point out the therapeutical importance of chloral. He had observed that chloral hydrate is decomposed by an alkali into chloroform and a formiate, and reasoned that if administered internally the alkali of the blood would have the same effect. To test the correctness of the theory he administered chloral hydrate to some rabbits and found that it produced sound sleep. He administered a dose of 17 grains to a lunatic. The result was a sleep of five hours. Another dose of 44 grains was given. This dose produced a sleep lasting for the rather alarming period of sixteen hours. From these experiments Liebreich inferred that his theory of the decomposition of chloral hydrate into chloroform was correct. However, the theory has been experimentally proved to be untenable. Chloral does not produce the distinct anæsthetic effects of chloroform. Animals under the influence of chloroform exhale chloroform from the lungs, while in the excreta and blood chloroform is readily detected. Animals under the influence of chloral hydrate exhale chloral from the lungs and chloroform is not found in their excreta or blood. Messrs. Mering and Muscullen made some experiments to disprove Liebreich's theory, and in examining the urine of persons who had taken for some time doses of 5 or 6 grains of chloral hydrate every night, discovered neither chloroform nor formic acid, but a trace of chloral. They also found a substance which reduced Fehling's solution and turned the plane of polarization to the left. They isolated this substance and obtained it in stellar groups of colourless silky crystals, having the properties of an acid. It was readily soluble in water, alcohol, and a mixture of alcohol and ether, but insoluble in pure ether. Ultimate analysis of the acid and examination of its barium and potassium salts led to the formula $C_7H_{12}Cl_2O_6$. This substance they named uro-chloralic acid. From the discovery of this body it would appear that chloral hydrate belongs to those bodies which, like benzoic acid, combine with some product of the organism and are eliminated in this condition.

When administered internally chloral acts as a hypnotic, sedative and antispasmodic. The B.P. dose is 5 to 30 grains. Fifty grains have proved fatal, while on the other hand 460 grains have been given without any alarming results. The person who received this large dose was addicted to excessive drinking and in such subjects large doses of chloral seem to be tolerated. Dr. Richardson, from experiments, concludes that an average adult man can only use up 7 grains of chloral hydrate per hour, so that we should bear in mind not to dispense a prescription ordering more than 140 or 160 grains per twenty-four hours without making inquiries, else accumulative poisoning may result.

As a remedy, chloral has become so popular that its range of application is as diversified as any drug or chemical of a century's standing. In proof of this we find our pharmaceutical liturature teeming with formulæ for the preparation of elixirs, cough mixtures, liniments, ointments, plasters, suppositories, caustic pencils, capsules, etc., all containing chloral.

Allow me to call special attention to one of these preparations,—the liniment of camphor and chloral. On mixing equal parts of chloral hydrate and camphor there is formed an oily liquid which smells of chloral and tastes of camphor. When ignited it burns with a white flame having an emerald green edge; is readily soluble in alcohol, ether and olive oil; treated with water it is converted into a soft translucent mass, from which, after some time, the chloral hydrate appears to be dissolved out, leaving the camphor in crystalline grains Mixed with $1\frac{1}{2}$ parts of chloroform the mixture remains clear, but a further addition of 3 parts renders it turbid. By careful distillation I was able to separate the chloral from the camphor.

Why does a mixture of chloral and camphor liquefy? Does the chloral dissolve the camphor or the camphor dissolve the chloral? Is the resulting liquid a mere solution or a chemical compound? I mixed 2 parts of chloral with 1 part of camphor and obtained a liquid. Then I made another mixture in inverse proportions, 2 parts of camphor and 1 part of chloral. I placed this mixture in a phial and put it in my trousers pocket. I carried it there for some hours, during which time of course it was submitted to a gentle heat. When I looked at this mixture it was liquid also. I placed it aside. Next time I examined it, I found it had become a soft crystalline mass. I had got thus far when my attention was directed to the following simple experiment by Saunders, which appears in the 'Year-Book of Pharmacy' for 1877:—"A lump of camphor and a lump of chloral hydrate were placed on a flat plate about an inch apart from each other. They were covered by a bell jar. In fifteen minutes the surface of the camphor was damp, while the chloral hydrate remained dry. In three hours the camphor was wet and standing in liquid, while the chloral hydrate remained still dry. In twelve hours the liquid had reached the chloral, the upper surface of which was still dry. In twenty hours both the chloral and camphor were half liquefied and the inner surface of the bell jar covered with moisture."

This experiment seems almost to point out that the vapour of chloral was the solvent; but 1 part of camphor forms a permanent liquid with $3\frac{1}{2}$ parts of chloral, while 1 part of chloral dissolves, with heat, 2 parts of camphor and solidifies on cooling, owing to camphor crystallizing out. It is probable that camphor is the solvent. Before quitting the subject I may state that a slight rise of temperature, 3° F., has been observed on mixing chloral and camphor together, and Messrs Cazeneuve and Imbert conclude that the liquid formed is an unstable molecular compound, similar to the combinations of camphor with alcohol, acetic acid and nitric acid.

With regard to making an ointment of chloral hydrate, chloral hydrate liquefies solid fats, so that if we were to mix it with lard or simple ointment our product would be far too soft. A little spermaceti must be added to give the ointment consistency. Then, again, in making suppositories we generally use oil of theobroma as an excipient. Try it as an excipient for chloral hydrate and we get a fine unctuous mass. In fact we must use something like equal parts of oil of theobroma and spermaceti to make a good suppository.

About 1874 Dr. Kean discovered that chloral hydrate possessed remarkable antiseptic powers, and in these rooms, March, 1876, Dr. Craig, of the Edinburgh School of Medicine, communicated a paper to the North British Branch giving the results of some experiments he made in this direction. As an antiseptic in treatment of wounds, ulcers, etc., he employed chloral hydrate with great success. He also used it in the dissecting room, for the preservation of anatomical specimens, with good results. Employing a solution of from 1 to $1\frac{1}{2}$ grains per ounce, he found it an excellent preservative for vegetable specimens, and showed leaves, fruits and flowers, which had been preserved for sixteen months. Thus chloral hydrate would be very useful in that we could have a fresh plant sent from a distant country in such a condition that it could be minutely examined by a botanist.

Chloral hydrate is the best antidote for strychnine, when promptly given, arresting both the force and frequency of the tetanic convulsions. Conversely, strychnine is an antidote to chloral hydrate.

Chloral is also antagonistic to calabar bean; but to act as an effectual antidote the slower acting chloral must be given within two minutes after the quicker acting calabar bean.

With regard to the medicinal properties of any of the other compounds of chloral, I have been unable to obtain any information. The only hint that any one of them had ever been tried was that the alcoholate seems to differ essentially from the hydrate in its physiological effects.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 7, Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—J. T. Barr, L. L. Garbutt, C. W. Stephens, P. H. Wright.

The President expressed his regret that a sufficient number of Fellows were not present to enable a ballot to take place; he hoped that a ballot would be held at the next meeting, on June 21, which would be the last meeting of the session.

Dr. Gladstone then communicated—

Laboratory Notes. By J. H. Gladstone and A. Tribe.—1. *On the Action of Light and Heat on Cane and Invert Sugars.*—The authors have investigated the action of their well-known copper-zinc couple on a 5 per cent. solution of sugar. No carbonic acid was evolved at ordinary temperatures, but at 100° C. carbonic acid was formed, and a small quantity of a substance which gave the iodoform reaction on treatment with iodine and potassium hydrate; this substance also gave acetic acid on treatment with potassium chromate and sulphuric acid. It was, therefore, thought at first that alcohol had been produced from sugar. Further investigations showed that the carbonic acid came from some oxycarbonate of zinc formed during the working of the couple, while the reducing body was a product of the action of heat upon the sugar solution. Many experiments were made in which a 5 per cent. solution of cane sugar was heated for many days, in all cases the iodoform-yielding substance was formed even in the absence of air. Some experiments were also made as to the influence of light, air, atmospheric germs on the conversion of cane sugar into glucose. The authors conclude that this conversion takes place with extreme slowness, when the cane sugar solution is exposed to the action of light and air, singly or jointly. Light appears to be detrimental to the development of fungoid growths in a solution of cane sugar exposed to atmospheric air. 2. *On Hydroxylamine.*—The copper-zinc couple reduces the hydrochloride of this base, ammonia being formed. 3. *On the Recovery of Iodine from Organic Iodide Residues.*—The residues are poured on an excess of copper-zinc couple wet with water or alcohol; zinc iodide is formed, which is extracted with hot water. The iodine is obtained in the free state by the action of hydrochloric acid and bleaching powder. 4. *A Residual Phenomenon of the Electrolysis of Oil of Vitriol.*—It was noticed that gas continued to be evolved from both the electrodes after the battery had been disconnected, this gas was oxygen. This phenomenon is probably due to the presence of Berthelot's persulphuric acid. 5. *On an Alleged Test for Alcohol.*—Davy suggests that traces of alcohol can be detected by the blue colour which is produced with a warm solution of molybdic anhydride in oil of vitriol. The authors find that many other reducing substances and sugar give the same reaction. 6. *Reaction of the Copper-zinc Couple on Nitric Oxide.*—When this gas is passed over the moist copper-zinc couple ammonia, but no protoxide of nitrogen, is formed. Free nitrogen was substituted for nitric oxide, but no evidence as to the formation of ammonia could be obtained. 7. *On the Reducing Action of Spongy Lead.*—Spongy lead, free from occluded hydrogen, reduces nitrates to nitrites, ammonia being simultaneously formed. This spongy lead has no action upon an aqueous solution of potassium chlorate, but the addition of 1 per cent. sulphuric acid causes a slow reduction to chloride. Lead filings cause similar reactions, but their activity is much less.

Mr. Warington said the fact recorded by the authors, that sugar solution when heated forms a reducing substance giving the iodoform reaction, was of great importance, and moreover threw some doubt on the conclusions drawn by Muntz, as to the occurrence of alcohol in almost all natural waters, these conclusions depending on the iodoform reaction.

The Secretary then read the following—

Note on a Basic Ammonia Copper Sulphate. By S. U. Pickering.—The author stated in a previous paper (*Chem. News*, xlvii., 182) that on dilution, ammonio-copper sulphate solution throws down a basic precipitate containing only traces of ammonia. With strong solutions, however, different results are obtained; with nearly saturated solutions a violet-blue substance is slowly deposited, which has the composition $4CuO,5SO_4\ 16NH_3$. When such a solution is diluted with a small quantity of water a violet-blue precipitate $CuSO_4\ 3CuO\ 2NH_3\ 5H_2O$ is deposited.

Notes on Loew and Bokorny's Researches on the Probable Aldehydic Nature of Albumin. By A. B. Griffiths.—The author states that he has gone over a good portion of the experiments which led the above chemists to their conclusions, and in the present paper details one or two observations he has noticed in the case of the protoplasm of spirogyra. The protoplasm, whether dead or alive, reduces a dilute alkaline solution of a cupric salt. The living cells when treated with a weak solution of sodium chloride under the microscope form crystals. The author is, therefore, inclined to think that the reducing body is a glucose and, moreover, it must be dextrose, because levulose does not form a crystalline compound with sodium chloride. The author does not give any analysis or say how the crystals were identified, but states that most likely they have the formula—

$$C_6H_{12}O_6NaCl,H_2O.$$

Note on the Action of Sulphuric Acid, Specific Gravity 1·84, *upon Potassium Iodide.* By H. Jackson.—It has long been known that when strong sulphuric acid acts upon potassium iodide, there are produced hydric sulphide, sulphur dioxide, iodine, hydriodic acid, hydropotassic sulphate and water; but no details as to the amounts produced have been published. The author finds that two principal reactions occur. The first when the sulphuric acid is in large excess, when the reaction is—

$$2KI + 3H_2SO_4 = I_2 + SO_2 + 2HKSO_4 + 2H_2O$$

the second when there is just sufficient sulphuric acid to satisfy the potassium iodide used.

$$8KI + 9H_2SO_4 = I_8 + H_2S + 8KHSO_4 + 4H_2O.$$

To obtain these reactions perfectly it is necessary to have the sulphuric acid boiling. The analytical numbers are given upon which the above reactions are founded.

Dr. Debus said the reaction was interesting, as in the second equation the hydriodic acid first evolved reduced the sulphuric acid, hydric sulphide being formed. Under certain conditions hydric sulphide was obtained from the action of zinc upon sulphuric acid, the nascent hydrogen reducing the sulphuric acid. In both cases the sulphur changed its valency.

The Action of Nitrous Anhydride on Glycerine. By O. Masson.—The author employed the pure glycerine of commerce and generated the nitrous anhydride by the action of nitric acid sp. gr. 1·35 on "porcelain arsenic." The gas was dried over fused calcium chloride and then passed direct into the glycerine. The reaction takes place quietly, the glycerine greatly increases in bulk and mobility; its colour changes through yellow to brown, finally becoming dark green. Two layers of liquid form, an aqueous solution of nitrous acid and of oxidation products of glycerine, and a layer which consists of the nitrous ether of glyceryl. These layers react upon each other and should therefore be separated as soon as possible. By passing a rapid current of dry hydrogen the author succeeded in distilling the ether at 100°, or 50° below its boiling point. Analysis indicated the formula $C_3H_5(NO_2)_3$. The liquid was distilled several times; it is amber coloured; boils with decomposition at 150°: burns with a whitish flame, but does not explode under the hammer. It does not mix with water, but the ether is decomposed at the surface of contact. It cannot be preserved pure; when enclosed in sealed tubes it produces pressure enough to shatter the glass.

Parliamentary and Law Proceedings.

The Pharmaceutical Society of Great Britain v. Copley.

At the Nottingham County Court, on Friday, the 15th inst., before S. B. Bristowe, Esq., Q.C., judge, the Council of the Pharmaceutical Society of Great Britain sued Mr. J. C. Copley, who carries on business at 51, Robin Hood Street, Nottingham, for the recovery of a penalty of £5 under the 15th section of the Pharmacy Act, 1868.

Mr. E. R. Turton, barrister, instructed by Messrs. Flux, Son and Co., appeared for the Society.

Mr. Barrows appeared for the defendant.

Mr. Turton said the action was brought under the 15th section of the Pharmacy Act, 1868. Contrary to the provisions of that section the defendant had kept an open shop for the retailing, dispensing or compounding of poisons, he not being a duly registered person. Mr. Turton then referred to the various sections of the Act bearing upon the case, and stated that it appeared that on May 12 last, Mr. Stroud went into the defendant's shop and purchased some laudanum, and the bottle was wrapped up in a handbill setting forth the defendant's name and qualifications. As he understood that Mr. Barrows admitted those facts, and that the defendant was the proprietor of the shop where the poison was bought, he submitted that the defendant had kept open shop for the sale of poison, and was, therefore, liable for the penalty sued for, and with those facts he left Mr. Barrows to show that the Act did not apply in the present case.

Mr. Barrows intimated that he admitted that the laudanum was sold in defendant's shop; he preferred to call witnesses before addressing the Court.

The defendant was called and said that he had in his employ Henry Edward Wakefield, a registered chemist; he had not sold poison in his shop, nor had he allowed any to be sold. He was an analytical chemist. He had authorized his assistant to sell poisons on his own account, but he had said that if he (Wakefield) liked to sell poisons at his own risk and with his own capital he could do so.

In reply to the Judge, defendant said that he was well acquainted with medical and pharmaceutical chemistry, and was a member of several learned societies.

Mr. Barrows: You prepare gentlemen to pass the examinations of the Pharmaceutical Society?—Yes, I do.

Mr. Turton: And you have failed to pass yourself?—Yes.

H. E. Wakefield was called and stated that he sold the laudanum at his own risk, the defendant did not share the profit. He was a duly registered chemist.

Mr. Barrows contended that the action was under a penal statute, and, therefore, it ought to be construed most strictly and not by inference.

His Honour pointed out that the section said "any person who shall sell or keep an open shop for the retailing, etc."

Mr. Barrows submitted that defendant kept an open shop for the sale of pharmaceutical preparations, but not an open shop for the sale of poisons. He referred his Honour to reported cases, and said that the Act was passed for the protection of the public, and submitted that the public had in no way been injured.

His Honour said the plaintiffs had made out their case and gave judgment, the penalty of £5 and costs.

Mr. Barrows asked for leave to appeal.

His Honour said it was a matter of some interest, and if he thought it desirable he would not refuse the request, but Mr. Barrows had better consider the matter.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* BROWN.

At the same Court the Council of the Pharmaceutical Society sued Mr. A. E. Brown, of 11, Sussex Street, Nottingham, to recover two penalties of £5 each under section 15 of the Pharmacy Act, 1868, one for keeping open shop for the sale of poison, not being a duly qualified person, and the second, for taking, using or exhibiting the title of "chemist."

Mr. Turton, barrister, instructed by Messrs. Flux, Son and Co., appeared for the Society.

Mr. Payne represented the defendant.

Henry Goodlud, of Nottingham, proved that on May 12 last he purchased two pennyworth of laudanum at defendant's shop. He produced the bottle in which it was contained, upon which defendant had placed a label bearing his name and address and the title "chemist."

Mr. J. B. Coleman, Analyst and Demonstrator of Chemistry at the University College, Nottingham, proved that he had analysed the contents of the bottle produced by last witness. He found the contents to be a tincture of opium.

Mr. Payne admitted that the Act had not been conformed with, but said that defendant would at once enrol himself as a member of the Pharmaceutical Society if the case was adjourned.

His Honour gave judgment for the plaintiffs for the two penalties, £10 with costs.

POISONING BY POTASSIUM CYANIDE.

An adjourned inquest on the body of the late Mr. John Odlum, who died suddenly at his residence, Hove, on May 30, was held on the 6th instant, by Mr. Wynne E. Baxter, Coroner for East Sussex.

Medical evidence having been given to the effect that death had resulted from poisoning by potassium cyanide,—

Horace Arthur Costerton, of 90, Western Road, Brighton, chemist, knew the deceased as a customer for some time past. He had bought recently some cyanide of potassium. On May 7, he came to witness's shop in his absence and asked his assistant to serve him with some cyanide in order to clean some silver. The assistant refused in the absence of witness to serve him with the cyanide of potassium, but on the following day deceased came and asked witness personally for the cyanide. Witness, knowing him well, served him with an ounce, obtaining his signature, as usual, in the poison book. On May 10, the deceased returned, saying that he had used the ounce, but it was not quite sufficient for his purposes. He asked for a further small quantity, and he was served with another half ounce, his signature being again given. These were the only two cases of deceased's being supplied with poison by witness. He should say the cyanide of potassium in the bottle produced was, as dissolved in the water, less than an ounce.

The Jury, after a short discussion, returned a verdict to the effect "That the deceased committed suicide whilst in a state of temporary insanity."—*Sussex Daily News.*

POISONING BY OPIUM.—A HERBALIST CENSURED.

On Friday, the 15th inst., the Leicester Borough Coroner, Mr. G. F. Harrison, held an inquest relative to the death of Charles Hanger, aged 51 years. It appeared that deceased had been ailing, and his daughter sent for a herbalist, named Whitley, who brought some medicine which was given according to direction. The symptoms, however, increased, and a medical man subsequently came, death ensued shortly afterwards.

James Whitley, the herbalist, said that on Sunday morning he was requested to see the deceased, who was suffering from chronic bronchitis. Deceased had some powders in his house, which witness had made up previously, and he told him to take one. He then went home and made up a bottle of medicine, which he took to the house of the deceased. On Monday night deceased was so much recovered that he came down stairs. On Tuesday, upon visiting, he found him much worse. On Wednesday he seemed a little better, and told witness he should like something to make him sleep. Witness went to Mr. Cleaver, a chemist, and bought three grains of opium. He made two and a half grains of it into a pill, and sent it for the deceased. About 9.30 on Thursday morning he went to see the deceased, and found his breathing very much worse, and he recommended that a doctor should be called in. He did not see the deceased again. He had been in business as a herbalist for twenty-five years.

In reply to the Foreman, witness said he had administered as much as two and a half grains of opium before, where there had been symptoms of typhoid fever, and there was a good deal of fever to contend against in this case.

Mr. G. C. Franklin, surgeon, had examined the body, and was of opinion that death was caused by bronchitis and an overdose of opium.

The Jury returned a verdict to the effect that death had been caused by bronchitis and an overdose of opium, indiscreetly administered by the man Whitley. Whitley was then called in, and censured by the Coroner.

Correspondence.

DEPOSITS FROM TINCTURES.

Sir,—As I am about to undertake the examination of deposits occurring in the B.P. tinctures, I should be glad if any readers would kindly forward me any which they may be able to obtain, with a label stating by what method the tinctures have been prepared.

17, *Bloomsbury Square, W.C.* R. A. CRIPPS.

J. Fingland.—(1) *C. pallescens*; (2 and 3) *C. panicea*; (4) *C. curta*; (5) *A. aquatilis*; (6 and 7) *C. vulgaris*; (8) *C. ampullacea*; (9) *C. teretiuscula*; (10) *C. fulva*; (11) *C. muricata*; (12) *C. hirta*. Please not to send more than six specimens at one time in future.

"*Crinis.*"—A solution of borax is sometimes used, but the condition is probably one requiring internal treatment rather than a local application.

"*Alpha.*"—The question is rather one for the opinion of medical men, who are by no means agreed as to the action of chrysophanic acid.

"*Salix.*"—*Salix fragilis*, probably; a twig bearing stipules should always be sent in the case of species of *Salix*.

R. A. Hoyle.—(1) *Eriophoron polystachion*; (2) *Luzula sylvatica*; (3) *Pogonatum juniperinum*; (4) *Luzula pilosa*; (5) *Melica uniflora*. The specimens sent previously were too fragmentary to name with certainty.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. G. Johnson, Dr. Senier, Messrs. P. Wells, Proctor, Jones, Junior Assistant.

"THE MONTH."

The refreshing showers of the last few weeks have given quite a new start to vegetation, and a large number of medicinal plants are consequently coming into blossom. The tall spikes of digitalis are ornamenting the hedgerows, and the pretty lilac-blue flowers of dulcamara are peeping out from the wealth of foliage through which its long straggling stems climb. In chalky woods the belladonna is beginning to put forth its lurid purplish-brown bells, and in the cottage garden the aconite (*A. Napellus*) is opening its helmet-shaped blossoms. At the Royal Botanic Gardens, Regent's Park, this species may be seen in blossom, while *A. paniculatum*, *A. ferox*, and *A. autumnale* are not showing any signs of flowering. An interesting hybrid at these gardens has been formed by cross-fertilization between the *Rheum officinale*, Baillon, and *R. australe*, Don. The plant has the reddish inflorescence and entire leaves of the latter, and the habit and size of the former. The *Rheum officinale* is now a splendid sight, its tall branching inflorescence being nearly 8 feet high, while not far off an equally tall but less branching inflorescence of *Rheum palmatum* forms almost as conspicuous an object. Other medicinal plants at present in blossom in the Gardens are, the black and white mustard, rue, hemlock, buckthorn, mulberry and pellitory of the wall. Several rare or uncommon British plants may also be seen in blossom at the present time, among which may be mentioned *Silene quinquevulnera*, *S. italica*, *Geranium pratense*, and *Reseda alba*. In one of the flower-beds may also be noticed *Orobanche minor*, apparently growing on *Nepeta Glechoma*. In the Economic House the singular *Xylophylla longifolia* is in blossom, the flattened peduncles looking like leaves with flowers at their margins. In the pots in the orchid house the male and female fructification of *Marchantia polymorpha* is now in a fit state for dissection.

One of the handsomest of our native spurges, *E. Lathyris*, is now in excellent condition for examination of the flowers and fruit, and is perhaps the best plant that could be chosen at this time of year for the purpose of studying the character of the genus and order. The leaves, unlike those of all the other British species (except *E. Peplis*), are opposite and decussate. The young fruits bear some resemblance to capers, for which they are sometimes pickled as a substitute, or even mistaken for the true caper. Hence the name of "caper spurge" applied to this plant. The seeds when recent are, according to Pereira, acrid and narcotic, and contain an oil similar in properties to croton oil, of which the dose is three to ten drops. The use of the pickled fruits would therefore be dangerous in quantity, especially if gathered when nearly ripe. A section of the spongy pericarp of the unripe fruit forms an interesting object for the microscope, the mesocarp being composed of a loose network of cells. The seeds were formerly used in medicine under the name of *Semina cataputiæ minora*.

One of the most common plants in the hedge-rows at this time of year is the *Galium Aparine*, which, were it not for the minute hooked prickles which everywhere cover its stem, causing it to adhere to the clothes of the passer-by, might easily be overlooked, its greenish-white flowers being very small and inconspicuous. It has long been known as a popular domestic remedy for "impurity of the blood," and indeed was brought under medical notice some years ago by Dr. Winn, in the treatment of lepra. Dr. Quinlan, who not long since directed attention to another of our indigenous medicinal plants, *Verbascum Thapsus*, in the treatment of phthisis, now gives the results of his experiments with *Galium Aparine*. He finds that in ulcerated sores a poultice made by beating the fresh herb into a pulp in a mortar acts as a slight steady stimulant and powerful promoter of healthy granulation. In one case mentioned by him in the *British Medical Journal* (June 16, p. 1174), in which skin-grafting and sponge-grafting proved useless, a sore 8½ inches long and extending nearly round a leg was reduced to half the size in a month by the use of a poultice of this plant. As there is a difficulty in obtaining the plant in a fresh state in the winter and spring, Dr. Quinlan recommends that it should be preserved during the winter months by the process of ensilage, the plant being chopped into small pieces and rammed down by screw pressure into glazed earthenware jars with air-tight covers, which should be buried in the ground. Thus preserved, it has been found quite fresh and sweet at the end of a month.

The ancients seem to have understood the secret of preserving the colours of flowers. In some funeral wreaths found in the coffins of the Egyptian kings, Amenhotep I. and Aahmes I., the colours of the flowers were admirably preserved, so that they were easily recognized although placed on the breasts of the mummies at least 1700 years B.C. Among others were florets of the safflower (*Carthamus tinctorius*), *Acacia nilotica* and *Sesbania ægyptiaca*, plants which are still used in medicine or the arts in Egypt. There was also found in an Egyptian tomb a basket of the lichen, *Evernia furfuracea*, which at the present day is sold in the drug bazaar in every town in Egypt. Mixed with this lichen were fragments of *Usnea plicata*, and the straw of a grass, *Gymnathelia lanigera* (*Andropogon laniger*, Desf.), from Nubia, which at the present day is used by the natives as a remedy against affections of the chest and stomach, the odour of the grass (the *Juncus odoratus* of old writers: 'Pharmacographia,' 1874, p. 662) being still preserved to some extent. Mixed also with this lichen was another (*Ramalina græca*) found only in the Greek Archipelago, thus proving that commercial intercourse existed between the Greeks and Egyptians, 1000 years before Christ. A set of the wreaths, the best that could be obtained after the selection made for the Museum of Boulak, has been presented to the Kew Museum by Mr. Maspero, through Dr. Schweinfurth, and were recently exhibited at the Royal Society. They may now be seen in a case on the first floor, in No. 1 Museum, Kew Gardens.

In an editorial article in the *Gardeners' Chronicle* (June 23, p. 792), there is an interesting summary of little known facts relating to the structure of the leaf buds, the gyrating movements of the young shoots and the arrangement of the leaves in different coniferous plants, which is well worthy of reading by those who may find a walk through a pine wood somewhat monotonous, as it shows that there are modes of growth and development which enable the species of this somewhat difficult group of plants to be easily recognized. It also opens a wide field for further observation.

It is generally supposed that plants will only graft well on others of the same natural order. A cultivator of the Ardèche, named Marcel, whose vines had been invaded by the phylloxera, has, however, succeeded in grafting a vine on the common bramble (*Brit. Med. Journ.*, p. 1097). Two brambles thus grafted with French vines have been sent by M. Henzé, Inspector-General of Agriculture, to the Versailles gardens, where the experiment will be continued.

Viola pedata, a plant official in the secondary list of the last United States Pharmacopœia, is now recommended in the *Gardeners' Chronicle* (p. 762) as an ornamental plant, especially the white-flowered variety. Although introduced into this country in 1759, it does not appear to have met with the favour its beauty deserves.

Arnica montana is now in bloom in botanical gardens, and when well grown, with flower-heads 2–3 inches across, is a really handsome plant.

At the evening meeting of the Royal Horticultural Society, held in the rooms of the Linnean Society on the 12th inst., a specimen of *Curcuma Zedoaria* in flower was exhibited. This plant is the source of the zerumbet root, formerly used in medicine in this country. Another medicinal plant, *Asimina triloba*, was exhibited by the Curator of the Cambridge Botanical Gardens. A very interesting series of Irises, arranged in a circle and showing every gradation of hybridism between two species, was exhibited by Professor Michael Foster, who takes great interest in this group of plants.

At the meeting of the Edinburgh Botanical Society, on June 14, a specimen of the costus plant, *Aplotaxis auriculata*, was exhibited in flower for the first time since it was sown, in November, 1873, from seeds sent by Dr. Bellew, from Yarkand. It had been grown in the open ground. The fragrant root of this plant, which has an odour resembling that of violets, is occasionally sent to this country, being an article of considerable traffic in the East for use in perfumery, in the manufacture of incense, and for protecting clothes from the attack of moths.

A case of poisoning by laburnum flowers is described (*Brit. Med. Journ.*, June 9, p. 1117), in which a child four years of age had eaten some of the blossoms. The symptoms were similar to those produced by eating the pods, the surface of the body being cold, the pupils dilated, and vomiting frequent. Although cases of poisoning by the pods occur somewhat frequently they are rarely fatal, owing to the emetic action of the plant, and the treatment with an ordinary emetic followed by a stimulant usually ends in recovery, as it did in this case.

Some interesting information on amber is contributed in a review in *Nature* (June 14, p. 152) of Goppert and Menge's 'Die Flora des Bernsteins.' It is there stated that amber is the produce of at least six species of the fir tribe, the chief being close allies of the common spruce and the American *Pinus Strobus*. The group of coniferæ of the amber flora comprise representatives from nearly every geographical province. It is estimated that although the annual yield of amber is 200,000 to 300,000 lbs., there is still sufficient in the bed of the Baltic Sea to supply the same quantity yearly for thirty thousand years to come.

Bonaccorsi, who commenced studying the antagonism of various drugs in 1877, has lately come to the conclusion, as the results of his experiments, that morphia is antagonistic to nicotine, and that in cases of nicotine poisoning opium or morphia is to be preferred to any other remedy (*Practitioner*, p. 459). He does not find any antagonism between morphia and hyoscyamine, or between morphia and daturine.

A newly observed action of euonymin is mentioned in the *British Medical Journal* (June 2, p. 1060) by Dr. E. A. Cook. He finds it at first causes an increase in the amount of uric acid excreted, followed by a decrease in the amount, even if the use of the drug be continued.

On page 1064 of the same journal, Dr. J. Beddoe states that if the extract of *Cannabis indica* be prescribed in the form of a pill, the addition of an equal weight, or a somewhat greater quantity, of sulphate of potash will cause its action to be tolerably speedy and certain by causing the minute division of the extract.

Dr. G. C. Wallich, in the *British Medical Journal* (June 23, p. 1224), throws some light on the conflicting statements which have been made as to the value of *Cannabis indica*. He states that he found, when residing in India, that the uncertain action of the drug was due to inherent differences in the composition of the extract incident to its being grown either on the plains or in the hilly districts of India, the extract obtained from plants grown on the hills being much superior to that grown on the plains.

The oxytocic action of quinine having been called in question recently, Dr. U. Hartigan, of Hong Kong, writes to the *British Medical Journal* (p. 1064) to say that he has found it increase the menstrual flow, and that in doses of 3 to 5 grains it causes "labour pains," whilst a dose of 10 grains produces abortion. He has also learned that the Chinese take it for the purpose of producing abortion, following its use by copious draughts of tea. Quinine is so commonly resorted to as a domestic remedy for neuralgia that it is well this action should be as widely known as possible.

In an article in the *Medical Press* (June 6, p. 487), Dr. D. H. Cullimore recommends the use of the moxa in certain chronic inflammatory diseases of the spinal cord, and some intractable and often incurable diseases depending thereon. Instead of using the artemisia of China, or other substances commonly used for this purpose, he recommends that the moxa should be made of a piece of brown paper 15 inches long by 4 broad, saturated with a solution of nitrate of potassium of the strength of 1 drachm to 1 ounce of water. The paper is then dried and rolled into a cylinder so that it resembles a short cigar without tapering ends. It is applied by lighting one end and placing the other on the skin in the vicinity of the subjacent disease, the neighbouring parts being protected with alum paper having a central hole. The burning part is never allowed to come in contact with the skin.

A new preparation of ergotin is described in *New Remedies* (p. 171). It is in the form of small cylinders of gelatin, each containing 3 grains of ergotin, which is mixed with the gelatin when in a melted state. These cylinders are kept in a small test-tube in the pocket case, and when wanted for use one of them is dissolved in the test tube in a quantity of water corresponding to the desired volume by means of a gentle heat, for which the flame of a match is sufficient.

The use of small doses of medicines frequently repeated instead of larger doses given three times a day seems to find advocates in the United States as well as in this country. Dr. A. A. Smith, in a lecture delivered some weeks ago and mentioned in the *Medical Times and Gazette* (June 2, p. 621), recommends chlorate of potash in grain doses every half hour in scarlet fever as not being liable to produce dangerous inflammation of the kidney, which sometimes results from a large dose; also, salicylate of sodium in doses of 2 grains every half hour for nettle rash, 5–10 minims of fluid extract of jaborandi every half hour in Bright's disease, and bromide of sodium in $\frac{1}{2}$ or 1 grain doses in the nervous complaints of children. Many other drugs are mentioned as being given with advantage in small often-repeated doses, such as aconite, digitalis, tartar emetic, Calabar bean, cantharides, ergot, hamamelis and gelsemium.

Drs. Weir Mitchell and Reichert have recently published some interesting facts relating to the venom of serpents. They find that all the venoms they have examined present certain characteristics in common. They are invariably of acid reaction, and, when dried, soluble in water save for a slight cloudiness. The authors do not find an alkaloid in any of them, but in every case the poison appears to be made up of three distinct proteid bodies. These they have named respectively, peptic, globulin and albumin venoms. The first, which they say is a peptone, is less active than the combined poisons, but reduces the blood pressure, induces œdema, and finally produces putrefactive effects. The second is an extremely virulent substance, $\frac{1}{20}$ of a grain being sufficient to kill a strong pigeon in two hours; it gives rise in a few minutes after injection to enormous infiltration of blood into the neighbouring tissue. The third is doubtfully poisonous.

At a meeting of the Physiological Society of Berlin (May 11), Professor Brieger reported further results of his studies of the poisons formed by the decomposition of animal bodies. He obtained the hydrochlorate of a diamine base in crystals, having the formula of $C_5H_{14}N_2H_2Cl_2$, which no longer possessed the toxic properties of the extracts of the products of decomposition. A second crystalline substance, but which was extremely poisonous, has the formula $C_5H_{11}NCl$. One milligram of this substance in solution, subcutaneously injected into a rabbit, produced symptoms characteristic of fish poison, and death in convulsions in a short time. The first-mentioned body could only be prepared from decomposing meat, but not from the later stages of putrescence, nor from decomposing fibrin or other albuminous substances. It would throw some light on fish poisoning if the alkaloid which produced similar symptoms could be obtained from decomposing fish. It would also be interesting if the effect of milk on the alkaloid could be ascertained, since milk is commonly used as an antidote in cases of fish poisoning, and Professor Brieger has shown that these bases are decomposed with extraordinary facility.

Dr. George Thin, who has been investigating the identity of the bacillus of leprosy obtained from different parts of the world (*Brit. Med. Journ.*, June 16, p. 1178), finds that the *Bacillus lepræ* is the same in all cases and that it closely resembles that of tuberculosis in size, in beaded appearance and in its action with regard to the dyes methylanilin, fuchsin and gentian violet.

In a recent meeting of the Crefeld circle of the German Pharmaceutical Association, Dr. Brunnengräber stated (*Pharm. Zeit.*, No. 48, p. 387) that whilst examining a number of samples of quinine sulphate from various manufacturers he had observed the presence in the solutions of what appeared to be fine threads, which at first he thought were accidental impurities, but afterwards discovered, upon microscopic examination, to be fungoid growths (*Aspergillus glaucus*), attached to minute fragments of linen and cotton fibre. The presence of this fungus he attributes to the fact that makers of quinine sulphate, in order to retain as much water of crystallization as possible, dry the salt at as low a temperature as they can, and possibly do this by spreading the salt out upon linen or calico, which would account for it becoming contaminated with both the fungus spores and the fibres. Dr. Brunnengräber explains in this way the known instability of quinine, morphine and atropine solutions, and he recommends a preliminary boiling and filtration when it is desired to have a solution that will remain clear and unaltered.

When the weak base caffeine ($C_8H_{10}N_4O_2$) is submitted to the action of boiling baryta water it is converted, with separation of baric carbonate, into a stronger base ($C_7H_{12}N_4O$), which has been named "caffeidine." According to Dr. Maly, however, caffeidine is the product of a secondary reaction, there being an intermediate formation of a monobasic acid, represented by the formula $C_8H_{12}N_4O_3$ (*Pharm. Post*, xvi., 268). This acid may be conveniently prepared by allowing caffeine to digest at the ordinary temperature with a solution of an equivalent of potash until it has all disappeared, which requires about a fortnight, when upon neutralizing the solution with acetate of copper the acid is combined as a sky-blue, crystalline, scarcely soluble copper salt ($C_8H_{11}Cu_2N_4O_3$), from which the acid is obtainable by decomposing with sulphuretted hydrogen, concentrating in a vacuum, dissolving in chloroform and precipitating by benzol. Upon boiling with water the acid splits up into carbonic anhydride and caffeidine; it is, therefore, caffeidincarbonic acid. Theobromine is not similarly attacked by alkalies and yields neither a corresponding acid nor "theobromidine;" in fact it forms compounds with some bases, that with barium being especially characteristic.

Strychnine is not very freely soluble in strong acids, but is more readily dissolved by dilute acids. An explanation of this is put forward by Messrs. Hanriot and Blarez (*Comptes Rendus*, xcvi., 1504), which is that in presence of an excess of acid a salt is formed that is less soluble in an acid liquid than in water. Thus when a concentrated solution of a neutral salt of strychnine is treated with a little of the corresponding acid a precipitate is formed, and the same occurs even in a dilute solution, but more slowly. In the case of the sulphate crystals have been obtained, which gave upon analysis results corresponding fairly to the composition of an acid sulphate of strychnia ($C_{22}H_{22}N_2O_2,SO_4H_2$). This salt is very soluble in pure water, but much less soluble in an acid liquid; hence its crystallization. But if the liquid be neutralized with a few drops of ammonia the salt redissolves. The same chemists have also described (*Comptes Rendus*, xcvi., 1671) an acid containing nitrogen, which has been obtained by oxidizing strychnine with potassium permanganate. The silver salt, which is said to be very stable when exposed to light, is represented by the formula $C_{11}H_{10}AgNO_3,H_2O$. Neither the free acid, nor any of its salts, has been obtained in a crystalline form.

Several interesting compounds of chinoline with other bodies have recently been described. According to Herr Rhoussopoulos (*Berichte*, xvi., 202), when chinoline is allowed to react on iodoform at the ordinary temperature a beautifully crystalline compound is formed, having the composition of methan-chinoline hydriodate and represented by the formula $CH(C_9H_7NI)_3$. The compound is conveniently obtained in handsome, large, colourless, transparent needles by mixing ethereal solutions of one equivalent of iodoform and three equivalents of chinoline and allowing the mixture to stand for about an hour. The crystals are soluble in acetic ether, benzol and ligroin, but insoluble in cold water, acids or alkalies. When treated with alcohol, or heated with acids or alkalies, the compound splits up again into chinoline and iodoform. Chloroform does not appear to undergo any similar reaction with chinoline in the cold, but when the mixture is heated to a temperature above 300° C. decomposition takes place, the products of which have not been fully examined. When chloral and chinoline are allowed to react directly upon each other a white mass is formed, having the consistence of butter, which refuses to crystallize and is insoluble in nearly all solvents. But when solutions of chinoline and chloral in ether, or other solvents, are mixed together, only a small quantity of the butter-like compound is formed, and upon removing this by filtration and evaporating the solvent, radiating groups of crystals are formed. The crystals are insoluble in water and are decomposed by alcohol and alkalies; after washing and recrystallizing from benzol they gave upon analysis results showing that they consist of a compound of equal molecules of chinoline, chloral and water, which may be represented by the formula $C_9H_7N.CCl_3COH.H_2O$.

Herr Hock also has been experimenting with a view to preparing compounds that shall combine the therapeutic properties of chinoline and the antiseptic properties of phenol. He reports, however, (*Berichte*, xvi., 885) that when carbolic acid and chinoline are brought together in equivalent proportions they yield, under a considerable rise of temperature, a clear liquid from which he has not succeeded in separating a definite compound. But when resorcin and chinoline are melted together on a water-bath, in the proportion of one molecule of the former to one of the latter, the mixture forms upon cooling a crystalline mass, which can be easily purified by repeated washing and recrystallization from absolute alcohol. A pure preparation may also be obtained by mixing solutions of chinoline and resorcin in dilute hydrochloric acid, precipitating by means of sodium carbonate, and recrystallizing the precipitate from absolute alcohol. The results of an analysis showed that the new compound is a combination of two molecules of chinoline with one of resorcin. Herr Hock states that this resorcin-chinoline possesses marked antiseptic and antipyretic properties, which are being investigated in the hospital at Bern. The compound has a bitter, somewhat acrid taste, and melts at 102° C. It is slightly soluble in cold water (1 in 400), but freely soluble in alcohol, ether and chloroform. In the low-boiling portions of petroleum it is insoluble. Resorcin-chinoline has scarcely any alkaline reaction, though it dissolves completely in dilute hydrochloric acid; but if such a solution be shaken with ether the resorcin is taken up and hydrochlorate of chinoline is left in the solution. It is also decomposed by other acids and alkalies as well as by continued boiling in water. An analogous compound with hydroquinone has also been obtained, and Herr Hock is continuing his experiments upon the formation of others with pyrocatechin, pyrogallol, etc.

Messrs. Lieber and Haitinger (*Ber.*, xvi., 1263) have obtained pyridine from chelidonic acid from *Chelidonia majus*, and from meconic acid, by distilling the acids produced by the action of ammonia on these bodies with zinc dust.

At a recent meeting of the Royal Society of Edinburgh (*Nature*, p. 167), Mr. D. B. Dott read a paper on "The Acids of Opium," in which he stated that contrary to the usual opinion the principal acid in opium (judged by its acidifying powers) is sulphuric and not meconic acid, a considerable portion of the morphia being always combined with sulphuric acid.

In a paper on the occurrence of salicylic acid in the Violacæ (*Pharm. Journ.*, [3], xii., 627) Herr Mandelin confirmed the presence in *Viola tricolor*, var. *arvensis*, of a yellow substance that had been mentioned by previous observers. He has now made a closer investigation of this compound and reports (*Pharm. Zeit. f. Russl.*, xxii., 339) that it is a glucoside, splitting up in the presence of water into three molecules of sugar and one of a body identical with quercetin ($C_{24}H_{16}O_{11}$) obtained in the decomposition of quercitrin derived from the bark of *Quercus tinctoria*. This new glucoside has been named "violoquercitrin;" it is represented by the formula $C_{42}H_{42}O_{24}$, and its decomposition by the equation $C_{42}H_{42}O_{24} + 5H_2O = C_{24}H_{16}O_{11} + 3C_6H_{12}O_6$. The decomposition is not, however, so simple as this, a small quantity of a third body being produced, which is characterized by its beautiful fluorescence in alkaline liquids.

In the *Répertoire de Pharmacie* (xi., 246), Messrs. Adrian and Moreaux describe a process by which they have succeeded in preparing quassiin from Surinam quassia wood (*Quassia amara*) in a crystalline form and in considerable quantity. It was obtained by crystallization from alcohol in white light crystals, very soluble in chloroform, soluble in about 90 parts of cold absolute alcohol and in 35 to 40 parts of 80° alcohol, scarcely soluble in ether and soluble in about 300 parts of hot water, from which it is deposited again in the crystalline form upon cooling. The yield of crystals was from 1·25 to 1·50 gram per kilogram of wood; whilst Christensen obtained less than half that quantity, still in an impure condition (see before p. 146). A still further quantity of quassiin can be separated from the mother-liquor, but this appears to be an uncrystallizable modification; it is very soluble in absolute alcohol, more soluble in ether than crystallizable quassiin, and slightly soluble in water.

About a dozen years since M. Duclaux affirmed that copper is normally present in cacao beans, and that its occurrence in manufactured "cocoa" and "chocolate" is not therefore necessarily referable to the use of insufficiently tinned copper vessels, as had previously been supposed. This statement is now confirmed by Dr. Galippe, who reports (*Répertoire*, xi., 277) that he has found copper to be a constant constituent in cacao beans from different sources, both unroasted and roasted, in varying proportions ranging from 0·0112 gram to 0·0292 gram per kilogram. As might be expected, he has also found copper in chocolate, in proportions varying from 0·005 gram to 0·125 gram per kilogram; some samples of chocolate would therefore appear to contain as much, or even more, copper than is added to preserved peas to give them an acceptable colour. The principal seat of the copper in the bean is the episperm, which is not used in the manufacture of fine chocolates. The *débris* is, however, sometimes bought up by makers of low-priced chocolate, and this would account for a considerable proportion of copper occurring in some samples of chocolate of inferior quality; but the fact that others contain hardly any would seem to suggest that they are equally poor in cacao bean.

Nickel is coming into such general use for plating purposes that it is satisfactory to learn that poisoning by the use of nickel-plated instruments appears to be almost impossible, even when food which comes into contact with the metal is acid. Schulz gave to a dog weighing 4 kilograms separate doses of 0·5 gram of acetate of nickel until 10·5 grams had been taken without producing any ill effect; on the contrary, the animal increased 1 kilogram in weight during the treatment. Schulz also found that traces only of nickel were dissolved by sour milk after eight days' contact with a nickel plated vessel (*Lancet*, June 2, p. 970).

Herr Grünning states that a pure solution of hydrobromic acid may be conveniently obtained by the decomposition of potassium bromide with phosphoric acid and collection of the liberated gas in water. He recommends (*Pharm. Zeit. f. Russl.*, xxii., 315) 100 grams of coarsely powdered potassium bromide to be placed, together with 280 grams of phosphoric acid, sp. gr. 1·304, in a glass retort of half a litre capacity, provided with a delivery tube, and heated over a flame with wire gauze interposed. The bumping of the liquid in the first part of the reaction is liable to break the retort, but it may be diminished by directing the flame on to the side of the vessel; after a a short time the liquid boils quietly until the whole of the salt is converted into potassium metaphosphate. At first water passes over, then some aqueous acid, and afterwards pure hydrobromic acid gas, which should be conducted into distilled water, care being taken to prevent any liquid being drawn back into the retort upon the absorption of the gas. Any chlorine impurity in the potassium bromide would pass over in the first portion of the acid distillate, which should, therefore, be separated and tested for hydrochloric acid.

The incrustation which occurs in the vacuum pans used in the manufacture of sugar from beetroot has already been found to contain the calcium salts of citric, aconitic, tricarballylic and malonic acids. Herr von Lippmann (*Ber.*, xvi., 1078) has isolated another acid from the same deposit. The crude calcium salts were decomposed by dilute sulphuric acid and the resulting solution treated with ether; this when evaporated left a syrupy residue, which on standing for two years yielded needle-shaped crystals of an acid substance that was very soluble in water, alcohol and ether, and upon analysis gave the formula $C_6H_8O_8$. The analysis of the barium and calcium salts showed it to be a tribasic acid, the calcium salt having the formula $Ca_3(C_6H_5O_8)_2$; the corresponding sodium and potassium salts were also obtained and found to be very soluble in water. The substance was evidently identical with the oxycitric acid, obtained by heating chloro-citric acid ($C_6H_7ClO_7$)—which is produced by the action of hypochlorous acid upon aconitic acid—with caustic alkalies. Aconitic acid ($C_6H_6O_6$), tricarballylic acid ($C_6H_8O_6$), citric acid ($C_6H_8O_7$), and oxycitric acid ($C_6H_8O_8$), are all closely related, and their simultaneous occurrence in the beet-root residues is extremely interesting. Citric acid when heated loses water and is converted into aconitic acid ($C_6H_8O_7 - H_2O = C_6H_6O_6$) and aconitic acid by the addition of hydrogen becomes tricarballylic acid ($C_6H_6O_6 + H_2 = C_6H_8O_6$).

It is a curious fact in the history of many great inventions that several experimenters have been on the brink of the discovery, but it has been reserved for one master-mind to bring out the practical result of the teaching of a multitude of experiments made by different investigators. Professor Silvanus P. Thompson illustrates this in some historical notes on physical subjects (*Nature*, June 7, p. 130), in which he shows that the occurrence of a brilliant spark between charcoal points in connection with a voltaic pile had been mentioned by at least three observers in the course of the years 1800 and 1802; but none of these writers spoke of the properties of the arc as a continuous luminous spark. This was probably not produced until 1808 or 1809, when Sir Humphrey Davy, working at the Royal Institution with the large battery of two thousand Wollaston cells, succeeded in obtaining a voltaic arc that could be extended to 4 inches without rupture. It only remained then to devise machinery for maintaining the carbons at a proper distance apart. In like manner Philipp Reis described in the *Journal of the Physical Society of Frankfort-on-Main* as early as 1860–61 an apparatus in which the galvanic current was utilized to reproduce the tones of divers instruments and even to a certain degree the human voice. Concerning its designation the inventor says, "Since the length of the conducting wire may be extended for this purpose just as far as in direct telegraphy, I give to my instrument the name 'telephone.'" Again, in the year 1802, one "Citoyen Martin" advertised in Paris, as a "spectacle extraordinaire et amusant," that he would show "l'expérience du *télégraphie* plus rapide que la lumière."

Herr Pawlewski (*Ber.*, xvi., 1298) has devised a modification of Dumas' apparatus for the determination of vapour densities, which enables one apparatus to be employed for any number of experiments, the capacity of the apparatus being determined once for all. Two forms of apparatus are described, the simpler being merely a conical bulb capable of holding from 20 to 30 c.c., having a tube from 10 to 12 c.m. long, of capillary bore, fitted on and bent a little sideways; this tube is blown out before tapering to a point in a slightly conical form, and upon this end a tightly fitting indiarubber cap is placed. The use of this cap does away with the necessity of sealing the end of the tube when full of vapour, as is necessary in Dumas' method, at the same time enabling the apparatus to be used for any number of experiments. In place of the bulb used in Dumas' method a small beaker is employed which contains the water, oil, paraffin or other substance used, depending upon the temperature required, and in this the apparatus is immersed. Owing to the difficulty of getting such an apparatus as this, having but one opening, dry and pure after use a second form of the apparatus is described. This has two pieces of capillary tube sealed, the one bent a little sideways and constructed as in the first apparatus, the other fitted with a stopper, and used for the introduction of the substance. This form of apparatus can easily be purified after use by aspiration in the ordinary way.

Professor F W. Clarke (*Science*, i., 485) places on record the fact that a battery cell can be constructed of three non-miscible liquids. A cell is described which consists of layers of mercury, dilute sulphuric acid, and a solution of iodine in ether. Upon connecting the uppermost and lowest layers with insulated wires evidence of a fairly strong current of electricity was obtained with a galvanometer. Theoretically, the resistance of a three-liquid cell ought to diminish with rise of temperature, and Professor Clarke suggests that perhaps a combination of solid plates with the upper and lower liquids would yield a voltaic cell in which the internal resistance would be constant for varying temperatures.

The Bakerian Lecture of the Royal Society was this year delivered by Mr. Crookes, who communicated some new and important results of his investigation upon electric discharges in high vacua. It will be remembered that Mr. Crookes had previously shown that many substances when exposed to the molecular discharge from the negative electrode in a highly vacuous tube emit phosphorescent light, the colour of which varies with different compounds. While engaged in the investigation of the phosphorescence of various substances by means of the spectroscope, Mr. Crookes noted the repeated occurrence of a band having a citron colour. It was most favourably observed by treating the substance with strong sulphuric acid, expelling the excess of acid by heat and then igniting the sulphate to redness. The residue from this treatment gave the band distinctly. A compound which behaved thus was treated by the ordinary chemical methods of separation, and the group precipitates separately examined. In this way the characteristic band was tracked to the precipitate which contained the calcium as oxalate. This calcium oxalate was chemically tested and nothing but calcium was found, the ordinary flame spectrum yielded only the calcium lines, and finally the atomic weight was determined and found to be 39·9 (Ca=40). An examination of the principal native compounds of calcium showed that they all gave the citron band when treated as above described, but certain specimens of lime were found to fail in this respect and hence the conclusion was inevitable that the result was not due to calcium itself, but to some substance constantly associated with it in quantity too small to be revealed by ordinary chemical means. Upon examining a number of other minerals it was found that they nearly all yielded the characteristic citron band, and after a considerable amount of work, special attention was devoted to the minerals cerite and zircon, from which nearly all the rare metals of the earths which they contain were isolated and examined, with the final result that the citron band was without doubt characteristic of yttrium, especially when in the form of sulphate. The spectrum of the phosphorescence yielded by the ignited sulphate in a vacuous tube consists of a broad red band, an intensely brilliant citron band and two equally strong green bands. When only traces are present the citron band alone is seen. Mr. Crookes had not suspected yttrium as the cause of this phenomenon, as pure yttria precipitates by ammonia had been previously examined and gave no phosphorescence, and consequently no citron band. This same specimen when converted into sulphate and ignited at once yielded the distinctive spectrum. Starting from the fact that the number of bands in the spectrum of yttrium is dependent upon the amount of this substance present, a spectroscopic method for the approximate estimation of yttria was devised. By this means it was found that pink coral contained 1 part of yttrium in 200, strontianite 1 part in 500, calcite 1 part 10,000, ox-bone 1 part in 10,000, and tobacco ash 1 part in 1,000,000. Mr. Crookes's results point to a new method of spectrum analysis evidently much more delicate than the ordinary method, in which the spectrum of the body is observed while under the influence of the molecular discharge in a vacuous tube as above described.

SYRUP OF IODIDE OF IRON.*

BY ALVIN G. HAMMER.

The chemical combination of iodine and iron was first brought to the notice of the profession by MM. Baup and Caillot (*Journal de Pharmacie*, August, 1828), and by them recommended in the manufacture of iodide of potassium.

An aqueous solution for medicinal use was subsequently prepared by M. Durand, the formula of which was published in the Journal of the Philadelphia College of Pharmacy for January, 1883. This aqueous solution was, however, not very permanent, due to the fact that the iron salt is oxidized and precipitated out of solution as a sesquioxide of iron, and the iodine is liberated as free iodine. This objectionable feature of its decomposition was to be remedied by the addition of sugar to the solution, and the preservative agent was first recommended by M. Frederking, in 1839. About the same time the subject of protecting the solution of this iron salt was being investigated by Professor Proctor, who published his researches "on the power of saccharine substances in general and uncrystallizable sugar in particular, of protecting the solution of protoiodide of iron from decomposition," in the *American Journal of Pharmacy* for 1840, and subsequently, in the same volume, he again referred to the same subject, stating that he had tried the following saccharine substances as protecting agencies: sugar of milk, manna, sugar cane, honey and uncrystallizable sugar. In summing up Professor Proctor says that either uncrystallizable honey or uncrystallizable sugar (molasses) are the best protective agents of a saccharine character. What seems very remarkable is the fact that such a definite recommendation, based upon the observation of Professor Proctor, should have altogether gone unheeded by the framers of the Pharmacopœia and that subsequent investigators, who are numbered by hosts, should not have taken into consideration the results of his investigation. Another surprising fact is that much diversity of opinion still exists among investigators of this syrup as to what causes the chemical changes are due, and in what they consist. Professor Wayne, in a communication to the *American Journal of Pharmacy*, pointed out the conversion of the cane sugar into that of grape sugar, which change he ascribed to the action of hydriodic acid generated during the process of decomposition of the iodide of iron; but he seems to have overlooked the very important fact that grape sugar might be the very agent to prevent a chemical change in the freshly-prepared syrup.

* A paper read at a meeting of the Iowa Pharmaceutical Association. Reprinted from the *Weekly Drug News and American Pharmacist.*

Professor Maisch, in papers published in the *American Journal of Pharmacy*, 1854-5, states that the chemical change which takes place in the preparation is due to the liberation of free iodine and the precipitation of sesquioxide of iron, and if this decomposed syrup be now exposed to the action of direct sunlight, the free iodine is converted into iodic acid, which forms with the precipitated oxide of iron an iodate of the sesquioxide of iron which salt dissolves in the syrupy liquid, and thus forms a colourless solution. This explanation seems somewhat improbable to me, from the fact that in no specimen of the decomposed syrup that I have met with had the precipitation of the oxide of iron and the liberation of free iodine proceeded beyond a certain degree, and then and there ceased. Now, whenever this decomposed syrup was exposed to the action of sunlight, it would become colourless, and thereafter not again undergo the change which takes place in freshly-prepared syrup of iodide of iron. To determine the correctness of Professor Maisch's theory, I subjected a sample of the syrup of iodide of iron which had undergone decomposition, and had been exposed to the action of sunlight, until it had become perfectly colourless, to the following tests for iodic acid.

With chloride of barium, no precipitate; no reaction with starch and dilute hydrochloric acid when the test was performed by the exclusion of air. When this exclusion was not guarded against the iodine test was obtained, this would indicate the absence of iodic acid. Professor Maisch, no doubt, came to his conclusion by the reaction he obtained with sulphuric acid, which liberated free iodine. It seems to me, however, that this reaction does not prove the presence of iodic acid, for it is a well-known fact that sulphuric acid, if not largely diluted, will liberate free iodine in metallic iodides. In testing for sesquioxide of iron the following were the reactions obtained, which would indicate the entire absence of this oxide of iron: Ferrocyanide of potassium, a white precipitate, which after a few moments acquired a bluish tint; neither tannin nor sulphocyanide of potassium produced any change; carbonate of potassium, a whitish deposit, which soon turned to a green colour; phosphate of sodium, a whitish precipitate, which finally acquired a greenish colour. These results leave no doubt in my mind that the sesquioxide of iron, as first formed in the decomposed iodide of iron syrup, is reduced by the combined action of the sugar and sunlight to the state of a protoiodide of iron.

I will now enumerate a number of experiments made with different processes in preparing this syrup:

No. 1. Made according to the formula of the U.S. Pharmacopœia; it began to change in about three weeks, becoming gradually dark brown; exposed to sunlight, it becomes colourless, having a slight sediment of a light colour.

No. 2. Made like number one, with the addition of twenty drops of a solution of hyposulphite of soda (of the strength of twenty grains of the salt to a fluid ounce of water); this specimen of syrup began to change in three weeks.

No. 3. Made like number one, with the addition of ten grains citric acid to twenty fluid ounces of the syrnp; this specimen remained unchanged for about a month, then rapidly acquired a dark brown colour.

No. 4. Made like number one, substituting iron by hydrogen for iron wire, and an addition of ten grains citric acid to twenty fluid ounces of the finished syrup, retaining its colour for nearly two months.

No. 5. This specimen was made like number one, using a pure crystallized sugar (rock candy) for the ordinary crushed sugar; this syrup changed its colour and underwent decomposition in about ten days; a sample of this syrup kept in a dark place, changed in about the same time.

No. 6. This specimen was made by the formula of the German Pharmacopœia, the syrup retained its colour some two months, when it gradually became quite dark brown.

Samples of all the above described experiments were subjected to the same favourable conditions of temperature, light, etc.: also the same sample of sugar was employed in all specimens, excepting number five, which was made with white rock candy, and I am fully satisfied by this result that the purer the sample of cane sugar the less is its preservative qualities. This fact led me to investigate the changes that had taken place in the sugar. The article employed was what is known as crushed sugar, and yielded a syrup up to all the requirements of the Pharmacopœia; when this syrup was tested for grape sugar, previous to the addition of the solution of the iodide of iron, it was found to be entirely free from it; also, it was not present for several days in the fresh prepared syrup of iodide of iron; but the moment that the preparation indicated the least change of colour, just so soon a grape sugar reaction was obtainable. When a certain per cent. of grape sugar had been formed, the change seemed to come to a stop, and proceed no further. If, now the syrup was submitted to sunlight or heat, the decoloration was effected, and the preparation became a permanent one. This fact led me to substitute grape sugar for cane sugar in the formula of the syrup, and although the sample of grape sugar employed was not absolutely a pure saccharine (it containing a certain per cent. of soluble starch or dextrine), yet when exposed for two months to all the varying influences of light and air, the preparation so produced has remained unchanged in colour and chemical composition. The only change that is perceptible is where the syrup has dried in the neck of the vial, which had been left uncorked; here the colour is very decidedly of a dark red, while the body of the syrup in the bottle is a light green. The query arises, What are the causes of the changes which take place, and how can the same be obviated to make a permanent and stable combination of this valuable medicinal preparation?

The following theory is based upon the results of my experimentations: An aqueous solution of iodide of iron is partially acted upon by the oxygen of the air, and changed into free iodine and sesquioxide of iron; the free iodine is converted by heat or direct sunlight into hydriodic acid, and if cane sugar is presented to this acid, decomposition takes place, grape sugar is formed, and free iodine is again liberated; the remaining portion of the unconverted cane sugar at the same time is exerting its action upon the precipitated oxide of iron, deoxidizing it and thereby increasing the per cent. of grape sugar, the liberated iodine again combining with the deoxidized iron to form proto-oxide of iron, and when this is reached it prevents further decompostion of the preparation, and it may now be exposed to oxidizing influences; provided, however, a certain per cent. of grape sugar is present in the preparation. Now the remedy to prevent this decomposition in the preparation seems an easy one, namely, to incorporate a certain per cent. of grape sugar in the preparation, or to produce the same during the process of forming the chemical combination of the iron and iodine. With this latter fact in view, I offer the following formula which, will yield a syrup which, under ordinary circumstances, will remain permanent for such a period as saccharine solutions usually can be relied upon:

Syrup of Iodide of Iron.

Take of Iodine	2 troy ounces.
Iron in the form of wire and cut in pieces	300 grains.
Distilled water	3 fluid ounces.
Syrup, sufficient quantity.	

Introduce the iodine, iron and distilled water into a flask of thin glass: shake the flask occasionally, until the reaction is about to cease, and is acquiring a greenish colour; now add to the mixture four fluid ounces of simple syrup, and then heat the mixture slowly, until it is brought to the boiling point; then, having introduced twelve fluid ounces of syrup into a graduated bottle, heat it, by means of a water-bath, to 212°, and through a small funnel inserted into the mouth of the bottle, filter into it the solution already prepared; when this has passed, close the bottle, shake it thoroughly, and when the liquid has cooled add sufficient syrup to make the whole measure twenty fluid ounces.

In conclusion, I will say that I believe that in the above modified formula of United States Pharmacopœia I have accomplished the object of presenting to the profession a formula for this syrup which is quite permanent, due to the fact that during the chemical action between the iron and iodine the cane sugar, which had been added in the form of simple syrup, is converted partially into grape sugar, which does away with the addition of foreign substances, like citric acid, etc., to the preparation. The formation and preservative action of grape sugar will also explain the fact occasionally cited by colleagues, regarding the success they have had at one time or another in preparing a syrup of iodide of iron which was permanent. "Due to an accident while filtering the just finished solution of iodide of iron—the paper filter gave way, the turbid liquid was thereby mixed with the simple syrup and to rescue the preparation it became necessary to heat the mixture and pass the same again through a filter, when, lo and behold! a beautiful green-coloured syrup was the product, which also left nothing wanting in way of permancy." This all is due to the fact that the iodide of of iron acted chemically upon the cane sugar, and converted it partially into grape sugar.

Whenever grape sugar of commerce can be obtained in sufficient purity which will fit it for medicinal preparations, then we can easily modify the formula by simply employing this saccharine body without any further manipulation, by adding it to the solution of iodide of iron.

NOTES ON SOME ABNORMAL FLOWERS.*

BY E. ERNEST SEWELL.

A century has almost elapsed since Goethe first published his essay on the 'Metamorphosis of Plants,' in which he pointed out the relationship existing between the various organs of Phanerogams. Earlier investigators, it is true, had recognized that "the leaf was the type of the whole plant," but Goethe revived the theory in a more complete form, and his work is now usually regarded as the foundation of our knowledge of the subject. The common flowers of our gardens afford us many illustrations of its truth; for instance, in the roses and camellias every stage of transition is observable between a perfect stamen and a beautifully rounded petal, and often we see no sharp line of distinction between petal and sepal. Among wild flowers, again, cases constantly occur in which one organ partakes more or less of the structure peculiar to another, as in species of *Geum* and *Primula*, where the sepals are frequently replaced by ordinary green leaves.

In a primrose recently sent to me, while the calyx was little altered, the segments of the corolla had assumed the colour and other peculiarities of the radical leaves,† differing from them in size, and in having the petioles united to form the corolla tube. The short stamens were inserted halfway down this corolla tube, as in normal specimens. The pistil was greatly elongated, and had partially unfolded, thus also revealing its structural relation to the leaf. This "phyllody of the carpel," as it is called, is quite commonly found in primroses, though perhaps the best example of it and the one most frequently quoted is to be found in the flowers of the double cherry.

When we speak of a carpel, stamen or petal as a modified or metamorphosed leaf, it is, of course, necessary to remember that the term leaf is used in rather a wider sense than when we speak of the leaves of a tree—meaning its foliage. For even these foliage leaves, although so much simpler than the floral leaves, have apparently undergone progressive changes in order to fit them for their special functions of assimilation and transpiration, just as the parts of the flower have been gradually differentiated so that they may best fulfil their function of reproducing the species.

Sometimes a single flower will furnish us with more than one example of this reversion to a primitive leaf-type, as in the case of a double hyacinth which I met with a few months ago. It had blossomed indoors in an ordinary hyacinth glass; and this method of water culture had apparently affected its vitality in some way, for the scape bore much fewer dark blue flowers than usual, although many of them were very large, as if to make up for their numerical scarcity in some measure. The lower part of the perianth (D, Fig. 1) in these larger flowers was greatly thickened, while a little higher up it divided laterally into three whorls (1, 2, 3, A), each whorl, of course, having six lobes like an ordinary flower.

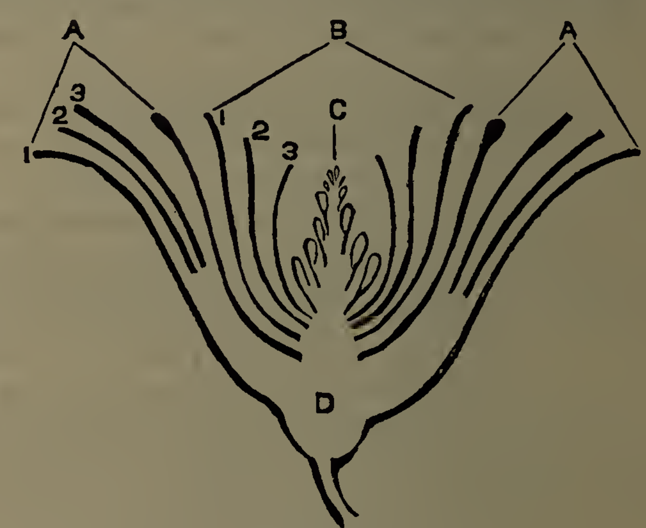

Fig. 1.

Some of the lobes of the outside whorl (A, 1) were quite green, while to be tipped with green was the rule rather than the exception. All the segments of the third whorl were more or less thickened and wrinkled at the apex, and so were some of those of the second. Between these three whorls and the central tuft of green leaves (B) two incomplete cycles of petalloid stamens were placed, also purple in colour, and presenting the usual variations of form commonly found in such transitional structures.

One or two anthers were quite normal and contained ripe pollen. In others, one anther lobe would be fairly well formed, whilst the other would be represented by a thin smooth expansion of the petalloid filament or connective. In these cases the true anther lobe was always more deeply coloured than the other as though the same amount of colouring matter had been supplied to each, but in the one it was spread over a large surface instead of being concentrated into a small compass, as in the other.

Two wrinkles or furrows on each side of the flattened connective replaced the anther in some cases. Each of these furrows appeared to correspond to a loculus or pollen-sac, for they were filled with small masses of yellow pollen, which looked as if they were growing there, and under a magnifying lens reminded one of a little yellow fungus growing in the cracks of a tree's trunk, though I suppose it would be more scientifically correct to compare each furrow or open loculus to the sporangium of a Lycopod.*

Turning now to the *Gynœcium*, or rather to the place where the *Gynœcium* ought to be, we find a complete change of colour; a tuft of green leaves (Fig. 1, B) having replaced the carpels. These were still arranged in whorls of six, and the particular flower I am describing had not more than three of these whorls, surrounding a central cone of much smaller scales (C).

The outside lobes of this green tuft were larger than those within, and some had reflexed points or projections

* A paper read before the School of Pharmacy Students' Association, May 24.

† A very similar occurrence was reported in the *Gardeners' Chronicle*, May 19, 1883.

* Sachs' 'Text-book of Botany' (Vines), p. 542.

from the apex, which were also coloured reddish-purple, and apparently corresponded to the sessile stigmas.

Others were characterized by having the upper part of the leaf converted into a kind of pointed hood, which I could not understand at first, but in another flower I found two of these hoods (Fig. 2, B) folded over one

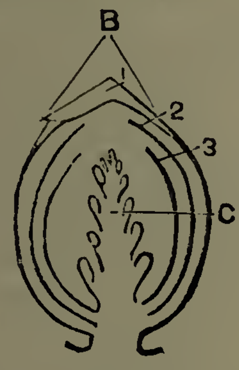

Fig. 2.

another, and in such a manner that it looked like a perfect ovary, until examining it more closely I saw a foliar arrangement (C) within, similar to that of the other flowers near it.

Supposing this outer enclosing whorl to represent the carpellary leaves, it is rather difficult to see what other organs the next two whorls (2 and 3, B, Fig. 1) are morphologically equivalent to. Probably they do not correspond to any distinct part of a normal ovary but are merely repetitions of the outer green whorl formed in a similar way to the inner whorls of the perianth (2 and 3, A, Fig. 1).

The centre of the flower has now to be described. It consisted essentially of a prolongation of the flower axis, covered with small scales, which were white or pale yellow in colour; and they were further distinguished from the surrounding green leaves by the thin fragile nature of their tissue.

The sheathing way in which each scale sprang from the central axis was very noticeable and interesting, although it was only what would be expected when we consider the nature of the other leaves; at the same time they were not so pointed or tapering as the large leaves springing from the base of the scape, but were almost as broad as they were long, having both apex and margins incurved in such a manner as irresistibly to suggest the idea that they represented the ovules of the normal plant. In fact, so much did they resemble ovules with their delicate white tissue, that in the flower first examined I did not immediately recognize their foliar structure, though the resemblance was not quite so marked in most of the other flowers. Their number, too, though of less importance, would tend to support this theory, for although rather difficult to ascertain accurately, I found it varied from eighteen to twenty-four in different flowers. The number found in each of the three cells of the normal ovary is not quite constant, but I have generally found it to be from six to nine.

Dr. Masters, in his 'Vegetable Teratology' (a most interesting work), says, "The ovules of a prolified flower are either unaffected, or they occur in a rudimentary form, or lastly they may be present in the guise of small leaves." But I cannot find after considerable search that there has been any case recorded in which the ovules of a monocotyledonous flower had assumed the form of "small leaves"; in fact, some authorities expressly state that such an occurrence has not hitherto been observed.

This fact in itself might make some hesitate to regard the structures which I have just described as really modified ovules, and perhaps their view would be strengthened if they saw only the upper flowers of the raceme; for it was more particularly some of the lower and larger flowers in which the central scales were so distinctly different from the surrounding carpellary segments; while in the flowers which expanded afterwards, or had not fully expanded, we find a series of whorls gradually diminishing in size from the perianth to the centre. It is very common in "double" flowers to find that the number of whorls is increased at the expense of the ovary and ovules, and in this case we further see that while the plant was comparatively strong some attempt was apparently made to form ovules in the lower flowers, but as the vitality of the plant decreased as it grew older it was unable to differentiate them at all from the surrounding whorls of leaves.

It might still be objected that these axial scales are not in the right position for ovules, in fact that they ought to be found on the margins of the carpellary leaves. I was inclined to think so myself at first, but found on consulting the work already alluded to, that Dr. Masters states* that "teratology shows that ovules may be formed indifferently on leaf-organs or on stem-organs," so now I incline to the opinion that teratology in the case of the hyacinth under consideration shows that the ovules are formed on a "stem-organ." Again, when we consider that in these monocotyledons each leaf grows in a sheathing manner, it is not so readily conceivable that an ovule,—the foliar structure of which has been frequently demonstrated in other plants,—should spring in a sheathing manner from the margin of a leaf, as that it should so spring from a central axis; while there is no reason to suppose that its insertion would be different from that of the other leaves of the same plant. The discussion of the exact nature of the ovule in any particular case can, perhaps, only be decided by expert botanical physiologists, but it is usually admitted that teratology throws much side-light on such a discussion. Sachs takes the view that in plants in which the placentation is axile, as in *Primulaceæ*, or where there is a single erect ovule in each ovary, as in *Piperaceæ*, the ovules spring from the axis of the flower, and are independent of the carpellary leaves. Teratology confirms this view, as the ovules of species of *Primula* have not unfrequently been found in a phyllodic state rising from the central axis. It will be remembered that in *Liliaceæ*,—the natural order to which *Hyacinthus orientalis* belongs,—the placentation is axile though not "free-central."

In order to obtain further evidence on this point, I have examined several other double hyacinths, and have invariably found the gynœcium more or less abnormal, some having free carpellary leaves; but in no other case have I seen the ovules also transformed into leaves or scales. Thus, while the ovules were quite perfect the carpels were phyllodic, so that in one flower in particular the ovules were laid bare, and visible when the flower was looked at from above, clearly indicating that they were not inserted on the margins of the carpellary leaves. In these cases the central axis was greatly swollen and of a fleshy mucilaginous nature, absorbing many of the lower ovules, and in some cases filling the cells of the ovary, when such were formed. On the outside and upper surface of this mass the remaining ovules made their appearance, though sometimes they were not quite round, owing, probably, to the pressure of surrounding tissue.

In two other flowers peculiar structures were observable rising from the axils of carpellary leaves (Fig. 3, *c*.),

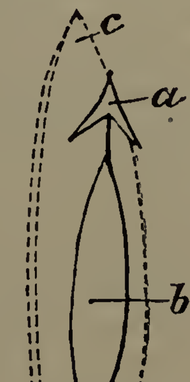

Fig. 3.

* 'Vegetable Teratology,' p. 483.

thus being within the gynœcium. An idea of their shape will be better conveyed in a rough sketch (Fig. 3) than in words. The upper part (*a*), resembling an arrowhead, was coloured either yellowish brown or purple, while the lower part (*b*) was translucent and very thin. It will be seen that though they resemble stamens in form they were placed quite out of the right position for such organs, and, as I only found them in two flowers, I was unable to make out their exact morphological relations.

Comparatively little, I believe, is at present known of the exact causes which give rise to a departure from the normal type; but if we knew all about the laws which regulate the growth of cells under peculiar external conditions, and could observe how, in their living state, as they increase and multiply themselves, they sometimes build up the simple flattened form of a petal instead of a more complex stamen, or of a green leaf instead of a carpel, then I think that we should find that even these so-called "monstrosities" are just as truly the results of unchanging laws, as the most perfect Alpine gentian or Californian Sequoia.

THE USE OF METHYLATED ALCOHOL IN LINIMENT AND TINCTURE OF IODINE.*

BY E. GREGORY.

My attention has been called, by a short paragraph in the February number of the *Canadian Pharmaceutical Journal*, to the fact that Mr. Peter MacEwan, of Edinburgh, had made a very interesting report concerning a sample of liniment of iodine, which had exhibited extraordinary pungency. As I have had a slightly unpleasant experience with a somewhat similar compound, a few notes on the subject may not be out of place.

We have a market here for the tincture of iodine made according to the U.S.P., which is a simple solution of iodine in alcohol. It is used only for external application. Some time last summer, my clerk suggested that it might be made from methylated alcohol, and, contrary to usual custom, I consented to make trial of half a gallon. After preparation it was carefully examined, and it seemed as if the odour of methyl alcohol was entirely covered by that of iodine, and, in no other respect did it seem to differ from the same tincture made with ordinary alcohol. For a time all went well, but, at the end of about a month, a patient complained that he could not use it on his knee, because "it burnt him and made his eyes smart when he was applying it." This complaint was disregarded, but soon there were more of the same kind, and we then concluded to withdraw it from general sale, and confine it to veterinary practice. Before this happened, however, a physician had got hold of some of the tincture, which he used in his gynecological practice, causing to his patient a few minutes of intense suffering, and three or four days confinement to a recumbent position, from the very great soreness produced by the application. I have just examined the last few ounces of this tincture, and on pouring out the liquid, the extremely pungent fumes filled the whole store, causing the eyes of both clerks and customers to water very freely. So pungent was it that although the day was cold and blustering, we were compelled to open all the doors and thoroughly ventilate the place.

At first I was inclined to think that the formation of a small quantity of iodide of methyl might account for the great pungency developed, but soon abandoned that theory and had laid the matter over for further consideration and experiment. I am now convinced that Mr. MacEwan has struck the key-note when he suggests that allyl alcohol may be present, which unites with the iodine to form some iodo-allyl compound. In confirmation of this it may be stated that the odour of the tincture was decidedly "garlicky," and the effect upon the nose and eyes very similar to that of oil of mustard, but more powerful. Mr. MacEwan states that he prepared some iodine liniment, omitting the camphor, and found that the pungency was not produced, arguing from this experiment that the camphor had in some way influenced the development of pungency. It will be seen, however, that my experience establishes the fact that camphor has nothing to do with the reaction.

In view of the above facts it would be interesting to inquire if a certain brand of "crystal methyl" has entered, to any extent, into the composition of tinctures and other pharmaceutical preparations, and what the chemical and therapeutical results of such a course are likely to be. It is well known that it has been much pushed and recommended as having scarcely any more odour than ordinary alcohol.

Should time and opportunity be afforded me I will endeavour to follow up this subject by such experiments as the busy avocations and slender resources of a country pharmacy will permit.

* From the *Canadian Pharmaceutical Journal*, June, 1883.

KEFIR, A NEW MILK-FERMENT.*

Whilst, during the last few years koumiss has been introduced into Western Europe, and even into America, a new drink prepared from cow's milk by a process of fermentation imperfectly understood is coming into use in Russia. This drink is kefir, and it has for long formed the chief article of diet among the mountaineers in the neighbourhood of Mount Elbruz and Kasbek, in the Caucasus. It forms a thick white fluid, with a faintly acid flavour, said to resemble certain light wines. The mountaineers themselves call it "ghippo." The inhabitants of the plains near the Caucasus, and the Russian settlers, who term it kefir, kifir, or khiafar, make use of it, not for the table, but as a popular remedy for anæmia, struma, gastric catarrh, and chronic bronchitis. According to the Moscow *Medical Gazette*, where a contribution on the subject has recently appeared, Dr. Kern being the author, the preparation of kefir is very simple. The mountaineers make it by filling a bag made of goat-skin with milk, then a tenacious mass, of the size of a walnut, of a material which they term "kefir-seed," and the precise origin of which is unknown, is added to the milk. In a few hours the process of fermentation sets in actively. When prepared in wooden or glass vessels, the kefir tastes better. After a lapse of twenty-four hours a weak kefir is produced; when the process is allowed to continue for three days, the kefir becomes very strong. The source of the ferment is scrupulously concealed by the Caucasian mountaineers, who, with the humour of the English cook who once sold a secret for making "fundied cheese," the "secret" being that, the cheese must be fundied after toasting and before the addition of pepper, cannot be persuaded to enlighten strangers to any greater extent than in supplying a small sample of the ferment, in the form of dry dark-brown earth-like masses, but steadfastly refusing to say whence they are obtained. One of these fragments dropped into milk begins rapidly to effervesce, turns milk-white, and assumes the form of a mulberry, then fermentation proceeds at once. If a piece, thus transformed, be dropped into another bowl of milk, it rapidly increases in size, and also causes fermentation. Dr. Kern has carefully examined specimens of this "kefir-seed," which consists chiefly of masses of zooglœa, holding together collections of a bacterium which he calls *Dispora Caucasica.* The yeast-fungus, *Saccharomyces cerevisiœ,* is always found associated with this new germ. "Kefir-seed" retains its vitality after remaining for months in its dry condition. Dr. Kern has a great belief in the future of kefir, which has all the virtues of koumiss, and possesses one great advantage over the latter fluid, in that it is just as good when prepared from cow's as from mare's milk.

The Pharmaceutical Journal.

SATURDAY, JUNE 30, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE FORTY-FOURTH ANNUAL REPORT OF THE REGISTRAR-GENERAL.

ALTHOUGH just a year and a half has elapsed since the close of the period to which the Report of the Registrar-General just issued refers, the delay finds a full explanation in the elaborate tables by which, like its predecessors, it is accompanied. To one section of these, the tables relating to the deaths during the year 1881, it will not be out of place to make reference in these columns, not only because they convey some important information as to the result of the increased interest in sanitary measures which has become developed in this country during recent years, but also they incidentally disclose the extent to which the wilful or intentional use of poisons is known to have led to fatal results. This latter subject at least may be assumed to present some points of special interest to the readers of this Journal, but before referring to it further we purpose mentioning some facts of more general interest as relating to the effect of recent sanitary legislation on the public health.

The year 1881 may be said to have completed a decade since the Public Health Act came into operation in 1872, and nothing stands out more distinctly and unmistakably in the series of reports issued during these ten years from the Registrar-General's office than the wonderful effect which recent sanitary operations have had in saving life. This is shown by the fact that the deaths registered in England and Wales in 1881—which numbered 491,935—were, notwithstanding the increased population, absolutely fewer than in any of the preceding twelve years. In 1877, the year when the lowest previous death-rate occurred, the deaths were in the proportion of one to every forty-nine persons living; but in 1881 only one person died out of each fifty-three living. Or, to spread the comparison over a longer period, in the ten years of 1862 to 1871 inclusive the death-rate had been 22·6 per 1000, and there were no indications of a tendency to fall lower, the average being exactly reached in the last mentioned year. But upon the Public Health Act coming into force, the death-rate at once commenced to fall and continued to abate every year, with one exception, until 1881, when it was only 18·9 per 1000. The exception was in 1875, when the rate was 22·7 per 1000. In that year, however, a second and more stringent Act came into force, and from that time until 1881 the death-rate in no year reached 22 per 1000, the average being only 20·5.

This decline in the death-rate has been shared by the population in all parts of the country, by both sexes, and by persons of every age, and the Registrar-General argues, very reasonably, we think, that as the improvement has now been maintained through a series of years, it can hardly be attributed, even by the most sceptical, to a succession of seasons favourable to health. Indeed, he claims that the saving in life is the direct return for the money and labour expended in sanitary improvements, and he enters into some calculations as to the *quid pro quo* which the country has already received for its enormous expenditure in this direction. Briefly stated, his conclusions, after eliminating as far as possible disturbing influences, are that in the year 1881 alone about 92,000 lives were saved, and—assuming that for every fatal case of illness there are four or five that end in recovery—probably nearly half a million cases of illness were avoided; whilst extending the estimate over the ten years from 1872 to 1881 inclusive, he states that nearly four hundred thousand persons were living in England and Wales at the end of the year 1881 who would probably have died before that time had the old *régime* continued. It is important to note that this improvement has not been equal during the ten years, but has on the whole shown a progressive rate of increase throughout that period.

Pharmacists, who have had special opportunities of watching the tendencies of modern medical practice, will not be surprised to learn that by far the largest decrease in the death-rate has been manifested in connection with the classes of zymotic and parasitic diseases, and this is of course quite consistent with the claim put forward as to the beneficial results from improved sanitation. In the important zymotic class, with few exceptions,—the most important being diphtheria, which reached the mean rate of the previous decade,—the reduction extended to every class. Enteric fever fell from a mean of 326 per million to 218; typhus from 58 per million to 21; and other or ill-defined forms of continued fever from 105 per million to 44. Measles, scarlet fever and whooping cough showed a great diminution in fatal cases, whilst although the mortality from small-pox, owing to the outbreak in London, was greater than it had been for some years, it did not reach the decennial average. Deaths from diarrhœa, dysentery and cholera were also far less numerous, but this was probably owing to the absence of long continuance of hot weather in the summer of 1881.

In the class of "Violent Deaths" no less than 569 fatal cases of poisoning are recorded as having occurred in England and Wales during the year

1881, 368 of the victims having been males and 201 females. This class is subdivided into "Deaths from Accident and Negligence," of which there were 220 amongst males and 120 amongst females, and "Deaths by Suicide," of which there were 147 among males and 81 among females; only one case of murder by poisoning is recorded as having taken place in 1881. It should be mentioned, however, that a considerable number of the deaths attributed to poisoning through "accident or negligence" were probably the result of employment in some noxious calling, the deaths of as many as 52 males and 14 females being referred to lead poisoning. Of course also the number of cases referred to poisoning by alcohol is capable of being largely modified according to the views held by juries upon the drink question. As might be expected opium and its preparations were the most frequent agents in the accidental deaths of both sexes; they were also used most frequently in cases of suicide by males, but carbolic acid was the poison used for the purpose of self-destruction most frequently by females. In fact carbolic acid was the cause of death in 50 cases, or nearly 1 in 7 of all the fatal cases of poisoning during the year. The deaths by poisoning were in the proportion of 1157 to each million of total deaths from all causes, and compared with the number living of each sex, they were 29 to each million of males and 15 to each million of females. One other point worth mentioning, respecting the cases of suicide by poison, is that the largest proportion occurred among males between the ages of 35 and 45, and among females between the ages of 15 and 20.

The following statement, condensed from the several tables, will show at a glance the various poisons to which death has been attributed and the number of fatal cases in the two sexes referred to each, the accidental deaths being also distinguished from the suicides. The deaths from the vapours of chloroform and ether, which numbered 22 and 7 respectively, only one being a suicide, are classed under another head in the Report.

Kind of Poison not stated	70	17	11	19	23

It is evident from the foregoing table that, probably owing to want of precision in the returns made by coroners, at present very little uniformity obtains in the method of classification of deaths by poisoning. Thus as many as 129 cases are huddled together under the head of "opium, laudanum, morphia," whilst a few others in which a preparation of opium was no doubt the noxious ingredient are set out in detail. Again it seems very likely that most of the cases of poisoning by phosphorus and by strychnine have more in common than is indicated by the classification under three different heads. But the least satisfactory feature is the return of no less than 70 cases, or about one-eighth of the whole, without the kind of poison being stated, which suggests that either many juries are satisfied with a modicum of evidence or the responsible officials are very chary as to the amount of information they transmit to the Registrar-General.

The second reading of the Medical Acts Amendment Bill was adjourned from Thursday the 21st until Thursday the 28th inst., when it was the thirteenth order of the day.

* * *

We learn from a statement in an evening newspaper that on Wednesday afternoon an assistant in a chemist's shop in Partick was apprehended in connection with the death of a young man from poison, apparently the case referred to in this Journal last week, but up to the time of going to press no report of the proceedings has reached us.

* * *

Some little time ago several "druggists" were charged before the Grenoble "tribunal correctionel" with a breach of the law which in France restricts the sale of simple drugs in medicinal quantities, pharmaceutical products and specialties to pharmacists. The case having been dismissed in respect to the sale of specialties, the decision has been the subject of an appeal in the interest of the pharmaceutical fraternity. It was pleaded by the defendants that specialties constitute secret remedies, the sale of which by pharmaciens is illegal; but the Court held that they are as a rule only modifications of official preparations, coming within the definition of pharmaceutical preparations, and therefore imposed upon each offender a fine of five hundred francs. The decision has naturally given great satisfaction to the pharmaciens.

* * *

Fortunately it does not often fall to our lot to have to chronicle the death in one week of two men of such high scientific attainments as General Edward Sabine and Dr. William Spottiswoode, the former an Ex-President and the latter actual President of the Royal Society, and both of them past Presidents of the British Association. Sir Edward Sabine died on Tuesday, at Richmond, in his ninety fifth year, and Dr. Spottiswoode on Wednesday, in London, aged fifty-eight.

The last number of the *British Medical Journal* contains a series of three reports on the subject of arsenical poisoning. The first is by Dr. T. Lauder Brunton on the evidence regarding the injurious effects on health arising from arsenical wall-papers and other articles containing arsenic, which although at present somewhat limited he considers sufficient to justify vigorous action. The second report is from a committee of the National Health Society appointed to consider the subject of the occurrence of arsenic in domestic fabrics. It deals especially with the limits to the amount of arsenic which should be fixed by legislation, and the standard test for its detection which should be adopted, the one recommended and described being a modification of Marsh's test. The last report, by Dr. Stevenson, is on the behaviour of arsenic in contact with putrefying organic substances, in which the writer explains that the reason why in some cases highly arsenical papers have been used without injury to health, whilst in others papers containing much less arsenic have produced distressing consequences, may be that sometimes volatile arsenical bases are formed similar to those which Professor Selmi has found in the corpses of persons who had died from arsenical poisoning.

The chemists and druggists of Toronto have just escaped in a fairly creditable manner from the operations of the city analyst. Twenty-three samples were obtained, including potassium iodide and bromide, cream of tartar, sodium bicarbonate, powdered acacia and powdered rhubarb. The analyst reported to the Dominion Inland Revenue Department that all the samples, when analysed, proved to be pure, except the powdered rhubarb, which contained flour; but even about this sample there was evidently some doubt, as the analysis is to be repeated.

* * *

If official recognition could secure success the Executive of the International Pharmaceutical Exhibition at Vienna are entitled to congratulation. We learn that the Archduke Karl Ludwig, who had consented to allow his name to be used as patron of the exhibition, has now, upon his return from Moscow, accepted an invitation to conduct the opening ceremony. The Executive Committee has also received an intimation from the Minister of Public Worship and Instruction that Professor Dr. Aug. Vogl will be deputed to represent the department on the larger Exhibition Committee.

* * *

According to the *Brooklyn Eagle*, whilst a "clerk" in a drug store at Sag Harbour was putting up a prescription including chlorate of potash and tannic acid the mixture exploded and burnt his eyes and face very badly.

* * *

In the "annual museum" held in connection with the forthcoming meeting of the British Medical Association in Liverpool, there will be, as usual, a section devoted to the exhibition of "new chemicals and apparatus, new drugs and their preparations, and new articles of diet for invalids." Applications for space by intending exhibitors of drugs, etc., should be made as soon as possible to Dr. T. Bushby, Clarence Street, Liverpool.

* * *

In a letter to the *British Medical Journal* last week, Mr. J. Dale, of Stockton-on-Tees, suggests that no person, however superior his attainments, who keeps an open shop in which he sells hair oil, tooth-brushes, etc., should have his name included in the Medical Register.

* * *

According to a return just presented to the House of Commons the quantity of coal exported from British and Irish ports to foreign countries and British Settlements abroad during the year 1882 was 19,926,011 tons, of the declared value of £8,954,448. Besides the coal there were 466,249 tons of cinders and 542,188 tons of patent fuel exported. The largest exports were from Cardiff, closely followed by Newcastle, the two ports sending away between them one half of the whole, whilst among the customers France, Germany, Italy and Russia rank in the order in which they are named.

The Albert Medal of the Society of Arts for "distinguished merit in promoting arts, manufactures or commerce," has this year been awarded to Sir Joseph D. Hooker, the eminent Director of the Royal Gardens at Kew.

Provincial Transactions.

HAWICK PHARMACEUTICAL ASSOCIATION.

The above Association held its first general meeting since its formation, in the Chemical Laboratory, Oliver Place, on Tuesday, 19th inst., Mr. Maben, Hon. President, in the chair.

The minutes of the former meeting having been read and approved, the Secretary intimated the following donations for the museum and library:—From Mr. J. C. Waldie, New York (formerly of Hawick): a series of specimens of capsules, capsulets, capsuloids and empty capsules; thermaline, a substitute for quinine, and seidlitine. From the Hon. President: Attfield's 'Chemistry;' Bell and Redwood's 'History of Pharmacy;' Gladstone's 'Life of Faraday;' and Kingzett's 'Animal Chemistry.'

A vote of thanks having been passed to the respective donors, the President, Mr. John Grieve, read a paper on "Evolution and Natural Selection."

At the outset of the paper, in which the subject was treated in an erudite and comprehensive manner, the essayist said that, though the idea of evolution had occurred to many minds, to some even so far back as twenty-five centuries ago, it was not until Darwin furnished the simple solution of natural selection to account for the origin of species that the evidence of descent obtained a *locus standi.* The remains of human bones, and implements fashioned by human hands found in caverns, etc., along with the bones of extinct animals, pointed to a remote antiquity, and anthropology proved that the earlier man had existed, the more savage and degraded was his condition. Man's development, in which a repetition of his descent might be traced, and his possession of rudimentary organs, which are the homologues of those structures that perform some observable functions in those animals which have them more perfectly developed, were adduced as evidences of his origin from the lower animals. The connections between certain distinct groups of animals were described, and the likeness existing between them explained on the ground of heredity, and the unlikeness as due to variation. In the development of animals there was clearly presented a picture of their descent, as all animals, in their successive embryonic stages, progressively imitated very closely those animals lower in the scale of creation. Natural selection was afterwards dealt with, and was stated to be the law of nature which determined those changes of structure which would be of advantage to the organism in adapting it to its environment, and which transmitted those advantageous characters. The ways in which natural selection acted, in connection with the survival of the fittest, were explained, and the essayist finally dealt in a critical manner with the objections most commonly advanced against Darwin's theory, including that of primogeniture.

A vote of thanks having been awarded to Mr. Grieve, a discussion took place in which several of the members took part.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 21, Dr. W. H. Perkin, F.R.S., President, in the chair.

A ballot was held, and the Scrutators, Dr. Thorne and Mr. Meldola, declared the following gentlemen duly elected Fellows of the Society:—G. S. Bowler, C. Beringer, T. H. Coleman, A. Esilman, H. E. Harrison, C. Hulke, H. Heap, B. Hobbs, C. T. Heycock, W. J. Livingstone, B. P. Lascelles, H. R. Mill, M. F. Purcell, J. E. Richardson, F. G. Roberts, W. R. Riffell, A. Smith, E. H. B. Stephenson, A. W. Soward, A. H. Samuel, D. Wilson, R. Williams.

The President then called on Professor McLeod to read a paper—

On Evaporation in Vacuo.—The ordinary method of evaporation *in vacuo* over sulphuric acid is very slow, for three reasons: the aqueous vapour reaches the surface of the acid by diffusion only, the surface of the sulphuric acid is limited, and as the dilute sulphuric acid floats on the concentrated acid, the absorption of aqueous vapour is much retarded; lastly, heat is supplied but slowly to the evaporating liquid, being almost entirely that reaching it by radiation. In one experiment 50 c.c. of water placed *in vacuo* over 250 c.c. of sulphuric acid required two and a quarter days for complete evaporation. The author was led to try some experiments on the evaporation of water at low temperatures by some remarks of Professor Mallet (*Chem. News*, xlvi., 62, 73, etc.), and the method was suggested by Wright's apparatus for distillation of mercury (*ibid.*, xliv., 311); a somewhat similar apparatus is described by Mallet (*ibid.*, xlvii., 218, 252). The author used a Körting's jet pump to produce the vacuum. In one form of apparatus the water was evaporated in a glass dish with ground top which pressed a red indiarubber ring against a brass ring soldered to a copper dome. The aqueous vapour was condensed in a copper vessel consisting of a truncated cone within a cylinder. The tube by which the water to be evaporated is supplied ends in a small glass funnel, the mouth of which touches the inside of the dish. The dish is surrounded by a water-bath at 50°; the temperature of the water in the dish was found to be 26°. 50 c.c. of water can be evaporated in two hours. Instead of the dish, the author has used a wide test tube or a combustion tube, so that the water residue can be evaporated in the tube afterwards used for effecting its combustion. In another modification, described by the author, the condenser is replaced by a wide vertical tube, down the inner surface of which a thin layer of sulphuric acid is allowed to flow; the aqueous vapour is thus rapidly absorbed, and passes down the fall tube as dilute sulphuric acid. It is necessary to cool the sulphuric acid by a flow of cold water. The author exhibited this apparatus at work, and incidentally described a useful valve for preventing the loss of a vacuum, which occurs when using Körting's pump if the water pressure be suddenly diminished. The stream of water passes down a narrow glass tube into an elongated bulb, from the bottom of which it issues by a T piece. In this bulb floats a piece of glass tube filled with air and closed at both ends so that it just floats in water. The upper end of this float is ground, so that if the water stream stops, the float rises and stoppers up the narrow glass tube; the vacuum is thus preserved.

Mr. Thorp said the paper was of great interest to water analysts; he was afraid that it might be difficult to mix the water residue in the combustion tube perfectly with oxide of copper, and there seemed to him a possibility of the introduction of small pieces of indiarubber.

Dr. Roscoe then communicated a paper—

On the Preparation of the Pentathionates. By S. Shaw.—Professor Spring (*Annalen*, 213 [3], 329) expresses doubts as to the existence of pentathionic acid and the pentathionates, and especially combats the statements of Lewes (*Chem. Soc. Journ.*, March, 1881), who prepared and analysed the potassium and barium salts. The author therefore repeated Lewes's work and has been able to confirm completely his results. He has succeeded in preparing perfectly clear transparent crystals of potassium pentathionate which can be recrystallized; these differ in form from the tetrathionate, give a white precipitate of sulphur when treated with caustic potash, and on analysis proved to contain two atoms of potassium to five of sulphur.

Appended to this paper is a—

Note on Pentathionic Acid. By Watson Smith.—In it it is proved that Wackenroder's solution prepared with excess of sulphur dioxide does not bleach dilute indigo solutions. When to half neutralized Wackenroder solution caustic potash is added no precipitate is produced, because in the presence of free sulphurous acid thiosulphate is formed. If, however the solution be evaporated the sulphur dioxide is expelled and the sulphites and thiosulphates are decomposed; a liquid is then obtained which gives with caustic potash a precipitate of sulphur from the decomposition of the pentathionates.

Dr. Debus said that Mr. Lewes was still working at the subject and had obtained crystals of potassium pentathionate more than an inch in length. The pentathionates could only be prepared and recrystallized from acid solutions. If one-half of a solution was neutralized and the other half added, the pentathionates were decomposed. The quantity of base required must be calculated and then added to the acid solution.

Dr. Armstrong then read a—

Note on Hydrocarbons from Camphor. By Dr. Armstrong.—The author in a previous communication of December 1877, announced that he was engaged in an examination of the mixture of hydrocarbons produced by the action of several of the so-called dehydyating agents on camphor. Owing to the complex character of the product, the time occupied in fractional distillation, etc., but little progress had been made in the research; during the last few months, however, the author has in conjunction with Dr. Miller repeated the whole of the previous work on a very large scale, and satisfactory methods of separation have been devised so that it will soon be possible to publish a complete account of the investigation. An exhaustive study has been made of the actions of phosphoric anhydride, phosphorus pentasulphide, zinc chloride and of iodine. The author gave some account of the action with zinc chloride; after describing the methods of operating and separating the products, he stated that in the main C_{10} compounds are produced under the conditions which have been maintained in carrying out the reaction. The phenol produced is carvacrol, and the chief constituents of the hydrocarbon mixture are $C_{10}H_{20}$ and two $C_{10}H_{14}$ hydrocarbons; relatively small quantities of both higher and lower homologues of $C_{10}H_{14}$ are also present, together with one or more hydrocarbons which are carbonized by sulphuric acid, and are not yet satisfactorily identified. The two $C_{10}H_{14}$ hydrocarbons are isomers of cymene; the barium salt of one of these is almost insoluble in water, the sodium salt crystallizing with one molecule of water in large nacreous plates; the barium sulpho salt of the other hydrocarbon is easily soluble and closely resembles ordinary barium cymene sulphonate, with which previous observers have identified it. For a long time the author of the present note was similarly mistaken; the salt, however, contains 3½ molecules of water of crystallization, and is convertible into a magnesium salt which is highly characteristic, and is altogether different from ordinary magnesium cymene sulphonate. Although two other easily soluble barium sulpho salts derived from $C_{10}H_{14}$ hydrocarbons have been isolated, one crystallizing with 9 molecules of water in long flat prisms, the other with 7½ molecules in small glistening plates, no indication of the presence of ordinary cymene in the product from the action of zinc chloride has been obtained. A not inconsiderable quantity of camphorone, $C_9H_{12}O$, is also produced. The product of the action of iodine on camphor does not contain cymene, but yields the sulpho salt resembling that of ordinary cymene referred to above.

In answer to Dr. Tilden, Dr. Armstrong said that he was quite satisfied that the hydrocarbons were $C_{10}H_{14}$, and not $C_{10}H_{16}$ hydrocarbons.

Mr. V. H. Veley then read a paper—

On the Rate of the Decomposition of Ammonium Nitrate.—The author has carefully measured the rate at which gas is evolved by heating pure ammonium nitrate at a constant temperature. He has arrived at the following conclusions:—That the rate of decomposition into nitrous oxide and water is dependent, not only on the mass of the salt, but on the proportion of free nitric acid present. If the reaction of the salt be rendered alkaline, the rate gradually increases as the proportion of free acid increases; a period of maximum velocity is then reached corresponding to the greatest proportion of free acid; the rate then slowly decreases with the decrease of free acid. An excess of ammonia completely stops the reaction, even when the temperature is raised 50° or 60° above the normal temperature of decomposition. If the reaction of the salt be rendered acid at starting, the rate of decomposition gradually decreases as the acid decreases. After heating the salt for thirteen to sixteen hours the rate of change becomes practically constant. The apparatus used in the research was exhibited, and the method illustrated before the meeting by the author.

Professor Ramsay then shortly described and exhibited a new gas burner for heating combustion tubes. The burner consists of a Bunsen burner, on the top of which fits a brass T piece, the top of the T is about 6 inches long and 1 inch in diameter. It has a longitudinal slit cut in it on the top; the ends are closed by pieces of sheet brass which are arranged so that they support the tube to be heated. By a simple arrangement any third of the slit can be closed or opened. A series of these tubes can be connected together by a bayonet catch, so that any length of tube can be supported and heated. The tube is covered by a length of asbestos cardboard. The principal advantages are that the arrangement is cheap and cools quickly, so that seven combustions can be performed in a day.

The two following papers were taken as read:—

Note on the Action of Allylic Iodide upon Phenol in the Presence of Zinc or Aluminium Foil. By P. F. Frankland and T. Turner.—A colourless liquid was obtained boiling at 223° to 225°; it proved to be orthopropylphenol.

On a Bye-product of the Manufacture of Aurin. By A. Claparède and Watson Smith.—When aurin is prepared from phenol, oxalic acid and sulphuric acid, a quantity of white crystals are formed on the lids of the aurin pots. The authors have purified and analysed these crystals, which consist of a phenylortho oxalic ether,

$C{=}(HO)_2$
$|\ \diagdown OC_6H_5$
$|\ \diagup OC_6H_5$. This substance melts at 123° to 124°; it is
$C{=}(HO)_2$

formed when phenol and anhydrous oxalic acid are distilled together.

The Society then adjourned over the summer recess.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a Council meeting, held May 30, the following officers were elected for the coming session:—Mr. C. Parkinson, President; Messrs. J. C. Braithwaite and H. H. Millhouse, Vice-Presidents; Mr. J. Hills Hartridge, Honorary Treasurer; Mr. W. Temple Cooper, Junr., Honorary Secretary; Mr. H. Cracknell, Honorary Assistant Secretary and Librarian.

The Council decided to open the rooms of the Association on the following Wednesday evenings during the summer months at nine o'clock:—June 20, July 4 and 18, August 1, 15 and 29, September 12 and 26. The Council having subscribed to Mudie's Library, members will be able to obtain books, other than works of fiction, mentioned in Mudie's Catalogue, a copy of which is kept at the rooms, on those evenings on which the rooms are open, subject to the rules drawn up by the Council, a copy of which will be fowarded to each member.

ROYAL INSTITUTION OF GREAT BRITAIN.

The Ultra-Violet Spectra of the Elements.*

BY PROFESSOR GEORGE D. LIVEING, M.A., F.R.S.

It seems probable that the range of our vision as regards colour is closely connected with the intensity of that part of the solar radiation which reaches us on the earth, for Langley's observations on the intensity of the sun's rays in different parts of the spectrum bring out the fact that the region of greatest intensity falls nearly

* Read Friday, March 9, 1883.

in the middle of the visible spectrum, and includes those colours to which our eyes are most sensitive. The ultra-violet rays, those which lie beyond the violet on the more refrangible side, are not, however, absolutely invisible, for, by carefully excluding light of lower refrangibility, Herschel found that he could see some distance beyond the Fraunhofer line H, into what he called the lavender-grey; and Helmholtz has succeeded in seeing nearly all the strong lines in the solar spectrum almost or quite up to its limit. Still these rays may fairly be said to be beyond ordinary vision; and from their power of chemical action they used to be distinguished as "actinic" rays. We know now that they have no monopoly of chemical activity, and we recognize no difference between luminous and actinic rays, the visible and the ultra-violet, except in their oscillation frequencies; that is, in the rate at which the successive pulsations of the ray succeed one another, and in the colour and refrangibility which are directly dependent on that rate. That the ultra-violet part of the solar spectrum extended at least as far above the line H as F is below it, has been known since the time of Wollaston, who observed its effect in blackening silver salts; but it is only about twenty years since Stokes made known to us the great length and intensity of the ultra-violet spectrum of the electric spark. Stokes used his own invention, a fluorescent screen, for observing the rays; and at the very time when Stokes published his discovery, W. A. Miller published photographs of the spectra of sparks taken between various metallic electrodes. Both these methods, that of fluorescent screens and that of photography, have been used by Professor Dewar and me in our researches. For the method of fluorescence we have used a modification of Soret's eye-piece, substituting for the uranium glass-plate a wedge-shaped vessel full of a solution of æsculine, placed with its edge horizontal so that we look down on the fluorescent liquid. The wedge form of the vessel has the advantage of refracting out of the line of vision all the rays except those which produce fluorescence, a matter of no small importance when faint light is to be observed.

Now, although the intensity of the sun's rays falls away rapidly beyond the Fraunhofer line H, and comes to nothing about as far above H as F is below it, it is far otherwise with the radiation of our terrestrial elements when heated up in the electric spark or arc, or even in some cases in flames; some of those elements which we know to be abundant in the sun, such as iron and magnesium, exhibit their most intense radiation, their strongest and most persistent rays, in the ultra-violet region, in waves which succeed one another at the shortest intervals. Indeed those metals so readily take up certain ultra-violet vibrations, that when there is much metal in the arc, and it is confined in a crucible of lime or magnesia, they often give their characteristic lines strongly reversed, dark absorption-bands being produced by the slightly cooled vapour which is outside the arc. The spectrum of iron is of all metals the most complicated, and those of the other elements which are most closely related to iron in chemical characters come next to it in the number and complication of their ultra-violet lines. Manganese and chromium are especially remarkable for showing many groups of closely-set lines. It is probably not without significance that this group of elements which exhibit the greatest variety in their chemical relations, and produce combinations of the greatest number of types and the most complicated spectra, are also those which produce the most highly-coloured compounds. In marked contrast to the thick-set ranks of iron, manganese, and chromium lines, are the few scattered rays exhibited by those metals which form their combinations each chiefly on a single type, such as aluminium, and the alkali and alkaline earth metals. These spectra are probably even simpler than at first sight they seem to be. That of lithium is the simplest: a series of single lines succeeding one another at decreasing intervals, and with diminishing intensity, closely resembling in these respects the spectrum of hydrogen. In the case of hydrogen, we know that the oscillation frequencies of some of its rays are related in a simple harmonic ratio. We are not able to say that the relation is so simple in the case of lithium; but still the whole series are probably overtones of a fundamental vibration, not so simply related as the harmonics of a uniform stretched string, but, like the overtones of a string which is not of uniform thickness, or is loaded at different points, similarly related in origin, though not exact harmonics. That the different rays are in many cases so related as overtones of a fundamental vibration appears more plainly, perhaps, when not single lines but groups of two, three, or four lines recur. Potassium shows a series of pairs to which the well-known violet pair, and perhaps that in the red also, belong. Calcium, magnesium, and zinc, each show a series of triplets, which are alternately sharply defined and diffuse. In other cases the same characters may be traced, though less readily, because there is sometimes more than one such series of lines or groups. The alkali metals have each one such series in the visible spectrum, and another in the ultra-violet. It may happen in other cases that two or more such series overlap, and it may then be very difficult to distinguish and separate them.

In some cases elements show at a lower temperature a far more complicated spectrum than they do at higher temperatures further removed from their points of liquefaction. This has been observed by Roscoe and Schuster in the case of the alkali metals potassium and sodium, which give at temperatures only a little above their boiling-points absorption spectra which consist of closely-set fine lines, producing an appearance of shaded bands quite unlike their emission spectra at higher temperatures. In some few cases we have observed similar "fluted" or "venetian blind" spectra, as they have been called, in the ultra-violet, as, for example, one produced by tin; but in general the temperature of the arc, which we have chiefly used in our observations on metals, is high enough to carry the metals beyond the stage in which their vibrations are constrained by the state approaching to liquefaction.

But though metals do not often show spectra of this class at the high temperature of the arc, it is otherwise with metalloids and with compounds. Nitrogen gives in the arc as well as in the spark a channelled spectrum of singular beauty, extending with but short breaks almost to the extremity of the ultra-violet region which we have examined. These multitudinous lines of nitrogen constantly present in the arc taken in air, help to make the problem of unravelling the spectrum of the arc, and assigning each line to its proper source, far more difficult than it might at first sight be supposed. Carbon, which in the arc frequently gives a channelled spectrum in the visible region, gives only a limited number of lines in the ultra-violet; but cyanogen gives one set of flutings near the line L, and another near N, which are so brilliant in the arc as to obscure the metallic lines in their neighbourhood. To the same class we may refer the spectrum of water.

The series of lines produced by the same element, which, I have spoken of as overtones of a fundamental vibration, have been likened to these channellings, but in reality they are very different. In the series, which I have supposed to have a sort of harmonic relation, the successive lines or groups of lines invariably become nearer to one another as the wave-lengths become shorter, and at the same time they diminish in strength and sharpness; whereas in the channelled spectra the strongest lines are at the end where they are most closely set, and they generally diminish in strength as they get further apart. Also increase of distance between the lines of channelled spectra is sometimes towards the less, sometimes towards the more, refrangible end of the spectrum.

I have before observed that a great part of the ultra-violet spectra of the elements which we have observed lies entirely beyond the limit of the solar spectrum; that limit is the line U at wave-length 2947. But though this is the limit of the solar radiation which reaches us on the earth, we can hardly suppose that the sun itself, or the photosphere, emits no radiation of shorter wave-length. We know there is plenty of iron and magnesium in the sun, and the strongest radiations at high temperatures of these elements are of shorter wave-length than U. Moreover, the continuous spectra of incandescent solids in many cases extend far beyond U. The continuous spectrum of burning magnesium reaches quite up to the wave-length 2380, that of the flame of carbon disulphide mixed with hydrogen and fed with oxygen reaches even further, that of lime heated with an oxyhydrogen blowpipe, though feeble beyond the limit of the solar spectrum, extends up to wave-length 2680. The temperature of the sun cannot be less than that of any of these sources of heat, so that we are forced to suppose that the radiation, more refrangible than U, which leaves the body of the sun, is stopped somewhere either in our atmosphere, or in planetary space, or in the atmosphere of the sun himself. Now Cornu has found that when the thickness of our atmosphere traversed by the sun's rays is diminished as much as possible by taking the sun at its greatest altitude, and making the observation from an elevated station (the Riffelberg), the solar spectrum only reaches to wave length 2932, that is, only a very trifle beyond U. We must therefore suppose that the absorbent substance, whatever it be, is not in our atmosphere. The same reason will lead us to reject the notion that the absorption can be due to matter in planetary space, for it is not easy to suppose that the gases which pervade that space in extreme tenuity can differ much from those in our atmosphere, because the earth in its annual course must pick them up whatever they are, and they must then diffuse into our atmosphere, and we must in time have them in a more condensed state in our atmosphere than in planetary space. The absorbent is therefore probably neither in our atmosphere nor in planetary space, and we must look for it in the solar atmosphere. When we notice how much of the radiation of our terrestrial elements is of shorter wave length than the solar line U, we might almost fancy that the blotting out of the sun's light beyond that point is simply due to an increase in the number and breadth of the Fraunhofer lines. Indeed, we have frequently observed the strong magnesium line, wave length 2852, expanded so that the dark absorption band in its middle reached quite up to U on one side and equally far on the other side, and this, together with such expansion of the strong iron lines beyond as we have occasionally observed, would go a long way towards completely hiding all light above U. But such expansions of iron and magnesium lines, high in the scale of refrangibility, do not occur without a considerable expansion of the lines of the same elements lower in the scale, expansions far exceeding what we actually observe in the Fraunhofer lines. Moreover, the Fraunhofer lines, though dark by comparison with the brightness of the photosphere, are themselves luminous, even bright, when there is no other still brighter light wherewith to contrast them, so that if there were no other absorbent action the solar spectrum would be continued by the emitted rays of the metallic vapours which produce these lines. Probably then the absorbent is something at a lower temperature, higher in the solar atmosphere. A change of temperature may, and in some cases certainly does imply such a change of state that there may be a corresponding change in the particular vibrations which can be most easily taken up.

The metals in the liquid and solid states are so very opaque that we should hardly be able to discern their absorption spectra; nevertheless, in very thin films they are translucent in different degrees. Gold leaf, as is well known, transmits a green light, and we have found that a thin film of gold, chemically deposited on a plate of quartz, is fairly transparent for all the ultra-violet rays, so that its selective absorption is almost wholly of the less refrangible rays. Silver deposited in a similar way produces a very different effect. It is almost wholly opaque, except for one rather narrow band which begins a little below the solar line P, and extends with diminishing transparency to about S. Cornu has before noticed this property of silver, but placed the transparent band at wave length 270 instead of 330. Dr. W. A. Miller has observed that the light reflected by gold is equally distributed all through the ultra-violet, but feebler than that reflected by other metals; while that reflected by silver is characterized by giving a sudden cessation of the photographic image for a certain distance. These characters of the reflected rays he attributed to absorption by the metal.

When we examine the absorption produced by the haloid elements, we find that chlorine absorbs a wide band in the ultra-violet with its centre near the solar line P, extending, when the chlorine is in small quantity, from N to T, increasing in width on both sides when the quantity of chlorine is increased, but still leaving the rays above wave length 2550 unabsorbed.

Bromine vapour shows an absorption band which begins in the visible spectrum, and extends, when the bromine is in small quantity, up to L, and when the bromine is in greater quantity, up to P. From that point, up to about wave-length 2500, the vapour is transparent, but beyond it is again absorbent, the absorption increasing gradually with the refrangibility of the rays.

Iodine vapour, when thin, is transparent for ultra-violet rays, but produces strong absorption in the violet region. With thicker vapour this absorption extends nearly to H, but the vapour is still transparent for rays more refrangible than H.

Lecoq de Boisbaudran has observed that in the spectra of similar elements we may trace a shifting of similar lines, or groups of lines, towards the less refrangible side as the atomic weight is increased. Thus the violet pair of lines given by potassium is represented by an indigo pair in the case of rubidium, and a blue pair in the case of cæsium; and the indigo line of calcium is represented by a blue line in the spectrum of strontium, and by a green line in the spectrum of barium.

We may observe something of the same kind in regard to the haloid elements: the absorption band which in the case of the element of lowest atomic weight, namely chlorine, is altogether ultra-violet, is shifted towards the less refrangible side in the case of bromine, and lies altogether in the visible region in the case of iodine, the element of highest atomic weight.

It is remarkable that bromine in the liquid state and iodine in solution show absorptions quite different from those of their vapours. A thin film of liquid bromine between two quartz plates is transparent for a band which ends just where the transparency of the vapour begins, while the film is opaque for rays both above and below this band. Iodine dissolved in carbon disulphide is also transparent for a certain distance, but the band is shifted to a less refrangible region lying between G and H.

Compound gases and vapours show, as might be expected, various absorptions of ultra-violet rays. The absorbent action of coal gas begins at about the wave-length 2680, and above 2580 it is nearly complete. Sulphurous acid has an absorption band extending from about R (3179) to rays of wave-length 2630, with a weaker absorption extending some way beyond these limits on both sides. Sulphuretted hydrogen produces a pretty complete obliteration of all rays above wave-length 2580. Vapour of carbon disulphide in very small quantity produces an absorption extending from P to T, shading away at each end. With more vapour this band widens, and a second absorption band begins at about the wave-length 2580. Chlorine peroxide gives a succession of nine shaded bands at nearly equal intervals between M and S, while in the highest regions of the spectrum it seems to be quite transparent.

I mentioned at the outset the probable connection between the intensity of the solar radiation and the sensitiveness of our eyes to rays of different colours. The consideration of ultra-violet absorption spectra leads to the mention of another fact connected with vision, or rather with the construction of the eyes of the higher animals. Soret has investigated, and recently Chardonnet has more fully examined, the limits of transparency of the crystalline, cornea, and vitreous humour of the eyes of various animals and man, and found them all more or less transparent for ultra-violet rays. The limit of transparency in many cases approaches, but never exceeds, the limit of the solar spectrum. Chardonnet places the limit of transparency of the crystalline of the human eye as low as M, which is not consistent with the observations of Herschel and Helmholtz before mentioned, but this inconsistency is probably due to alterations which had taken place after death in the eyes experimented on by Chardonnet. That the transparency of the materials of the eye does not extend beyond the solar line U, Chardonnet regards as a provision of nature to protect the retina from the extreme radiations of artificial lights; but I venture to offer a different explanation, which is, that the selection of the materials of the eye has been determined not by what they will absorb, but by what they will transmit. If the materials in question were in any great degree opaque to the ultra-violet solar rays, these rays must be absorbed and must either be used in heating the absorbent, or do work upon it in some form, perhaps alter it chemically, and so impair its efficiency as part of an optical instrument. I see, then, in the selection of these materials for our eyes an instance, one amongst many, of the marvellous adaptation of our organization to the natural, rather than to the artificial surroundings in which we are placed.

Parliamentary and Law Proceedings.

Prosecution of a Chemist under the Sale of Food and Drugs Act.

At the Glasgow Sheriff Summary Court on Friday, June 22, before Sheriff Balfour, William Kennedy, chemist, 59, Trongate, Glasgow, was charged with contravening the 7th section of the Sale of Food and Drugs Act, 1875, through an assistant, for whom he was responsible, dispensing a prescription presented by Robert Inglis, sanitary inspector, on June 4, not in accordance with the specified compounds stated by the prescriber, Dr. Neil Carmichael, 29, South Cumberland Street. The compound was to contain a certain drug, called methyl salicylate, but on an analysis by Dr. Wallace that drug was not found in it.

Mr. Hays, who appeared for the defendant, asked leave to make a statement with the view of inducing the prosecutor to withdraw the charge.

Mr. Ross, who appeared on behalf of the prosecution, said such a course would be irregular before the accused had pleaded to the charge one way or another.

The Sheriff suggested that Mr. Kennedy should plead first.

Mr. Kennedy having pleaded guilty,

Mr. Hays said: Since the complaint was served inquiries have been made and information obtained in regard to the matter complained of. It is understood that the medical prescription referred to in the complaint was prepared by Dr. Carmichael, and the ground of complaint is that the compounded drug contained no methyl salicylate. That statement is substantially correct, and the explanation of the fact is a very simple one. As Dr. Carmichael well knows, the drug methyl salicylate is not to be found in the British Pharmacopœia, and generally speaking is not known in Glasgow; and in point of fact, it is not kept by any chemist in Glasgow. Dr. Carmichael is the only medical man in Glasgow who prescribes it, and it appears to be a drug of American origin, recently discovered; and I find that as late as the month of June last year Dr. Carmichael, at a meeting of the Glasgow Southern Medical Society, called attention to it, and this, I believe, was its first introduction in Glasgow. I also find from Watt's 'Dictionary of Chemistry,' which is a high authority, and also from Dr. Carmichael's paper to the Medical Society referred to, that this methyl salicylate is a volatile oil or essence obtained from the *Gaultheria procumbens*, commonly known as "wintergreen." The plant distilled with water yields an oil consisting of acid salicylate of methyl (90 per cent.), and a terebine (10 per cent.), separable by fractional distillation. When this medical prescription was presented at Mr. Kennedy's place of business Mr. Kennedy was absent. It was handed to his principal assistant, Mr. Slogie, a gentleman of much experience and a most careful and accurate dispenser, and who has been admitted by the Pharmaceutical Society as a competent dispenser of drugs. Mr. Slogie had never heard before of methyl salicylate, and after examining the other ingredients of the prescription, he came to the conclusion that what was really wanted was salicylate of soda. and this he supplied instead of methyl salicylate, which is not kept in stock by Mr. Kennedy, or, it is believed, by any other chemist in Glasgow. Mr. Slogie was assisted in coming to the conclusion at which he arrived by reason of the fact that salicylate of soda, which is a drug extensively used in the treatment of rheumatism, was in complete keeping with the other ingredients of the prescription, which, on the face of it, appeared to him to be intended for the treatment of rheumatism. It will not be denied that this salicylate of soda is quite in harmony with the other ingredients of the prescription. I would call your lordship's special attention to this important point in the case. Keeping in mind what I have already mentioned that methyl salicylate is extracted to the extent of 90 per cent. from oil of gaultheria, had Dr. Carmichael, in making up his prescription, inserted *oil of gaultheria* instead of methyl salicylate, no mistake would have been made, because that is a well-known drug, and is kept in stock by all chemists, and he would have got practically what he prescribed. It had been ascertained that Dr. Carmichael had accepted this oil of gaultheria instead of methyl salicylate, and it had been further ascertained that Dr. Carmichael recently applied to a well-known apothecary establishment in Glasgow for this methyl salicylate, and none being kept there, a small quantity was obtained from the makers of it, who are, it is understood, in Germany; but finding the price too expensive, Dr. Carmichael set to preparing it himself by fractional distillation—as described in his paper read to the Medical Society. No similar prescription by Dr. Carmichael had ever been presented at Mr. Kennedy's place of business. The only fault which his assistant committed was in not asking an explanation of what was meant by methyl salicylate. But it is a well-known fact that chemists were constantly in the habit of spelling out prescriptions by medical men, and I suppose, acting on this practice, the assistant supplied the one thing for the other. He did supply a salicylate, but not that of methyl. There was not the slightest suspicion of fraud in the case and no injury could possibly have been done to any one by the substitution of the salicylate of soda. It may be that according to the strict letter of Section 7 of the Sale of Food and Drugs Act, 1875, there was an infringement of the law, but in the very peculiar circumstances of this case, which I have explained, it would be a great hardship to inflict a penalty, and I therefore ask your lordship to deal as leniently as possible with Mr. Kennedy.

Mr. Ross contradicted Mr. Hay's statement that no similar prescription had been presented to Mr. Kennedy before. Dr. Carmichael gave the same prescription to a patient on the Thursday preceding June 4, and it was dispensed in Mr. Kennedy's shop. It was in consequence of the medicine supplied on that occasion being discovered by Dr. Carmichael to be of the wrong sort that the prosecution arose. The colour of the two medicines, however, was quite different. Dr. Carmichael sent the same prescription to the Sanitary Inspector, who sent an officer to get it dispensed by Mr. Kennedy, and subsequently the prescription was presented at the Apothecaries' Company's warehouse, and a correct compounding of the specified ingredients was obtained.

The Sheriff remarked that assuming that Dr. Carmichael thought that the medicine could not be got in Glasgow, it was a curious thing for him to give the prescription. There was some semblance of a trap being laid for the chemists in such a proceeding.

Mr. Ross pointed out that the doctor had got the drug in the city previously.

Mr. Hays said the drug was only to be obtained from the Apothecaries' Company, and it had been specially manufactured by them to the order of Dr. Carmichael.

Sheriff Balfour, in giving his judgment, said he was left in the dark with regard to two particulars of the case which very much affected the gravity of the offence. The first particular was whether Dr. Carmichael, who made out this prescription, ever got this salicylate of methyl dispensed before in Glasgow. It appeared to be a drug of quite recent American origin, and had been introduced into this country about a year ago. Dr. Carmichael appeared to know well enough about it, but whether or not he ever got it dispensed in Glasgow prior to sending out this prescription is a point on which no information had been given. The other point that his lordship was left in doubt about was the real difference between the two ingredients—whether it is an injurious thing to dispense salicylate of soda instead of salicylate of methyl. From the samples of both drugs before his lordship, he saw they were quite difference in appearance. With these two elements of the case left out, he could only deal with the remaining element, which constituted a sufficiently grave offence on the part of the respondent. It appeared that after this prescription was sent to Mr. Kennedy, Dr. Carmichael sent out another prescription to the Glasgow Apothecaries' Company, and he got that prescription properly dispensed. The Glasgow Apothecaries' Company adopted the proper expedient, and in place of being in doubt as to what the salicylate of methyl was, and dispensing another article in its place, they very properly sent to Dr. Carmichael and got the salicylate of methyl from him. That was where the offence of Mr. Kennedy lay, and that was where his agent had very properly admitted that there was an offence. He would have inflicted a heavier penalty if he had been satisfied that this was a drug commonly known in Glasgow and dispensed all over the town; but from the fact of a well-known establishment like the Glasgow Apothecaries' Company not having it in stock, and requiring to send to Dr. Carmichael for it, it seemed that although it had been introduced in Glasgow for a year, its supply was an uncommon thing amongst chemists. It was perfectly clear that Mr. Slogie should have sent to Dr. Carmichael to ascertain what the drug was, and where it was to be had. He had no right to dispense salicylate of soda in its place. He would inflict a penalty of £4, without expenses.—*Glasgow Herald.*

Alleged Supply of Laudanum for Paregoric.

Mr. F. Price, district coroner, held an inquest this week, at Salford, touching the death of George Henry Dodd, an illegitimate child, five months old. According to the evidence, the deceased became unwell about a month ago, and his mother gave him some paregoric, which was purchased at the shop of Mr. Lucas, chemist, Broughton Road. On Friday last the mother sent a little girl for another pennyworth of paregoric, but instead of going to Mr. Lucas's shop, she went to Mr. Peatson's in Broughton Road. She was served by Mrs. Peatson, and a portion of the contents of the bottle was administered to the deceased by its mother. The deceased at once fell asleep, and not awaking, and the mother observing that he breathed heavily, gave him some brandy and water. The child was taken to a medical man, who gave him some medicine, but he died without recovering consciousness.

Mr. James Gray, surgeon, said the deceased was brought to him in a state of complete stupor. The pupils of the eyes were contracted, and the symptoms were those of narcotic poisoning. He applied stimulants without effect. The mother said she had given it something from a small bottle which she produced. In his (Mr. Gray's) opinion, the bottle contained laudanum, pure and simple. The bottle had evidently contained peppermint, and the smell of laudanum was, therefore, not so apparent.

A Juryman: Do you think the child has been poisoned?

Mr. Gray: That is quite evident.

The Coroner, in summing up, said the person who supplied the narcotic might be guilty of manslaughter for supplying laudanum instead of paregoric, but as Mrs. Peatson denied serving the laudanum, no criminal charge could be sustained on the evidence of the little girl.

The Jury returned a verdict "that the deceased died from an overdose of laudanum, inadvertently administered to him by his mother."—*Manchester Evening News.*

Poisoning by Chlorodyne.

On Tuesday morning Sir John Humphreys held an inquest at the Town Hall, Old Street, Shoreditch, on the body of John Berry, aged 33, newspaper reporter. Deceased suffered from heart disease, and was in the habit of taking chlorodyne to ease the pain. On Saturday night he took a dose and went to bed. About thr ee o'clock next morning his wife heard him making a peculiar noise, and discovered that he was in an insensible condition. A doctor was sent for, but deceased expired a few minutes after his arrival. The doctor who made the *post-mortem* said death was caused by prussic acid, and in chlorodyne there was a certain amount of that acid.

The Jury returned a verdict of "Death by misadventure."

***[It is not quite clear upon what ground death in this case was attributed to prussic acid poisoning; at any rate, it is not the only conclusion that would be consistent with the facts as reported.—Ed. Ph. Journ.]

Chemistry in the Law Courts.

THE BADISCHE ANILIN UND SODA FABRIK V. LEVENSTEIN.

In the Chancery Division of the High Court of Justice, on Wednesday last, Mr. Justice Pearson delivered judgment in this case, which was commenced on March 5, and has been thirteen days before the Court.

The plaintiffs were a company incorporated in Germany, and were the owners of a patent taken out by them through their agent in England in the year 1878 for "improvements in the production of colouring matters suitable for dyeing and printing," and their claim was for an injunction to restrain the defendants, Messrs. Levenstein, who are manufacturers of materials for dyeing, from manufacturing, selling, or making any profitable use of any dyes or colouring matters being the same as the "Fast Blackley Red" sold by the plaintiffs, or any dyes or colouring matters made according to the plaintiffs' inventions, or by any process being a colourable imitation thereof. The questions which arose in the case were of great difficulty, and involved a considerable acquaintance with the technical language used in the science of chemistry. A fact of some public interest was stated during the hearing of this case, which was that the manufacture of chemicals used for dyeing purposes is almost entirely in the hands of Germans, who make immense profits by the sale in England of these most necessary articles. The plaintiffs, by their specification, stated that their invention consisted in the production of red and brown colouring matters, in chemical language termed the "sulpho-acids of oxyazo-naphthaline." They then described four simple processes for producing this result, and claimed as their invention the production of the colouring matters by any one of the processes so described. The first process was as follows:—Naphthylamine is converted into its diazo compound by the action of nitric acid and in a manner well known to chemists, and equal molecules of the diazo compound thus obtained and of naphthol, or naphthylic alcohol, are allowed to react upon one another, by preference in an alkaline solution, according to the employment of either of the two isomeric modifications of naphthylic alcohol known as alpha naphthol and beta naphthol; the result of this operation is a precipitate containing either of the two corresponding and isomeric modifications of oxyazo-naphthaline, and which may be termed "alpha and beta oxyazo-naphthaline" respectively. These azo-compounds are further converted into their sulpho-acids by any method now in use for the preparation of organic sulpho-acids, such as, for instance, by heating them with fuming sulphuric acid until the mixture is found to produce a clear solution with water. The excess of sulphuric acid may then be removed by any of the known means for effecting this purpose and the colouring matter may be obtained in a solid state by precipitation or evaporation. In this manner brown colouring matters are obtained from alpha oxyazo-naphthaline, and red colouring matters from beta oxyazo-naphthaline. An example of the manner in which the first process could be carried out was then given:—"About 10 lbs. of naphthylamine are mixed with or dissolved in about 2 gallons of concentrated or strong muriatic acid and about 100 gallons of cold water, and thereto an aqueous solution of nitrate of sodium is added, containing about $4\frac{8}{10}$ lbs. of pure nitrate of sodium, or as much as will be found necessary to convert the naphthylamine into its diazo compound, or into hydrochlorate of diazo-naphthaline. The solution thus obtained is added to an aqueous and strongly alkaline solution of about 10 lb. of either of the two isomeric naphthols, or of a mixture of the same, when a dark-red or brown precipitate will be produced, consisting of oxyazo-naphthaline, which is to be filtered, washed and dried. In order to obtain the sulpho-acids of oxyazo-naphthaline, about 10 lbs. of the oxyazo-naphthaline are dissolved in about 20 lbs. of fuming sulphuric acid, containing about 80 per cent. of anhydrous sulphuric acid, and the mixture is heated at a temperature of about 100° C. for about two hours, or until a sample of the mixture will be found to produce a solution with water. The further treatment consists in removing the free sulphuric acid contained in the mixture by any of the known means for effecting this purpose, such as, for instance, by neutralization with caustic lime, and the colouring matter may be obtained in a solid state, by preference in the state of a sodium salt in a manner well understood by chemists." The three other processes were then described, which in some respects varied from the first process. The objections raised by the defendants was that the specification did not sufficiently describe and ascertain the nature of the alleged invention, or in what manner the same was to be performed, and did not sufficiently distinguish which of the matters and things therein described were claimed to be new, and that the specification was in other respects vague and insufficient. In support of the plaintiffs' case, several witnesses learned in the science of chemistry were examined at considerable length, and in their evidence it was stated that the colouring matters for which the patent had been secured were capable of being produced by the different processes described in the specification. The defence, in support of which many scientific witnesses gave evidence, was principally to this effect—that it would be impossible to carry out the processes by the means stated in the specification, on this account, that if the oxyazo-naphthaline were to be united with the fuming sulphuric acid of the strength therein described, it would be dangerous to human life, and it was proposed that an experiment should be tried on a small scale in the presence of the Judge, for the purpose of explaining and proving the defendants' allegations. Mr. Justice Pearson having consented to this experiment being tried, an arrrangement was made for carrying it out in a separate room, and there could be no doubt that the process, as exhibited by the defendants, supported their theory, while the contention of the plaintiffs was that the experiment was not properly carried out. At the conclusion of the arguments and evidence on both sides, the learned Judge stated that he should not decide the case without having an experiment made by an independent scientific chemist appointed by the Court. In pursuance of this decision, Professor Roscoe was appointed by the Judge, with the sanction of all parties, and a report was made by him. After this report had been made to the Court and communicated to the parties, this further contention was raised. It was said by the defendant that he really and truly carried out his manufacture of the several articles by a totally different process from that described in the plaintiffs' specification, and that he was willing to communicate what he termed his secret process to the plaintiffs if they would undertake not to divulge it. The plaintiffs declined to give the required undertaking, and, after much discussion, it was proposed by the Judge and approved by the counsel on both sides that the secret process should be stated to the Court in private, and accordingly the arguments were continued for three days in the Court with closed doors.

In the course of an elaborate judgment Mr. Justice Pearson said: There could be no doubt that Mr. Levenstein was entitled to great praise for the knowledge and perseverance which had enabled him to carry out his process; he would even assume that the process might be conducted more easily and more cheaply than that adopted by the plaintiffs; but still it was only another method, by using well-known ingredients, of arriving at the same result. There was no dispute that, so far as the materials were concerned, Mr. Levenstein used the same, or he used equivalents for them, and taking all the circumstances into consideration he could not come to any other conclusion than that the plaintiffs were entitled to their injunction. He regretted very much to be obliged to decide against Mr. Levenstein, but the law compelled him to do so. He must, therefore, grant the injunction, and the defendant must pay the costs of the action.
